Tip: You can similarly add pages, fields, or characters by setting the nType value to 2 (for pages), 3 (for fields), or 4 (for characters).

4. Use the AddRule method to specify the structure of a document. This step gets the SetupNode object for the NewNode document in the Setup DCO. The step then adds a rule that requires one instance of the page NewPage to exist for the document structure to be valid. If a page node for NewPage does not exist, the method creates NewPage automatically.

```
TDCOLib.DCOSetup m_oDCOSetup = m_oDCO.SetupObject();
TDCOLib.DCOSetupNode m_oDCOSetupNode =
    m_oDCOSetup.GetNodeByName(1, "NewNode");
m_oDCOSetupNode.AddRule(2, "NewPage", 0, 1, 1);
```

After the execution of the code, the following line is added to the Setup DCO beneath the NewNode document type.

```
<D type="NewNode">
.
.
.
<P type="NewPage" pos="0" min="1" max="1"/> <!-- New line added -->
```

Additionally, if NewPage does not exist, the following page node is created in the Setup DCO:

```
<P type="NewPage">
    <V n="ID">0</V>
    <V n="TYPE">Page</V>
    <V n="STATUS">0</V>
```

```

    <V n="IMAGEFILE"></V>
    <V n="DATAFILE"></V>
    <V n="TEMPLATE IMAGE"></V>
    <V n="MIN_TYPES">0</V>
    <V n="MAX_TYPES">0</V>
</P>

```

5. Use the Read method, Write method, and the XML property to export the document hierarchy to an external location, which can be a content repository, a database, or a web server. This example exports the document hierarchy to a temporary location on a local server:

```

m_oDCO.Read("C:\\C:\\Datacap\\NEW\\dco_NEW\\NEW.XML");
strDCOXml = m_oDCO.XML;
m_oDCO.Write ("c:\\temp_location\\new_application.xml")

```

The Read method stores the document hierarchy in a setup object. The XML property assigns the XML file to a variable, and the Write method writes the document hierarchy (setup DCO) to a new location.

[WriteSetup method](#)

[AddNode method](#)

[AddRule method](#)

DCO APIs

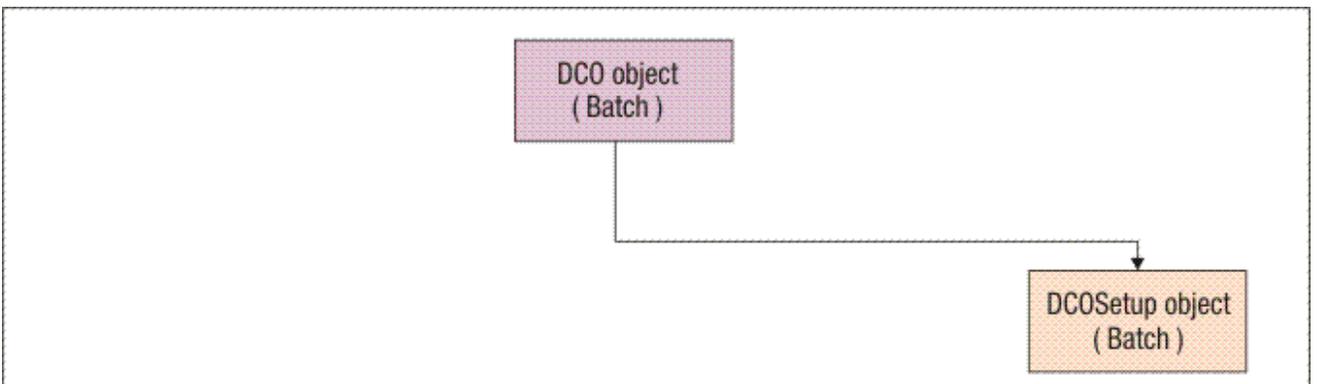

The DCO APIs include properties and methods that you can use to modify the runtime batch hierarchy, which is also known as the runtime DCO. For example, when your business requirements change, you can use these APIs to add or remove documents and pages, or change the names or values of object types.

When you create a runtime DCO object (`m_oDCO` in this example), a corresponding `DCOSetup` object is created automatically. The `DCOSetup` object is a child of the DCO object.

```

TDCOLib.IDCO m_oDCO = new TDCOLib.DCOClass();
//Creating a runtime DCO object

```

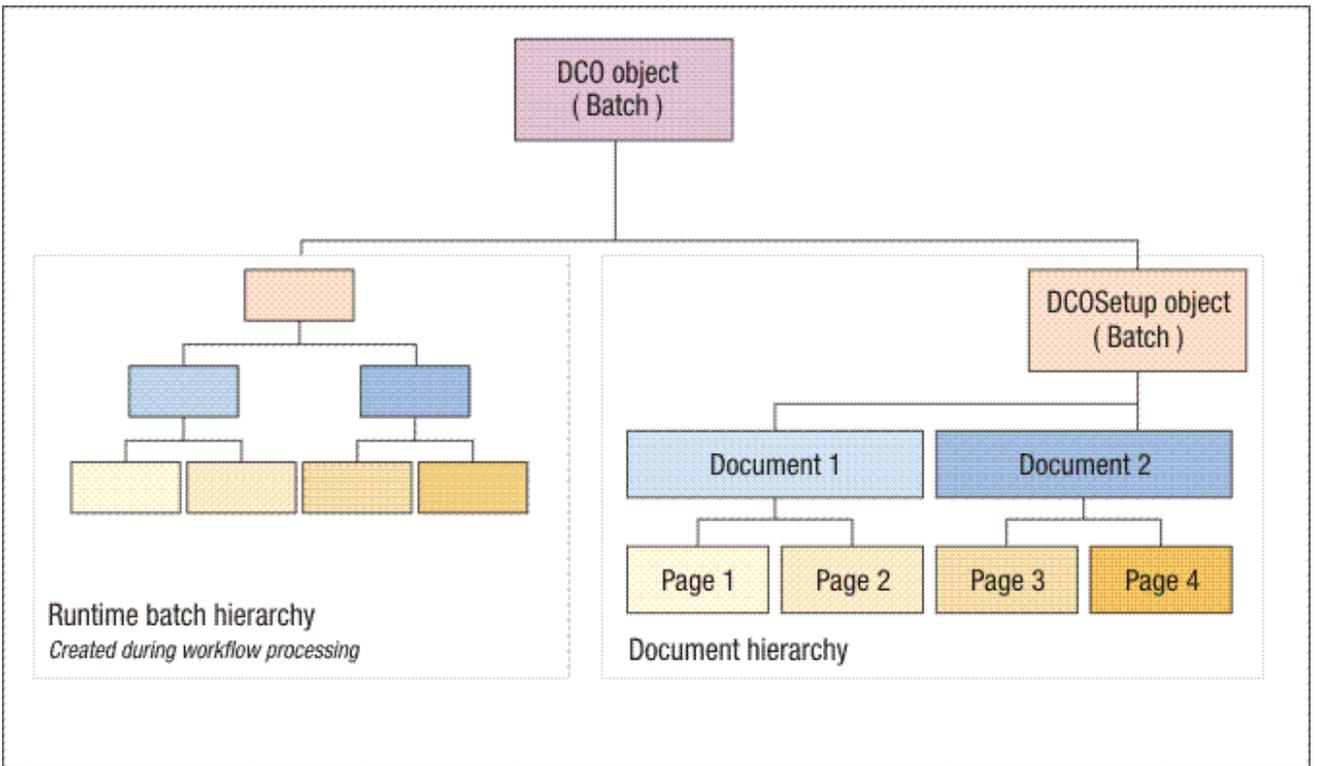

Because the `DCOSetup` object is empty, you need to populate the `DCOSetup` object from the Setup DCO file of the application.

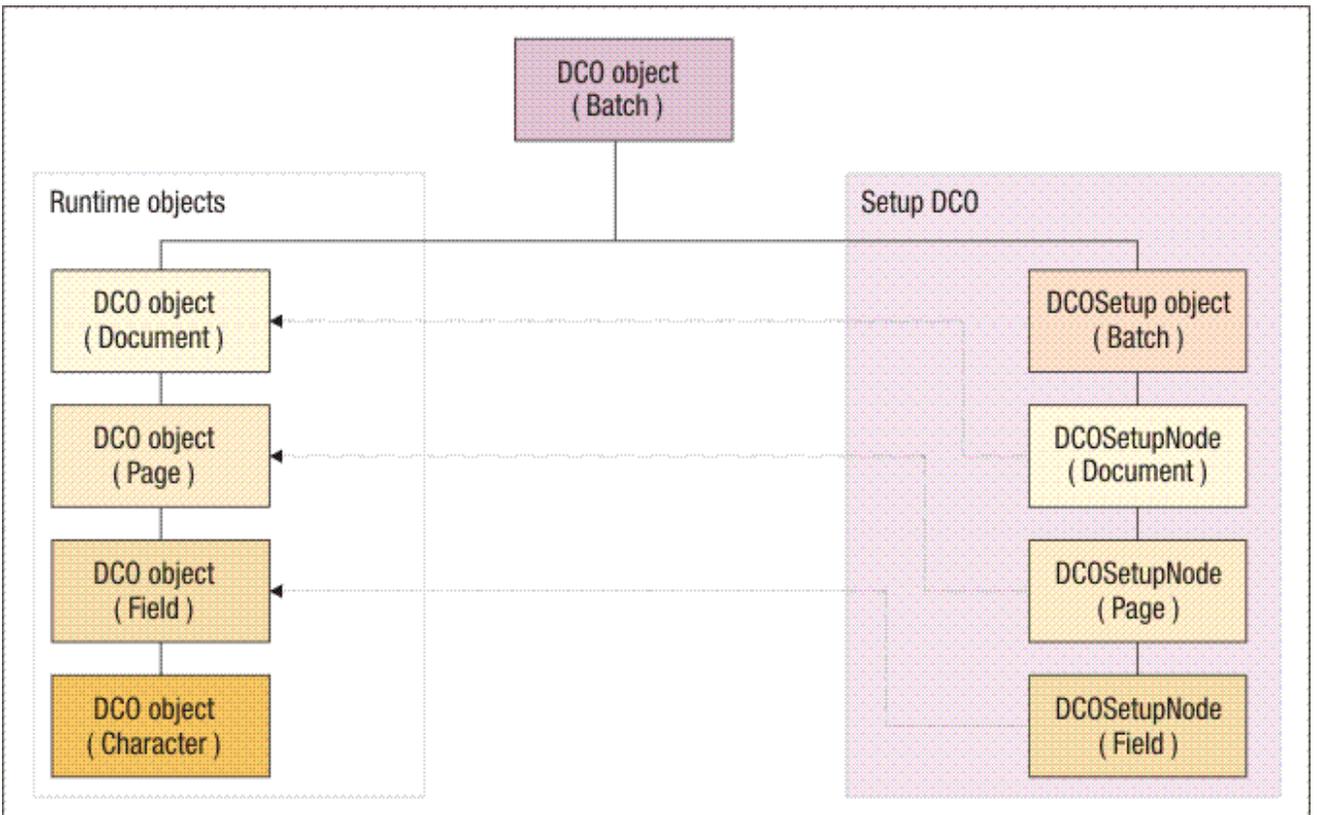

```

m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
//Reading a Setup DCO file

```

As workflow tasks process scanned pages, Datacap creates a hierarchy of child objects beneath the runtime DCO object. Each child object in the runtime batch hierarchy corresponds to an object in the Setup DCO:

You use the DCO API properties to change the names of object types, and you can use methods to add or remove child objects.

- [DCO properties](#)

You can use DCO properties to access or modify the names and values of DCO objects, including

documents, pages, fields, and characters. You can also use DCO properties to modify metadata, which includes confidence levels, IDs, types, statuses, and variables. Generally, you use the properties to pass values to methods that complete actions on the associated objects.

- [DCO methods](#)
You can use DCO methods to complete actions on DCO objects, such as adding documents to batches, pages to documents, or fields to pages. You can also use the DCO methods to search for and change metadata values, including confidence levels, indexes, variables, and alternative text for verification.

Parent topic: [Datacap object API reference](#)

DCO properties

You can use DCO properties to access or modify the names and values of DCO objects, including documents, pages, fields, and characters. You can also use DCO properties to modify metadata, which includes confidence levels, IDs, types, statuses, and variables. Generally, you use the properties to pass values to methods that complete actions on the associated objects.

- [AltConfidenceString property](#)
The AltConfidenceString property sets or gets the confidence level of characters in the field value.
- [AltText property](#)
The AltText property sets or gets the alternative character data that is associated with a field. You use this property with multiple-pass verification tasks and when you need to display alternative text options to an operator.
- [CharConfidence property](#)
The CharConfidence property sets or gets the confidence level of the value of a character.
- [CharValue property](#)
The CharValue property sets or gets the data value of a character, which can be a digit in a multiple-digit number or a single character in a string. You can use this property to search for or assign a value to a character in a field.
- [ConfidenceString property](#)
The ConfidenceString property sets or gets the confidence values for the primary character data in a field object.
- [ID property](#)
The ID property sets or gets the unique identifier of an object, which can be a batch, document, or page.
- [ImageName property](#)
The ImageName property sets or gets the full path and the file name of the image file that is associated with a page object. You can use this property when you are modifying the order of pages in a batch.
- [Status property](#)
The Status property sets or gets the status of an object. The status is a numerical value that indicates success, failure, error, problem, or other status that depends on the type of object. For example, you can use this property to locate pages with a status of 1, which indicates that there was a problem during the page identification task.
- [Text property](#)
The Text property sets or gets the primary character data that is associated with a field.
- [Type property](#)
The Type property sets or gets the object name. You can use this property to search for document types or page types in a batch and change the name of the object.
- [Variable property](#)
The Variable property sets or gets the value of a named variable. You can use this property when you first need to obtain a value that you pass afterward to another variable or object, such as a field.
- [XML property](#)
The XML property sets or gets the XML file that is associated with an object. You can use this property to populate a run time object from the Setup DCO file and assign the XML file to a variable.

Parent topic: [DCO APIs](#)

AltConfidenceString property

The AltConfidenceString property sets or gets the confidence level of characters in the field value.

VBScript restriction: Because extended properties are not supported through the C# .NET Interop interface, you must instead use the [set_AltConfidenceString](#) method or the [get_AltConfidenceString method](#) method.

Syntax

VBScript

```
oDCO.AltConfidenceString (nIndex as Long) as String.
```

Applies to

Field objects only.

Type

Read and write.

Arguments

nIndex

0 specifies the primary value. Where the field contains multiple recognition, voting, or multi-pass data entry values, 1 specifies the first alternative, 2 specifies the second alternative, and so on.

Return value

String that contains the confidence level of each character.

VBScript example

The following example sets the confidence string for the first alternative in the Total field:

```
objTotalField.AltConfidenceString(1) = "987999"
```

In the example, the Total field consists of 6 characters, and the confidence level of each character is 9, 8, 7, 9, 9, and 9.

Parent topic: [DCO properties](#)

[AltText property](#)

[CharConfidence property](#)

[ConfidenceString property](#)

[get_AltConfidenceString method](#)

AltText property

The AltText property sets or gets the alternative character data that is associated with a field. You use this property with multiple-pass verification tasks and when you need to display alternative text options to an

operator.

VBScript restriction: Because extended properties are not supported through the C# .NET Interop interface, you must instead use the [set_AltText method](#) or the [get_AltText method](#).

Syntax

VBScript

```
oDCO.AltText (nIndex as Long) as String
```

Applies to

Field objects only.

Type

Read and write.

Arguments

nIndex

0 specifies the primary value. When the field contains multiple recognition, voting, or multiple-pass data entry values, 1 specifies the first alternative, 2 specifies the second alternative, and so on.

Returns

String containing the alternative text. The string is stored in the page XML file in ASCII format.

VBScript example

This example shows the first alternative value (231.77) for the Total field that an operator entered during a multiple-pass verification task.

```
objTotalField.AltText(1) = "231.77"
```

Parent topic: [DCO properties](#)

Related reference:

[AltConfidenceString property](#)

[Text property](#)

[CharValue property](#)

CharConfidence property

The CharConfidence property sets or gets the confidence level of the value of a character.

VBScript restriction: Because extended properties are not supported through the C# .NET Interop interface, you must instead use the [set_CharConfidence method](#) or the [get_CharConfidence method](#).

The confidence level of each character is a digit from 0 (lowest confidence) to 9 (highest confidence). If the confidence level for a four-character field is 9999, each of the 4 characters has a confidence level of 9.

Syntax

VBScript

```
oDCO.CharConfidence (nIndex as Long) as Long
```

Applies to

Character objects only.

Type

Read and write.

Arguments

nIndex

0 specifies the primary value. When the field contains multiple recognition, voting, or multiple-pass data entry values, 1 specifies the first alternative, 2 specifies the second alternative, and so on.

VBScript example

This example sets the confidence level of the primary character to 9, or the highest confidence level.

```
oDCO.CharConfidence(0)=9 ` high confidence  
conf = oDCO.CharConfidence(0)
```

Parent topic: [DCO properties](#)

Related reference:

[CharValue property](#)

[AltConfidenceString property](#)

CharValue property

The CharValue property sets or gets the data value of a character, which can be a digit in a multiple-digit number or a single character in a string. You can use this property to search for or assign a value to a character in a field.

VBScript restriction: Because extended properties are not supported through the C# .NET Interop interface, you must instead use the [set_CharValue method](#) or the [get_CharValue method](#).

Syntax

VBScript

```
oDCO.CharValue (nIndex as Long) as String.
```

Applies to

Character objects only.

Type

Read and write.

Arguments

nIndex

0 specifies the primary value. When the field contains multiple recognition, voting, or multiple-pass data entry values, 1 specifies the first alternative, 2 specifies the second alternative, and so on.

Parent topic: [DCO properties](#)

Related reference:

[AddValue method](#)

[CharConfidence property](#)

[DeleteValue method](#)

ConfidenceString property

The ConfidenceString property sets or gets the confidence values for the primary character data in a field object.

The value of each character can be 0 - 9 and corresponds to integer confidence levels of 0 to 9. After Datacap scans a page and applies recognition rules, Datacap generates an XML file that contains confidence levels for characters in each field on a page. The XML code adds a value of 1 to the confidence level so that the range in XML is 1 - 10.

In this XML sample for the Vendor field, the fourth character contains a confidence level of 6 for the primary character value. The first alternative character value has confidence level of 8, and the second alternative character value has a confidence level of 4.

```
<F
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev501_Vendor">
  <V n="TYPE">Vendor</V>
  <V n="Position">0,0,0,0</V>
  <V n="Status">1</V>
  <C cn="6,8,10" cr="0,0,0,0">83,49,53</C>
  <C cn="6,8,10" cr="0,0,0,0">116,50,54</C>
  <C cn="6,8,10" cr="0,0,0,0">105,51,55</C>
  <C cn="6,8,4" cr="0,0,0,0">110,52,56</C>
```

Syntax

VBScript

```
oDCO.ConfidenceString as String
```

C#

```
string ConfidenceString { set; get; }
```

Applies to

Field objects only.

Type

Read and write.

C# example

This example sets and gets the confidence string that is associated with the primary character data in the Vendor field. The root of the search in this case is the page object.

```
m_oDCOPage.FindChild("Vendor").ConfidenceString = "7777";
string strReturn = m_oDCOPage.FindChild("Vendor").ConfidenceString;
```

- The confidence levels that you specify are the internal confidence levels (0 - 9). When you write them to the page XML file, field object and parent page object confidence values are raised by 1 because the XML values range 1 - 10.
- If the field contains more characters than specified when you are setting the confidence string, the last specified character is used for all remaining characters. For example, if you specify 1234 but the field has 10 characters, the remaining 6 characters are assigned a confidence value of 4.

Parent topic: [DCO properties](#)

[Text property](#)

[Write method](#)

ID property

The ID property sets or gets the unique identifier of an object, which can be a batch, document, or page.

This property provides access to the `id` attribute of an object. For example, the `id` attribute for a batch, document, page, and field can be <B

```
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev544_20100096">, <D
```

```
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev544_20100096.001.01">, <P
```

```
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev544_TM000001">, and <F
```

```
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev544_Vendor">. You can pass the value of the id attribute to a variable or custom action.
```

Syntax

VBScript

```
oDCO.ID as String
```

C#

```
string ID { set; get; }
```

Applies to

All objects. The ID property typically has a value for a batch and for all child nodes, including documents, pages, and fields, but not for characters.

Type

Read and write.

Parent topic: [DCO properties](#)

ImageName property

The ImageName property sets or gets the full path and the file name of the image file that is associated with a page object. You can use this property when you are modifying the order of pages in a batch.

This property provides access to the variable *IMAGEFILE*.

Syntax

VBScript

```
oDCO.ImageName as String
```

C#

```
string ImageName { set; get; }
```

Applies to

Page objects only.

Type

Read and write.

C# example

The following example sets and gets the full path and the file name for the image file that is associated with the page object with ID "TM000001":

```
m_oDCO.FindChild("TM000001").ImageName = "C:\\Datacap\\APT\\batches  
\\20100096.001\\tm000001.tif";  
strImageName = m_oDCO.FindChild("TM000001").ImageName;
```

Parent topic: [DCO properties](#)

Status property

The Status property sets or gets the status of an object. The status is a numerical value that indicates success, failure, error, problem, or other status that depends on the type of object. For example, you can use this property to locate pages with a status of 1, which indicates that there was a problem during the page identification task.

This property provides access to the *STATUS* variable, which is one of the standard variables that are installed with Datacap.

Syntax

VBScript

```
oDCO.Status as Long
```

C#

```
int Status { set; get; }
```

Applies to

All object types.

Type

Read and write.

Parent topic: [DCO properties](#)

Related information:

[Standard Variable Reference](#)

Text property

The Text property sets or gets the primary character data that is associated with a field.

The characters of a field are stored as ASCII values in the page data XML file. In this sample XML node for the Vendor field, the fourth character contains a primary text value of 97. The first alternative text value is 52, and the second alternative text value is 97.

```
<F
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev594_Vendor">
  <V n="TYPE">Vendor</V>
  <V n="Position">0,0,0,0</V>
  <V n="STATUS">1</V>
  <C cn="10,8,10" cr="0,0,0,0">68,49,68</C>
  <C cn="10,8,10" cr="0,0,0,0">97,50,97</C>
  <C cn="10,8,10" cr="0,0,0,0">116,51,116</C>
  <C cn="10,8,10" cr="0,0,0,0">97,52,97</C>
</F>
```

Syntax

VBScript

```
Text as String
```

C#

```
string Text { set; get; }
```

Applies to

Field objects only.

Type

Read and write.

C# example

This example sets the primary character data in the Vendor field to IBM. The confidence values (cn attribute) are automatically set to high (9 in the code; 10 in the page XML file).

```
m_oDCOPage.FindChild("Vendor").Text = "IBM";
```

- The text is the value that a task, such as Profiler, adds to a runtime field object.
- If you use this property to replace existing data, all characters are assigned high confidence, unless you specify otherwise by using the `ConfidenceString` property.

Parent topic: [DCO properties](#)

Related reference:

[AltText property](#)

[ConfidenceString property](#)

Type property

The `Type` property sets or gets the object name. You can use this property to search for document types or page types in a batch and change the name of the object.

This property provides access to the `TYPE` variable, which is one of the standard variables that are installed with Datacap.

Syntax

VBScript

```
objRT.Type as String
```

C#

```
string Type { set; get; }
```

Applies to

Any object, but it is used primarily for documents and pages.

Type

Read and write.

Example

This example sets the name of the document object to 1040ez:

```
oDCO.Type = "1040ez"
```

Parent topic: [DCO properties](#)

Related reference:

[get_Variable method](#)

[set_Variable method](#)

Related information:

[Standard Variable Reference](#)

Variable property

The `Variable` property sets or gets the value of a named variable. You can use this property when you first need to obtain a value that you pass afterward to another variable or object, such as a field.

VBScript restriction: Because extended properties are not supported through the C# .NET Interop interface, you must instead use [set_Variable](#) or [get_Variable](#).

Syntax

VBScript

```
oDCO.Variable(lpszName as String) As Variant.
```

Arguments

`lpszName`

The name of the variable of which you need to set or get the value.

Applies to

All objects.

Type

Read and write.

VBScript example

This example checks the value of the *Handwriting* variable. If *Handwriting* is greater than 0, then the code sets the value of the *Checked* variable to 1 to indicate that a check box is selected.

```
If oDCO.Variable("HandWriting") > 0 Then
    WriteLog("HandWriting is TRUE")
End If
oDCO.Variable("Checked") = 1
```

Parent topic: [DCO properties](#)

Related reference:

[AddVariable method](#)

[GetChild method](#)

[GetVariableValue method](#)

XML property

The XML property sets or gets the XML file that is associated with an object. You can use this property to populate a run time object from the Setup DCO file and assign the XML file to a variable.

Syntax

C#

```
string XML { set; get; }
```

Arguments

None.

Returns

String containing the XML file name.

Applies to

All object types.

C# example

This example populates the runtime batch object from the DCO Setup file, and then assigns the XML file to the variable *strDCOXml*.

```
m_oDCO.Read("C:\\Datacap\\APT\\batches\\20100096.001\\Verify.xml");  
strDCOXml = m_oDCO.XML;
```

Parent topic: [DCO properties](#)

DCO methods

You can use DCO methods to complete actions on DCO objects, such as adding documents to batches, pages to documents, or fields to pages. You can also use the DCO methods to search for and change metadata values, including confidence levels, indexes, variables, and alternative text for verification.

- [AddChild method](#)
The `AddChild` method adds a child object to the parent runtime DCO object. You can use the `AddChild` method to add a field to a page or add a page to a document. You can add only a child that is at the same or a lower level than this object in the hierarchy.
- [AddValue method](#)
The `AddValue` method adds a character data value (ASCII code) and the associated confidence level to the character object. You can use this method to correct optical character recognition (OCR) errors.
- [AddVariable method](#)
The `AddVariable` method adds a variable and its value to an object, such as a batch, document, page, or field. You can use this method when you need to pass values to a custom action. For example, your organization might introduce a new security regulation that requires a new field for identification on certain page types.
- [AddVariableFloat method](#)
The `AddVariableFloat` method adds a variable of type `double` and its value to an object.
- [AddVariableInt method](#)
The `AddVariableInt` method adds an integer variable and its value to an object. You can use this method when you need to pass values to custom actions.
- [AddVariableString method](#)
The `AddVariableString` method adds a string variable and its value to an object. You can use this method when you need to pass values to custom actions.
- [CheckIntegrity method](#)
The `CheckIntegrity` method determines whether a batch conforms to the document integrity rules that are specified in the Setup DCO file.
- [Clear method](#)
The `Clear` method removes all of the child objects of a runtime object, but does not remove the object itself. For example, you can use this method when a document contains corrupted or incorrect pages.
- [CreateDocuments method](#)
The `CreateDocuments` method uses the Setup DCO file to determine the document type that is associated with each page in a batch and creates the required document objects.
- [CreateFields method](#)
The `CreateFields` method creates a runtime field object for each field that is specified within the

corresponding page (or field) node in the document hierarchy.

- [DeleteChild method](#)
The `DeleteChild` method removes the specified child object from the runtime DCO object.
- [DeleteValue method](#)
The `DeleteValue` method deletes a data value and the corresponding confidence level value of a character object.
- [DeleteVariable method](#)
The `DeleteVariable` method removes a variable, including variables such as `TYPE` or `STATUS` that are installed with Datacap, and its value from a runtime DCO object.
- [FindChild method](#)
The `FindChild` method gets an interface to a child object that is referenced by ID (name). You can use this method when you need to get the interface to a child object for which you only know the name.
- [FindChildIndex method](#)
The `FindChildIndex` method returns the index of the specified child object that is contained within a runtime DCO object. You can use this method when you know the name of the child object, and you need to pass the position of the child object to a variable.
- [FindRouteChild method](#)
The `FindRouteChild` method returns the interface to an object that is specified by using the path through the document hierarchy. You use this method to save or restore execution points during an action process.
- [FindVariable method](#)
The `FindVariable` method returns the index of a variable by using the ID (name) of the variable. You can use this method when you need to pass the value of a variable to another variable or action.
- [get_AltConfidenceString method](#)
The `get_AltConfidenceString` method gets the confidence level of each character in the referenced field. You can use this method when you need to pass the confidence level of a string to a variable or action.
- [get_AltText method](#)
The `get_AltText` method gets the primary or alternative character data that is associated with a field.
- [get_CharConfidence method](#)
The `get_CharConfidence` method gets the primary or alternative character data that is associated with a field. You can use this method when you need to pass the character data value to a variable or action.
- [get_CharValue method](#)
The `get_CharValue` method gets the ASCII data value of the primary character or alternative character. You can use this method when you need to pass the character data value to a variable or action.
- [get_OMRValue method](#)
The `get_OMRValue` method gets the positions within the optical mark recognition (OMR) field of the check boxes that are selected. You can use this method to pass the positions to variables or actions, such as those that are used in verification functions to confirm that check boxes are selected.
- [get_Variable method](#)
The `get_Variable` method gets the value of a referenced variable by using the ID (name) of the variable. You can use this method to pass the value of a named variable to an action for further processing.
- [GetChild method](#)
The `GetChild` method gets a referenced child object by using the index of the child object. You can use this method to retrieve a field on a page when you know the position, but not the name.
- [GetLastError method](#)
The `GetLastError` method retrieves the text of the last error that is encountered during a DCO read operation or write operation, and clears the error.
- [GetPosition method](#)
The `GetPosition` method gets the position of a field or character on a page. You can use this method for fields or characters that are located at identical positions on multiple pages in a batch.
- [GetRoute method](#)
The `GetRoute` method gets the path through the document hierarchy to an object.

- [GetVariableName method](#)
The `GetVariableName` method gets the name (ID) of a variable from the index of the variable. You can use this method when you know the position of a variable within an object, but you do not know the name of the variable.
- [GetVariableValue method](#)
The `GetVariableValue` method gets the value of a referenced variable by using the index of the variable.
- [IsError method](#)
The `IsError` method indicates whether an error occurred during a prior `Read` operation or `Write` operation.
- [IsRoute method](#)
The `IsRoute` method indicates whether the specified path is the valid path through the runtime hierarchy for an object.
- [IsValid method](#)
The `IsValid` method confirms that the interface of a DCO object is valid and is connected to an actual object.
- [MoveChild method](#)
The `MoveChild` method moves a child of a runtime DCO object to a different index location. You can use this method to reorganize or correct batches, documents, pages, or fields.
- [MoveIn method](#)
The `MoveIn` method moves the specified runtime DCO object from the current parent to a different parent.
- [NumOfChildren method](#)
The `NumOfChildren` method returns the number of child objects that is associated with the runtime DCO object.
- [NumOfVars method](#)
The `NumOfVars` method returns the number of variables that is associated with the runtime DCO object.
- [ObjectType method](#)
The `ObjectType` method returns a numeric value that indicates the object type.
- [Parent](#)
The `Parent` method returns the parent of the runtime DCO object.
- [Read method](#)
The `Read` method reads the runtime information from a Runtime DCO file or a page data file, and writes the information into the DCO object.
- [ReadSetup method](#)
The `ReadSetup` method reads the document hierarchy setup information from the specified Setup DCO file and writes the information into the Setup object and SetupNode object.
- [SetPosition method](#)
The `SetPosition` method sets the position of the runtime field or character object on the page. This method is useful for making corrections to zonal recognition on a page.
- [SetupNode method](#)
The `SetupNode` method accesses the SetupNode object that is associated with the current object. You can use this method to get the name of the object in the document hierarchy that corresponds to the object in the runtime batch hierarchy.
- [SetupObject method](#)
The `SetupObject` method returns the Setup object that is associated with the current batch-level runtime DCO object. You can use this method when a batch contains unidentified pages and you need to modify the runtime batch hierarchy.
- [set_AltConfidenceString](#)
The `set_AltConfidenceString` method sets the confidence level of each character in the referenced field.
- [set_AltText method](#)
The `set_AltText` method sets the primary character data or alternative character data that is associated with a field. You can use this method for multi-pass verification tasks and double-blind data entry tasks.

- [set_CharConfidence method](#)
The set_CharConfidence method sets the confidence level for the primary value or of the alternative value of a character in a field.
- [set_CharValue method](#)
The set_CharValue method sets the ASCII data value of the primary character or alternative character.
- [set_OMRValue](#)
The set_OMRValue method sets the character values within the OMR field to indicate whether a check box is selected.
- [set_Variable method](#)
The set_Variable method sets the value of a referenced variable by using the name of the variable.
- [Write method](#)
The Write method saves the runtime batch object to a batch file, or a page object to a page file. When it writes a batch object, this method also writes all of the child objects, including documents, pages, and fields.
- [WriteSetup method](#)
The WriteSetup method writes the Setup object and SetupNode objects to the Setup DCO file. You use this method after you read a setup DCO file from an external location.

Parent topic: [DCO APIs](#)

AddChild method

The AddChild method adds a child object to the parent runtime DCO object. You can use the AddChild method to add a field to a page or add a page to a document. You can add only a child that is at the same or a lower level than this object in the hierarchy.

Syntax

VBScript

```
oDCO.AddChild (ObjectType as Long, ID as String,  
Placement as Long) as Object
```

C#

```
TDCOLib.DCO AddChild(int nType, string lpszID, int nIndex)
```

Applies to

All objects.

Arguments

nType

The type of the child object:

- 0=Batch
- 1=Document
- 2=Page
- 3=Field
- 4=Character

lpszID

A string with the ID of the new object. Use an empty string for character objects.

nIndex

The index of the child object relative to other child objects of the same parent. If necessary, existing child objects are moved down to accommodate a new child object.

-1: Adds the new child object to the end of the list.

0: Adds the new child object to the beginning of the list.

Returns

The child object of the specified type.

C# examples

The first example creates a field object under the parent page object. The field is added to the page data file as the last field in the list by using a value of -1.

```
m_oDCOField = m_oDCOPage.AddChild(3, "NewField", -1);
```

The second example adds a character object to the parent field object. The new character is added at the beginning of the list (0) and all existing character fields move down one position.

```
m_oDCOChar = m_oDCOField.AddChild(4, "", 0);
```

- You cannot add a parent to a child. For example, you cannot add a page object to a field object.
- You cannot assign an ID that is already used by another child of the same parent.

Parent topic: [DCO methods](#)

Related reference:

[DeleteChild method](#)

AddValue method

The AddValue method adds a character data value (ASCII code) and the associated confidence level to the character object. You can use this method to correct optical character recognition (OCR) errors.

In addition to the primary data value, each character in a field can have multiple alternative data values. Each of the alternative data values has an associated confidence level (0 - 9 internally and 1 - 10 in the page XML file). Each time that you add a value by using the AddValue method, the new value is appended to the list of existing values. Also, a new confidence level is appended to the list of existing confidence levels.

In the following example, the fourth character contains a primary confidence level value of 6, a first alternative confidence level of 8, and a second alternative confidence level of 10. The fourth character also contains a primary character value of 110, a first alternative character value of 52, and a second alternative character value of 56.

```
<F
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev489_Vend
or">
    <V n="TYPE">Vendor</V>
    <V n="Position">0,0,0,0</V>
    <V n="STATUS">1</V>
    <C n="6,8,10" cr="0,0,0,0">83,49,53</C>
    <C n="6,8,10" cr="0,0,0,0">116,50,54</C>
    <C n="6,8,10" cr="0,0,0,0">105,51,55</C>
    <C n="6,8,10" cr="0,0,0,0">110,52,56</C>
</F>
```

Syntax

VBScript

```
oDCO.AddValue (Value as Long, Confidence as Long) as Boolean
```

C#

```
int AddValue(int nValue, int nConfidence)
```

Applies to

Character objects only.

Arguments

nValue

The ASCII code of the character.

nConfidence

A number between 0 (low) and 9 (high) representing the confidence level.

Returns

VBScript

Returns true if successful; returns false if unsuccessful.

C#

Returns 1 if successful; returns 0 if unsuccessful.

C# example

This example adds the ASCII character 50 with a confidence level of 3 to the character object:

```
m_oDCOChar.AddValue(50,3);
```

Parent topic: [DCO methods](#)

Related reference:

[DeleteValue method](#)

AddVariable method

The AddVariable method adds a variable and its value to an object, such as a batch, document, page, or field. You can use this method when you need to pass values to a custom action. For example, your organization might introduce a new security regulation that requires a new field for identification on certain page types.

Syntax

VBScript

```
oDCO.AddVariable (strName as String, newValue as Variant) as Boolean
```

C#

```
bool m_oDCO.AddVariable (string strName, object newValue)
```

Arguments

strName

The variable name.
newValue
The value of the variable.

Returns

Returns true if successful; returns false if unsuccessful.

Applies to

All objects.

Examples

VBScript

This example adds the *Company* variable with a value of IBM to the page object.

```
Dim page
Call objField.AddVariable ("Company", IBM)
factor = objField.Variable("Company")
```

C#

This example adds the variable *Company* and the value IBM to page TM000001 in the runtime batch.

```
TDCOLib.IDCO m_oChild = m_oDCO.FindChild("TM000001");
if (m_oChild != null
)
{
m_oChild.AddVariable("Company", "IBM");
}
```

The resulting XML code is shown in the following example:

```
<?xml-stylesheet type="text/xsl"
href="#_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_..\..
\dco.xsl"?>
<B
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev490
_20100096.001">
  <V n="TYPE">APT</V>
  <V n="STATUS">0</V>
  <D
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev490
_20100096.001.01">
  <V n="TYPE">Invoice</V>
  <V n="STATUS">0</V>
  <P
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev490
_TM000001">
  <V n="TYPE">Main_Page</V>
  <V n="STATUS">0</V>
  <V n="Company">IBM</V>
```

Parent topic: [DCO methods](#)

Related reference:

[DeleteVariable method](#)

[set_Variable method](#)

[Variable property](#)

AddVariableFloat method

The `AddVariableFloat` method adds a variable of type `double` and its value to an object.

Syntax

VBScript

```
oDCO.AddVariableFloat (strName as String, fValue as Double) as Boolean
```

C#

```
bool AddVariableFloat(string strName, double fValue)
```

Applies to

All object types.

Arguments

`strName`

The variable name.

`fValue`

The value of the variable as a double.

Returns

Returns true if successful; returns false if unsuccessful.

Example

See [AddVariable method](#).

Parent topic: [DCO methods](#)

Related reference:
[set_Variable method](#)

AddVariableInt method

The `AddVariableInt` method adds an integer variable and its value to an object. You can use this method when you need to pass values to custom actions.

Syntax

VBScript

```
oDCO.AddVariableInt (strName as String, nValue as Integer) as Boolean.
```

C#

```
bool AddVariableInt(string strName, int nValue)
```

Applies to

All object types.

Arguments

strName

The variable name

nValue

The value of the variable as an integer. This method also accepts a double, but rounds the double to the nearest integer before the method assigns the value to the object.

Returns

Returns true if successful; returns false if unsuccessful.

Example

See [AddVariable method](#).

Parent topic: [DCO methods](#)

Related reference:

[set_Variable method](#)

AddVariableString method

The `AddVariableString` method adds a string variable and its value to an object. You can use this method when you need to pass values to custom actions.

Syntax

C#

```
bool AddVariableString(string strName, string strValue)
```

VBScript

```
oDCO.AddVariableString (strName as String, strValue as String) as Boolean
```

Applies to

All objects types.

Arguments

strName

The variable name.

strValue

The value of the variable as a string.

Returns

Returns true if successful; returns false if unsuccessful.

Example

See [AddVariable method](#).

Parent topic: [DCO methods](#)

Related reference:
[set_Variable method](#)

CheckIntegrity method

The `CheckIntegrity` method determines whether a batch conforms to the document integrity rules that are specified in the Setup DCO file.

This method is typically used after the [CreateDocuments method](#).

Syntax

VBScript

```
oDCO.CheckIntegrity (pLastChecked as Object ) as Long.
```

C#

```
int CheckIntegrity(out object pLastChecked)
```

Arguments

`pLastChecked`

Variable to contain the last object that is checked in case of an error.

Returns

One of the following values:

0

Passed

1

Has more child objects than allowed by the `max` attribute.

2

Has fewer child objects than required by the `min` attribute.

3

Invalid member. A child object is not of a type that is supported by the parent.

4

A child object is in the wrong position relative to other child objects as specified by the `pos` attribute.

Applies to

All object types except character objects. When applied to a batch or document, the method checks to the page level but not lower to a field or character object. When applied to a page, the method checks fields on that page.

VBScript example

This example creates documents in a batch and applies integrity rules. If an error is encountered, the code opens a message box that displays the type of error (1-4). The message box also displays the object and the ID that are the source of the error.

```
Dim DocInt
Dim LastChecked
Call oDCO.CreateDocuments
DocInt = oDCO.CheckIntegrity(LastChecked)
If DocInt > 0 Then
msgbox "Document Integrity problem = " & DocInt
msgbox "Detected at " & LastChecked.ObjectType & " type object ID " & LastChecked.ID
End If
```

C# example

This example populates the runtime and setup DCO objects, and checks the integrity of the runtime batch.

```
m_oDCO.Read("C:\\Datacap\\APT\\batches\\20100096.001\\Verify.xml");
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
Object pLastChecked = null;
int nRetVal = m_oDCO.CheckIntegrity(out pLastChecked);
```

Parent topic: [DCO methods](#)

Clear method

The `Clear` method removes all of the child objects of a runtime object, but does not remove the object itself. For example, you can use this method when a document contains corrupted or incorrect pages.

Syntax

VBScript

```
oDCO.Clear ( ) as Boolean.
```

C#

```
bool Clear()
```

Arguments

None.

Returns

Returns true if successful; returns false if unsuccessful.

Applies to

All object types.

VBScript example

This example instantiates a field-level object, uses `Clear ()` to remove any child objects, and then assigns a value to the `ID` property of the object.

```
Dim objFldTwo
Set objFldTwo = DCOSetup.GetNode(3,8)
objFldTwo.Clear
objFldTwo.ID = Tax2
```

Parent topic: [DCO methods](#)

Related reference:

[DeleteChild method](#)

CreateDocuments method

The `CreateDocuments` method uses the Setup DCO file to determine the document type that is associated with each page in a batch and creates the required document objects.

This method is normally called after the page identification task to assign pages to documents within the runtime hierarchy.

Syntax

VBScript

```
oDCO.CreateDocuments ( ) as Boolean.
```

C#

```
bool CreateDocuments()
```

Applies to

Batch objects only.

Arguments

None.

Returns

Returns true if successful; returns false if unsuccessful.

VBScript example

This example reads the Setup DCO file (BDOcs.xml), creates the document objects, and confirms that the batch conforms to the document integrity rules.

```
Call oDCO.ReadSetup ("c:\Datacap\BDOcs\dco_APT\BDOcs.xml")
Call objBatch.CreateDocuments
Call objBatch.CheckIntegrity
```

Parent topic: [DCO methods](#)

Related reference:

[CheckIntegrity method](#)

CreateFields method

The `CreateFields` method creates a runtime field object for each field that is specified within the corresponding page (or field) node in the document hierarchy.

For example, the `1040EZ` page node in the following document hierarchy has rules for three field objects. So, `CreateFields ()` creates three field objects (`Tax Year`, `SSN`, `Spouse SSN`).

```
<P type="1040EZ">
  (
    <V n="ID">0</V>
    <V n="TYPE">Page</V>
    <V n="STATUS">0</V>
    <V n="IMAGEFILE"></V>
    <V n="DATAFILE"></V>
    <V n="TEMPLATE IMAGE"></V>
    <V n="MIN_TYPES">1</V>
    <V n="MAX_TYPES">0</V>
    <V n="rules"><in><r
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev503_3"
rs="4" /><r
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev503_1"
rs="5" /><r
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev503_2"
rs="6" /></in></V>
    <F type="Tax Year" pos="0" min="0" max="0"/>      <!-- Rule 0 -->
    <F type="SSN" pos="0" min="0" max="0"/>          <!-- Rule 1 -->
    <F type="Spouse SSN" pos="0" min="0" max="0"/>   <!-- Rule 2 -->
  </P>
```

The child objects are used to hold the field data that is generated during the field recognition process. This method ensures that a data file is created for the current page when a batch is saved.

Syntax

VBScript

```
oDCO.CreateFields( ) as Boolean.
```

C#

```
bool CreateFields()
```

Arguments

None.

Returns

Returns true if successful; returns false if unsuccessful.

Applies to

Page objects or field objects.

Parent topic: [DCO methods](#)

Related reference:

[Write method](#)

DeleteChild method

The `DeleteChild` method removes the specified child object from the runtime DCO object.

Syntax

VBScript

```
oDCO.DeleteChild (nIndex subscript as Long ) as Boolean
```

C#

```
bool DeleteChild(int nIndex)
```

Applies to

Any object

Arguments

`nIndex`

Index of the child to delete, where 0 is the first child.

Returns

Returns true if successful; returns false if unsuccessful.

C# example

This example removes the first field object of the runtime page object.

```
m_oDCOPage.DeleteChild(0);
```

Parent topic: [DCO methods](#)

Related reference:

[AddChild method](#)

[Clear method](#)

DeleteValue method

The `DeleteValue` method deletes a data value and the corresponding confidence level value of a character object.

In the following example, the fourth character contains a primary confidence level value of 6, a first alternative confidence level of 8, and a second alternative confidence level of 10. The fourth character also contains a primary character value of 110, a first alternative character value of 52, and a second alternative character value of 56.

```
<F
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev508_Vendor">
    <V n="TYPE">Vendor</V>
    <V n="Position">0,0,0,0</V>
    <V n="STATUS">1</V>
    <C n="6,8,10" cr="0,0,0,0">83,49,53</C>
    <C n="6,8,10" cr="0,0,0,0">116,50,54</C>
    <C n="6,8,10" cr="0,0,0,0">105,51,55</C>
```

```
<C n="6,8,10" cr="0,0,0,0">110,52,56</C>
```

```
</F>
```

Syntax

VBScript

```
oDCO.DeleteValue (nIndexValue as Long) as Boolean
```

C#

```
bool DeleteValue(int nIndexValue)
```

Applies to

Character objects only.

Arguments

nIndexValue

The index of the value to be deleted, where 0 is the primary value, 1 is the first alternative value, and so on.

Returns

Returns true if successful; returns false if unsuccessful.

C# example

This example deletes the first alternative character value and the first alternative confidence level value.

```
m_oDCOChar.DeleteValue(1);
```

Character XML before: `"\t<C cn="10,9" cr="0,0,0,0">83,99</C>\n"`

Character XML after: `"\t<C cn="10" cr="0,0,0,0">83</C>\n"`

Parent topic: [DCO methods](#)

Related reference:

[AddValue method](#)

DeleteVariable method

The `DeleteVariable` method removes a variable, including variables such as TYPE or STATUS that are installed with Datacap, and its value from a runtime DCO object.

Syntax

VBScript

```
oDCO.DeleteVariable (lpszName as String ) as Boolean
```

C#

```
bool DeleteVariable(string lpszName)
```

Applies to

All objects.

Arguments

lpszName
The name of the variable to delete (case sensitive).

Returns

Returns true if successful; returns false if unsuccessful.

Parent topic: [DCO methods](#)

Related reference:
[AddVariable method](#)

FindChild method

The FindChild method gets an interface to a child object that is referenced by ID (name). You can use this method when you need to get the interface to a child object for which you only know the name.

If the method references a field and the same ID is used within multiple page objects, the method returns the first matching field.

Syntax

VBScript

```
oDCO.FindChild (lpszName as String) as Boolean.
```

C#

```
TDCOLib.DCO.FindChild(string lpszName)
```

Arguments

lpszName
The ID (name) of the child object.

Returns

Returns an interface to the child object if successful; returns nothing if unsuccessful.

Applies to

All objects.

VBScript example

This example returns the interface to the Client_ID field, and displays the interface in a message box.

```
Dim objRTClFld  
Set objRTClFld=oDCO.FindChild("Client_ID")  
msgbox objRTClFld.ID
```

To retrieve a child object by index instead of ID, use [GetChild method](#)

C# example

This example returns an interface to the Vendor field:

```
m_oDCOField = m_oDCOPage.FindChild("Vendor");
```

Parent topic: [DCO methods](#)

Related reference:

[AddChild method](#)

[DeleteChild method](#)

[FindChildIndex method](#)

FindChildIndex method

The FindChildIndex method returns the index of the specified child object that is contained within a runtime DCO object. You can use this method when you know the name of the child object, and you need to pass the position of the child object to a variable.

Syntax

VBScript

```
oDCO.FindChildIndex (lpszName as String ) as Long
```

C#

```
int FindChildIndex(string lpszName)
```

Applies to

All objects except batch.

Arguments

lpszName

The ID (name) of the child object.

Returns

Returns the index of the specified child object, where 0 is the first child; returns -1 if the specified child is not found.

VBScript example

This example returns the index of the Client_ID field, and passes the index to the GetChild method.

```
Dim ClientFldVal  
ClientFldVal = objRTSurvey.FindChildIndex("Client_ID")  
Call objRTSurvey.GetChild(ClientFldVal)
```

C# example

This example returns the index of the Vendor field:

```
int nVendorIndex = m_oDCOPage.FindChildIndex("Vendor");
```

Parent topic: [DCO methods](#)

Related reference:

[FindChild method](#)

[GetChild method](#)

FindRouteChild method

The FindRouteChild method returns the interface to an object that is specified by using the path through the document hierarchy. You use this method to save or restore execution points during an action process.

The use of the path through a document hierarchy is shown in this example:

```
B/D(20100028.002.01)/P(TM000001)/F(Vendor)
```

Syntax

C#

```
TDCOLib.DCO FindRouteChild(string bszRoute)
```

Arguments

bszRoute

The route through the document hierarchy. (See the C# example.)

Returns

Returns an interface to the specified object; returns null if the route is invalid.

C# example

This example gets an interface to the Vendor field object on page TM000001:

```
m_oDCOField = m_oDCO.FindRouteChild("B/D(20100028.002.01)/P(TM000001)/F(Vendor)");
```

Parent topic: [DCO methods](#)

Related reference:

[GetRoute method](#)

FindVariable method

The FindVariable method returns the index of a variable by using the ID (name) of the variable. You can use this method when you need to pass the value of a variable to another variable or action.

Syntax

VBScript

```
oDCO FindVariable (lpszName as String ) Variables Index subscript as Long
```

C#

```
int FindVariable(string lpszName)
```

Arguments

lpszName
The variable ID (name).

Returns

Returns the index of the specified variable, where 0 is the first variable; Returns -1 if the specified variable is not found.

Applies to

All objects.

VBScript example

This example returns the index of the *Length* variable, and displays the index in a message box:

```
Dim VarLength
varLength = oDCO.FindVariable("Length")
if varLength > 0 then
    msgbox oDCO.Variable(varLength)
end if
```

Parent topic: [DCO methods](#)

Related reference:

[get_Variable method](#)

[set_Variable method](#)

[Variable property](#)

get_AltConfidenceString method

The `get_AltConfidenceString` method gets the confidence level of each character in the referenced field. You can use this method when you need to pass the confidence level of a string to a variable or action.

.NET only: For VBScript, use the [AltConfidenceString property](#) instead.

The confidence level of each character is a digit from 0 (lowest confidence) to 9 (highest confidence). If the confidence level for a four-character field is 9999, each of the 4 characters has a confidence level of 9. The XML code adds a value of 1 to the confidence level so that the range in XML is 1-10. In the following example XML setup node for the field, `Vendor`, the confidence level for the primary character is 6. The confidence level for the first alternative character is 8, and the confidence level for the second alternative is 10.

```
<F
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev527_Vendor">
    <V n="TYPE">Vendor</V>
    <V n="Position">0,0,0,0</V>
    <V n="STATUS">1</V>
    <C cn="6,8,10" cr="0,0,0,0">83,49,53</C>
    <C cn="6,8,10" cr="0,0,0,0">116,50,54</C>
    <C cn="6,8,10" cr="0,0,0,0">105,51,55</C>
```

```
</F> <C cn="6,8,10" cr="0,0,0,0">110,52,56</C>
```

Syntax

C#

```
string get_AltConfidenceString(int nIndex)
```

Applies to

Field objects only.

Arguments

nIndex

0 specifies the primary value. Where the field contains multiple recognition, voting, or multiple-pass data entry values, 1 specifies the first alternative, 2 specifies the second alternative, and so on. (See the C# example.)

Returns

String containing the confidence level of each character. The returned digits are always one less than the digits that are stored in the page XML file. (See the C# example.)

C# example

The following example gets the confidence string for the second alternative.

```
string strAltConf = m_oVendorField.get_AltConfidenceString(2)
```

Referencing the XML code example for the Vendor field, the return value in this case is 9999, because the returned value is always the stored value minus 1.

Parent topic: [DCO methods](#)

Related reference:

[ConfidenceString property](#)
[get_CharConfidence method](#)
[set_AltConfidenceString](#)
[set_CharConfidence method](#)

get_AltText method

The `get_AltText` method gets the primary or alternative character data that is associated with a field.

.NET only: For VBScript, use [AltText property](#) instead.

Primary and alternative values are stored in ASCII format in the page XML file, as shown in the following example:

```
<F  
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev528_Vend  
or">  
    <V n="TYPE">Vendor</V>  
    <V n="Position">0,0,0,0</V>  
    <V n="STATUS">1</V>  
    <C n="6,8,10" cr="0,0,0,0">83,49,68</C>
```

```
<C n="6,8,10" cr="0,0,0,0">116,50,97</C>
<C n="6,8,10" cr="0,0,0,0">105,51,116</C>
<C n="6,8,10" cr="0,0,0,0">110,52,97</C>
</F>
```

For the fourth character, the primary text value is 110. The first alternative text value is 52, and the second alternative text value is 97.

Syntax

C#

```
string get_AltText(int nIndex)
```

Applies to

Field objects only.

Arguments

nIndex

0 specifies the primary value. When the field contains multiple recognition, voting, or multiple-pass data entry values, 1 specifies the first alternative, 2 specifies the second alternative, and so on.

Returns

String containing the alternative text.

Example

This example gets the second alternative text value from the Vendor field. Using the page XML example, the returned string is 68,97,116,97. The root of the search in this case is the page DCO.

```
string sAltText = m_oDCOPage.FindChild("Vendor").get_AltText(2);
```

Parent topic: [DCO methods](#)

Related reference:

[get_CharValue method](#)

[set_AltText method](#)

[Text property](#)

get_CharConfidence method

The `get_CharConfidence` method gets the primary or alternative character data that is associated with a field. You can use this method when you need to pass the character data value to a variable or action.

.NET only: For VBScript, use [CharConfidence property](#) instead.

This method gets the confidence level (cn) of the primary character value or alternative value. Within the XML file, the confidence level is a digit from 1 (lowest confidence) to 10 (highest confidence). In the following example XML setup node for the field, `Vendor`, the character primary confidence level is 6. The first alternative confidence level is 8, and the second alternative confidence level is 10.

```
<F
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev529_Vendor">
```

```
<V n="TYPE">Vendor</V>
<V n="Position">0,0,0,0</V>
<V n="STATUS">1</V>
<C cn="6,8,10" cr="0,0,0,0">83,49,53</C>
<C cn="6,8,10" cr="0,0,0,0">116,50,54</C>
<C cn="6,8,10" cr="0,0,0,0">105,51,55</C>
<C cn="6,8,4" cr="0,0,0,0">110,52,56</C>
</F>
```

Syntax

C#

```
int get_CharConfidence(int nIndex)
```

Applies to

Character objects only,

Arguments

nIndex

0 specifies the primary value. When the field contains multiple recognition, voting, or multiple-pass data entry values, 1 specifies the first alternative, 2 specifies the second alternative, and so on.

Returns

Integer representing the confidence level.

- `get_CharConfidence` returns the value as it is stored in the XML file. The field-level functions, such as [get_AltConfidenceString method](#), return the internal representation, which is the stored value minus 1.

C# example

This example gets the confidence level of second alternative value of the fourth character (index = 3) in the Vendor field. By using the example XML setup node, the returned value is 4. The root of the search in this case is the page DCO.

```
nConfLevel = m_oDCOPage.FindChild("Vendor").GetChild(3).get_CharConfidence(2);
```

Parent topic: [DCO methods](#)

Related reference:

[get_AltText method](#)

[get_CharValue method](#)

[set_CharConfidence method](#)

get_CharValue method

The `get_CharValue` method gets the ASCII data value of the primary character or alternative character. You can use this method when you need to pass the character data value to a variable or action.

.NET only: For VBScript, use [CharValue property](#) instead.

In the following example XML setup node for the field, `Vendor`, the fourth character has an ASCII data value of 110 for the primary character. Also, the ASCII data value is 52 for the first alternative character and 56 for the second alternative character.

```
<F
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev530_Vendor">
    <V n="TYPE">Vendor</V>
    <V n="Position">0,0,0,0</V>
    <V n="STATUS">1</V>
    <C cn="6,8,10" cr="0,0,0,0">83,49,53</C>
    <C cn="6,8,10" cr="0,0,0,0">116,50,54</C>
    <C cn="6,8,10" cr="0,0,0,0">105,51,55</C>
    <C cn="6,8,10" cr="0,0,0,0">110,52,56</C>
</F>
```

Syntax

C#

```
int get_CharValue(int nIndex)
```

Applies to

Character objects only.

Arguments

nIndex

0 specifies the primary value. Where the field contains multiple recognition, voting, or multi-pass data entry values, 1 specifies the first alternative, 2 specifies the second alternative, and so on.

Returns

Integer representing the ASCII character value.

- To get the converted text of the entire field, use [get_AltText method](#).

C# example

This example gets the second alternative value of the fourth character (index = 3) in the Vendor field. By using the example XML setup node, the returned value is 56. The root of the search in this case is the page DCO.

```
nCharValue = m_oDCOPage.FindChild("Vendor").GetChild(3).get_CharValue(2);
```

Parent topic: [DCO methods](#)

Related reference:

[get_CharConfidence method](#)

[set_CharValue method](#)

get_OMRValue method

The `get_OMRValue` method gets the positions within the optical mark recognition (OMR) field of the check boxes that are selected. You can use this method to pass the positions to variables or actions, such as those that are used in verification functions to confirm that check boxes are selected.

Each character in an OMR field is assigned the value 0 (ASCII 48 = not selected) or 1 (ASCII 49 = selected), and the resulting binary string is expressed as a decimal. The following XML example is 000100, which equals 4 in decimal. So, the return value is 4.

```
<F
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev532_1a">
  <V n="TYPE">1a</V>
  <V n="Position">120,1025,853,1169</V>
  <V n="STATUS">0</V>
  <V n="DensityString">BAAVAA</V>
  <C cn="10" cr="519,1132,559,1170">48</C> <!--48 indicates option not selected-->
  <C cn="10" cr="563,1132,603,1170">48</C>
  <C cn="10" cr="607,1132,647,1170">48</C>
  <C cn="10" cr="652,1132,692,1170">49</C> <!--49 indicates option selected-->
  <C cn="10" cr="697,1132,737,1170">48</C>
  <C cn="10" cr="763,1132,803,1170">48</C>
</F>
```

Syntax

C#

```
int get_OMRValue(int nIndex)
```

Arguments

nIndex

0 specifies the primary value. When the field contains multiple recognition, voting, or multi-pass data entry values, 1 specifies the first alternative, 2 specifies the second alternative, and so on.

Returns

The positions of the selected OMR check boxes (See the XML example.)

Applies to

OMR fields only.

Parent topic: [DCO methods](#)

Related reference:

[get_CharValue method](#)

[set_OMRValue](#)

get_Variable method

The `get_Variable` method gets the value of a referenced variable by using the ID (name) of the variable. You can use this method to pass the value of a named variable to an action for further processing.

.NET only: For VBScript, use [Variable property](#) instead.

If the specified variable does not exist in the runtime object, but does exist in the associated setup node object, the `get_Variable` method returns the value from the setup node.

A number of variables are defined and installed with Datacap. For a listing of these variables, see the *Standard Variable Reference* in IBM® Knowledge Center for Datacap.

Syntax

C#

```
string get_Variable(string lpszName)
```

Arguments

lpszName

The name of the variable of which you need the value.

Applies to

All objects.

C# example

This example gets the value of the *Company* variable.

```
string CompanyName = m_oDCO.get_Variable("Company")
```

Parent topic: [DCO methods](#)

Related reference:

[GetVariableName method](#)

[GetVariableValue method](#)

[set_Variable method](#)

GetChild method

The `GetChild` method gets a referenced child object by using the index of the child object. You can use this method to retrieve a field on a page when you know the position, but not the name.

Syntax

VBScript

```
oDCO.GetChild (nIndex as Long ) as Object
```

C#

```
TDCOLib.DCO.GetChild(int nIndex)
```

Arguments

nIndex

The index of the child, where 0 is the first child

Returns

Returns the child object if successful; returns nothing otherwise.

Applies to

All objects.

VBScript example

This example gets the name of the first four fields on a page, and displays each name in a message box.

```
Dim objViewField(4)
Dim I
i = 0
Do While i < 4
    Set objViewField(i) = oDCO.GetChild(i)
    msgbox objViewField(i).Text
    i = i + 1
Loop
```

C# example

This example returns the first field object on the page:

```
m_oDCOField = m_oDCOPage.FindChild(0);
```

- You can retrieve a child object by ID instead of by index by using the [FindChild method](#).
- You can create a loop by using the GetChild method with the [NumOfChildren method](#) to get all of the child objects that are associated with an object.

Parent topic: [DCO methods](#)

Related reference:

[FindChildIndex method](#)

GetLastError method

The GetLastError method retrieves the text of the last error that is encountered during a DCO read operation or write operation, and clears the error.

Before you call the GetLastError method, you can check whether an error string exists by calling the [IsError method](#).

Syntax

VBScript

```
objRTBatch.GetLastError as Boolean
```

C#

```
string GetLastError()
```

Arguments

None.

Returns

Returns true if successful; returns false if unsuccessful.

Applies to

Batch objects only.

VBScript example

```
objBatch.BatchDir = c:\Datacap\MQSW\Batches
bStatus = objBatch.Write rulerunner.xml
If bStatus <> True Then
    msgbox objBatch.GetLastError
End if
```

Parent topic: [DCO methods](#)

Related reference:

[Read method](#)

[Write method](#)

GetPosition method

The `GetPosition` method gets the position of a field or character on a page. You can use this method for fields or characters that are located at identical positions on multiple pages in a batch.

- For field objects, the position is defined by the *Position* variable of the field.

```
<V n="Position">0,0,0,0</V>
```

- For character objects, the position is defined by the `cr` attribute of the character.

```
<C cn="10" cr="0,0,0,0">83</C>
```

Syntax

VBScript

```
oDCO.GetPosition(pnLeft as Long, pnTop as Long, nRight as Long, pnBottom as Long) as Boolean
```

C#

```
bool GetPosition(out object pnLeft, out object pnTop, out object pnRight, out object pnBottom)
```

Arguments

Argument	Description
pnLeft	Variable for the distance from the left side of the page to the left edge of the object (in pixels)
pnTop	Variable for the distance from the top of the page to top edge of the object (in pixels)
pnRight	Variable for the distance from the left side of the page to right edge of the object (in pixels)
pnBottom	Variable for the distance from the top of the page to bottom edge of the object (in pixels)

Returns

Returns true if successful; returns false if unsuccessful.

Applies to

Field and character objects only.

VBScript example

This example gets a field's distance in pixels from the left, top, right, and bottom of a page, and displays the values in a message box.

```
Dim L,T,R,B
oDCO.GetPosition "L,T,R,B"
msgbox "The field's position is " L & ", " & T & ", " & R & ", " & B
```

C# example

This example finds the Vendor field on a page, and gets the field's distance in pixels from the left, top, right, and bottom of a page.

```
m_oDCOField = m_oDCOPage.FindChild("Vendor");
object pLeft, pTop, pRight, pBottom;
m_oDCOField.GetPosition(out pLeft, out pTop, out pRight, out pBottom);
```

Parent topic: [DCO methods](#)

Related reference:
[SetPosition method](#)

GetRoute method

The GetRoute method gets the path through the document hierarchy to an object.

Use the argument to specify whether you want the path through the Runtime DCO (`True`) or the Setup DCO (`False`).

Syntax

```
C#
string GetRoute(bool bRuntime)
```

Arguments

bRuntime
True for the Runtime DCO path; False for the Setup DCO path

Returns

String with the path.

Applies to

Any object type.

C# example

In the first example, `GetRoute ()` returns the path through the Runtime DCO to the Vendor field on page TM000001.

```
m_oDCO.Read("C:\\Datacap\\APT\\batches\\20100096.001\\Verify.xml");
m_oDCOPage = m_oDCO.FindChild("TM000001");
m_oDCOField = m_oDCOPage.FindChild("Vendor");
string strRoute = m_oDCOField.GetRoute(true);
```

The returned string has the following format: B/D(20100096.001.01)/P(TM000001)/F(Vendor).

In the next example, `GetRoute()` returns the path through the Setup DCO to the Details field.

```
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");  
m_oDCOField = m_oDCO.FindChild("Details");  
string returnString = m_oDCOField.GetRoute(false);
```

The returned string has the following format: B/D[Invoice]/P[Main_Page]/F[Details].

Parent topic: [DCO methods](#)

Related reference:

[FindRouteChild method](#)

[IsRoute method](#)

GetVariableName method

The `GetVariableName` method gets the name (ID) of a variable from the index of the variable. You can use this method when you know the position of a variable within an object, but you do not know the name of the variable.

Syntax

VBScript

```
oDCO.VariableName(nIndex subscript as Long) as String
```

C#

```
string GetVariableName(int nIndex)
```

Applies to

All objects.

Arguments

nIndex

The index of the variable.

Returns

Returns the name of the variable; returns an empty string if a variable with the specified index does not exist.

VBScript example

This example returns the name of the third variable in a field object.

```
Dim VarID  
VarID = objField.VariableName(2)
```

Parent topic: [DCO methods](#)

Related reference:

[FindVariable method](#)

[NumOfVars method](#)

GetVariableValue method

The GetVariableValue method gets the value of a referenced variable by using the index of the variable.

Syntax

VBScript

```
oDCO.VariableName(nIndex subscript as Long) as Variant
```

C#

```
object GetVariableValue(int nIndex)
```

Applies to

All objects.

Arguments

nIndex

The index of the variable, the value of which you want to get, where 0 is the first variable.

Returns

Returns an object that contains the value of the variable; returns nothing if there is an error.

VBScript example

This example gets the value of the third variable in a field object, and displays the value of the variable in a message box.

```
Dim VarVal  
VarVal = objField.VariableValue(2)  
msgbox VarVal
```

Tip: To get the value of a referenced variable by using the ID (name) of the variable, use the [Variable property](#) property.

C# example

This example gets the value of the 10th variable that is defined on page 1 of the runtime batch.

```
object oVarValue = m_oDCO.FindChild("TM000001").GetVariableValue(9);
```

Tip: To get the value of a referenced variable by using the ID (name) of the variable, use the [get_Variable method](#) method.

Parent topic: [DCO methods](#)

Related reference:
[FindVariable method](#)

IsError method

The IsError method indicates whether an error occurred during a prior Read operation or Write operation.

If `IsError` returns true, use the [GetLastError method](#) to get the associated error message. The `IsError` flag is cleared upon calling `GetLastError`.

Syntax

VBScript

```
oDCO.IsError as Boolean
```

C#

```
bool IsError()
```

Applies to

Batch object only.

Arguments

None.

Returns

Returns true if the `IsError` flag is set; Returns false if the `IsError` flag is not set.

VBScript example

This example checks if there are any errors for the Rulerunner task. If an error is found, it displays the error to a message box.

```
objBatch.BatchDir = "c:\Datacap\MQSW\Batches"  
' clear any old errors  
sOldError = objBatch.GetLastError  
Call objBatch.Write ("rulerunner.xml")  
If objBatch.IsError <> 0 Then  
    msgbox objBatch.GetLastError  
End if
```

Parent topic: [DCO methods](#)

Related reference:

[Read method](#)

[Write method](#)

IsRoute method

The `IsRoute` method indicates whether the specified path is the valid path through the runtime hierarchy for an object.

Syntax

C#

```
bool IsRoute(string lpszRoute)
```

Arguments

lpszRoute

The path through the runtime hierarchy. (See the C# example.)

Returns

Returns true if the specified path matches the path for this object; returns false if the specified path does not match the path for this object.

C# example

The following example gets an interface to the Vendor field and then uses `GetRoute` to confirm the path.

```
m_oDCOField = m_oDCO.FindChild("TM000001").FindChild("Vendor");  
bool bRouteOK = m_oDCOField.IsRoute("B/D(20100028.002.01)/P(TM000001)/F(Vendor)");
```

Parent topic: [DCO methods](#)

Related reference:

[FindRouteChild method](#)

[GetRoute method](#)

IsValid method

The `IsValid` method confirms that the interface of a DCO object is valid and is connected to an actual object.

Syntax

VBScript

```
oDCO.IsValid as Boolean
```

C#

```
bool IsValid()
```

Arguments

None.

Returns

Returns true if the interface is valid; returns false if the interface is invalid.

Applies to

Field objects only.

C# example

The following call returns `False`:

```
TDCOLib.IDCO m_oNullDCOObject = new TDCOLib.DCOClass();  
bResult = m_oNullDCOObject.IsValid();
```

Parent topic: [DCO methods](#)

MoveChild method

The `MoveChild` method moves a child of a runtime DCO object to a different index location. You can use this method to reorganize or correct batches, documents, pages, or fields.

Description

For example, `MoveChild(0, 2)` moves the object at position 0 to position 2. When you use this method, `MoveChild` reindexes the other child objects, as needed.

Table 1. Example implementation of `MoveChild` method

Index	Value		Index	Value
0	One	MoveChild(0, 2)	0	Two
1	Two		1	Three
2	Three		2	One
Before			After	

Syntax

VBScript

```
oDCO.MoveChild(nOldIndex as Long, nNewIndex as Long) as Boolean
```

C#

```
bool MoveChild(int nOldIndex, int nNewIndex)
```

Arguments

`nOldIndex`

Index value of the current position, of the child object, where 0 is the first child

`nNewIndex`

Index value of the new position of the child object

Returns

True if successful; False otherwise

Applies to

All objects

C# Example

This example moves the first field on page TM000001 to the third position.

```
m_oDCO.FindChild("TM000001").MoveChild(0, 2);
```

See also

[FindChild method](#), [MoveIn method](#)

Parent topic: [DCO methods](#)

MoveIn method

The `MoveIn` method moves the specified runtime DCO object from the current parent to a different parent.

Syntax

VBScript

```
oDCO.MoveIn(pNewParent as Object, nIndex as Long) as Boolean.
```

C#

```
bool MoveIn(object pNewParent, int nIndex)
```

Applies to

All objects

Arguments

`pNewParent`

A valid runtime DCO object as the new parent

`nIndex`

The index value for the child in the new parent. An index value of `-1` places the child at the end.

Returns

True if successful; False otherwise

C# Example

The following example moves the Vendor field from page `TM000002` to the end of page `TM000001`.

```
m_oDCOField = m_oDCO.FindChild("TM000002").FindChild("Vendor");  
m_oDCOPage = m_oDCO.FindChild("TM000001");  
m_oDCOField.MoveIn(m_oDCOPage, -1);
```

See also

[MoveChild method](#)

Parent topic: [DCO methods](#)

NumOfChildren method

The `NumOfChildren` method returns the number of child objects that is associated with the runtime DCO object.

Syntax

VBScript

```
oDCO.NumOfChildren as Long
```

C#

```
int NumOfChildren()
```

Arguments

None

Returns

The number of child objects that is associated with this object.

Applies to

All objects

VBScript Example

```
Dim CntPgChildren  
CntPgChildren = oDCO.NumOfChildren  
msgbox "Page 1 has " & CntPgChildren & " children"
```

C# Example

This example returns the number of fields on page TM000001.

```
int nNumFields = m_oDCO.FindChild("TM000001").NumOfChildren();
```

See also

[GetChild method](#)

Parent topic: [DCO methods](#)

NumOfVars method

The `NumOfVars` method returns the number of variables that is associated with the runtime DCO object.

Syntax

VBScript

```
oDCO.NumOfVars as Long
```

C#

```
int NumOfVars()
```

Arguments

None

Returns

A count of the variables of the object

Applies to

All objects

Example

This example returns the number of variables that is associated with the Vendor field.

```
int nNumVars = m_oDCO.FindChild("TM000001").FindChild("Vendor").NumOfChildren();
```

See also

[GetVariableValue method](#), [GetVariableName method](#)

Parent topic: [DCO methods](#)

ObjectType method

The `ObjectType` method returns a numeric value that indicates the object type.

Syntax

VBScript

```
oDCO.ObjectType as Long
```

C#

```
int ObjectType ()
```

Arguments

None.

Returns

A value that indicates the object type (0=batch, 1=document, 2=page, 3=field, 4=character).

Applies to

All objects

Example

VBScript

```
If oDCO.ObjectType <> 2 Then  
msgbox "The object is not a page!"  
End if
```

Parent topic: [DCO methods](#)

Parent

The `Parent` method returns the parent of the runtime DCO object.

Syntax

VBScript

```
oDCO.Parent as oDCO Object
```

C#

```
TDCOLib.DCO Parent()
```

Arguments

None

Returns

The parent object, or nothing (null) if the method is applied to a batch object.

Applies to

All objects except batch

Example

VBScript

```
If oField.Parent = Nothing Then  
msgbox "Cannot access the page!"  
End if
```

Parent topic: [DCO methods](#)

Read method

The `Read` method reads the runtime information from a Runtime DCO file or a page data file, and writes the information into the DCO object.

This method can read a Runtime DCO file (for example, `Verify.xml`), or a page data file (for example, `tm000001.xml`) of an application. Because new DCO objects are created as batch objects by default, you must first create a child object of type `page` before using the `Read` method to directly read the page data file. Runtime information files are located in the `batches` folder of an application, and include the data that are denoted by the following properties:

```
|--m_oDCO  
|  |--BatchDir(string)  
|  |--BatchPriority(int)  
|  |--ConfidenceString(string)  
|  |--ID(string)  
|  |--ImageName(string)  
|  |--Options(string)  
|  |--Status(int)
```

```
|--Text (string)
|--Type (string)
|--XML (string)
|--AltConfidenceString (string) *
|--AltText (string) *
|--CharConfidence (int) *
|--CharValue (int) *
|--OMRValue (int) *
|--Variable (string) *
```

* These extended properties are accessible directly from VBScript or through the corresponding get method or set method in .NET.

Syntax

VBScript

```
oDCO.Read (FilePath as String) as Boolean
```

C#

```
bool Read(string lpszFileName)
```

Applies to

Batch or page objects only.

Arguments

`lpszFileName`

The full path and name of the file to read.

Returns

Returns true if successful; returns false if unsuccessful.

Example

The first example reads the Runtime DCO file into an existing batch level DCO object:

```
m_oDCOBatch.Read("C:\\Datacap\\APT\\batches\\20100096.001\\Verify.xml");
```

The second example creates a runtime DCO object with a page data file only:

```
TDCOLib.DCO m_oDCO = new TDCOLib.DCO();
TDCOLib.DCO m_oDCOPage = new TDCOLib.DCO();
m_oDCOPage = m_oDCO.AddChild(2, "NewChildPage", -1);
m_oDCOPage.Read("C:\\Datacap\\APT\\batches\\20100096.001\\tm000001.xml");
```

If there is an error, the [IsError method](#) returns true and the [GetLastError method](#) returns the last error message.

Parent topic: [DCO methods](#)

Related reference:

[CreateFields method](#)

[FindChild method](#)

[ReadSetup method](#)

[Write method](#)

ReadSetup method

The ReadSetup method reads the document hierarchy setup information from the specified Setup DCO file and writes the information into the Setup object and SetupNode object.

This sample file shows properties that the ReadSetup method can process.

```
|--Setup
  |--Path (string)
  |--DictionaryName*
  |--Value*
  |--Word*

|--SetupNode
  |--MaxNumOfChildren (int)
  |--MinNumOfChildren (int)
  |--Name (string)
  |--ObjectType (int)
  |--RuleChildName*
  |--RuleMaxNumber*
  |--RuleMinNumber*
  |--RuleObjectType*
  |--RulePosition*
  |--Variable*
  |--VariableName*
  |--VariableValue*
```

* Extended properties that are accessible directly from VBScript or through the corresponding get method or set method in .NET.

Syntax

VBScript

```
oDCO.ReadSetup (FileName as String) as Boolean
```

C#

```
bool IDCO.ReadSetup(string lpszFileName)
```

Arguments

lpszFileName

Full path and name for the Setup DCO XML file. (See the following example.)

Returns

Returns true if successful; returns false if unsuccessful.

C# example

This example populates the Setup object and SetupNode object from APT.XML, changes the name of the first dictionary to Datacap, and writes the objects back to the Setup DCO.

```
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
m_oDCO.SetupObject().set_DictionaryName(0, "Datacap");
m_oDCO.WriteSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
```

Parent topic: [DCO methods](#)

Related reference:

[SetupNode method](#)

[SetupObject method](#)

[WriteSetup method](#)

SetPosition method

The SetPosition method sets the position of the runtime field or character object on the page. This method is useful for making corrections to zonal recognition on a page.

- For field objects, the position is defined by the *Position* variable of the field.

```
<V n="Position">0,0,0,0</V>
```

- For character objects, the position is defined by the `cr` attribute of the character.

```
<C cn="10" cr="0,0,0,0">83</C>
```

Syntax

VBScript

```
oDCO.SetPosition (nLeft as Long, nTop as Long, nRight as Long,  
nBottom as Long) as Boolean
```

C#

```
bool SetPosition(int nLeft, int nTop, int nRight, int nBottom)
```

Applies to

Field or character objects.

Arguments

`nLeft`

Distance from the left side of the page to the left edge of the object (in pixels)

`nTop`

Distance from the top of the page to the top edge of the object (in pixels)

`nRight`

Distance from the left side of the page to the right edge of the object (in pixels)

`nBottom`

Distance from the top of the page to the bottom edge of the object (in pixels)

Returns

Returns true if successful; returns false if unsuccessful.

Example

VBScript

```
Call oDCO.SetPosition (115, 450, 138, 400)
```

Parent topic: [DCO methods](#)

Related reference:[GetPosition method](#)

SetupNode method

The `SetupNode` method accesses the `SetupNode` object that is associated with the current object. You can use this method to get the name of the object in the document hierarchy that corresponds to the object in the runtime batch hierarchy.

Syntax

VBScript

```
oDCO.SetupNode as Object
```

C#

```
TDCOLib.DCOSetupNode SetupNode()
```

Arguments

None.

Returns

The setup object that corresponds to this runtime object. If you created this object dynamically at run time, and the object is not based on a `SetupNode`, then the method returns nothing (null).

Applies to

All objects.

C# example

This example populates the batch level `Setup` object and `SetupNode` object from the Setup DCO file and points `m_oDCOSetupNode` to the `SetupNode` object of the `Vendor` field.

```
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");  
TDCOLib.DCOSetupNode m_oDCOSetupNode =  
m_oDCO.FindChild("TM000001").FindChild("Vendor").SetupNode();
```

Parent topic: [DCO methods](#)**Related reference:**[ReadSetup method](#)[SetupObject method](#)[WriteSetup method](#)

SetupObject method

The `SetupObject` method returns the `Setup` object that is associated with the current batch-level runtime DCO object. You can use this method when a batch contains unidentified pages and you need to modify the runtime batch hierarchy.

Syntax

VBScript

```
oDCO.SetupObject as Object
```

C#

```
TDCOLib.DCOSetup SetupObject()
```

Applies to

Batch objects only.

Arguments

None.

Returns

The setup object.

C# example

This example populates the batch level Setup and SetupNode objects from the Setup DCO file and points `m_oDCOSetup` to the Setup object:

```
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");  
TDCOLib.DCOSetup m_oDCOSetup = m_oDCO.SetupObject();
```

For a complete example, see [ReadSetup](#).

Parent topic: [DCO methods](#)

Related reference:

[WriteSetup method](#)

set_AltConfidenceString

The `set_AltConfidenceString` method sets the confidence level of each character in the referenced field.

Description

Important: .NET only. For VBScript, use the [AltConfidenceString](#) property instead.

The confidence level of each character is a digit from 0 (lowest confidence) to 9 (highest confidence). For example, if the confidence level for a four-character field is 9999, each of the 4 characters has a confidence level of 9.

```
<F  
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev575_Vendor">  
  <V n="TYPE">Vendor</V>  
  <V n="Position">0,0,0,0</V>  
  <V n="STATUS">1</V>  
  <C cn="6,8,10" cr=0,0,0,0">83,49,53</C>  
  <C cn="6,8,10" cr=0,0,0,0">116,50,54</C>  
  <C cn="6,8,10" cr=0,0,0,0">105,51,55</C>
```

```
<C cn="6,8,10" cr=0,0,0,0">110,52,56</C>
</F>
```

In the sample XML file, the primary confidence level is 6. The first alternative confidence level is 8, and the second alternative confidence level is 10. The value that is stored is always the value set + 1.

Syntax

C#

```
void set_AltConfidenceString(int nIndex, string pVal)
```

Applies to

Field objects only

Arguments

nIndex

0 specifies the primary value. Where the field contains multiple recognition, voting, or multipass data entry values, 1 specifies the first alternative, 2 specifies the second alternative, and so on. (See the following example).

pVal

A string that contains the confidence level of each character (for example, "9999"). The digits that are stored in the page XML file are always one greater than the digits you specify in pVal (See the following example).

Comments

- To set or get the primary confidence level, you can also use the [ConfidenceString](#) property.
- To set or get the confidence level on individual characters, use [set_CharConfidence](#) or [get_CharConfidence](#).

Example

C#

The following example sets the confidence string for the second alternative.

```
m_oVendorField.set_AltConfidenceString(2, "9999")
```

The value 9999 is stored as 10,10,10,10 because the value that is stored is always the value set + 1.

See also

[get_AltConfidenceString](#), [set_AltText](#)

Parent topic: [DCO methods](#)

set_AltText method

The `set_AltText` method sets the primary character data or alternative character data that is associated with a field. You can use this method for multi-pass verification tasks and double-blind data entry tasks.

.NET restriction: For VBScript, use the [AltText](#) property instead.

The `set_AltText` method sets primary and alternative values that are stored in the page XML file in ASCII format, as shown in the following example:

```
F
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev576_Vendor">
  <V n="TYPE">Vendor</V>
  <V n="Position">0,0,0,0</V>
  <V n="STATUS">1</V>
  <C cn="6,8,10" cr="0,0,0,0">83,49,68</C>
  <C cn="6,8,10" cr="0,0,0,0">116,50,97</C>
  <C cn="6,8,10" cr="0,0,0,0">105,51,116</C>
  <C cn="6,8,10" cr="0,0,0,0">110,52,97</C>
</F>
```

In the sample XML file, the primary text value for the fourth character is 110. The first alternative text value is 52, and the second alternative text value is 97.

Syntax

C#

```
void set_AltText(int nIndex, string pVal)
```

Applies to

Field objects only.

Arguments

`nIndex`

0 specifies the primary value. Where the field contains multiple recognition, voting, or multi-pass data entry values, 1 specifies the first alternative, 2 specifies the second alternative, and so on.

`pVal`

String containing the alternative text.

C# example

This example sets the alternative value 1 in the field object.

```
m_oField.set_AltText(1, "Hello");
```

- Use the `set_AltConfidenceString` method to specify a confidence level other than the default value of 9 (high confidence).
- Use the `Text` property to set the primary field value.
- Use the `set_CharValue` method to set individual characters.

Parent topic: [DCO methods](#)

Related reference:

[get_AltText method](#)

[set_AltConfidenceString](#)

[Text property](#)

[set_CharValue method](#)

set_CharConfidence method

The `set_CharConfidence` method sets the confidence level for the primary value or of the alternative value of a character in a field.

.NET Restriction: For VBScript, use the [CharConfidence](#) property instead.

The confidence level is determined by the `cn` attribute. Within the page XML file, the confidence level is a digit from 1 (lowest confidence) to 10 (highest confidence). In the following XML sample, the primary confidence level of the fourth character is 6. The first alternative confidence level is 8, and the second alternative confidence level is 4.

```
F
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev577_Vendor">
  <V n="TYPE">Vendor</V>
  <V n="Position">0,0,0,0</V>
  <V n="STATUS">1</V>
  <C cn="6,8,10" cr="0,0,0,0">83,49,53</C>
  <C cn="6,8,10" cr="0,0,0,0">116,50,54</C>
  <C cn="6,8,10" cr="0,0,0,0">105,51,55</C>
  <C cn="6,8,4" cr="0,0,0,0">110,52,56</C>
</F>
```

Syntax

C#

```
void set_CharConfidence(int nIndex, int pVal)
```

Arguments

`nIndex`

0 specifies the primary value. Where the field contains multiple recognition, voting, or multipass data entry values, 1 specifies the first alternative, 2 specifies the second alternative, and so on.

`pVal`

The confidence value (1-10), as stored in the XML file.

This method sets the value as it is stored in the XML file (1-10). For field-level functions such as [set_AltConfidenceString](#), you specify the internal representation, which is the stored value minus 1.

C# example

This example sets the confidence level of second alternative value of the fourth character (index = 3) in the `Vendor` field. The root of the search in this case is the page DCO.

```
m_oDCOPage.FindChild("Vendor").GetChild(3).set_CharConfidence(2, 4);
```

Parent topic: [DCO methods](#)

Related reference:

[get_CharConfidence method](#)

set_CharValue method

The `set_CharValue` method sets the ASCII data value of the primary character or alternative character.

.NET Restriction: For VBScript, use the [CharValue](#) instead.

To set the text of the entire field, use the [set_AltText](#). In the following sample XML file, the primary value for the fourth character is 110. The first alternative value is 52, and the second alternative value is 56.

```
F
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev578_Vendor">
  <V n="TYPE">Vendor</V>
  <V n="Position">0,0,0,0</V>
  <V n="STATUS">1</V>
  <C cn="6,8,10" cr="0,0,0,0">83,49,53</C>
  <C cn="6,8,10" cr="0,0,0,0">116,50,54</C>
  <C cn="6,8,10" cr="0,0,0,0">105,51,55</C>
  <C cn="6,8,10" cr="0,0,0,0">110,52,56</C>
</F>
```

Syntax

C#

```
void set_CharValue(int nIndex, int pVal)
```

Applies to

Character objects only.

Arguments

nIndex

0 specifies the primary value. Where the field contains multiple recognition, voting, or multipass data entry values, 1 specifies the first alternative, 2 specifies the second alternative, and so on.

Returns

Nothing.

C# example

This example sets the second alternative value of the fourth character (index = 3) in the `Vendor` field. The root of the search in this case is the page DCO.

```
m_oDCOPage.FindChild("Vendor").GetChild(3).set_CharValue(2, 56);
```

Parent topic: [DCO methods](#)

Related reference:

[get_CharValue method](#)

[set_CharConfidence method](#)

set_OMRValue

The `set_OMRValue` method sets the character values within the OMR field to indicate whether a check box is selected.

Description

Each character is assigned the value 0 (ASCII 48; not selected) or 1 (ASCII 49; selected) and the resulting binary string is expressed as a decimal. The following XML example represents a row of six check boxes and the binary string is 001000, which equals 8 in decimal. So, the required value is 8.

```
<F
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_dcdev580_1a">
  <V n="TYPE">1a</V>
  <V n="Position">120,1025,853,1169</V>
  <V n="STATUS">0</V>
  <V n="DensityString">BAAVAA</V>
  <C cn="10" cr="519,1132,559,1170">48</C>  <-- 48 indicates option not selected
  <C cn="10" cr="563,1132,603,1170">48</C>
  <C cn="10" cr="607,1132,647,1170">48</C>
  <C cn="10" cr="652,1132,692,1170">49</C>  <-- 49 indicates option selected
  <C cn="10" cr="697,1132,737,1170">48</C>
  <C cn="10" cr="763,1132,803,1170">48</C>
</F>
```

Syntax

C#

```
void set_OMRValue(int nIndex, int pVal)
```

Arguments

nIndex

0 specifies the primary value. Where the field contains multiple recognition, voting, or multi-pass data entry values, 1 specifies the first alternative, 2 specifies the second alternative, and so on.

pVal

A number that reflects the state of each OMR check box. (See the XML example.)

See also

[get_OMRValue](#), [get_CharValue](#)

Parent topic: [DCO methods](#)

set_Variable method

The `set_Variable` method sets the value of a referenced variable by using the name of the variable.

Description

.NET restriction: For VBScript, use the [Variable](#) instead.

If you set a variable that does not exist in the runtime object, this method automatically creates the variable.

Datacap uses a number of standard variables. For a listing of these variables, see the *Standard Variable Reference* in this IBM® Knowledge Center.

Syntax

C#

```
string set_Variable(string lpszName, string pVal)
```

Arguments

lpszName
The name of the variable, the value of which you want to set.

pVal
The value.

Applies to

All objects.

C# example

The following example assigns the value `IBM` to the variable `Company`.

```
m_oDCO.set_Variable("Company", "IBM")
```

The method either sets the value if the variable exists, or creates a new variable with the specified value. The following sample XML node shows the resulting variable and the value:

```
<V n="Company">IBM</V>
```

Parent topic: [DCO methods](#)

Related reference:

[AddVariable method](#)

[get_Variable method](#)

Related information:

[Standard Variable Reference](#)

Write method

The Write method saves the runtime batch object to a batch file, or a page object to a page file. When it writes a batch object, this method also writes all of the child objects, including documents, pages, and fields.

When you create a batch with an application that you developed in Datacap Studio, Datacap saves the batch as an XML file. The file is named after the last completed task in the workflow of the application. When you create a batch with an application that you developed outside of Datacap Studio, you can use the Write method to save the batch object to a file.

Syntax

VBScript

```
oDCO.Write(lpszFileName as String) as Boolean
```

C#

```
bool Write(string lpszFileName)
```

Applies to

Batch or page objects.

Arguments

lpszFileName
The full path and name of the output file.

Returns

Returns true if successful; returns false if unsuccessful.

C# example

This example writes the 20030086.003 batch object and the page objects of the batch to Verify.xml file.

```
bStatus = objBatch.Write ("c:\Datacap\MQSW\Batches\20030085.003\Verify.xml")
objPage.CreateFields
bStatus = objPage.Write ("c:\Datacap\BDOcs\Batches\20030085.003" & objPage.ID)
```

Parent topic: [DCO methods](#)

Related reference:

[Read method](#)

[WriteSetup method](#)

WriteSetup method

The WriteSetup method writes the Setup object and SetupNode objects to the Setup DCO file. You use this method after you read a setup DCO file from an external location.

Syntax

VBScript

```
oDCO.WriteSetup(FileName as String) as Boolean
```

C#

```
bool WriteSetup(string lpszFileName)
```

Applies to

Batch objects only.

Arguments

lpszFileName

Full path and name for the Setup DCO file (for example, C:\Datacap\APT\dco_APT\APT.xml).

Returns

Returns true if successful; Returns false if unsuccessful.

Example

See [ReadSetup](#) for an example.

Parent topic: [DCO methods](#)

Related reference:

[ReadSetup method](#)

[Write method](#)

DCOSetup API

The DCOSetup APIs include properties and methods that you can use to create or modify the document hierarchy. Datacap saves the document hierarchy as the setup DCO file in XML format, for example, C:\Datacap*application name*\dco_*application name*\dco_*application name*.xml.

In the setup DCO file, each document, page, and field type is defined as a separate node, as shown in this sample XML code:

```
<?xml-stylesheet type="text/xsl"
href="#_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.develop.doc_...\dco.
xsl"?>
<S>
  <B type="batch_name"> 1

  [Variables and rules associated with this batch]

  </B>
  <D type="document_name"> 2

  [Variables and rules associated with this document]

  </D>

  [more document types]

  <P type="page_name"> 3

  [Variables and rules associated with this page]

  </P>

  [more page types]

  <F type="field_name"> 4

  [Variables and rules associated with this field]

  </F>

  [more field types]

  <DICTIONARY n="dict_name"> 5

  [Terms (words and values) in this dictionary]

  </DICTIONARY>

  [more document types]
```

- 1 Setup node for the batch
- 2 Setup node for the document
- 3 Setup node for the page
- 4 Setup node for the field
- 5 Setup node for the dictionary

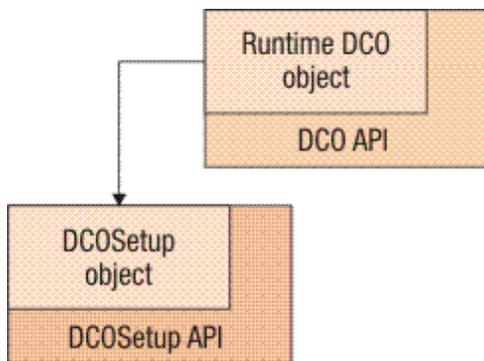

When you use an API to populate the DCOSetup object with child nodes from the Setup DCO file, each node becomes a separate DCOSetupNode object.

You use the DCOSetup APIs to modify the DCOSetup object and use the DCOSetupNode APIs to modify the child DCOSetupNode objects.

When you create a runtime DCO object (`m_oDCO` in this example), Datacap automatically creates a corresponding DCOSetup object and updates the setup DCO file.

```
TDCOLib.IDCO m_oDCO = new TDCOLib.DCOClass();
```

You can use the SetupObject method to access the DCOSetup object either directly or by first obtaining an interface to the DCOSetup object:

Accessing the DCOSetup Object Directly

```
m_oDCO.SetupObject().AddNode(1, "NewDoc1");
```

Accessing the DCOSetup object through an interface

```
TDCOLib.DCOSetup m_oDCOSetup = m_oDCO.SetupObject();
//Obtaining an interface

m_oDCOSetup.AddNode(1, "NewDoc2");
//Accessing the DCOSetup object through the interface
```

The DCOSetup object is initially null. You populate the DCOSetup object and the child objects in one of the following ways:

Use the ReadSetup method from an existing Setup DCO file

```
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
```

The ReadSetup method parses the XML file and creates all of the child DCOSetupNode objects, such as documents, pages, and fields, that are defined for the document hierarchy.

Use the AddNode method

```
m_oDCO.SetupObject().AddNode(1, "NewDoc1");
```

If you are creating a Setup DCO or modifying an existing Setup DCO, you can write the memory resident object hierarchy to disk by using the WriteSetup method:

```
m_oDCO.WriteSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
```

- [DCOSetup properties](#)
You can use DCOSetup properties to access DCOSetup objects and modify metadata, including dictionary paths, terms, names, and key values that are used in verification tasks.
- [DCOSetup methods](#)
DCOSetup methods enable access to DCO nodes and dictionaries. You can use DCOSetup methods to obtain and modify metadata, including names, values, terms, and quantities. You can also use these methods to create or delete nodes.

[WriteSetup method](#)

DCOSetup properties

You can use DCOSetup properties to access DCOSetup objects and modify metadata, including dictionary paths, terms, names, and key values that are used in verification tasks.

- [DictionaryName property](#)
The DictionaryName property sets or gets the name of a dictionary in the Setup DCO.
- [Path property](#)
The Path property sets or gets the path to the setup DCO file.
- [Value property](#)
The Value property sets or gets the key value of a dictionary term in the Setup DCO file. You can use this property when you need to pass a value to a variable.
- [Word property](#)
The Word property sets or gets the word value in a dictionary term in the setup DCO file. You can use this property to pass a value to a variable.

Parent topic: [DCOSetup API](#)

DictionaryName property

The DictionaryName property sets or gets the name of a dictionary in the Setup DCO.

VBScript only: Because extended properties are not supported through the C# .NET Interop interface, you must instead use the [set_DictionaryName method](#) or the [get_DictionaryName method](#).

Syntax

VBScript

```
oSO.DictionaryName(DictIndex as Long) as String
```

Arguments

DictIndex

The number that indicates the location of the dictionary in the setup DCO, with 0 being the first dictionary, 1 being the second, and so on.

Type

Read and write.

VBScript example

This example sets the name of the first dictionary in the setup DCO file to `Vendors` and the name of the second dictionary to `Customers`.

```
oSO.DictionaryName(0) = "Vendors"  
oSO.DictionaryName(1) = "Customers"
```

Parent topic: [DCOSetup properties](#)

Related reference:

[Value property](#)

[Word property](#)

Path property

The Path property sets or gets the path to the setup DCO file.

Syntax

VBScript

```
oSO.Path as String
```

C#

```
string Path { set; get; }
```

Type

Read and write.

VBScript example

This example sets the path to the BDCcs.xml setup DCO file:

```
oSO.Path = "c:\Datacap\BDOcs\dco_BDOcs\BDOcs.xml"
```

Parent topic: [DCOSetup properties](#)

Related reference:

Value property

The Value property sets or gets the key value of a dictionary term in the Setup DCO file. You can use this property when you need to pass a value to a variable.

VBScript restriction: Because extended properties are not supported through the C# .NET Interop interface, you must instead use the [set_Value method](#) or the [get_Value method](#).

The following example defines one dictionary with four words, where `RoutingInstructions` is the dictionary name. The text in each set of quotation marks is the key value that is associated with the word that follows it. Datacap uses the key value to identify words in the dictionary that are displayed to an operator during a verification task. Datacap populates the associated field with the word that the operator selects.

```
<DICTIONARY n="RoutingInstructions">
  <WORD v="None">None</WORD>
  <WORD v="Delete">Delete</WORD>
  <WORD v="Rescan">Rescan</WORD>
  <WORD v="Review">Review</WORD>
</DICTIONARY>
```

Syntax

VBScript

```
oSO.Value(nDictionary subscript as Long, nIndex subscript as Long) as String
```

Type

Read and write.

Arguments

`nDictionary`

The index of the dictionary in the setup object, where 0 is the first dictionary.

`nIndex`

The index of the entry in the dictionary, where 0 is the first entry.

VBScript example

This example sets the key value of the seventh entry in the first dictionary to 123.

```
oSO.Value(0,6) = "123"
```

Parent topic: [DCOSetup properties](#)

Related reference:

[DictionaryName property](#)

[Word property](#)

Word property

The Word property sets or gets the word value in a dictionary term in the setup DCO file. You can use this property to pass a value to a variable.

VBScript restriction: Because extended properties are not supported through the C# .NET Interop interface, you must instead use [set_Word](#) or [get_Word](#).

The following sample setup DCO XML file defines one dictionary with four words, where `RoutingInstructions` is the dictionary name. The text in each set of quotation marks is the key value that is associated with the word that follows it.

```
<DICTIONARY n="RoutingInstructions">
  <WORD v="None">None</WORD>
  <WORD v="Delete">Delete</WORD>
  <WORD v="Rescan">Rescan</WORD>
  <WORD v="Review">Review</WORD>
</DICTIONARY>
```

Datacap uses the key value to identify words in the dictionary that are displayed to an operator during a verification task. Datacap populates the associated field with the word that the operator selects.

Syntax

VBScript

```
oSO.Word(nDictionary as Long, nIndex as Long) as String
```

Type

Read and write.

Arguments

`nDictionary`

The index of the dictionary within the Setup object, where 0 is the first dictionary.

`nIndex`

The index of the entry within the dictionary, where 0 is the first entry.

VBScript example

This example compares the value of the `VendorName` field to the seventh entry in the first dictionary in the Setup DCO file:

```
oSO.Word(0,6) = "FreightLiners"
If VendorName = oSO.Word(0,6) then...
```

DCOSetup methods

DCOSetup methods enable access to DCO nodes and dictionaries. You can use DCOSetup methods to obtain and modify metadata, including names, values, terms, and quantities. You can also use these methods to create or delete nodes.

- [AddNode method](#)

The `AddNode` method adds a node to the Setup DCO object at the end of the section for the type specified (batch, document, page, field, character).

- [DeleteNode method](#)
The `DeleteNode` method reads the value of the `nIndex` argument and deletes the corresponding node from the Setup DCO.
- [DeleteNodeByName Method](#)
The `DeleteNodeByName` method deletes a node from the Setup DCO by referencing the node's name.
- [get_DictionaryName method](#)
The `get_DictionaryName` method gets the name of a dictionary from the Setup DCO.
- [get_Value method](#)
The `get_Value` method gets the key value of a term in a dictionary from the Setup DCO.
- [get_Word method](#)
The `get_Word` method gets the word value from a dictionary term.
- [GetNode method](#)
The `GetNode` method gets an interface to a `SetupNode` object in the Setup DCO by using an index value. You can use this method when you know the position of the object but not the name.
- [GetNodeByName method](#)
The `GetNodeByName` method accesses a `SetupNode` object from the Setup DCO by using the object name.
- [NumOfDictionaries method](#)
The `NumOfDictionaries` method returns the number of dictionaries that are defined in the Setup DCO.
- [NumOfNodes method](#)
The `NumOfNodes` method gets the number of documents, pages, fields, or character nodes in the Setup DCO.
- [NumOfWords](#)
The `NumOfWords` method returns the number of words that are defined in the dictionary in the Setup DCO.
- [ReadLock](#)
The `ReadLock` method locks, and prevents other applications from writing to, the specified Setup DCO file.
- [ReadSetup](#)
This method is identical to `DCO.ReadSetup`, except that you call it from a `DCOSetup` object.
- [set_DictionaryName method](#)
The `set_DictionaryName` method sets the name of a dictionary within the Setup DCO.
- [set_Value method](#)
The `set_Value` method sets the key value in a dictionary term.
- [set_Word method](#)
The `set_Word` method sets the word value in a dictionary term.
- [ShowSetupDialog](#)
The `ShowSetupDialog` method is identical to `DCO.ShowSetupDialog`, except that you call it from a `DCOSetup` object.
- [UnlockIt](#)
The `UnlockIt` method unlocks the Setup DCO file that was locked previously with the `ReadLock` method.
- [WriteSetup method](#)
The `WriteSetup` method is identical to `DCO.WriteSetup`, except that you call it from a `DCOSetup` object.

Parent topic: [DCOSetup API](#)

AddNode method

The `AddNode` method adds a node to the Setup DCO object at the end of the section for the type specified (batch, document, page, field, character).

Syntax

VBScript

```
oSO.AddNode (Type as Long, Name as String) as Boolean
```

C#

```
bool AddNode(int nType, string lpszNodeName)
```

Arguments

nType

Specify one of the following number values to indicate the type of node to add:

0 = Batch

1 = Document

2 = Page

3 = Field

4 = Character

lpszNodeName

The name of the new node. This name is referenced as the node's `type` attribute in the Setup DCO file, as shown in this example:

```
<D type="NewDocNode">
```

Returns

Returns true if successful; returns false if unsuccessful.

C# example

The following example adds a document node to the Setup DCO:

```
m_oDCOSetup.AddNode(1, "NewDocNode");
```

The new node inherits its attributes and variables from the object template in the file `C:\Datacap\dcshared\dcotemp.xml`. The resulting Setup object is shown in this sample:

```
<D type="NewDocNode">  
  <V n="ID">0</V>  
  <V n="TYPE">Document</V>  
  <V n="STATUS">0</V>  
  <V n="DOC DATA">0</V>  
  <V n="MIN_TYPES">0</V>  
  <V n="MAX_TYPES">0</V>  
</D>
```

Related reference:

[DeleteNode method](#)

[WriteSetup method](#)

DeleteNode method

The `DeleteNode` method reads the value of the `nIndex` argument and deletes the corresponding node from the Setup DCO.

Syntax

VBScript

```
oSO.DeleteNode(nType as Long, nIndex subscript as Long) as Boolean
```

C#

```
bool DeleteNode(int nType, int nIndex)
```

Arguments

nType

The type of the node to delete:

0 = Batch

1 = Document

2 = Page

3 = Field

4 = Character

nIndex

The index of the node to delete, where 0 is the first node of the specified type.

Returns

Returns true if successful; returns false if unsuccessful.

C# example

The following example deletes the third document node (type = 1, index = 2) from the Setup DCO:

```
m_oDCOSetup.DeleteNode(1, 2);
```

Parent topic: [DCOSetup methods](#)

Related reference:

[AddNode method](#)

[DeleteNodeByName Method](#)

DeleteNodeByName Method

The `DeleteNodeByName` method deletes a node from the Setup DCO by referencing the node's name.

Description

`DeleteNodeByName` references a node through the node's name, and deletes the node.

Syntax

VBScript

```
oSO.DeleteNode(nType as Long, lpszName as String) as Boolean
```

C#

```
bool DeleteNodeByName(int nType, string lpszName)
```

Arguments

nType

The type of the node to delete:

0 = Batch

1 = Document

2 = Page

3 = Field

4 = Character

lpszName

The name of the node to delete, as referenced in the node's type attribute:

```
<D type="NewDocNode">
```

Returns

True if successful; False otherwise.

VBScript Example

```
Dim OK
OK = oSO.DeleteNodeByName(3, "Total")
msgbox OK
msgbox "The number of fields remaining is " & oSO.NumOfNodes(3)
```

C# Example

The following example deletes the document node, "NewDocNode," from the Setup DCO:

```
m_oDCOSetup.DeleteNode(1, "NewDocNode");
```

See Also

[DeleteNode method](#), [AddNode method](#)

Parent topic: [DCOSetup methods](#)

get_DictionaryName method

The get_DictionaryName method gets the name of a dictionary from the Setup DCO.

.NET restriction: For VBScript, use the [DictionaryName property](#) instead.

Syntax

C#

```
string get_DictionaryName(int nDictionary)
```

Arguments

nDictionary

The index of the dictionary within the Setup DCO, where 0 is the first dictionary.

Returns

The name of the dictionary.

C# example

This example gets the name of the first dictionary from the Setup DCO file, APT.XML:

```
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");  
string strDictName = m_oDCO.SetupObject().get_DictionaryName(0);
```

Parent topic: [DCOSetup methods](#)

Related reference:

[ReadSetup method](#)

[SetupObject method](#)

[set_DictionaryName method](#)

[WriteSetup method](#)

get_Value method

The `get_Value` method gets the key value of a term in a dictionary from the Setup DCO.

.NET restriction: For VBScript, use the [Value property](#) instead.

In this sample XML code, `RoutingInstructions` is the name of the dictionary, which is followed by the key value and word pairs ("None",None, and so on).

```
<DICT n="RoutingInstructions">  
  <W v="None">None</W>  
  <W v="Delete">Delete</W>  
  <W v="Rescan">Rescan</W>  
  <W v="Review">Review</W>  
</Dict>
```

Syntax

C#

```
string get_Value(int nDictionary, int nIndex)
```

Arguments

`nDictionary`

The index of the dictionary within the Setup object, where 0 is the first dictionary.

`nIndex`

The index of the term within the dictionary, where 0 is the first term.

C# example

This example gets the key value on the second term in the first dictionary:

```
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");  
string strDictValue = m_oDCO.SetupObject().get_Value(0, 1);
```

Parent topic: [DCOSetup methods](#)

Related reference:

[set_Value method](#)

get_Word method

The `get_Word` method gets the word value from a dictionary term.

.NET restriction: For VBScript, use the [Word property](#) instead.

In the following XML sample, `RoutingInstructions` is the name of the dictionary, which is followed by the key value and word value pairs ("None", None, and so on):

```
<DICT n="RoutingInstructions">
  <W v="None">None</W>
  <W v="Delete">Delete</W>
  <W v="Rescan">Rescan</W>
  <W v="Review">Review</W>
</Dict>
```

Syntax

C#

```
string get_Word(int nDictionary, int nIndex)
```

Arguments

`nDictionary`

The index of the dictionary within the Setup object, where 0 is the first dictionary

`nIndex`

The index of the term within the dictionary, where 0 is the first term

C# example

This example gets the word value on the second term in the first dictionary:

```
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
string strDictWord = m_oDCO.SetupObject().get_Word(0, 1);
```

Parent topic: [DCOSetup methods](#)

Related reference:

[set_Word method](#)

GetNode method

The `GetNode` method gets an interface to a `SetupNode` object in the Setup DCO by using an index value. You can use this method when you know the position of the object but not the name.

Syntax

VBScript

```
oSO.GetNode(nType as Long, nIndex as Long) child node as node object
```

C#

```
TDCOLib.DCOSetupNode GetNode(int nType, int nIndex)
```

Arguments

nType

Value indicating the component type:

0 = Batch

1 = Document

2 = Page

3 = Field

nIndex

Value of the node's index, where 0 is the first node of the specified type in the Setup DCO

Returns

The SetupNode object on success; nothing (null) on failure.

C# example

The following example gets an interface to the first node of type `page` from the Setup DCO:

```
m_oDCOSetupNode = m_oDCOSetup.GetNode(2, 0);
```

Parent topic: [DCOSetup methods](#)

Related reference:

[GetNodeByName method](#)

GetNodeByName method

The `GetNodeByName` method accesses a `SetupNode` object from the Setup DCO by using the object name.

Syntax

VBScript

```
oSO.GetNodeByName(nType as Long, lpszName as String) as child node as node object
```

C#

```
TDCOLib.DCOSetupNode GetNodeByName(int nType, string lpszName)
```

Arguments

nType

Value indicating the component type:

0 = Batch

1 = Document

2 = Page

3 = Field

lpszName

The node's name, as referenced in the node's `type` attribute:

```
<P type="Main_Page">
```

Returns

The SetupNode object on success; nothing (null) on failure.

C# Example

The following example gets an interface to the node "Main_Page" of type "page" from the Setup DCO:

```
m_oDCOSetupNode = m_oDCOSetup.GetNodeByName(2, "Main_Page");
```

See also

[GetNode method](#)

Parent topic: [DCOSetup methods](#)

NumOfDictionaries method

The NumOfDictionaries method returns the number of dictionaries that are defined in the Setup DCO.

```
<DICTIONARIES n="RoutingInstructions">
  <W v="None">None</W>
  <W v="Delete">Delete</W>
  <W v="Rescan">Rescan</W>
  <W v="Review">Review</W>
</DICTIONARIES>
```

In the sample XML code, there is one dictionary that is called RoutingInstructions.

Syntax

VBScript

```
oSO.NumOfDictionaries( ) as Long
```

C#

```
int NumOfDictionaries()
```

Arguments

None

Returns

The number of dictionaries defined in this Setup DCO.

See also

[NumOfWords](#), [DictionaryName](#) property

Parent topic: [DCOSetup methods](#)

NumOfNodes method

The `NumOfNodes` method gets the number of documents, pages, fields, or character nodes in the Setup DCO.

Syntax

VBScript

```
oSO.NumOfNodes(nType as Long) as Long
```

C#

```
int NumOfNodes(int nType)
```

Arguments

`nType`

Value indicating the object type:

0 = Batch

1 = Document

2 = Page

3 = Field

4 = Character

Returns

Value specifying the number of nodes of the specified type.

VBScript Example

This example reads the Setup DCO and gets the number of field nodes:

```
Dim FlDs
Call oSO.ReadSetup("C:\Datacap\APT\dco_APT\APT.xml")
nFlDs = oSO.NumOfNodes(3)
msgbox nFlDs
```

C#

This example reads the Setup DCO and gets the number of field nodes:

```
m_oDCO.ReadSetup("C:\Datacap\APT\dco_APT\APT.xml");
TDCOLib.DCOSetup m_oDCOSetup = m_oDCO.SetupObject();
int numNodes = m_oDCOSetup.NumOfNodes(3);
```

See also

[AddNode method](#), [get_DictionaryName method](#), [GetNodeByName method](#), [DeleteNode method](#)

Parent topic: [DCOSetup methods](#)

NumOfWords

The `NumOfWords` method returns the number of words that are defined in the dictionary in the Setup DCO.

Description

The following example defines one dictionary with four words, where `RoutingInstructions` is the dictionary name, and the text in each set of quotation marks is the key value that is associated with the word that follows it.

```
<DICTIONARY n="RoutingInstructions">
  <WORD v="None">None</WORD>
  <WORD v="Delete">Delete</WORD>
  <WORD v="Rescan">Rescan</WORD>
  <WORD v="Review">Review</WORD>
</DICTIONARY>
```

Syntax

VBScript

```
oSO.NumOfWords (nDictionary subscript as Long) as Long
```

C#

```
int NumOfWords(int nDictionary)
```

Arguments

`nDictionary`

The index of the dictionary, where 0 is the first dictionary in the Setup DCO.

Returns

The number of words in the dictionary.

See also

[NumOfDictionaries](#)

Parent topic: [DCOSetup methods](#)

ReadLock

The `ReadLock` method locks, and prevents other applications from writing to, the specified Setup DCO file.

Description

`ReadLock` attempts to obtain the lock every 50 milliseconds. After 300 unsuccessful attempts, `ReadLock` stops the attempt and returns `False`. The attempt fails when another process locked the file.

Syntax

C#

```
bool ReadLock(string lpszPath)
```

Arguments

`lpszPath`

Full path and file name to the Setup DCO file.

Returns

True if successful; False otherwise.

See also

[UnlockIt](#)

Parent topic: [DCOSetup methods](#)

ReadSetup

This method is identical to `DCO.ReadSetup`, except that you call it from a `DCOSetup` object.

See [DCO.ReadSetup](#) for details.

Parent topic: [DCOSetup methods](#)

set_DictionaryName method

The `set_DictionaryName` method sets the name of a dictionary within the Setup DCO.

Syntax

C#

```
void set_DictionaryName(int nDictionary, string pVal)
```

Arguments

`nDictionary`

The index of the dictionary within the Setup DCO, where 0 is the first dictionary.

`pVal`

The new dictionary name.

Returns

Nothing.

C# example

This C# example sets the name of the first dictionary in the Setup DCO file `APT.XML`:

```
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");  
string strDictName = m_oDCO.SetupObject().set_DictionaryName(0, "Datacap");  
m_oDCO.WriteSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
```

Parent topic: [DCOSetup methods](#)

Related reference:

[get_DictionaryName method](#)

[ReadSetup method](#)

[SetupObject method](#)

[WriteSetup method](#)

set_Value method

The set_Value method sets the key value in a dictionary term.

.NET restriction: For VBScript, use the [Value](#) instead.

The following example defines one dictionary with four words, where `RoutingInstructions` is the dictionary name. The text in each set of quotation marks is the key value that is associated with the word that follows it.

```
<DICTIONARY n="RoutingInstructions">
  <WORD v="None">None</WORD>
  <WORD v="Delete">Delete</WORD>
  <WORD v="Rescan">Rescan</WORD>
  <WORD v="Review">Review</WORD>
</DICTIONARY>
```

Syntax

C#

```
void set_Value(int nDictionary, int nIndex, string pVal)
```

Arguments

nDictionary

The index of the dictionary within the Setup object, where 0 is the first dictionary.

nIndex

The index of the term within the dictionary, where 0 is the first term.

pVal

The key value.

Returns

Nothing

C# example

This example sets the key value on the second term in the first dictionary to `Delete`:

```
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
m_oDCO.SetupObject().set_Value(0, 1, "Delete");
m_oDCO.WriteSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
```

Parent topic: [DCOSetup methods](#)

Related reference:

[get_Value method](#)

set_Word method

The set_Word method sets the word value in a dictionary term.

.NET restriction: For VBScript, use the [Word](#) instead.

The following example defines one dictionary with four words, where `RoutingInstructions` is the dictionary name. The text in each set of quotation marks is the key value that is associated with the word that follows it.

```
<DICT n="RoutingInstructions">
  <W v="None">None</W>
  <W v="Delete">Delete</W>
  <W v="Rescan">Rescan</W>
  <W v="Review">Review</W>
</DICT>
```

Syntax

C#

```
void set_Word(int nDictionary, int nIndex, string pVal)
```

Arguments

nDictionary

The index of the dictionary within the Setup object, where 0 is the first dictionary.

nIndex

The index of the term within the dictionary, where 0 is the first term.

pVal

The key value.

C# example

This example sets the word value on the second term in the first dictionary to `Delete`:

```
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
m_oDCO.SetupObject().set_Word(0, 1, "Delete");
m_oDCO.WriteSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
```

Parent topic: [DCOSetup methods](#)

Related reference:

[get_Word method](#)

ShowSetupDialog

The `ShowSetupDialog` method is identical to `DCO.ShowSetupDialog`, except that you call it from a `DCOSetup` object.

Parent topic: [DCOSetup methods](#)

UnlockIt

The `UnlockIt` method unlocks the Setup DCO file that was locked previously with the `ReadLock` method.

Syntax

C#

```
bool UnlockIt()
```

Arguments

None

Returns

True if successful; False otherwise.

See also

[ReadLock](#)

Parent topic: [DCOSetup methods](#)

WriteSetup method

The `WriteSetup` method is identical to `DCO.WriteSetup`, except that you call it from a `DCOSetup` object.

For more information, see [DCO.WriteSetup](#).

Parent topic: [DCOSetup methods](#)

DCOSetupNode APIs

You can use the `DCOSetupNode` API properties and methods to access and modify Setup DCO child objects, including rules and variables.

Each runtime DCO object inherits attributes and variables from the corresponding `DCOSetupNode` object. For example, as demonstrated in the following setup node sample, all documents that are identified as `Invoice` documents include the `TYPE`, `STATUS`, `DOC DATA`, `MIN_TYPES`, `MAX_TYPES`, and `rules` variables. The `Invoice` document object must also contain at least one `Main_Page` page object. Similarly, all runtime objects that are identified as `Main_Page` types must be in the first position of the `Invoice` document.

```
<D type="Invoice"> 1
  <V n="ID">0</V>
  <V n="TYPE">Document</V>
  <V n="STATUS">0</V>
  <V n="DOC DATA">0</V>
  <V n="MIN_TYPES">0</V> 2
  <V n="MAX_TYPES">0</V>
  <V n="rules"><in><r id="1" rs="11" />
  /><r id="5" rs="7" /><r
  id="4" rs="16" /></in></V>

  <P type="Main_Page" pos="1" min="1" max="1"/>
  <P type="Trailing_Page" pos="0" min="0" max="0"/> 3
  <P type="Attachment" pos="0" min="0" max="0"/>
</D>
```

1 Setup node for the document type `Invoice`

2 Variables

3 Parameters

`DCOSetupNode` objects are created and accessed through the parent `DCOSetup` object.

The `SetupNode` object also defines the document integrity rules for that object type. The following example specifies that a Tax Return document must have at least one (`min="1"`) and at most one (`max="1"`) page of type `1040EZ`. The relative position attribute (`pos="2"`) specifies that the `1040EZ` page must come after the `TaxSep` page (if present) and before the `Attachment` page (if present):

```

<D type="Tax Return">
  <V n="ID">0</V>
  <V n="ID">0</V>
  <V n="TYPE">Document</V>
  <V n="STATUS">0</V>
  <V n="DOC_DATA">0</V>
  <V n="MIN_TYPES">2</V>
  <V n="MAX_TYPES">0</V>
  <V n="rules"></V>
  <P type="TaxSep" pos="1" min="0" max="1"/>
  <P type="1040EZ" pos="2" min="1" max="1"/>      <--- Rule for page 1040EZ
  <P type="Attachment" pos="3" min="0" max="0"/>
</D>

```

The `max="0"` value means unlimited. In the example, there can be any number of attachment pages. The `MIN_TYPES` and `MAX_TYPES` variables define the minimum and maximum number of child object types that must be present at run time to constitute a valid document. The `MIN_TYPES` value (2) specifies that each runtime document must have at least two different page types.

After you obtain an interface to the `DCOSetup` object, you can obtain an interface to any `DCOSetupNode` object by using the [GetNode method](#) or the [GetNodeByName method](#), as shown in the following example:

```
TDCOLib.DCOSetupNode m_oDCOSetupNode = m_oDCOSetup.GetNodeByName(2, "Main_Page");
```

Through the `DCOSetup` object interface, you can access all of the `DCOSetupNode` object properties and methods.

- [DCOSetupNode properties](#)
You can use `DCOSetupNode` properties to access `DCOSetup` objects and modify metadata, including names, types, and values. You can also use these properties to modify rules, variables, and child objects.
- [DCOSetupNode methods](#)
You can use `DCOSetupNode` methods to add or delete rules and variables. You can also use these methods to obtain and modify metadata, including names, number attributes, object types, and values. You might use these methods when the business requirements of your organization change and require different rules and variables.

Parent topic: [Datacap object API reference](#)

DCOSetupNode properties

You can use `DCOSetupNode` properties to access `DCOSetup` objects and modify metadata, including names, types, and values. You can also use these properties to modify rules, variables, and child objects.

- [Name property](#)
The `Name` property sets or gets the name of the `SetupNode` object.
- [ObjectType property](#)
The `ObjectType` property sets or gets the `SetupNode` object type, such as a batch, document, page, field, or character.
- [RuleChildName](#)
The `RuleChildName` property sets or gets the name of a rule that is referenced by an index.
- [RuleMaxNum](#)
The `RuleMaxNum` property sets or gets the `max` attribute for a rule.
- [RuleMinNum](#)
The `RuleMinNum` property sets or gets the `min` attribute for a rule.
- [RuleObjectType](#)
The `RuleObjectType` property sets or gets the type of an object.

- [RulePosition](#)
The `RulePosition` property determines the order of rules, and optionally restricts the order of child objects within a parent object at run time.
- [Variable](#)
The `Variable` property sets or gets the value that is associated with a variable in the `SetupNode` object. You can use this property to identify objects (for example, pages) that require special processing when a variable contains a specific value.
- [VariableName](#)
The `VariableName` property sets or gets the name of a variable that is accessed by an index in the `DCOSetupNode` object. You can use this property to identify objects (for example, pages) that require special processing when a variable contains a specific value. This property is useful when a node contains many child objects and variables.
- [VariableValue](#)
The `VariableValue` property sets or gets the value of an indexed variable from the `DCOSetupNode` object. You can use this property to identify objects (for example, pages) when a node contains many child objects and variables.

Parent topic: [DCOSetupNode APIs](#)

Name property

The `Name` property sets or gets the name of the `SetupNode` object.

The `SetupNode` object name is saved as the `type` attribute in the Setup DCO XML file:

```
<D type="NodeName">
```

The name is the identifier that is used to refer to child objects within the Setup DCO, as shown in this example:

```
<P type="Main_Page">
.
.
.
  <F type="Vendor" pos="0" min="0" max="0"/>  <!--Referencing the Vendor node by
name
```

Syntax

VBScript

```
oSNO.Name as String
```

C#

```
string Name { set; get; }
```

Type

Read and write.

VBScript example

In the following example, the code populates a setup object from the `BDOcs.xml` setup DCO file. The code then uses the `Name` property to update the name of the second node of type `Page` to `Invoice` in the `Setup` object. The example also writes the updated Setup DCO file to disk.

```

Call oSO.ReadSetup("c:\Datacap\BDOcs\dco_BDOcs\BDOcs.xml")
Dim objInvPage
Set objInvPage = oSO.GetNode(2,1)
objInvPage.Name = "Invoice"
Call oSO.WriteSetup("c:\Datacap\BDOcs\dco_BDOcs\BDOcs.xml")

```

C# example

In the following example, after the code populates a setup object from the APT.XML setup DCO file, the code uses the `Name` property to update the name of the `TM000001` node to `Invoice` in the Setup object. The example also writes the updated Setup DCO file to disk.

```

m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
TDCOLib.DCOSetupNode m_oDCOSetupNode = m_oDCO.FindChild("TM000001").SetupNode();
m_oDCOSetupNode.Name = "Invoice";
m_oDCO.WriteSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");

```

Parent topic: [DCOSetupNode properties](#)

Related reference:

[AddNode method](#)

[GetNode method](#)

[GetNodeByName method](#)

ObjectType property

The `ObjectType` property sets or gets the `SetupNode` object type, such as a batch, document, page, field, or character.

Use one of these number values to determine the `SetupNode` object type:

Object type

- 0 = Batch.
- 1 = Document.
- 2 = Page.
- 3 = Field.
- 4 = Character.

Syntax

VBScript

```
oSNO.ObjectType as Long
```

C#

```
int ObjectType { set; get; }
```

Type

Read and write.

VBScript example

This example gets a `SetupNode` object for the `Total` field and sends the type (3 = Field) to a script debugger:

```
Dim objTotal
Set objTotal = oSO.GetNodeByName(3, "Total")
Debug.write objTotal.ObjectType
```

Parent topic: [DCOSetupNode properties](#)

Related reference:

[GetNodeByName method](#)

[RuleObjectType](#)

RuleChildName

The RuleChildName property sets or gets the name of a rule that is referenced by an index.

Description

Important: VBScript only. Extended properties are not supported through the C# .NET Interop interface.

Instead, use [set_RuleChildName](#) or [get_RuleChildName](#).

For more information, see [get_RuleChildName](#).

Syntax

VBScript

```
oSNO.RuleChildName(nIndex as Long) as String
```

Arguments

nIndex

The index of the rule, where 0 is the first rule.

Type

Read and write

Example

VBScript

```
Dim objDoc
Set objDoc = MQDCO.GetNodebyName(1, "Doc")
Call objDoc.AddRule (2, "Page1", 1, 1, 3)
msgbox "The name of Rule 1 is " & objDoc.RuleChildName(0)
```

See also

[AddRule](#)

Parent topic: [DCOSetupNode properties](#)

RuleMaxNum

The RuleMaxNum property sets or gets the max attribute for a rule.

Description

Important: VBScript only. Extended properties are not supported through the C# .NET Interop interface. Instead, use [set_RuleMaxNumber](#) or [get_RuleMaxNumber](#). For more information, see [get_RuleMaxNumber](#).

Syntax

VBScript

```
oSNO.RuleMaxNum (RuleIndex as Long)
```

Arguments

RuleIndex

The index of the rule, where 0 is the first rule under this SetupNode object.

Type

Read and write

Example

VBScript

```
Dim MaxTotal  
MaxTotal = objInv.RuleMaxNum(3)  
msgbox MaxTotal
```

See also

[RuleMinNum](#)

Parent topic: [DCOSetupNode properties](#)

RuleMinNum

The RuleMinNum property sets or gets the `min` attribute for a rule.

Description

Important: VBScript only. Extended properties are not supported through the C# .NET Interop interface. Instead, use [set_RuleMinNumber](#) or [get_RuleMinNumber](#).

For more information, see [get_RuleMinNumber](#).

Syntax

VBScript

```
oSNO.RuleMinNum (RuleIndex as Long) as Long
```

Arguments

RuleIndex

The index of the rule, where 0 is the first rule under this SetupNode object.

Type

Read and write

Example

VBScript

```
Dim MinSSN
MinSSN = objPageTwo.RuleMinNum(0)
msgbox MinSSN
```

See also

[RuleMaxNum](#)

Parent topic: [DCOSetupNode properties](#)

RuleObjectType

The RuleObjectType property sets or gets the type of an object.

Description

Important: VBScript only. Extended properties are not supported through the C# .NET Interop interface. Instead, use [set_RuleObjectType](#) or [get_RuleObjectType](#).

The object type is determined by a value 0-3.

0 = Batch

1 = Document

2 = Page

3 = Field

Syntax

VBScript

```
oSNO.RuleObjectType (Index as Long) as Long
```

Arguments

Index

The index of the rule, where 0 is the first rule under this SetupNode object.

Type

Read and write

Example

VBScript

```
Dim TypeSSN
TypeSSN = objPageTwo.RuleObjType(0)
msgbox TypeSSN
```

See also

[get_RuleObjectType](#)

Parent topic: [DCOSetupNode properties](#)

RulePosition

The RulePosition property determines the order of rules, and optionally restricts the order of child objects within a parent object at run time.

Description

Important: VBScript only. Extended properties are not supported through the C# .NET Interop interface. Instead, use [set_RulePosition](#) or [get_RulePosition](#).

All child objects with rules that specify `Position=1` must appear before any child objects with higher position values (greater than 1). A `Position=0` means that the child item can appear in any order.

Syntax

VBScript

```
oSNO.RulePosition (Index as Long) as Long
```

Type

Read and write

Arguments

Index

The index of the rule, where 0 is the first rule under this SetupNode object.

Parent topic: [DCOSetupNode properties](#)

Variable

The Variable property sets or gets the value that is associated with a variable in the SetupNode object. You can use this property to identify objects (for example, pages) that require special processing when a variable contains a specific value.

Description

Important: VBScript only. Extended properties are not supported through the C# .NET Interop interface. Instead, use [set_Variable](#) or [get_Variable](#).

Syntax

VBScript

```
oSNO.Variable (VarName as String) as Variant
```

Type

Read and write

Arguments

VarName

Name of the variable (case sensitive)

Example

VBScript

```
Call objTotal.AddVariable ("Length", "10")  
msgbox objTotal.Variable("Length")
```

See also

[get_ Variable](#)

Parent topic: [DCOSetupNode properties](#)

VariableName

The `VariableName` property sets or gets the name of a variable that is accessed by an index in the `DCOSetupNode` object. You can use this property to identify objects (for example, pages) that require special processing when a variable contains a specific value. This property is useful when a node contains many child objects and variables.

Description

Important: VBScript only. Extended properties are not supported through the C# .NET Interop interface. Instead, use [set_ VariableName](#) or [get_ VariableName](#).

Syntax

VBScript

```
oSNO.VariableName (Node as Long) as String
```

Type

Read and write.

Arguments

Node

The index of the variable, where 0 is the first variable that is defined in the `DCOSetupNode` object.

See also

[get_ VariableName](#)

Parent topic: [DCOSetupNode properties](#)

VariableValue

The `VariableValue` property sets or gets the value of an indexed variable from the `DCOSetupNode` object. You can use this property to identify objects (for example, pages) when a node contains many child objects and variables.

Description

Important: VBScript only. Extended properties are not supported through the C# .NET Interop interface. Instead, use [set_RuleObjectType](#) or [get_RuleObjectType](#).

Syntax

VBScript

```
oSNO.VariableValue (Node as Long) as Variant
```

Arguments

Node

The index of the variable, where 0 is the first variable that is defined in the `DCOSetupNode` object.

Data type

Variant

Example

VBScript

This example displays the current value that is assigned to the third variable that is linked to the `objTotal` node:

```
msgbox objTotal.VariableValue(2)
```

read/write

Read and write

DCOSetupNode methods

You can use `DCOSetupNode` methods to add or delete rules and variables. You can also use these methods to obtain and modify metadata, including names, number attributes, object types, and values. You might use these methods when the business requirements of your organization change and require different rules and variables.

- [AddRule method](#)
The `AddRule` method adds a document integrity rule to a `SetupNode` object. For example, you can use this method to add a rule that specifies that a document type must contain a specific page type.
- [AddVariable method](#)
The `AddVariable` method adds a variable to a `SetupNode` object and assigns a default value.
- [DeleteRule method](#)
The `DeleteRule` method deletes the specified document integrity rule from a `SetupNode` object.
- [DeleteVariable method](#)
The `DeleteVariable` method deletes the specified variable that is referenced by an index, from a setup node.
- [DeleteVariableByName method](#)
The `DeleteVariableByName` method deletes the specified variable that is referenced by name from a setup node.
- [FindRule method](#)
The `FindRule` method uses a specified name to search for a `SetupNode` child object.
- [get_RuleChildName method](#)
The `get_RuleChildName` method gets the name of the rule under the current `SetupNode` object.
- [get_RuleMaxNumber Method](#)
The `get_RuleMaxNumber` method gets the maximum number of child objects of the specified type that can be associated with the parent object without violating a document integrity rule.
- [get_RuleMinNumber method](#)
The `get_RuleMinNumber` method gets the minimum number of child objects of the specified type that must be associated with the parent object to avoid violating a document integrity rule.
- [get_RuleObjectType method](#)
The `get_RuleObjectType` method gets the type of an object.
- [get_RulePosition method](#)
The `get_RulePosition` method gets the `pos` attribute of a specified rule within a `SetupNode` object. The `pos` attribute determines the position of an object type relative to other objects of the same type within the parent node. You can use this method to verify the order of pages in a document and ensure document integrity.
- [get_Variable method](#)
The `get_Variable` method gets the value of a variable from the `SetupNode` object. You can use this method to identify objects (for example, pages) that require special processing when a variable contains a specific value.
- [get_VariableName method](#)
The `get_VariableName` method gets the name of an indexed variable from the `SetupNode` object. You can use this method to identify objects (for example, pages) that require special processing when a variable contains a specific value. This method is useful when a node contains many child objects and variables.
- [get_VariableValue Method](#)
The `get_VariableValue` method gets the value of an indexed variable from the `SetupNode` object. You can use this method to identify objects (for example, pages) that require special processing when a variable contains a specific value. This method is useful when a node contains many child objects and variables.
- [GetRule method](#)
The `GetRule` method gets the `SetupNode` object that is referenced by a specified rule. You can use this method to identify objects (for example, pages) that require special processing when a node contains many child objects and rules.
- [NumOfRules method](#)
The `NumOfRules` method returns the number of rules that is within a `SetupNode` object.
- [NumOfVariables Method](#)
The `NumOfVariables` method returns the number of variables that is within a `SetupNode` object.

- [set_RuleChildName](#)
The `set_RuleChildName` method sets the name of the rule under the current `SetupNode` object.
- [set_RuleMaxNumber](#)
The `set_RuleMaxNumber` method sets the maximum number of child objects of the specified type that can be associated with the parent object without violating a document integrity rule.
- [set_RuleMinNumber](#)
The `set_RuleMinNumber` method sets the minimum number of child objects of the specified type that must be associated with the parent object to avoid violating a document integrity rule.
- [set_RuleObjectType](#)
The `set_RuleObjectType` method sets the type of an object.
- [set_RulePosition](#)
The `set_RulePosition` method sets the `pos` attribute of a specified rule within a `SetupNode` object. The `pos` attribute determines the position of an object type relative to other objects of the same type within the parent node. You can use this method to determine the order of pages in a document and ensure document integrity.
- [set_Variable](#)
The `set_Variable` method sets the value of a variable from the `SetupNode` object. You can use this method to determine which objects (for example, pages) require special processing when a variable contains a specific value.
- [set_VariableName](#)
The `set_VariableName` method sets the name of an indexed variable within a `SetupNode` object. You can use this method to identify variables within a node that contains many child objects.
- [set_VariableValue](#)
The `set_VariableValue` method sets the value of an indexed variable from the `SetupNode` object. You can use this method to identify objects (for example, pages) when a node contains many child objects and variables.

Parent topic: [DCOSetupNode APIs](#)

AddRule method

The `AddRule` method adds a document integrity rule to a `SetupNode` object. For example, you can use this method to add a rule that specifies that a document type must contain a specific page type.

Document integrity rules specify the required structure of the document. For example, a rule for the document type `Invoice` might specify that documents of this type must have a page of type `Main_Page`. A rule for the page type `Main_Page` might specify that pages of this type must have a field of type `Invoice_Total`.

If a `SetupNode` object for the specified child object does not exist, this method creates the `SetupNode` object.

Syntax

VBScript

```
AddRule(ObjectType as Long, lpszChildName as String,
         nPosition as Long, MinNumber as Long, MaxNumber as Long)
         as Boolean
```

C#

```
int AddRule(int nObjectType, string lpszChildName,
            short nPosition, short nMinNumber, short nMaxNumber)
```

Arguments

nObjectType

Use one of the following number values to determine the object type of the child node:

0 = Batch

1 = Document

2 = Page

3 = Field

lpszChildName

The name of the child object, which is stored as the `type` attribute of the rule.

nPosition

The `position` that child objects of this type must be relative to other child items at run time. In the DCO Setup window, this value is the `Order` property of the child node.

nMinNumber

The minimum number of instances of this child object that must exist for the document structure to be valid.

nMaxNumber

The maximum number of instances of this child object that can exist for the document structure to be valid.

Returns

Returns true if successful; returns false if unsuccessful.

C# example

This example gets the `SetupNode` object for the Invoice document in the Setup DCO. The example then adds a rule that requires one instance of the page `NewPage` to exist for the document structure to be valid. If a page node for `NewPage` does not exist, the method creates `NewPage` automatically.

```
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
TDCOLib.DCOSetup m_oDCOSetup = m_oDCO.SetupObject();
TDCOLib.DCOSetupNode m_oDCOSetupNode =
    m_oDCOSetup.GetNodeByName(1, "Invoice");
m_oDCOSetupNode.AddRule(2, "NewPage", 0, 1, 1);
```

The following line is added to the Setup DCO:

```
<D type="Invoice">
.
.
.
<P type="NewPage" pos="0" min="1" max="1"/> <!-- New line added -->
```

Additionally, if `NewPage` does not exist, the following page node is created:

```
<P type="NewPage">
    <V n="ID">0</V>
    <V n="TYPE">Page</V>
    <V n="STATUS">0</V>
    <V n="IMAGEFILE"></V>
    <V n="DATAFILE"></V>
    <V n="TEMPLATE IMAGE"></V>
    <V n="MIN_TYPES">0</V>
    <V n="MAX_TYPES">0</V>
</P>
```

Parent topic: [DCOSetupNode methods](#)

[DeleteRule method](#)

AddVariable method

The AddVariable method adds a variable to a SetupNode object and assigns a default value.

By default, all SetupNode objects include the standard variables that are installed with Datacap. For more information, see the *Standard Variable Reference* section in IBM® Knowledge Center for Datacap.

Syntax

VBScript

```
oSNO.AddVariable(lpszName as String, lpszValue as String) as Boolean
```

C#

```
bool AddVariable(string lpszName, string lpszValue)
```

Applies to

All node types.

Arguments

lpszName

Name of the new variable.

lpszValue

Default value (always a string)

Returns

Returns true if successful; returns false if unsuccessful.

C# example

This example gets the SetupNode object for the Invoice document in the APT.XML Setup DCO file and adds a variable *NewVar* with a default value *True*:

```
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");  
TDCOLib.DCOSetup m_oDCOSetup = m_oDCO.SetupObject();  
TDCOLib.DCOSetupNode m_oDCOSetupNode =  
    m_oDCOSetup.GetNodeByName(1, "Invoice");  
m_oDCOSetupNode.AddVariable("NewVar", "True");
```

The following line is added to the Setup DCO:

```
<D type="Invoice">  
    .  
    .  
    .  
<V n="NewVar">True</V> <!-- New line added -->
```

Parent topic: [DCOSetupNode methods](#)

Related information:

DeleteRule method

The `DeleteRule` method deletes the specified document integrity rule from a `SetupNode` object.

Description

For a description of document integrity rules, see [AddRule method](#).

Syntax

VBScript

```
oSNO.DeleteRule(nIndex as Long) as Boolean
```

C#

```
bool DeleteRule(int nIndex)
```

Arguments

`nIndex`

The index of the rule to delete, where 0 is the first rule that is specified under this `SetupNode` object.

Returns

True if successful; False otherwise.

See also

[AddRule method](#)

Parent topic: [DCOSetupNode methods](#)

DeleteVariable method

The `DeleteVariable` method deletes the specified variable that is referenced by an index, from a setup node.

Syntax

VBScript

```
oSNO.DeleteVariable(VarIndex as Long) as Boolean
```

C#

```
bool DeleteVariable(int nIndex)
```

Applies to

All node types.

Arguments

VarIndex

The index of the variable to delete, where 0 is the first variable.

Returns

True if successful; False otherwise.

See also

[AddVariable method](#), [DeleteVariableByName method](#)

Parent topic: [DCOSetupNode methods](#)

DeleteVariableByName method

The `DeleteVariableByName` method deletes the specified variable that is referenced by name from a setup node.

Syntax

VBScript

```
oSNO.DeleteVariableByName(lpszName as String) as Boolean
```

C#

```
bool DeleteVariableByName(string lpszName)
```

Applies to

All node types

Arguments

lpszName

The variable name

Returns

True if successful; False otherwise.

See also

[AddVariable method](#), [DeleteVariable method](#)

Parent topic: [DCOSetupNode methods](#)

FindRule method

The `FindRule` method uses a specified name to search for a `SetupNode` child object.

Syntax

VBScript

```
oSNO.FindRule(lpszName as String) child node as node object
```

C#

```
TDCOLib.DCOSetupNode FindRule(string lpszName)
```

Arguments

lpszName
The name of the rule.

Returns

The child node if successful; or nothing (null) otherwise.

Applies to

Any SetupNode object

See also

[GetRule method](#)

Parent topic: [DCOSetupNode methods](#)

get_RuleChildName method

The `get_RuleChildName` method gets the name of the rule under the current SetupNode object.

Attention: .NET only. For VBScript, use the [RuleChildName](#) property instead.

Description

The name of the rule is the `type` attribute in the Setup DCO XML file, and is the same name as the child node to which the rule applies. In the following rule for documents of type `Invoice`, the name of the rule is `Main_Page`.

```
<D type="Invoice">  
  .  
  .  
  <P type="Main_Page" pos="0" min="1" max="1"/>    <!--Rule-->
```

Syntax

C#

```
string get_RuleChildName(int nIndex)
```

Arguments

nIndex
The index of the rule, where 0 is the first rule under this SetupNode object.

C# Example

This example gets the name of the first rule under the current SetupNode object:

```
string strRuleName = m_oDCOSetupNode.get_RuleChildName(0);
```

See also

[set_RuleChildName](#)

Parent topic: [DCOSetupNode methods](#)

get_RuleMaxNumber Method

The `get_RuleMaxNumber` method gets the maximum number of child objects of the specified type that can be associated with the parent object without violating a document integrity rule.

Attention: .NET only. For VBScript, use the [RuleMaxNum](#) property instead.

Description

The maximum number is the `max` attribute in the Setup DCO XML file. In the following rule, the maximum number of pages of type `Main_Page` that a document of type `Invoice` can have is 1.

```
<D type="Invoice">
  .
  .
  <P type="Main_Page" pos="0" min="1" max="1"/>    <!--Rule-->
```

Syntax

C#

```
int get_RuleMaxNumber(int nIndex)
```

Arguments

nIndex

The index of the rule, where 0 is the first rule under the current SetupNode object.

C# Example

This example gets the `max` attribute of the first rule under the current SetupNode object:

```
int nMaxNum = m_oDCOSetupNode.get_RuleMaxNumber(0);
```

See also

[set_RuleMaxNumber](#)

Parent topic: [DCOSetupNode methods](#)

get_RuleMinNumber method

The `get_RuleMinNumber` method gets the minimum number of child objects of the specified type that must be associated with the parent object to avoid violating a document integrity rule.

Attention: .NET only. For VBScript, use the [RuleMinNum](#) property instead.

Description

The minimum number is the `min` attribute in the Setup DCO XML file. In the following rule, the minimum number of pages of type `Main_Page` that a document of type `Invoice` must have is 1.

```
<D type="Invoice">
  .
  .
  <P type="Main_Page" pos="0" min="1" max="1"/>    <!--Rule-->
```

Syntax

C#

```
int get_RuleMinNumber(int nIndex)
```

Arguments

nIndex

The index of the rule index, where 0 is the first rule under the current `SetupNode` object.

C# example

This example gets the `min` attribute of the first rule under the current `SetupNode` object.

```
int nMinNum = m_oDCOSetupNode.get_RuleMinNumber(0);
```

See also

[set_RuleMinNumber](#)

Parent topic: [DCOSetupNode methods](#)

get_RuleObjectType method

The `get_RuleObjectType` method gets the type of an object.

Attention: .NET only. For VBScript, use the [RuleObjectType](#) property instead.

Description

The type of an object is defined by a value range of 0-3.

0 = Batch

1 = Document

2 = Page

3 = Field

In the following rule for documents of type `Invoice`, the object type is 2 (Page).

```
<D type="Invoice">
  .
  .
  <P type="Main_Page" pos="0" min="1" max="1"/>    <!--Rule-->
```

Syntax

C#

```
int get_RuleObjectType(int nIndex)
```

Arguments

nIndex

The index of the rule index, where 0 is the first rule under the current SetupNode object.

C# Example

This example gets the object type for the first rule under the current SetupNode object.

```
int nRuleType = m_oDCOSetupNode.get_RuleObjectType(0);
```

See also

[set_RuleObjectType](#)

Parent topic: [DCOSetupNode methods](#)

get_RulePosition method

The `get_RulePosition` method gets the `pos` attribute of a specified rule within a SetupNode object. The `pos` attribute determines the position of an object type relative to other objects of the same type within the parent node. You can use this method to verify the order of pages in a document and ensure document integrity.

Attention: .NET only. For VBScript, use the [RulePosition](#) property instead.

Description

The following rules specify position requirements for documents of type `Tax Return`.

- A `TaxSep` page must come before the `1040EZ` page and any `Attachment` pages.
- The `1040EZ` page must come before any `Attachment` pages.

```
<D type="Tax Return">
.
.
  <P type="TaxSep" pos="1" min="0" max="1"/>           <!--Rule 0-->
  <P type="1040EZ" pos="2" min="1" max="1"/>         <!--Rule 1-->
  <P type="Attachment" pos="3" min="0" max="0"/>     <!--Rule 2-->
```

If a rule has `pos="0"`, then the corresponding object type is not included in the process that confirms document integrity. For details about document integrity, see [DCOSetupNode APIs](#).

Syntax

C#

```
int get_RulePosition(int nIndex)
```

Arguments

nIndex

The index of the rule, where 0 is the first rule under the current SetupNode object.

C# Example

This example gets the position attribute for the first rule under the current SetupNode object.

```
int nPosValue = m_oDCOSetupNode.get_RulePosition(0);
```

See also

[set_RulePosition](#)

Parent topic: [DCOSetupNode methods](#)

get_Variable method

The `get_Variable` method gets the value of a variable from the SetupNode object. You can use this method to identify objects (for example, pages) that require special processing when a variable contains a specific value.

Attention: .NET only. For VBScript, use the [Variable property](#) property instead.

Description

The following example shows three variables that are associated with the page node `Main_Page` in the Setup DCO file.

```
<P type="Main_Page">
  <V n="ID">0</V>           0
  <V n="TYPE">Page</V>      1
  <V n="STATUS">0</V>      2
```

0 Variable 0 (name = ID, value = 0)

1 Variable 1 (name = TYPE, value = Page)

2 Variable 2 (name = STATUS, value = 0)

Syntax

C#

```
string get_Variable(string lpszName)
```

Arguments

lpszName

The variable name (case sensitive)

C# Example

The following example gets the value of the variable `TYPE` from the page node `Main_Page` in the Setup DCO.

```
TDCOLib.DCOSetupNode m_oDCOSetupNode = m_oDCOSetup.GetNodeByName(2, "Main_Page");
string strValue = m_oDCOSetupNode.get_Variable("TYPE");
```

See also

[get_VariableName method](#), [get_VariableValue Method](#), [set_Variable](#)

Parent topic: [DCOSetupNode methods](#)

get_VariableName method

The `get_VariableName` method gets the name of an indexed variable from the `SetupNode` object. You can use this method to identify objects (for example, pages) that require special processing when a variable contains a specific value. This method is useful when a node contains many child objects and variables.

Attention: .NET only. For VBScript, use the [VariableName](#) property instead.

Description

The following example shows three variables that are associated with the page node `Main_Page` in the Setup DCO file:

```
<P type="Main_Page">
  <V n="ID">0</V>           0
  <V n="TYPE">Page</V>      1
  <V n="STATUS">0</V>      2
```

0 Variable 0 (name = ID, value = 0)

1 Variable 1 (name = TYPE, value = Page)

2 Variable 2 (name = STATUS, value = 0)

Syntax

C#

```
string get_VariableName(int nIndex)
```

Arguments

`nIndex`

The index of the variable, where 0 is the first variable that is defined in the `SetupNode` object

C# Example

The following example gets the name of the first variable that is defined within the page node, `Main_Page`, in the Setup DCO.

```
TDCOLib.DCOSetupNode m_oDCOSetupNode = m_oDCOSetup.GetNodeByName(2, "Main_Page");
string varName = m_oDCOSetupNode.get_VariableName(0);
```

Parent topic: [DCOSetupNode methods](#)

get_VariableValue Method

The `get_VariableValue` method gets the value of an indexed variable from the `SetupNode` object. You can use this method to identify objects (for example, pages) that require special processing when a variable contains a specific value. This method is useful when a node contains many child objects and variables.

Attention: .NET only. For VBScript, use the [VariableValue](#) property instead.

Description

The following example shows three variables that are associated with the page node, `Main_Page`, in the Setup DCO file:

```
<P type="Main_Page">
  <V n="ID">0</V>          0
  <V n="TYPE">Page</V>    1
  <V n="STATUS">0</V>     2
```

0 Variable 0 (name = ID, value = 0)

1 Variable 1 (name = TYPE, value = Page)

2 Variable 2 (name = STATUS, value = 0)

Syntax

C#

```
string get_VariableValue(int nIndex)
```

Arguments

nIndex

The index of the variable, where 0 is the first variable defined in the `SetupNode` object

C# Example

The following example gets the value of the first variable defined with the page node, `Main_Page`, in the Setup DCO:

```
TDCOLib.DCOSetupNode m_oDCOSetupNode = m_oDCOSetup.GetNodeByName(2, "Main_Page");
string varValue = m_oDCOSetupNode.get_VariableValue(0);
```

See also

[get_Variable](#) method, [get_VariableName](#) method, [set_VariableValue](#)

Parent topic: [DCOSetupNode methods](#)

GetRule method

The `GetRule` method gets the `SetupNode` object that is referenced by a specified rule. You can use this method to identify objects (for example, pages) that require special processing when a node contains many child objects and rules.

Description

For example, the following rule references a page of type `Main_Page`. So, `GetRule` returns the `Main_Page SetupNode` object.

```
<D type="Invoice">
  .
  .
  <P type="Main_Page" pos="0" min="1" max="1"/>      <!--Rule referencing page
"Main_Page" -->
```

Syntax

VBScript

```
oSNO.GetRule(nIndex as Long) child node as node object
```

C#

```
TDCOLib.DCOSetupNode GetRule(int nIndex)
```

Arguments

`nIndex`

The index of the rule, where 0 is the first rule under this `SetupNode` object.

Applies to

All node types

Returns

Child node object if successful; otherwise nothing (null).

C# Example

This example gets the `SetupNode` object for the `Invoice` document in the Setup DCO and then gets the first rule under this node. It then gets the `SetupNode` object for the child object that is referenced by this rule.

```
m_oDCO.ReadSetup("C:\\Datacap\\APT\\dco_APT\\APT.XML");
TDCOLib.DCOSetup m_oDCOSetup = m_oDCO.SetupObject();
TDCOLib.DCOSetupNode m_oDCOSetupNode = m_oDCOSetup.GetNodeByName(1, "Invoice");
TDCOLib.DCOSetupNode m_oDCOSetupNode2 = m_oDCOSetupNode.GetRule(0);
```

[AddRule method](#)

Parent topic: [DCOSetupNode methods](#)

NumOfRules method

The `NumOfRules` method returns the number of rules that is within a `SetupNode` object.

Syntax

VBScript

```
oSNO.NumOfRules ( ) as Long
```

C#

```
int NumOfRules ()
```

Arguments

None

Returns

The number of rules in this SetupNode object.

Applies to

All node types

C# Example

This example returns the number of rules that is contained in the current SetupNode object.

```
int nNumRules = m_oDCOSetupNode.NumOfRules ();
```

See also

[AddRule method](#)

Parent topic: [DCOSetupNode methods](#)

NumOfVariables Method

The `NumOfVariables` method returns the number of variables that is within a SetupNode object.

Description

This method returns user-defined variables and standard variables. (For more information, see the *Standard Variable Reference*).

Syntax

VBScript

```
oSNO.NumOfVariables ( ) as Long
```

C#

```
int NumOfVariables ()
```

Arguments

None

Returns

The number of variables in this SetupNode object.

C# Example

The following example returns the number of rules within the current SetupNode object:

```
int nNumVars = m_oDCOSetupNode.NumOfVariables();
```

Parent topic: [DCOSetupNode methods](#)

set_RuleChildName

The `set_RuleChildName` method sets the name of the rule under the current SetupNode object.

Description

Important: .NET only. For VBScript, use the [RuleChildName](#) property instead. For more information, see [get_RuleChildName](#).

Syntax

C#

```
void set_RuleChildName(int nIndex, string pVal)
```

Arguments

nIndex

The index of the rule, where 0 is the first rule under this SetupNode object.

See also

[get_RuleChildName](#)

Parent topic: [DCOSetupNode methods](#)

set_RuleMaxNumber

The `set_RuleMaxNumber` method sets the maximum number of child objects of the specified type that can be associated with the parent object without violating a document integrity rule.

Description

Important: .NET only. For VBScript, use the [RuleMaxNum](#) property instead. For more information, see [get_RuleMaxNumber](#).

Syntax

C#

```
void set_RuleMaxNumber(int nIndex, int pVal)
```

Arguments

- nIndex
The index of the rule, where 0 is the first rule under this SetupNode object.
- pVal
The maximum number of child objects.

See also

[get_RuleMaxNumber](#)

Parent topic: [DCOSetupNode methods](#)

set_RuleMinNumber

The `set_RuleMinNumber` method sets the minimum number of child objects of the specified type that must be associated with the parent object to avoid violating a document integrity rule.

Description

Important: .NET only. For VBScript, use the [RuleMinNum](#) property instead.

For more information, see [get_RuleMinNumber](#).

Syntax

```
C#  
  
void set_RuleMinNumber(int nIndex, int pVal)
```

Arguments

- nIndex
The index of the rule, where 0 is the first rule under the current SetupNode object.
- pVal
The minimum number of child objects.

See also

[get_RuleMinNumber](#)

Parent topic: [DCOSetupNode methods](#)

set_RuleObjectType

The `set_RuleObjectType` method sets the type of an object.

Description

Important: .NET only. For VBScript, use the [RuleObjectType](#) property instead.

For more information, see [get_RuleObjectType](#).

Syntax

C#

```
void set_RuleObjectType(int nIndex, int pVal)
```

Arguments

nIndex

The index of the rule, where 0 is the first rule under this SetupNode object.

pVal

The object type:

0 = Batch

1 = Document

2 = Page

3 = Field

See also

[get_RuleObjectType](#)

Parent topic: [DCOSetupNode methods](#)

set_RulePosition

The `set_RulePosition` method sets the `pos` attribute of a specified rule within a SetupNode object. The `pos` attribute determines the position of an object type relative to other objects of the same type within the parent node. You can use this method to determine the order of pages in a document and ensure document integrity.

Description

Important: .NET only. For VBScript, use the [RulePosition](#) property instead.

For more information, see [get_RulePosition](#).

Syntax

C#

```
void set_RulePosition(int nIndex, int pVal)
```

Arguments

nIndex

The index of the rule, where 0 is the first rule under this SetupNode object.

pVal

The position of the rule.

See also

[get_RulePosition](#)

Parent topic: [DCOSetupNode methods](#)

set_Variable

The `set_Variable` method sets the value of a variable from the `SetupNode` object. You can use this method to determine which objects (for example, pages) require special processing when a variable contains a specific value.

Description

Important: .NET only. For VBScript, use the [Variable](#) property instead.
For more information, see [get_Variable](#).

Syntax

C#

```
void set_Variable(string lpszName, string pVal)
```

Arguments

`lpszName`
The variable name (case sensitive).

`pVal`
The value (always a string).

See also

[get_Variable](#)

Parent topic: [DCOSetupNode methods](#)

set_VariableName

The `set_VariableName` method sets the name of an indexed variable within a `SetupNode` object. You can use this method to identify variables within a node that contains many child objects.

Description

Important: .NET only. For VBScript, use the [VariableName](#) property instead.

Syntax

C#

```
void set_VariableName(int nIndex, string pVal)
```

Arguments

`nIndex`
The index of the variable, where 0 is the first variable that is defined in the `SetupNode` object.

`pVal`
The variable name.

See also

[get_VariableName](#)

Parent topic: [DCOSetupNode methods](#)

set_VariableValue

The `set_VariableValue` method sets the value of an indexed variable from the `SetupNode` object. You can use this method to identify objects (for example, pages) when a node contains many child objects and variables.

Description

Important: .NET only. For VBScript, use the [VariableValue](#) property instead.

Syntax

C#

```
void set_VariableValue(int nIndex, string pVal)
```

Arguments

nIndex

The index of the variable, where 0 is the first variable that is defined in the `SetupNode` object.

pVal

The variable value (always a string).

Integrating with other products

Datacap integrates with other IBM enterprise content management solutions to enhance your capture applications.

- [Transactional capture](#)
Using Datacap Transactional capture, you can scan documents directly in IBM® Case Manager and IBM Content Navigator.

Transactional capture for IBM Content Navigator and IBM Case Manager

Use Datacap Transactional Capture to scan documents directly in IBM® Content Navigator and IBM Case Manager. You can also add documents to a Datacap batch from an IBM Content Navigator repository.

When you scan a document, you specify a document class and document properties, and then upload the document to a repository. You can also configure Datacap Transactional Capture to automatically populate document properties from the scanned document.

- [Sample workflows](#)
Transactional capture sample workflows show how you can access Datacap functionality in IBM Content Navigator and IBM Case Manager to scan documents and add documents to batches.

- [Configuring Datacap for transactional capture](#)
Use configuration steps in IBM Datacap to use transactional capture in IBM Content Navigator and IBM Case Manager.
- [Configuring scanning in IBM Content Navigator](#)
Configure IBM Content Navigator to enable scanning. Optionally, you can also enable automatic data capture.
- [Configuring scanning in IBM Case Manager](#)
You can configure IBM Case Manager to enable scanning. Optionally, you can also enable automatic data capture.
- [Configuring IBM Content Navigator for adding documents to batches](#)
Configuration steps are required to add documents in IBM Content Navigator to Datacap batches.

Sample workflows

Transactional capture sample workflows show how you can access Datacap functionality in IBM® Content Navigator and IBM Case Manager to scan documents and add documents to batches.

- [Configuring your workstation for scanning](#)
The first time that you scan in Case Manager Client or IBM Content Navigator, you might be prompted to download and run a program called DynamicWebTwainHTML5Edition.exe. You must install Web TWAIN scanning software on your workstation before you can scan. This is done one time only.
- [Scanning documents in IBM Content Navigator](#)
In this sample workflow, you scan a document in IBM Content Navigator by using the Scan Document or Add Document actions. This feature is available when you configure IBM Datacap and IBM Content Navigator for transactional capture.
- [Scanning documents in IBM Case Manager](#)
In this sample workflow, you scan a document in IBM Case Manager by selecting the Add Document from Scanner option. This feature is available when you configure IBM Datacap and IBM Case Manager for transactional capture.
- [Adding documents to a batch from an IBM Content Navigator repository](#)
In this sample workflow, you add a document in an IBM Content Navigator repository to a Datacap batch by clicking Add to Batch. Then you verify and submit the batch by using Datacap Navigator. This feature is available when you configure IBM Datacap and IBM Content Navigator for transactional capture.

Parent topic: [Transactional capture for IBM Content Navigator and IBM Case Manager](#)

Configuring your workstation for scanning

The first time that you scan in Case Manager Client or IBM® Content Navigator, you might be prompted to download and run a program called DynamicWebTwainHTML5Edition.exe. You must install Web TWAIN scanning software on your workstation before you can scan. This is done one time only.

Procedure

To install Web TWAIN scanning software:

1. When prompted, click the link on the Information window to download and save the DynamicWebTwainHTML5Edition.exe file.
2. Close the Information window.
3. Run the file to install the software on your workstation.

Parent topic: [Sample workflows](#)

Scanning documents in IBM Content Navigator

In this sample workflow, you scan a document in IBM® Content Navigator by using the Scan Document or Add Document actions. This feature is available when you configure IBM Datacap and IBM Content Navigator for transactional capture.

Procedure

To scan document in IBM Content Navigator:

1. Log in to an IBM Content Navigator desktop that contains a custom content list menu with the Add Document action for transactional capture.
2. Click Scan Document or Add Document to scan documents.
3. In the Save in field, select a location in your repository where you want to save the scanned document.
4. In the What do you want to save? field, select Document from scanner.
5. Select your scanner from the drop-down list, adjust scanner settings if necessary, load the document in the scanner, click Scan, and wait until the pages are scanned.
If want to import images from the repository, select Import from Directory and click Scan. Scanned images are displayed in a thumbnail strip. Double-click an image to view a full page.
6. Select a document class from the Class drop-down list.
7. If you configured transactional capture for automatic data capture, click Capture to populate properties of the document class. If SSO is not enabled, you are prompted to log in to the Datacap repository. You can specify whether to capture data from the current page or from all pages. Only matched field values are populated in the document properties.
8. Click Add to save the document.

Parent topic: [Sample workflows](#)

Scanning documents in IBM Case Manager

In this sample workflow, you scan a document in IBM® Case Manager by selecting the Add Document from Scanner option. This feature is available when you configure IBM Datacap and IBM Case Manager for transactional capture.

Procedure

To scan a document in IBM Case Manager:

1. Log in to Case Manager Client.
2. Double-click a case to open it.
3. On the Document tab, click the Add button and select Add Document from Scanner.
4. Select your scanner from the drop-down list. If you do not have a scanner, or if you want to import images instead, select Import from Directory.
5. Load the document in the scanner, click Scan > Append, and wait until the pages are scanned.
6. Images are scanned into the thumbnail strip. Double-click the first image to view a full page.
7. Select a document class from the drop-down list and fill in the document properties. If you configured transactional capture for automatic data capture, click Capture to populate properties of the document class. If SSO is not enabled, you are prompted to log in to the Datacap repository. You can specify whether to capture data from the current page or from all pages. Only matched field values are populated in the document properties.
8. Click Add to save the document in the case folder.

Parent topic: [Sample workflows](#)

Adding documents to a batch from an IBM Content Navigator repository

In this sample workflow, you add a document in an IBM® Content Navigator repository to a Datacap batch by clicking Add to Batch. Then you verify and submit the batch by using Datacap Navigator. This feature is available when you configure IBM Datacap and IBM Content Navigator for transactional capture.

Procedure

To add a document to a batch:

1. Log in to IBM Content Navigator and browse to a document in the repository.
2. Select the document to view the document properties. The class name should match the document type in the Setup DCO file of your Datacap application.
3. Click Add to Batch. A window is displayed with the new Datacap batch number.
4. Log in to Datacap Navigator and view the new batch in Job Monitor. Verify and submit the batch.

Parent topic: [Sample workflows](#)

Configuring Datacap for transactional capture

Use configuration steps in IBM® Datacap to use transactional capture in IBM Content Navigator and IBM Case Manager.

Procedure

To configure Datacap for transactional capture, complete the following steps:

1. Deploy the Datacap Navigator plug-in in IBM Content Navigator. For instructions, see [Datacap Navigator installation steps](#).
2. Create a Datacap application for transactional capture. In the Datacap application Setup DCO, document types must have the same symbolic names as document classes that are defined in your IBM Content Navigator repository.
3. Optional: Configure transactional capture to capture data from documents. Captured data populates document fields in the field entry panel when you scan documents. Otherwise, you must manually enter data in document fields. Captured data also populates document properties when you add documents to a new Datacap batch.
 - a. Use Datacap Studio to create a task profile named TransactionCaptureOCR. For more information about using Datacap Studio, see [Quick tour of the user interface](#).
 - b. Under the TransactionCaptureOCR task profile, add rulesets that recognize data in scanned documents and generate page data files. For example, for the TravelDocs sample Datacap application, add the following rulesets:
 - ImageFix
 - PageID
 - CreateDocs
 - Document Integrity
 - Recognize
 - Clean
 - Validate

When you scan a document, transactional capture populates the corresponding document fields with the recognized data from the page data files.

- c. In your Datacap application, ensure that the page types contain fields that have the same symbolic names as the properties under the document class of your repository such as IBM FileNet® Content Manager or IBM Content Manager Enterprise Edition.
- 4. For adding documents to batches only: Ensure that the user who adds documents to batches has permissions to create batches in Datacap. For more information, see [Users, groups, and stations administration](#).
- 5. Optional: For adding documents to batches only: In an IBM Content Navigator repository, one document can contain multiple TIF files. You can create rulesets or a task profile to split the document into multiple TIF files, when you add documents to a batch. Otherwise, single document that contains multiple TIF files is added to the batch. Create rulesets to split a document into multiple TIF files:
 - a. In Datacap Studio, right-click the Convert Files To Images ruleset and select Install in application.
 - b. Select the following options:

Setting	Value
File naming pattern	Hierarchical
Source Page	<ul style="list-style-type: none"> ■ Remove page after processing ■ Multipage TIFF Expansion

- c. Click Save.
- d. Add the ruleset to the PageID profile.
- 6. Add your Datacap application as a Datacap repository in IBM Content Navigator. For more information, see [Adding applications to Datacap Navigator](#).
- 7. Add the Datacap application to your desktop by using the IBM Content Navigator administration tool.
- 8. Enable SSO between Datacap and IBM Content Navigator repositories. If you do not enable SSO, you are prompted to log on to the Datacap repository when you scan documents and add documents to batches in IBM Content Navigator and IBM Case Manager. For more information, see [Configuring single sign-on \(SSO\) for Datacap Navigator](#).

Parent topic: [Transactional capture for IBM Content Navigator and IBM Case Manager](#)

Configuring scanning in IBM Content Navigator

Configure IBM® Content Navigator to enable scanning. Optionally, you can also enable automatic data capture.

Before you begin

Ensure that Datacap is configured for transactional capture. For instructions, see [Configuring Datacap for transactional capture](#).

Procedure

To configure scanning in IBM Content Navigator:

1. Create a custom content list menu with the Add Document action by using the IBM Content Navigator administration tool.
 - a. Access the IBM Content Navigator administration tool. In a browser, enter a URL with the following format:

```
http://host_name:port_number/context_root/?desktop=admin
```

By default, the context root is `navigator`.
 - b. Click Menus in the left pane.
 - c. Create a custom content list that contains the Add Document action and the Scan Document action for transactional capture.

Important: Two Add Document actions are available for selection. To choose the correct action, place your mouse cursor over the Add Document actions to display the action properties. Select the Add Document action with the following property: Plug-in: DatacapWebPlugin.

d. Assign the custom content list to the content list toolbar of the desktop.

- Optional: Configure your IBM Content Navigator repository for automatic data capture. When configured, data captured from scanned documents populates document fields in the field entry panel. Document classes must have properties that are mapped to page level fields in the Datacap application setup DCO. For example, you can configure an IBM FileNet® Content Manager repository for automatic data capture with the TravelDocs sample Datacap application. The TravelDocs setup DCO contains a Car_Rental document type and a Pickup_Date field in the Rental_Agreement page type. To configure the repository, create a Car_Rental document class the repository, and create a Pickup_Date property for the Car_Rental document class.

Important: Specify the string data type for properties in your repository.

Parent topic: [Transactional capture for IBM Content Navigator and IBM Case Manager](#)

Configuring scanning in IBM Case Manager

You can configure IBM® Case Manager to enable scanning. Optionally, you can also enable automatic data capture.

Before you begin

Ensure that Datacap is configured for transactional capture. For instructions, see [Configuring Datacap for transactional capture](#).

About this task

The following sample configuration adds an option called Add Document from Scanner to the Add button in Case Manager Client. Case workers can select the scan option among the other options for adding documents.

Procedure

To configure scanning in IBM Case Manager:

- Optional: Configure your IBM Case Manager repository for automatic data capture. When configured, data captured from scanned documents populates document fields in the field entry panel. Document classes must have properties that are mapped to page level fields in the Datacap application setup DCO. For example, you can configure an IBM FileNet® Content Manager repository for automatic data capture with the TravelDocs sample Datacap application. The TravelDocs setup DCO contains a Car_Rental document type, and a Pickup_Date field that is in the Rental_Agreement page type. To configure the repository, create a Car_Rental document class in the repository, and create a Pickup_Date property for the Car_Rental document class.
Important: Specify the string data type for properties in your repository.
- Log in to Case Manager Builder.
- On the Manage Solutions page, create a new solution or click Edit on the solution that you want to add transactional capture to.
- Optional: If you are configuring IBM Case Manager for automatic data capture, click the Properties tab, click Add PropertyReuse Property, and select all properties that you created for data capture.
- On the Pages tab, click the Open Page Designer icon for the Case Details page that is used for the solution.
- Click the Edit Settings icon for the Case Information widget.

7. Select a location for the scan function. For example, you can add the scan function to the Add button menu on the Documents view toolbar. Click the Toolbars tab, click Add Menu Item, and select Scan Document from the list of actions.
8. Enter a label for the menu item, such as Add Document from Scanner. Then, click OK.
9. The menu item is added to the list. Click OK at the bottom of the Case Information window to save your changes.
10. On the Page Designer page, click Save and then click Close to save your changes.
11. On the solution page, click Save and Close.
12. Click the Commit link on the solution.
13. Click the Deploy link on the solution.
14. Click Deploy in the Confirmation window, wait for the deployment to complete, log out of Case Manager Builder, and close the browser.

Parent topic: [Transactional capture for IBM Content Navigator and IBM Case Manager](#)

Configuring IBM Content Navigator for adding documents to batches

Configuration steps are required to add documents in IBM® Content Navigator to Datacap batches.

Before you begin

Ensure that Datacap is configured for transactional capture. For instructions, see [Configuring Datacap for transactional capture](#).

About this task

When you add a document to a new batch on Datacap Server from an IBM Content Navigator repository, a DCO document is created for each added document. The DCO document contains a page of type Other and the content of the added document. Document properties are saved as document variables in the batch.

Procedure

To configure IBM Content Navigator for adding documents to batches:

1. Access the IBM Content Navigator administration tool. In a browser, enter a URL with the following format:

```
http://host_name:port_number/context_root/?desktop=admin
```

By default, the context root is `navigator`.

2. Click Menus in the left pane.
3. Create a custom content list that contains the Add to Batch action.

Parent topic: [Transactional capture for IBM Content Navigator and IBM Case Manager](#)

Troubleshooting and support

When you experience problems, you might need to perform troubleshooting tasks to determine the corrective action to take.

- [Troubleshooting process overview](#)
Troubleshooting is a systematic approach to solving a problem. The goal of troubleshooting is to determine why something does not work as expected and how to resolve the problem. You can search live, Web-based support resources by using the Web search form under Searching knowledge bases in the left navigation pane.
- [Troubleshooting Datacap security and authentication](#)
You might encounter problems when you start the Datacap system or log on to a component. For example, in a client/server environment, you might see a problem with the automatic encryption key import feature.
- [Troubleshooting Rulerunner](#)
You might need to troubleshoot problems when you use Rulerunner to automatically process background tasks when batches are pending.
- [Troubleshooting FastDoc](#)
You might need to troubleshoot problems when you use FastDoc to scan, process, verify, and export documents.
- [Troubleshooting Datacap web services](#)
If the file upload fails on large files or the PUT request method endpoints are not working, you can check to ensure that your configurations are correct.
- [Log files](#)
To obtain adequate logging information for troubleshooting purposes, you must enable logging for the client and for the Rulerunner Service.

Troubleshooting process overview

Troubleshooting is a systematic approach to solving a problem. The goal of troubleshooting is to determine why something does not work as expected and how to resolve the problem. You can search live, Web-based support resources by using the Web search form under Searching knowledge bases in the left navigation pane.

The first step in the troubleshooting process is to describe the problem completely. Problem descriptions help you and the IBM Support representative know where to start to find the cause of the problem. This step includes asking yourself basic questions:

- What are the symptoms of the problem?
- Where does the problem occur?
- When does the problem occur?
- Under which conditions does the problem occur?
- Can the problem be reproduced?

The answers to these questions typically lead to a good description of the problem, which can then lead you a problem resolution.

What are the symptoms of the problem?

When starting to describe a problem, the most obvious question is "What is the problem?" This question might seem straightforward; however, you can break it down into several focused questions that create a more descriptive picture of the problem. These questions can include:

- Who, or what, is reporting the problem?
- What are the error codes and messages?
- How does the system fail? For example, is it a loop, hang, crash, performance degradation, or incorrect result?

Where does the problem occur?

Determining where the problem originates is not always easy, but it is one of the most important steps in resolving a problem. Many layers of technology can exist between the reporting and failing components. Networks, disks, and drivers are only a few of the components to consider when you are investigating problems.

The following questions help you to focus on where the problem occurs to isolate the problem layer:

- Is the problem specific to one platform or operating system, or is it common across multiple platforms or operating systems?
- Is the current environment and configuration supported?

If one layer reports the problem, the problem does not necessarily originate in that layer. Part of identifying where a problem originates is understanding the environment in which it exists. Take some time to completely describe the problem environment, including the operating system and version, all corresponding software and versions, and hardware information. Confirm that you are running within an environment that is a supported configuration; many problems can be traced back to incompatible levels of software that are not intended to run together or have not been fully tested together.

When does the problem occur?

Develop a detailed timeline of events leading up to a failure, especially for those cases that are one-time occurrences. You can most easily develop a timeline by working backward: Start at the time an error was reported (as precisely as possible, even down to the millisecond), and work backward through the available logs and information. Typically, you need to look only as far as the first suspicious event that you find in a diagnostic log.

To develop a detailed timeline of events, answer these questions:

- Does the problem happen only at a certain time of day or night?
- How often does the problem happen?
- What sequence of events leads up to the time that the problem is reported?
- Does the problem happen after an environment change, such as upgrading or installing software or hardware?

Responding to these types of questions can give you a frame of reference in which to investigate the problem.

Under which conditions does the problem occur?

Knowing which systems and applications are running at the time that a problem occurs is an important part of troubleshooting. These questions about your environment can help you to identify the root cause of the problem:

- Does the problem always occur when the same task is being performed?
- Does a certain sequence of events need to occur for the problem to surface?
- Do any other applications fail at the same time?

Answering these types of questions can help you explain the environment in which the problem occurs and correlate any dependencies. Remember that just because multiple problems might have occurred around the same time, the problems are not necessarily related.

Can the problem be reproduced?

From a troubleshooting standpoint, the ideal problem is one that can be reproduced. Typically, when a problem can be reproduced you have a larger set of tools or procedures at your disposal to help you investigate. Consequently, problems that you can reproduce are often easier to debug and solve. However, problems that

you can reproduce can have a disadvantage: If the problem is of significant business impact, you do not want it to recur. If possible, re-create the problem in a test or development environment, which typically offers you more flexibility and control during your investigation.

- Can the problem be re-created on a test system?
- Are multiple users or applications encountering the same type of problem?
- Can the problem be re-created by running a single command, a set of commands, or a particular application?
- [Searching knowledge bases](#)
You can often find solutions to problems by searching IBM knowledge bases. You can optimize your results by using available resources, support tools, and search methods.
- [Getting fixes from Fix Central](#)
You can use Fix Central to find the fixes that are recommended by IBM Support for a variety of products. With Fix Central, you can search, select, order, and download fixes for your system with a choice of delivery options.
- [Contacting IBM Software Support](#)
IBM® Software Support provides assistance with product defects, answering FAQs, and performing rediscovery.
- [Subscribing to Support updates](#)
To stay informed of important information about the IBM products that you use, you can subscribe to updates.

Searching knowledge bases

You can often find solutions to problems by searching IBM knowledge bases. You can optimize your results by using available resources, support tools, and search methods.

About this task

IBM® provides extensive documentation within Knowledge Center. You can find useful information by searching Knowledge Center, but sometimes you need to look beyond Knowledge Center to answer your questions or resolve problems.

Procedure

To search knowledge bases for information that you need, use one or more of the following approaches:

- Search for content by using the IBM Support Assistant (ISA). ISA is a no-charge software serviceability workbench that helps you answer questions and resolve problems with some IBM software products. You can find instructions for downloading and installing ISA on the [ISA website](#) (www.ibm.com/software/support/isa/). Some IBM products have not fully implemented support for ISA.
- Find the content that you need by using the IBM Support Portal: <http://www.ibm.com/supportportal> (www.ibm.com/supportportal).

The IBM Support Portal is a unified, centralized view of all technical support tools and information for all IBM systems, software, and services. The IBM Support Portal lets you access the IBM electronic support portfolio from one place. You can tailor the pages to focus on the information and resources that you need for problem prevention and faster problem resolution. Familiarize yourself with the IBM Support Portal by viewing the [demo videos](#) (https://www.ibm.com/blogs/SPNA/entry/the_ibm_support_portal_videos) about this tool. These videos introduce you to the IBM Support Portal, explore troubleshooting and other resources, and demonstrate how you can tailor the page by moving, adding, and deleting portlets.

- To search multiple Internet resources for your product, expand Searching knowledge bases in the navigation frame to the left and select Web search. From this topic, you can conduct a Google search or search within IBM developerWorks®. You can also link directly to the support portal for this product where you can search a variety of resources including:
 - IBM technotes
 - IBM downloads
 - IBM Redbooks®
- Search for content by using the IBM masthead search. You can use the IBM masthead search by typing your search string into the Search field at the top of any ibm.com® page.
- Search for content by using any external search engine, such as Google, Yahoo, or Bing. If you use an external search engine, your results are more likely to include information that is outside the ibm.com domain. However, sometimes you can find useful problem-solving information about IBM products in newsgroups, forums, and blogs that are not on ibm.com.
Tip: Include "IBM" and the name of the product in your search if you are looking for information about an IBM product.

[Contacting IBM Software Support](#)

Getting fixes from Fix Central

You can use Fix Central to find the fixes that are recommended by IBM Support for a variety of products. With Fix Central, you can search, select, order, and download fixes for your system with a choice of delivery options.

Procedure

To find and install fixes:

1. Go to [Fix Central](http://www.ibm.com/support/fixcentral) (www.ibm.com/support/fixcentral) to download the installation program for product fixes. Fix Central provides download, installation, and configuration instructions for the installation program.
2. Select Enterprise Content Management as your product group, then select your product, version and platform, and click Continue.
3. Browse or search for fixes based on criteria such as (Authorized Program Analysis Report) APAR number or fix ID, or just request a list of recommended fixes.
4. If you have already registered for My support, sign in and skip to the next step. If you have not registered, click Register now. Complete the registration form using your email address as your IBM ID and click Submit.
5. Select and download the fix using your preferred download method. When downloading the file, ensure that the name of the maintenance file is not changed. This change might be intentional, or it might be an inadvertent change that is caused by certain web browsers or download utilities.
6. Apply the fix.
7. Optional: Subscribe to receive weekly email notifications about fixes and other IBM Support updates.

Contacting IBM Software Support

IBM® Software Support provides assistance with product defects, answering FAQs, and performing rediscovery.

About this task

After trying to find your answer or solution by using other self-help options such as technotes, you can contact IBM Software Support. Before you contact IBM Software Support, your company must have an active IBM software subscription and support contract, and you must be authorized to submit problems to IBM. The type of software subscription and support contract that you need depends on the type of product you have. For information about the types of available support, see the Support portfolio topic in the [Software Support Handbook](#).

Procedure

Complete the following steps to contact IBM Software Support with a problem:

1. Define the problem, gather background information, and determine the severity of the problem. To determine the severity level, you need to understand and assess the business impact of the problem you are reporting. Use the following criteria:

Severity	Business impact
1	Critical business impact: You are unable to use the program, resulting in a critical impact on operations. This condition requires an immediate solution.
2	Significant business impact: The program is usable but is severely limited.
3	Some business impact: The program is usable with less significant features (not critical to operations) unavailable.
4	Minimal business impact: The problem causes little impact on operations, or a reasonable circumvention to the problem has been implemented.

For more information, including examples of each severity level, see the "Getting IBM support" topic in the *IBM Software Support Handbook*.

2. Gather diagnostic information. Use the Web search form (under Troubleshooting and support > Searching knowledge bases in the navigation pane of this Knowledge Center) to search for the keyword `mustgather` to see whether there are specific files or other diagnostic information to gather.

For example:

- o What software versions were you running when the problem occurred?
- o Do you have logs, traces, and messages that are related to the problem symptoms? IBM Software Support is likely to ask for this information.
- o Can the problem be re-created? If so, what steps led to the failure?
- o Have any changes been made to the system (for example, hardware, operating system, networking software, and so on)?
- o Are you currently using a workaround for this problem? If so, please be prepared to explain it when you report the problem.

3. Submit the problem to IBM Support.

IBM Support Assistant (ISA)

Go to the Software support site to use the [IBM Support Assistant](#) (www.ibm.com/software/support/isa/).

Online

Go to the [IBM Support Portal](#) (www.ibm.com/software/support/). You can open, update, and view all your Service Requests from the Service Request portlet on the Service Request page.

Phone

For the phone number to call in your country, see the [Directory of worldwide contacts](#) web page (www.ibm.com/planetwide/).

Results

If the problem that you submit is for a software defect or for missing or inaccurate documentation, IBM Support creates an Authorized Program Analysis Report (APAR). The APAR describes the problem in detail. Whenever possible, IBM Support provides a workaround that you can implement until the APAR is resolved and a fix is delivered. IBM publishes resolved APARs on the IBM Support website daily, so that other users who experience the same problem can benefit from the same resolution.

Subscribing to Support updates

To stay informed of important information about the IBM products that you use, you can subscribe to updates.

About this task

By subscribing to receive updates, you can receive important technical information and updates for specific Support tools and resources. You can subscribe to updates by using one of two approaches:

RSS feeds and social media subscriptions

For general information about RSS, including steps for getting started and a list of RSS-enabled IBM web pages, visit the IBM Software Support RSS feeds site.

My Notifications

With My Notifications, you can subscribe to Support updates for any IBM product. You can specify that you want to receive daily or weekly email announcements. You can specify what type of information you want to receive (such as publications, hints and tips, product flashes (also known as alerts), downloads, and drivers). My Notifications enables you to customize and categorize the products about which you want to be informed and the delivery methods that best suit your needs.

Procedure

To subscribe to Support updates:

1. Go to the [IBM® Support Portal](#) and click Sign in to create, manage, or view your subscriptions in the Notifications pane.
2. If you have already registered for My support, sign in and skip to the next step. If you have not registered, click Register now. Complete the registration form using your email address as your IBM ID and click Submit.
3. Identify what and how you want to receive updates.
 - a. Click the Subscribe tab.
 - b. Click Information Management or another software brand or type of hardware.
 - c. Select one or more products by name, for example, Content Manager Enterprise Edition or FileNet® Content Manager, and click Continue.
 - d. Select your preferences for how to receive updates, whether by e-mail, online in a designated folder, or as an RSS or Atom feed.
 - e. Select the types of documentation updates you want to receive, for example, new information about product downloads and discussion group comments.
 - f. Click Submit.

Results

Until you modify your RSS feeds and My Notifications preferences, you receive notifications of updates that you have requested. You can modify your preferences when needed (for example, if you stop using one product and begin using another product).

Troubleshooting tips for IBM Datacap

This section provides a collection of troubleshooting tips for IBM Datacap.

- [Invalid character when scanning document by using Dynamic Web TWAIN HTML5 driver](#)
When scanning a document by using Dynamic Web TWAIN HTML5 driver, the response header shows an invalid character (*).
- [Scanner settings do not persist when scanning using Dynamic Web TWAIN Interface](#)
In Datacap Navigator, when scanning using the Dynamic Web TWAIN Interface, the scanner settings do not persist and sometimes also causes application crash.
- [After image rotation, snippet shows image in its original orientation](#)
In Datacap Navigator, when the image is rotated, snippet for the field shows image in its original orientation.
- [AppScan issues: Physical path disclosure and hidden directory detection](#)
When a user runs Taskmaster Web (tmWeb .Net) from the same machine it is installed on, in case of error 403 or error 404, the complete error page path or hidden directories are displayed .
- [Document integrity check fails to identify batch level variables “MIN TYPES” and “MAX TYPES”](#)
In the document hierarchy, at the batch level, document integrity check fails to identify batch level variables *MIN TYPES* and *MAX TYPES*.

Invalid character when scanning document by using Dynamic Web TWAIN HTML5 driver

When scanning a document by using Dynamic Web TWAIN HTML5 driver, the response header shows an invalid character (*).

Symptoms

When scanning a document using Dynamic Web TWAIN HTML5 driver, the response header shows an invalid character (*).

Example:

```
HTTP/1.1 200 OK
Connection:keep-alive
Server: dynamic_lws
Access-Control-Allow-Origin: *
Content-Type: text/json
Content-Length: 100
```

```
{
  "id" : "901931755",
  "method" : "IfAllowLocalCache",
  "result" : [ true ],
  "cmdId" : ""
}
```

Causes

The Dynamic Web TWAIN HTML5 Driver had a security vulnerability in which `Access-Control-Allow-Origin` in the response header was set to the wildcard character (*).

Resolving the problem

User response: The security vulnerability in Dynamic Web TWAIN HTML5 Driver was fixed by setting the `Access-Control-Allow-Origin` in response header to the authorized URL used to access the service.

To implement this fix, complete the following steps:

1. Before you connect a workstation to Datacap Navigator, uninstall the currently installed version of the Dynamic Web TWAIN HTML5 Driver by using the Programs and Features option in Microsoft Windows Control Panel.
2. The next time that you use the *Scan* task from Datacap Navigator Job Monitor, the system will prompt you to download *DynamicWebTWAINHTML5Edition.exe*.
3. Download this executable file and follow the installation wizard to complete the installation. Verify that the installed version is **12.2.7427**.
4. Now, proceed with the Scan task. You are prompted to authorize the operation by selecting one of the following options:
 - o Allow Once
 - o Always Allow
 - o Block Once
 - o Always Block

The *Allow Once* and *Block Once* options are only applied for the current session, whereas the *Always Allow* and *Always Block* options remain effective until changed by the user.

System administrator response: The following updated files are available in the directory [Datacap install folder]\tmweb.java.

- *DynamicWebTWAINHTML5Edition.msi*: For Microsoft Windows
- *DynamicWebTWAINHTML5MACFullEdition.pkg*: For Apple Mac OS

The system administrators must use the appropriate file to preinstall the updated Dynamic Web TWAIN HTML5 Driver on any scan workstation that connects to the updated Datacap Navigator server.

Note: Do not use any other MSI file in the [Datacap install folder]\tmweb.java directory.

Result:

After you install the updated Dynamic Web TWAIN HTML5 Driver and perform the document scan action, the response header displays an authorized URL in place of the wildcard character (*).

Example:

```
HTTP/1.1 200 OK
Connection:keep-alive
Server: dynamic_lws
Access-Control-Allow-Origin:<my_allowed-url>
```

```
Content-Type: text/json
Content-Length: 100
{
  "id" : "901931755",
  "method" : "IfAllowLocalCache",
  "result" : [ true ],
  "cmdId" : ""
}
```

Parent topic: [Troubleshooting tips for IBM Datacap](#)

Scanner settings do not persist when scanning using Dynamic Web TWAIN Interface

In Datacap Navigator, when scanning using the Dynamic Web TWAIN Interface, the scanner settings do not persist and sometimes also causes application crash.

Symptoms

In Datacap Navigator, when scanning using the Dynamic Web TWAIN Interface, the scanner settings do not persist. This sometimes causes the application to hang and crash.

Causes

Datacap applications prior to Version 9.1.1 did not support skipping the blank pages during scan process, hence there was no option to persist the scanner setting for skipping the blank pages using the Dynamic Web TWAIN API.

Resolving the problem

User response: You can now skip the blank pages during the scan process, by using the Advanced Task scanner settings. After you configure the Skip Blank Pages option, the setting is persisted.

Perform the following steps to resolve this issue in the Datacap Navigator.

1. Add the line of code (highlighted in the following code-snippet) as the last child element of the ScannerSet paragraph in your application scan task XML.

Note: For OOTB application *TravelDocs*, the file to be updated is `nscan.set.xml`

```
<V label="Enable Autofeeder" n="Autofeed" tip="Controls scanner source
- manual vs. autofeeder option" type="checkbox">1</V>
<V label="Use Duplex Mode" n="Duplex" tip="When enabled - scans both
sides of the image - duplex mode" type="checkbox">0</V>
<V label="Pixel Type" n="PixelFormat" tip="Specify pixel type for scanning
(0-BnW, 1-Grayscale, 2-RGB)" type="text">0</V>
<V label="Bit Depth" n="Bits" tip="Specify bitdepth for above image type"
type="text">1</V>
<V label="Image Resolution DPI" n="Resolution" tip="Specify image resolution
(X and Y resolution assumed the same) DPI" type="text">200</V>
<V label="Paper Size" n="PaperSize" tip="Specify paper size for scanning
(0-none, 1-A4, 2-JISB5)" type="text">0</V>
<V label="Image format" n="Extension"
tip="Specify extension for the scanned images: tif, jpeg, bmp, png"
type="text">tif</V>
<V label="Skip Blank Pages" n="SkipBlankPages"
tip="Specify whether to discard blank pages, default is do not discard.
```

For some scanners, duplex must be unchecked for this to be enabled."
`type="checkbox">0</v>`

2. Take a backup of DatacapWebPlugin.jar file before proceeding to update it, in case you need to revert the fix later.
3. Stop the IBM WebSphere Application Server service.
4. Replace the updated DatacapWebPlugin.jar in the Datacap installation folder.
Note: Example: C:\Datacap\tmweb.java
5. Start the IBM WebSphere Application Server service.
6. Log in to admin desktop.
Note: Example URL of Admin desktop: <http://localhost:9080/navigator/?desktop=admin>
7. Click on Plug-ins, and select the Datacap Navigator. Click Edit, then Load. Next click Save and Close. Next, click Close to exit and then log out from the application.
8. Now, log on to your desktop and test the fix. To change the skip blank pages value, go to NScan application. Open the Advanced tab. In the section Scanner Setup, select or clear the Skip Blank Pages check box.

Note: If you want to revert this fix in the Datacap Navigator, complete the steps 3 - 7 using the backed-up copy of DatacapWebPlugin.jar.

Parent topic: [Troubleshooting tips for IBM Datacap](#)

After image rotation, snippet shows image in its original orientation

In Datacap Navigator, when the image is rotated, snippet for the field shows image in its original orientation.

Symptoms

In Datacap Navigator, when the image is rotated, snippet for the field shows image in its original orientation.

Causes

This issue sometimes occurs when a document is ingested upside down in the Datacap Navigator.

Resolving the problem

User response: If a document is ingested upside down and the user notices it during the Verify process, user can resolve this issue by performing the following steps in the Datacap Navigator.

1. In Datacap Navigator, open Job Monitor.
2. Click the image in the Batch Structure to open the image in the viewer.
3. Use the viewer Actions to rotate the image to the desired orientation.
4. Click Hold button. The image is saved in the new orientation.
5. Repeat the steps 2-4 for other images, if required.

The image snippet or the selected words in the image are now shown in the correct orientation, and you can update the necessary content in the Field Details section.

Parent topic: [Troubleshooting tips for IBM Datacap](#)

AppScan issues: Physical path disclosure and hidden directory detection

When a user runs Taskmaster Web (tmWeb .Net) from the same machine it is installed on, in case of error 403 or error 404, the complete error page path or hidden directories are displayed .

Symptoms

Example: Consider that Taskmaster Web (tmWeb.Net) is installed on machine 1. It has a web.config file, which contains “mode” attribute in <customErrors> tag. This property can have three values:

- *off*
- *on*
- *remoteonly*

Now consider that user A is accessing Taskmaster Web from a remote machine, and user B is accessing the Taskmaster Web from same machine on which it is hosted, that is, machine 1. While navigating the Taskmaster Web, a page experiences error 403 or error 404.

If the mode property is set to **remoteonly**:

- The remote user A will see the a user-defined error message, without any physical path disclosure.
- However, the user B will be redirected to a technical error page that displays the complete physical path.

If the mode property is set to **on**:

- In this case, both users A and B will be re-directed to an error page that shows a user-defined error message, without any physical path disclosure.

If the mode property is set to **off**:

- In this case, both users A and B will be redirected to the default technical error page of ASP.NET, with physical path disclosure.

Resolving the problem

User response:

Important: In order to avoid displaying the technical error page with physical path and hidden directories, as a best practice it is recommended that no user should run Taskmaster Web (tmWeb Net) on the same machine where it is installed.

To fix this issue, complete the following steps:

1. On the machine where Taskmaster Web (tmWeb .Net) is installed, open the web.config file, located in the directory C:\Datacap\tmweb.net.
2. **To fix Error Page Path Disclosure:**
 - a. Under the <system.webServer> node, add the code-snippet highlighted below:

```
<system.webServer>
....
.....
  <httpErrors errorMode="Custom">
    <remove statusCode="404" />
    <error statusCode="404" path="/error.aspx"
responseMode="ExecuteURL" />
  </httpErrors> </system.webServer>
```

- b. Under the <system.web> node, add the code-snippet highlighted below:

```
<system.web>
....
```

```
.....  
<customErrors mode="On" defaultRedirect="~/error.aspx"/>  
</system.web>
```

3. To fix Hidden Directory Detection:

a. Under the `<system.webServer>` node, add the code-snippet highlighted below:

```
<system.webServer>  
  <httpErrors errorMode="Custom">  
    <error statusCode="403" subStatusCode="14" path="/error.aspx"  
    responseMode="ExecuteURL" />  
  </httpErrors>  
</system.webServer>
```

4. After updating the web.config file, it is recommended to restart the Internet Information Server (IIS) web server.

Parent topic: [Troubleshooting tips for IBM Datacap](#)

Document integrity check fails to identify batch level variables “MIN TYPES” and “MAX TYPES”

In the document hierarchy, at the batch level, document integrity check fails to identify batch level variables *MIN TYPES* and *MAX TYPES*.

Symptoms

User sets either one or both the variables *MIN TYPES* and *MAX TYPES* at batch level node in document hierarchy. However, the document integrity check passes for a batch that does not contain documents more than the value of *MIN TYPES* and less than the value of *MAX TYPES*.

Causes

In setup DCO there are variables named *MIN_TYPES* and *MAX_TYPES* at every level in hierarchy. However, at the batch level, the variable names do not contain underscore and have spaces instead, such as "*MIN TYPES*". The document integrity code however checks for *MIN_TYPES* and not for *MIN TYPES*

Resolving the problem

Instead of setting variables *MIN TYPES* and *MAX TYPES*, add new variables *MIN_TYPES* and *MAX_TYPES* and set the desired value to these variables.

Parent topic: [Troubleshooting tips for IBM Datacap](#)

Troubleshooting Datacap security and authentication

You might encounter problems when you start the Datacap system or log on to a component. For example, in a client/server environment, you might see a problem with the automatic encryption key import feature.

- [Automatic key import feature fails to apply the new encryption keys](#)
In a client/server environment, the latest encryption keys must be applied when you start a Datacap component. If encryption keys are not applied, you receive authentication errors.

Automatic key import feature fails to apply the new encryption keys

In a client/server environment, the latest encryption keys must be applied when you start a Datacap component. If encryption keys are not applied, you receive authentication errors.

Symptoms

In a client/server environment, when an Datacap component is started on a client computer for the first time, the component cannot communicate with the Datacap server. Authentication errors result.

Causes

This problem can occur when the automatic key import feature fails to apply the new encryption keys as expected when you start the component. This issue impedes communication between the client computer and the Datacap server.

Resolving the problem

Ensure that you imported the latest keys from the Datacap server keystore by using the documented procedure in *Importing encryption keys to IBM® Datacap computers*. Restart the Datacap component. If communication problems still persist, import the keys manually.

To import the keys manually, copy the `dcskey.exe` file from the Datacap server to the client computer. Then, run the `dcskey.exe /i` command from the Microsoft Windows desktop, either from the Start > Run command or from a command prompt.

Parent topic: [Troubleshooting Datacap security and authentication](#)

Related information

[Importing encryption keys to Datacap computers](#)

Troubleshooting Rulerunner

You might need to troubleshoot problems when you use Rulerunner to automatically process background tasks when batches are pending.

You run these steps to troubleshoot Rulerunner.

- [First things to check](#)
When you troubleshoot the Rulerunner Service, you can complete some tasks to ensure that your system is set up correctly. For example, ensure the correct version of Datacap is installed on all computers. The tasks also include running a batch manually, and checking the Windows Event View logs on the Rulerunner server.
- [Viewing Windows Event Viewer logs on Rulerunner server](#)
You can open the Windows Event Viewer and view the Application and System Logs on the Rulerunner server that hosts the Rulerunner Service. The Rulerunner server must be running on Windows.
- [Stopping the Rulerunner Service](#)
You must stop the Rulerunner Service to do system maintenance and back up your environment. Also, to upgrade or remove Datacap software, or clear the Rulerunner Service service memory.
- [Enabling Rulerunner processing logs](#)
Rulerunner processing logs can be created on the Rulerunner server that hosts Rulerunner. Task-specific logs can be created on the Server that hosts Datacap and the application files.

- [Starting the Rulerunner Service](#)
After you set up or change the Rulerunner Service, go to the Rulerunner Manager and start the Rulerunner service.
- [Viewing Rulerunner processing logs](#)
The Rulerunner processing logs provide information to help identify the cause of error conditions. The error conditions might include Datacap server connection failures, inconsistent domain account group names for authentication, or incorrect database path structures in the Application Manager.

First things to check

When you troubleshoot the Rulerunner Service, you can complete some tasks to ensure that your system is set up correctly. For example, ensure the correct version of Datacap is installed on all computers. The tasks also include running a batch manually, and checking the Windows Event View logs on the Rulerunner server.

Make sure that Datacap 9.0 or later is installed on all of the computers in your system.

Ensure that you can run a batch manually by using a Datacap client on a workstation or from a browser. If you cannot manually run batches through the tasks that Rulerunner is to process, your application setup needs to be corrected. Review your installation and configuration of the application and review the installation and configuration topics to troubleshoot your setup.

If you can run a batch manually, through the tasks that Rulerunner is configured to process. And your application is set up properly. And you need to do Rulerunner specific troubleshooting. Follow the instructions in [Viewing Windows Event Viewer logs on Rulerunner server](#) to stop Rulerunner, enable logging, restart Rulerunner, and check the log files for errors.

If Rulerunner starts then stops immediately and the log files indicate that Rulerunner cannot connect to the Datacap Server Service:

- If a firewall is enabled on the Server hosting the Datacap Server Service, ensure that TCP/IP port 2402 was opened.
- When you use Windows Authentication, check with your system administrator to make sure that you selected the correct Windows Authentication template in the Datacap Server Manager.

Parent topic: [Troubleshooting Rulerunner](#)

Viewing Windows Event Viewer logs on Rulerunner server

You can open the Windows Event Viewer and view the Application and System Logs on the Rulerunner server that hosts the Rulerunner Service. The Rulerunner server must be running on Windows.

Procedure

To view Windows Event Viewer logs on Rulerunner server:

1. On the Rulerunner server, in the Start menu click Control Panel > Administrative Tools > Event Viewer > Windows Logs > Application.
2. Select Action > Refresh to ensure that you are seeing all recent messages.
3. Locate the first or last event from the most recent Rulerunner Service run and double-click the entry to view the properties of the event.

Ignore the message:

```
The description for Event ID ( 0 ) in Source... cannot be found...  
The following information is part of the event:
```

The information that follows this text is relevant.

The first event reads:

```
Service Started
```

Subsequent events indicate that the individual threads have each started. There are three initialization attempts with intervals of 2, 4 and 8 seconds apart and errors are logged if they occur.

Any warning or error events indicate a problem, the first warning, or error is typically the most significant.

4. Select System. Entries for individual events are displayed in the details pane.
5. Double-click an entry to view the properties of the event. Messages indicate that the Rulerunner Service was able to log on.

Any warning or error events indicate a problem, the first warning, or error is typically the most significant.

Parent topic: [Troubleshooting Rulerunner](#)

Stopping the Rulerunner Service

You must stop the Rulerunner Service to do system maintenance and back up your environment. Also, to upgrade or remove Datacap software, or clear the Rulerunner Service service memory.

About this task

If you try to stop the Rulerunner Service service while it is processing job tasks, the service completes its current work before it shuts down.

Procedure

To stop the Rulerunner Service:

1. On the Rulerunner server, in the Start menu select IBM Datacap Services > Datacap Rulerunner Manager. If the User Account Control window opens, click Yes.
2. If the Status is Stopped, close the Rulerunner Manager window.
3. If the Status is Running, click Stop.

Parent topic: [Troubleshooting Rulerunner](#)

Enabling Rulerunner processing logs

Rulerunner processing logs can be created on the Rulerunner server that hosts Rulerunner. Task-specific logs can be created on the Server that hosts Datacap and the application files.

About this task

You must have 10 GB or more of disk space on each server for storing these logs. Remember to change the level of detail that is written to the logs or to turn them off when you no longer need them.

Procedure

To enable Rulerunner processing logs:

1. On Rulerunner server, in the Start menu click IBM Datacap Services > Rulerunner Manager.
2. If the Status displayed for the Rulerunner Service is Running, click Stop.
3. Click the Rulerunner Login tab.
4. Select the Windows Authentication option, and click Connect.
5. Click the Logging tab.
6. On the Rulerunner Log tab, move the Application Event Log level slider to Serious and critical.
7. On the Rulerunner Log tab, move the Thread Log level slider to All, then click Save.
8. Ensure that the Output to folder option is selected. Change or make a note of the path in the Output to field. This path is where the logs are created and you need this information later.
9. Change other options as wanted, then click Save.
10. Click the RSS Log tab, move the sliders to All for Level of detail written to the RRS logs slider and the Severity level of messages logged.
11. Select the Batch Log option. Change other options as wanted, then click Save.
12. Click the Rulerunner Login tab.
13. Click Disconnect.
Important: Complete the following steps to ensure that the Rulerunner authentication credentials are set properly.
14. When you are using:
 - o Windows Authentication - Select the Windows Authentication option.
 - o Datacap Authentication - Select the Datacap Authentication option, enter the user ID and Password that is used by Rulerunner, the name of the Rulerunner server as the Station ID.
15. Click Save.
16. Close the Rulerunner Manager window.

Parent topic: [Troubleshooting Rulerunner](#)

Starting the Rulerunner Service

After you set up or change the Rulerunner Service, go to the Rulerunner Manager and start the Rulerunner service.

Procedure

Follow this procedure to start the Rulerunner Service.

1. Go to Start > IBM Datacap Services > Datacap Rulerunner Manager. If the User Account Control window opens, click Yes.
2. If the Status is Stopped, click Start. The Status changes to Running.
3. Close the Rulerunner Manager window.

Parent topic: [Troubleshooting Rulerunner](#)

Viewing Rulerunner processing logs

The Rulerunner processing logs provide information to help identify the cause of error conditions. The error conditions might include Datacap server connection failures, inconsistent domain account group names for authentication, or incorrect database path structures in the Application Manager.

About this task

When you enable logging and restart Rulerunner, Rulerunner processes batches and writes the processing information to the logs. You can view the various Rulerunner logs to get this information.

Procedure

To view Rulerunner processing logs:

1. On the Rulerunner server, start Windows Explorer, open the folder in which the logs were created. The default is C:\Datacap\. The folder is defined by Rulerunner Manager. Click the Logging - Rulerunner Log tab and select Output to folder.
2. Open the Rulerunner.log file in a text editor such as Notepad and look for errors.
3. Open the Rulerunner thread log files in a text editor. Look for the messages that begin with EstablishConnection. A successful log would be similar to this example:

```
EstablishConnection: Connecting to application [APT].
EstablishConnection: GetServer returned [127.0.0.1].
EstablishConnection: Connecting to TM Server [127.0.0.1:2402].
EstablishConnection: Connecting to Admin DB
[PROVIDER=MSACCESS;DSN=C:\Datacap\APT\APTAdm.mdb;].
EstablishConnection: Connecting to Engine DB
[PROVIDER=MSACCESS;DSN=C:\Datacap\APT\APTEng.mdb;].
EstablishConnection: TM Login [admin station=1].
EstablishConnection: Login successful.
```

4. Error conditions can include one or more of the following examples:
 - If you are connecting to the Datacap Server fails, then the Datacap Server Service is not responsive or a network failure occurred.
 - If you are connecting to the Admin or Engine database of the application fails, use the Datacap Application Manager. To ensure that the paths to the databases are correct.
 - If Rulerunner fails to log in to the Datacap Server, do the following steps.
 - Ensure that the Rulerunner Service is set up properly by reviewing the Rulerunner related instructions.
 - Ensure that the Rulerunner domain account was added to the correct security group. And, in your Datacap application, a matching group is set up with a name that ends in the complete domain name (for example, XYZ.com, not XYZ).
5. On the Server, start Windows Explorer, go to and open the batches folder of the application. The default folder is C:\Datacap\Application\Batches.
6. Open the taskname_rrs.log in a text editor and look for errors. For example, open pageid_rrs.log or recognize_rrs.log.

During processing, when Rulerunner fails to run a batch from a particular application, there is a delay interval before the next attempt. Rulerunner doubles the delay each time 2 - 64 seconds.

Parent topic: [Troubleshooting Rulerunner](#)

Troubleshooting FastDoc

You might need to troubleshoot problems when you use FastDoc to scan, process, verify, and export documents.

Some of the common issues that might require troubleshooting include these issues:

- FastDoc client issues like poor barcode recognition, documents types are not assigned, and scanners are not displayed.
- FastDoc application issues such as extra data is found in captured data and index data is not picked up in a zoned field.
- FastDoc client export issues that include errors during the export and SharePoint Connector upload errors from the Export_rrs.log file.

- [Barcode recognition is poor](#)
FastDoc is set up to capture the value of any type of barcode. If you cannot capture barcode values, the barcodes might be blurred or somehow damaged.
- [Document type is not automatically assigned](#)
FastDoc does not automatically assign a document type to a document that was set up by your Administrator. There is something wrong with the fingerprint of that document.
- [Scanner is not listed as an option](#)
When you try to select a scanner from the TWAIN Scan Source list, your scanner is not listed as an available option.
- [Extra data included in captured data](#)
A zone for a field on a particular document is created incorrectly, such as with the wrong location or the wrong size. Unwanted data can be included in the field during document processing. For example, the field label or data from the previous line or the next line might be included in the field.
- [Index data not picked up automatically in zoned field](#)

- [SharePoint upload returns a properties update error in Export_rrs.log](#)
The characteristics of the index values passed by FastDoc to SharePoint must match the characteristics of the SharePoint columns.
- [FastDoc labels cannot be displayed](#)
Labels are not displayed in "Configure documents, pages, and fields" icon, due to Windows environment issue.

Barcode recognition is poor

FastDoc is set up to capture the value of any type of barcode. If you cannot capture barcode values, the barcodes might be blurred or somehow damaged.

When barcode recognition is poor, you can use the Resolution dial on the TWAIN Scan or ISIS Scan panel to increase the resolution before you begin scanning the documents. Then, during the Verify process, you redraw the zone around the barcode.

Attention: When you scan an image with a different DPI, you must create a new fingerprint. If the barcode type is set to Any, change it to the barcode type that is used.

You can also reprint the barcodes and apply them to the problem pages or enter the barcode values manually.

Parent topic: [Troubleshooting FastDoc](#)

Document type is not automatically assigned

FastDoc does not automatically assign a document type to a document that was set up by your Administrator. There is something wrong with the fingerprint of that document.

When you click Fingerprint, the fingerprint ID number is displayed with Add and Delete options. If the fingerprint is new, zone the fields to save the positions to the new fingerprint. The new fingerprint is recognized the next time that you run the task. If the wrong type is matched, click Fingerprint and click New to force the creation of a new fingerprint. Optionally, you can click Delete to remove the fingerprint that was matched if it is no longer used.

Parent topic: [Troubleshooting FastDoc](#)

Scanner is not listed as an option

When you try to select a scanner from the TWAIN Scan Source list, your scanner is not listed as an available option.

Use the scanner manufacturer instructions and driver software to ensure that your scanner and scanner driver are installed correctly and that you can use the scanner to scan documents successfully outside of FastDoc.

Parent topic: [Troubleshooting FastDoc](#)

Extra data included in captured data

A zone for a field on a particular document is created incorrectly, such as with the wrong location or the wrong size. Unwanted data can be included in the field during document processing. For example, the field label or data from the previous line or the next line might be included in the field.

To correct this problem, click Fingerprint to see the Fingerprint ID of the document. On the Fingerprint dialog, click Delete to remove the fingerprint. Then, rescan the document, reassign the Document Type to the document, and re-create the zones so that unwanted data is not captured.

Parent topic: [Troubleshooting FastDoc](#)

Index data not picked up automatically in zoned field

A zone for a field on a particular document is created incorrectly, such as in the wrong location or the wrong size. The index data for the field is not automatically picked up.

To correct this problem, click Fingerprint to see the Fingerprint ID of the document. On the Fingerprint dialog, click Delete to remove the fingerprint. Then, rescan the document, reassign the Document Type to the document, and re-create the zones so that the index data is correctly included.

Parent topic: [Troubleshooting FastDoc](#)

Correcting export errors

An error message displays when you export images from FastDoc.

About this task

The following error message displays during export:

```
There was a problem exporting batchXYZ.  
Some documents may not have been exported.  
Check your settings.
```

You must ensure that your export settings are set up correctly and look in the Export_rrs.log file of the batch to find any problems.

Procedure

To correct export settings:

1. Open FastDoc as Administrator, scan a sample of the Document Type that you are having problems with, and click Next Task.
2. After Recognize completes and the Verify panel is displayed with the image displayed in the Active Image pane, click Document Type Settings and ensure that your export settings are correctly set up.
3. Open the batch folder and the Export_rrs.log file, and search for lines that contain the words error or abort. The surrounding lines contain information about the error condition.
4. When you export to SharePoint, see the following topics when the error is related to uploading to SharePoint:
 - [SharePoint upload results in Could not check in file error in export_rrs.log](#)
 - [SharePoint upload results in Could not find list error in export_rrs.log](#)
 - [SharePoint upload results in Could not update properties error in export_rrs.log](#)
5. When you export to IBM® FileNet® Content Manager, verify the following export settings, make corrections where needed, and rerun the export.
 - The URL of the Content Manager into which you want to export documents
 - The Object Store and Document Class on the Content Manager
 - The folder on the Content Manager where you want to store the documents

Parent topic: [Troubleshooting FastDoc](#)

SharePoint upload returns file check-in error in Export_rrs.log

The required columns in a SharePoint library do not include default values. FastDoc can upload the first document in the batch and update the properties for that document. But FastDoc cannot complete the SharePoint check-in process for the first document.

This problem results in a checked-out SharePoint document that only the FastDoc user can see. Other SharePoint users cannot see the document.

In addition, FastDoc is unable to continue processing the remaining documents from the same batch. Those documents were not uploaded to SharePoint at all.

When you get this error, ask your SharePoint Administrator to edit the Document Library Settings for each required column. Add a default value for each, for example, No Value Available. Then, delete the document that was uploaded but not checked in.

After the SharePoint Administrator changes Document Library Settings for each required column, reprocess the entire batch of documents by using the FastDoc Client.

Parent topic: [Troubleshooting FastDoc](#)

SharePoint upload returns a list not found error in Export_rrs.log

The SharePoint Administrator who created a library, then later changed the name that is displayed to users. You used the display name when you set up your export to SharePoint Document Type Settings, the upload to SharePoint fails.

The SharePoint site URL must reflect the original name, not the name that is displayed to users. Obtain the original name from your SharePoint Administrator and change the URL in FastDoc.

Parent topic: [Troubleshooting FastDoc](#)

SharePoint upload returns a properties update error in Export_rrs.log

The characteristics of the index values passed by FastDoc to SharePoint must match the characteristics of the SharePoint columns.

If the index values are not set up properly in FastDoc, they are rejected by SharePoint. The `Could not update Properties` error can occur for a number of reasons, and the error message provides information for the error. For example, if you passed an index value to a SharePoint Date column without identifying it as a Date in FastDoc.

```
Error code: '0x8102001c' Invalid date/time value
A date/time field contains invalid data.
Please check the value and try again.
```

Parent topic: [Troubleshooting FastDoc](#)

FastDoc labels cannot be displayed

Labels are not displayed in "Configure documents, pages, and fields" icon, due to Windows environment issue.

In FastDoc Admin, under the "Configure documents, pages, and fields" icon, the labels are not displayed. The labels that are related to the validate fields option for a field property do not appear.

This is an environment issue that is specific to Windows 2008 R2. To overcome this problem, you can use a version of windows that is compatible with Fastdoc (example, Windows 7, Windows 10).

Parent topic: [Troubleshooting FastDoc](#)

Troubleshooting Datacap web services

If the file upload fails on large files or the PUT request method endpoints are not working, you can check to ensure that your configurations are correct.

Slow log on times possibly caused by network related configurations.

It may be possible to improve log on times by adding the IP address of the Datacap Server to the hosts file on the web services computer.

The file upload fails for SetFile or UploadFile

If the file upload fails on large files when you are using the POST methods SetFile or UploadFile, check that `maxAllowedContentLength` and `maxRequestLength` are configured correctly. You can adjust the value of the `maxAllowedContentLength` and `maxRequestLength` settings in the web.config file. The maximum size message that can be uploaded depends on your web server, proxy server, and client.

The PUT request method GrabBatch, ReleaseBatch, or SetPageFileName does not work

If the PUT request method GrabBatch, ReleaseBatch, or SetPageFileName is not working, ensure that the WebDAV Publishing role service is not installed and that the PUT request method is allowed. The WebDAV Publishing role service prevents the Datacap Web Services PUT method from functioning. You can verify in the Server Manager that the WebDAV Publishing role service is not installed.

- In the Start menu on the web server, select IBM Datacap Services > Datacap Server Manager.
- In the Server Manager hierarchy pane, expand Roles and select Web Server (IIS).
- In the Web Server (IIS) pane, expand Role Services. Under Common HTTP Features, ensure that the WebDAV Publishing role service is not installed.

Related information:

[Verifying that IIS components are installed](#)

Log files

To obtain adequate logging information for troubleshooting purposes, you must enable logging for the client and for the Rulerunner Service.

Adequate logging includes information about a client, such as Datacap Desktop and the Rulerunner Service, which applies rules to an action that a task requires. Maximum logging can be enabled all of the time for a test or development system. However, because maximum logging negatively impacts system performance, you can set the logging to the minimum level on a production server.

- [Enabling logging for Datacap Desktop](#)
To enable logging for Datacap Desktop, you must edit the dcDesktop.exe.config file and enable logging for Rulerunner Service. To confirm that logging is functional, complete an action in Datacap Desktop and review the Rulerunner Service RRS.log file and the dcdesktop.log file.
- [Enabling logging for FastDoc](#)
To enable logging for FastDoc, you must edit the FastDoc.exe.config file and enable logging for Rulerunner Service. To confirm that logging is functional, complete an action in FastDoc and review the RRS.log file and the FastDoc.log file.
- [Enabling logging for Rulerunner Service](#)
To enable logging for Rulerunner Service, you must configure the logging options in Rulerunner Manager. To confirm that logging is functional, complete a task where rules are applied, and review the rulerunner.log file, therulerunner_thread_atm.log file, and the *task_rrs*.log file.
- [Enabling logging for Datacap Server service](#)
To enable logging for Datacap Server service, you must configure the logging options in the Datacap Server Manager. To confirm that logging is functional, complete a task in a workflow and review the tms.log file.
- [Enabling logging for the Datacap Web Client](#)
To enable logging for Datacap Web Client, you must edit the server.ini file. To confirm that logging is functional, complete a task in Datacap Web Client and review the tmweb.log file and the pacuerr.log file.
- [Enabling the Datacap Web Services log](#)
When you enable logging for Datacap Web Services in the c:\Datacap\wtm\web.config file, the wTM and aTM logs are created.

Related information:

[Set Rulerunner logging by application and task](#)

Enabling logging for Datacap Desktop

To enable logging for Datacap Desktop, you must edit the `dcDesktop.exe.config` file and enable logging for Rulerunner Service. To confirm that logging is functional, complete an action in Datacap Desktop and review the Rulerunner Service `RRS.log` file and the `dcdesktop.log` file.

About this task

Although there are different levels of logging, these steps enable maximum logging to troubleshoot Datacap Desktop when problems occur.

Procedure

To enable logging for Datacap Desktop:

1. Enable executable file logging.
 - a. Go to the `\Datacap\DcDesktop` folder and open the `dcDesktop.exe.config` file.
 - b. In the User Settings section, enter these values.
 - `WriteLog = True`
 - `LogSeverity = 5`
 - `LogPath = dcdesktop.log`
 - `LogOverwrite = True`
 - `LogFlushBuffer = True`
 - `LogShowTime = True`
 - c. Save the file.
2. Enable Rulerunner Service logging.
 - a. Start Datacap Web Client and log in to the application that is to be run, and select the Administrator tab.
 - b. Expand the Workflow, highlight the task for which logging is needed, and click Setup.
 - c. In the Rulerunner Service log settings section, under Rulerunner settings, set the Rulerunner service log field to 5 and select the Flush Buffer check box.

Note: Selecting the Flush Buffer option slows down the process because every line that is logged is written to the log file on disk, instead of being buffered in memory.
 - d. Scroll to the end of Webpage Dialog and click Save.
3. Start Datacap Desktop and start a task for which logging information is needed. Two log files are generated:
 - o The `X_rrs.log`, where `X` is the name of the task. The file is in the batch folder of the application (for example, `C:\datacap\TravelDocs\batches\20130924.00001\pageid_rrs.log`), and contains information about actions that are completed by the Rulerunner engine.
 - o The `dcdesktop.log.Y` file, where `Y` is the log sequence number. This file is in the `\Users\username\AppData\Local\IBM\IBM Datacap\9.0.0.0` folder, and contains information about the Datacap Desktop executable file.

What to do next

Disable Datacap Desktop Rulerunner logging by setting `WriteLog = False` in the `dcDesktop.exe.config` file. You cannot completely disable the Datacap Desktop executable file logging, but you can create minimum logging by setting Rulerunner service log, Batch log, and Action log level to 0. Be sure to clear the Flush Buffer check box to avoid reduced performance.

Parent topic: [Log files](#)

Enabling logging for FastDoc

To enable logging for FastDoc, you must edit the FastDoc.exe.config file and enable logging for Rulerunner Service. To confirm that logging is functional, complete an action in FastDoc and review the RRS.log file and the FastDoc.log file.

About this task

Although there are different levels of logging, these steps enable maximum logging to troubleshoot FastDoc when problems occur.

Procedure

To enable logging for FastDoc:

1. Enable executable file logging.
 - a. Go to the \Datacap\FastDoc folder and open the FastDoc.exe.config file.
 - b. In the User Settings section, set `Log = True` and save the file.
2. If you are running FastDoc in Local Mode, enable logging for the Rulerunner Service by completing these steps.
 - a. Go to the \Datacap\FastDoc folder and open the BatchProfiles.xml file.
 - b. Locate the `rrslog` tag that is specific to the task for which logging is needed and set `ServiceLog="5"`.
 - c. Save the BatchProfiles.xml file.
3. If you are running FastDoc in Datacap Mode, enable logging for the Rulerunner Service by completing these steps.
 - a. In the Rulerunner Service log settings for the workflow task in your web client administration panel, set the Rulerunner service log field to 5 and select the Flush Buffer check box.
Note: Selecting the Flush Buffer option slows down the process because every line that is logged is written to the log file on disk, instead of being buffered in memory.
4. Start FastDoc and start a task for which logging information is needed. Two log files are generated:
 - o The `X_rrs.log`, where `X` is the name of the task. The file is in the batch folder of the application (for example, `C:\datacap\TravelDocs\batches\20130924.00001\pageid_rrs.log`), and contains information about actions that are completed by the Rulerunner engine.
 - o The `FastDoc.log`. This file is in the `\Users\username\AppData\Local\IBM\IBM Datacap\9.0.0.xx` folder, and contains information about the FastDoc executable file.

What to do next

Disable the FastDoc executable file logging by setting `Log = False` in the FastDoc.exe.config file. You cannot completely disable the FastDoc Rulerunner logging, but you can create minimum logging by setting Rulerunner service log, Batch log, and Action log level to 0. Be sure to clear the Flush Buffer check box to avoid reduced performance.

Parent topic: [Log files](#)

Enabling logging for Rulerunner Service

To enable logging for Rulerunner Service, you must configure the logging options in Rulerunner Manager. To confirm that logging is functional, complete a task where rules are applied, and review the rulerunner.log file, therulerunner_thread_atm.log file, and the `task_rrs.log` file.

About this task

Although there are different levels of logging, these steps enable maximum logging to troubleshoot Rulerunner Service when problems occur.

Procedure

To enable logging for Rulerunner Service:

1. Start Rulerunner Manager.
2. Click the Rulerunner Login tab.
3. Enter the login information, as needed, and click Connect.
4. Click the Logging tab, and then select Quick Log at the end of the page.
5. Move the slider to Debug.
6. Click Save.
7. On the Rulerunner Login tab, click Disconnect, and exit from Rulerunner Manager.
8. Complete a task for which logging information is needed. These log files are generated:
 - o The RulerunnerX.log, where X is the thread. The default location of the file is C:\datacap, and contains general logging information for the Rulerunner process.
 - o The Rulerunner_thread_X_atmY.log, where X is the name of the task and Y is the log sequence number. The default location of the file is C:\datacap, and contains detailed logging information for the Rulerunner process.
 - o The Z_rrs.log, where Z is the name of the task. The file is in the batch folder of the application (for example, C:\datacap\TravelDocs\batches\20130924.00001\pageid_rrs.log), and contains information about actions that are completed by the Rulerunner engine.

Tip: You do not need to restart the Rulerunner Service after you save the logging configuration settings. The service automatically retrieves the changes after all of the pending tasks are completed. However, you can restart the service to immediately implement the changes.

The Rulerunner Service uses managed logging for all of the log files except the rrs log file. When the log files are full, Rulerunner deletes the oldest file and creates a new file. Managed logging provides the option of keeping logging enabled without using excessive hard disk space.

Parent topic: [Log files](#)

Enabling logging for Datacap Server service

To enable logging for Datacap Server service, you must configure the logging options in the Datacap Server Manager. To confirm that logging is functional, complete a task in a workflow and review the tms.log file.

About this task

Although there are different levels of logging, these steps enable maximum logging to troubleshoot Datacap Server service when problems occur.

Procedure

To enable logging for Datacap Server service:

1. Start Datacap Server Manager.
2. Click the Logging tab, and then click the Datacap log tab.
3. Move the slider to All and select the Output to file check box.
4. Click Save and exit from Datacap Server Manager.
5. Complete a task in a workflow for which logging information is needed. Datacap Server Manager generates 1 - 5 log files with the name tms.log.X.log, where X is the log number. The location of the log

files is in the Datacap installation directory. (The default is C:\datacap.)

Tip: You do not need to restart the Datacap Server service after you save the logging configuration settings. The service automatically retrieves the changes after a few seconds.

The Datacap Server service uses managed logging. After the log files are full, Datacap deletes the oldest file and creates a new file. Managed logging provides the option of keeping logging enabled without using excessive hard disk space.

Parent topic: [Log files](#)

Enabling logging for the Datacap Web Client

To enable logging for Datacap Web Client, you must edit the server.ini file. To confirm that logging is functional, complete a task in Datacap Web Client and review the tmweb.log file and the pacuerr.log file.

About this task

Although there are different levels of logging, these steps enable maximum logging to troubleshoot Datacap Web Client when problems occur.

Procedure

To enable logging for Datacap Web Client:

1. Go to the \Datacap\tmweb.net folder and open the server.ini file.
2. In the [General] section, set WriteLog = 1.
3. In the [Log] section, enter these values.
 - Path = C:\Datacap\TaskRun\tmweb.log (or other valid path and file name).
 - Overwrite = 1
 - ShowTime = 1
 - FlushBuffer = 1
4. Save the server.ini file.
5. Restart IIS.
6. Start Datacap Web Client, log in to the application for which logging information is required, and complete a task in a workflow. Two log files are generated.
 - tmweb.log.X.log, where X is the log sequence number. The file is in the C:\Datacap\TaskRun folder, or the folder that was specified in the Path configuration setting.
 - Datacap Web Client also contains an error log that is always enabled. If the web page itself encounters an error and times out, Datacap generates a file that is called pacuerr.log, which is in the C:\Datacap\tmweb.net\App_Data folder.

What to do next

Disable Datacap Web Client logging by setting WriteLog = 0 in the server.ini file and restarting IIS.

Parent topic: [Log files](#)

Enabling the Datacap Web Services log

When you enable logging for Datacap Web Services in the c:\Datacap\wtm\web.config file, the wTM and aTM logs are created.

Procedure

Enable logging for Datacap Web Services.

1. Navigate to the c:\Datacap\wtm folder and open the web.config file.
2. In the `<IBM.Datacap.Web.Properties.Settings>` section, set `logEnable` to `True`. Enter the other settings values, including the `logPath` and the `logSeverity` settings. You can control the level of detail that is written to the log by entering one of the following values in the `logSeverity` setting.
 - o 0 - No messages are logged
 - o 1-3 - Logs warnings and exceptions
 - o 4-6 - Logs information, warnings, and exceptions
 - o 7-9 - Logs the maximum amount of detail

Example

```
<setting name="logSeverity" serializeAs="String">
<value>4</value>
</setting>
<setting name="logOverwrite" serializeAs="String">
<value>False</value>
</setting>
<setting name="logPath" serializeAs="String">
<value>c:\</value>
</setting>
<setting name="logTime" serializeAs="String">
<value>True</value>
</setting>
<setting name="logFlushBuffer" serializeAs="String">
<value>True</value>
</setting>
<setting name="logEnable" serializeAs="String">
<value>True</value>
</setting>
```

Best Practices for optimal text recognition

This document provides information about text recognition in general, and detailed guidance to achieve the best results when processing documents by using IBM® Datacap.

To know about best practices for optimal text recognition, see [Best Practices for optimal text recognition in IBM Datacap](#).

Best practices for source control of Datacap applications

This document discusses the implications of using source control on a Datacap application.

Datacap applications are consisted of a collection of files and databases. Source control can help track when an application has been updated and the user that performed the update. This document discusses the implications of using source control on a Datacap application.

- [Parts of a Datacap Application](#)
A Datacap is primarily a collection of files. Here is a review of the components and how they relate to source control.
- [Source Control of Datacap applications](#)
There are several components that together comprise a Datacap application. The database portion is the

primary piece that does not fit into complete source control solution because it is not a "file" unless Microsoft Access is being used.

Parts of a Datacap Application

A Datacap is primarily a collection of files. Here is a review of the components and how they relate to source control.

Batch Directories

By default, a batch directory is in a subdirectory of the main application. The batch directory can be moved to any location and is not required to be under the application. Typically there is no reason to source control a batch. It is created and then usually not kept as a whole unit. What is saved from a batch varies from application to application and usually ends up in an external repository. Batches are never versioned. A batch is created and then lives in its final state until important artifacts are saved and discarded. A batch is not expected to be managed by using a source control system.

A batch directory can also exist outside of the application by using the web service to run batches. In this environment, batches are created in its own protected location and are deleted after completion.

Databases

A Datacap database stores several types of data:

- Administrative
- Engine
- Fingerprint
- Lookup
- Other custom data

Administrative Database

Administrative settings regarding users along with some configuration settings such as shortcuts and some task configuration settings.

Engine Database

The Engine database contains the information regarding the batches. The batch IDs, who ran the batch, time for the batch and statistics.

Fingerprint Database

The fingerprint database holds the information regarding the fingerprints that have been created for the application.

Lookup Database

The lookup database is a custom database. APT provides a sample database that could be used as-is, but can also have its schema altered by the user.

Custom Database

Datacap actions support generic SQL.

Database Details

The following table identifies the following for each type of database:

- If a specific schema defined by the Datacap application is required.
- If the database is supported by the Application Copy tool to migrate database data. The tool does not update database schemas. If the database schema is not a Datacap schema, then the user is responsible for creating necessary scripts and steps to move the data from the test environment to a production environment.
- If the database data is typically moved from test to production.

Table 1. DB Types

DB Type	Datacap Schema	Application Copy	Production Rollout
Administrative	Yes	Yes	Changes need to be moved to production. If there are differences in production vs. test, such as different users, then a partial move might be performed.
Engine	Yes	Yes	Typically changes are not moved to production. An updated schema should be applied to the production database, but the table data is not moved to production.
Fingerprint	Yes	Yes	Changes need to be moved to production.
Lookup	No	No	Depends on application. Typically it would be expected to be moved.
Custom	No	No	Depends on application. Typically it would be expected to be moved.

Database Source Control Implications

For a test or demonstration application, an Access database may be used. An Access database is a single file that would be treated as a binary “blob” object by source control. Typical test and production systems use a production grade database such as DB2.

The changes to the database would be controlled and tracked by the database software and not by a source control system.

A rollout from a test environment would need to be coordinated so that new files are placed into production at the same time as any database updates.

Fingerprint Directory & Fingerprint Service

The fingerprint directory contains the images, CCO files, and FPXML files that are used for fingerprinting. The images and CCO files are binary while the FPXML is text. This directory typically lives under the application’s root directory. If the fingerprint web service is used, then the location of the fingerprints could be elsewhere in a network environment.

A fingerprint may need to be moved from test to production depending on the application. For example, with a learning application, such as APT, fingerprints are created during production. There would not be fingerprints to move from test to production. Similarly, there would not be fingerprints to manage in source control.

When using a form application, fingerprints are typically pre-created in a development environment. These fingerprints would ultimately be moved to a production environment and would likely want to be source controlled.

As mentioned, fingerprints may be managed by a fingerprint service and potentially could be shared with multiple applications. Moving these fingerprints to a production environment needs to be synchronized with moving of the application updates.

Fingerprints maintained by the fingerprint service would be considered a separate component to manage with source control as it is not necessarily tied to an application or a single application.

DCO Directory

The DCO directory has a `_DCO` suffix. It contains the setup DCO object and a number of configuration files, such as task settings files, INI files, key files, and any other custom files that were created by the user for their application. This directory can be a mix of text and binary files.

The files in the DCO directory may not be known by Datacap Studio or FastDoc. For example, the user could create one or more custom keyfile that is used by a locate action. Other custom files could be accessed by custom actions.

The rules directory is a child of this directory. The rules directory contains all of the rules for the application. This directory will also contain the binary files of compiled rulesets that are added to the application along with their configuration settings files.

For some applications, such as APT, this directory contains additional files such as “Add Vendor Demo” and “Fingerprint Maintenance Tool” along with corresponding subdirectories that contain translated resources for these applications. These files could be source controlled although they are typically only updated with a new product install and are not considered part of the “application” as they are application utilities.

Additional Custom Directories

An application could have any number other additional directories in any given location. They could be somewhere under the application tree or somewhere else on the machine or network. One example would be the “Graphics” directory that is part of the APT application. An application that performs signature matching can have one or more directories to store reference images. Any kind of custom directory could be created and accessed by standard actions or custom actions.

These directories are not created or known by Datacap Studio or FastDoc. The only way they could be found by these two applications would be by scanning the directories under the application folder, provided they are within the application folder.

Custom Panels

There are two kinds of customizable panels. Datacap Navigator and Datacap Desktop.

Navigator

The customizations to the Navigator files are stored in the application directory in a folder called “Navigator”. This directory can contain additional subdirectories and the files are text-based files that are created by the Navigator client.

Datacap Desktop

It is possible to create custom panels for applications that are displayed from within Datacap Desktop. These panels are written in C# using Microsoft Visual Studio and the binary files are in the Datacap Desktop directory. The source files used to build the panels would be managed separately from the application.

If the panels are updated, then it is a manual process for the user to move them to the production directories as required. They are not copied with the Application Copy tool.

Custom Actions

A user can create custom actions that expand the capabilities of the Datacap application to provide special processing that is not included in the base system. This will be source code written in C# or in Visual Basic Script. For both types of actions, the source code used to build the binaries would be created in Microsoft Visual Studio. It is also possible to use a plain text editor to create VB actions with a plain text editor because it does not need to be pre-compiled.

C# Actions

The binary files for this kind of custom action can live anywhere. There are two different ways to create a C# action. There can be a single DLL or a DLL with a corresponding RRX. If it is a single DLL, it can reside in the RRS directory or in the application rules directory.

If the DLL is a combination of a DLL and RRX file, then the RRX resides in the RRS or application rules directory and the DLL can reside in any directory but typically it is placed in the \Datacap\DCShared\Net directory.

VB Actions

An RRX file that is a visual basic script file needs to sit in either the RRS directory or in the application's rules directory.

Parent topic: [Best practices for source control of Datacap applications](#)

Source Control of Datacap applications

There are several components that together comprise a Datacap application. The database portion is the primary piece that does not fit into complete source control solution because it is not a "file" unless Microsoft Access is being used.

Introduction

Assuming that an application is within source control, it is assumed that there are several reasons for source control.

- Moving changes to production in a controlled manner.
- Controlling changes to an application.
- Tracking who changed an application.

Source Control Application Rollout

When strictly controlling who updates an application with source control, it would be assumed that there would not be a manual step to place the software in the production system. There would need to be an automated process to take what is in source control and place it into the target production system.

This would need to be able to place the contents of the application directories along with any directories that are external to the application. So, if there is a directory that is used externally, possibly fingerprints or other custom directories, the automated process would need to take those directories and files from source control and place them into the target systems.

As the database portion is not managed by source control, some kind of custom step is needed to move any database updates to the production database in a synchronized manner.

Manual Source Control

It is possible to source control an application without direct source control repository integration with Datacap Studio or FastDoc. Typically, source control has a directory structure that is the location of the managed source files that have been retrieved from source control and placed in a managed source area where the developer has access. Source control applications such as RTC and GIT can monitor a directory and all of the files and subdirectories.

A manual solution would have the application sitting in source control with all of the required folders and files. In the case where folders are outside an application, then the developer would need to manually copy them to a subdirectory to manager it together with the application and then the drop process that occurs after check-in would need to know that a directory needs to live in a location outside the application. This is similar to a kind of build script that runs after files are checked into a source control system.

Monitoring the Application Directories

There are two basic ways that a source control system tracks changes in a directory.

In some source control systems, such as RTC and GIT, the managed directory is scanned for changes and the system identifies the files that have been changed compared to the files that exist in the source control system.

Another approach used by some source control systems, such as TFS, requires the user to identify each file that has been updated to allow it to be checked into the source control system.

A user can directly work on an application and make changes as needed. When the user has a consistent set of changes, the user can have the source control scan the directories and check in the changed files. These would then go through the source control's process to distribute changes to production as defined by the user. It is possible that it will placed into some area and can be moved to production at an interval decided by the user.

Text Files and Binary Files

A Datacap application is comprised of text readable files and binary files. Most of the configuration files are stored as XML. These include but are not limited to the setup DCO, collection.xml, rulesets, ini, key, ruleset config, rrx, navigator configuration files, app files, and user created text files.

An application also can have files that are binary such as images, cco, custom actions, compiled rulesets, an Access database, and user created binary files.

Multiple Developers

Datacap Studio has built-in locking of rulesets, setup DCO, and profiles. In a source control environment, this locking is not able to prevent simultaneous updates because developers are working on separate copies of the same application. This implies that all of the coordination of application updates between multiple developers must be handled exclusively by the source control system.

Simultaneous Updates

As one developer updates an application, another developer working on that application can use the source control system to obtain the updated files. If the user accepting the updates has not updated the same file, then they can be added to the application without issue.

If the user accepting the updates has updated one or more of the same files, then the changes must be reconciled. If the changes are to a text-based file, then it can be possible to merge the changes together as long as they do not intersect. It may take manual intervention to reconcile the changes. This is similar to what is done when a code source file is updated. If different areas of the source code are updated, it may be possible to easily integrate changes. If the same area is updated, then manual steps are required to analyze the changes and integrate. In some cases it could mean to accept the updated file as-is and then reapply the changes.

If the file updated by both users is binary, then there is no other alternative but to accept the binary file as is and reapply changes with whatever the tool is that modifies the binary files, if they are still necessary.

Some text files, while are technically user editable, may be too complex to merge by hand. Some examples are the ruleset configuration files. These kinds of files may need to be treated like a binary file when accepting updates and applying changes.

Some repository systems, allow a user to lock a file. Locking a file would prevent another user from checking in a change until the first user has checked-in their own change and unlocked the file. Depending on the desired working style of the developers, this approach could be taken to lock some key files through the source control system when they are going to be updated. This would for other developers to wait for the updates to be finished before making their own updates to a locked file.

Shared Databases

As mentioned, only Access databases have a possibility of being managed as binary files. For any production application, Access database is not used. This means that if multiple developers are working on the same application, the database they are using is likely a shared development database on a separate machine.

If two developers are truly working simultaneously, it is possible for one to make a change to the database that requires the second developer to obtain updates to keep working.

All changes to the database would be controlled and tracked separately by the database itself, not a source control system.

Deploying Database Changes to a Production Environment

When an application has been updated to a state where it is ready to be rolled out to a production environment, the changes made within the source control system need to be moved out synchronized with the database changes.

The traditional way of moving an application from test to production is using the Application Copy tool. This can be run in an interactive GUI or command line. It is possible to have the source system run this tool every time there is a check-in and move the files and database changes to the production system.

It is likely that it is not practical to move out to production with every check-in, so there could be a manual step of some sort that runs the tool.

While the tool can copy the application and databases, there are some components that it does not support. These components would need to be handled with scripts or manual steps. These include:

- Custom action libraries
- Database tables other than Administrator and Fingerprints
- Any custom files.

A variant approach is to have the source control system place all of the files into the production system and use the application copy tool only to move the administrator and fingerprint databases to production databases.

FastDoc keyboard shortcuts

FastDoc provides keyboard navigation to make it more accessible to users with limited dexterity, low vision, or other disabilities.

You can use the keyboard to navigate through FastDoc without using a mouse. Use the following table to determine which keys to use. The keys that you use affect the item that currently has focus. Focus is indicated by a dotted line around the item.

To Do This	Do This
Assign the focus to the Active Image pane	CTRL+I
Assign the focus to the Active Stream pane	CTRL+D
Autofit the active image horizontally and vertically	CTRL+1
Autofit the active image horizontally	CTRL+2
Autofit the active image vertically	CTRL+3
Clear the current field	CTRL+Z
Click N Key to capture data from image	Click in the index field in the Verify pane, then click and drag the mouse on the image to draw a new zone. The zone can be empty or it can contain data.

To Do This	Do This
Finish the current task and go to the next available task	CTRL+K CTRL+T
Go to next Low Confidence or error field	ALT+L
Make the current page a trailing page	ALT+CTRL+PgDn
Make the current page the first page of a document	ALT+CTRL+PgUp
Move the image down	SHIFT+ALT+Numeric Keypad 8
Move the image to the left	SHIFT+ALT+Numeric Keypad 6
Move the image to the right	SHIFT+ALT+Numeric Keypad 4
Move the image up	SHIFT+ALT+Numeric Keypad 2
Move the image or pan to the left or right	Click and drag with right mouse button ALT+Right or Left arrows ALT+Click and drag with left mouse button
Move the image or pan up or down	Click and drag with right mouse button ALT+Up or Downarrows ALT+Click and drag with left mouse button
Go to the next image	PgDn
Go to the previous image	PgUp
Place the focus in the Document Type list	ALT+G
Quit the current task and put the batch on hold	CTRL+Q CTRL+S
Run validations	ALT+V
Run validations and display next problem document	CTRL+F
Toggle between Zoom 100% and Autofit both horizontally and vertically	CTRL+0 CTRL+Double-click left mouse button on image Click middle mouse button
Toggle the current image as the first page of the document or as a trailing page	ALT+D
Zoom 100% (view actual size)	CTRL+~

To Do This	Do This
Zoom in to expand the image expands	Double-click image with left mouse button CTRL+I then pull mouse wheel toward you CTRL+Home CTRL+I then CTRL+Up arrow CTRL+ "+/=" key CTRL+Plus
Zoom out to shrink the image shrinks	Double-click image with left mouse button CTRL+I then push mouse wheel away from you CTRL+End CTRL+I then CTRL+Down arrow CTRL+ "_/-" key CTRL+Minus

Datacap Web Services REST API methods

Datacap Web Services is a Windows web service or Microsoft IIS-based web service for interaction with Datacap through a simple, platform-independent, representational state transfer (REST) application programming interface (API). Datacap Web Services supports the HTTP GET, POST, and PUT methods for you to create, update, and release a batch.

Admin

The Admin endpoints are for administrative tasks such as adding users or editing the workflow.

Queue

The Queue endpoints are for working with batches.

Transaction

The Transaction endpoints are for running rules without using Datacap Server and databases.

- [Session/Logon](#)

This method initiates a new session with the Datacap Server and logs on to the Datacap application. The response header includes a `wTmId` cookie and value that must be included in subsequent requests to maintain the session.

- [Session/Logoff](#)

This method logs off the Datacap application and ends the session with the Datacap Server.

- [Session/ChangeUserPassword](#)

You can change your password by using the web services ChangeUserPassword POST method. Your password can be changed by you or an administrator with privileges to change passwords.

- [Rules/Execute](#)

This method runs rules on a batch.

- [Queue/CreateBatch](#)

This method creates a new batch record in the application's Engine Database. The new batch record is uniquely identified by a batch queue ID.

- [Queue/DeleteBatches](#)
This method deletes batches that are associated with an application name.
- [Queue/CheckIntegrity](#)
This method checks the integrity of a batch by using the application name and the queue ID. The page file must be uploaded to the server before you run the CheckIntegrity GET method.
- [Queue/SaveBatchAttribute](#)
This method saves the batch attributes, including extra batch attributes.
- [Queue/GetBatchAttributes](#)
This method returns the attributes of a batch that is associated with a Datacap application name and queue ID.
- [Queue/GetBatchId](#)
This method returns the ID for a batch that is associated with a Datacap application name and queue ID.
- [Queue/GetBatchHistory](#)
This method returns the batch history details of a batch that is associated with the Datacap application name and the queue ID.
- [Queue/GetBatchList](#)
This method returns a list of batches that are based on the application name, page size, page index, sort column, and optional filters.
- [Queue/GrabBatch](#)
This method sets the batch status to `running` for the pending task that is associated with a Datacap application name and queue ID.
- [Queue/GrabNextPendingBatchOnJobTaskList](#)
This method sets the next pending batch status to `running` by using the application, job name list, and task name list. The job name list and the task name list define the job and task pair that is to be used.
- [Queue/ReleaseBatch](#)
This method releases a batch that is associated with a Datacap application name, queue ID, and status. When the current task is complete, the batch is released for processing the next task in the workflow.
- [Queue/GetCCO](#)
This method returns the CCO information for an image file by using the application name, the batch queue ID, and the image file name.
- [Queue/UploadFile](#)
This method uploads a file to a batch folder that is associated with the application name and queue ID. A page object is added to the page file.
- [Queue/SetFile](#)
This method uploads a file or multiple files to a batch folder that is associated with the application name, queue ID, file name, and file extension. A page object is not added to the page file.
- [Queue/GetFile](#)
This method returns a file that is associated with a Datacap application name, queue ID, file name, and file extension.
- [Queue/CopyFilesToCache](#)
This method copies files from the batch folder to the cache folder without downloading the files to the client. When files are uploaded or downloaded, they are placed in the cache. This method is used to run rules on data files such as, `tm000001.xml` and `tm00000.cco`, for pages that were not downloaded.
- [Queue/SetPageFileName](#)
This method assigns a name to the page file for the batch that is associated with a Datacap application, queue ID, file name, and file extension.
- [Queue/GetPageFile](#)
This method returns the contents of the page file for a batch that is associated with a Datacap application name and queue ID.
- [Queue/GetPageFileName](#)
This method returns the name of the page file of a batch that is associated with a Datacap application name and queue ID.

- [Admin/GetApplicationList](#)
This method returns a list of applications that are defined in the Datacap Application Manager.
- [Admin/GetProgramFile](#)
This method returns the requested program settings file that is associated with the application name and the file name. The user must have administrator workflow permission.
- [Admin/SetUserPermissionList](#)
This method saves the job and task index pair list for which the user has permission.
- [Admin/SetGroupPermissionList](#)
This method saves the job and task index pair list for which the group has permission.
- [Admin/GetUserPermissionList](#)
This method returns a job and task index pair list for which the user has permissions.
- [Admin/GetGroupPermissionList](#)
This method returns a job and task index pair list for which the group has permissions.
- [Admin/SaveTask](#)
This method saves task properties such as the application name, description of the task, and program file name. You can queue the batch by a user or station and set the task properties mode for normal processing, batch creation, or task routing.
- [Admin/GetMobileProfiles](#)
This method returns the mobile profiles of the application for which you have permission. Each mobile profile represents one job that is enabled for mobile capture and includes image requirements and batch-level fields that can be entered on the mobile device.
- [Transaction/Start](#)
This method starts a transaction and creates a new transaction ID. With the transaction endpoints, you can run rules without connecting to a Datacap Server, or database.
- [Transaction/SetFile](#)
This method uploads a file to a transaction by using the transaction ID, file name, and file extension. A page object is not added to the page file.
- [Transaction/Execute](#)
This method runs rules for a transaction.
- [Transaction/GetFile](#)
This method returns a file in a transaction by using the transaction ID, file name, and file extension.
- [Transaction/GetFileList](#)
This method gets a list of files in a transaction by using the transaction ID and mode.
- [Transaction/End](#)
This method ends the transaction and removes files that are associated with the transaction ID.

Session/Logon

This method initiates a new session with the Datacap Server and logs on to the Datacap application. The response header includes a `wTmId` cookie and value that must be included in subsequent requests to maintain the session.

The session timeout is specified in `wtm\web.config` file. If the number of minutes is exceeded, the session expires and the user must log on again.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Session/Logon`

Request content

The request for this method contains no content.

Response content

The `Set-Cookie` session value `wTmId=<session cookie>` that is returned by this method is kept within the session header of subsequent requests.

This method returns one of the following response codes.

Table 1. Response codes for the POST Logon method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
411 Length Required	The service refuses to accept the request without a defined <code>Content-Length</code> . The client can repeat the request if it adds a valid <code>Content-Length</code> header field that contains the length of the message body in the request message.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

POST Logon method JSON request example

```
{
  "application": "String content",
  "password": "String content",
  "station": "String content",
  "user": "String content"
}
```

POST Logon method XML request example

```
<LogonProperties>
  <application>String content</application>
  <password>String content</password>
  <station>String content</station>
  <user>String content</user>
</LogonProperties>
```

Parent topic: [Datacap Web Services REST API methods](#)

Session/Logoff

This method logs off the Datacap application and ends the session with the Datacap Server.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Session/Logoff`

Request content

The request content includes the `wTmId` cookie the request header.

Response content

The response for this method contains no content.

This method returns one of the following response codes.

Table 1. Response codes for the POST Logoff method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
411 Length Required	The service refuses to accept the request without a defined <code>Content-Length</code> . The client can repeat the request if it adds a valid <code>Content-Length</code> header field that contains the length of the message body in the request message.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

POST Logoff method JSON request example

```
{
  "application": "String content",
  "password": "String content",
  "station": "String content",
  "user": "String content"
}
```

POST Logoff method XML request example

```
<LogoffProperties>
  <application>String content</application>
  <password>String content</password>
  <station>String content</station>
  <user>String content</user>
</LogoffProperties>
```

Parent topic: [Datacap Web Services REST API methods](#)

Session/ChangeUserPassword

You can change your password by using the web services `ChangeUserPassword` POST method. Your password can be changed by you or an administrator with privileges to change passwords.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Session/ChangeUserPassword`

Request content

The request contains application, password, and user information.

Response content

The response contains the change result with a true/false string in the *changeResult* attribute. The response also provides a message that states the change is complete or the change failed.

This method returns one of the following response codes.

Table 1. Response codes for the POST ChangeUserPassword method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
411 Length Required	The service refuses to accept the request without a defined <code>Content-Length</code> . The client can repeat the request if it adds a valid <code>Content-Length</code> header field that contains the length of the message body in the request message.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

POST ChangeUserPassword method JSON request example

```
{
  "application": "String content",
  "newPassword": "String content",
  "oldPassword": "String content",
  "user": "String content"
}
```

POST ChangeUserPassword method XML request example

```
<ChangePasswordProperties>
  <application>String content</application>
  <newPassword>String content</newPassword>
  <oldPassword>String content</oldPassword>
  <user>String content</user>
</ChangePasswordProperties>
```

POST ChangeUserPassword method JSON response example

```
{
  "changeResult": true/false,
  "msg": "String content"
}
```

POST ChangeUserPassword method XML response example

```
<ChangePasswordResult>
  <changeResult>true</changeResult>
  <msg>String content</msg>
</ChangePasswordResult>
```

Parent topic: [Datacap Web Services REST API methods](#)

Rules/Execute

This method runs rules on a batch.

Files that are retrieved from the batch folder or sent to the batch folder are cached in a session folder on the Datacap Web Services server. When the web services session ends, the session folder is deleted. When the application closes, all folders are deleted.

The Execute POST method does not update batch attributes. If one of the values is changed by the rules, such as *Priority*, the batch attributes must be updated by using *SaveBatchAttribute*.

Caching is not required to run rules. If the *BatchDir* value is specified, the Datacap Web Services accesses the batch folder directly. The *BatchDir* value must be empty when the web.config setting *enableCache* is set to True to run rules against the files in the cache folder. If *enableCache* is set to False, you must specify a batch folder in *BatchDir*.

- *Result* is not needed when you are posting. It is the result of rules execution. You can post with `<Result></Result>`.
- If you post the *TargetDCOObject* property as empty, the page is targeted.
- *ChildCondition* is not needed when you are posting. It is the result of rules execution that is set by the action *Task_RaiseCondition*. *ChildCondition* can be empty or omitted when you post.
- *ChildrenQuantity* is not needed when you are posting. It is the result of rules execution as set by the action *Task_NumberOfSplits*. *ChildrenQuantity* can be empty or omitted when you post.
- *XtraBatchFields* are custom fields added to the Job Monitor. See *Creating a custom column in the Job Monitor*. The caller can use the *SaveBatchAttribute* endpoint to update the custom fields in the database after the actions change them. *XtraBatchFields* can be empty or omitted when you post. If actions need access to extra batch fields, the caller must pass *XtraBatchFields*, as in the following example.

```
<XtraBatchFields>
  <KeyValueOfstringstring
    xmlns=""http://schemas.microsoft.com/2003/10/Serialization/Arrays"">
    <Key>pb_FieldA</Key>
    <Value>ValueA</Value>
  </KeyValueOfstringstring>
</XtraBatchFields>
```

- *AllowOverride* means that the actions are allowed to override failed validations. *AllowOverride* can be omitted when you are posting. If *AllowOverride* is included, the value must be set but it is not used. In the response, *AllowOverride* is set to False, if the action *SetIsOverrideable* is called with a parameter of *False* and a validation failed.
- *DocsInBatch* is the number of documents in the batch, which you can find in the page file. *DocsInBatch* can be used by actions.
- *PagesInBatch* is the number of pages in the batch, which you can find in the page file. *PagesInBatch* can be used by actions.
- *AppName* (application name) and *Workflow* (workflow name) are not always the same.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Rules/Execute`

Request content

The request content for this method runs the rules on a batch.

Response content

The response for this method contains the same content as the Request content.

This method returns one of the following response codes.

Table 1. Response codes for the POST Execute method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
411 Length Required	The service refuses to accept the request without a defined <code>Content-Length</code> . The client can repeat the request if it adds a valid <code>Content-Length</code> header field that contains the length of the message body in the request message.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Queue/CreateBatch

This method creates a new batch record in the application's Engine Database. The new batch record is uniquely identified by a batch queue ID.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Queue/CreateBatch`

Request content

The request contains the application name and the job name. The request can also contain the batch folder name, the new page file name, and the name of an existing page file.

Table 1. Request content attributes for the CreateBatch POST method

Attribute Name	Description
<i>application</i>	The Datacap application name that is shown in the datacap.xml file. The application name is required and must be the first attribute.
<i>job</i>	The job name that is shown in a Datacap application workflow. The job name is required and the batch creation task must be the first task in the job.
<i>batchFolder</i>	The name of the batch folder that is created is optional. When this variable is not included, the batch folder is assigned a name by Datacap.
<i>pageFile</i>	The name of the page file that is created is optional. When this variable is not included, the page file is assigned a name by Datacap. Do not include a <i>pageFile</i> attribute with a blank value. The following are the <i>pageFile</i> value options. <ul style="list-style-type: none">• The string to use as the file name.• A file attribute that specifies an existing page file.• The XML content of the page file.
<i>file</i>	The name of an existing page file is optional. When you include this attribute, you must embed it as a child node of <i>pageFile</i> and provide the full path, file name, and file extension. When you use this variable, you must also include the <i>batchFolder</i> variable.

Response content

The response for this method returns the following batch attributes.

Table 2. Response content attributes for the CreateBatch POST method

Attribute name	Description of value
<i>batchID</i>	The batch ID that is assigned to the batch by Datacap.
<i>job</i>	The name of the job.
<i>queueId</i>	The unique identifier that is assigned to the batch by Datacap.
<i>status</i>	The status of the batch.
<i>task</i>	The name of the task.

This method returns one of the following response codes.

Table 3. Response codes for the CreateBatch POST method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
411 Length Required	The service refuses to accept the request without a defined <code>Content-Length</code> . The client can repeat the request if it adds a valid <code>Content-Length</code> header field that contains the length of the message body in the request message.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

CreateBatch POST method XML request example 1

Datacap creates the batch folder and manages the adding of each file to the DCO page file, such as adding the *tm000001* node to scan.xml. The request content contains an empty text value for the *batchFolder* node. The message content does not contain a *pageFile* node.

```
<createBatchAttributes>
  <application>APT</application>
  <batchFolder></batchFolder>
  <job>Main Job</job>
</createBatchAttributes>
```

CreateBatch POST method XML request example 2

Datacap creates the batch folder and the client manages the DCO page file. The request content *batchFolder* node contains the XML to use for the page file. The *B id* batch node attribute must be blank. This method is useful for transferring metadata with or without the page objects. If page objects are specified, the UploadFile endpoint must be used instead of SetFile.

```
<createBatchAttributes>
  <application>APT</application>
```

```

    <batchFolder></batchFolder>
    <job>Main Job</job>
    <pageFile>
<B
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.install.doc_dcdws034_">
  <V n="STATUS">0</V>
  <V n="TYPE">FastDoc</V>
  <P
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.install.doc_dcdws034_TM00
0001">
    <V n="TYPE">Other</V>
    <V n="Status">49</V>
    <V n="IMAGEFILE">TM000001.tif</V>
  </P>
</B>
</pageFile>
</createBatchAttributes>

```

CreateBatch POST method XML request example 3

The client creates the batch folder and manages the DCO page file. The page file name is provided and the page file is separately uploaded. The request content message body *pageFile* node text contains the name of the page file, such as scan.xml. After CreateBatch is called, then SetFile is called to upload the page file.

```

<createBatchAttributes>
  <application>APT</application>
  <batchFolder>C:\Datacap\Batches\20130328.000087</batchFolder>
  <job>Main Job</job>
  <pageFile><file>scan.xml</file></pageFile>
</createBatchAttributes>

```

Queue/DeleteBatches

This method deletes batches that are associated with an application name.

URI

http://{IP address}:{Port}/ServicewTM.svc/Queue/DeleteBatches/{*application*}

The URI for this method includes the following path elements.

Table 1. Path elements for the POST DeleteBatches method

Name	Type	Required?	Description
{ <i>application</i> }	String	Yes	The name of the application for which batches are to be deleted.

Request content

The request deletes the batches that are associated with the application name.

Response content

The response for this method contains no content.

This method returns one of the following response codes.

Table 2. Response codes for the POST DeleteBatches method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
411 Length Required	The service refuses to accept the request without a defined <code>Content-Length</code> . The client can repeat the request if it adds a valid <code>Content-Length</code> header field that contains the length of the message body in the request message.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Queue/CheckIntegrity

This method checks the integrity of a batch by using the application name and the queue ID. The page file must be uploaded to the server before you run the CheckIntegrity GET method.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Queue/CheckIntegrity/{application}/{queueId}`

The URI for this method includes the following path elements.

Table 1. Path elements for the GET CheckIntegrity method

Name	Type	Required?	Description
<code>{application}</code>	String	Yes	The name of the application for which the batch integrity is checked.
<code>{queueId}</code>	String	Yes	The unique identifier that is assigned to the batch.

Request content

The request for this method contains no content.

Response content

The response for this method returns the ID, message, and returnCode content.

ID - In case of error, the last object that is checked.

message - Return message.

returnCode - One of the following values is returned.

0 = Passed.

1 = Has more child objects that allowed by the maximum attribute.

2 = Has fewer child objects than required by the minimum attribute.

3 = Invalid member – a child object is not of a type that is supported by the parent.

4 = A child object is in the wrong position relative to other child objects as specified by the position attribute.

This method also returns one of the following response codes.

Table 2. Response codes to the GET CheckIntegrity method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service due to malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Queue/GetBatchAttributes

This method returns the attributes of a batch that is associated with a Datacap application name and queue ID.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Queue/GetBatchAttributes/{application}/{queueId}`

The URI for this method includes the following path elements.

Table 1. Path elements for the GET GetBatchAttributes method

Name	Type	Required?	Description
<i>{application}</i>	String	Yes	The name of the application for which the batch attributes are to be returned.
<i>{queueId}</i>	String	Yes	The unique identifier that is assigned to the batch.

Request body

The request for this method contains no content.

Response content

The response contains the following batch attributes.

Table 2. Response content for the GET GetBatchAttributes method

Attribute Name	Description
<i>batchID</i>	The batch ID that is assigned to the batch.
<i>job</i>	The name of the job.
<i>queueID</i>	The unique identifier that is assigned to the batch.
<i>status</i>	The status of the batch.
<i>task</i>	The name of the task.

This method also returns one of the following response codes.

Table 3. Response codes for the GET GetBatchAttributes method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Queue/GetBatchId

This method returns the ID for a batch that is associated with a Datacap application name and queue ID.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Queue/GetBatchId/{application}/{queueId}`

The URI for the GET method includes the following path elements.

Table 1. Path elements for the GetBatchId GET method

Name	Type	Required?	Description
<i>{application}</i>	String	Yes	The name of the application for which the batch ID is to be returned.
<i>{queueId}</i>	String	Yes	The unique identifier that is assigned to the batch.

Request body

The request for this method contains no content.

Response content

The response contains the batch ID.

This method also returns one of the following response codes.

Table 2. Response codes for the GET GetBatchId method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Parent topic: [Datacap Web Services REST API methods](#)

Queue/GetBatchHistory

This method returns the batch history details of a batch that is associated with the Datacap application name and the queue ID.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Queue/GetBatchHistory/{application}/{queueId}`

The URI for this method includes the following path elements.

Table 1. Path elements for the GET GetBatchHistory method

Name	Type	Required?	Description
<i>{application}</i>	String	Yes	The name of the application for which the batch history is to be returned.
<i>{queueId}</i>	String	Yes	The unique identifier that is assigned to the batch.

Request body

The request for this method contains no content.

Response content

The response contains the batch history details.

This method also returns one of the following response codes.

Table 2. Response codes for the GET GetBatchHistory method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Parent topic: [Datacap Web Services REST API methods](#)

Queue/GetBatchList

This method returns a list of batches that are based on the application name, page size, page index, sort column, and optional filters.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Queue/GetBatchList/{application}/{pageSize}/{pageIndex}/{sort}`

The URI for this method includes the following path elements.

Table 1. Path elements for the GET GetBatchList method

Name	Type	Required?	Description
<code>{application}</code>	String	Yes	The name of the application for which the list of batches is to be returned.
<code>{pageSize}</code>	String	Yes	The maximum number of batches in a list that you can retrieve. If you set the <code>pageSize</code> value to 0 to return a list of all batches, you must include optional filtering to avoid a performance impact on the Datacap Server and Datacap Web Services.
<code>{pageIndex}</code>	String	Yes	The specific batches in a list that you want to retrieve. For example, if there are 30 batches and your <code>pageSize</code> is 10, enter 0 to retrieve the list of the first 10 batches. Enter 1 to retrieve the list of the second 10 batches and enter 2 to retrieve the list of the last 10 batches.
<code>{sort}</code>	String	Yes	You can sort the list of batches by any column in the response.

Name	Type	Required?	Description
Optional filters	String	No	When you add an optional filter, you must use the format, databaseField=Operator Value. If you add more than one optional filter, you must put an ampersand between the filters. In the following example, this method returns a list of the first 10 batches that have a pending status and a priority value of 1. "http://localhost:55287/ServicewTM.svc/Queue/GetBatchList/a/ppname/10/0/qu_id?qu_status== pending&qu_priority== 1 Date filtering is not supported.

Request content

The request for this method contains no content.

Response content

The response for this method returns a list of batches.

This method also returns one of the following response codes:

Table 2. Response codes to the GET GetBatchList method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service due to malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the Request-Line is not allowed for the resource that is identified by the Request-URI. The response must include an Allow header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Queue/GrabBatch

This method sets the batch status to `running` for the pending task that is associated with a Datacap application name and queue ID.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Queue/GrabBatch/{application}/{queueId}`

The URI for this method includes the following path elements.

Table 1. Path elements for the PUT GrabBatch method

Name	Type	Required?	Description
<code>{application}</code>	String	Yes	The name of the application for which the batch status is set to <code>running</code> .
<code>{queueId}</code>	String	Yes	The unique identifier that is assigned to the batch.

Request content

The request for this method contains no content.

Response content

The response sets the batch status to `running` for the pending task.

This method returns one of the following response codes.

Table 2. Response codes for the PUT GrabBatch method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Parent topic: [Datacap Web Services REST API methods](#)

Queue/GrabNextPendingBatchOnJobTaskList

This method sets the next pending batch status to `running` by using the application, job name list, and task name list. The job name list and the task name list define the job and task pair that is to be used.

URI

`http://{IP address}:`
`{Port}/ServicewTM.svc/Queue/GrabNextPendingBatchOnJobTaskList/{application}/{jobNameList}/{taskNameList}`

The URI for this method includes the following path elements.

Table 1. Path elements for the PUT method

Name	Type	Required?	Description
<code>{application}</code>	String	Yes	The name of the application for which the next pending batch status is to be set.
<code>{jobNameList}</code>	String	Yes	The list of job names that are separated by a comma, such as <code>Main Job, Web Job</code> .
<code>{taskNameList}</code>	String	Yes	The list of task names that are separated by a comma, such as <code>VScan, Verify, Export</code>

Request content

The request for this method contains no content.

Response content

The response sets the status of the next pending batch on the job and task list to `running`.

This method also returns one of the following response codes.

Table 2. Response codes for the PUT GrabNextPendingBatchOnJobTaskList method

Response Code	Description
201 Created	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Queue/ReleaseBatch

This method releases a batch that is associated with a Datacap application name, queue ID, and status. When the current task is complete, the batch is released for processing the next task in the workflow.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Queue/ReleaseBatch/{application}/{queueId}/{status}`

The URI for this method includes the following path elements.

Table 1. Path elements for the PUT ReleaseBatch method

Name	Type	Required?	Description
<code>{application}</code>	String	Yes	The name of the application for which the batch is released.
<code>{queueId}</code>	String	Yes	The unique identifier that is assigned to the batch.
<code>{status}</code>	String	Yes	The following are the value options for <code>status</code> . <ul style="list-style-type: none">• hold• finished• canceled• aborted• offline

Request content

Table 2. Request content attributes for the PUT ReleaseBatch method

Attribute Name	Description
<code>pageFile</code>	Optional. The XML contents of the page file for the batch.

For examples of how to specify the XML contents for the `pageFile` attribute, see [Queue/CreateBatch](#).

Response content

The response releases the batch for the next task in the workflow to process.

This method returns one of the following response codes.

Table 3. Response codes for the PUT ReleaseBatch method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Queue/GetCCO

This method returns the CCO information for an image file by using the application name, the batch queue ID, and the image file name.

URI

`http://{IP address}:{Port}/ServiceWtm.svc/Queue/GetCCO/{application}/{queueId}/{imageFilename}`

The URI for this method includes the following path elements.

Table 1. Path elements for the GET GetCCO method

Name	Type	Required?	Description
<code>{application}</code>	String	Yes	The name of the application for which the CCO information is returned.
<code>{queueId}</code>	String	Yes	The unique identifier that is assigned to the batch.
<code>{imageFilename}</code>	String	Yes	The name of the image file. You must not include the file name extension.

Request content

The request for this method contains no content.

Response content

The response content is the CCO information for the image file.

This method also returns one of the following response codes.

Table 2. Response codes for the GET GetCCO method

Response Code	Description
201 Created	The request was fulfilled and resulted in the creation of a new resource.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included authorization credentials, then the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Queue/UploadFile

This method uploads a file to a batch folder that is associated with the application name and queue ID. A page object is added to the page file.

Files can be transferred as a binary string or by using Base64 encoding. When Base64 encoding is used, you must add `Content-Transfer-Encoding: base64` to the header when you are streaming, or to the form part for multipart/form-data. For Base64 encoding, you can specify the `Content-Type`: as the file type. The UploadFile request can accept a byte stream as the message body or the message body can use the multipart/form-data format where the file byte stream is contained in each part.

The sequentially numbered page object is created in the page file. The task settings contain the page file name. The page *TYPE* is always set to *Other*, and *STATUS* is always set to 49. The page object contains the following information.

```

<P
id="__dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.install.doc_dcdws044_tm00
0001">
  <V n="TYPE">Other</V>
  <V n="STATUS">49</V>
  <V n="IMAGEFILE">tm000001.tif</V>
</P>

```

You can adjust the value of the `maxAllowedContentLength` and `maxRequestLength` settings in the `web.config` file. The maximum size message that can be uploaded depends on your web server, proxy server, and client.

URI

`http://{IP address}:{Port}/ServiceWtm.svc/Queue/UploadFile/{application}/{queueId}`

The URI for this method includes the following path elements.

Table 1. Path elements for the POST UploadFile method

Name	Type	Required?	Description
<code>{application}</code>	String	Yes	The name of the application for which the file is to be uploaded.
<code>{queueId}</code>	String	Yes	The unique identifier that is assigned to the batch.

Request content

The request content contains a multipart/form-data message, including the file or files that are to be uploaded.

Response content

The response returns the original file name and the page ID.

This method returns one of the following response codes.

Table 2. Response codes for the POST UploadFile method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
411 Length Required	The service refuses to accept the request without a defined <code>Content-Length</code> . The client can repeat the request if it adds a valid <code>Content-Length</code> header field that contains the length of the message body in the request message.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Parent topic: [Datacap Web Services REST API methods](#)

Queue/SetFile

This method uploads a file or multiple files to a batch folder that is associated with the application name, queue ID, file name, and file extension. A page object is not added to the page file.

Files can be transferred as a binary string or by using Base64 encoding. When Base64 encoding is used, you must add `Content-Transfer-Encoding: base64` to the header when you are streaming, or to the form part for multipart/form-data. For Base64 encoding, you can specify the `Content-Type`: as the file type. The SetFile request can accept a byte stream as the message body or can have the message body use the multipart/form-data format where the file byte stream is contained in each part.

If you specify a header field file name, then it is used as the file name for the uploaded the file. If you do not specify a header field file name, then the `{fileName}` in the SetFile URI is used as the file name for the uploaded file.

You can adjust the value of the `maxAllowedContentLength` and `maxRequestLength` settings in the `web.config` file. The maximum size message that can be uploaded depends on your web server, proxy server, and client.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Queue/SetFile/{application}/{queueId}/{fileName}/{fileExtension}`

The URI for this method includes the following path elements.

Table 1. Path elements for the POST SetFile method

Name	Type	Required?	Description
------	------	-----------	-------------

Name	Type	Required?	Description
{application}	String	Yes	The name of the application for which the file is to be uploaded.
{fileName}	String	Yes	The name of the file that is to be uploaded.
{fileExtension}	String	Yes	The file name extension of the file that is to be returned, such as exe. Do not include the file name path, set.xml.

Request content

The request content contains file that is to be uploaded.

Response content

The response for this method contains no content.

This method returns one of the following response codes.

Table 2. Response codes for the POST SetFile method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
411 Length Required	The service refuses to accept the request without a defined <code>Content-Length</code> . The client can repeat the request if it adds a valid <code>Content-Length</code> header field that contains the length of the message body in the request message.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Queue/GetFile

This method returns a file that is associated with a Datacap application name, queue ID, file name, and file extension.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Queue/GetFile/{application}/{queueId}/{fileName}/{fileExtension}`

The URI for this method includes the following path elements.

Table 1. Path elements for the GET GetFile method

Name	Type	Required?	Description
{application}	String	Yes	The name of the application for which the file is to be returned.

Name	Type	Required?	Description
<i>{queueId}</i>	String	Yes	The unique identifier that is assigned to the batch.
<i>{fileName}</i>	String	Yes	The name of the file in the batches directory that is to be returned. The <i>{fileName}</i> must not have a dot such as verify.1 or a plus sign such as batch+profiler.
<i>{fileExtension}</i>	String	Yes	The file name extension of the file that is to be returned, such as xml. Do not include the file name path, such as verify.xml.

Request body

The request for this method contains no content.

Response content

The response returns the file.

This method returns one of the following response codes.

Table 2. Response codes for the GET GetFile method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Parent topic: [Datacap Web Services REST API methods](#)

Queue/CopyFilesToCache

This method copies files from the batch folder to the cache folder without downloading the files to the client. When files are uploaded or downloaded, they are placed in the cache. This method is used to run rules on data files such as, tm000001.xml and tm00000.cco, for pages that were not downloaded.

If the file is cached and an endpoint is used to retrieve a file from the batch folder, the cached file is returned. If the file is not in the cache, the file is returned from the batch folder and added to the cache. When you are calling an endpoint that adds or updates a batch file, the file is saved to the cache but it is not saved to the batch folder. When the batch is released, all files are copied from the cache and will write over files that are in the batch folder.

The `wTmId` header value that is returned by the POST method `Session/Logon` must be in the session header.

URI

http://{IP address}:{Port}/ServiceWtm.svc/Queue/CopyFilesToCache/{application}/{queueId}

The URI for this method includes the following path elements.

Table 1. Path elements for the POST CopyFilesToCache method

Name	Type	Required?	Description
{application}	String	Yes	The name of the application for which the files are to be copied to the cache folder.
{queueId}	String	Yes	The unique identifier that is assigned to the batch.

Request content

The request content is the message body.

Response content

The response for this method contains no content.

This method returns one of the following response codes.

Table 2. Response codes for the POST CopyFilesToCache method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
411 Length Required	The service refuses to accept the request without a defined <code>Content-Length</code> . The client can repeat the request if it adds a valid <code>Content-Length</code> header field that contains the length of the message body in the request message.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Admin/GetUserPermissionList

This method returns a job and task index pair list for which the user has permissions.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Admin/GetUserPermissionList/{application}/{userInd}`

The URI for this method includes the following path elements.

Table 1. Path elements for the GET GetUserPermissionList method

Name	Type	Required?	Description
<code>{application}</code>	String	Yes	The name of the application for which the permissions list is to be returned.

Name	Type	Required?	Description
{userInd}	String	Yes	The index for a user is the value in the us_ind column of the tmuser table in the Administration database.

Request content

The request for this method contains no content.

Response content

The response contains the job and task index pair list for which the user has permission. If -1 is returned for the task and job, the object has permission to all job and task pairs.

Table 2. Response elements for the GET GetUserPermissionList method

Name	Description
Job	The value of jb_ind from the job table of the Admin database.
Task	The value of ts_ind from the tasks table of the Admin database.

This method returns one of the following response codes.

Table 3. Response codes for the GET GetUserPermissionList method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request already included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Admin/GetGroupPermissionList

This method returns a job and task index pair list for which the group has permissions.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Admin/GetGroupPermissionList/{application}/{groupInd}`

The URI for this method includes the following path elements:

Table 1. Path elements for the GET GetGroupPermissionList method

Name	Type	Required?	Description
<i>{application}</i>	String	Yes	The name of the application for which the permissions list is to be returned.
<i>{groupInd}</i>	String	Yes	The index for a group is the value in the gr_ind column of the tmgroup table in the Admin database.

Request content

The request for this method contains no content.

Response content

The response contains the job and task index pair list for which the group has permission. If -1 is returned for the task and job, the object has permission to all job and task pairs.

Table 2. Response elements for the GET GetGroupPermissionList method

Name	Description
------	-------------

Name	Description
Job	The value of <code>jb_ind</code> from the job table of the Admin database.
Task	The value of <code>ts_ind</code> from the tasks table of the Admin database.

This method also returns one of the following response codes.

Table 3. Response codes for the GET GetGroupPermissionList method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

GET GetGroupPermissionList method JSON response example

```
{ "Permissions": [{ "Job": "10", "Task": "12" }] }
{ "Permissions": [{ "Job": "10", "Task": "14" }] }
{ "Permissions": [{ "Job": "10", "Task": "15" }] }
{ "Permissions": [{ "Job": "10", "Task": "16" }] }
```

GET GetGroupPermissionList method XML response example

```
<PermissionList><Permissions>
  <PermissionList.JobTaskPair><Job>10</Job><Task>12</Task>
</PermissionList.JobTaskPair>
  <PermissionList.JobTaskPair><Job>10</Job><Task>14</Task>
</PermissionList.JobTaskPair>
  <PermissionList.JobTaskPair><Job>10</Job><Task>15</Task>

Admin/SaveTask

This method saves task properties such as the application name, description of the task, and program file name. You can queue the batch by a user or station and set the task properties mode for normal processing, batch creation, or task routing.

URI

`http://{IP address}:{Port}/ServiceWtm.svc/Admin/SaveTask`

Request content

The request contains the name of the application that is defined in the Application Manager and the following task properties content.

Table 1. Task properties for the POST method

Task Property	Description
conditions	A comma-separated list of conditions, such as <code>Skip_Verify</code> .
desc	The description of the task, such as Identify, Recognize, or Flag Problems.
id	The value of <code>ts_ind</code> from the tasks table of the Administration database. When you are creating a new task, <code>id</code> must be empty.
jobId	The job index value of <code>jb_ind</code> from the job table of the Administration database. The <code>jobId</code> is optional for an existing task but is required for a new task.
mode	Sets the task as normal processing, batch creation, or task routing. <ul style="list-style-type: none">• 2 - Normal processing• 3 - Batch creation• 6 - Routing task
name	The task name, such as <code>Profiler</code> .
program	The executable file or web page file that is used by the task, such as <code>FastDoc.exe</code> . You can use <code>Rulerunner.exe</code> for a background task when the tasks are run by a client.
queueBy	The value specifies the user and station to which the batch is queued. <ul style="list-style-type: none">• 0 - No user or station is specified• 1 - Station• 2 - User• 3 - Other Station• 4 - Other User• 5 - Station And User• 6 - Station And Other User• 7 - User And Other Station• 8 - Other Station And Other User
store	The value specifies the user ID or station ID that is stored with the batch. <ul style="list-style-type: none">• 0 - No user ID or station ID is stored.• 1 - The station ID is stored.• 2 - The user ID is stored.• 3 - The user ID and the station ID are stored.

Response content

The response for this method contains no content.

This method returns one of the following response codes.

Table 2. Response codes for the POST SaveTask method

Response Code	Description
---------------	-------------

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
411 Length Required	The service refuses to accept the request without a defined <code>Content-Length</code> . The client can repeat the request if it adds a valid <code>Content-Length</code> header field that contains the length of the message body in the request message.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

POST SaveTask method JSON request example

```
{
  "application": "APT",
  "conditions": "Skip_Verify",
  "desc": "Identify, Recognize, Flag Problems",
  "id": "14",
  "jobId": "10",
  "mode": "3",
  "name": "Profiler",
  "program": "FastDoc.exe",
  "queueBy": "0",
  "store": "0"
}
```

POST SaveTask method XML request example

```
<TaskProperties>
  <application>APT</application>
  <conditions>Skip_Verify</conditions>
  <desc>Identify, Recognize, Flag Problems</desc>
  <id>14</id>
  <jobId>10</jobId>
  <mode>3</mode>
  <name>Profiler</name>
  <program>FastDoc.exe</program>
  <queueBy>0</queueBy>
  <store>0</store>
</TaskProperties>
```

Parent topic: [Datacap Web Services REST API methods](#)

Admin/GetMobileProfiles

This method returns the mobile profiles of the application for which you have permission. Each mobile profile represents one job that is enabled for mobile capture and includes image requirements and batch-level fields that can be entered on the mobile device.

The profile settings are a combination of task settings, batch fields, and batch level dictionaries in the Setup DCO. A list of the Start Batch Panel fields is saved to the profile on the mobile client.

In Datacap Web Client, you can set a batch creation task for a job to use the Mobile Capture program. The GET method adds a mobile profile to the returned list for each job and task pair. In addition to the task settings, the profile includes the job and task IDs, the job and task indexes, and batch fields. The batch fields include the *DataType* variables and a database column from the tmbatch table that is updated with the field value.

URI

http://{IP address}:{Port}/ServiceWM.svc/Admin/GetMobileProfiles/{application}

The URI for this method includes the following path elements.

Table 1. Path element for the GET GetMobileProfiles method

Name	Type	Required?	Description
{application}	String	Yes	The name of the application for which the mobile profiles are to be returned.

Request content

The request for this method contains no content.

Response content

The response for this method contains the mobile profiles for the Datacap application.

Table 2. Mobile Capture profile settings descriptions

Name	Description
<i>DataType</i>	The following are the values for the <i>DataType</i> node for the batch level fields. <ul style="list-style-type: none"> • 0 - None • 1 - Alphabetic A-Z • 2 - Alphanumeric A-Z, 0-9 • 4 - INT 16K, 32K plus or minus • 5 - INT 32 BigInteger • 6 - 32-bit floating point • 7 - 64-bit floating point • 8 - Date • 9 - Time HH:MM[:SS] • 16 - Currency
<i>DatabaseColumn</i>	The <i>DatabaseColumn</i> node for the batch level fields is not currently enabled.
<i>PageTypes Key and Value pair</i>	If the Setup DCO contains a dictionary that is called <i>PageNames</i> , the dictionary is returned. The <i>Key</i> is the DCO type and the <i>Value</i> is the display name. If the Setup DCO does not contain a dictionary, all page types are returned.
<i>DocumentTypes Key and Value pair</i>	If the Setup DCO contains a dictionary that is called <i>DocumentNames</i> , the dictionary is returned. The <i>Key</i> is the DCO type and the <i>Value</i> is the display name. If the Setup DCO does not contain a dictionary, all document types are returned.
<i>Job</i>	The job ID assigned to the job by Datacap.
<i>JobIndex</i>	The value of <i>jb_ind</i> from the job table of the Administration database.

Name	Description
<i>Task</i>	The task ID assigned to the task by Datacap.
<i>TaskIndex</i>	The value of ts_ind from the tasks table of the Administration database.

This method also returns one of the following response codes.

Table 3. The wTM response to the GET GetMobileProfiles method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Parent topic: [Datacap Web Services REST API methods](#)

Transaction/Start

This method starts a transaction and creates a new transaction ID. With the transaction endpoints, you can run rules without connecting to a Datacap Server, or database.

The response header includes a `wTmId` cookie and value that must be included in subsequent requests to maintain the session.

If an existing `wTmId` cookie is not provided and security is disabled in the configuration, a new `wTmId` will be returned in the `wTmId` cookie. The `wTmId` cookie must be included in all subsequent calls.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Transaction/Start`

Request content

The request for this method contains no content.

Response content

The response for this method returns the following attributes.

Table 1. Response content attributes for the Start GET method

Attribute name	Description of value
<code>{transactionId}</code>	The transaction ID that is assigned to the transaction by Datacap.

GET Transaction/Start method JSON response example

```
"String content"
```

GET Transaction/Start method XML response example

```
<string xmlns="http://schemas.microsoft.com/2003/10/Serialization/">String  
content</string>
```

Parent topic: [Datacap Web Services REST API methods](#)

Transaction/SetFile

This method uploads a file to a transaction by using the transaction ID, file name, and file extension. A page object is not added to the page file.

To run rules, the following resource must be uploaded: a page file, such as scan.xml, containing references to page objects, if there are any.

If files are referenced in the page file and will be used by rules, those files must also be uploaded by using SetFile.

This method can be used to update a page file, for example, verify.xml. Files can be uploaded by streaming the file or by using the multipart/form-data content type. If you are streaming the file, specify the content type as the file type of the file that is being uploaded.

Files can be transferred as a binary string or by using Base64 encoding. When Base64 encoding is used, you must add `Content-Transfer-Encoding: base64` to the header when you are streaming, or as the last property in the message part before the file if you are using multipart/form-data. The SetFile request can accept a byte stream as the message body or can have the message body use the multipart/form-data format where the file byte stream is contained in each part.

If you specify a header field file name, then it is used as the file name for the uploaded file. If you do not specify a header field file name, then the `{fileName}` in the SetFile URI is used as the file name for the uploaded file.

You can adjust the value of the `maxAllowedContentLength` and `maxRequestLength` settings in the web.config file. The maximum size message that can be uploaded depends on your web server, proxy server, and client.

URI

```
http://{IP address}:{Port}/ServicewTM.svc/Transaction/SetFile/{transactionID}/{fileName}/{fileExtension}
```

The URI for this method includes the following path elements.

Table 1. Path elements for the POST SetFile method

Name	Type	Required?	Description
<i>{transactionId}</i>	String	Yes	The transaction ID for which the file is to be uploaded.
<i>{fileName}</i>	String	Yes	The name of the file that is to be uploaded. Note: The <i>{fileName}</i> must not have a dot such as verify.1 or a plus sign such as batch+profiler.
<i>{fileExtension}</i>	String	Yes	The file name extension of the file that is to be returned, such as exe. Do not include the file name path, set.xml.

Request content

The request content contains file that is to be uploaded.

Response content

The response for this method contains no content.

This method returns one of the following response codes.

Table 2. Response codes for the POST SetFile method

Response Code	Description
201 Created	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
411 Length Required	The service refuses to accept the request without a defined <code>Content-Length</code> . The client can repeat the request if it adds a valid <code>Content-Length</code> header field that contains the length of the message body in the request message.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Parent topic: [Datacap Web Services REST API methods](#)

Transaction/Execute

This method runs rules for a transaction.

Rulesets is a comma separated list of rulesets to run in the order provided.

- *Workflow* - The workflow that is the value of the top level of a group of jobs and can be found in the web client administrator.
- *Messages* - A list of messages can be returned that are set by using a custom action.

URI

http://{IP address}:{Port}/ServiceWtm.svc/Transaction/Execute

Request content

The request content for this method runs the rules on a transaction.

Response content

The response for this method contains the same content as the Request content.

This method returns one of the following response codes.

Table 1. Response codes for the POST Execute method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
411 Length Required	The service refuses to accept the request without a defined <code>Content-Length</code> . The client can repeat the request if it adds a valid <code>Content-Length</code> header field that contains the length of the message body in the request message.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Transaction/GetFile

This method returns a file in a transaction by using the transaction ID, file name, and file extension.

This method can be used to retrieve the recognition results in the data file (for example, tm000001.xml) or in the HTML output (for example, tm000001.htm).

URI

`http://{IP address}:{Port}/ServicewTM.svc/Transaction/GetFile/{transactionId}/{fileName}/{fileExtension}`

The URI for this method includes the following path elements.

Table 1. Path elements for the GET Transaction.GetFile method

Name	Type	Required?	Description
<code>{transactionId}</code>	String	Yes	The transaction ID for which the file is to be returned.
<code>{fileName}</code>	String	Yes	The name of the file in the file directory that is to be returned.
<code>{fileExtension}</code>	String	Yes	The file name extension of the file that is to be returned, such as xml. Do not include the file name path, such as verify.xml.

Request body

The request for this method contains no content.

Response content

The response returns the file. The response body is a byte stream.

This method returns one of the following response codes.

Table 2. Response codes for the GET Transaction.GetFile method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Parent topic: [Datacap Web Services REST API methods](#)

Transaction/GetFileList

This method gets a list of files in a transaction by using the transaction ID and mode.

When a file is uploaded, the created timestamp is set to the current time. When `GetFileList` is called, any files that were created by rules will be added to the list and `IsNew` will be true. Any files that were updated will have the modified property updated and `IsModified` will be true.

URI

`http://{IP address}:{Port}/ServicewTM.svc/Transaction/GetFileList/{transactionId}/{mode}`

The URI for this method includes the following path elements.

Table 1. Path elements for the GET GetFileList method

Name	Type	Required?	Description
<code>{transactionId}</code>	String	Yes	The transaction ID for which the list of files is to be returned.
<code>{mode}</code>	String	Yes	The { All, New, Modified } Mode values are All, New, Modified. New If the mode value is New, only files that were created by rules will be added to the list. Modified If the mode value is Modified, only files that were modified will be added to the list. .

Request content

The request for this method contains no content.

Response content

The response for this method returns a list of files.

This method also returns one of the following response codes:

Table 2. Response codes to the GET GetFileList method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service due to malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Transaction/End

This method ends the transaction and removes files that are associated with the transaction ID.

URI

http://{IP address}:{Port}/ServiceWTM.svc/Transaction/End/{transactionId}

The URI for this method includes the following path elements.

Table 1. Path elements for the POST DeleteBatches method

Name	Type	Required?	Description
{transactionId}	String	Yes	The name of the transaction for which batches are to be deleted.

Request content

The request deletes the files that are associated with the transaction ID.

Response content

The response for this method contains no content.

This method returns one of the following response codes.

Table 2. Response codes for the POST DeleteBatches method

Response Code	Description
200 OK	The request was successful.
400 Bad Request	The request was not understood by the service because of malformed syntax.
401 Unauthorized	The request requires user authentication. If the request included valid credentials, the 401 response indicates that authorization was refused for those credentials.
405 Method Not Allowed	The method that is specified in the <code>Request-Line</code> is not allowed for the resource that is identified by the <code>Request-URI</code> . The response must include an <code>Allow</code> header that contains a list of valid methods for the requested resource.
411 Length Required	The service refuses to accept the request without a defined <code>Content-Length</code> . The client can repeat the request if it adds a valid <code>Content-Length</code> header field that contains the length of the message body in the request message.
500 Internal Error	An unexpected condition was encountered that prevented the service from fulfilling the request.

Fingerprint Maintenance Tool reference

Use the Fingerprint Maintenance Tool (FMT) to manage your fingerprints and synchronize information between the Fingerprint database, the Document Hierarchy, and Fingerprint XML data files.

- [Fingerprint Maintenance Tool configuration settings](#)
The Settings.ini file that is installed with the APT application in the C:\Datacap\APT\dco_APT folder contains information that is required by the Fingerprint Maintenance Tool.
- [Fingerprint Maintenance Tool buttons](#)
Use the following Fingerprint Maintenance Tool buttons to view, modify, and search for fingerprints.
- [Fingerprint Maintenance Tool fields](#)
List and description of the fields that you use for maintaining fingerprints. Fingerprints are used both for

page identification and for specifying recognition zones.

Related tasks:

[Maintaining fingerprints by using the Fingerprint Maintenance Tool](#)

Fingerprint Maintenance Tool configuration settings

The Settings.ini file that is installed with the APT application in the C:\Datacap\APT\dco_APT folder contains information that is required by the Fingerprint Maintenance Tool.

Database Section

Contains the connection strings to one or more databases that are used by the Fingerprint Maintenance Tool.

FingerprintDatabase Setting

Defines the connection string to the Fingerprint database used by the Fingerprint Maintenance Tool. For example:

```
FingerprintDatabase=Provider=Microsoft.Jet.OLEDB.4.0;  
Data Source=C:\Datacap\apt\process\APTFingerprint.mdb;  
Persist Security Info=False
```

Paths Section

Contains path information that is required by the Fingerprint Maintenance Tool.

FingerprintDirectory Setting

Defines the path to the application's folder that contains the application's fingerprint files (TIFF, CCO, or Fingerprint XML files). For example:

```
FingerprintDirectory=c:\datacap\apt\Fingerprint
```

FingerprintBackupDirectory Setting

Defines the path to the folder that contains backup copies of the Fingerprint XML files that are made when fingerprints are added to an application. If this folder does not exist, it is created when the Fingerprint Maintenance executable is started. For example:

```
FingerprintBackupDirectory=c:\datacap\apt\Fingerprint Backup
```

SetupDCO Setting

Defines the path to the application's Setup DCO file. For example:

```
SetupDCO=c:\datacap\apt\dco_APT\APT.xml
```

FMT Section

Contains the SQL query that is used by the Fingerprint Maintenance Tool. For example:

```
[FMT]  
FilteredSummary=Select Template.tp_TemplateID,Template.tp_DateAdded,  
Template.tp_HitCount,Template.tp_LastHit,Host.hs_RefName FROM Template,  
Host WHERE host.hs_HostID = Template.tp_HostID
```

Parent topic: [Fingerprint Maintenance Tool reference](#)

Fingerprint Maintenance Tool buttons

Use the following Fingerprint Maintenance Tool buttons to view, modify, and search for fingerprints.

Add Selected

Adds the selected fingerprints to the application's Fingerprint database and setup DCO, and copies the associated TIFF and CCO files into the application's Fingerprint folder.

Delete Selected

Deletes the selected fingerprint, including the TIFF, CCO, and fingerprint XML files, and the associated entry in the Fingerprint database.

Export Selected

Exports copies of the selected fingerprints, including the TIFF, CCO, and fingerprint XML files, to the application's \fingerprint\Fingerprint Export folder.

Find FPXML Files

Finds any fingerprint XML files that are in the application's \fingerprint folder.

Find Problems

Displays all fingerprints for which one or more components are missing from the Fingerprint Directory, such as the TIFF, CCO, or fingerprint XML files, or when the entry for the fingerprint in the application's Fingerprint database is missing.

Select All

Selects all displayed fingerprints.

Show Statistics

Displays all existing fingerprints and statistics that are related to each.

Parent topic: [Fingerprint Maintenance Tool reference](#)

Fingerprint Maintenance Tool fields

List and description of the fields that you use for maintaining fingerprints. Fingerprints are used both for page identification and for specifying recognition zones.

Backup Directory

Displays the full path to the folder that contains backup copies of the fingerprint XML files that are made when fingerprints are added to an application. If this folder does not exist, it is created when the Fingerprint Maintenance executable is started.

CCO

An X in this column indicates that the CCO file associated with this fingerprint is missing from the application's Fingerprint Directory.

Database

An X in this column indicates that the entry that is associated with this fingerprint is missing from the application's Fingerprint database.

Date Added

Displays the date that the fingerprint was either created in or added to this application from another.

Document Hierarchy

Displays the full path and file name of the application's Setup DCO.

Fingerprint

Displays the fingerprint's Fingerprint ID.

Fingerprint Database

Displays the connection string information that is related to the application's Fingerprint database.

Fingerprint Directory

Displays the full path to the directory in which the fingerprint-related files (TIFF, CCO, XML) are stored.

FPXML

An X in this column indicates that the XML file associated with this fingerprint is missing from the Fingerprint Directory.

Hits/Month

This field is an estimate of how many times per month the fingerprint is matched. This estimate is based on the age of the fingerprint and the number of times the fingerprint was matched to date. This estimate is calculated by first calculating the age of the fingerprint (in months) by the number of times it was matched.

For example, if a fingerprint is one month old (30 days) and was matched one time, the Hits/Month value is 1.0000. If the fingerprint is two months old (60 days) and was matched one time, the Hits/Month value is 0.5000.

HostName

The HostName is the Document Type assigned to the document associated with this fingerprint.

Last Hit

Displays the date on which the fingerprint was last matched.

Setup DCO

An X indicates that the Setup DCO is missing.

Status

The Status field indicates the status of the Fingerprint Maintenance Tool. The status is listed as Done, missing (denoted with an X), or Testing.

TIFF

An X in this column indicates the TIF file that is associated with this fingerprint is missing from the Fingerprint Directory.

Total Hits

Indicates the number of times the fingerprint was matched since it was created.

Parent topic: [Fingerprint Maintenance Tool reference](#)

Smart Parameter Special Variable Reference

Special variables are for use with smart parameters. Smart parameters do not work with all actions.

Check the action help  in Datacap Studio for compatibility information.

- [Special variables for accessing the application configuration file](#)
These variable return information that is related to the application configuration (.app) file.
- [Special variables for accessing the runtime hierarchy](#)
These variables return information that is related to documents, batches, pages, and fields.
- [Special variables for accessing job and task information](#)
These variables return metadata that is related to a particular job or task, such as the job name or operator.
- [Accessing Parent, Sibling and Child Objects with Smart Parameter Navigation](#)
When running rules in a Datacap application, you can use smart parameters to access information from parent or child DCO nodes.
- [Miscellaneous special variables](#)
Miscellaneous special variables can be used with Smart parameters.
- [Smart Parameter Build control](#)
In Datacap Studio, you can use the Smart Parameter Build control to create an expression that is evaluated at run time that allows you to obtain data from Datacap objects and variables. In Datacap Studio, when you select an action that takes a string parameter, the Parameters section displays the details of the selected action along with a button that displays three dots. By using this button, you can open Smart Parameter Build control.

Special variables for accessing the application configuration file

These variable return information that is related to the application configuration (.app) file.

- @APPPATH(<key_path>)
- @APPVAR(<key_path>)

Parent topic: [Smart Parameter Special Variable Reference](#)

@APPPATH(<key_path>)

Description

Retrieves the path to a file or folder from the application's configuration (.app) file. Use the Datacap Application Manager to modify the information that is contained in this file. Do not edit the file directly.

Syntax

```
@APPPATH(key_path)
```

Arguments

key_path Specifies the path through the XML hierarchy to field you want:

- If the field name is unique within the file, you can specify just the field name.
- If the field name is not unique within the file, you must specify the path to the instance you want. For example, you might have multiple workflows. If you do not specify the path, you get the first instance. To obtain the path, move the mouse pointer over the field in the Datacap Application Manager and read the path from the tooltip.

Examples

You can use @APPPATH to retrieve the following information from the application configuration file.

Field name	Key name	Example	Notes
Application fields			
Batches folder	runtime	@APPPATH(runtime)	(Field name is unique)
Export folder	export	@APPPATH(export)	(Field name is unique)
Fingerprint folder	fingerprint	@APPPATH(fingerprint)	(Field name is unique)
Workflow fields			
Setup DCO	setupdco	@APPPATH(setupdco)	(assumes single workflow)
Rules folder	rules	@APPPATH(dco_Workflow1/rules)	(specifies Workflow 1)
VScan source folder	vscanimagedir	@APPPATH(vscanimagedir)	(assumes single workflow)

Field name	Key name	Example	Notes
Imagefix INI	imagefix	@APPPATH(dco_Workflow2/imagefix)	(specifies Workflow 2)

Parent topic: [Special variables for accessing the application configuration file](#)

@APPVAR(<key_path>)

Description

Retrieves a connection string, value, or other attribute from the application configuration (.app) file. Use the Datacap Application Manager to modify the information that is contained in this file. Do not edit the file directly.

Attention: Before Datacap 8.0, this parameter returns the value for the specified variable as defined in the [Variables] section in paths.ini. The .ini file is in the process folder of the application.

The Datacap Application Manager encrypts the connection strings and decryption is handled by the standard actions.

Syntax

```
@APPVAR(key_path[:attribute])
```

Arguments

key_path - Specifies the path to field you want. See @APPPATH for details.

attribute - Specifies the attribute name (optional):

- For custom values, use "v" (if you do not specify an attribute, "v" is assumed).
- For connection strings, use "cs".

The easiest way to get the path and attribute is to look in the Datacap Application Manager:

- On the Application and Datacap tabs, move the mouse pointer over the field and read the smart parameter value from the tooltip.
- On the Custom Values tab, read the smart parameter value that is displayed in each section.

Examples

You can use @APPVAR to retrieve the following information from the application configuration file.

Field name	Key name:attribute	Example	Notes®
Workflow fields			
Lookup database	lookupdb:cs	@APPVAR(lookupdb:cs)	(Workflow 1)
Fingerprint database	fingerprintconn:cs	@APPVAR(fingerprintconn:cs)	(one workflow)
Export database	exportdb:cs	@APPVAR(dco_Wkflw1/exportdb:cs)	(Workflow 1)

Field name	Key name:attribute	Example	Notes®
Datacap fields			
Engine database	tmengine:cs	@APPVAR(tmengine:cs)	(Field is unique)
Admin database	tadmin:cs	@APPVAR(tadmin:cs)	(Field is unique)
Custom values			
General string values	values/gen/<value_name>	@APPVAR(values/gen/Value1)	(Value1)
Connection strings	values/dsn/<value_name>:cs	@APPVAR(values/dsn/DB1:cs)	(CS for DB1)
Datacap connection strings	values/tmsdn/<value_name>:cs	@APPVAR(values/tmsdn/TMDB1:cs)	(CS for TMDB1)
Advanced values	values/adv/<value_name>	@APPVAR(values/adv/Value1)	(Value1)

[Storing passwords, connection strings, and other parameters in the .app file](#)

Special variables for accessing the runtime hierarchy

These variables return information that is related to documents, batches, pages, and fields.

- [@BATCHID](#)
- [@ID](#)
- [@STATUS](#)
- [@VALUE](#)
- [@VAR\(<variable_name>\)](#)
- [@B.<variable_name>](#)
- [@D.<variable_name>](#)
- [@P.<variable_name>](#)
- [@F.<variable_name>](#)
- [@X.<variable_name>](#)
- [@B\<field_name>\[.<variable_name>\]](#)
- [@D\<field_name>\[.<variable_name>\]](#)
- [@P\<field_name>\[.<variable_name>\]](#)
- [@F\<field_name>\[.<variable_name>\]](#)
- [@X\<field_name>\[.<variable_name>\]](#)

Parent topic: [Smart Parameter Special Variable Reference](#)

@BATCHID

Description

Returns the value of the id attribute for the current batch.

Example

In this example, the smart parameter returns the ID of the current batch.

Action and return value	XML example (if applicable)
Action: rr_Get("@BATCHID") Return value: 20110046.001	<B id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar002_20110046.001"> <V n="TYPE">TravelDocs</V> <V n="STATUS">1</V>

Parent topic: [Special variables for accessing the runtime hierarchy](#)

@ID

Description

Returns the value of the id attribute for the current object. For example, if the rule that contains this special variable is bound to a page, the current object is the current page.

Example

In this example, the rule that contains the action is bound to a page and the smart parameter returns the ID of the current page.

Action and return value	XML example (if applicable)
Action: rr_Get("@ID") Return value: TM000001	<P id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar015_TM000001"> <V n="TYPE">Rental_Agreement</V> <V n="STATUS">1</V>

Parent topic: [Special variables for accessing the runtime hierarchy](#)

@STATUS

Description

Returns the value of the STATUS variable for the current object. STATUS is also a setup property and might specify a special characteristic (for example, -1 indicates a hidden field).

Example

In this example, the rule that contains the action is bound to a page and the smart parameter returns the status of the current page.

Action and return value	XML example (if applicable)
Action: rr_Get("@STATUS") Return value: 1	<P id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvvar026_TM000001"> <V n="TYPE">Rental_Agreement</V> <V n="STATUS">1</V>

Parent topic: [Special variables for accessing the runtime hierarchy](#)

@VALUE

Description

Returns the text of the current object (usually a field).

Example

In this example, the rule that contains the action is bound to a field and the smart parameter returns the text of the current field. If the current object is not a field, @VALUE looks for a value in a variable *Text* of the calling object.

Action and return value	XML example (if applicable)
Action: rr_Get("@VALUE") Return value: SUV	<F id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvvar032_Car_Type"> <V n="TYPE">Car_Type</V> <C cn="10" cr="588,748,600,769">83</C> <-- ASCII `S` <C cn="10" cr="605,748,620,769">85</C> <-- ASCII `U` <C cn="10" cr="625,748,643,769">86</C> <-- ASCII `V` </F>

Parent topic: [Special variables for accessing the runtime hierarchy](#)

@VAR(<variable_name>)

Description

Returns the value of the specified variable on the current object.

Example

In this example, the rule that contains the action is bound to a page. The smart parameter returns the value of the *TYPE* variable for the current page.

Action and return value	XML example (if applicable)

Action and return value	XML example (if applicable)
Action: <code>rr_Get("@VAR(TYPE)")</code>) Return value: Rental_Agreement	<pre><<P id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.refere nce.doc_dcvar033_TM000001"> <V n="TYPE">Rental_Agreement</V> <V n="STATUS">1</V></pre>

Parent topic: [Special variables for accessing the runtime hierarchy](#)

@B.<variable_name>

Description

Accesses the value of the specified variable on batch DCO node. The current DCO node does not need to be batch level. The current node can be a batch, document, page or field node and this syntax accesses the parent batch node.

Example

In this example, the smart parameter returns the value of the *TYPE* variable for the batch. The second example creates a new variable *Name* at the batch level and sets the value to “Fred”.

Action and return value	XML example (if applicable)
Action: <code>rr_Get("@B.TYPE")</code> Return value: TravelDocs <code>rrSet("Fred","@B.Name")</code> Creates the variable <i>Name</i> and sets its value to “Fred”	<pre><B id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc .reference.doc_dcvar104_20110046.001"> <V n="TYPE">TravelDocs</V> <V n="STATUS">1</V></pre>

Parent topic: [Special variables for accessing the runtime hierarchy](#)

@D.<variable_name>

Description

Accesses the value of the specified variable on the current, or parent, document DCO node. The current DCO node does not need to be a document level node. The current node can be a document, page or field node and this syntax accesses the parent document node.

Example

In the first example, the smart parameter returns the value of the *TYPE* variable for the current document. In the second example, the *TYPE* is changed to *Hotel_Rental*.

Action and return value	XML example (if applicable)
-------------------------	-----------------------------

Action and return value	XML example (if applicable)
Action: <code>rr_Get("@D.TYPE")</code> Return value: Car_Rental <code>rrSet("Hotel_Rental", "@D.TYPE")</code> Sets the variable <i>TYPE</i> to <i>Hotel_Rental</i>	<pre><D id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar105_20110046.001.01"> <V n="TYPE">Car_Rental</V> <V n="STATUS">0</V></pre>

Parent topic: [Special variables for accessing the runtime hierarchy](#)

@P.<variable_name>

Description

Accesses the value of the specified variable on the current, or parent, page DCO node. The current DCO node does not need to be field level. The current node can be a page or field node and this syntax accesses the parent page node.

Example

In this example, the smart parameter returns the value of the *TemplateID* variable for the current page.

Action and return value	XML example (if applicable)
Action: <code>rr_Get("@P.TemplateID")</code> Return value: 556	<pre><P id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar024_TM000001"> <V n="TYPE">Rental Agreement</V> <V n="TemplateID">555</V></pre>

Parent topic: [Special variables for accessing the runtime hierarchy](#)

@F.<variable_name>

Description

Accesses the value of the specified variable within the current field.

Example

In this example, the smart parameter returns the value of the *TYPE* variable for the current field.

Action and return value	XML example (if applicable)

Action and return value	XML example (if applicable)
Action: <code>rr_Get("@F.TYPE")</code>) Return value: Pickup_Date	<pre><F id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference .doc_dcvar014_Pickup_Date"> <V n="TYPE">Pickup_Date</V> <V n="Position">183,402,535,463</V></pre>

Parent topic: [Special variables for accessing the runtime hierarchy](#)

@X.<variable_name>

Description

Accesses the text of the specified variable on the current node. This smart parameter enhances the portability of the rules by working generically on the current DCO node. For example, a function that is written for the page level can be reused at another level by simply tying the ruleset to a new DCO object without having to update the @X smart variable to the new level .

Example

In the first example, the smart parameter returns the value of the *TYPE* variable for the current document. In the second example, the *TYPE* is changed to *Hotel_Rental*.

Action and return value	XML example (if applicable)
-------------------------	-----------------------------

Action and return value	XML example (if applicable)
<p>Action:</p> <pre> RegexFind_InBlock("Invoice..") GoSiblingBlockNext("1") GetSelectedBlockType("@X.SelectedBlock") </pre> <p>Return value: The variable <i>SelectedBlock</i> is set to "Word". If the variable <i>SelectedBlock</i> does not exist, it is created.</p>	<pre> <Block pos="1242,794,1593,819" s="4"> <L pos="1242,794,1593,819" s="4"> <W pos="1242,794,1381,818" v="Invoice#:" s="4" cn="999999999"> <C pos="1242,794,1247,818" v="I" s="4" cn="9" /> <C pos="1251,800,1267,818" v="n" s="4" cn="9" /> <C pos="1270,801,1287,818" v="v" s="4" cn="9" /> <C pos="1289,800,1307,819" v="o" s="4" cn="9" /> <C pos="1311,794,1315,818" v="i" s="4" cn="9" /> <C pos="1319,800,1335,819" v="c" s="4" cn="9" /> <C pos="1337,800,1354,819" v="e" s="4" cn="9" /> <C pos="1355,794,1373,818" v="#" s="4" cn="9" /> <C pos="1377,801,1381,818" v=":" s="4" cn="9" /> </W> <W pos="1503,794,1593,818" v="23857" s="4" cn="99999"> <C pos="1503,794,1519,818" v="2" s="4" cn="9" /> <C pos="1522,794,1538,819" v="3" s="4" cn="9" /> <C pos="1540,794,1556,819" v="8" s="4" cn="9" /> <C pos="1559,795,1575,819" v="5" s="4" cn="9" /> <C pos="1577,795,1593,818" v="7" s="4" cn="9" /> </W> </L> </Block> </pre>

Parent topic: [Special variables for accessing the runtime hierarchy](#)

@B\`<field_name>`[.`<variable_name>`]

Description

Accesses the text of the specified field on the current batch, or the value of the specified variable of the specified field on the current batch.

Example

In this example, the smart parameter returns the value of the Text variable for the batch-level field *Field2*

Action and return value	XML example (if applicable)
-------------------------	-----------------------------

Action and return value	XML example (if applicable)
Action: <code>rr_Get("@B\Field2)</code> Return value: The text value of <i>Field2</i>	<pre> <B type="APT"> <V n="ID">0</V> <V n="TYPE">Batch</V> <V n="STATUS">0</V> <V n="MIN TYPES">0</V> <V n="MAX TYPES">0</V> <V n="rules">&lt;in /&gt;&lt;out /&gt; </V> <P type="Other" pos="0" min="0" max="0"/> <D type="Document" pos="0" min="0" max="0"/> <F type="Field2" pos="0" min="0" max="0"/> </pre>

Parent topic: [Special variables for accessing the runtime hierarchy](#)

@D<field_name>[.<variable_name>]

Description

Accesses the text of the specified field on the current or parent document, or the value of the specified variable of the specified field on the current document.

Example

In this example, the smart parameter returns the value of the *TYPE* variable for the field “Field1”, which is directly attached to the current document.

Action and return value	XML example (if applicable)
Action: <code>rr_Get("@D\Page\Field1.TYPE")</code> Return value: Field	<pre> <F type="Field1"> <V n="ID">0</V> <V n="TYPE">Field</V> <V n="STATUS">0</V> <V n="Position">0,0,0,0</V> <V n="MIN TYPES">0</V> <V n="MAX TYPES">0</V> <V n="length"></V> <V n="ReqConf">8</V> <V n="rules">&lt;in /&gt;&lt;out /&gt;</V> </F> </pre>

Parent topic: [Special variables for accessing the runtime hierarchy](#)

@P<field_name>[.<variable_name>]

Description

Finds the parent page of the calling DCO. Then, find the child with the *dco_id* or *dco_type* of the parent page. Then, find the variable of this name on the specified child of the parent page.

The character values used in the following examples are ASCII codes, but they might be Unicode as well.

Example

In the first example, the smart parameter returns the text of the Car_Type field on the current page.

In the second example, the smart parameter returns the value of the TYPE variable of the Car_Type field.

Action and return value	XML example (if applicable)
Action: rr_Get("@P\Car_Type") Return value: SUV	<pre><F id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar023_Car_Type"> <V n="TYPE">Car_Type</V> <C cn="10" cr="588,748,600,769">83</C> <-- ASCII `S' <C cn="10" cr="605,748,620,769">85</C> <-- ASCII `U' <C cn="10" cr="625,748,643,769">86</C> <-- ASCII `V' </F></pre>
Action: rr_Get("@P\Car_Type.TYPE") Return value: Car_Type	<pre><F id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar023_Car_Type"> <V n="TYPE">Car_Type</V> <C cn="10" cr="588,748,600,769">83</C> <-- ASCII `S' <C cn="10" cr="605,748,620,769">85</C> <-- ASCII `U' <C cn="10" cr="625,748,643,769">86</C> <-- ASCII `V' </F></pre>

Parent topic: [Special variables for accessing the runtime hierarchy](#)

@F\<field_name>[.<variable_name>]

Description

Accesses the text of the specified subfield of the current field, for example, a field within a line item. Or returns the value of the specified variable of the specified subfield.

Example

In these examples, the rule that contains the action is bound to a field with subfields. In the first example, the smart parameter returns the text of the Unit_Cost subfield of the current field.

In the second example, the smart parameter returns the value of the Unit_Cost subfield TYPE variable.

Action and return value	XML example (if applicable)
Action: rr_Get("@F\Unit_Cost") Return value: \$9.90	<pre><F id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar013_Other_Charges_Line_Item0"> <V n="TYPE">Other_Charges_Line_Item</V> <F id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar013_Unit_Cost"> <V n="TYPE">Unit_Cost</V> <C cn="10" cr="1290,511,1305,540">36</C> <-- ASCII ` \$ ' <C cn="10" cr="1308,515,1321,536">57</C> <-- ASCII ` 9 ' <C cn="10" cr="1325,533,1329,536">46</C> <-- ASCII ` . Parent topic: [Special variables for accessing the runtime hierarchy](#)

@X\<field_name>[.<variable_name>]

Description

Accesses the text of the specified field on the current node, or the value of the specified variable of the specified field on the current node. This smart parameter enhances the portability of the rules by providing generic access to the current DCO node.

For example, a function that is written for the page level can be reused at another level by simply tying the ruleset to a new DCO object without having to update the `@X` smart parameter to the new level.

Example

This example shows actions being called on a document level node.

Action	XML example (if applicable)
Action: <code>rr_Get("@X.TYPE")</code> Return Value: Car_Rental	D id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.r eference.doc_dcvr103_20110046.001.01"> <V n="TYPE">Car_Rental</V> <V n="STATUS">0</V>
Action: <code>rrSet("Hotel_Rental", "@X.TYPE")</code> Sets the variable <code>TYPE</code> to "Hotel_Rental"	

Parent topic: [Special variables for accessing the runtime hierarchy](#)

Special variables for accessing job and task information

These variables return metadata that is related to a particular job or task, such as the job name or operator.

- [@JOBID](#)
- [@JOBNAME](#)
- [@OPERATOR](#)
- [@STATION](#)
- [@TASKID](#)
- [@TASKNAME](#)

Parent topic: [Smart Parameter Special Variable Reference](#)

@JOBID

Description

Returns the ID of the current job. This ID is the value that is specified in the ID field on the Datacap Administrator Workflow tab.

Example

In this example, the smart parameter returns the ID of the current job.

Action and return value	XML example (if applicable)
Action: rr_Get("@JOBID")	
Return value: Main Job	

Parent topic: [Special variables for accessing job and task information](#)

@JOBNAME

Description

Returns the name of the current job. This name is the value that is specified in the Description field on the Datacap Administrator Workflow tab.

Example

In this example, the smart parameter returns the name of the current job.

Action and return value	XML example (if applicable)
Action: rr_Get("@JOBNAME")	
Return value: Main Job	

Parent topic: [Special variables for accessing job and task information](#)

@OPERATOR

Description

Returns the user name of the person who ran the job.

Example

In this example, the smart parameter returns the name of the person who ran the job.

Action and return value	XML example (if applicable)
Action: rr_Get("@OPERATOR")	
Return value: admin	

Parent topic: [Special variables for accessing job and task information](#)

@STATION

Description

Returns the ID of the station that runs the job. This ID is the value that is specified in the ID field on the Datacap Administrator Workflow tab.

Example

In this example, the smart parameter returns the ID of the station that runs the current job.

Action and return value	XML example (if applicable)
Action: rr_Get("@STATION")	
Return value: 1	

Parent topic: [Special variables for accessing job and task information](#)

@TASKID

Description

Returns the ID of the current task. This ID is the value that is specified in the ID field on the Datacap Administrator Workflow tab.

Example

In this example, the smart parameter returns the ID of the current task.

Action and return value	XML example (if applicable)
Action: rr_Get("@TASKID")	
Return value: Export	

Parent topic: [Special variables for accessing job and task information](#)

@TASKNAME

Description

Returns the name of the current task. This name is the value that is specified in the Description field on the Datacap Administrator Workflow tab.

Example

In this example, the smart parameter returns the name of the current task.

Action and return value	XML example (if applicable)
Action: rr_Get("@TASKNAME")	
Return value: Export	

Parent topic: [Special variables for accessing job and task information](#)

Accessing Parent, Sibling and Child Objects with Smart Parameter Navigation

When running rules in a Datacap application, you can use smart parameters to access information from parent or child DCO nodes.

This feature allows the rules running on the current object to access other objects and their variables for both reading and writing. For example, while on a page level node, it is possible to access the parent batch or document node for the object, or navigation can be to a child field object.

Smart Parameter Navigation BNF Syntax

`<expression>: <level>[.<variable >] | <level>\<type>[\<type>][.<variable>]`

`<level>: @B | @D | @P | @F | @X`

`<variable>`: The name of a variable in the DCO.

`<type>`: The ID of a DCO object.

- [Level Identifier](#)
- [Variable Identifier](#)
- [Type Identifier](#)

Parent topic: [Smart Parameter Special Variable Reference](#)

Level Identifier

Description

The level identifiers, B, D, P, F, X denote the starting level of the expression. The level is always relative to the current DCO object. B = Batch level, D = Document level, P = Page level, F = Field level, X = current level.

For example, if the current DCO is a page object, then @P accesses the current object, as will @X.

@B accesses the parent batch object and @D accesses the parent document.

When a level identifier is used alone, without an identifying DCO name, then the object that is accessed is in the direct parent or child hierarchy of the current object.

As a review, the typical object hierarchy is: Batch -> Document -> Page -> Field.

A batch can have 1 or more documents, a document can have 1 or more pages and a page can have one or more fields. In some situations, a field can also have one or more child fields.

Parent topic: [Accessing Parent, Sibling and Child Objects with Smart Parameter Navigation](#)

Variable Identifier

Description

The variable identifier is the name of the variable to access on the specified DCO object. If a variable does not exist, the contents are considered to be empty. If a variable name is not specified, then the “TEXT” variable of the object is accessed, making @X equivalent to @X.TEXT.

Example

For example, assuming the current object is a page level object:

@X.MyVar accesses “MyVar” on the current object.

`@P.MyVar` also accesses “MyVar” on the current page.

`@D.MyVar` accesses “MyVar” on the parent document object.

`@F.MyVar` accesses “MyVar” on the current field object.

When a variable name is not specified, then the “TEXT” variable of the object is accessed. Again, using the example of these smart parameters on a page level object:

`@X` accesses “TEXT” on the current object.

`@P` also accesses “TEXT” on the current page.

`@D` accesses “TEXT” on the parent document object.

`@F` accesses the “TEXT” property on current field object.

Example of Variable Use In Actions

You can use Smart parameters and navigation as parameter input to any action whose parameters support smart parameters. The Smart Parameters provide an additional and powerful tool to create applications in which the input parameter value can be determined at runtime. The `rrSet`, `rrCompare`, and `rrCompareNot` are some of the common actions that use smart parameters, but the usage of Smart Parameters is not limited to these actions.

The following is a page level example where a barcode type is checked and if it is “Invoice”, the page type is set to “Invoice”.

```
rrCompare("@X. GetBarCode", "Invoice")
SetPageType("Invoice")
```

The following example shows to how accomplish the same objective in a different way, where the page type is always set to the barcode value directly.

```
SetPageType("@X. GetBarCode")
```

Note:

The application in the above examples must handle the cases where the page is an unexpected type or the barcode is not read.

In the following page level example, a FileNet property is set to the ID of the document level object.

```
FNP8_SetProperty("DocumentTitle", "@D.ID")
```

In the following field level example, a FileNet property is set to the text value of the field, or as in the second example the ‘TEXT’ variable value if the calling object is a Batch, Document or Page DCO node.

```
FNP8_SetProperty("InvoiceNumber", "@F") OR FNP8_SetProperty("InvoiceNumber", "@X")
```

Parent topic: [Accessing Parent, Sibling and Child Objects with Smart Parameter Navigation](#)

Type Identifier

Description

The name identifier in the smart parameter navigation syntax allows access to sibling nodes, either above or below the current object. The target object is identified by the object ID. The navigation expression must start

with the target level and the object ID.

To illustrate, consider the following hierarchy and types:

B T1 -->	D T2 -->	P T3 -->	F T4
			F T5
		P T6 -->	F T7
			F T8

This hierarchy always has only one batch object. This runtime DCO contains 2 document objects, 3 page objects and 6 field objects. The document object ID2 contains 2 pages, each with 2 fields. The “T” is a shorthand way to indicate the different object type names.

The following examples show navigation of the DCO using the hierarchy illustrated above.

If the current object is page T3, this accesses the TEXT value second field: “@F|T5”. Here, the variable “MyVar” is accessed on the same field object: “@F|T5.MyVar”.

The following example accesses the second field of the second page from the document level object T2:

```
@D\T6\T8.MyVar
```

If on the page object T3, this example accesses the sibling page T6:

```
@D\T6.MyVar
```

Example of Type Use In Actions

There are some cases where specifying navigation of specific types is useful. Here is an example where the current object is a document object which is creating a PDF of all pages and the author of the PDF is contained in a field object of the main page. The value of the `y_PDFAuthor` variable is saved to the calling document object for later use by a subsequent action; for example when creating a PDF.

```
rrSet("@P\main_page\myfield.TEXT", "@X.y_PDFAuthor")
```

Another similar example where a document level object sets a FileNet property obtained from a field object.

```
FNP8_SetProperty("DocumentTitle, @P\mypage\myfield.TEXT ")
```

Parent topic: [Accessing Parent, Sibling and Child Objects with Smart Parameter Navigation](#)

Miscellaneous special variables

Miscellaneous special variables can be used with Smart parameters.

- [@CHR\(<unicode_value>\)](#)
- [@DATE\(<format>\)](#)
- [@DCO\(<property_name>\)](#)
- [@DICT_VALUE\(<field>\)](#)
- [@DICT_WORD\(<field>\)](#)
- [@DICT_VINDEX\(<csv_string>\)](#)
- [@DICT_WINDEX\(csv_string\)](#)
- [@EMPTY](#)
- [@LOCALE](#)
- [@PATH\(<key>\)](#)

- @PILOT(<property_name>)
- @PROJECTDIR
- @PROCESSDIR
- @STRING(<string_value>)
- @TIME(<format>)
- @TYPE

Parent topic: [Smart Parameter Special Variable Reference](#)

@CHR(<unicode_value>)

Description

Returns the character corresponding to the specified UNICODE.

Example

In this example, the smart parameter returns the character corresponding to UNICODE value 38.

Action and return value	XML example (if applicable)
Action: rr_Get("@CHR(38)") Return value: &	

Parent topic: [Miscellaneous special variables](#)

@DATE(<format>)

Description

Returns the current date in the format specified. The default format is "MM/DD/YYYY".

To set a @DATE attribute, ensure that the date value is in one of the date formats accepted by IBM Content Manager.

Valid date formats are:

- "yyyy-MM-dd"
- "yyyy/MM/dd"
- "MM-dd-yyyy"
- "MM/dd/yyyy"

You can reformat a date field by calling the `Validations.IsFieldDateWithReformat` function on the current field.

```
IsFieldDateWithReformat ("yyyy/MM/dd")
```

Example

In this example, the smart parameter returns the current date.

Action and return value	XML example (if applicable)

Action and return value	XML example (if applicable)
Action: rr_Get("@DATE(mm.dd.yyyy)") Return value: 12.31.2010	

Parent topic: [Miscellaneous special variables](#)

@DCO(<property_name>)

Description

Returns the value of the specified DCO object property. The DCO object is an internal data structure that contains the current runtime batch hierarchy information. This information includes the batch ID (ID), batch type (TYPE), batch status (STATUS), and the full runtime batch hierarchy XML.

Example

In this example, the rule that contains the action is bound to a page. The example also contains the smart parameter returns the portion of the runtime batch hierarchy XML for the current page.

Action and return value	XML example (if applicable)
Action: rr_Get("@DCO(XML)") Return value: <?xml-stylesheet type="text/xsl" href="#_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_...\dco.xsl"?><P id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar006_TM000001"><F id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar006_Pickup_Date"> <V n="TYPE">Pickup_Date</V><V n="Position">0,0,0,0</V><V n="STATUS">0</V></F>	

Parent topic: [Miscellaneous special variables](#)

@DICT_VALUE(<field>)

Description

This special variable works with OMR fields (RecogType=4) that are bound to a dictionary. It returns the dictionary values corresponding to the items that are selected in the specified OMR field.

Example

In this example, the rule that contains the rr_Get action is bound to a page that contains an OMR field (Options). The OMR field has three subfields and is bound to the dictionary shown in the XML code. On the current page all three options are selected, so the return string contains all three dictionary values.

Action and return value	XML example (if applicable)
Action: rr_Get("@DICT_VALUE(Options)") Return value: Navigation System Child Seat Fuel Service	<pre><DICT n="Options"> <W v="Navigation System">Navigation System</W> <W v="Child Seat">Child Seat</W> <W v="Fuel Service">Fuel Service</W> </DICT></pre>

Parent topic: [Miscellaneous special variables](#)

@DICT_WORD(<field>)

Description

Same as @DICT_VALUE, except this special variable returns the dictionary words corresponding to the selected items.

Parent topic: [Miscellaneous special variables](#)

@DICT_VINDEX(<csv_string>)

Description

This special variable works with actions bound to an OMR field (RecogType=4) where the OMR field is bound to a dictionary. The parameter returns a string of 1's and 0's corresponding to the dictionary values you specify as a comma-separated list.

Example

In this example, the rule that contains the rr_Get action is bound to an OMR field. The OMR field has three subfields and is bound to the dictionary shown on the right. The values that are specified correspond to the second and third items in the dictionary, so the return value is 011. The rr_Get sets the character values on the three OMR subfields to 0, 1, and 1.

Action and return value	XML example (if applicable)
Action: rr_Get("@DICT_VINDEX(Fuel Service,Child Seat)") Return value: 011	<pre><DICT n="Options"> <W v="Nav System">Nav System</W> <W v="Child Seat">Child Seat</W> <W v="Fuel Service">Fuel Service</W> </DICT></pre>

Parent topic: [Miscellaneous special variables](#)

@DICT_WINDEX(csv_string)

Description

Same as @DICT_VINDEX, except the argument for this special variable uses the dictionary words.

Parent topic: [Miscellaneous special variables](#)

@EMPTY

Description

This special variable represents an empty string.

Example

In this example, rrSet clears the custom page variable *MyVar*.

Action and return value	XML example (if applicable)
Action: rrSet("@EMPTY","@P.MyVar")	

Parent topic: [Miscellaneous special variables](#)

@LOCALE

Description

Returns one of the following values:

hr_locale	The value of variable hr_locale is returned if the value of that variable is not empty. For information, see hr_locale .
System locale	Otherwise, if the value of hr_locale is empty, the system locale is returned.

Example

Action	XML example (if applicable)	Description
<code>rrSet("@LOCALE", "@X.CurrentLocale")</code>		Shows how to save the current locale so that you can later determine what locale was in effect (such as after batch processing). The current locale is saved in the following manner: @LOCALE obtains the current locale, and rrSet saves that value in a variable that is called CurrentLocale for the current DCO object.
<code>rrSet("@LOCALE", "@X.CurrentLocale") rrSet("en-GB", "@X.hr_locale") // perform actions that are // affected by // locale such as recognition or // validations rrSet("@X.CurrentLocale", "@X.hr_locale")</code>		Shows how to save and restore the original locale so that you can temporarily use a different locale.

Parent topic: [Miscellaneous special variables](#)

@PATH(<key>)

Description

Returns the full path for the specified identifier as defined in the [PATHS] section of paths.ini, in the dco_<app_name> folder of the application. The function that is supported by this special variable was replaced by the Datacap Application Manager and the @APPPATH special variable.

Example

In this example, the smart parameter returns the path to the image folder of the APT application. This folder is defined in the paths.ini file that is shown on the right.

Action and return value	XML example (if applicable)
Action: rr_Get("@PATH(VscanImageDir)") Return value: C:\Datacap\APT\Images\Input	[Paths] VscanImageDir=..\Images\Input ProcessDir=..\dco_APT RRXDir=..\..\dco_APT\Rules FingerprintDir=..\Fingerprint ExportDir=..\Export

Parent topic: [Miscellaneous special variables](#)

@PILOT(<property_name>)

Description

Returns the value of the specified Pilot object property. The Pilot object is an internal data structure that is configured by Datacap at the start of task execution. It contains the information that is required to run the task. Such as the batch folder (BATCHDIR), the batch ID (BATCHID), the input DCO file (DCOFILE), the task priority (PRIORITY)

The PILOT object properties that you can use to get values from Datacap and provide them to actions are.

- BATCHID
- BATCHDIR
- OPERATOR
- STATION
- CHILDRENQUANTITY
- PRIORITY
- PROJECTPATH
- CAPTION
- PAGESINBATCH
- DOCSINBATCH
- EXPECTEDPAGES
- ADJUSTEDPAGES
- ADJUSTEDDOCS
- JOBNAME
- FORMPROFILE
- DCOFILE
- JOBID
- TASKID

Example

In this example, the smart parameter returns the input DCO file for the current task.

Action and return value	XML example (if applicable)
-------------------------	-----------------------------

Action and return value	XML example (if applicable)
Action: rr_Get("PILOT(DCOFILE)")	
Return value: C:\Datacap\TravelDocs\batches\20110004.004\Export.xml	

Parent topic: [Miscellaneous special variables](#)

@PROJECTDIR

Description

Returns the path and file name for the setup (.xml) file of the current task. The path is relative to the *dco_folder of the application*.

Example

Action and return value	XML example (if applicable)
Action: rr_Get("@PROJECTDIR")	
Return value: \RRS_VScan.bpp	

Parent topic: [Miscellaneous special variables](#)

@PROCESSDIR

Description

Returns the full path to the *dco_<app_name>* folder of the application.

Example

Action and return value	XML example (if applicable)
Action: rr_Get("@PROCESSDIR")	
Return value: C:\Datacap\TravelDocs\dco_TravelDocs	

Parent topic: [Miscellaneous special variables](#)

@STRING(<string_value>)

Description

Returns the value that is specified as a string.

Example

Action and return value	XML example (if applicable)
Action: rr_Get("@STRING(MyString)")	
Return value: MyString	

@TIME(<format>)

Description

Returns the current time in the format specified. If you do not specify a format like @TIME(), defaults to HH:MM:SS.

Example

Action and return value	XML example (if applicable)
Action: rr_Get("@TIME(HH:MM)")	
Return value: 10:45	

Parent topic: [Miscellaneous special variables](#)

@TYPE

Description

Returns the type of the current object (Batch, Document, Page, or Field)

Example

Action and return value	XML example (if applicable)
Action: rr_Get("@TYPE")	
Return value: Page	

Parent topic: [Miscellaneous special variables](#)

Smart Parameter Build control

In Datacap Studio, you can use the Smart Parameter Build control to create an expression that is evaluated at run time that allows you to obtain data from Datacap objects and variables. In Datacap Studio, when you select an action that takes a string parameter, the Parameters section displays the details of the selected action along with a button that displays three dots. By using this button, you can open Smart Parameter Build control.

To create smart parameter expression, complete the following steps:

1. In the Smart Parameter Build window, from the Category list, select a smart parameter category. For example, Batch, Configuration, Navigation, and Objects.

When you select a category, the Element field displays all the elements that belong to the selected category.

2. Select an element.

When you select an element, the Preview field displays a smart parameter. For example, if you select Batch Identifier element, the Preview field displays the @BATCHID smart parameter.

3. To add the smart parameter to the expression, click the Add button.

The Smart Parameter Expression field displays the parameter. You can change the smart parameter expression in the Smart Parameter Expression field, and add text that you want.

4. Under the Evaluation section, click the Evaluate button.

Note: When you click the Evaluate button, Smart Parameter Build attempts to evaluate the current smart parameter expression. However, the results you get can be different at run time. For example, when Smart Parameter Build tries to evaluate @BATCHID, there is no batch running so there is no Batch ID for it. So interactively, Smart Parameter Build returns a sample Batch ID after you click the Evaluate button.

Other components are not evaluated so cannot return values. For example, if the expression is @B.MyRuntimeVariable, it does not exist at setup time so Smart Parameter Build evaluates to an empty string at setup time. At runtime, Smart Parameter Build evaluates whatever the variable contains.

5. Click Save Expression, the Parameters section in Desktop Studio displays the smart parameter. For example, @BATCHID.

You can also specify two or multiple smart parameters in an expression. To specify two or more parameters, select another element from the Element list, for example, Job Name, and then click Add. The Smart Parameter Expression field displays the value as @BATCHID+@JOBNAME. You can specify values such as @BATCHID:+:@JOBNAME.

Many objects are created at run time so the Smart Parameter Builder cannot show the objects because they do not exist, and to access these runtime only variables and objects, you must manually type the objects that you want to access at run time.

The Smart Parameter Build control runs at setup time so the DCO objects might not exist and the evaluation result can be different at run time. You must edit expressions manually to access objects only available at run time or to add your own custom text. You can use a "+" sign to separate unique smart parameters.

For the Navigation category, the Elements field displays the elements that belong to Navigation category. In this case, the setup time and runtime become apparent. For example, if you select the Page element, the Object field displays subobjects. The list displays the subobjects that are part of the DCO tree in Datacap Studio at setup time.

Select a subobject, such as Object Shipping, and click Navigate. The Smart Parameter Builder window displays the corresponding field, such as Navigated to: Object Shipping. You can select any one of the displayed variables of Page object, and click Add.

At run time, on a typical application various variables are added by using actions or application. However, the variables do not exist at setup time.

Parent topic: [Smart Parameter Special Variable Reference](#)

Standard Variable Reference

Standard variables can be used on batches, documents, pages, and fields.

- [Variables that are used on all object types](#)
Some variables are available for all object types.
- [Batch variables](#)
These standard variables can be used only on batch object types.
- [Document variables](#)
These standard variables can be used only on document object types.

- [Page variables](#)
These standard variables can be used only on page object types.
- [Field variables](#)
These standard variables can be used only on field object types.

Variables that are used on all object types

Some variables are available for all object types.

- [MAX_TYPES](#)
- [MESSAGE](#)
- [MIN_TYPES](#)
- [rules](#)
- [STATUS](#)
- [TYPE](#)
- [hr_locale](#)
The hr_locale variable specifies the locale value that is used by the recognition engines to validate currency, numerals, and date data types for localization.
- [The hr_SyncImg variable](#)
The hr_SyncImg variable affects the Click N Key during the verification task.

Parent topic: [Standard Variable Reference](#)

MAX_TYPES

Applies to

Applies	Does not apply
Setup DCO	Runtime DCO

Description

Specifies the maximum number of child object types that can be present at run time to meet document integrity requirements (0 = no maximum).

Parent topic: [Variables that are used on all object types](#)

MESSAGE

Applies to

Applies	Does not apply
Runtime DCO	Setup DCO

Description

Used by many validation and look up actions to report errors.

Example

This example shows an error message that is written to the runtime hierarchy by a failed validation action.

```
<V n="MESSAGE">Failed Calculation:377.73=477.73</V>
```

Parent topic: [Variables that are used on all object types](#)

MIN_TYPES

Applies to

Applies	Does not apply
Setup DCO	Runtime DCO

Description

Specifies the minimum number of child object types that must be present at runtime to meet document integrity requirements.

Parent topic: [Variables that are used on all object types](#)

rules

Applies to

Applies to: Setup DCO Does not apply: Runtime DCO

Description

Stores the rule map of an object that is established in Datacap Studio.

For example, you can map one or more rules to an object in the Document hierarchy. When you select the rule in the Document hierarchy object to which you mapped the rule, Datacap Studio displays the DCO.Rule Map in the Properties tab. The values in the DCO.Rule Map include the Ruleset ID and the Rule name. The Ruleset ID references the position of the ruleset on the Rulesets tab in Datacap Studio, and the Rule name references the position of the rule in the ruleset. For example, if an object is mapped with a rule named Vendor, which is part of the Validate ruleset, then the Rule name value can be 4 and the Ruleset ID can be 6. These values mean that the Validate ruleset is in the sixth position in the Ruleset tab, and the Vendor rule is in the fourth position within the Validate ruleset. The corresponding line in the Setup DCO is `<r`

`id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar070_4"`
`rs="6" />`. If the object is mapped with five different rules, then the Setup DCO can be similar to this sample:

```
<in>
<r
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar070_4"
rs="6" />
<r
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar070_2"
rs="13" />
<r
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar070_9"
rs="7" />
<r
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar070_3"
rs="14" />
<r
```

```
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcvar070_6"
rs="16" />
</in>
```

Example

This example shows how the XML in the sample is stored in the Setup DCO file.

```
<V n="rules"><in><r id="4">
rs="6" /><r id="2" rs="13"
/><r id="9" rs="7" /><r
id="3" rs="14" /><r
id="6" rs="16" /></in></V>
```

Parent topic: [Variables that are used on all object types](#)

STATUS

Applies to

Setup DCO, Runtime DCO

Description

Specifies the status of the object. The status is initially zero or not present in the Setup DCO. The status is updated at run time depending on the object type and the rules and actions of the task. Some common status values are shown in this table with their conventional meanings. Specific applications can use other status values.

Value	Status	Applies to	Assigned by
49	ScanOK	Page objects	Scan tasks
0	OK	Batch, document, and page objects	Rulerunner tasks
1	Problem		
2	Overridden	Pages that fail validation but are overridden by the operator.	Verify tasks
48	RecogDoneOK	Page objects	Recognition tasks
0	OK	Field objects	Any task
1	Error		Can specify -1 in Setup DCO
-1	Ignore		

A few less common status values are shown in this table.

Value	Status
51	CannotFindAnchor
52	DontNeedVerification
70	RescanPage

Value	Status
71	VerificationFailed
72	PageOnHold
73	PageOverridden
74	NoData
75	DeletedPage
77	DeleteApproved
79	ReviewPage
128	DeletedDoc
145	ReviewDoc

Example

```
<V n="STATUS">1</V>
```

Parent topic: [Variables that are used on all object types](#)

TYPE

Applies to

Applies	Does not apply
Setup DCO	
Runtime DCO	

Description

In the Setup DCO, TYPE specifies the object type (batch, document, page, or field), for example:

```
<V n="TYPE">Page</V>
```

TYPE is updated in the Runtime DCO to specify the object name, for example:

```
<V n="TYPE">Rental_Agreement</V>
```

Parent topic: [Variables that are used on all object types](#)

hr_locale

The hr_locale variable specifies the locale value that is used by the recognition engines to validate currency, numerals, and date data types for localization.

Applies to

Global DCO

Description

The `hr_locale` variable uses the BCP 47 defined language values for language-region, language code ID, and locale description. For example, the `hr_locale` variable for the English language in the United States, reads `en-US, 1033, English (United States)`.

The value of this variable is set in terms of the DCO hierarchy. For example, if this variable is set at the batch level, it is also automatically set at the document and page level. For more information about the hierarchy, see [Relation of the document hierarchy to the runtime batch hierarchy](#).

Parent topic: [Variables that are used on all object types](#)

The `hr_SyncImg` variable

The `hr_SyncImg` variable affects the Click N Key during the verification task.

Applies to

The `hr_SyncImg` applicable only when dealing with multi page documents where the data might be located on a trailing page.

Description

By setting this variable to the appropriate value the operator can locate a field on the trailing page. If this variable is not set, or is equal to zero, you cannot draw any fields on a trailing page, because as soon as you click a field in the verify panel while a trailing page is in image view, the displayed image changes and the first page is displayed in an image view.

You can use the following possible values for this variable:

- 0 - Do not sync
- 1 - Sync always
- 2 - Sync only when field position is not empty or all zeros

Parent topic: [Variables that are used on all object types](#)

Batch variables

These standard variables can be used only on batch object types.

- [LAST_RR_PROFILE](#)
- [ScanSrcChannel](#)

Parent topic: [Standard Variable Reference](#)

LAST_RR_PROFILE

Applies to

Does not apply: Setup DCO Applies to: Runtime DCO

Description

Specifies the name of the last task profile that ran.

Example

```
<V n="LAST_RR_TPROFILE">Rulerunner:m:eRun</V>
```

Parent topic: [Batch variables](#)

ScanSrcChannel

Applies to

Does not apply: Setup DCO Applies to: Runtime DCO

Description

The input channel of the batch. For example: the input channel can be a fax or scanner, or some other application-specific source. If your application sets this variable before the Export Statistics ruleset is run, the Datacap Dashboard will use the value to group the batch in the Dashboard. If your application does not set *ScanSrcChannel*, the Export Statistics ruleset uses the current Job Name as the value for the source.

Example

```
<V n="ScanSrcChannel">Fax 213-555-7001</V>
```

Parent topic: [Batch variables](#)

Document variables

These standard variables can be used only on document object types.

- [DD](#)

Parent topic: [Standard Variable Reference](#)

DD

Applies to

Runtime DCO

Description

Used by some scan tasks - DD contains the value that is imprinted on the first page of the document by a scanner, or an externally assigned document ID.

Parent topic: [Document variables](#)

Page variables

These standard variables can be used only on page object types.

- [Confidence](#)

- [DATAFILE](#)
- [Fingerprint Created](#)
- [Image_Offset](#)
- [IMAGEFILE](#)
- [Latitude](#)
- [Longitude](#)
- [PAGE_HEIGHT](#)
- [PAGE_WIDTH](#)
- [PageName](#)
- [PatternConfidence](#)
- [PD](#)
- [ScanSrcInputFolder](#)
- [ScanSrcFileName](#)
- [ScanSrcSubFolder](#)
- [ScanSrcPath](#)
- [TEMPLATE IMAGE](#)
- [TemplateID](#)

Parent topic: [Standard Variable Reference](#)

Confidence

Applies to

• Setup DCO | [Runtime DCO](#)

Description

Specifies the confidence level achieved during fingerprint matching.

Parent topic: [Page variables](#)

DATAFILE

Applies to

[Runtime DCO](#)

Description

Specifies the name of the data XML file that is associated with the page. DATAFILE is initially blank in the Setup DCO and is assigned at run time (for example, TM000001.xml).

Parent topic: [Page variables](#)

Fingerprint Created

Applies to

[Runtime DCO](#)

Description

Specifies whether or not Datacap added a fingerprint for the page to the fingerprint library, which happens when fingerprint matching fails and the argument to the FindFingerprint action is True.

Example

```
<V n="Fingerprint Created">No</V>
```

Parent topic: [Page variables](#)

Image_Offset

Applies to

Runtime DCO

Description

Specifies the offset in pixels (x, y) between the runtime page image and the fingerprint image.

Example

```
<V n="Image_Offset">-100,-100</V>
```

Parent topic: [Page variables](#)

IMAGEFILE

Applies to

- Setup DCO
- Runtime DCO

Description

Specifies the name of the associated runtime image file. IMAGEFILE is blank in the Setup DCO and is assigned at run time.

Example

```
<V n="IMAGEFILE">tm000010.tif</V>
```

Parent topic: [Page variables](#)

Latitude

Applies to

Applies	Does not apply

Description

When capturing images on a mobile device, the Latitude variable stores the latitude value of the GPS location at capture time.

Parent topic: [Page variables](#)

Longitude

Applies to

Applies	Does not apply
Runtime DCO	Setup DCO

Description

When capturing images on a mobile device, the Longitude variable stores the longitude value of the GPS location at capture time.

Parent topic: [Page variables](#)

PAGE_HEIGHT

Applies to

Applies	Does not apply
Setup DCO	Runtime DCO

Description

This variable is used for automatic zonal OCR to store the height of the image for the last page type on which a zone was drawn.

Parent topic: [Page variables](#)

PAGE_WIDTH

Applies to

Applies	Does not apply
Setup DCO	Runtime DCO

Description

This variable is used for automatic zonal OCR to store the width of the image for the last page type on which a zone was drawn.

Parent topic: [Page variables](#)

PageName

Applies to

Applies	Does not apply
Runtime DCO	Runtime DCO

Description

The PageName variable is used by scan tasks only and specifies the file name without the path or the file extension. The variable parses the ScanSrcPath variable, and selects a substring between the last slash and the first period after that.

Here is an example with multiple periods in the file name, and PageName ignores all characters after the first period:

```
<V n="ScanSrcPath">C:\datacap\APT\Images\Input\APT003.filename3.tif</V>
```

```
<V n="PageName">APT003</V>
```

Parent topic: [Page variables](#)

PatternConfidence

Applies to

Applies	Does not apply
Runtime DCO	Setup DCO

Description

Specifies the confidence level achieved when pattern matching is used for page identification.

Example

```
<V n="PatternConfidence">10</V>
```

Parent topic: [Page variables](#)

PD

Applies to

Applies	Does not apply

Runtime DCO	Setup DCO
-------------	-----------

Description

Used by isscan tasks only - specifies the page data string.

Parent topic: [Page variables](#)

ScanSrcInputFolder

Applies to

Applies	Does Not Apply
Runtime DCO	Setup DCO

Description

The full path of the input folder for this file. This variable is set indirectly by the mv_retain_folder action.

Example

```
<V n="ScanSrcInputFolder">c:\shared\group1</V>
```

Parent topic: [Page variables](#)

Related reference:
[mv_retain_folder](#)

ScanSrcFileName

Applies to

Applies	Does Not Apply
Runtime DCO	Setup DCO

Description

The original name of the file without the path. This variable is set indirectly by the mv_retain_folder action.

Example

```
<V n="ScanSrcFileName">invoice_0001.tif</V>
```

Parent topic: [Page variables](#)

Related reference:
[mv_retain_folder](#)

ScanSrcSubFolder

Applies to

Applies	Does Not Apply
Runtime DCO	Setup DCO

Description

The relative path of the input folder in which the file was found, which includes the root input folder name but not the root folder path. This variable is set indirectly by the mv_retain_folder action.

Example

```
<V n="ScanSrcSubFolder">\shared\group1\batch1</V>
```

Parent topic: [Page variables](#)

Related reference:

[mv_retain_folder](#)

ScanSrcPath

Applies to

Applies	Does Not Apply
Runtime DCO	Setup DCO

Description

Used by scan tasks only - specifies the full path and file name to the original image file.

Example

```
<V n="ScanSrcPath">c:\datacap\apt\images\input\invoice_0001.tif</V>
```

Parent topic: [Page variables](#)

TEMPLATE IMAGE

Applies to

Setup DCO and Runtime DCO

Description

Specifies the name of the matching fingerprint (CCO) file. The value is blank in the Setup DCO and is assigned at runtime.

Parent topic: [Page variables](#)

TemplateID

Applies to

Applies	Does not apply
Runtime DCO	Setup DCO

Description

Specifies the ID of the matching fingerprint.

Example

```
<V n="TemplateID">567</V>
```

Parent topic: [Page variables](#)

DataType

Applies to

Setup DCO

Verification panels that support this variable

Datacap Navigator

Datacap Web Client (VeriFine.aspx)

Description

Specifies the type of characters the user can enter into the field in the Verify panel. Use the following codes to specify the allowed data type:

Value	Description
0	Alphanumeric
1	Integer
2	Float
3	Date
4	Time
5	Currency

Parent topic: [Field variables](#)

DensityString

Applies to

Runtime DCO

Description

This variable is used for OMR zones, one character per zone, where the character represents the percentage of black pixels within the zone according to the following formula.

Character's ASCII code value = Percentage black pixels + 48

For example, if the zone has 20% black pixels, the result is ASCII code 68 = 'D'.

Example

This example represents a field with three OMR check boxes.

```
<V n="DensityString">@@D</V>
```

Parent topic: [Field variables](#)

DICT

Applies to

Setup DCO

Verification panels that support this variable

Datacap Desktop

Datacap Navigator

Datacap Web Client (VeriFine.aspx and aindex.aspx)

Description

Used with selection fields and specifies the name of a dictionary (within this Setup DCO) containing a list of possible values.

Parent topic: [Field variables](#)

Index

Applies to

Runtime DCO

Description

Used in FormSpec to optionally specify the field's index.

Parent topic: [Field variables](#)

label

Applies to

Setup DCO

Verification panels that support this variable

- Datacap Desktop
- Datacap Navigator
- Datacap Web Client (VeriFine.aspx)
- Datacap Web Client (aindex.aspx)

Description

The value of this variable, if specified, defines the label that is displayed beside the field in the supported verification panels. If not specified, the `type` attribute of the field is used as the label.

Parent topic: [Field variables](#)

Location

Applies to

Applies	Does not apply
Runtime DCO	Setup DCO

Description

When capturing images on a mobile device, the Location variable stores the address of the GPS location at capture time.

Parent topic: [Field variables](#)

Lookup

Applies to

Applies	Does not apply
Setup DCO	Runtime DCO

Verification panels that support this variable

Support this variable	Do not support this variable
Datacap Desktop	N/A
Datacap Navigator	
Datacap Web Client (VeriFine.aspx)	
Datacap Web Client (aindex.aspx)	

Description

Specifies a database lookup statement that gets run during verification when the user clicks the hyperlinked field label. A list of matching entries from the database that is specified by the dns attribute is displayed. The selected entry is used to populate the fields that are specified in the flist attribute.

Example

The following sample Lookup value gets a list of car types from the lookup database that is specified in the application configuration (.app) file. The sample code then populates the Car_Type field with the selected value.

```
<SQL flist='Car_Type' dsn="*/lookupdb:cs">SELECT Car_Type FROM Car_Types</SQL>
```

The next example (from APT) gets a list of matching vendor names, ZIP codes, and vendor IDs from the application's lookup database. The list is then displayed to the user. The SQL statement uses the text in the Vendor field as the search string. The user can then, for example, enter the first letter and see a list of vendor names that start with that letter. Upon selecting a vendor from the list, it populates the Vendor, Remittance_Zip, and Vendor_Number fields with the information for the selected vendor.

Attention: The carriage return in the following example is only for readability; it is not technically required.

```
<SQL flist='Vendor,Remittance_Zip,Vendor_Number' dsn="*/lookupdb:cs">
SELECT VendorName,VendorZip,VendorID FROM VendorTable WHERE VendorName LIKE
```

```
'@@Vendor@@%'</SQL>
```

Note in this example the special syntax that is required to reference a field value from the SQL statement: @@Vendor@@%. Note also that WHERE <column> = '<value>' is not supported.

Parent topic: [Field variables](#)

LookupEx

Applies to

Applies	Does not apply
Setup DCO	Runtime DCO

Verification panels that support this variable

Support this variable:	Do not support this variable:
Datacap Web Client (VeriFine.aspx)	Datacap Desktop
	Datacap Navigator
	Datacap Web Client (aindex.aspx)

Description

Specifies a database lookup statement that gets run during verification when the user leaves the field (for example, by clicking or moving to the next field). LookupEx is typically used to populate other fields that are based on current field's value. The structure of the lookup statement is similar to that of the Lookup variable.

Example

The sample LookupEx value looks up the vendor name that is based on the ID in the VendorID field and populates the VendorName field with the result.

Attention: The carriage return in the following example is only for readability; it is not technically required.

```
<SQL flist='VendorName' dsn="*/lookupdb:cs">  
SELECT Vendor FROM VendorTable WHERE VendorID LIKE '@@VendorID@%'</SQL>
```

For more information about the LookupEx variable, see the [Lookup](#) variable.

Parent topic: [Field variables](#)

MaxLength

Applies to

Applies	Does not apply
Setup DCO	Runtime DCO

Verification panels that support this variable

Support this variable	Do not support this variable
Datacap Web Client (VeriFine.aspx)	Datacap Desktop Datacap Navigator Datacap Web Client (aindex.aspx)

Description

Specifies the maximum number of characters the user can type into the field in the Verify panel.

Parent topic: [Field variables](#)

METRIC

Applies to

Applies	Does not apply
Setup DCO	Runtime DCO

Description

Specifies the size of the search region that is used during geometric pattern matching. The dimensions that are specified are relative to the anchor field. For example, METRIC=200,300 creates a search region 200 pixels larger left and right and 300 pixels larger above and below.

Parent topic: [Field variables](#)

MultiLine

Applies to

Applies	Does not apply
Setup DCO	Runtime DCO

Verification panels that support this variable

Support this variable	Do not support this variable
Datacap Desktop	Datacap Navigator Datacap Web Client (VeriFine.aspx) Datacap Web Client (aindex.aspx)

Description

When set to '1,' Multiline shows the field as a multiline edit field in the Datacap Desktop Verify pane.

Parent topic: [Field variables](#)

MultiPunch

Applies to

Applies	Does not apply
Setup DCO	Runtime DCO

Verification panels that support this variable

Support this variable	Do not support this variable
Datacap Desktop	Datacap Web Client (aindex.aspx)
Datacap Navigator	
Datacap Web Client (VeriFine.aspx)	

Description

Used when the field contains multiple OMR (check box) options. When MultiPunch is set to '1,' multiple selections are allowed; otherwise only one selection is allowed.

Parent topic: [Field variables](#)

PatternMatch

Applies to

Applies to	Does not apply
Setup DCO	Runtime DCO

Description

Some PatternMatch actions require anchor fields, which are used to adjust the image registration. You can identify one or more fields as an anchor field in the Zones on Datacap Studio.

To identify a field as an anchor field, lock the DCO, right-click the anchor field, and select Manage Variables. Create the variable PatternMatch, if it does not exist, and set the value to 1.

When the PatternMatch variable is set to 1, the field is an anchor field for pattern matching.

Parent topic: [Field variables](#)

PictureString

Applies to

Applies	Does not apply
---------	----------------

Verification panels that support this variable

Support this variable	Do not support this variable
Datacap Web Client (VeriFine.aspx)	Datacap Desktop Datacap Navigator Datacap Web Client (aindex.aspx)

Description

Specifies which characters the user can type into the field according to this key.

Value	Characters allowed
A	Alphabetic or space
a	Alphabetic, punctuation, or space
D	(Date) numeric digit, minus sign, decimal point (period), forward slash
F	(Float) numeric digit, minus sign, or decimal point (period)
f	Numeric digit or punctuation
L	Lowercase alphabetic or space
l	Lowercase alphabetic, punctuation, or space
N	Numeric digit
n	Uppercase alphabetic character, numeric digit, or space.
P	Punctuation or space
T	(time) numeric digit, A, P, M, or colon
U	Uppercase alphabetic or space
u	Uppercase alphabetic, punctuation, or space
X	Alphabetic, numeric digit, or space
x	Alphabetic, numeric digit, punctuation, or space
Z	Any character
#	Numeric digit or minus sign

Example

- `PictureString="A"` - Any upper/lower case letter or space is allowed (no numbers or special characters)
- `PictureString=""` - All characters are allowed (default)

Tip: If you specify more than one-character set code, the first code applies to the first character that is typed by the user. The second code applies to the second character that is typed by the user, a third code applies to the third character that is typed, and so on. The last code applies to all remaining characters that are typed.

Setup DCO	Runtime DCO

Verification panels that support this variable

Support this variable:	Do not support this variable:
Datacap Desktop	Datacap Web Client (aindex.aspx)
Datacap Navigator	
Datacap Web Client (VeriFine.aspx)	

Description

Specifies a database lookup statement that converts an edit field in a verification panel into a drop-down list with values from a database. A list of matching entries from the database that is specified by the dns attribute is displayed. The selected entry is used to populate the fields that are specified in the flist attribute.

Example

This sample Lookup value retrieves a list of car types from the lookup database that is specified in the application configuration (.app) file. This sample then populates the list in the Car_Type field.

```
<SQL flist='Car_Type' dsn="*/lookupdb:cs">SELECT Car_Type FROM Car_Types</SQL>
```

Note that you can populate multiple fields simultaneously (see the Lookup variable for an example).

If you also configure the DICT variable, DICT variable values are displayed in the drop-down list at runtime in Datacap Navigator.

Parent topic: [Field variables](#)

Runtime DCO	

Verification panels that support this variable

Support this variable:	Do not support this variable:
Datacap Navigator	Datacap Desktop
Datacap Web Client (aindex.aspx)	Datacap Web Client (VeriFine.aspx)

Description

If defined for a field (the value must be empty), the field in the Verify panel becomes sticky. If the user enters a value and submits a page, the field value populates across all pages of that type in the current batch. The field must be initially empty for automatic population to work.

Parent topic: [Field variables](#)

Zone_Offset

Applies to

Applies	Does not apply
Setup DCO	Runtime DCO

Description

Used with anchor fields during geometric pattern matching. Specifies the offset in pixels (x, y) between the anchor's position on the runtime page image and its position in the fingerprint image.

Parent topic: [Field variables](#)

Application-specific variable reference

Some variables have been designed for use only with specific Datacap applications.

- [Medical Claims 5010 form configuration parameters](#)
The configuration variables for the Medical Claims 5010 Institutional and Professional forms can be found in the configuration .ini files (5010_Inst.ini and 5010_Prof.ini).

Medical Claims 5010 form configuration parameters

The configuration variables for the Medical Claims 5010 Institutional and Professional forms can be found in the configuration .ini files (5010_Inst.ini and 5010_Prof.ini).

- [5010 Institutional form configuration variables](#)
The following variables are configured in the 5010_Inst.ini configuration file.
- [5010 Professional form configuration variables](#)
The following variables are configured in the 5010_Prof.ini configuration file.

Parent topic: [Application-specific variable reference](#)

5010 Institutional form configuration variables

The following variables are configured in the 5010_Inst.ini configuration file.

Table 1. General

Variable	Default	Description
Implied Decimal	TRUE	When set to TRUE, this boolean variable normalizes all currency data values to have a two-digit value for cents such as 0.00. The variable then formats output for 837 requirements of no leading or trailing zeros.
PreFilter	TRUE	This boolean variable filters character output to EDI elements when set to TRUE. The only characters allowed are Comma, Hyphen, Period, 0-9, and A-Z. Lower case a-z characters are capitalized.

Table 2. Log

Variable	Default	Description
SegmentLog	TRUE	When set to TRUE, this boolean variable adds a single log entry to the RRS log when a segment is counted for adding to the EDI export stream.
SegmentReport	FALSE	When set to TRUE, this variable saves all segment logs added to the export stream and outputs the stream to the RRS log file as a summary after the EDI is created. This variable does not affect output.

Table 3. X12N

Variable	Default	Description
SegmentSeparator	*	Segment Separator character which indicates the start/end of 837 segment elements.
SegmentTerminator	~	Segment Terminator character which indicates the end of a single 837 segment.
RepetitionSeparator	^	Delimiter character used to separate repeated occurrences of a simple data element or composite data structure.

Vari abl e	D e f a u l t	Description
Ter min ator Plu sLin eFe ed	F A L S E	When set to TRUE , this variable adds a line feed and carriage return to the end of each Segment Terminator character. Typically this option is disabled in a production environment, and is only used for debugging the output data. Attention: The program will by default also create a file named EDI_OutputText.txt which performs the same debugging function. This file is generated using the output file to ensure data integrity, and cannot be disabled.
Sup pre ssS Vda teS pan	F A L S E	When this variable is set to TRUE , there is no creation of a DTP RD8 date span in the service line even if Type of Bill is Inpatient type.
AllU ppe rCa se	F A L S E	When set to TRUE , all output characters are converted to uppercase. Restriction: Use of the Prefilter option forces all characters to uppercase regardless of this option.
App end ToL ast GS GE	F A L S E	When merging individual claim EDI files, this option chooses whether the new claim is added as the first claim in a new GS/GE loop in the merged file. When this option is set to FALSE , each claim will be created in a new GS/GE and ST/SE loop in the merged file. When this option is set to TRUE , then each claim will be added to the existing GS/GE loop in the merged file. See the AppendToLastSTSE option for ST/SE information when added with this option set to TRUE .
App end ToL ast STS E	F A L S E	When merging individual claim EDI files, this option chooses whether the new claim is added as the first claim in a new ST/SE loop in the merged file. When this option is set to FALSE , each claim will be created in a new ST/SE loop within the existing GS/GE loop in the merged file. When this option is set to TRUE , then each claim will be added to the existing GS/GE loop in a new ST/SE loop in the merged file.

Table 4. ISA_Header

Vari able	D e f a u l t	Description
Auth oriza tionI nfor mation		Sets value for ISA02. Limited to ten characters, empty by default. A value placed here will automatically set ISA01 from 00 (default-No authorization info present) to 03 (Additional Data Identification).

Variable	Default	Description
SecurityInformation		Sets value for ISA04. Limited to ten characters, empty by default. A value placed here will automatically set ISA03 from 00 (default-No Security Info present) to 01 (Password).
InterchangeSenderQualifier	ZZ	Sets value for ISA05. Code indicating the type of Sender ID. Value codes are: 01, 14, 20, 27, 28, 29, 30, 33 or ZZ. Standard setting is ZZ.
InterchangeSenderID	DACAAP	Sets value for ISA06. Sender ID value, limited to 15 characters.
InterchangeReceiverQualifier	ZZ	Sets value for ISA07. Code indicating the type of Receiver ID. Value codes are: 01, 14, 20, 27, 28, 29, 30, 33 or ZZ. Standard setting is ZZ.
InterchangeReceiverID	00000	Sets value for ISA08. Receiver ID value, limited to 15 characters.
InterchangeControlNumber	BATCH	Sets the value for ISA13. Valid values are BATCH or a fixed value. Use of BATCH will use the current batch ID - right-justified and minus decimal characters. Any other entry is treated as a fixed output value for this element. This value is limited to fifteen numeric characters. Attention: By default, if the Batch ID is a split batch alphanumerical value, then the new value will be the 3 digit Julian Day, followed by the three digit daily batch number, and then concluded with the integer conversion of the alphanumerical split batch value. The maximum length of the split batch number is limited to 3 digits. Alternatively, the value for ISA(13) also supports smart parameters, so that entries can generate or create their own unique values and include it in the export.

Variable	Default	Description
AcknowledgmentRequested	0	Sets value for ISA14. Valid values are 0 (No Acknowledgement Default) or 1 (Interchange Acknowledgement Requested)
TestIndicator	P	Sets value for ISA15. Valid values are P (production) or T (test).
ComponentElementSeparator	<	Sets value for ISA16 the sub-element separator value. Segment Elements have multiple values are required to separate the values with a predefined character. Recommended are : or <.

Table 5. GS_Header

Variable	Default	Description
SenderCode	DATA CAP EXPORT	GS02 value limited to 15 characters.
ReceiverCode	00000	GS03 value limited to 15 characters, Defaults to 00000.
EDIStandard	005010X223A2	GS08 EDI version identifier code.

Table 6. Header

Variable	Default	Description
SubmitterName	The Defaults NM103 setting.	Sets the Loop 1000A NM1(03) value. Limited to 60 characters.
SubmitterPhone	The Defaults PER04 setting.	Sets the Loop 1000A PER(03) value.
SubmitterID	The GS_Header SenderCode setting value. If SenderCode is blank this value defaults to the Defaults NM109 setting.	Sets the Loop 1000A NM1(09) value. The standard setting is usually blank which fills this value with the GS_Header SenderCode value.
ReceiverName	The Defaults NM103 setting.	Sets the Loop 1000B NM1(03) value.
ReceiverID	00000	
SequenceSerialNumber	The value found in ST(02)	Sets the BHT(03) Reference ID value. Limited to 50 characters.

Variable	Default	Description
TransactionSetControlSource	The current Document ID value	Sets ST(02) value to use a Batch parameter. Entry is the parameter name to use as the source for the ST(02) value.
PayerIDNumber	123456789	Sets Loop 2000B SBR(03) value if field 11 Plan and Policy are empty. See also the CheckJobID settings in this setting section. Also sets Loop 2010BB NM1(09) if field 11 Policy number is empty. Note this value is overridden if the setting 2010BB_BC PrimaryPayerIDNumber has a value.
CheckJobID	FALSE	<p>When set to TRUE, this variable enables the ValueByJobID (Key) utility to retrieve values based on the JobID of the task. This allows the processing of claims for multiple entities, such as different payers.</p> <p>For example, the following function looks in the Header section for the number of different JobID's for which to check:</p> <pre>[Header] CheckJobID=TRUE/FALSE numJobID=2 numJobID[1]=JobName1 numJobID[2]=JobName2</pre> <p>Use values for paramter 'Key' (PayerIDNumber in example) as follows:</p> <pre>[JobName1] PayerIDNumber=1111111 [JobName2] PayerIDNumber=2222222</pre> <p>The example shows ini entries numJobID, numJobID[n] and JobName[n] PayerIDNumber that must be created by the user.</p>

Table 7. FileNameFormat

Variable	Default	Description
FileHeader	00501_	The default file name is the Page or Doc ID with decimals removed and spaces replaced with the underscore character. This is an option to place the specified text leading the default file name. For example if the Doc ID 2012004.03 is used and the FileHeader contains 00501_ then the file name becomes 00501_201200403. This can be used in conjunction with the FileTrailer option.
FileTrailer		The default file name is the Page or Doc ID with decimals removed and spaces replaced with the underscore character. This is an option to place the specified text trailing the default file name. For example if the Doc ID 2012004.03 is used and the FileTrailer contains _0500 then the file name becomes 201200403_0500. This can be used in conjunction with the FileHeader option.
MergeFileHeader	5010	If no File name is specified when calling to merge the 5010 file, the default file name becomes the batch Id. This is an option to place the specified text leading the default file name.
MergeFileTrailer		If no File name is specified when calling to merge the 5010 file, the default file name becomes the batch Id. This is an option to place the specified text trailing the default file name. The default value is blank.

Table 8. Defaults

Variable	Default	Description
NM103		General default for NM1(03) segment element values. Loops 1000A, 1000B, 2010BA, 2010CA, 2310A, 2310B, 2310C, 2330A, 2330B, 2420A.
NM104		General default for NM1(04) segment element values. Loops 2010BA, 2010CA, 2310A, 2310B, 2310CDF, 2330A, 2420A.
NM109		General default for NM1(09) segment element values. Loops 1000A, 1000B, 2010BA, 2310A, 2310CDF, 2330A, 2330B.
N301		General default for N3(01) segment element values. All instances.
N401		General default for N4(01) segment element values. All instances.
N402		General default for N4(02) segment element values. All instances.
N403		General default for N4(03) segment element values. All instances.

Variable	Default	Description
PER04		General default for PER(04) segment element values. Loop 1000A, 2010AA
DMG02		General default for DMG(02) segment element values. Loop 2000CA, 2010BA.
CLM07		Value for setting Loop 2300 CLM(07). Default is blank.
CLM08		Value for setting Loop 2300 CLM(08) if field 53 is not N or Y. Default is blank.
CLM09		Value for setting Loop 2300 CLM(09) if field 52 is not I or Y. Default is blank.
HI_BK		Default principle diagnosis code if no diagnosis fields on the claim are filled. Default is blank. Loop 2300 HI BK.
SV201		Default Loop 2400 SV2(1) RevCode if captured value is blank or all zeros. Default is blank.
OccDt		Default Date Value. Loop 2300 DTP 434 & 345, also Loop 2300 default date if procedure date is not valid, and occurrence span dates, Loop 2400 DTP 472

Table 9. ImpliedDecimalON

Variable	Default	Description
BuildLog	FALSE	TRUE/FALSE value. Adds RRS logging when building EDI if the ImpliedDecimal setting is enabled. See the General settings.

Table 10. 2000B

Variable	Default	Description
SubscriberIsPatient	FALSE	TRUE/FALSE. Setting for forcing EDI to output Subscriber is the Patient. Default is false.
UseCurrentPayer	See description	Value is a Regular expression that is tested against the value in field 50. If a match is found this is the Payer for this claim. Otherwise default is the last payer a, b or c on the completed form. Example: If payer is always Medicaid. Use of regular expression <code>MED[iI11T]iI11T]D</code> will find the correct field 50 line to assign. Default is blank and uses last payer on form.

Variable	Default	Description
UsePreviousPayer	Sequence	Value is a Regular expression that is tested against the value in field 50. If a match is found the line before the match becomes the Payer info for this claim. Otherwise default is the last payer a, b or c on the completed form. Example: If payer is always listed before Medicaid. Use of regular expression MED[<i>iI11T</i>]CA[<i>iI11T</i>]D will find the prior field 50 line to assign. Default is blank and uses last payer on form. Attention: Both UseCurrentPayer and UsePreviousPayer can be used simultaneously. Use Previous takes priority if both expressions match.

Table 11. 2010BB_BC

Variable	Default	Description
PrimaryPayerName		Setting to use for all processed claims for Loop 2010BB NM1(03). Takes priority over captured value as well as default value set in Header PayerName section.
PrimaryPayerIDNumber		Setting to use for all processed claims for Loop 2010BB NM1(09). Takes priority over default value set in Header PayerIDNumber section.
PrimaryPayerAddress		Value to place in Loop 2010BB N3(01).
PrimaryPayerCity		Value to place in Loop 2010BB N4(01).
PrimaryPayerState		Value to place in Loop 2010BB N4(02).
PrimaryPayerZip		Value to place in Loop 2010BB N4(03).

Table 12. 2300

Variable	Default	Description
PatientReason		Default value for Patient Reason for admission if field 69 is blank. Outpatient Claims only, default is blank.
DischargeStatus	01	Default value for Loop 2300 CL1(03) if field 17 is blank.
CalculateTotal	TRUE	TRUE/FALSE. Option to calculate the lineitem total using service line data instead of the field 28 total charges field for Loop 2300 CLM(02).

Table 13. 2310A

Variable	Default	Description
CreateOutpatient	FALSE	TRUE/FALSE. Setting to optionally always export Loop 2310A even if Type of Bill is outpatient.
ExportSecondaryID	FALSE	TRUE/FALSE. Optionally export a REF 1G segment in this loop with the value from field 76.

Table 14. 2320

Variable	Default	Description
OI03	Y	Value for Loop 2320 OI(03).
OI06	Y	Value for Loop 2320 OI(06).

Table 15. 2330A

Variable	Default	Description
UsePatientAddress	FALSE	TRUE/FALSE. Option to use always use field 9 address values for Loop 2330A N4 segment if patient is not the subscriber.
SubscriberCity		Default value for Loop 2330A N4(01) if patient is not the subscriber and UsePatientAddress is not enabled.
SubscriberState		Default value for Loop 2330A N4(02) if patient is not the subscriber and UsePatientAddress is not enabled
SubscriberZip		Default value for Loop 2330A N4(03) if patient is not the subscriber and UsePatientAddress is not enabled

Table 16. 2330B

Variable	Default	Description
PayerCity		Value to place in Loop 2330B N4(01).
PayerState		Value to place in Loop 2330B N4(02).
PayerZip		Value to place in Loop 2330B N4(03).
PayerIDNumber		Value to place in loop 2330B NM1(09) if field 51 is blank.

Table 17. N3

Variable	Default	Description
BuildLog	FALSE	TRUE/FALSE value. Adds more detailed RRS logging when creating N3 segments.
KeepTrailingSeparators	FALSE	TRUE/FALSE value. Option to not remove blank trailing elements from N3 segments.

Table 18. N4

Variable	Default	Description
BuildLog	FALSE	TRUE/FALSE value. Adds more detailed RRS logging when creating N4 segments.
KeepTrailingSeparators	FALSE	TRUE/FALSE value. Option to not remove blank trailing elements from N4 segments.

Table 19. REF

Variable	Default	Description
BuildLog	FALSE	TRUE/FALSE value. Adds more detailed RRS logging when creating REF segments.

Parent topic: [Medical Claims 5010 form configuration parameters](#)

5010 Professional form configuration variables

The following variables are configured in the 5010_Prof.ini configuration file.

Table 1. General

Variable	Default	Description
ImpliedDecimalON	TRUE	When set to TRUE, this boolean variable normalizes all currency data values to have a two-digit value for cents such as 0.00. The variable then formats output for 837 requirements of no leading or trailing zeros.
PreFilter	TRUE	This boolean variable filters character output to EDI elements when set to TRUE. The only characters allowed are Comma, Hyphen, Period, 0-9, and A-Z. Lower case a-z characters are capitalized.

Table 2. Log

Variable	Default	Description
SegmentLog	TRUE	When set to TRUE, this boolean variable adds a single log entry to the RRS log when a segment is counted for adding to the EDI export stream.
SegmentReport	FALSE	When set to TRUE, this variable saves all segment logs added to the export stream and outputs the stream to the RRS log file as a summary after the EDI is created. This variable does not affect output.

Table 3. X12N

Variable	Default	Description
SegmentSeparator	*	Segment Separator character which indicates the start/end of 837 segment elements.
SegmentTerminator	~	Segment Terminator character which indicates the end of a single 837 segment.

Variable	Default	Description
RepetitionSeparator	^	Delimiter character used to separate repeated occurrences of a simple data element or composite data structure.
TerminatorPlusLineFeed	FALSE	When set to <code>TRUE</code> , this variable adds a line feed and carriage return to the end of each Segment Terminator character. Typically this option is disabled in a production environment, and is only used for debugging the output data. Attention: The program will by default also create a file named EDI_OutputText.txt which performs the same debugging function. This file is generated using the output file to ensure data integrity, and cannot be disabled.
AllUpperCase	FALSE	When set to <code>TRUE</code> , all output characters are converted to uppercase. Restriction: Use of the Prefilter option forces all characters to uppercase regardless of this option.
AppendToLastGS/GE	FALSE	When merging individual claim EDI files, this option chooses whether the new claim is added as the first claim in a new GS/GE loop in the merged file. When this option is set to <code>FALSE</code> , each claim will be created in a new GS/GE and ST/SE loop in the merged file. When this option is set to <code>TRUE</code> , then each claim will be added to the existing GS/GE loop in the merged file. See the AppendToLastSTSE option for ST/SE information when added with this option set to <code>TRUE</code> .
AppendToLastSTSE	FALSE	When merging individual claim EDI files, this option chooses whether the new claim is added as the first claim in a new ST/SE loop in the merged file. When this option is set to <code>FALSE</code> , each claim will be created in a new ST/SE loop within the existing GS/GE loop in the merged file. When this option is set to <code>TRUE</code> , then each claim will be added to the existing GS/GE loop in a new ST/SE loop in the merged file.

Table 4. ISA Header

Variable	Default	Description
AuthorizationInformation		Sets the value for ISA02. Limited to ten characters, and blank by default. A value placed here will automatically set ISA01 from 00 (default-No authorization info present) to 03 (Additional Data Identification).
SecurityInformation		Sets the value for ISA04. Limited to ten characters, and blank by default. A value placed here will automatically set ISA03 from 00 (default-No Security Info present) to 01 (Password).

Variable	Default	Description
InterchangeSenderQualifier	Z Z	Sets the value for ISA05. This is a code indicating the type of Sender ID. Value codes are: 01, 14, 20, 27, 28, 29, 30, 33 or ZZ.
InterchangeSenderID		Sets value for ISA06. Sender ID value, limited to 15 characters.
InterchangeReceiverQualifier	Z Z	Sets the value for ISA07. This is a code indicating the type of Receiver ID. Value codes are: 01, 14, 20, 27, 28, 29, 30, 33 or ZZ.
InterchangeReceiverID		Sets value for ISA08. Receiver ID value, limited to 15 characters.
InterchangeControlNum		Sets the value for ISA13. Valid values are BATCH or a fixed value. Use of BATCH will use the current batch ID - right-justified and minus decimal characters. Any other entry is treated as a fixed output value for this element. This value is limited to fifteen numeric characters.
AcknowledgmentRequested		Sets the value for ISA14. Valid values are 0 (No Acknowledgement Default) or 1 (Interchange Acknowledgement Requested).
TestIndicator	P	Sets the value for ISA15. Valid values are P (production) or T (test).
ComponentElementSeparator	<	Sets the value for ISA16 the sub-element separator value. Segment elements that have multiple values are required to separate the values with a predefined character. Recommended values include : or <.

Table 5. GS_Header

Variable	Default	Description
SenderCode	DATA CAP EXPORT	GS02 value limited to 15 characters.
ReceiverCode	00000	GS03 value limited to 15 characters, Defaults to 00000.
EDIstandard	005010X222A1	GS08 EDI version identifier code.

Table 6. Header

Variable	Default	Description
SubmitterName	The Defaults NM103 setting.	Sets the Loop 1000A NM1(03) value. Limited to 60 characters.
SubmitterPhone	The Defaults PER04 setting.	Sets the Loop 1000A PER(03) value.

Variable	Default	Description
SubmitterID	The GS_Header SenderCode setting value. If SenderCode is blank this value defaults to the Defaults NM109 setting.	Sets the Loop 1000A NM1(09) value. The standard setting is usually blank which fills this value with the GS_Header SenderCode value.
ReceiverName	The Defaults NM103 setting.	Sets the Loop 1000B NM1(03) value.
ReceiverID	00000	
SequenceSerialNumber	The value found in ST(02)	Sets the BHT(03) Reference ID value. Limited to 50 characters.
TransactionSetControlSource	The current Document ID value	Sets ST(02) value to use a Batch parameter. Entry is the parameter name to use as the source for the ST(02) value.
PayerIDNumber	123456789	Sets Loop 2000B SBR(03) value if field 11 Plan and Policy are empty. See also the CheckJobID settings in this setting section. Also sets Loop 2010BB NM1(09) if field 11 Policy number is empty. Note this value is overridden if the setting 2010BB_BC PrimaryPayerIDNumber has a value.

Variable	Default	Description
CheckJobID	FALSE	<p>When set to TRUE, this variable enables the ValueByJobID (Key) utility to retrieve values based on the JobID of the task. This allows the processing of claims for multiple entities, such as different payers.</p> <p>For example, the following function looks in the Header section for the number of different JobID's for which to check:</p> <pre>[Header] CheckJobID=TRUE/FALSE numJobID=2 numJobID[1]=JobName1 numJobID[2]=JobName2</pre> <p>Use values for paramter 'Key' (PayerIDNumber in example) as follows:</p> <pre>[JobName1] PayerIDNumber=1111111 [JobName2] PayerIDNumber=2222222</pre> <p>The example shows ini entries numJobID, numJobID[n] and JobName[n] PayerIDNumber that must be created by the user.</p>

Table 7. FileNameFormat

Variable	Default	Description
FileHeader	0	The default file name is the Page or Doc ID with decimals removed and spaces replaced with the underscore character. This is an option to place the specified text leading the default file name. For example if the Doc ID 2012004.03 is used and the FileHeader contains 00501_ then the file name becomes 00501_201200403. This can be used in conjunction with the FileTrailer option.
FileTrailer	0	The default file name is the Page or Doc ID with decimals removed and spaces replaced with the underscore character. This is an option to place the specified text trailing the default file name. For example if the Doc ID 2012004.03 is used and the FileTrailer contains _0500 then the file name becomes 201200403_0500. This can be used in conjunction with the FileHeader option.

Variable	Default	Description
MergeFileHeader	5010-	If no File name is specified when calling to merge the 5010 file, the default file name becomes the batch Id. This is an option to place the specified text leading the default file name.
MergeFileTrailer		If no File name is specified when calling to merge the 5010 file, the default file name becomes the batch Id. This is an option to place the specified text trailing the default file name. The default value is blank.

Table 8. Defaults

Variable	Default	Description
NM103		General default for NM1(03) segment element values. Loops 1000A, 1000B, 2010BA, 2010CA, 2310A, 2310B, 2310C, 2330A, 2330B, 2420A.
NM104		General default for NM1(04) segment element values. Loops 2010BA, 2010CA, 2310A, 2310B, 2310CDF, 2330A, 2420A.
NM109		General default for NM1(09) segment element values. Loops 1000A, 1000B, 2010BA, 2310A, 2310CDF, 2330A, 2330B.
N301		General default for N3(01) segment element values. All instances.
N401		General default for N4(01) segment element values. All instances.
N402		General default for N4(02) segment element values. All instances.
N403		General default for N4(03) segment element values. All instances.
PER04		General default for PER(04) segment element values. Loop 1000A, 2010AA
DMG02		General default for DMG(02) segment element values. Loop 2000CA, 2010BA.

Table 9. ImpliedDecimalON

Variable	Default	Description
BuildLog	FALSE	TRUE/FALSE value. Adds RRS logging when building EDI if the ImpliedDecimal setting is enabled. See the General settings.

Table 10. 2000B

Vari able	D e f a u l t	Description
Sub scri berI sPat ient	F A L S E	TRUE/FALSE. Setting for forcing EDI to output Subscriber is the Patient. Default is false.
SBR 03		Sets a default value for SBR03 to be used if the 11IPolNo field is empty.
NO_ SBR 03	F A L S E	When set to TRUE SBR03 will always map as empty. When this variable is set to TRUE and the SBR04 variable is used, then if the if 11cIPlan field is blank, the value for SBR03 will be mapped to the Header section's PayerIDNumber variable.
SBR 04		Sets a default value for SBR04 to be used if the 11cIPlan field is empty.
SBR 09	Z Z	Setting for Loop 2000B SBR(09) claim filing indicator code. Standard values are 11 to 17, AM, BL, CH, CI, DS, FI, HM, LM, MA, MB, MC, OF, TV, VA, WC, and ZZ. This setting is FindValue enabled, so if another value is placed in this setting on the current page, then the document will be searched for a field or variable with this value. The search order is: <ul style="list-style-type: none"> 1. Page Field 2. Page Variable 3. Document Variable <p>If no DCO nodes with this id are found, the value is used.</p>

Table 11. 2010AA

Variabl e	D e f a u l t	Description
BOXPat tern	T R U E	Setting this attribute to TRUE enables detection using a regular expression for <i>PO Box</i> values in the loop 2010AA street address field. If a PO Box is detected, the field value is set to the DefaultStreetAddress setting value by default.
Remap BOX2P ayTo	F A L S E	When this variable is set to TRUE, if a POBox is detected in the field 32 address line, and the field 31 address also has a value, then the field 32 address is remapped to loop 2010AB and the field 31 address is mapped to loop 2010AA.
Default StreetA ddress		Value to replace in the street address field if a PO Box is detected in the address field.

Table 12. 2010BB_BC

Variable	Default	Description
PrimaryPayerName		Setting to use for all processed claims for Loop 2010BB NM1(03). Takes priority over captured value as well as default value set in Header PayerName section.
PrimaryPayerIDNumber		Setting to use for all processed claims for Loop 2010BB NM1(09). Takes priority over default value set in the Header section's PayerIDNumber variable.
PrimaryPayerAddress		Value to place in Loop 2010BB N3(01).
PrimaryPayerCity		Value to place in Loop 2010BB N4(01).
PrimaryPayerState		Value to place in Loop 2010BB N4(02).
PrimaryPayerZip		Value to place in Loop 2010BB N4(03).

Table 13. 2300

Variable	Default	Description
CalculateTotal	TRUE	TRUE/FALSE. Option to calculate the lineitem total using service line data instead of the field 28 total charges field for Loop 2300 CLM(02).
REF D9		Value for Loop 2300 Ref D9 segment. By default, this value is blank, and no Ref D9 is exported. This setting is FindValue enabled, so if another value is placed in this setting on the current page, then the document will be searched for a field or variable with this value. The search order is: <ol style="list-style-type: none"> 1. Page Field 2. Page Variable 3. Document Variable <p>If no DCO nodes with this id are found, the value is used.</p>
REF EA	The <i>dvDCN</i> document variable	Value for Loop 2300 Ref EA segment. This setting is FindValue enabled, so if another value is placed in this setting on the current page, then the document will be searched for a field or variable with this value. The search order is: <ol style="list-style-type: none"> 1. Page Field 2. Page Variable 3. Document Variable <p>If no DCO nodes with this id are found, the value is used.</p>

Table 14. 2310A

Variable	Default	Description
----------	---------	-------------

Variable	Default	Description
AlwaysInclude	FALSE	Setting this value to TRUE will always export Loop 2310A even if fields 23 or 19 do not have a captured value.

Table 15. 2320

Variable	Default	Description
SearchOrder	Z	<p>Value for the Loop 2320 SPR(09) claim filing indicator code. Standard values are 11 to 17, AM, BL, CH, CI, DS, FI, HM, LM, MA, MB, MC, OF, TV, VA, WC, and ZZ. This setting is FindValue enabled, so if another value is placed in this setting on the current page, then the document will be searched for a field or variable with this value. The search order is:</p> <ol style="list-style-type: none"> 1. Page Field 2. Page Variable 3. Document Variable <p>If no DCO nodes with this id are found, the value is used.</p>

Table 16. Loop2320

Variable	Default	Description
OI03	Y	Value for Loop 2320 OI(03).
OI04		Value for Loop 2320 OI(04).
OI06	Y	Value for Loop 2320 OI(06).

Table 17. 2330B

Variable	Default	Description
OtherPayerAddress		Value to place in Loop 2330B N3(01)
OtherPayerCity		Value to place in Loop 2330B N4(01).
OtherPayerState		Value to place in Loop 2330B N4(02).
OtherPayerZip		Value to place in Loop 2330B N4(03).

Table 18. 2400

Variable	Default	Description
AutoPopulateUnit	TRUE	When set to TRUE, this variable will auto populate SV1(03) with MJ and SV1(04) with the service line INFO field if the INFO field has a captured value. Otherwise SV1(03) uses UN and SV1(04) is filled with the Days field value.

Variable	Default	Description
RoundCharges	TRUE	When set to TRUE, this variable toggles rounding of SV1(04) to a whole number.

Table 19. N3

Variable	Default	Description
POBoxDetect	FALSE	When set to TRUE this variable will enable evaluation of all N3 segments for POBox values, and will remap the POBox to the second address line in the N3 segment if the second line is blank.
BuildLog	FALSE	When set to TRUE, this variable will add more detailed RRS logging when creating N3 segments.
KeepTrailingSeparators	FALSE	When set to TRUE, this variable will not remove blank trailing elements from N3 segments.

Table 20. N4

Variable	Default	Description
BuildLog	FALSE	TRUE/FALSE value. Adds more detailed RRS logging when creating N4 segments.
KeepTrailingSeparators	FALSE	TRUE/FALSE value. Option to not remove blank trailing elements from N4 segments.

Table 21. REF

Variable	Default	Description
BuildLog	FALSE	TRUE/FALSE value. Adds more detailed RRS logging when creating REF segments.

Action library summaries

Information is available for all actions from within Datacap Studio. To access the embedded help, select an action on the Actions Library tab and click the  button.

Descriptions of the available actions are provided in the sections that follow.

- [Global actions](#)
You can use the global actions with any of the Datacap applications.
- [Application specific actions](#)
The Datacap applications use actions that are specific to them.

Global actions

You can use the global actions with any of the Datacap applications.

- [Datacap supported image types](#)
Datacap supports different input files and formats as an image input for the recognition and other different tasks.
- [Autodoc actions](#)
Use the Autodoc actions to create fingerprints and match pages to fingerprints by using the local fingerprint service or a web fingerprint service.
- [Barcode_P actions](#)
Use the Barcode_P actions to locate and read PDF-417 barcodes.
- [ClassifyLayout actions](#)
Use the ClassifyLayout actions to identify page types based on page layout templates.
- [CC actions](#)
Use the CC actions to identify types of pages and other text with IBM® Content Classification technology.
- [Cco2cco actions](#)
Use the Cco2cco actions to sort and filter the words and lines in a fingerprint CCO file.
- [CheckProcessing actions](#)
Use the Check Processing actions to extract data from checks originating from Argentina, Brazil, Canada, France, India, UK and US.
- [CMISClient actions](#)
Content Management Interoperability Services (IBM CMIS) is an open standard that CMISClient actions use to enable communication between Datacap applications and content management systems over the internet.
- [ColorToBW actions](#)
Use the ColorToBW actions to change the color depth of an image.
- [Convert actions](#)
Use the Convert actions to convert various electronic document files into TIFF image files.
- [DatacapBOX actions](#)
Use the DatacapBOX actions to move files between your Datacap system and Box.com.
- [Dcclip actions](#)
Use the Dcclip action to clip a portion of each page image and save it as a separate TIFF file.
- [DCImageFix actions](#)
Use the DCImageFix actions to clean up and enhance page images.
- [DCO actions](#)
Use the DCO actions to set up and modify the runtime batch hierarchy (runtime DCO) information.
- [dcpdf actions](#)
Use the dcpdf actions to convert PDF files to TIFF at the start of the workflow. You can also convert the TIFF files in a document into a PDF file.
- [DocumentAnalytics actions](#)
Use the DocumentAnalytics actions to identify the content type of text blocks and extract data elements from the page layout file.
- [DocumentAnalytics.VisualRecognitionClassifier actions](#)
Visual Recognition Classifier is an IBM Watson service, which can be trained to classify image-based documents. The default instance name: DocumentAnalytics.Undoable-in-transactional.
- [DocumentAnalytics.NaturalLanguageClassifier actions](#)
Natural Language Classifier is an IBM Watson service, which can be trained to classify documents or sections of documents. That based on the text that is contained in the document or the section of a document. The default instance name: DocumentAnalytics.NaturalLanguageClassifierActions.
- [Documentum actions](#)
Use the Documentum actions to upload documents to an EMC Documentum repository.
- [Email actions](#)
Use the email actions to compose and then send an email by using CDOSYS and an SMTP server. These actions also support Outlook, which requires the Outlook user to be logged on to the computer and security prompts might be displayed for each message.

- [Equalize actions](#)
Use the Equalize action to equalize the x and y resolutions of an image.
- [Ewsml actions](#)
Use the Ewsml actions to import image file attachments from an Exchange Server into the current batch by using Exchange Web Service (EWS).
- [Export actions](#)
Use the Export actions to set up and write information to the export text file.
- [ExportDB actions](#)
Use the ExportDB actions to set up and write information to an export database. You build the record in memory before you commit it to the database by using AddRecord.
- [ExportXML actions](#)
Use the ExportXML actions to set up and write information to an export XML file.
- [FileIO actions](#)
Use the FileIO actions to do various file system functions.
- [FileNetIDM actions](#)
Use the FileNetIDM actions to upload documents into an FileNet® Image Services library
- [FileNet P8 actions](#)
Use the FileNet P8 actions to export data to a FileNet P8 repository.
- [FingerprintMaintenance actions](#)
Use the FingerprintMaintenance actions to delete fingerprints from the fingerprint library of the application.
- [FPXML actions](#)
Use the FPXML actions to store zone coordinates in an external XML file instead of the document hierarchy (setup DCO). These actions are useful for porting fingerprints between systems or to avoid making frequent modifications to the document hierarchy.
- [Grayscale actions](#)
Use the Grayscale action to convert grayscale TIFF images to black-and-white.
- [HandwritingRecognition actions](#)
Use the Handwriting Recognition actions to perform cursive recognition of the configured fields using the Parascript FormXtra Recognition Engine.
- [IBMCM actions](#)
Use the IBMCM actions to upload documents into an IBM Content Manager Connector repository.
- [ICR_C actions](#)
Use the ICR_C actions to recognize constrained (unconnected) hand or computer printed characters. These actions use the OpenText RecoStar engine.
- [ImageConvert actions](#)
Use the ImageConvert actions to combine image files or to convert image files to JPEG or TIFF.
- [ImageFix actions](#)
The ImageFix actions are older versions of the DCImageFix action. Use the DCImageFix actions instead.
- [Email actions](#)
Use the Email actions to import image attachments from a mail server into the current batch by using IMAP.
- [Imprint actions](#)
Use the Imprint actions to imprint text over an image, or for blackout or whiteout redactions.
- [Intellocate actions](#)
Use the Intellocate actions to update the existing field position information in the document hierarchy (setup DCO) or to add position information for a new fingerprint.
- [Invoice actions](#)
Use the Invoice actions to process invoices by using the Datacap Accounts Payable application.
- [IOverlay actions](#)
Use the IOverlay actions to combine the current page image with a background image. You can use this action to reapply a form background that dropped out during scanning.

- [Locate actions](#)
Use the Locate actions in combination with full text recognition to locate words or regular expressions on the page. And to move around the page by line or word.
- [Lookup actions](#)
Use the Lookup actions to validate field values by using database lookups and populate fields with lookup results.
- [MC_Identify](#)
Use the MC_Identify actions to identify claim forms in a batch.
- [MC_Validation](#)
Use the MC_Validation actions to validate medical claim form information.
- [mvscan actions](#)
Use mvscan actions in place of the vscan actions to create batches from files that are stored on your local disk. The mvscan actions can handle large numbers of files that are stored in the input folder.
- [Maintenance Manager actions](#)
The Maintenance Manager actions are divided into setup, batch processing, logging, and reporting categories.
- [OCR_J actions](#)
The OCR_J actions use the Rosetta Stone Japanese OCR engine to perform OCR for Japanese machine print and Japanese handwriting.
- [OCR_A actions](#)
Use the OCR_A actions to do text recognition by using the FineReader OCR engine.
- [OCR_N actions](#)
Use the OCR_N actions to do recognition by using the NovoDynamics engine. The OCR_N actions can run recognition on a full page or on all of the field zones that are defined for the current page.
- [OCR_SR actions](#)
Use the OCR_SR actions to do recognition and image rotation by using the updated Nuance OmniPage OCR engine. You can run recognition actions on field zones and pages. The results can be processed by actions in other libraries and ultimately displayed to the user for verification. The results can also be written out to files in several possible file formats.
- [OpenTextFaxServer actions](#)
Use the OpenTextFaxServer actions to import faxes from an OpenTextFaxServer.
- [PatternMatch actions](#)
Use the PatternMatch actions for pattern-based page identification and for page registration (alignment). Page registration is important when you are working with OMR check boxes.
- [Picture actions](#)
Use the Picture actions to do field validations by picture strings. Picture strings define the supported format of a field such as a social security number, phone number, date.
- [POLR actions](#)
Use the POLR action matches line items from your invoice image to the corresponding purchase order.
- [Recog_Shared actions](#)
Use the Recog_Shared actions to do various fingerprint and recognition-related functions.
- [runner actions](#)
Use the runner actions to do miscellaneous utility functions.
- [SharedRecognitionTools actions](#)
Use the actions in this library after you perform OCR. For example, you might perform OCR with actions from the OCR_A or OCR_SR libraries and then use the actions in this library. Actions that can produce the layout XML include OCR_SR.Recognize and OCR_A.Recognize, both of which can process color images and PDF files. To use the Locate actions and perform click 'n' key during verification, use the action CreateCcoFromLayout to create a CCO file for the page after producing the layout XML file.
- [SignatureValidation actions](#)
Use the Signature Validation actions to detect and validate signatures on a document or zone.
- [SPEXport actions](#)
Use the SPEXport actions to upload documents to a Microsoft SharePoint library.

- [Split actions](#)
Use the Split action to split a batch into smaller batches so each can be processed separately.
- [Statistics actions](#)
These statistics actions are used by the Profile Statistics and Export Statistics rulesets to save information about field recognition accuracy and page classification accuracy.
- [TifMerge actions](#)
Use the TifMerge actions to combine individual TIFF images into a multi-page TIFF file. This action is typically run at the end of the workflow so that you can upload or release the batch images as a single file.
- [TM524 actions](#)
The TM524 actions are for compatibility with older versions of Datacap and are no longer used
- [Validations actions](#)
Use the Validations actions to check and modify the content and format of the current field value.
- [Vote actions](#)
Use the Vote action when you do multi-pass data entry to check whether the first and second passes match.
- [Vscan actions](#)
Use the Vscan actions to create a batch by using existing image files.
- [Web Services actions](#)
This library of actions facilitates communication with external web services. You can use these actions to retrieve formatted responses or image files. The actions can handle both XML and JSON formatted responses, with XML as the default choice. You will need to know the web service's endpoint, any applicable parameters, and the response type before using these actions.
- [Zones actions](#)
Use the Zones actions to work with the zones that define the position of each field on the page.

Parent topic: [Action library summaries](#)

Datacap supported image types

Datacap supports different input files and formats as an image input for the recognition and other different tasks.

When you perform recognition of text or barcodes, it is recommended to use a file format that supports lossless compression. Lossy compression, such as JPEG compression, is intended for photographic content, not textual content. Lossy compression can cause line edges to become soft or blurred, which can degrade characters and barcodes, causing recognition errors.

The following is the list of image types which Datacap supports:

Action Library	Action/Feature	Input Image Type	Color Depth	Compression	Notes
Barcode P	All actions	TIF, BMP, JPEG, PNG	Up to 24 bit	TIF - Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	

Action Library	Action/Feature	Input Image Type	Color Depth	Compression	Notes
ColorToBW	C2BW_Convert	TIF, BMP, JPEG, PNG	Up to 24 bit	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	
Convert.Images	ImageToTIFF	BMP, JPEG, PNG (non-interlaced)	Up to 24 bit	Uncompressed, Standard	
Dcclip	dci_clipfield	TIF		CCITT Group 3 & 4, Huffman encoding, LZW, Packbits, Uncompressed	
Grayscale	ConvertGrayToBW	TIF	8 bpp	Huffman encoding, LZW, Packbits, Uncompressed	
ICR_C	All image input actions	TIF	1 bpp	Fax, Huffman, LZW, Uncompressed	
CheckProcessing	ProcessCheck	JPEG	Depends on country	N/A	
CheckProcessing	ProcessCheck	TIF	Depends on country	CCITT Group 3 & 4, Huffman encoding, LZW, Packbits, Uncompressed	
Image Enhancement	Adjust Brightness/Contrast	TIF, JPEG, BMP	8 gray, 24 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	It does not support 1, 8 bpp color.

Action Library	Action/Feature	Input Image Type	Color Depth	Compression	Notes
Image Enhancement	Auto Rotate	TIF, BMP	1 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed	It does not support 8 color, 8 gray, 24 bpp.
Image Enhancement	Binaries	TIF, JPEG, BMP	1, 8 color, 8 gray, 24 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	
Image Enhancement	Border Removal	TIF, JPEG, BMP	1, 8 gray, 24 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	It does not support 8 color.
Image Enhancement	Close Filter	TIF, JPEG, BMP	8 gray, 24 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	It does not support 1, 8 color bpp.

Action Library	Action/Feature	Input Image Type	Color Depth	Compression	Notes
Image Enhancement	Deskew	TIF, JPEG, BMP	1, 8 gray, 24 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	It does not support 8 color.
Image Enhancement	Despeckle	TIF, BMP	1 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	It does not support 8 color, 8 gray, 24 bpp.
Image Enhancement	Dilate	TIF, JPEG, BMP	1, 8 gray, 24 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	It does not support 8 color.
Image Enhancement	Erode	TIF, JPEG, BMP	1, 8 gray, 24 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	It does not support 8 color.

Action Library	Action/Feature	Input Image Type	Color Depth	Compression	Notes
Image Enhancement	Flip	TIF, JPEG, BMP	1, 8 gray, 24 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	It does not support 8 color.
Image Enhancement	Image Detergent	TIF, JPEG, BMP	24 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	It does not support 1, 8 color, 8 gray bpp.
Image Enhancement	Image Registration	TIF, JPEG, BMP	1, 8 gray, 24 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	It does not support 8 color.
Image Enhancement	Inverse Text Correction	TIF, BMP	1 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed	It does not support 8 color, 8 gray, 24 bpp.

Action Library	Action/Feature	Input Image Type	Color Depth	Compression	Notes
Image Enhancement	Mirror	TIF, JPEG, BMP	1, 8 gray, 24 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	It does not support 8 color.
Image Enhancement	Remove Blobs	TIF, BMP	1 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed	It does not support 8 color, 8 gray, 24 bpp.
Image Enhancement	Remove Combs	TIF, BMP	1 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed	It does not support 8 color, 8 gray, 24 bpp.
Image Enhancement	Remove Dot Shading	TIF, BMP	1 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed	It does not support 8 color, 8 gray, 24 bpp.
Image Enhancement	Remove Hole Punch	TIF, BMP	1 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed	It does not support 8 color, 8 gray, 24 bpp.

Action Library	Action/Feature	Input Image Type	Color Depth	Compression	Notes
Image Enhancement	Remove Lines	TIF, BMP	1 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed	It does not support 8 color, 8 gray, 24 bpp.
Image Enhancement	Rotate Image	TIF, JPEG, BMP	1, 8 color, 8 gray	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	
Image Enhancement	Smooth Background	TIF, JPEG, BMP	8 gray, 24 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed JPEG - Standard Encoding	It does not support 1, 8 color, 8 gray bpp.
Image Enhancement	Smooth Objects	TIF, BMP	1 bpp	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed	It does not support 8 color, 8 gray, 24 bpp.
ImageConvert	AppendAllImages	TIF	1 bpp, 8 bpp grayscale, 24 bpp	TIF - CCITT Group 3 & 4, Huffman encoding, LZW, Packbits, Uncompressed	It does not support 8 bpp color.
ImageConvert	AppendAllImages_ByType	TIF	1 bpp, 8 bpp grayscale, 24 bpp	CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed	It does not support 8 bpp color.

Action Library	Action/Feature	Input Image Type	Color Depth	Compression	Notes
ImageConvert	AppendImage	TIF	1 bpp, 8 bpp grayscale, 24 bpp	CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed	It does not support 8 bpp color.
ImageConvert	AppendImage_StartAsNew	TIF	1 bpp, 8 bpp grayscale, 24 bpp	CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed	It does not support 8 bpp color.
ImageConvert	ConvertToJPEG	TIF, BMP, PNG	Up to 24 bit	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed	
ImageConvert	ConvertToTIFF	BMP, JPEG, PNG	Up to 24 bit	Uncompressed, Standard	
ImageConvert	RescaleImage	TIF, BMP, JPEG, PNG	Up to 24 bit	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed	
ImageConvert	SetImageDPIByWidth	TIF, BMP, JPEG, PNG	Up to 24 bit	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed	
OCR_A	All image input actions	TIF, BMP, JPEG, PNG	Up to 24 bit	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed	

Action Library	Action/Feature	Input Image Type	Color Depth	Compression	Notes
OCR_SR	All impage input actions	TIF, BMP, JPEG, PNG	Up to 24 bit	TIF - CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed BMP - Uncompressed	
TifMerge	TifMerge_Merge Images	TIF		CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed	
TifMerge	TifMerge_MyImage	TIF		CCITT Group 3 & 4, Huffman, LZW, Packbits, Uncompressed	

Parent topic: [Global actions](#)

Autodoc actions

Use the Autodoc actions to create fingerprints and match pages to fingerprints by using the local fingerprint service or a web fingerprint service.

The Autodoc actions connect you to a fingerprint service. You run these actions to specify how to create fingerprints, set up fingerprint matching processes, and update fingerprint statistics.

- [BlankPagesIDBySize](#)
Uses the size of the Image file to determine if the file represents a blank page.
- [CalculateOffset](#)
Sets the standard Offset value to be used when matching source pages to fingerprints.
- [CreateFingerprint](#)
Adds the image (TIF) file of the current page and the fingerprint (CCO) file to the fingerprint library of the application. The resulting fingerprint consists of the Image file (.tif) of the page and its Processing file (.cco).
- [DeleteFingerprint](#)
Removes the image (TIF) file of the current page and the fingerprint (CCO) file from the fingerprint library of the application.
- [FindBlackFingerprint](#)
Attempts to match black forms to fingerprints in the fingerprints directory of an application. If a match does not occur, the action responds according to the parameters that you enter.
- [FindFingerprint](#)
Attempts to match the current page to a fingerprint and creates a new fingerprint if a match does not occur.
- [MergeCCOs_ByType](#)
Merges the fingerprint files (.cco) that are associated with Page objects of the Document Hierarchy.
- [MergeLayoutByType](#)
This action merges the layout files (*layout.xml) associated with Page objects of the Document Hierarchy.

- [SetApplicationID](#)
Used with the Fingerprint Service to limit a fingerprint search to the specified application.
- [SetFilter_HostName](#)
Limits a fingerprint match to the specified fingerprint class only.
- [SetFilter_PageType](#)
Limits a fingerprint match to the specified page type only.
- [SetFingerprint](#)
Sets the class and page type after you create a new fingerprint.
- [SetFingerprintDir](#)
Specifies the Fingerprint directory of your application.
- [SetFingerprintFailureThreshold](#)
Specifies the percentage of fingerprint upload failures to ignore when you use the Fingerprint web service.
- [SetFingerprintSearchArea](#)
Specifies the portion of the current page that is used during fingerprint matching.
- [SetFingerprintWebServiceURL](#)
Specifies the URL that links to the Fingerprint web service.
- [SetMaxOffset](#)
Sets the maximum offset value to use while matching source pages to fingerprints.
- [SetProblemValue](#)
Uses the decimal value that you supply as a parameter to set a minimum Matching Tolerance Rating.
- [UpdateFingerprintStats](#)
Updates the fingerprint statistics in the Fingerprint database.

Parent topic: [Global actions](#)

BlankPagesIDBySize

Uses the size of the Image file to determine if the file represents a blank page.

Syntax

```
bool BlankPagesIDBySize (StrParam)
```

Parameters

A three-part, comma-separated value consisting of:

1. Numeric value indicating the maximum size in bytes that qualifies a page as a blank page.
2. String value representing the Page Type of a blank page.
3. Numeric value (0, 1 or 2) to designate which pages in a multi-page Image file are to be evaluated.

The third parameter is optional.

- 0 = both sides of a two-page Image file.
- 1 = odd pages only.
- 2 = even images only.

»

Returns

False if any of the following conditions apply:

- The parameter is invalid
- The rule with this action is bound to a field object of the document hierarchy
- Any child image of the calling object qualifies as a blank page based on the specified byte size

Otherwise, this action returns True.◀

Level

Batch, Document, or Page levels.

Details

Any page with an Image file smaller than the size parameter (in bytes) is assigned the Page Type value you enter as a parameter.

Example

```
BlankPagesIDBySize ("1000,Blank_Page")
```

Parent topic: [Autodoc actions](#)

CalculateOffset

Sets the standard Offset value to be used when matching source pages to fingerprints.

Syntax

```
bool CalculateOffset ()
```

Returns

False if the action is not applied at the Page level or an error occurs. Otherwise, True.

Level

Page level only.

Details

Calculates the Confidence and Image_Offset variables (similarity with the Fingerprint and image shift compared with the Fingerprint image) for the page based on its relation to the page's fingerprint. The fingerprint ID must previously be set using Findfingerprint, SetFingerprint or some other method.

Example

```
CalculateOffset ()
```

Parent topic: [Autodoc actions](#)

CreateFingerprint

Adds the image (TIF) file of the current page and the fingerprint (CCO) file to the fingerprint library of the application. The resulting fingerprint consists of the Image file (.tif) of the page and its Processing file (.cco).

Syntax

```
bool CreateFingerprint()
```

Parameters

None.

Returns

False if the rule with this action is not bound to a Page object of the Document Hierarchy; if the current page does not have an Image file; or if the fingerprint's two files cannot be created. Otherwise, True.

Level

Page level only.

Details

Creates a fingerprint for the current source page. The resulting fingerprint will consist of two files: the page's Image file (.tif) and its Processing file (.cco).

Attention: A SetFingerprintDir action must precede this action.

Example

```
SetFingerprintDir("C:\ParentDirectory\Application\fingerprint")  
CreateFingerprint() CreateFingerprint()
```

Parent topic: [Autodoc actions](#)

Related reference:

[SetFingerprintDir](#)

[DeleteFingerprint](#)

DeleteFingerprint

Removes the image (TIF) file of the current page and the fingerprint (CCO) file from the fingerprint library of the application.

Syntax

```
bool DeleteFingerprint()
```

Parameters

None.

Returns

Always returns True. Under certain conditions the action will be unable to delete the fingerprint but will still return True. For example if the action is not applied at the Page level or if the fingerprint's Image file cannot be found. Please review the log file if DeleteFingerprint does not perform as expected.

Level

Page level only.

Details

Deletes the Image file (.tif) And Processing file (.cco) of the current page's fingerprint from the application's fingerprint directory, and its record from the Fingerprint database.

Attention: A SetFingerprintDir action must precede this action.

Example

```
SetFingerprintDir ("C:\ParentDirectory\Application\fingerprint")
DeleteFingerprint ()
```

Parent topic: [Autodoc actions](#)

Related reference:

[SetFingerprintDir](#)

[CreateFingerprint](#)

FindBlackFingerprint

Attempts to match black forms to fingerprints in the fingerprints directory of an application. If a match does not occur, the action responds according to the parameters that you enter.

Syntax

```
bool FindBlackFingerprint (StrParam)
```

Parameters

Two comma-separated values (the second is optional)

1. True or False: True If a fingerprint match is not found, a new fingerprint is created and the two fingerprint files (.tif and .cco) are placed in the fingerprint directory. False, if the task is to proceed without creating a new fingerprint.
2. Optional: The Page Type that is to be assigned to the newly created fingerprint if the first parameter is True. If you do not include this parameter, the action assigns the Page Type of the current page.

Returns

False, if the action is not applied at the Page level or if the first parameter is False and a fingerprint match does not occur. Otherwise, True.

Level

Page level only.

Details

This action attempts to match black forms to fingerprints in the fingerprints directory of an application.

If a match does not occur, the action responds according to the parameters you enter.

Example:

```
AnalyzeImage ()
SetSearchArea ("0.5")
SetProblemValue ("0.7")
SetFingerprintDir ("ParentDirectory\Application\fingerprint")
FindBlackFingerprint ("True, PageType")
```

In this sequence, the FindBlackFingerprint action uses only the first 50% of the fingerprint to search for a match. It accepts a match of 0.7 or higher.

If no match is found, the sequence creates a new fingerprint and stores it in the location that is specified by the SetFingerprintDir action.

If the parameter is set to False, no fingerprint is created when a match is not found.

Parent topic: [Autodoc actions](#)

FindFingerprint

Attempts to match the current page to a fingerprint and creates a new fingerprint if a match does not occur.

Syntax

```
bool FindFingerprint (StrParam)
```

Parameters

Two comma-separated values (the second is optional).

1. A True / False value: True, if a task is to create a new fingerprint and add it to the fingerprint directory when a match does not occur; False, if the task is to proceed without creating a new fingerprint.
2. Optional: The Page Type that is to be assigned to the newly created fingerprint. If omitted, the current Page Type of the current page is used.

Returns

False if the action is not applied at the Page level, or if the parameter is False and a fingerprint match does not occur. Otherwise, True. If a new Fingerprint cannot be added, the action still returns True.

Level

Page level only.

Details

This action attempts to match the current source page to a fingerprint, and creates a new fingerprint if a match does not occur. Include this action after a rule's SetSearchArea, SetProblemValue, and SetFingerprintDir actions.

Example

```
AnalyzeImage ()
RotateImage ()
RecognizePageOCR_S ()
SetSearchArea ("0.5")
SetProblemValue ("0.7")
```

```
SetFingerprintDir ("\\ParentDirectory\\Application\\Fingerprint")
FindFingerprint ("True, Invoice_Page")
```

In this example sequence, the FindFingerprint action uses only the first 50% of the current page to search for a match. However, it accepts a match of 0.7 or higher. If no match is found, the sequence creates a new fingerprint and stores it in the location that is specified by the SetFingerprintDir action. If the parameter is set to False, a new fingerprint is not created when there is no match.

Parent topic: [Autodoc actions](#)

MergeCCOs_ByType

Merges the fingerprint files (.cco) that are associated with Page objects of the Document Hierarchy.

Syntax

```
bool MergeCCOs_ByType (StrParam)
```

Parameters

Comma-separated String values that indicate the Page Types of the Document Hierarchy objects to be merged.

Returns

False, if a Fingerprint file (.cco) for one of the Page Types is not available. Otherwise, True.

Level

Document level only.

Details

Merges the Fingerprint files (.cco) associated with Page objects of the Document Hierarchy.

Example

```
MergeCCOs_ByType ("Invoice_Page, Invoice_Cont")
```

The MergeCCOs_ByType action allows all values of the source pages to be assigned to a single, searchable Fingerprint Processing file (.cco).

Parent topic: [Autodoc actions](#)

MergeLayoutByType

This action merges the layout files (*layout.xml) associated with Page objects of the Document Hierarchy.

Syntax

```
bool MergeLayoutByType (string PageTypesToMerge)
```

Parameters

Comma-separated string values that indicate the Page Types of the Document Hierarchy objects to be merged. Smart parameters are supported.

Returns

False, if a layout file (*layout.xml) for one of the Page Types is not available or if the merged layout cannot be created. Otherwise, True.

Level

Document level only.

Details

The layout.xml for the first page that is merged becomes the new merged layout.xml. The merged layout.xml can be then loaded to create a merged CCO for the merged pages. The layout file for the first merged page is updated to contain the recognition results from the layout block information for all of the merged pages.

Only pages that are contained in the current document object are merged. A layout file must exist for each of the pages to be merged. Only page types that are indicated by the parameter are included in the merged file.

Example

```
MergeLayoutByType ("Main_Page,Trailing_Page")
```

The MergeLayoutByType action combines all of the text of the pages in the current DCO document of type Main_Page and Trailing_Page into a single, searchable layout file.

Parent topic: [Autodoc actions](#)

SetApplicationID

Used with the Fingerprint Service to limit a fingerprint search to the specified application.

Syntax

```
bool SetApplicationID(StrParam)
```

Parameters

String parameter that represents unique Application ID. Smart parameters are supported.

This value is used to retrieve a correct list of fingerprints that are loaded to the server.

Returns

False, if action SetFingerprintWebServiceURL() was not called. Otherwise, True.

Level

Batch, Document, or Page levels.

Details

Uses this action to specify unique application name, if multiple applications are using the same Fingerprint Service.

Example

```
SetFingerprintWebServiceURL (http://'FPSEVERNAME'/fpsevice/Service.asmx?WSDL)
SetApplicationID("1040ez")
```

Parent topic: [Autodoc actions](#)

SetFilter_HostName

Limits a fingerprint match to the specified fingerprint class only.

Syntax

```
bool SetFilter_HostName (StrParam)
```

Parameters

The String value of the Fingerprint Class you want to use as the filter.

Returns

Always True.

Level

Page level.

Details

Sets the Fingerprint Class filter for the identification (matching) algorithm. Smart Parameters are supported.

The filter forces the fingerprint-matching algorithm to use only fingerprints associated with the specified Fingerprint Class.

To disable this filter, call with an empty string as the parameter.

Example

```
SetFilter_HostName ("MyFingerprintClass")
```

Parent topic: [Autodoc actions](#)

SetFilter_PageType

Limits a fingerprint match to the specified page type only.

Syntax

```
bool SetFilter_PageType (StrParam)
```

Parameters

The String value of the Page Type you want to use as the filter.

Returns

Always True.

Level

All levels, but generally at the Page level.

Details

Sets the Page Type Filter For the identification (matching) algorithm. Smart Parameters are supported.

The filter will force the fingerprint-matching algorithm to use only fingerprints associated with that Page Type.

Example

```
SetFilter_PageType ("Invoice_Page")
```

Parent topic: [Autodoc actions](#)

SetFingerprint

Sets the class and page type after you create a new fingerprint.

Syntax

```
bool SetFingerprint (StrParam)
```

Parameters

A two-part, comma-separated value consisting of:

1. The Fingerprint Class value. Smart parameters are supported. Alternatively, the name of the Field on this page that specifies the Fingerprint Class.
2. (optional) The Fingerprint ID value. Smart parameters are supported. Alternatively, the name of the Field on this page that specifies the Fingerprint ID.

Returns

False if either parameter is invalid. Otherwise, True.

Level

Page level only.

Details

Sets a newly created fingerprint's Fingerprint Class and Fingerprint Class ID values.

After the mandatory Fingerprint Class value and optional Fingerprint Class ID have been manually assigned by a fingerprint creation task, this action places these values into the Host table of the application's Fingerprint database - as RefName and RefID values.

Example

```
SetFingerprint("@P\VendorName,@P\VendorID")
```

In this example, runtime values of the VendorName and VendorID Field objects will populate the Host table of the application's Fingerprint Database. Alternative method:

```
SetFingerprint("@VendorName,@VendorID")
```

Parent topic: [Autodoc actions](#)

SetFingerprintDir

Specifies the Fingerprint directory of your application.

Syntax

```
bool SetFingerprintDir(StrParam)
```

Parameters

A String value that specifies the directory's name and path. Smart parameters are supported. A Drive ID, such as C:\, is optional.

Returns

Always True.

Level

All levels, but usually applied at the Page level.

Details

Sets the Fingerprint directory of your application. This directory contains the application's fingerprints.

Example

```
SetFingerprintDir("C:\ParentDirectory\Application\Fingerprint")
```

This action identifies the location and path of an application's Fingerprint directory.

Parent topic: [Autodoc actions](#)

SetFingerprintFailureThreshold

Specifies the percentage of fingerprint upload failures to ignore when you use the Fingerprint web service.

Syntax

```
bool SetFingerprintFailureThreshold(StrParam)
```

Parameters

Int parameter that represents percent threshold of fingerprint upload failures to ignore. Smart parameters are supported.

The batch aborts if the percentage of fingerprints that are failed to load exceeds this value.

Returns

Returns False when:

- The fingerprint service is not configured using action `SetFingerprintWebServiceURL()`.

Returns **False** and aborts the batch when:

- The input parameter is not a value from 0 to 100.
- If the percentage of fingerprints that failed to load is greater than the threshold.
- If no fingerprints have been loaded and at least one has failed to load.

Otherwise, True.

Level

Batch, Document, or Page levels.

Details

Uses this action to set the maximum number of fingerprint upload failures to ignore. If the application has been set using the action `SetApplicationID`, then the threshold will be set for that specific application only.

Example

```
FindFingerprint (True)
SetFingerprintFailureThreshold ("10")
```

Parent topic: [Autodoc actions](#)

SetFingerprintSearchArea

Specifies the portion of the current page that is used during fingerprint matching.

Syntax

```
bool SetFingerprintSearchArea(string matchStart, string matchEnd)
```

Parameters

string matchStart

string matchEnd

Parameters

Two parameters:

1. A decimal value from 0.01 (1%) to 1.00 (all) to indicate how much of the page is to be matched. If the second parameter is empty the first parameter represents the bottom of the area for matching, starting

from the top of the page. If the second parameter is not empty, the first parameter is the top or start of the area for matching. For example, a single parameter of 0.5 indicates that fingerprint matching is limited to the first half of the page (0 - 50%). Decimal separators must be appropriate for the current locale. In applications that might be used in locales with different decimal separators, use percentage notation.

2. Optional: A decimal value from 0.01 (1%) to 1.0 (all) to indicate the end point on the page to be used for fingerprint matching. If this parameter is supplied, the first parameter is the starting point. For example: if the first parameter is 0.6, and the second parameter is 1.0, the last 40% of the page is used for fingerprint matching (60-100%).

Attention: In both cases, you can replace a decimal value with a percentage. To indicate that the value is a percentage, the action can use a number followed by `p`, such as `50p` to represent 50%.

When you are using the percentage values, the number must be a whole number and must not contain a decimal separator. Decimal separators must be appropriate for the current locale. In applications that are used in locales with different decimal separators, use percentage notation.

Returns

False, if the first parameter is missing or is not numeric. Also returns False, if the second parameter is not numeric. Otherwise, True.

Level

All levels, but generally at the Page level.

Details

This action uses the numeric values that you supply to determine the portion of the current page that is used to find a matching fingerprint.

Example

```
SetFingerprintSearchArea ("0.5", "")
```

This example compares lines and words in the upper 50% of the current page to the lines and words in the same portion of each fingerprint. Notice that the second parameter is empty.

```
SetFingerprintSearchArea ("0.5", "1.0")
```

This example compares lines and words in the lower 50% of the current page to the lines and words in the same portion of each fingerprint. You can replace a parameter's decimal value with a percentage(`p`) or metric(`m`) number.

Parent topic: [Autodoc actions](#)

Related reference:
[SetProblemValue](#)

SetFingerprintWebServiceURL

Specifies the URL that links to the Fingerprint web service.

Syntax

```
bool SetFingerprintWebServiceURL (StrParam)
```

Parameters

String value specifying the URL that is the link to the Fingerprint Web Service. Smart parameters are supported.

Returns

Always True.

Level

All levels.

Details

Add `SetFingerprintWebServiceURL` with its single parameter to the function and move so it is prior to `SetFingerprintDir` action.

Attention: this action is not effective unless the Fingerprint Service has been installed and configured.

Example

```
SetFingerprintWebServiceURL("http://www.grandcorp.AR.com/fpservice/")
SetFingerprintDir("\ParentDirectory\Application\Fingerprint")
```

Parent topic: [Autodoc actions](#)

SetMaxOffset

Sets the maximum offset value to use while matching source pages to fingerprints.

Syntax

```
bool SetMaxOffset(StrParam)
```

Parameters

Integer value between 1 and 255.

Returns

False, if the parameter is invalid. Otherwise, True.

Level

All levels.

Details

Sets the Maximum Offset value while matching source pages to fingerprints.

This action has no effect when used with the Fingerprint Service. The actual shift is four times the maximum offset value in pixels ($4 * \text{MaxOffset}$). Increasing this value improves but slows the matching process.

The default value is 6: $4 * 6 = 24$ pixels.

Example

```
SetMaxOffset ("12")
```

This example results in a Maximum Offset value of 48 pixels, which is greater than the 24 pixel default.

Parent topic: [Autodoc actions](#)

SetProblemValue

Uses the decimal value that you supply as a parameter to set a minimum Matching Tolerance Rating.

Syntax

```
bool SetProblemValue (StrParam)
```

Parameters

A decimal value from 0.00 (Lowest Tolerance) to 0.99 (Highest Tolerance). The decimal separator must be appropriate for the locale.

Returns

False, if the parameter is missing or the parameter is not numeric. Otherwise, True.

Level

All, but usually at the Page level.

Details

Uses the decimal value that you supply as a parameter to set a minimum Matching Tolerance Rating.

Important: A lower rating results in lower tolerance and a greater chance for a match, but also a greater chance for a False match.

Example

```
AnalyzeImage ()  
CreateFields ()  
RotateImage ()  
RecognizePageOCR-S ()  
SetSearchArea ("0.5")  
SetProblemValue ("0.70")  
SetFingerprintDir ("\\ParentDirectory\\Application\\Fingerprint")  
FindFingerprint ("True")
```

In this sequence, the FindFingerprint action assigns a Matching Tolerance Rating that is not overly restrictive or unrealistically accepting. If the rule's conditions do not result in a match, and True is used as the parameter for the FindFingerprint action, a new fingerprint is added to the library.

Parent topic: [Autodoc actions](#)

UpdateFingerprintStats

Updates the fingerprint statistics in the Fingerprint database.

Syntax

```
bool UpdateFingerprintStats()
```

Parameters

None.

Returns

False if called from any level other than Page level, or the Fingerprint database is not accessible. Otherwise, True.

Level

Page level.

Details

Use this action to increment the count for the current page and update the fingerprint statistics in the fingerprint database.

Example

```
UpdateFingerprintStats()
```

Parent topic: [Autodoc actions](#)

Barcode_P actions

Use the Barcode_P actions to locate and read PDF-417 barcodes.

The Barcode_P actions recognizes various barcode types, searches the page for all barcodes and writes them to a list, and reads the value of the barcodes.

- [Get2DCodeBP](#)
Recognizes PDF-417 codes.
- [GetAllBarcodesBP](#)
Searches the current page for all barcodes and writes them to the *GetBarCodeList* variable of the calling object.
- [GetBarcodeBP](#)
Recognizes arbitrary 1D or 2D codes.
- [GetDataMatrixCodeBP](#)
Recognizes Data Matrix codes
- [IdentifyByBarcodesBP](#)
Updates the current page type if a barcode match is found.
- [MatchBarcodeBP](#)
Searches all the barcodes on the current page and checks if one of them matches the value that you entered as a parameter.
- [MatchBarcodePrefixBP](#)
Searches all the barcodes on the current page and checks if one of them matches the value that you entered as a parameter.
- [ReadBarCodeBP](#)
Tests to determine if the first barcode on the current page contains the value that is specified by the

- parameter.
- [SetMinimumConfidenceBP](#)
Sets the minimum confidence level that is required for barcodes that are read by the engine to be accepted.

Parent topic: [Global actions](#)

Get2DCodeBP

Recognizes PDF-417 codes.

Member of namespace

Barcode_P

Syntax

```
bool Get2DCodeBP ()
```

Parameters

None.

Returns

True if the action is called at the page level or field level. Otherwise, False.

In addition the calling object's value and variable *GetBarcode* is filled with the bar code value. This action also stores barcode information such as confidence, coordinates, code name, and size. If the object's barcode settings are set to read more than one barcode, and more than one barcode is found, barcodes are also stored in the variable *GetBarcodeX* where X is the index of the barcode found.

Level

Page or Field level only.

Details

Use this action if your page has PDF-417 codes. Any field must have a Position assigned when bar code reading is performed. For example the application would invoke the CreateFields action, and if the field has Position defined in the Document Hierarchy, it is ready for barcode reading. If anchors or fingerprint matching are used, ReadZones or other registration may be required to align the fields correctly.

Example:

```
Get2DCodeBP ()
```

Parent topic: [Barcode_P actions](#)

GetAllBarcodesBP

Searches the current page for all barcodes and writes them to the *GetBarcodeList* variable of the calling object.

Member of namespace

Barcode_P

Syntax

```
bool GetAllBarcodesBP (StrParam)
```

Parameters

The separator to use when storing multiple barcodes. The default separator is a comma.

Returns

True if the action is called at the page level or field level. Otherwise, False.

In addition the calling object's value and variable *GetBarcode* is filled with the bar code value. This action also stores barcode information such as confidence, coordinates, code name, and size. If the barcode settings of the object are set to read more than one barcode, and more than one barcode is found, barcodes are also stored in the variable *GetBarcodeX* where X is the index of the barcode found.

Level

Page and field level.

Details

Searches all the barcodes on the current page and stores them in the *GetBarcodeList* variable of the calling object. Each barcode value is separated using the string separator value entered as a parameter.

If the engine does not detect any barcodes, then the variable *GetBarcodeList* is not populated nor created.

Example:

```
GetAllBarcodesBP (",")
```

Parent topic: [Barcode_P actions](#)

GetBarcodeBP

Recognizes arbitrary 1D or 2D codes.

Member of namespace

Barcode_P

Syntax

```
bool GetBarcodeBP ()
```

Parameters

None.

Returns

True, if the action is called at the page level or field level. Otherwise, False.

In addition, the calling object's value and variable *GetBarcode* is filled with the barcode value. This action also stores barcode information such as confidence, coordinates, code name, and size. If the object's barcode settings are set to read more than one barcode, and more than one barcode is found, barcodes are also stored in the variable *GetBarcodeX* where X is the index of the barcode found.

Level

Page or Field level only.

Details

Use this action if your page has 1D or 2D barcodes. Any field must have a Position assigned when barcode reading is performed. For example, the application starts the CreateFields action, and if the field has Position defined in the Document Hierarchy, it is ready for barcode reading. If anchors or fingerprint matching is used, ReadZones or other registration might be needed to align the fields correctly.

To explicitly tell the engine which barcode types to be read, the field/page being recognized contains a variable or setup property called *bp_tp*. If the *bp_tp* variable is empty or does not exist, the engine defaults to Unknown. See the information for Unknown in the valid barcode types.

The value of this variable must be a combination of the barcode types. This variable is automatically set when you choose the barcode types through the Zones tab in Datacap Studio, under the BAR/P recognition settings.

Multiple types can be read by adding the values of their codes together.

When the barcode type is set to Patch Code, the following string values might be returned by the engine. The string value depends on the type of Patch Code that is found:

- Patch 1 - 1100
- Patch 2 - 1001
- Patch 3 - 1010
- Patch 4 / Toggle Patch - 0110
- Patch 6 - 0011
- Patch T / Transfer patch - 0101

Important: The barcode type must be set explicitly to PatchCode, when you want to recognize PatchCodes. The default barcode type setting is Unknown and it does not detect PatchCodes.

Valid barcode types

- 0 - Unknown. Detects all barcode types automatically, except for PatchCode and PDF417. The PatchCode and PDF417 barcode types must be set explicitly to be detected.

Minimum and Maximum Settings

Multiple barcodes can exist and be recognized on a single page. The DCO variable *bp_su* controls the maximum number of barcodes attempts to be read on a single page. If not specified, the default maximum is 10.

The minimum number of expected barcodes can be specified by using the DCO variable *bp_minExpected*. This setting controls when image enhancement takes place. Unless specified, the minimum expected barcodes will default to the same value as the maximum number of barcodes setting.

If the number of recognized barcodes is equal to or more than the specified minimum, image enhancement is skipped. If the minimum number of barcodes is not reached, and if image enhancement is enabled, then barcode recognition is performed a second time. The recognition uses the configured type of image enhancement in an attempt to read the barcode.

For example, if the configured minimum barcode is 1 and the maximum is 10, first barcode recognition is performed without any image enhancement and attempt to read up to 10 barcodes. If at least one barcode is read, the action completes. If 0 barcodes are read, the action performs the specified image enhancement and attempts again to recognize the barcodes on the page. If 0 barcodes are read and no image enhancement is configured, the action completes without a second attempt at recognition.

Image Enhancement

Image enhancement might be necessary in order to help read damaged or poorly scanned barcodes. Depending on the problem with the barcode, different types of enhancements might make the barcode readable. The *barcode_p* actions offer a way to enhance the image before it reads the barcode. To enable this feature, set the variable *bp_enhance* to "1". This feature alters only the image for barcode recognition. The original image in the batch is left unchanged. The image enhancements are not cumulative, enable just the feature that is needed.

Depending on the type of image enhancement that is needed, you need to set the following extra variables:

- Smooth Zoom *bp_zoom* - This feature is automatically enabled when the variable *bp_enhance* is set to "1". To disable smooth zoom set the variable to "0". It is disabled automatically if one of the other image enhancement settings are enabled.

The following enhancement settings are disabled by default and can be enabled when the variable is set to "1":

- Blur *bp_blur* - Blurs the image, which can help jagged lines.
- Dilate *bp_dilate* - Expands the pixels, which make the lines thicker.
- Erode *bp_erode* - Removes pixels along line edges.
- Flip *bp_flip* - It is usually not necessary to flip the image for an upside-down barcode to recognize.
- Resize *bp_resize* - Enlarges the image, which can help small barcodes.

Note: Although image enhancement is turned on by setting the *bp_enhance* variable, enhancement is performed only if the number of recognized barcodes in the first recognition attempt is less than the minimum barcodes setting.

Barcode Orientation

Barcode orientation defaults to both horizontal and vertical. Specifying the orientation might help in detection of barcodes. If necessary, the orientation can be configured by setting the DCO variable *bp_or*.

0 = Horizontal and Vertical.

1 = Horizontal.

2 = Vertical.

3 = Horizontal, Vertical, and Diagonal.

Barcode Byte Mode

In rare cases, barcodes can contain null characters within the data stream. If null characters occur, the full length of the barcode can be truncated returning only the characters up to the first null character. To treat a barcode as byte data, set the DCO variable *BarcodeUseByte* to "1". This setting treats the stream as bytes and also convert any null characters to spaces so the entire string can then be utilized in other parts of the application.

When in byte mode, the default replacement character of a space can be set to a different replacement character by setting the DCO variable *BarcodeReplacementChar* to the desired replacement character.

Note: Unicode characters are not supported by the byte mode.

Example

```
GetBarcodeBP ()
```

Parent topic: [Barcode_P actions](#)

GetDataMatrixCodeBP

Recognizes Data Matrix codes

Member of namespace

Barcode_P

Syntax

```
bool GetDataMatrixCodeBP()
```

Parameters

None.

Returns

True if the action is called at the page level or field level. Otherwise, False.

In addition the calling object's value and variable *GetBarcode* is filled with the bar code value. This action also stores barcode information such as confidence, coordinates, code name, and size. If the object's barcode settings are set to read more than one barcode, and more than one barcode is found, barcodes are also stored in the variable *GetBarcodeX* where X is the index of the barcode found.

Level

Page or Field level only.

Details

Use this action if your page or field has Data Matrix codes. Any field must have a Position assigned when bar code reading is performed. For example the application would invoke the CreateFields action, and if the field has Position defined in the Document Hierarchy, it is ready for barcode reading. If anchors or fingerprint matching are used, ReadZones or other registration may be required to align the fields correctly.

Example:

```
GetDataMatrixCodeBP()
```

Parent topic: [Barcode_P actions](#)

IdentifyByBarcodesBP

Updates the current page type if a barcode match is found.

Syntax

```
bool IdentifyByBarcodesBP(string barcodePageMappings, string mappingsDelim, string keyValuePair, bool caseSensitive)
```

Parameters

barcodePageMappings

A delimited list of barcode value-page type mappings that are evaluated to determine whether matching barcodes exist on the current page. For more information, see the Details section.

If any of these mappings are regular expressions, set the batch variable *BarcodeRegex* to true. If this variable is not set to true, the regular expressions are not recognized as regular expressions.

mappingsDelim

(Optional) Delimiter separating mappings. Default: comma.

keyValueSep

(Optional) Delimiter that is used to separate the barcode value and the page type in an individual mapping. Default: equals sign (=).

caseSensitive

(Optional) True enforces case sensitivity when you evaluate the list of barcodes that are found on the page. Default: False.

Returns

True, if a match is found. Otherwise, False.

Level

Page level

Details

This action searches all of the barcodes that are found on the current page for a match from the provided mappings by using the *GetBarcodeList* variable. If a barcode value is found, this action updates the type of the current page by using the corresponding input mapping.

The GetAllBarcodesBP action is called if the *GetBarcodeList* variable does not exist. If the GetAllBarcodesBP action was called earlier with a string parameter, use an identical symbol for the mappingsDelim parameter.

If multiple barcode values are found, the page type that is assigned is the first corresponding value from the *GetBarcodeList* variable.

Example

```
IdentifyByBarcodesBP (Separator=Separator_PageAttach=Attachment_Page,,,)
IdentifyByBarcodesBP (Separator=Separator_Page%Attach=Attachment_Page,%,,,)
IdentifyByBarcodesBP (Separator|Separator_Page%Attach|Attachment_Page,%|, True)
```

Parent topic: [Barcode_P actions](#)

MatchBarcodeBP

Searches all the barcodes on the current page and checks if one of them matches the value that you entered as a parameter.

Member of namespace

Barcode_P

Syntax

```
bool MatchBarcodeBP (StrParam)
```

Parameters

The String value of the barcode.

Returns

True if the action is called at the page level or field level and one of the barcode values on the page matches the parameter value. The parameter value must not be empty. Otherwise, False.

In addition the calling object's value and variable *GetBarcode* is filled with the bar code value. This action also stores barcode information such as confidence, coordinates, code name, and size. If the object's barcode settings are set to read more than one barcode, and more than one barcode is found, barcodes are also stored in the variable *GetBarcodeX* where X is the index of the barcode found.

Level

Page level and field level.

Details

Searches all the barcodes on the current page and checks if one of the barcodes matches the parameter value. If a match occurs, the barcode's value is placed into a page level variable called *GetBarcode*. Refer to action *GetBarcode* for information regarding barcode configuration in Datacap Studio.

Example:

```
MatchBarcodeBP ("2008")
```

Parent topic: [Barcode_P actions](#)

Related reference:

[GetBarcodeBP](#)

MatchBarcodePrefixBP

Searches all the barcodes on the current page and checks if one of them matches the value that you entered as a parameter.

Member of namespace

Barcode_P

Syntax

```
bool MatchBarcodePrefixBP (StrParam)
```

Parameters

The String value of the barcode.

Returns

True if the action is called at the page level or field level and one of the barcode values on the page matches the parameter value. The parameter value must not be empty. Otherwise, False.

In addition the calling object's value and variable *GetBarcode* is filled with the bar code value. This action also stores barcode information such as confidence, coordinates, code name, and size. If the object's barcode settings are set to read more than one barcode, and more than one barcode is found, barcodes are also stored in the variable *GetBarcodeX* where X is the index of the barcode found.

Level

Page level and field level.

Details

Searches all the barcodes on the current page and checks if one of the barcodes starts with the parameter value. If a match occurs, the value of the barcode is placed into a page level variable called *GetBarCode*.

Refer to the *GetBarCode* action for information regarding barcode configuration in Datacap Studio.

Example:

```
MatchBarcodePrefixBP("ATM")
```

Parent topic: [Barcode_P actions](#)

Related reference:

[GetBarcodeBP](#)

ReadBarCodeBP

Tests to determine if the first barcode on the current page contains the value that is specified by the parameter.

Member of namespace

Barcode_P

Syntax

```
bool ReadBarCodeBP(StrParam)
```

Parameters

A single string value of the barcode.

Returns

True if the first barcode on the page has a value that matches the parameter. Otherwise, False.

Level

Page level only.

Details

Checks if the current page contains a barcode with the value specified by the parameter. This action uses the first barcode it encounters. One possible use of this action is to identify a document's Separator page. Refer to action *GetBarCode* for information regarding barcode configuration in Datacap Studio.

Example:

```
ReadBarCodeBP("Separator")  
SetPageType("Separator")
```

This example looks for a barcode with the value "Separator". If found, the second action, a DCO action, establishes the page as a Separator page.

Parent topic: [Barcode_P actions](#)

Related reference:

[GetBarcodeBP](#)

SetMinimumConfidenceBP

Sets the minimum confidence level that is required for barcodes that are read by the engine to be accepted.

Syntax

```
bool SetMinimumConfidenceBP(StrParam)
```

Parameters

An integer value that represents the minimum confidence level that is required for barcodes that are read by the engine to be accepted. Valid values are in the range of 1-10. The default value, when this engine is not used, is 7.

Returns

False if the confidence value cannot be set either because it is invalid or if an error occurs or if the action is called at a level other than page or field. Otherwise, True.

Level

Page or Field level only

Details

Sets the minimum confidence level that is required for barcodes that are read by the engine to be accepted.

Example

```
SetMinimumConfidenceBP(5)  
GetBarcodeBP()
```

Parent topic: [Barcode_P actions](#)

ClassifyLayout actions

Use the ClassifyLayout actions to identify page types based on page layout templates.

Important: These actions are technology preview code. Preview code is not intended for use in production; you use this code as is and without IBM support. If you use any preview code in your application, you might need to make updates to your application in later Datacap releases. Report any issues with the ClassifyLayout preview code on the [Datacap developerWorks forum](#).

A layout template consists of page layout features with an associated page type. Here are some of the layout features that are used:

- Title (required)

- Page number
- Average font size
- The presence and locations of tables and graphics

These templates are stored in the Fingerprint database.

- [Feedback](#)
Adds a layout template of the current page to the Fingerprint database.
- [Identify](#)
For page identification purposes, creates page variables whose values reflect the most closely matching layout template in the Fingerprint database for the current page.

Parent topic: [Global actions](#)

Feedback

Adds a layout template of the current page to the Fingerprint database.

Important: These actions are technology preview code. Preview code is not intended for use in production; you use this code as is and without IBM support. If you use any preview code in your application, you might need to make updates to your application in later Datacap releases. Report any issues with the ClassifyLayout preview code on the [Datacap developerWorks forum](#).

Member of namespace

ClassifyLayout

Syntax

```
bool Feedback ()
```

Returns

True if the action completes without errors. Otherwise, if the action is called for an object other than a page object or if an internal error occurs, the action returns False.

Level

Page level.

Details

Use this action in the following ways to train the application to identify page types from layout templates:

- To initially provide a base set of templates
- To incrementally add new templates to improve accuracy

After you train the application, you can use the Identify action to identify a new page by finding the most closely matching template.

Call this action in the following circumstances:

- After you confirm that the page type as specified by the Page type field is correct
- After you call the Identify action

Typically, you call this action at export time.

This action compares the values of the Page type field and the acidType variable (which is set by the Identify action). If the values are not the same, a layout template of the current page is added to the database.

Example

```
// Mandatory prerequisites
Recognize()
Identify()

// Give feedback
Feedback()
```

Parent topic: [ClassifyLayout actions](#)

Identify

For page identification purposes, creates page variables whose values reflect the most closely matching layout template in the Fingerprint database for the current page.

Important: These actions are technology preview code. Preview code is not intended for use in production; you use this code as is and without IBM support. If you use any preview code in your application, you might need to make updates to your application in later Datacap releases. Report any issues with the ClassifyLayout preview code on the [Datacap developerWorks forum](#).

Member of namespace

ClassifyLayout

Syntax

```
bool Identify()
```

Returns

True if the action completes without errors. Otherwise, if the action is called for an object other than a page object or if an internal error occurs, the action returns False.

Level

Page level.

Details

Use this action to search the previously learned layout templates to find the closest match to the current page layout. The layout must contain a title in order for matching to succeed. If a similar layout is found, the following page variables are set:

Page variable	Variable value
acidType	The associated page type of the most closely matching layout template.

Page variable	Variable value
acidPageNo	The page number of the most closely matching template. For example, if the most closely matching template was for the second page of a three page document, the acidPageNo value is "2/3". If the most closely matching template has no associated page number, the acidPageNo value is "0/0".
acidTitle	The page title, if any, of the most closely matching template.

Before you call this action, you must call an OCR action that produces an XML layout file for the current page. Two examples of such actions are the Recognize actions in the OCR_A and OCR_S libraries.

Example

```
// Mandatory prerequisite: An action that performs OCR for the page
// The OCR action must create an XML layout file (such as OCR_SR/recognize or
OCR_A/recognize)
Recognize()

// Identify page type
Identify()

// Optionally copy the acidType field value as the page type
rrSet("acidType", "Page type")
```

Parent topic: [ClassifyLayout actions](#)

CC actions

Use the CC actions to identify types of pages and other text with IBM® Content Classification technology.

In general, CC actions are oriented towards either the use of an IBM Content Classification knowledge base or the use of an IBM Content Classification decision plan. For more information, see [IBM Content Classification: Category and rule-based classification](#).

The CC actions can be classified as follows:

Table 1. CC methods by page identification method

	Category-based classification	Rule-based classification
Common settings	<ul style="list-style-type: none"> • SetListenerURLCC 	
Settings	<ul style="list-style-type: none"> • SetKnowledgeBaseCC • SetLanguageCC • SetProblemValueCC 	<ul style="list-style-type: none"> • SetDecisionPlanCC • SetDecisionPlanFieldsCC
Main methods	<ul style="list-style-type: none"> • ClassifyCC • ClassifyTextCC • UpdateKnowledgeBaseCC 	<ul style="list-style-type: none"> • RunDecisionPlanCC • RunDecisionPlanForBlocksCC • RunDecisionPlanForTextCC

The settings affect the behavior of the main methods.

- [ClassifyCC](#)
Identifies the page type for the current page by using category-based classification.
- [ClassifyTextCC](#)
Finds matching categories for the specified text by using category-based classification.

- [RunDecisionPlanCC](#)
For both page type identification and data import purposes, creates page variables by using rule-based classification. This classification is based on the page's text.
- [RunDecisionPlanForBlocksCC](#)
For both page type identification and data import purposes, creates page variables by using rule-based classification. The classification is based on a specified list of page text blocks that indicate the page text to use.
- [RunDecisionPlanForTextCC](#)
For both page type identification and data import purposes, creates page variables by using rule-based classification. The classification is based on the specified text.
- [SetDecisionPlanCC](#)
A setting for the name of the IBM Content Classification decision plan.
- [SetDecisionPlanFieldsCC](#)
A setting for a comma-separated field name list for those fields that are to be created on the current DCO object in accordance with rule-based classification.
- [SetKnowledgeBaseCC](#)
A setting for the name of the IBM Content Classification knowledge base to use.
- [SetLanguageCC](#)
A setting for the language to be used for finding matching categories in an IBM Content Classification knowledge base. Any categories in the knowledge base that do not belong to the specified language are excluded as possible matches.
- [SetListenerURLCC](#)
A setting for the URL of the IBM Content Classification listener.
- [SetProblemValueCC](#)
A setting for the minimum category match score, which is the minimum score for a category to be considered a match with a piece of text. Valid values are 0.0 – 1.0, inclusive. For example, you might set the minimum score to 0.9.
- [UpdateKnowledgeBaseCC](#)
Updates the CC Knowledge Base.
- [Category match variables](#)
Some CC actions set page variables on the calling DCO object to return data for the matching categories. What constitutes a matching category is determined by the minimum category match score (as set by the SetProblemValueCC action).

Parent topic: [Global actions](#)

ClassifyCC

Identifies the page type for the current page by using category-based classification.

Member of namespace

CC

Syntax

```
bool ClassifyCC ()
```

Returns

True if a category is matched. Otherwise, this action returns False.

Level

Page level.

Details

Use this action to set the following items:

Item	Description	Comments
Page type field	If matching categories are found, the value of the page type field is set to the ID of the matching category with the highest confidence score. Otherwise, if no matching categories are found, the page type is unchanged.	The page type is updated by this action only if the variable UpdateDCOType has a value other than "0". If you do not want the page type to be updated, set UpdateDCOType to "0" before you call this action.
Match variables	Some variables are set to contain category match data. For more information, see Category match variables .	

Example

```
// Mandatory prerequisite: An action that performs OCR for the page
Recognize()

// Mandatory settings
SetListenerURLCC("http://localhost:18087")
SetKnowledgeBaseCC("Mortgage")
SetLanguageCC("English")

// Optional settings
SetProblemValueCC(0.9)

// Identify the page type
ClassifyCC()
```

Parent topic: [CC actions](#)

ClassifyTextCC

Finds matching categories for the specified text by using category-based classification.

Member of namespace

CC

Syntax

```
bool ClassifyTextCC(string TextToClassify)
```

Parameters

TextToClassify

The text to be categorized.

Smart parameters are supported.

Returns

True if the action completes successfully. Otherwise, this action returns False.

Level

All levels.

Details

Use this action to set the following items:

Item	Description
Match variables	Some variables are set to contain category match data. For more information, see Category match variables .

Example

```
// Mandatory prerequisite: An action that performs OCR for the page
// The OCR action must create an XML layout file (such as OCR_SR/recognize or
OCR_A/recognize)
Recognize()

// Mandatory settings
SetListenerURLCC("http://localhost:18087")
SetKnowledgeBaseCC("Mortgage")
SetLanguageCC("English")

// Optional settings
SetProblemValueCC(0.9)

// Find matching categories
ClassifyTextCC("Place text to classify here")
```

Parent topic: [CC actions](#)

RunDecisionPlanCC

For both page type identification and data import purposes, creates page variables by using rule-based classification. This classification is based on the page's text.

Member of namespace

CC

Syntax

```
bool RunDecisionPlanCC()
```

Returns

True if the action completes successfully. Otherwise, this action returns False.

Level

Page level.

Details

Use this action to set the following items:

Item	Description
Page variables	The page's text is run against the decision plan. (The decision plan is specified by the SetDecisionPlanCC action). Page variables are created in accordance with the SetDecisionPlanFieldsCC setting and the rules of the decision plan. For more information, see IBM Content Classification: Category and rule-based classification .
Match variables	Some variables are set to contain category match data. For more information, see Category match variables .

Example

```
// Mandatory prerequisite: An action that performs OCR for the page
Recognize ()

// Mandatory settings
SetListenerURLCC ("http://localhost:18087")
SetDecisionPlanCC ("Mortgage")
SetDecisionPlansFieldsCC ("EmployeeID.Date")

// Run the decision plan
RunDecisionPlanCC ()
```

Parent topic: [CC actions](#)

RunDecisionPlanForBlocksCC

For both page type identification and data import purposes, creates page variables by using rule-based classification. The classification is based on a specified list of page text blocks that indicate the page text to use.

Member of namespace

CC

Syntax

```
bool RunDecisionPlanForBlocksCC (string blockTypes)
```

Parameters

blockTypes

A comma-separated list of one or more of the following block types:

- Block
- Table
- Header
- Footer
- Title
- H1

- H2
- H3
- Barcode

For general information about block types, see [DocumentAnalytics actions](#).

Important:

- Block types must be defined as input fields in the decision plan. For example, to use the Barcode block type, a Barcode input field must be defined in the decision plan. For information about adding input fields to a decision plan and mapping XML nodes to them, see [Configuring rule-based classification by using a decision plan](#).
- Depending on the version of IBM® Content Classification that you installed, you might need to make some XML configuration file changes. These changes are required to ensure that the IBM Content Classification server properly parses text blocks. For more information, see [Configuring content classification for XML layout block parsing](#).

Smart parameters are supported.

Returns

True if the action completes successfully. Otherwise, this action returns False.

Level

Page level.

Details

Use this action to set the following items:

Item	Description
Page variables	Based on the specified block types and the page's XML layout file, a portion of the page's text is run against the decision plan. (The decision plan is specified by the SetDecisionPlanCC action). For example, suppose that the blockTypes parameter specifies the following block type only: <i>Table</i> . In this case, the page's text that is run against the decision plan consists of those page text blocks that belong to the block type <i>Table</i> . Page text in other text blocks is ignored. Page variables are created in accordance with the SetDecisionPlanFieldsCC setting and the rules of the decision plan. For more information, see IBM Content Classification: Category and rule-based classification .
Match variables	Some variables are set to contain category match data. For more information, see Category match variables .

Example

```
// Mandatory prerequisite: An action that performs OCR for the page
// The OCR action must create an XML layout file (such as OCR_SR/recognize or
OCR_A/recognize)
Recognize()

// Mandatory settings
SetListenerURLCC("http://localhost:18087")
SetKnowledgeBaseCC("Mortgage")
SetDecisionPlanCC("Mortgage")
```

```
SetDecisionPlansFieldsCC("Title,Loan,Loan Type")

// Run decision plan
RunDecisionPlanForBlocksCC("Table,Block")
```

Parent topic: [CC actions](#)

RunDecisionPlanForTextCC

For both page type identification and data import purposes, creates page variables by using rule-based classification. The classification is based on the specified text.

Member of namespace

CC

Syntax

```
bool RunDecisionPlanForTextCC(string TextToClassify)
```

Parameters

TextToClassify

The text to run against the decision plan.

Smart parameters are supported.

Returns

True if the action completes successfully. Otherwise, this action returns False.

Level

All levels.

Details

Use this action to set the following items:

Item	Description
Page variables	The specified text is run against the decision plan. (The decision plan is specified by the SetDecisionPlanCC action). Page variables are created in accordance with the SetDecisionPlanFieldsCC setting and the rules of the decision plan.
Match variables	Some variables are set to contain category match data. For more information, see Category match variables .

Example

```
// Mandatory prerequisite: An action that performs OCR for the page
Recognize()

// Mandatory settings
SetListenerURLCC("http://localhost:18087")
SetKnowledgeBaseCC("Mortgage")
```

```
SetDecisionPlanCC("Mortgage")
SetDecisionPlansFieldsCC("Title,Loan,Loan Type")

// Run the decision plan
RunDecisionPlanForTextCC(@F)
```

Parent topic: [CC actions](#)

SetDecisionPlanCC

A setting for the name of the IBM® Content Classification decision plan.

Smart parameters are supported.

Member of namespace

CC

Syntax

```
bool SetDecisionPlanCC(string DecisionPlanName)
```

Returns

False if the parameter value is empty. Otherwise, this action returns True.

Level

All levels.

Details

Example

```
SetDecisionPlanCC("Mortgage")
```

Parent topic: [CC actions](#)

SetDecisionPlanFieldsCC

A setting for a comma-separated field name list for those fields that are to be created on the current DCO object in accordance with rule-based classification.

Member of namespace

CC

Syntax

```
bool SetDecisionPlanFieldsCC(string DPFields)
```

Returns

False if the parameter value is empty. Otherwise, this action returns True.

Level

All levels.

Details

Example

```
SetDecisionPlanFieldsCC("Title,Loan,Loan Type")
```

Parent topic: [CC actions](#)

SetKnowledgeBaseCC

A setting for the name of the IBM® Content Classification knowledge base to use.

Smart parameters are supported.

Member of namespace

CC

Syntax

```
bool SetKnowledgeBaseCC(string KnowledgeBaseName)
```

Returns

False if the parameter value is empty. Otherwise, this action returns True.

Level

All levels.

Details

Example

```
// Set the name of the knowledge base  
SetKnowledgeBaseCC("Mortgage")
```

Parent topic: [CC actions](#)

SetLanguageCC

A setting for the language to be used for finding matching categories in an IBM® Content Classification knowledge base. Any categories in the knowledge base that do not belong to the specified language are excluded as possible matches.

Member of namespace

CC

Syntax

```
bool SetLanguageCC(string LanguageName)
```

Returns

Always True.

Level

All levels.

Details

Example

```
SetLanguageCC("English")
```

Parent topic: [CC actions](#)

SetListenerURLCC

A setting for the URL of the IBM® Content Classification listener.

Smart parameters are supported.

Member of namespace

CC

Syntax

```
bool SetListenerURLCC(string URL)
```

Returns

True if the URL is successfully set. Otherwise, this action returns False. This action does not test that the listener exists and is running.

Level

All.

Details

Example

```
SetListenerURLCC("http://localhost18087")
```

Parent topic: [CC actions](#)

SetProblemValueCC

A setting for the minimum category match score, which is the minimum score for a category to be considered a match with a piece of text. Valid values are 0.0 – 1.0, inclusive. For example, you might set the minimum score to 0.9.

Tip: For the passed parameter value, use the appropriate decimal character for your system locale as defined for your application in the Datacap Application Manager. For example, if the decimal character is a comma, you would specify the minimum score as 0,9 instead of 0.9.

Member of namespace

CC

Syntax

```
bool SetProblemValueCC(double MinScore)
```

Returns

True if the parameter value is valid. Otherwise, this action returns False.

Level

All levels.

Details

Example

```
SetProblemValueCC(0.9)
```

Parent topic: [CC actions](#)

UpdateKnowledgeBaseCC

Updates the CC Knowledge Base.

Member of namespace

CC

Syntax

```
bool UpdateKnowledgeBaseCC()
```

Parameters

None.

Returns

True if the IBM® Content Classification Knowledge Base is successfully updated. Otherwise, False.

Level

Page level.

Details

Provides classification feedback to the IBM Content Classification server.

Important: This method is to be used to provide feedback to a previously trained knowledge base, and not to be used as the primary method for training a knowledge base from scratch.

Although training via feedback is not recommended to build the knowledge base, it is recommended that it is used to submit feedback on classification data returned on a "trained" category. For instance, let us use a knowledge base that contains 5 categories, 4 of which have been trained. When ClassifyCC runs, it will either return a match or no match. When a match is found, it is recommended to provide feedback (using UpdateKnowledgeBaseCC) to the knowledge base to assert that the classification was correct.

When there is no match (no category returned) or there is a mismatch (wrong category returned), the recommended process is to export a copy of the document to a folder and train the knowledge base with these new documents via the IBM Content Classification Workbench. After the new documents have been added, the knowledge based should be exported, and documents processed in Datacap to provide feedback. The training should be done in a non Production system, then moved to Production after testing.

Although it is recommended that this procedure is used to submit feedback on trained categories, it should be done for a period of time, and not indefinitely, since this can cause the knowledge base to grow very large.

In conclusion, this action should be used only for documents where the classification result was correct, and should only be used during a period of time until the training on the knowledge base is complete.

Example

```
// Mandatory settings
SetListenerURLCC("http://localhost:18087")
SetKnowledgeBaseCC("Mortgage")
ClassifyCC()

// Update the knowledge base
UpdateKnowledgeBaseCC()
```

Parent topic: [CC actions](#)

Category match variables

Some CC actions set page variables on the calling DCO object to return data for the matching categories. What constitutes a matching category is determined by the minimum category match score (as set by the SetProblemValueCC action).

The following table lists these variables:

MatchingCategoriesCount	The number of matching categories
MatchingCategoryX	A list of the matching categories
MatchingCategoryConfX	A list of the matching category scores

Parent topic: [CC actions](#)

Cco2cco actions

Use the Cco2cco actions to sort and filter the words and lines in a fingerprint CCO file.

This normalization is only required after full page recognition by an OCR or ICR action that does not automatically normalize the CCO. The OCR/S, OCR/A, and ICR/C actions normalize automatically.

- [NormalizeCCO](#)
The NormalizeCCO action sorts and filters the words and lines in a Fingerprint file (.cco) that are created by a Recognition engine, for use by navigation and pattern match actions. This action is only required after full page recognition by an OCR or ICR action that does not automatically normalize the CCO.
- [SetMaxCharacterHeightAVG](#)
Sets the maximum height of characters, by percentage over the average, that is allowed by the Cco2cco and NormalizeCCO actions.
- [SetMaxCharacterHeightTMM](#)
Sets the maximum height of characters, by absolute value, that is allowed by the Cco2cco and NormalizeCCO actions.

Parent topic: [Global actions](#)

NormalizeCCO

The NormalizeCCO action sorts and filters the words and lines in a Fingerprint file (.cco) that are created by a Recognition engine, for use by navigation and pattern match actions. This action is only required after full page recognition by an OCR or ICR action that does not automatically normalize the CCO.

Member of namespace

Cco2cco

Syntax

```
bool NormalizeCCO ()
```

Returns

Always True.

Level

Page.

Details

This action sorts the words and lines in a Fingerprint file (.cco) created by a recognition engine, for use by navigation and pattern match actions. The action is called by full-page recognition actions for ICR/C, OCR/S, and OCR/A. This action must always be called before the Locate actions or the pat_RecogMatch_ID action are used to find recognized text on a page.

In this context, the fingerprint is calculated for a particular image in a batch, not in the Fingerprint database that contains fingerprints for various page types and layout variations that are defined for a particular application.

There are two types of Fingerprint files. One type is based on the image geometry. The second type is based on recognized text. The AnalyzeImage action creates a geometric fingerprint that contains lines and words that are based only on the black pixels in the image. Full-page recognition actions, such as RecognizePageOCR_S, RecognizePageICR_C, RecognizePageOCR_A, create a fingerprint that is based on the results of recognition; that is, both geometry and text of the recognized characters, words and lines.

In Recognition-based fingerprints, the order of lines and words might appear to be arbitrary, especially if the page contains images, tables, stamps, or blocks of text with varying font sizes. This can cause unpredictable results from Locate actions that navigate geometrically. The word-matching and phrase-matching action pat_RecogMatch_ID also requires well-ordered text to work reliably.

The NormalizeCCO action reorders the words of text in a Recognition-based fingerprint into lines and words in standard reading order, from top to bottom and left to right.

Important: NormalizeCCO discards any "words" or blocks that contain characters taller than 1/4 inch, or the height set by SetMaxCharacterHeightTMM().

If the AnalyzeImage action is called before full-page recognition, the recognized text is placed into the geometry that is created by AnalyzeImage. This hybrid Fingerprint file is not always suitable for cco2cco. To force creation of a pure recognition-based fingerprint, call SetFingerprintRecogPriority(True) before full-page recognition. This guarantees that any existing geometric fingerprint is ignored, and it applies to OCR_S and ICR_C only.

The full page recognition actions from the ICR_C, OCR_A, and OCR_S libraries call NormalizeCCO() automatically unless the action CCONormalization_OFF (from the Recog_Shared library) is called before recognition. The full page recognition from the OCR_SR library, however, requires that NormalizeCCO() to be called manually post recognition.

Example:

```
SetFingerprintRecogPriority(True)
RecognizePageOCR_S()
NormalizeCCO()
pat_RecogMatch_ID()
```

Parent topic: [Cco2cco actions](#)

SetMaxCharacterHeightAVG

Sets the maximum height of characters, by percentage over the average, that is allowed by the Cco2cco and NormalizeCCO actions.

Member of namespace

Cco2cco

Syntax

```
bool SetMaxCharacterHeightAVG(strParam)
```

Parameters

One or two digit Integer value sets the percent maximum height of characters over the average to permit in the CCO. Off by default. Parameter of zero (0) or less turns off this functionality.

Returns

Always True.

Level

Page.

Details

Example:

```
SetMaxCharacterHeightAVG (15)
NormalizeCCO ()
```

Parent topic: [Cco2cco actions](#)

SetMaxCharacterHeightTMM

Sets the maximum height of characters, by absolute value, that is allowed by the Cco2cco and NormalizeCCO actions.

Member of namespace

Cco2cco

Syntax

```
bool SetMaxCharacterHeightTMM(strParam)
```

Parameters

Integer: maximum height of characters to permit in the CCO, in 1/10 mm units. Default is 64, or approx 1/4 inch (50 pixels at 200 DPI).

Returns

Always True.

Level

Page.

Details

Example:

```
SetMaxCharacterHeightTMM (75)
NormalizeCCO ()
```

Parent topic: [Cco2cco actions](#)

CheckProcessing actions

Use the Check Processing actions to extract data from checks originating from Argentina, Brazil, Canada, France, India, UK and US.

Supported image formats

This library supports single page TIF and JPEG images with a resolution of 200 DPI to 300 DPI.

US checks

The image must be black and white (1 bpp) or grayscale (8 bpp). Color is not supported for US checks. If you have colored US checks, these checks must be converted prior to calling recognition.

Brazilian checks

The checks can be black and white (1 bpp), 8 bit grayscale (8bpp) or 24 bit color (24 bpp) images. The Brazilian engine uses the color information when performing recognition, but color is not required.

Other international countries

For other countries, the checks can be black and white (1 bpp), 8 bit grayscale (8bpp) or 24 bit color (24 bpp) images. However, the color information is not used. The engine automatically converts the image to black and white prior to performing recognition. If you provide images with 24 bit color or 8 bit gray scale to the engines, these images are automatically binarized in memory before the recognition, leaving the original image unchanged. If desired, you can use actions to binarize images before processing, so you have a black and white image of the check saved within the batch.

Check Borders

The check image must be the size of the check itself. You must crop any borders or white space around the check image making the image the same size as the physical check or recognition might not be correct. You can use the image enhancement ruleset to deskew and remove the check border.

The following shows a specific example ruleset and functions configured to process checks originating from the US. The page is first converted to black and white, and then run through the check processing action.

```
Ruleset Detect Checks
Function Process Check
  OCR_AConvertImageToBW("tio")
  ProcessCheck("USA", "false", "None")
```

- [ProcessCheck](#)
Performs data extraction from checks originating from various regions.
- [CheckProcessingBrazil](#)
Performs data extraction from checks originating from Brazil.
- [CheckProcessingCanada](#)
Performs data extraction from checks originating from Canada.
- [CheckProcessingFrance](#)
Performs data extraction from checks originating from France.
- [CheckProcessingIndia](#)
Performs data extraction from checks originating from India.
- [CheckProcessingUK](#)
Performs data extraction from checks originating from the United Kingdom.
- [CheckProcessingUs](#)
Performs data extraction from checks originating from the United States.

Parent topic: [Global actions](#)

ProcessCheck

Performs data extraction from checks originating from various regions.

Syntax

```
bool ProcessCheck (string country, string createFields, string  
checkBackSideImagePath)
```

Parameters

country:

The three-letter ISO code that identifies the country for the check to recognize. The following countries are supported:

- Argentina
- Brazil
- Canada
- France
- India
- UK
- US

createFields:

When set to true, runtime DCO fields are created with the extracted data.

checkBackSideImagePath:

The path to the backside check image. If you do not provide image path, then the next subsequent page is used at the back image. To capture only fields on the front of the check, use the value "None". This parameter is used only when the country is India. The back side image parameter is ignored for all other countries.

Smart parameters are supported.

Level

Page

Returns

True, if the current image is a check. Otherwise, False.

Details

Detects check images and stores the extracted data into variables at the page level. If a field is not read successfully by the recognition engine, it is not included in the results. If a country supports recognition of the Payee, then a vocabulary is required. Payee Vocabularies are created as a comma separated text file in the following format:

"word or phrase 1",weight

"word or phrase 2",weight

"word or phrase 3",weight

"word or phrase 4",weight

The weight is an integer value from 1 to 100, inclusive. The words that are expected should be given a higher weight and words expected less often should be given a lower weight. The DCO variable `payeeVocab` must be set on the page level object with the full path to the vocabulary file.

The following example shows how to specify the vocabulary file using smart parameters. The vocabulary file can exist anywhere and this example shows how to access a file that has been placed in the application's DCO directory.

```
rrSet("@PROCESSDIR+\MyVocabulary.txt", "@X.payeeVocab")
```

When a vocabulary is provided, an optional DCO page variable, `payeeVocabCoverage`, can be set with an integer value from 1 to 100. This variable defines the approximate percentage of input payee names that match entries in a specified vocabulary for payee line recognition. If `payeeVocabCoverage` is not specified, then default is set to 50 percent.

Recognized check fields for each country

Argentina (ARG)

Detects check images and stores the following extracted data into variables at the page level:

- Amount
- MICR

The following runtime DCO fields are created:

- Amount
- AmountFull
- CAR
- LAR
- MICR
- MICRAccountNumber
- MICRCheckNumber
- MICRRoutingNumber
- MICRData0
- MICRData1
- MICRData2

Brazil (BRA)

Detects check images and stores the following extracted data into variables at the page level:

- Amount
- Date
- AmountVerification
- CAR
- LAR
- LARCARMismatch
- MICR
- PayorId
- Place
- TopLine
- PresenceFront

The following runtime DCO fields are created:

- Amount
- AmountFull
- CAR
- LAR
- Date
- YearPresence
- MonthPresence
- DayPresence
- Interval
- MICR
- MICRData0
- MICRData1
- MICRData2
- AmountVerification
- CARAV
- LARAV
- PresenceFront
- TopLine
- C1
- C2
- C3
- PayorID
- Place

Canada (CAN)

Detects check images and stores the following extracted data into variables at the page level:

- Amount
- Date
- MICR

The following runtime DCO fields are created:

- Amount
- AmountFull
- CAR
- LAR
- Date
- YearPresence
- MonthPresence
- DayPresence
- Interval
- MICR
- MICRData0
- MICRData1
- MICRData2

France (FRA)

Detects check images and stores the following extracted data into variables at the page level:

- Amount
- Date

- AmountVerification
- CAR
- LAR
- LARCARMismatch
- MICR
- CheckSum
- PresenceFront

The following runtime DCO fields are created:

- Amount
- AmountFull
- CAR
- LAR
- Date
- YearPresence
- MonthPresence
- DayPresence
- Interval
- MICR
- MICRData0
- MICRData1
- MICRData2
- AmountVerification
- CARAV
- LARAV
- PresenceFront
- CheckSum

India (IND)

Detects check images and stores the following extracted data into variables at the page level:

- AccountNoFront
- AccountNoBack
- Amount
- Date
- AmountVerification
- CAR
- LAR
- LARCARMismatch
- CtsCompliance
- CurrencySymbol
- DdMmYyyyCompliance
- VerticalTextPresence
- DateBoxes
- MICR

Note: For India, the front and back check information can be recognized. The front image is obtained from the image belonging to the current page object. The back image is specified as the second parameter to this action. If a back image is not specified, then the image belonging to the next consecutive page is used. To capture the fields on the front of the check only, use the parameter "None" for the back check image.

UK (GBR)

Detects check images and stores the following extracted data into variables at the page level:

- Amount
- CAR
- LAR

The following runtime DCO fields are created:

- Amount
- AmountFull
- CAR
- LAR

US (USA)

Detects check images and stores the following extracted data into variables at the page level:

- Amount
- Date
- MICR
- CAR
- LAR
- DocumentType

The following runtime DCO fields are created:

- Amount
- Date
- Year
- Month
- Day
- MICR
- MICRAccountNumber
- MICRCheckNumber
- MICRRoutingNumber
- MICRAmount
- MICRData0
- MICRData1
- MICRData2
- CheckNumber
- PayeeLine
- CARLARMismatch

Note: The DCO fields may not be created or will be blank, if the text is not recognized or if the information is not on the check. For example, typically checks do not contain the amount in the MICR field. For any country that supports CAR/LAR, the engine attempts to recognize the LAR (Legal Amount) only if the CAR (Courtesy Amount) is not recognized or is recognized with low confidence. The DCO variable `courtesyAcceptLevel` can be set for US check processing to indicate the minimum confidence needed before attempting LAR recognition. The `courtesyAcceptLevel` can be set within the confidence range of 0 to 100. The Amount contains the recognized amount with a decimal separator. The AmountFull contains the amount without a decimal separator.

The MICRData fields contain the separate logical components of the recognized MICR, such as the Account Number, separated out into separate variables. If the MICR is not successfully recognized, then these variables may not exist.

MICR font CMC-7 and E-13B are supported. The CMC-7 font is used in Argentina, Brazil, France, and the E-13B font is used in Canada, India, UK, and US.

This example is a page level rule that performs check recognition on the current page for a French check.

```
ProcessCheck("FRA", "true", "None")
```

Parent topic: [CheckProcessing actions](#)

CheckProcessingBrazil

Performs data extraction from checks originating from Brazil.

Important: This action is deprecated and scheduled to be removed in a future release. Use the ProcessCheck action in the CheckProcessing library. For more information see [ProcessCheck](#).

This library supports single page, black and white or 8 bit gray-scale TIF and images, or color JPEG images with a resolution of 200-300 DPI. If the images are colored or 8 bit gray scale, these images are automatically binarized in memory before the recognition, leaving the original image untouched. You can use actions to binarize images before processing so you have a saved black and white image. You can use a separate action to convert to black and white before performing check recognition.

CAUTION:

The binarization of the separate action may not be identical to the method used during recognition.

The check image must be the size of the check itself. You must crop any borders or white space around the check image making the actual image the same size, as the check recognition might not be correct.

The following shows a specific example ruleset and functions configured to process checks originating from Brazil. The page is first converted to black and white, and then run through the check processing action.

```
Ruleset Detect Checks
Function Process Check
    OCR_AConvertImageToBW("tio")
    ProcessCheckBrazil(false)
```

- [ProcessCheckBrazil](#)

Parent topic: [CheckProcessing actions](#)

ProcessCheckBrazil

Important: This action is deprecated and scheduled to be removed in a future release. Use the ProcessCheck action in the CheckProcessing library. For more information, see [ProcessCheck](#).

Member of namespace

CheckProcessing

Syntax

```
bool ProcessCheckBrazil (bool createFields)
```

Parameters

createFields:

When set to true, runtime DCO fields are created with the extracted data.

Details

Detects check images and stores the following extracted data into variables at the page level:

- Amount
- Date
- AmountVerification
- CAR
- LAR
- LARCARMismatch
- MICR
- PayorId
- Place
- TopLine
- PresenceFront

Level

Page.

Returns

True, if the current image is a check. Otherwise, False.

```
OCR_AConvertImage2BW("tio")
ProcessCheckBrazil(true)
```

Parent topic: [CheckProcessingBrazil](#)

CheckProcessingCanada

Performs data extraction from checks originating from Canada.

Important: This action is deprecated and scheduled to be removed in a future release. Use the `ProcessCheck` action in the `CheckProcessing` library. For more information see [ProcessCheck](#).

This library supports single page, black and white or 8 bit gray-scale TIF and images, or color JPEG images with a resolution of 200-300 DPI. If the images are colored or 8 bit gray scale, these images are automatically binarized in memory before the recognition, leaving the original image untouched. You can use actions to binarize images before processing so you have a saved black and white image. You can use a separate action to convert to black and white before performing check recognition.

CAUTION:

The binarization of the separate action may not be identical to the method used during recognition.

The check image must be the size of the check itself. You must crop any borders or white space around the check image making the actual image the same size, as the check recognition might not be correct.

The following shows a specific example ruleset and functions configured to process checks originating from Canada. The page is first converted to black and white, and then run through the check processing action.

Parent topic: [CheckProcessing actions](#)

ProcessCheckFrance

Important: This action is deprecated and scheduled to be removed in a future release. Use the [ProcessCheck](#) action in the [CheckProcessing](#) library. For more information, see [ProcessCheck](#).

Member of namespace

CheckProcessing

Syntax

```
bool ProcessCheckFrance (bool createFields)
```

Parameters

createFields:

When set to true, runtime DCO fields are created with the extracted data.

Details

Detects check images and stores the following extracted data into variables at the page level:

- Amount
- Date
- AmountVerification
- CAR
- LAR
- LARCARMismatch
- MICR
- CheckSum
- PresenceFront

Level

Page.

Returns

True, if the current image is a check. Otherwise, False.

```
OCR_AConvertImage2BW("tio")  
ProcessCheckFrance(true)
```

Parent topic: [CheckProcessingFrance](#)

CheckProcessingIndia

Performs data extraction from checks originating from India.

Important: This action is deprecated and scheduled to be removed in a future release. Use the ProcessCheck action in the CheckProcessing library. For more information see [ProcessCheck](#).

This library supports single page, black and white or 8 bit gray-scale TIF and images, or color JPEG images with a resolution of 200-300 DPI. If the images are colored or 8 bit gray scale, these images are automatically binarized in memory before the recognition, leaving the original image untouched. You can use actions to binarize images before processing so you have a saved black and white image. You can use a separate action to convert to black and white before performing check recognition.

CAUTION:

The binarization of the separate action may not be identical to the method used during recognition.

The check image must be the size of the check itself. You must crop any borders or white space around the check image making the actual image the same size, as the check recognition might not be correct.

The following shows a specific example ruleset and functions configured to process checks originating from India. The page is first converted to black and white, and then run through the check processing action.

```
Ruleset Detect Checks  
  Function Process Check  
    OCR_AConvertImageToBW("tio")  
    ProcessCheckIndia(false)
```

- [ProcessCheckIndia](#)

Parent topic: [CheckProcessing actions](#)

ProcessCheckIndia

Important: This action is deprecated and scheduled to be removed in a future release. Use the ProcessCheck action in the CheckProcessing library. For more information, see [ProcessCheck](#).

Member of namespace

CheckProcessing

Syntax

```
bool ProcessCheckIndia (bool createFields, string checkBackSideImagePath)
```

Parameters

createFields

When set to true, runtime DCO fields are created with the extracted data.

checkBackSideImagePath (required)

Full path to the image for the back side of the check. Smart parameter supported.

Details

Detects check images and stores the following extracted data into variables at the page level:

- AccountNoFront
- AccountNoBack
- Amount
- Date
- AmountVerification
- CAR
- LAR
- LARCARMismatch
- CtsCompliance
- CurrencySymbol
- DdMmYyyyCompliance
- VerticalTextPresence
- DateBoxes
- MICR

Note: This action requires a front and back check image. The front image is obtained from the image that belongs to the current page object. The back image is specified as the second parameter to this action. If a back image is not specified, then the image that belongs to the next consecutive page is used.

Level

Page.

Returns

True, if the current image is a check and if the back image is also present. Otherwise, False.

```
OCR_AConvertImage2BW("tio")
ProcessCheckIndia(true, "c:\datacap\checks\batches\20150102.001\tm0000001_back.tif")
```

Parent topic: [CheckProcessingIndia](#)

CheckProcessingUK

Performs data extraction from checks originating from the United Kingdom.

Important: This action is deprecated and scheduled to be removed in a future release. Use the `ProcessCheck` action in the `CheckProcessing` library. For more information see [ProcessCheck](#).

This library supports single page, black and white or 8 bit gray-scale TIF and images, or color JPEG images with a resolution of 200-300 DPI. If the images are colored or 8 bit gray scale, these images are automatically binarized in memory before the recognition, leaving the original image untouched. You can use actions to binarize images before processing so you have a saved black and white image. You can use a separate action to convert to black and white before performing check recognition.

CAUTION:

The binarization of the separate action may not be identical to the method used during recognition.

The check image must be the size of the check itself. You must crop any borders or white space around the check image making the actual image the same size, as the check recognition might not be correct.

The following shows a specific example ruleset and functions configured to process checks originating from the United Kingdom. The page is first converted to black and white, and then run through the check processing action.

Parent topic: [CheckProcessing actions](#)

ProcessCheckUk

Important: This action is deprecated and scheduled to be removed in a future release. Use the [ProcessCheck](#) action in the [CheckProcessing](#) library. For more information, see [ProcessCheck](#).

Member of namespace

CheckProcessing

Syntax

```
bool ProcessCheckUk (bool createFields)
```

Parameters

createFields:

When set to true, runtime DCO fields are created with the extracted data.

Details

Detects check images and stores the following extracted data into variables at the page level:

- AccountNoFront
- AccountNoBack
- Amount
- Date
- AmountVerification
- CAR
- LAR
- LARCARMismatch
- CheckSum
- PresenceFront

Level

Page.

Returns

True, if the current image is a check. Otherwise, False.

```
OCR_AConvertImage2BW("tio")
ProcessCheckUk(true)
```

Parent topic: [CheckProcessingUK](#)

CheckProcessingUs

Performs data extraction from checks originating from the United States.

Important: This action is deprecated and scheduled to be removed in a future release. Use the `ProcessCheck` action in the `CheckProcessing` library. For more information see [ProcessCheck](#).

This library supports single-page, black-and-white or 8-bit gray-scale TIF images, or color JPEG images with a resolution of 200-300 DPI. If the images are colored or 8 bit gray scale, these images are automatically binarized in memory before the recognition, leaving the original image untouched. You can use actions to binarize images before processing so you have a saved black and white image. You can use a separate action to convert to black and white before performing check recognition.

CAUTION:

The binarization of the separate action may not be identical to the method used during recognition.

The check image must be the size of the check itself. You must crop any borders or white space around the check image making the actual image the same size, as the check recognition might not be correct.

The following shows a specific example ruleset and functions configured to process checks originating from the United States. The page is first converted to black and white, and then run through the check processing action.

```
Ruleset Detect Checks
Function Process Check
    OCR_AConvertImageToBW("tio")
    ProcessCheckUs(false)
```

- [ProcessCheckUs](#)
Detects check images and stores extracted data into variables at the page level.

Parent topic: [CheckProcessing actions](#)

ProcessCheckUs

Detects check images and stores extracted data into variables at the page level.

Important: This action is deprecated and scheduled to be removed in a future release. Use the `ProcessCheck` action in the `CheckProcessing` library. For more information, see [ProcessCheck](#).

Member of namespace

`CheckProcessing`

Syntax

```
bool ProcessCheckUs (bool createFields)
```

Parameters

`createFields:`

When set to true, runtime DCO fields are created with the extracted data.

`engine`

An integer value that determines which engine to use. The default value is 0, which uses the CheckPlus Engine. This engine has an 82% read rate, and 1% error rate. It extracts the check type, amount, MICR, date, and check number.

Details

Detects check images and stores the following extracted data into variables at the page level:

- Amount
- Date
- MICR (when read successfully)
- CAR (when read successfully)
- LAR (when read successfully)
- DocumentType

Level

Page

Returns

True, if the current image is a check. Otherwise, False.

```
OCR_AConvertImage2BW("tio")  
ProcessCheckUs(true,0)
```

Parent topic: [CheckProcessingUs](#)

CMISClient actions

Content Management Interoperability Services (IBM® CMIS) is an open standard that CMISClient actions use to enable communication between Datacap applications and content management systems over the internet.

The CMISClient actions configure the connection between Datacap applications and the IBM CMIS server. You run these actions to access the CMIS server, set up document attributes and folders on the server, and upload documents to the server for storage.

- [CMISCreateFolder](#)
Creates a folder on the CMIS server.
- [CMISCreateFolderCustomType](#)
Creates a folder on the CMIS server and allows specification of the folder type.
- [CMISDeleteFile](#)
Deletes a file on the CMIS server.
- [CMISDeleteFolder](#)
Deletes a folder on the CMIS server.
- [CMISDoesFileExist](#)
Tests that a file exists on the CMIS server.
- [CMISDoesFolderExist](#)
Tests that a folder exists on the CMIS server.
- [CMISDownloadFile](#)
Download a file that is on the CMIS server to a local hard disk.
- [CMISLogDocumentTypes](#)
Logs the document types defined on the CMIS server.

- [CMISLogin](#)
Supply login credentials and connect to the CMIS server.
- [CMISRefreshClientCache](#)
Refreshes the client-side cache.
- [CMISSetDocUploadProperty](#)
Sets the value of a property that belongs to the file that is uploaded.
- [CMISSetDocUploadType](#)
Sets the type of the file that will be uploaded.
- [CMISSetVersion](#)
Sets the version type of the file that is uploaded.
- [CMISUploadFile](#)
Upload a file to the CMIS server.
- [CMISUploadPage](#)
Upload the current DCO page to the CMIS server.

Parent topic: [Global actions](#)

CMISCreateFolder

Creates a folder on the CMIS server.

Member of namespace

CMISClient

Syntax

```
bool CMISCreateFolder(string cmisFolderParentPath, string cmisFolderName)
```

Parameters

cmisFolderParentPath

Type: string

cmisFolderName

Type: string

Parameters

- cmisFolderParentPath : The path of the parent folder.
- cmisFolderName : The name of the new folder.

Smart parameters are supported for all parameters.

Returns

True if the folder is created. Otherwise, False.

Level

All levels.

Details

Creates a folder on the configured CMIS server.

Note that objects created on the CMIS server may not be immediately accessible by the client. For example, the indexing service on your CMIS server may run on a configured interval, so your new object may not be available until the indexing service completes. If you are having trouble accessing newly created objects, check the settings and documentation of your CMIS server to determine when objects should become available.

Example:

```
CMISCreateFolder ("/MyParent", "MyNewFolder")
```

Creates the folder MyNewFolder in the MyParent folder.

Parent topic: [CMISClient actions](#)

CMISCreateFolderCustomType

Creates a folder on the CMIS server and allows specification of the folder type.

Member of namespace

CMISClient

Syntax

```
bool CMISCreateFolderCustomType (string cmisFolderPath, string cmisFolderName,  
string cmisFolderType)
```

Parameters

cmisFolderPath

Type: string

cmisFolderName

Type: string

cmisFolderType

Type: string

Parameters

- cmisFolderPath: The path of the parent folder.
- cmisFolderName: The name of the new folder.
- cmisFolderType: The type of the new folder.

Smart parameters are supported for all parameters.

Returns

True if the folder is created. Otherwise, False.

Level

All levels.

Details

Creates a folder on the configured CMIS server.

Note that objects created on the CMIS server may not be immediately accessible by the client. For example, the indexing service on your CMIS server may run on a configured interval, so your new object may not be available until the indexing service completes. If you are having trouble accessing newly created objects, check the settings and documentation of your CMIS server to determine when objects should become available.

Example:

```
CMISCreateFolderCustomType("/MyParent", "MyNewFolder", "MyType")
```

Creates the folder MyNewFolder in the MyParent folder.

Parent topic: [CMISClient actions](#)

CMISDeleteFile

Deletes a file on the CMIS server.

Member of namespace

CMISClient

Syntax

```
bool CMISDeleteFile(string cmisFilePath, bool ignoreFailure)
```

Parameters

cmisFilePath
Type: string
ignoreFailure
Type: bool

Parameters

- cmisFilePath : The file to delete on the CMIS server. Smart parameters are supported.
- ignoreFailure : Set to True to ignore any failure so the action will always return True.

Returns

If ignoreFailure is True, the action always returns True, even if the file could not be deleted. If ignoreFailure is False, returns True if the file is deleted, otherwise False is returned.

Level:

All levels.

Details

Deletes the specified file in the CMIS repository.

Some, but not all, repositories have the notion of a "soft" delete, which will perform the final deletion at a later time. You should assume that once the object is deleted, that it is deleted forever. If an object is deleted, it can

only be restored if the repository provides a mechanism to restore the object.

A delete failure can be ignored by using the `ignoreFailure` parameter. This allows actions to continue even if the delete should fail.

Example:

```
CMISDeleteFile("/MyFolder/MyDoc.txt", false)
```

This returns true if `MyDoc.txt` is deleted, otherwise it returns false.

```
CMISDeleteFile("/MyFolder/MyDoc.txt", true)
```

This always returns true, even if the file could not be deleted.

Parent topic: [CMISClient actions](#)

CMISDeleteFolder

Deletes a folder on the CMIS server.

Member of namespace

CMISClient

Syntax

```
bool CMISDeleteFolder(string cmisDirectoryPath, bool ignoreFailure)
```

Parameters

`cmisDirectoryPath`

Type: string

`ignoreFailure`

Type: bool

Parameters

- `cmisDirectoryPath` : The path of the folder to delete. Smart parameters are supported.
- `ignoreFailure` : Set to True to ignore any failure so the action will always return True.

Returns

If `ignoreFailure` is True, the action always returns True, even if the folder could not be deleted. If `ignoreFailure` is False, the action will return True if the directory is deleted, otherwise False is returned.

Level

All levels.

Details

The folder must be empty for the delete to be successful. Some, but not all, CMIS repositories have the notion of a "soft" delete where the deletion is performed at a later time. You should assume that once the object is

deleted, that it is deleted forever. If an object is deleted, it can only be restored if the repository provides a mechanism to restore the object.

A delete failure can be ignored by using the `ignoreFailure` parameter. This allows actions to continue even if the delete should fail.

Example:

```
CMISDeleteFolder("/MyFolder/AnotherFolder", false)
```

This returns true if `AnotherFolder` is deleted, otherwise it returns false.

```
CMISDeleteFolder("/MyFolder/AnotherFolder", true)
```

This always returns true, even if the folder is not deleted.

Parent topic: [CMISClient actions](#)

CMISDoesFileExist

Tests that a file exists on the CMIS server.

Member of namespace

CMISClient

Syntax

```
bool CMISDoesFileExist(string cmisFilePath, bool existenceResult)
```

Parameters

`cmisFilePath`
Type: string
`existenceResult`
Type: bool

Parameters

- `cmisFilePath` : The document and path to test for existence. Smart parameters are supported.
- `existenceResult` : If True the action will return True when the file exists, otherwise False is returned. If False the action will return false if the file exists, otherwise True is returned.

Returns

`existenceResult` if True, then return True if file exists. If False, return True if file does not exist.

Level

All levels.

Details

This action tests that the provided file exists in the connected CMIS repository. This action can be configured to return true if the file exists or return true if the file does not exist.

Example:

```
CMISDoesFolderExist("/MyFolder/MyDoc.txt", True)
```

Returns true if MyDoc.txt exists in the repository and returns false if it does not exist.

```
CMISDoesFolderExist("/MyFolder/MyDoc.txt", False)
```

Returns false if MyDoc.txt exists in the repository and returns true if MyFolder does not exist.

Parent topic: [CMISClient actions](#)

CMISDoesFolderExist

Tests that a folder exists on the CMIS server.

Member of namespace

CMISClient

Syntax

```
bool CMISDoesFolderExist(string cmisDirectoryPath, bool existenceResult)
```

Parameters

cmisDirectoryPath
Type: string
existenceResult
Type: bool

Parameters

- cmisDirectoryPath : The folder and path to test for existence. Smart parameters are supported.
- existenceResult : If True the action will return True when the folder exists, otherwise False is returned. If False the action will return False if the folder exists, otherwise True is returned.

Returns

existenceResult if True, then returns True if folder exists. If False, returns True if directory does not exist.

Level

All levels.

Details

Tests that the provided directory path exists in the connected CMIS repository. This action can be configured to return true if the folder exists or return true if the folder does not exist.

Example:

```
CMISDoesFolderExist("/MyFolder/AnotherFolder", True)
```

Returns true if "AnotherFolder" exists in the repository and returns false if it does not exist.

```
CMISDoesFolderExist("/MyFolder/AnotherFolder", False)
```

Returns false if "AnotherFolder" exists in the repository and returns true if the folder does not exist.

Parent topic: [CMISClient actions](#)

CMISDownloadFile

Download a file that is on the CMIS server to a local hard disk.

Member of namespace

CMISClient

Syntax

```
bool CMISDownloadFile(string cmisFileToDownload, string fullFileNameTarget)
```

Parameters

cmisFileToDownload

Type: string

fullFileNameTarget

Type: string

Parameters

- cmisFileToDownload : The file, with the full path, to download from the CMIS repository.
- fullFileNameTarget : The path and file name for the downloaded file. Smart parameters are supported for all parameters.

Returns

Returns True, if the download is successful. Otherwise, False.

Level:

All levels.

Details

Downloads a file from the CMIS repository to a local hard disk. The file in the repository is not changed. If the target file exists, it is overwritten.

Example:

```
CMISDownloadFile("/MyCMISDir/MyCMISFile.txt", "c:\MyLocalDir\MyLocalFile.txt")
```

Downloads a copy of the file MyCMISFile.txt and names it MyLocalFile.txt on the local system.

Parent topic: [CMISClient actions](#)

CMISLogDocumentTypes

Logs the document types defined on the CMIS server.

Member of namespace

CMISClient

Syntax

```
bool CMISLogDocumentTypes ()
```

Parameters

None.

Returns

Always True.

Level

All levels.

Details

This action will query the CMIS server and log all of the server defined document types to the RRS log, providing that logging is enabled. This is a diagnostic action and is not intended for use in a production environment, nor is it supported in a production environment. CMISLogin must be called prior to this action.

It may be useful for an developer to obtain this type information during application development and has no intended use other than this limited diagnostic. Be aware that depending on the number of types and attributes defined on the CMIS server, this action may be slow and create a large log file.

Example:

```
LogDocumentTypes ()
```

Parent topic: [CMISClient actions](#)

CMISLogin

Supply login credentials and connect to the CMIS server.

Member of namespace

CMISClient

Syntax

```
bool CMISLogin (string atomPubURL, string userID, string password,  
string repositoryID)
```

Parameters

atomPubURL
Type: string
userID
Type: string
password
Type: string
repositoryID
Type: string

Parameters

- atomPubURL : The AtomPub URL for your CMIS compatible repository.
- userID : The logon user ID.
- password : The password.
- repositoryID: Optionally specify the CMIS repository ID.

Smart parameters are supported for all parameters.

Returns

True if the login was successful. Otherwise, False.

Level

All levels.

Details

This action connects to a CMIS compatible repository by using an AtomPub URL. If the repository ID is blank, the connection is made to the first repository that is returned from the CMIS connection. This action must be called before you can use any of the other CMIS actions.

Example:

```
CMISLogin("http://localhost:8080/alfresco/service/api/cmisis", "MyUserID", "@APPVARIABLES/adv/cmisispassword")
```

The password is obtained from the application service and is set by using the Application Manager.

```
CMISLogin("http://localhost:8080/alfresco/service/api/cmisis", "MyUserID", "@APPVARIABLES/adv/cmisispassword", "MyRepositoryID")
```

This example passes the optional repository ID.

Parent topic: [CMISClient actions](#)

CMISRefreshClientCache

Refreshes the client-side cache.

Member of namespace

Syntax

```
bool CMISRefreshClientCache(string milliseconds)
```

Parameters

milliseconds
Type: string

Parameters

milliseconds : Refreshes the object local cache if it is older than the specified number of milliseconds. A value of 0 refreshes immediately. A value of -1 disables this refresh feature and the CMIS interface manages the cache itself. By default, this refresh is disabled. Smart parameters are supported.

Returns

Always True.

Level

All levels.

Details

CMIS client-side caching first checks the session cache, if an object exists in the client cache. If the required object is found, that object is used without contacting the repository. It is possible that it might be a stale object.

This action refreshes the client-side cache, if it is older than the time specified in the parameter. The value of 0 refreshes the cache immediately. This action affects all subsequent CMIS actions, refreshing each object as they are used. Call this action with a value of -1 to disable this automatic refresh.

Typically this action does not need to be called. It can be called when a specific application requires a cache refresh. If this action is not called, the CMIS interface manages the cache as appropriate.

Note: Objects that are created on the CMIS server might not be immediately accessible by the client. For example, the indexing service on your CMIS server might run on a configured interval, so a new object might not be available until the indexing service completes. This refresh setting does not affect components on the CMIS server, such as the indexing service interval. If you have trouble accessing newly created objects, check the settings and documentation of your CMIS server to determine when objects become available.

Example:

```
CMISRefreshClientCache("1000")
```

Refreshes the client local cache if it is older than 1 second.

Parent topic: [CMISClient actions](#)

CMISSetDocUploadProperty

Sets the value of a property that belongs to the file that is uploaded.

Member of namespace

CMISClient

Syntax

```
bool CMISSetDocUploadProperty(string cmisDocPropertyname, string cmisDocPropertyValue,
string valueType, bool isMulti)
```

Parameters

cmisDocPropertyname

Type: string

cmisDocPropertyValue

Type: string

valueType

Type: string

isMulti

Type: bool

Parameters

- cmisDocPropertyname : The name of the CMIS property to set.
- cmisDocPropertyValue : The value of the specified property.
- valueType : The CMIS type of the value. Must be string, integer, datetime, or boolean.
- isMulti : True, if the CMIS type is a multi-value type. False, if the CMIS type is single.

Smart parameters are supported for cmisDocPropertyname, cmisDocPropertyValue and valueType.

Returns

False, if the property cannot be set or the datetime parameter cannot not be processed. Otherwise, True.

Level

All levels.

Details

This action sets a value to the specified property for files or pages that are uploaded to the CMIS repository. Use of this action is optional. Standard CMIS properties are of the form CMIS:xxx. By convention, custom CMIS properties do not use the CMIS: prefix.

This action must be called before CMISUploadFile or CMISUploadPage. If multiple properties need to be set for a document upload, call this action multiple times to set multiple properties. The property must be defined for the document type within the CMIS repository. If the property or value is not valid for the document type, the error is not reported until the upload action is called. When the upload is complete, the property settings set with this action are discarded and this action needs to be called again to set any custom properties for another upload.

For a Boolean property type, the value must be either True or False.

The datetime type accepts an input string that specifies just the date or the date and time. The application attempts to parse the input date format based on the current locale. The action uses the locale set in the Application Service / *hr_locale* variable. If that is not set, the current OS locale is used to interpret the date/time. The action attempts to ignore unrecognized data, if possible. If the month, day, or year is missing, it attempts to use the values from the current date. If a time is not specified, then the time is set to 12:00 midnight. It is recommended to provide the full short date in the correct format for the current locale, and a full 4-digit year, to reduce the chance of the action guessing values incorrectly. Only Gregorian short date formats are supported.

Example input datetime strings in the en-US locale.

- 05/01/2009 14:57:32.8 becomes 5/1/2009 2:57:32 PM
- 2009-05-01 14:57:32.8 becomes 5/1/2009 2:57:32 PM
- 2009-05-01T14:57:32.8375298-04:00 becomes 5/1/2009 11:57:32 AM
- 5/01/2008 14:57:32.80 -07:00 becomes 5/1/2008 2:57:32 PM.

Example:

```
SetCMISDocUploadType("cmisbook:poem")
SetCMISDocUploadProperty("cmisbook:author", "Edgar Allan Poe", "string", False)
SetCMISDocUploadProperty("cmisbook:Title", "The Raven", "string", False)
CMISUploadPage("MyFile.txt", "/MyCMISDir", "text/plain")
```

This example uses a predefined custom document type and then sets the author and title properties of the uploaded file.

Parent topic: [CMISClient actions](#)

CMISSetDocUploadType

Sets the type of the file that will be uploaded.

Member of namespace

CMISClient

Syntax

```
bool CMISSetDocUploadType(string cmisDocType)
```

Parameters

cmisDocType
Type: string

Parameters

cmisDocType : The document type of the uploaded file. Smart parameters are supported.

Returns

Always returns True.

Level

All levels.

Details

This action sets the CMIS document type for the file that will be subsequently uploaded in a following upload action. Use of this action is optional. If it is not called, the value of `cmis:document` is used. To set the document type, this action must be called before `CMISUploadFile` or `CMISUploadPage`.

Standard CMIS properties are of the form `CMIS:xxx`. By convention, custom CMIS properties should not use the `CMIS:` prefix. Calling this action with an empty string, will reset the value back to the default `cmis:document` type. Once the upload is complete, the document type is reset to the default value and this action will need to be called again to set a custom value for another upload.

If the specified upload type is invalid or not defined on your CMIS server, an error will occur in the upload action.

Example:

```
SetCMISDocUploadType("cmisbook:poem")
SetCMISDocUploadProperty("cmisbook:author", "Edgar Allan Poe")
SetCMISDocUploadProperty("cmisbook:poemtitle", "The Raven")
CMISUploadPage("MyFile.txt", "/MyCMISDir", "text/plain")
```

This example uses a predefined custom document type and then sets the custom author and title properties of the uploaded file.

Parent topic: [CMISClient actions](#)

CMISSetVersion

Sets the version type of the file that is uploaded.

Member of namespace

CMISClient

Syntax

```
bool CMISSetVersion(string cmisVersion)
```

Parameters

`cmisVersion`
Type: string

Parameters

`cmisSetVersion` : The version of the uploaded document. It must be one of the following options: None, Major, Minor, CheckedOut. If this action is not called before the file upload, the None type is used.

Smart parameters are supported.

Returns

Always returns True. If the specified type is invalid or if a CMIS connection is not established, the version type defaults to None.

Level

All levels.

Details

Call this action before the `CMISUploadFile` action to set the version type of the uploaded file. The support for versions depends on the target repository. Check your repository documentation to determine which version types it supports when you are using the CMIS interface. The supported types might also vary based on the specific version configuration settings of your repository. This action is optional. If this action is not called, then the version type of None is used for uploaded files.

Example:

```
CMISSetVersion("Major")
CMISUploadFile("C:\MyDir\MyFile.txt", "MyFile.txt", "/MyCMISDir", "text/plain")
```

Parent topic: [CMISClient actions](#)

CMISUploadFile

Upload a file to the CMIS server.

Member of namespace

CMISClient

Syntax

```
bool CMISUploadFile(string fullyQualifiedFileName, string cmisUploadedName,
string cmisUploadDirectory, string mimeType)
```

Parameters

fullyQualifiedFileName

Type: string

cmisUploadedName

Type: string

cmisUploadDirectory

Type: string

mimeType

Type: string

Parameters

- fullyQualifiedFileName : The file name to upload with the full path specified.
- cmisUploadedName : The wanted final name of the file in the repository.
- cmisUploadDirectory : The full path for the folder within the repository where the file is stored.
- mimeType : The mime type of the uploaded file.

Smart parameters are supported for all parameters.

Returns

True, if the file is successfully uploaded. Otherwise, False.

Level

All levels.

Details

This action uploads a file to the configured repository. You can optionally set properties of the uploaded file using the actions `CMISSetDocUploadProperty` and `CMISSetDocUploadType`.

Note: Objects that are created on the CMIS server might not be immediately accessible by the client. For example, the indexing service on your CMIS server might run on a configured interval, so your new object might not be available until the indexing service completes. If you are not able to access newly created objects, check the settings and documentation of your CMIS server to determine when objects are available.

A record of uploaded files is placed in the file `UploadRecord.xml` in the batch directory.

Example:

```
SetCMISDocUploadType("cmisbook:poem")
SetCMISDocUploadProperty("cmisbook:author", "Edgar Allan Poe")
SetCMISDocUploadProperty("cmisbook:Title", "The Raven")
CMISUploadFile("C:\MyDir\MyFile.txt", "MyFile.txt", "/MyCMISDir", "text/plain")
```

The uploaded file is placed into the `\MyCMISDir` folder and be given the mime type of `text/plain`.

Parent topic: [CMISClient actions](#)

CMISUploadPage

Upload the current DCO page to the CMIS server.

Member of namespace

CMISClient

Syntax

```
bool CMISUploadPage(string cmisUploadedName, string cmisUploadDirectory,
string mimeType)
```

Parameters

`cmisUploadedName`

Type: string

`cmisUploadDirectory`

Type: string

`mimeType`

Type: string

Parameters

- `cmisUploadedName` : The desired final name of the file in the repository.
- `cmisUploadDirectory` : The full path for the folder within the repository where the file will be stored.
- `contentType` : The mime type of the uploaded file.

Smart parameters are supported for all parameters.

Returns

True if the file is successfully uploaded. Otherwise, False.

Level

All levels.

Details

This action uploads the current DCO page to the configured repository.

Note: Objects created on the CMIS server may not be immediately accessible. For example, the indexing service on your CMIS server may run on a configured interval, so your new object may not be available until the indexing service completes. If you are having trouble accessing newly created objects, check the settings and documentation of your CMIS server to determine when objects should become available.

A record of uploaded files will be placed in the file `UploadRecord.xml` in the batch directory.

Example:

```
SetCMISDocUploadType("cmisbook:poem")
SetCMISDocUploadProperty("cmisbook:author", "Edgar Allan Poe")
SetCMISDocUploadProperty("cmisbook:poemtitle", "The Raven")
CMISUploadPage("MyFile.txt", "/MyCMISDir", "text/plain")
```

This set of actions sets property values of the page that will be uploaded, then uploads the page. The current page is placed into the `\MyCMISDir` folder and be given the mime type of `text/plain`.

Parent topic: [CMISClient actions](#)

ColorToBW actions

Use the ColorToBW actions to change the color depth of an image.

The ColorToBW actions can specify the color-to-BW conversion settings and change the color depth of an image according to these conversion settings.

- [C2BW_Convert](#)
Changes the color depth of an image according to the conversion settings specified by using `C2BW_SetAttributes`.
- [C2BW_SetAttributes](#)
Specifies the color-to-BW conversion settings.

Parent topic: [Global actions](#)

C2BW_Convert

Changes the color depth of an image according to the conversion settings specified by using `C2BW_SetAttributes`.

Syntax

```
bool C2BW_Convert(sParam)
```

Parameters

C2BW_Convert always produces a TIF image. If the source image has a TIF extension, use this parameter to provide an extension to use for a backup of the original file.

If not provided, the parameter defaults to tio. If the source image does not have a TIF extension, this parameter is ignored and use a TIF extension and the original image name will not be changed.

Smart parameters are supported.

Returns

Always True.

Level

All Levels.

Details

Changes the color depth of an image based on a set of defined attributes, creating a new TIF image.

If action C2BW_SetAttributes is not called first, a black and white image will be created.

If called at the batch level converts all images. If called at the document level, images within the document are converted. If called on the page, or field level the page is converted.

The supported input image formats are TIF (including LZW compression), PNG, BMP and JPG.

Example

```
C2BW_SetAttributes("1","0","3")
C2BW_Convert("tic")
```

Parent topic: [ColorToBW actions](#)

Related reference:

[C2BW_SetAttributes](#)

C2BW_SetAttributes

Specifies the color-to-BW conversion settings.

Syntax

```
bool C2BW_SetAttributes(string BitsPerPixel, string Palette, string Dither)
```

Parameters

string BitsPerPixel

string Palette

string Dither

Parameters

Requires 3 numeric values to configure the output image specifications:

1. Bits per pixel - 1, 4, 8, 24. A bit depth of 1 will produce a black and white image. A bit depth of 4, 8 or 24 will produce a grayscale or color image depending on the selected palette.
2. Palette - 0 Optimized, 1 Fixed, 2 Grayscale.
3. Dither - 0 None, 1 Floyd-Steinberg, 2 Ordered, 3 Optimized.

Smart parameters are supported.

Returns

Always True.

Level

All levels.

Details

Adjusts the output of the action C2BW_Convert. Optionally called before C2BW_Convert to configure the desired image output specifications. If this action is not called, these default values are used by C2BW_Convert:

- BitsPerPixel = 1 (Black and White)
- Palette = 0 (Optimized)
- Dither = 0 (None)

Example

```
C2BW_SetAttributes("1","0","3")
C2BW_Convert(tic)
```

Parent topic: [ColorToBW actions](#)

[C2BW_Convert](#)

Convert actions

Use the Convert actions to convert various electronic document files into TIFF image files.

The convert actions can convert files from these formats; Microsoft Excel, HTML, Microsoft Outlook, PDF, RTF, Text, Microsoft Word.

- [Common actions](#)
Use the Common actions to define the properties that are used by all of the conversion libraries for exception handling.
- [Excel actions](#)
Use the Excel actions to convert a Microsoft Excel document file into TIFF image files.
- [Html actions](#)
Use the Html actions to convert an image file from HTML format to TIFF for recognition processing by Datacap.

- [Images actions](#)
Use the Images actions to convert various image formats into a black and white TIFF image file for recognition processing by Datacap.
- [Outlook actions](#)
Use the Outlook actions to convert the text of a Microsoft Outlook message file to a TIFF image file and save any attachments to disk. Saved attachments can then be processed as needed by subsequent actions.
- [Pdf actions](#)
Use the Pdf actions to convert an image file from PDF format to TIFF for recognition processing by Datacap.
- [PdfFRE actions](#)
Use the PdfFRE actions can use the Abbyy FineReader Engine to convert an image file from PDF format to TIFF for recognition processing by Datacap.
- [Rtf actions](#)
Use the Rtf actions to convert an image file from RTF format to TIFF for recognition processing by Datacap.
- [Tiff actions](#)
Use the Tiff action to convert a multi-page TIFF image file into multiple single page TIFF image files for recognition processing by Datacap.
- [Txt actions](#)
Use the Tiff actions to convert an image file from TXT format to TIFF for recognition processing by Datacap.
- [Word actions](#)
Use the Word actions to convert an image file from Microsoft Word format to TIFF for recognition processing by Datacap.
- [Zip actions](#)
Use the Zip actions to extract the images files in a compressed ZIP archive and convert them to separate TIFF files for recognition by Datacap.

Parent topic: [Global actions](#)

Common actions

Use the Common actions to define the properties that are used by all of the conversion libraries for exception handling.

The default behavior is to abort the batch. But you can enable continuing to run the batch after a failure to increment a variable or to raise a task condition if workflow routing is configured.

Exception handling can be isolated to specific file types, with the unspecified file types aborted upon exception.

- [DeleteSourceImagePages](#)
Removes source image DCO pages.
- [ExceptionSetFileTypes](#)
Sets the file types to be monitored for exception handling.
- [ExceptionSetHandler](#)
Sets the type of exception handling to use during a batch processing failure.
- [ExceptionSetVariableName](#)
Sets the runtime document hierarchy variable to increment upon execution.
- [ExceptionSetTaskCondition](#)
Sets the task condition to be raised upon execution.
- [SetNamePattern](#)
Changes the default naming pattern for the converted files.

- [SetNamePatternFileCheck](#)
Configures file checking behavior in naming pattern for converted files.
- [PDF compliance standards](#)
For some actions that create PDF documents, you can set the compliance standard for the produced PDF document.

Parent topic: [Convert actions](#)

DeleteSourceImagePages

Removes source image DCO pages.

Member of namespace

Convert

Syntax

```
bool DeleteSourceImagePages ()
```

Parameters

None

Returns

True, if the action is successful.

False, if an error is encountered.

Level

Batch.

Details

Removes pages where the associated file has been converted using the convert library actions. This action evaluates all the documents and pages, which are children of the batch folder. It deletes the pages that have generated new pages as a result of the convert actions.

Note: Pages are only deleted from the DCO but not the batch directory

Example:

```
DeleteSourceImagePages ()
```

Parent topic: [Common actions](#)

ExceptionSetFileTypes

Sets the file types to be monitored for exception handling.

Member of namespace

Convert

Syntax

```
bool ExceptionSetFileTypes(string types)
```

Parameters

types

Type: string

A comma delimited list of the file extensions to monitor.

Returns

Always True.

Level

Any level.

Details

Sets one or more file types to be monitored for special exception handling. Unspecified file types that encounter processing failures cause an abort without any further action. If this action is not called or the parameter is blank, then all file types are monitored.

Example:

```
ExceptionSetHandler(1)  
ExceptionSetFileTypes(.pdf, .doc, .docx, .xls, .xlsx, .txt)
```

Parent topic: [Common actions](#)

Related reference:

[ExceptionSetHandler](#)

ExceptionSetHandler

Sets the type of exception handling to use during a batch processing failure.

Member of namespace

Convert

Syntax

```
bool ExceptionSetHandler(int handler)
```

Parameters

handler

Type: integer

The type of exception handler.

Parameters

- 0: Abort the batch (Default).
- 1: Increment a variable in the runtime hierarchy, do not abort the batch.
- 2: Raise a task condition, do not abort the batch.

Returns

True, if a valid parameter is specified. Otherwise, False.

Level

Any level.

Details

Use this action to change or reset the abort behavior that is caused by conversion failures. Avoiding aborts can be useful when an external workflow process is already in place.

Example:

```
ExceptionHandler(0)
```

Parent topic: [Common actions](#)

Related reference:

[ExceptionHandlerFileTypes](#)

[ExceptionHandlerVariableName](#)

[ExceptionHandlerTaskCondition](#)

ExceptionHandlerVariableName

Sets the runtime document hierarchy variable to increment upon execution.

Member of namespace

Convert

Syntax

```
bool ExceptionSetVariableName(string varName)
```

Parameters

varName

Type: string

The variable to increment. Smart parameters are supported.

Returns

Always True.

Level

Any level.

Details

Sets the variable to increment upon execution.

The default value is `@B.ConvertExceptions` when the `ExceptionHandler` action is set to use the `var` variable value.

Example:

```
ExceptionHandler(1)
ExceptionSetVariableName(@B.PDFConvertExceptions)
```

Parent topic: [Common actions](#)

Related reference:
[ExceptionHandler](#)

ExceptionSetTaskCondition

Sets the task condition to be raised upon execution.

Member of namespace

Convert

Syntax

```
bool ExceptionSetTaskCondition(int taskCondition)
```

Parameters

`taskCondition`
Type: integer
A zero-based task condition index.

Returns

Always True.

Level

Any level.

Details

Sets the task condition, which is defined in workflow administration, to be raised upon execution.

Batch splitting is not supported.

Example:

```
ExceptionHandler(2)
ExceptionSetTaskCondition(0)
```

Parent topic: [Common actions](#)

Related reference:
[ExceptionHandler](#)

SetNamePattern

Changes the default naming pattern for the converted files.

Member of namespace

Convert

Syntax

```
bool SetNamePattern(string PatternType)
```

Parameters

PatternType

Type: string

A single positive numeric value.

Parameters

Value of 1 or 2.

- 1: Uses the default AlphaDecimal pattern, which consists of 4 pairs of 2 characters from 01 to ZZ.
- 2: Uses a TMxxxxxx pattern where xxxxxx is a number from 000001 to 999999.

Returns

True, if the setting is successful.

False, if the setting is rejected.

Level

Any level.

Details

Changes the default naming pattern for the converted files.

Example:

```
SetNamePattern(2)
```

Parent topic: [Common actions](#)

SetNamePatternFileCheck

Configures file checking behavior in naming pattern for converted files.

Member of namespace

Convert

Syntax

```
bool SetNamePatternFileCheck (bool fileCheck)
```

Parameters

- True - Enable file checking, naming pattern will increment count if preexisting files are found (Default).
- False - Disable file checking, preexisting files may be overwritten.

Returns

Always True.

Level

All.

Details

This action only applies to the AlphaDecimal naming pattern. Use this action to avoid appending files to the batch directory. When file checking is enabled, new output files do not overwrite the preexisting files in scenarios such as batch reprocessing, leading to increased disk consumption.

Example:

```
SetNamePatternFileCheck (False)
```

Parent topic: [Common actions](#)

PDF compliance standards

For some actions that create PDF documents, you can set the compliance standard for the produced PDF document.

Set the value of the variable `targetPdfCompliance` in accordance with the following table. This variable is on the DCO objects for which you are calling the action. The variable's value must be set before you call the action.

Standard	targetPdfCompliance value
Pdf15	No value is set. (This standard is the default standard.)
PdfA1a	"1"
PdfA1b	"2"

Parent topic: [Common actions](#)

Excel actions

Use the Excel actions to convert a Microsoft Excel document file into TIFF image files.

The Excel actions can resize columns or rows from a table, set page orientation, create blank pages, and print grid lines when you convert documents from Excel.

Restriction: The actions in the following table work with files from Excel 2000 or later.

- [ExcelAutoFitColumns](#)
Sets the automatic sizing of all columns for Excel Workbook converted to TIFF.
- [ExcelAutoFitRows](#)
Sets the automatic sizing of all rows for Excel Workbook converted to TIFF.
- [ExcelOrientationToLandscape](#)
Forces the orientation of Excel files to landscape for ExcelWorkbookToImage.
- [ExcelOrientationToPortrait](#)
Forces the orientation of Excel files to portrait for ExcelWorkbookToImage.
- [ExcelPrintBlankPage](#)
Determines if blank pages are created when converting Excel Workbook to TIFF.
- [ExcelPrintGridlines](#)
Enables or disables gridlines when converting Excel files to TIFF.
- [ExcelPrintQuality](#)
Adjusts the resolution of the image output by ExcelWorkbookToImage.
- [ExcelScalingFactor](#)
Forces the print scaling of Excel Workbook to a specific value for ExcelWorkbookToImage.
- [ExcelShapeMinArea](#)
Specifies the minimum area required for shape rendering for ExcelWorkbookToImage.
- [ExcelTiffCompression](#)
Sets the compression used in the TIFF output by ExcelWorkbookToImage.
- [ExcelWorkbookToImage](#)
Converts a page with *.xls or *.xlsx file to a page or pages in TIFF format.
- [ExcelWorkbookToImageEx](#)
Converts a page with *.xls or *.xlsx file to a page or pages in TIFF format.
- [ExcelWorkbookToPdf](#)
Converts .xls or .xlsx files to PDF document format.

Parent topic: [Convert actions](#)

ExcelAutoFitColumns

Sets the automatic sizing of all columns for Excel Workbook converted to TIFF.

Member of namespace

Convert

Syntax

```
bool ExcelAutoFitColumns (bool autoFitColumns)
```

Parameters

autoFitColumns
Type: bool

Parameters

autoFitColumns : A Boolean value that enables and disables the automatic sizing of columns in an Excel file.

True: The columns are set to automatically adjust the size based on the content.

False: The columns do not have their size adjusted.

Returns

Always True.

Level

Page level.

Details

This enables the auto sizing of columns to shrink or increase the size of the column to fit all of the data within the column. This action must be called before `ExcelWorkbookToImage`. If this action is not called, the setting that was saved in the original Excel file is used.

Example:

```
ExcelAutoFitColumns ("False")
ExcelWorkbookToImage ()
```

Parent topic: [Excel actions](#)

ExcelAutoFitRows

Sets the automatic sizing of all rows for Excel Workbook converted to TIFF.

Member of namespace

Convert

Syntax

```
bool ExcelAutoFitRows (bool autoFitRows)
```

Parameters

autoFitRows
Type: bool

Parameters

autoFitRows : A Boolean value that enables and disables the automatic sizing of rows in an Excel file.

True: The rows are set to automatically adjust the size based on the content.

False: The rows do not have their size adjusted.

Returns

Always True.

Level

Page level.

Details

This enables the auto sizing of rows to shrink or increase the size of the row to fit all of the data within the row. This action must be called before `ExcelWorkbookToImage`. If this action is not called, the setting that was saved in the original Excel file will be used.

Example:

```
ExcelAutoFitRows ("False")
ExcelWorkbookToImage ()
```

Parent topic: [Excel actions](#)

ExcelOrientationToLandscape

Forces the orientation of Excel files to landscape for `ExcelWorkbookToImage`.

Member of namespace

Convert

Syntax

```
bool ExcelOrientationToLandscape ()
```

Parameters

None.

Returns

Always True.

Level

Page level.

Details

The TIFF files created from `ExcelWorkbookToImage` will all be created with a landscape orientation. This action must be called before `ExcelWorkbookToImage`. If this action is not called, the portrait / landscape setting that was saved in the original Excel file is used.

Example:

```
ExcelOrientationToLandscape ()
ExcelWorkbookToImage ()
```

Parent topic: [Excel actions](#)

ExcelOrientationToPortrait

Forces the orientation of Excel files to portrait for ExcelWorkbookToImage.

Member of namespace

Convert

Syntax

```
bool ExcelOrientationToPortrait ()
```

Parameters

None.

Returns

Always True.

Level

Page level.

Details

The TIFF files created from ExcelWorkbookToImage will all be created with a portrait orientation. This action must be called before ExcelWorkbookToImage. If this action is not called, the portrait / landscape setting that was saved in the original Excel file is used.

Example:

```
ExcelOrientationToPortrait()  
ExcelWorkbookToImage()
```

Parent topic: [Excel actions](#)

ExcelPrintBlankPage

Determines if blank pages are created when converting Excel Workbook to TIFF.

Member of namespace

Convert

Syntax

```
bool ExcelPrintBlankPage (bool blankPage)
```

Parameters

blankPage

Type: bool

Parameters

blankPage : A Boolean value that enables or disables creation of blank TIFFs when there is a blank Excel page.

True: A blank TIFF is created if the page is blank.

False: A blank TIFF is not created if the page is blank.

Returns

Always True.

Level

Page level.

Details

When printing an Excel Workbook, it is typical to have overflow pages that sometimes have data and sometimes are blank. Setting the value to true creates a TIFF for the blank overflow pages in this process. If this action is not called before ExcelWorkbookToImage, then the default of False is used.

Example:

```
ExcelPrintBlankPage ("False")  
ExcelWorkbookToImage ()
```

Parent topic: [Excel actions](#)

ExcelPrintGridlines

Enables or disables gridlines when converting Excel files to TIFF.

Member of namespace

Convert

Syntax

```
bool ExcelPrintGridlines (bool gridlines)
```

Parameters

gridlines

Type: bool

Parameters

gridlines : A Boolean value that determines if gridlines are displayed in Excel files converted to TIFF.

True: Gridlines are included in the converted image.

False: Gridlines are not shown in the converted image.

Returns

Always True.

Level

Page level.

Details

The TIFF files created from `ExcelWorkbookToImage` will all use the specified grid setting when converted to TIFF. This action must be called before `ExcelWorkbookToImage`. If this action is not called, the grid line setting that was saved in the original Excel file is used.

Example:

```
ExcelPrintGridlines("False")
ExcelWorkbookToImage()
```

Parent topic: [Excel actions](#)

ExcelPrintQuality

Adjusts the resolution of the image output by `ExcelWorkbookToImage`.

Member of namespace

Convert

Syntax

```
bool ExcelPrintQuality (int dpi)
```

Parameters

dpi
Type: int

Parameters

dpi : A single positive numeric value for the dots per inch (dpi) of the output image.

Returns

False if the parameter is invalid. Otherwise, True.

Level

Page level.

Details

Sets the resolution of the output image for `ExcelWorkbookToImage`. If this action is not called, the default value of 200 dpi will be used. Typically, input documents for recognition are 200 dpi.

Example:

```
ExcelPrintQuality(200)
ExcelWorkbookToImage()
```

Parent topic: [Excel actions](#)

ExcelScalingFactor

Forces the print scaling of Excel Workbook to a specific value for `ExcelWorkbookToImage`.

Member of namespace

Convert

Syntax

```
bool ExcelScalingFactor (int percent)
```

Parameters

percent
Type: int

Parameters

percent: A positive integer that controls the scaling by percentage used when converting an Excel Workbook to TIFF. For example, a value of 100 means to print at 100%.

Returns

Always True.

Level

Page level.

Details

The TIFF files created from `ExcelWorkbookToImage` will all use the specified printing scale value when converted to TIFF. This action must be called before `ExcelWorkbookToImage`. If this action is not called, the scaling factor that was saved in the original Excel file is used.

Example:

```
ExcelScalingFactor(100)
ExcelWorkbookToImage()
```

Parent topic: [Excel actions](#)

ExcelShapeMinArea

Specifies the minimum area required for shape rendering for ExcelWorkbookToImage.

Member of namespace

Convert

Syntax

```
bool ExcelShapeMinArea (long minShapeArea)
```

Parameters

minShapeArea -1 to render all shapes, 0 to remove all shapes, or a positive pixel value. Default is -1.

Returns

Always True.

Level

Page level.

Details

Sets the minimum pixel area required by shape objects in a workbook. When a positive numeric value is specified, any shape whose area is less than the parameter value will not be output during ExcelWorkBookToImage. Shapes include object types such as lines, rectangles, and charts.

Example:

```
ExcelShapeMinArea (100)  
ExcelWorkbookToImage ()
```

Parent topic: [Excel actions](#)

ExcelTiffCompression

Sets the compression used in the TIFF output by ExcelWorkbookToImage.

Member of namespace

Convert

Syntax

```
bool ExcelTiffCompression (string tiffCompression)
```

Parameters

tiffCompression
Type: string

Parameters

tiffCompression is one of the following values to set the TIFF compression:

- NONE : A color image with no compression.
- LZW : A color image using LZW compression.
- CCITT4 : A black and white image with fax CCITT4 compression.

Returns

Always True.

Level

Page level.

Details

Sets the compression of the output image from ExcelWorkbookToImage. If this action is not called, the default value of CCITT4 is used. Typically, input documents for recognition are black and white with fax compression.

Example:

```
ExcelTiffCompression("CCITT4")
ExcelWorkbookToImage()
```

Parent topic: [Excel actions](#)

ExcelWorkbookToImage

Converts a page with *.xls or *.xlsx file to a page or pages in TIFF format.

Member of namespace

Convert

Syntax

```
bool ExcelWorkbookToImage ()
```

Parameters

None.

Returns

True if the file is successfully converted to a TIFF document.

False if the current page is not an Excel Workbook or if there is a failure in the conversion.

If the number of input files/pages exceeds the maximum allowed or if there is a failure in the conversion, the batch is set to abort.

Level

Page level.

Details

If the current page is an Excel Workbook, the file is converted to multiple TIFF files, one TIFF file for each page within the Workbook, based on the settings of the other Excel actions that configure the conversion settings.

Each new TIFF also has a new page created within the application environment which can be processed by subsequent rules. The original file name from which the page was extracted is stored in the *ParentImage* variable, for possible future reference within your application.

If the configured output image format and compression only supports black and white, such as CCITT4, colored text is exported as black and background shading is set to white.

Example:

```
ExcelPrintQuality(200)
ExcelTiffCompression(CCITT4)
ExcelPrintBlankPage(False)
ExcelWorkbookToImage()
```

Parent topic: [Excel actions](#)

ExcelWorkbookToImageEx

Converts a page with *.xls or *.xlsx file to a page or pages in TIFF format.

Member of namespace

Convert

Syntax

```
bool ExcelWorkbookToImageEx (int maxOutputPages, int startingSheet, bool
singleSheetOutput)
```

Parameters

maxOutputPages

0 to convert all pages within the spreadsheet, or a positive integer value. Default is 0.

startingSheet

Zero-based sheet index denoting the starting point of conversion. Default is 0.

singleSheetOutput

True to only convert the starting sheet regardless of how many pages are allowed by maxOutputPages. Default is false.

Returns

True if the file is successfully converted to a TIFF document.

False if the current page is not an Excel Workbook or if there is a failure in the conversion.

If the number of input files/pages exceeds the maximum allowed or if there is a failure in the conversion, the batch is set to abort.

Level

Page level.

Details

If the current page is an Excel Workbook, the file is converted to multiple TIFF files, one TIFF file for each page within the Workbook, based on the settings of the other Excel actions that configure the conversion settings.

The number of converted pages can be capped to avoid excessive output. You can also specify the starting sheet index. If the value is out of range then the last sheet will be used. Conversion is limited to a single sheet when specifically enabled (by using `singleSheetOutput` or when the maximum converted page count (`maxOutputPages`) has been met.

Each new TIFF also has a new page created within the application environment which can be processed by subsequent rules. The original file name from which the page was extracted is stored in the *ParentImage* variable, for possible future reference within your application.

If the configured output image format and compression only supports black and white, such as CCITT4, colored text is exported as black and background shading is set to white.

Example:

```
ExcelPrintQuality(200)
ExcelTiffCompression(CCITT4)
ExcelPrintBlankPage(False)
ExcelWorkbookToImageEx(5,0,false)
```

Parent topic: [Excel actions](#)

ExcelWorkbookToPdf

Converts .xls or .xlsx files to PDF document format.

Member of namespace

Convert

Syntax

```
bool ExcelWorkbookToPdf ()
```

Returns

True if the file conversion succeeds. Otherwise, the action returns False if the current page is not an Excel document or some other conversion failure occurs..

Level

Page level.

Details

Use this action to convert Excel files to a single PDF file. To set the compliance standard for the produced PDF document, set the value of the variable `targetPdfCompliance` in accordance with the following table:

Standard	targetPdfCompliance value
Pdf15	No value is set. (This standard is the default standard.)
PdfA1b	"1"

This action sets the batch to abort in the following circumstances:

- The number of input files or pages exceeds the allowed maximum.
- The conversion fails.

Example:

```
ExcelWorkbookToPdf
```

Parent topic: [Excel actions](#)

Html actions

Use the Html actions to convert an image file from HTML format to TIFF for recognition processing by Datacap.

The Html actions can specify output resolution and the compression algorithm to use when you convert documents from HTML to TIFF.

- [HtmlLayout](#)
Sets the custom layout settings that the `HtmlToImage` action uses for converting HTML pages to TIFF format.
- [HtmlPrintQuality](#)
Adjusts the resolution of the image output by `HtmlToImage`.
- [HtmlTiffCompression](#)
Sets the compression used in the TIFF output by `HtmlToImage`.
- [HtmlToImage](#)
Converts a page with `*.htm` or `*.html` file to a page or pages in TIFF format.
- [HtmlToPdf](#)
Converts `.htm` or `.html` files to PDF document format.

Parent topic: [Convert actions](#)

HtmlLayout

Sets the custom layout settings that the `HtmlToImage` action uses for converting HTML pages to TIFF format.

Member of namespace

Convert

Syntax

```
bool HtmlLayout(string sMargins, int tableFit, bool tableBorders, bool cellShading,  
bool
```

clearBackground)

Parameters

sMargins

A comma-delimited list of the left, top, right, and bottom margin sizes. Each item on the list is a positive integer that represents the margin size in inches multiplied by 10. For example, if the passed parameter value is “6,6,6,6”, all margin sizes are 0.6 inches. The default margin size is 0.5 inches.

tableFit

The conversion method to use for HTML tables. The method is specified by one of the following values:

0	Auto fit: Shrinks cells according to their contents.
1	Available space: Expands cells to the available page width.
2	Fixed width: Sizes cells according to their width properties.

The default method is auto fit.

tableBorders

Whether to render table borders. The following values are possible:

True	Table borders are rendered. Important: Rendering borders might cause issues later during CCO normalization, such as misbehavior during text location, click and key, and other operations. For more information about CCO normalization, see NormalizeCCO .
False	Table borders are not rendered.

The default value is False.

cellShading

Whether to render table cell shading. The following values are possible:

True	Table cells are rendered with shading. Important: Shading can have the following adverse effects: <ul style="list-style-type: none">• Speckling. Speckling can interfere with character recognition, fingerprint matching, and other operations.• Unreadable text. Unreadable text can occur for bitonal table cells that have background noise.
False	Table cells are not rendered with shading.

For color output, the default value is True. For all other output, the default value is False.

clearBackground

Whether to clear the background of the HTML page. The following values are possible:

True	The background is cleared. Doing so might improve the clarity of color output.
False	The background is not cleared.

The default value is False.

Returns

Always True.

Level

Page level.

Details

Example:

```
HtmlLayout ("25,25,25,25", 1, False, True, True)
HtmlToImage ()
```

Parent topic: [Html actions](#)

Related reference:

[HtmlToImage](#)

HtmlPrintQuality

Adjusts the resolution of the image output by `HtmlToImage`.

Member of namespace

Convert

Syntax

```
bool HtmlPrintQuality (int dpi)
```

Parameters

dpi

Type: int

A single positive numeric value for the dots per inch (dpi) of the output image.

Returns

False if the parameter is invalid. Otherwise, True.

Level

Page level.

Details

Sets the resolution of the output image for `HtmlToImage`. If this action is not called, the default value of 200 dpi is used. Typically, input documents for recognition are 200 dpi.

Example:

```
HtmlPrintQuality (200)
HtmlDocumentToImage ()
```

Parent topic: [Html actions](#)

HtmlTiffCompression

Sets the compression used in the TIFF output by HtmlToImage.

Member of namespace

Convert

Syntax

```
bool HtmlTiffCompression (string tiffCompression)
```

Parameters

tiffCompression

Type: string

A parameter of one of the following values to set the TIFF compression:

Parameters

- NONE : A color image with no compression.
- LZW : A color image using LZW compression.
- CCITT4 : A black and white image with fax CCITT4 compression.

Returns

Always True.

Level

Page level.

Details

Sets the compression of the output image from HtmlToImage. If this action is not called, the default value of CCITT4 is used. Typically, input documents for recognition are black and white with fax compression.

Example:

```
HtmlTiffCompression (CCITT4)  
HtmlToImage ()
```

Parent topic: [Html actions](#)

HtmlToImage

Converts a page with *.htm or *.html file to a page or pages in TIFF format.

Member of namespace

Convert

Syntax

```
bool HtmlToImage ()
```

Parameters

None.

Returns

True if the file is successfully converted to a TIFF document.

False if the current page is not an Html Document or if there is a failure in the conversion.

If the number of input files/pages exceeds the maximum allowed or if there is a failure in the conversion, the batch will be set to abort.

Level

Page level.

Details

If the current page is an Html Document, the file is converted to multiple TIFF files, one TIFF file for each page within the Document, based on the settings of the other Html actions that configure the conversion settings.

Each new TIFF also has a new page created within the application environment which can be processed by subsequent rules. The original file name from which the page was extracted is stored in the ParentImage variable, for possible future reference within your application.

If the configured output image format and compression only supports black and white, such as CCITT4, colored text is exported as black. Html table borders will not be rendered onto output images.

Example:

```
HtmlPrintQuality(200)
HtmlTiffCompression(CCITT4)
HtmlToImage()
```

Parent topic: [Html actions](#)

HtmlToPdf

Converts .htm or .html files to PDF document format.

Member of namespace

Convert

Syntax

```
bool HtmlToPdf ()
```

Returns

True if the file conversion succeeds. Otherwise, the action returns False if the current page is not an HTML document or some other conversion failure occurs..

Level

Page level.

Details

Use this action to convert HTML files to a single PDF file. For information about setting the compliance standard for the produced PDF document, see [PDF compliance standards](#).

This action sets the batch to abort in the following circumstances:

- The number of input files or pages exceeds the allowed maximum.
- The conversion fails.

Example:

```
HtmlToPdf
```

Parent topic: [Html actions](#)

Images actions

Use the Images actions to convert various image formats into a black and white TIFF image file for recognition processing by Datacap.

The Images actions can specify default DPI settings and image type file extensions for the images that you want to convert to TIFF.

- [ImageDefaultDPI](#)
Sets the default dpi (dots per inch) when converting images that do not have an embedded dpi value.
- [ImageFileTypesToConvert](#)
Sets the file extension values of image types to convert to tiff.
- [ImageMonoThreshold](#)
Sets the threshold value when converting Image to 1 bit tiff using threshold type conversion.
- [ImageMonoType](#)
Sets the method to use when converting color images to black and white tiffs.
- [ImageToTIFF](#)
Converts an Image file to TIFF format.

Parent topic: [Convert actions](#)

ImageDefaultDPI

Sets the default dpi (dots per inch) when converting images that do not have an embedded dpi value.

Member of namespace

Convert

Syntax

```
bool ImageDefaultDPI (short X, short Y)
```

Parameters

X

Type: short

Horizontal dpi (X axis). A positive numeric value normally ranging from 96 to 300

Y

Type: short

Vertical dpi (Y axis). A positive numeric value normally ranging from 96 to 300

Returns

False if there is a failure to set the default X or Y dpi value. Otherwise True.

Level

Page level.

Details

Sets the default dpi to use when converting color or grayscale images to TIFF when the source image does not have a dpi value.

Example:

```
ImageFileTypesToConvert (".jpg, .jpeg, gif, bmp")
ImageDefaultDPI ("200", "200")
ImageMonoType (4)
ImageMonoThreshold (9)
ImageToTIFF ()
```

Parent topic: [Images actions](#)

ImageFileTypesToConvert

Sets the file extension values of image types to convert to tiff.

Member of namespace

Convert

Syntax

```
bool ImageFileTypesToConvert (string fileextensions)
```

Parameters

fileextensions

Type: string

A CSV string of file extensions that defines the image types that will be converted.

Parameters

fileextensions : A CSV string of file extensions that defines the image types that will be converted.

Returns

Always True.

Level

Page level.

Details

Sets the file extension values of image types to convert to TIFF. The file types of JPEG, BMP, PNG, TIFF and GIF are supported. A period prefixing the extension is allowed, but not required. Because TIFF is supported, it is possible to use this action to convert a color TIFF to a Black and White TIFF.

This action must be used prior to ImageToTIFF.

Example:

```
ImageFileTypesToConvert (".jpg, .jpeg, gif, bmp")
ImageToTIFF ()
```

Parent topic: [Images actions](#)

ImageMonoThreshold

Sets the threshold value when converting Image to 1 bit tiff using threshold type conversion.

Member of namespace

Convert

Syntax

```
bool ImageMonoThreshold (short thresh)
```

Parameters

thresh

Type: short

A positive numeric value from 1 to 255.

Parameters

thresh: A positive numeric value from 1 to 255.

Returns

Always True.

Level

Page level.

Details

Sets the B/W conversion algorithm value to use when converting color or grey scale images to TIFF with the Threshold method option.

Example:

```
ImageFileTypesToConvert (".jpg, .jpeg, gif, bmp")
ImageMonoType (4)
ImageMonoThreshold (9)
ImageToTIFF ()
```

Parent topic: [Images actions](#)

ImageMonoType

Sets the method to use when converting color images to black and white tiffs.

Member of namespace

Convert

Syntax

```
bool ImageMonoType (int Mono)
```

Parameters

Mono
Type: int

Parameters

Mono : A positive numeric value of 1 to 4 for the type of conversion to use.

1. Convert image using Diffusion method.
2. Convert image using Halftone method.
3. Convert image using Bayer method.
4. Convert image using Threshold method with a threshold value. Value defaults to 10.

Returns

Always True.

Level

Page level.

Details

Sets the black and white conversion algorithm to use when converting color or grayscale images to TIFF. If you are using the threshold method, you must also call the ImageMonoThreshold action prior to converting the image with ImageToTIFF.

Error diffusion is a type of halftoning in which the quantization residual is distributed to neighboring pixels that have not yet been processed. Its main use is to convert a color image into a black and white image. Halftone is

the reprographic technique that simulates continuous tone imagery through the use of dots, varying either in size or in spacing. Bayer method is an image dithering algorithm that is commonly used to maintain a the characteristics of a photo image of higher colors in an image of less color depth. The threshold method makes individual pixels in an image black if their value is greater than the threshold value and the remaining pixels white.

For best results, you may need to experiment with the different types of images that you are expecting to process and select the conversion method that gives you the best results. If the resulting TIFF images are going to be used in a subsequent recognition process, pick the technique that works best to output dark, solid characters with as little background noise, or dithering around the characters, as possible.

Example:

```
ImageFileTypesToConvert(".jpg, .jpeg, gif, bmp")
ImageMonoType(1)
ImageToTIFF()
```

Parent topic: [Images actions](#)

ImageToTIFF

Converts an Image file to TIFF format.

Member of namespace

Convert

Syntax

```
bool ImageToTIFF ()
```

Parameters

None.

Returns

True if the file is successfully converted to a TIFF document.

False if the current page is not a supported Image type or if there is a failure in the conversion.

If the number of input files/pages exceeds the maximum allowed or if there is a failure in the conversion, the batch is set to abort.

Level

Page level.

Details

If the current page is an Image, the file will be converted to a single TIFF file. ImageFileTypesToConvert must be used along with ImageToTIFF. Only the image types set by a previous call to ImageFileTypesToConvert is converted to a TIFF. No images are converted if ImageFileTypesToConvert has not been set.

Each TIFF will also have a new page created within the application environment which can be processed by subsequent rules. The original file name from which the page was extracted is stored in the *ParentImage* variable, for possible future reference within your application.

Example:

```
ImageFileTypesToConvert (".jpg, .jpeg, gif, bmp")
ImageToTIFF ()
```

Parent topic: [Images actions](#)

Outlook actions

Use the Outlook actions to convert the text of a Microsoft Outlook message file to a TIFF image file and save any attachments to disk. Saved attachments can then be processed as needed by subsequent actions.

The Outlook actions can specify the image resolution and the compression algorithm that is used when you convert from Outlook to TIFF.

- [OutlookAttachmentTypeIndicator](#)
Determines if an email attachment type is set based on the extension or mime type.
- [OutlookMessageToAttachmentOnly](#)
Extracts attachments from *.msg or *.eml to pages without converting the MSG to a TIFF.
- [OutlookMessageToImageAndAttachment](#)
Converts a *.msg or *.eml file to a page or pages in TIFF format.
- [OutlookPrintQuality](#)
Adjusts the resolution of the image output by OutlookMessageToImageAndAttachment.
- [OutlookTiffCompression](#)
Sets the compression used in the TIFF output by OutlookMessageToImageAndAttachment.

Parent topic: [Convert actions](#)

OutlookAttachmentTypeIndicator

Determines if an email attachment type is set based on the extension or mime type.

Member of namespace

Convert

Syntax

```
bool OutlookAttachmentTypeIndicator (string typeIndicator)
```

Parameters

- MIME – The attachment type is determined by the email mime type.
- EXT – The attachment type is determined by the attachment extension.

Smart parameters are supported.

Returns

Always True.

Level

Any level.

Details

When you save e-mail attachments to a file, the file type can be set based on the mime type specified in the e-mail or based on the actual extension of the attachment. This action is useful when you receive emails which may sometimes have an incorrect extension or incorrect mime type, allowing the application to name the extension based on the setting. If the primary setting is blank, then the alternative method is used. For example, if the extension is set as the primary indicator and the attachment has a blank extension, then the mime type is used. If this action is not called, or if the provided `typeIndicator` parameter is incorrect, then the setting is default to "MIME" and saved attachments are named based on the mime type indicated in the e-mail. This action needs to be called prior to the action that performs the attachment extraction. In scenarios where the application needs to processes e-mails that have incorrect extensions, this action can be used to set the mime type as the indicator for the attachment file type. Conversely, if the application needs to process emails that have mime types set incorrectly, then the attachment extension can be set to the primary indicator for the file type extension.

Example:

```
OutlookAttachmentTypeIndicator ("EXT")
```

This example uses the extension of the attachment to determine the file type of the attachment saved to disk. If the attachment is named "MyFile.PDF" and the mime type is set to text/plain, then the extracted attachment has a PDF extension.

Parent topic: [Outlook actions](#)

OutlookMessageToAttachmentOnly

Extracts attachments from *.msg or *.eml to pages without converting the MSG to a TIFF.

Member of namespace

Convert

Syntax

```
bool OutlookMessageToAttachmentOnly ()
```

Parameters

None.

Returns

True, if the attachments are successfully extracted from the message, or if the message contains no attachments.

False, if the current page is not an Outlook Message or if there is a failure in the conversion.

If the number of input files/pages exceeds the maximum that is allowed or if there is a failure in the conversion, the batch is set to `abort`.

Level

Page level.

Details

If the current page is an Outlook Message, the attachments within the message are saved as separate files.

Each attachment or embedded image within the email is removed from the email and placed on disk. A new page entry is created for each attachment that can be processed by subsequent rules. The original file name from which the page was extracted will be stored in the *ParentImage* variable, for possible future reference within your application.

Example:

```
OutlookMessageToAttachmentOnly()
```

Parent topic: [Outlook actions](#)

Related reference:

[OutlookMessageToImageAndAttachment](#)

OutlookMessageToImageAndAttachment

Converts a *.msg or *.eml file to a page or pages in TIFF format.

Member of namespace

Convert

Syntax

```
bool OutlookMessageToImageAndAttachment ()
```

Parameters

None.

Returns

True if the file is successfully converted to a TIFF document.

False if the current page is not an Outlook Message or if there is a failure in the conversion.

If the number of input files/pages exceeds the maximum allowed or if there is a failure in the conversion, the batch is set to abort.

Level

Page level.

Details

If the current page is an Outlook Message, the file is converted to multiple TIFF files, one TIFF file for each page within the Message, based on the settings of the other Outlook actions that configure the conversion settings. A copy of the original MSG file without attachments is created and converted to TIFF as well.

Each new TIFF also has a new page created within the application environment which can be processed by subsequent rules. The original file name from which the page was extracted is stored in the *ParentImage* variable, for possible future reference within your application.

Each attachment or embedded image within the e-mail is removed from the e-mail and placed on disk. A new page entry will be created for each attachment that can be processed by rules.

If the configured output image format and compression only supports black and white, such as CCITT4, colored text is exported as black.

Example:

```
OutlookPrintQuality(200)
OutlookTiffCompression("CCITT4")
OutlookMessageToImageAndAttachment()
```

Parent topic: [Outlook actions](#)

OutlookPrintQuality

Adjusts the resolution of the image output by OutlookMessageToImageAndAttachment.

Member of namespace

Convert

Syntax

```
bool OutlookPrintQuality (int dpi)
```

Parameters

dpi
Type: int

Parameters

dpi : A single positive numeric value for the dots per inch (dpi) of the output image.

Returns

False if the parameter is invalid. Otherwise, True.

Level

Page level.

Details

Sets the resolution of the output image for OutlookMessageToImageAndAttachment. If this action is not called, the default value of 200 dpi is used. Typically, input documents for recognition are 200 dpi.

Example:

```
OutlookPrintQuality(200)
OutlookMessageToImageAndAttachment()
```

Parent topic: [Outlook actions](#)

OutlookTiffCompression

Sets the compression used in the TIFF output by OutlookMessageToImageAndAttachment.

Member of namespace

Convert

Syntax

```
bool OutlookTiffCompression (string tiffCompression)
```

Parameters

tiffCompression
Type: string

Parameters

tiffCompression : A parameter of one of the following values to set the TIFF compression:

- NONE : A color image with no compression.
- LZW : A color image using LZW compression.
- CCITT4 : A black and white image with fax CCITT4 compression.

Returns

Always True.

Level

Page level.

Details

Sets the compression of the output image from OutlookMessageToImageAndAttachment. If this action is not called, the default value of CCITT4 is used. Typically, input documents for recognition are black and white with fax compression.

Example:

```
OutlookTiffCompression("CCITT4")
OutlookMessageToImageAndAttachment()
```

Parent topic: [Outlook actions](#)

Pdf actions

Use the Pdf actions to convert an image file from PDF format to TIFF for recognition processing by Datacap.

The Pdf actions can specify bit depth of the output image, as well as the compression algorithm and conversion method to use when you convert from PDF to TIFF.

- [PDFBitDepth](#)
Sets the bit depth of the image output by PDFDocumentToImage.
- [PDFCompression](#)
Sets the compression method used in the TIFF output by PDFDocumentToImage.
- [PDFConversionMethod](#)
Sets the conversion method used in the TIFF output by PDFDocumentToImage.
- [PDFDocumentToImage](#)
Create a TIFF image for each page in a PDF file.
- [PDFGrayscale](#)
Sets the output by PDFDocumentToImage to be grayscale.
- [PDFHorizontalResolution](#)
Sets the output horizontal resolution for PDFDocumentToImage.
- [PDFQuality](#)
Sets the conversion quality for PDFDocumentToImage.
- [PDFVerticalResolution](#)
Sets the output vertical resolution for PDFDocumentToImage.

Parent topic: [Convert actions](#)

PDFBitDepth

Sets the bit depth of the image output by PDFDocumentToImage.

Member of namespace

Convert

Syntax

```
bool PDFBitDepth (int p_iVal)
```

Parameters

p_iVal
Type: int

Parameters

One of the following bit depth values are allowed.

- 1 : black and white.
- 8 : 256 color.
- 24 : True color.

Returns

Always True.

Level

Page level.

Details

Sets the bit depth for the output TIFF. The number of bits determine the color capacity of an image. If this action is not called, a default value of 1 is used. This action must be called before PDFDocumentToImage.

Example:

```
PDFBitDepth(1)
PDFDocumentToImage()
```

Parent topic: [Pdf actions](#)

PDFCompression

Sets the compression method used in the TIFF output by PDFDocumentToImage.

Member of namespace

Convert

Syntax

```
bool PDFCompression (int p_iVal)
```

Parameters

p_iVal
Type: int

Parameters

One of the following compression values are allowed.

- 1 : No compression.
- 2 : CCITT modified Huffman RLE.
- 3: CCITT Group 3 fax.
- 4: CCITT Group 4 fax.
- 5: LZW Lempel-Ziv and Welch
- 7 : JPEG

Returns

Always True.

Level

Page level.

Details

Sets the compression of the output image from `PDFDocumentToImage`. If this action is not called, the default value of `CCITT4` will be used. Typically, input documents for recognition are black and white with fax compression.

Example:

```
PDFBitDepth(1)
PDFCompression(4)
PDFDocumentToImage()
```

Parent topic: [Pdf actions](#)

PDFConversionMethod

Sets the conversion method used in the TIFF output by `PDFDocumentToImage`.

Member of namespace

Convert

Syntax

```
bool PDFConversionMethod (int p_iVal)
```

Parameters

`p_iVal`
Type: int

Parameters

A numeric value of one of the following.

- 1 : Uses method 1 of converting PDF to TIFF.
- 2 : Uses method 2 of converting PDF to TIFF.

Returns

Always True.

Level

Page level.

Details

There are two methods that can be used to convert a PDF to TIFF. The first method is slightly faster. The second method gives better results. If this action is not called, `PDFDocumentToImage` uses the second method by default, which produces a more accurate output TIFF.

Example:

```
PDFBitDepth(1)
PDFConversionMethod(2)
PDFDocumentToImage()
```

Parent topic: [Pdf actions](#)

PDFDocumentToImage

Create a TIFF image for each page in a PDF file.

Member of namespace

Convert

Syntax

```
bool PDFDocumentToImage ()
```

Parameters

None.

Returns

True if the file is successfully converted to a TIFF document.

False if the current page is not a PDF or if there is a failure in the conversion.

If the number of input files/pages exceeds the maximum allowed or if there is a failure in the conversion, the batch is set to abort.

Level

Page level.

Details

If the current page is a PDF, the file will be converted to multiple TIFF files, one TIFF file for each page within the document.

Each new TIFF also has a new page created within the application environment which can be processed by subsequent rules. The original file name from which the page was extracted is stored in the *ParentImage* variable, for possible future reference within your application.

Example:

```
PDFBitDepth(1)
PDFDocumentToImage()
```

Restriction: This Pdf action does not support Unicode characters in the file name or file path. If your content uses Unicode characters in the file names or file paths, use the PdfFRE action instead.

Tip: When using non-native system fonts, use the PdfFRE class instead of Pdf.

Parent topic: [Pdf actions](#)

PDFGrayscale

Sets the output by PDFDocumentToImage to be grayscale.

Member of namespace

Convert

Syntax

```
bool PDFGrayscale (bool p_bVal)
```

Parameters

p_bVal
Type: bool

Parameters

A Boolean value to set grayscale mode.

True: The resulting TIFF is converted to grayscale.

False: The resulting TIFF is not converted to grayscale.

Returns

Always True.

Level

Page level.

Details

Sets the PDF conversion to TIFF so the output images are grayscale. This action must be called before PDFDocumentToImage. If this action is not called, a default value of False is used by PDFDocumentToImage.

Example:

```
PDFGrayscale (True)  
PDFDocumentToImage ()
```

Parent topic: [Pdf actions](#)

PDFHorizontalResolution

Sets the output horizontal resolution for PDFDocumentToImage.

Member of namespace

Convert

Syntax

```
bool PDFHorizontalResolution (int p_iVal)
```

Parameters

p_iVal
Type: int

Parameters

p_iVal : A positive numeric value for the horizontal resolution in dots per inch (DPI).

Returns

Always True.

Level

Page level.

Details

Sets the horizontal resolution for PDF conversion to TIFF. It is recommended that the horizontal and vertical resolutions be kept the same, creating an isotropic image. If this action is not called, the default resolution of 200 is used. This action must be called before PDFDocumentToImage.

Example:

```
PDFBitDepth(1)  
PDFHorizontalResolution(200)  
PDFVerticalResolution(200)  
PDFDocumentToImage()
```

Parent topic: [Pdf actions](#)

PDFQuality

Sets the conversion quality for PDFDocumentToImage.

Member of namespace

Convert

Syntax

```
bool PDFQuality (int p_iVal)
```

Parameters

p_iVal
Type: int

Parameters

p_iVal : A positive numeric value between 0 and 100 that determines the image quality. 100 is the highest quality.

Returns

Always True.

Level

Page level.

Details

This determines the quality of the output TIFF. Choosing a higher value will give you a better output TIFF, but will increase processing time. This action must be called before PDFDocumentToImage. If PDFQuality is not called, the default value of 100 is used.

Example:

```
PDFBitDepth(1)
PDFQuality(100)
PDFDocumentToImage()
```

Parent topic: [Pdf actions](#)

PDFVerticalResolution

Sets the output vertical resolution for PDFDocumentToImage.

Member of namespace

Convert

Syntax

```
bool PDFVerticalResolution (int p_iVal)
```

Parameters

p_iVal
Type: int

Parameters

p_iVal : A positive numeric value for the vertical resolution in dots per inch (DPI).

Returns

Always True.

Level

Page level.

Details

Sets the vertical resolution for PDF conversion to TIFF. It is recommended that the horizontal and vertical resolutions be kept the same, creating an isotropic image. If this action is not called, the default resolution of 200 is used. This action must be called before `PDFDocumentToImage`.

Example:

```
PDFBitDepth(1)
PDFHorizontalResolution(200)
PDFVerticalResolution(200)
PDFDocumentToImage()
```

Parent topic: [Pdf actions](#)

PdfFRE actions

Use the PdfFRE actions can use the Abbyy FineReader Engine to convert an image file from PDF format to TIFF for recognition processing by Datacap.

The PdfFRE actions can specify bit depth of the output image, as well as the compression algorithm and conversion method to use when you convert from PDF to TIFF.

- [PDFFREDocumentToImage](#)
Converts a PDF file to TIFF format and extracts any searchable text.
- [PDFFREReleaseEngine](#)
Releases resources used by the conversion engine.
- [PDF image compression types](#)
An image from a PDF document can be compressed in a number of different ways.

Parent topic: [Convert actions](#)

PDFFREDocumentToImage

Converts a PDF file to TIFF format and extracts any searchable text.

Member of namespace

Convert

Syntax

```
bool PDFFREDocumentToImage (string resolution, string compressionBW, string
compressionColor, string compressionGray, string extensionBW, string extensionColor,
string extensionGray, string convertMode, string useFastBinarization, string
jpegQuality)
```

Parameters

Smart parameters are supported.

resolution

The resolution of extracted images. The valid values are 50 – 3200 dots per inch.

compressionBW

The compression of extracted black and white pages in the source PDF. For more information about the valid types, see [PDF image compression types](#).

compressionColor

The compression of extracted color pages in the source PDF. For more information about the valid types, see [PDF image compression types](#).

compressionGray

The compression of extracted grayscale pages in the source PDF. For more information about the valid types, see [PDF image compression types](#).

extensionBW

The file extension of extracted black and white pages in the source PDF.

extensionColor

The file extension of extracted color pages in the source PDF.

extensionGray

The file extension to use for grayscale pages that are extracted from the source PDF.

convertMode

Used to set the conversion mode. Following are the possible values:

0	Preserve color.
1	Convert all images to black and white.

useFastBinarization

This setting is relevant when you set the convertMode to 1. It causes the conversion function to use a faster binarization algorithm to convert pages to black and white during extraction. Following are the possible values:

True	Use the faster binarization algorithm, which might result in lower quality images.
False	Do not use the faster binarization algorithm.

jpegQuality

The quality of the color images that are extracted with JPEG compression. The valid levels are 0 – 100. The higher the value, the higher the quality.

Returns

True if the file is successfully converted to a TIFF document. False if the current page is not a supported Image type or if failure in the conversion occurs. If the number of input files/pages exceeds the maximum that is allowed or if failure in the conversion occurs, the batch is set to abort.

Level

Page level.

Details

If the current page is a PDF, the file is converted to multiple TIFF files, one TIFF file for each page within the document.

If the PDF document contains searchable text, a CCO file that contains the positions and text is also created for each page in the document.

Note: Call the NormalizeCCO action, from the CCO2CCO action library, in a subsequent ruleset to ensure the integrity of the CCO file. It is also needed if the application is using the navigation and pattern match actions to

find recognized text on a page or perform pattern matching.

Each new TIFF also has a new page that is created within the application environment, which can be processed by subsequent rules. The original file name from which the page is extracted is stored in the *ParentImage* variable, for possible future reference within your application.

To prevent creating a CCO and to ignore searchable text within a PDF, enable *convPdfIgnoreContent* by setting the variable to "1" in the page DCO before you call *PDFDocumentToImage*. When *y_createLayout* is set to "1", then *convPdfIgnoreContent* is automatically enabled.

It is recommended to turn OFF the CCO file creation feature, in the case where it is unlikely that the application might process searchable PDF documents, or in the case where full page OCR is needed later in the workflow.

Creating a Layout File

This action runs recognition in addition to text extraction. Before you call the action, enable this capability by setting the DCO variable *y_createLayout* to "1". By default, this feature is turned off.

When this option is turned on, a layout xml file (for example *tm000001_layout.xml*) is created per image that is extracted.

Note: When *y_createLayout* is enabled, a CCO file is not created by default. Use the action *CreateCcoFromLayout* in the *SharedRecognitionTools* library on each newly created page to convert each layout XML to a CCO to allow other CCO actions to operate on the text.

The layout file groups text into blocks as a person would look at the document. Each block might have the default type of block or a specific type such as title or table. Locate actions are available in the *DocumentAnalytics* action library to navigate in the block structure such as *GoSiblingBlockNext*. Whereas the CCO file, that is produced by other actions, groups text into lines that span the width of the page.

The layout XML file also retains font and color attributes, which are saved in CSS format, for the text, which is used for extracting data and reconstructing the document in a new format.

To use the Locate actions and perform click 'n' key during verification, use the action *CreateCcoFromLayout* action in the *SharedRecognitionTools* action library. This action creates a CCO file for the page after the layout XML file is produced.

Following are the types of elements (in the "Block Type/XML Node" format) that might be present in the layout XML file:

- Block/Block
- Header/Header
- Footer/Footer
- Title/Title
- Heading1/H1
- Heading2/H2
- Heading3/H3
- Picture/Picture
- Barcode/Barcode
- Space/S
- Tab/Tab
- Table/Table
- Row/Row
- Cell/Cell
- Paragraph/Para

- Line/L
- Sentence/Sent
- Word/W
- Character/C

Text Extraction versus Text Recognition

By default, the text included in the layout XML is obtained from a combination of automatic recognition that is run on each page of the PDF and from searchable text that is embedded within the PDF. Any images that are embedded on the page have the text that is recognized by the engine.

If areas of the page contain both an image and searchable text that is associated with the image, the engine decides whether the engine must use the searchable text or recognize the text from the matching image. Because the engine performs recognition, the confidence of the text might vary even if the same searchable text is embedded in the PDF.

The variable `y_contentReuseMode` can be used to force the engine to use only the recognized text on the page or only to use the embedded text on the page. One reason why you might decide only to use the embedded text is to prevent recognition and produce high confidence results.

A drawback of using the only embedded text is that if the embedded text is wrong or incomplete, recognition is not performed to capture that missing data. The resultant layout XML that is created is incomplete compared to what the user sees when the user views the PDF. Do not use this setting if the source PDF file is of the image-on-text type because in this case, the text layer is not extracted. If a text line contains characters that are not included in the alphabet of the selected recognition languages, this text is not be written to the result. Mode 0 or 1 must be used.

These settings of `y_contentReuseMode` can be set on the DCO node that is being converted:

- `rrSet("0", "@X.y_contentReuseMode")` - The default auto mode that uses a combination of recognition and embedded text.
- `rrSet("1", "@X.y_contentReuseMode")` - Only recognition is used to create the layout XML.
- `rrSet("2", "@X.y_contentReuseMode")` - Only embedded text is used to create the layout XML.

For more information about configuring the recognition language, refer the OCR_A action, [Recognize](#).

Including PDF Annotations

By default, text annotations included in the source PDF file are not included in the output image. "Free Text" annotations in source PDF can be included in the output image by setting the page DCO variable `y_IncludeAnnotation` to "1". Other types of PDF annotations are not supported, such as popup and ink annotations. This feature does not cause the text of a "Sticky note" to be displayed on the image and a sticky note icon might display on the final image regardless of this setting.

Example

```
PDFFREDocumentToImage(300,32,32,32,".bw.tif", ".color.tif", ".gray.tif", 0, false,100)
```

Parent topic: [PdfFRE actions](#)

PDFFREReleaseEngine

Releases resources used by the conversion engine.

Member of namespace

Syntax

```
bool PDFFREReleaseEngine ()
```

Returns

Always True.

Level

Any level. Typically at the Batch close.

Details

Releases resources used by the conversion engine. This action should only be called after all the PDFs have been processed or the engine is loaded, unloaded, loaded etc. You need to place this action in a rule that is called at the batch close and it is to be called after all pages are processed.

Example:

```
PDFFREReleaseEngine(300,32,32,32, ".bw.tif", ".color.tif", ".gray.tif", 0,
false,100)
```

This example performs the conversion, then releases all resources used by the engine.

Parent topic: [PdfFRE actions](#)

PDF image compression types

An image from a PDF document can be compressed in a number of different ways.

Here are the possible values that you can pass to compression-related parameters:

1	BmpBwUncompressed
2	BmpGrayUncompressed
3	BmpColorUncompressed
4	DcxBwPackbits
5	DcxGrayPackbits
6	DcxColorPackbits
7	JpegGrayJfif
8	JpegColorJfif
9	PcxBwPackbits
10	PcxGrayPackbits
11	PcxColorPackbits
12	PngBwPng
13	PngGrayPng

14	PngColorPng
15	TiffBwUncompressed
16	TiffBwCcittGroup3
18	TiffBwCcittGroup4
19	TiffBwPackBits
20	TiffGrayUncompressed
21	TiffGrayPackBits
22	TiffGrayJpegJfif
23	TiffColorUncompressed
24	TiffColorPackBits
25	TiffColorJpegJfif
28	Jpeg2kGray
29	Jpeg2kColor
31	TiffBwLZW
32	TiffGrayLZW
33	TiffColorLZW
34	TiffBwZip
35	TiffGrayZip
36	TiffColorZip
43	JBIG2

Parent topic: [PdfFRE actions](#)

Rtf actions

Use the Rtf actions to convert an image file from RTF format to TIFF for recognition processing by Datacap.

The Rtf actions can specify the output resolution and compression algorithm that is used when you convert from RTF to TIFF.

- [RtfPrintQuality](#)
Adjusts the resolution of the image output by RtfToImage.
- [RtfTiffCompression](#)
Sets the compression used in the TIFF output by RtfToImage.
- [RtfToImage](#)
Converts a page with *.rtf file to a page or pages in TIFF format.
- [RtfToPdf](#)
Converts .rtf files to PDF document format.

Parent topic: [Convert actions](#)

RtfPrintQuality

Adjusts the resolution of the image output by RtfToImage.

Member of namespace

Convert

Syntax

```
bool RtfPrintQuality (int dpi)
```

Parameters

dpi

Type: int

A single positive numeric value for the dots per inch (dpi) of the output image.

Returns

False if the parameter is invalid. Otherwise, True.

Level

Page level.

Details

Sets the resolution of the output image for `RtfToImage`. If this action is not called, the default value of 200 dpi is used. Typically, input documents for recognition are 200 dpi.

Example:

```
RtfPrintQuality(200)  
RtfToImage()
```

Parent topic: [Rtf actions](#)

RtfTiffCompression

Sets the compression used in the TIFF output by `RtfToImage`.

Member of namespace

Convert

Syntax

```
bool RtfTiffCompression (string tiffCompression)
```

Parameters

tiffCompression

Type: string

A parameter of one of the following values to set the TIFF compression:

Parameters

- NONE : A color image with no compression.
- LZW : A color image using LZW compression.
- CCITT4 : A black and white image with fax CCITT4 compression.

Returns

Always True.

Level

Page level.

Details

Sets the compression of the output image from RtfToImage. If this action is not called, the default value of CCITT4 is used. Typically, input documents for recognition are black and white with fax compression.

Example:

```
RtfTiffCompression (CCITT4)  
RtfToImage ()
```

Parent topic: [Rtf actions](#)

RtfToImage

Converts a page with *.rtf file to a page or pages in TIFF format.

Member of namespace

Convert

Syntax

```
bool RtfToImage ()
```

Parameters

None.

Returns

True if the file is successfully converted to a TIFF document.

False if the current page is not a Rtf Document or if there is a failure in the conversion.

If the number of input files/pages exceeds the maximum allowed or if there is a failure in the conversion, the batch is set to abort.

Level

Page level.

Details

If the current page is a Rtf Document, the file will be converted to multiple TIFF files, one TIFF file for each page within the Document, based on the settings of the other Rtf actions that configure the conversion settings.

Each new TIFF also has a new page created within the application environment which can be processed by subsequent rules. The original file name from which the page was extracted is stored in the *ParentImage* variable, for possible future reference in your application.

If the configured output image format and compression only supports black and white, such as CCITT4, colored text is exported as black.

Example:

```
RtfPrintQuality(200)
RtfTiffCompression(CCITT4)
RtfToImage()
```

Parent topic: [Rtf actions](#)

RtfToPdf

Converts .rtf files to PDF document format.

Member of namespace

Convert

Syntax

```
bool RtfToPdf ()
```

Returns

True if the file conversion succeeds. Otherwise, the action returns False if the current page is not an RTF document or some other conversion failure occurs..

Level

Page level.

Details

Use this action to convert RTF files to a single PDF file. For information about setting the compliance standard for the produced PDF document, see [PDF compliance standards](#).

This action sets the batch to abort in the following circumstances:

- The number of input files or pages exceeds the allowed maximum.
- The conversion fails.

Example:

```
RtfToPdf
```

Parent topic: [Rtf actions](#)

Tiff actions

Use the Tiff action to convert a multi-page TIFF image file into multiple single page TIFF image files for recognition processing by Datacap.

The Tiff actions can split a multi-page TIFF image file into individual pages and set the compression method that is used by the SplitMultipageTiff action in the TIFF output.

- [SplitMultipageTiff](#)
Creates separate images for each page in a multipage Tiff file.
- [SplitTIFFCompression](#)
Sets the compression method used in the TIFF output by SplitMultipageTiff.

Parent topic: [Convert actions](#)

SplitMultipageTiff

Creates separate images for each page in a multipage Tiff file.

Member of namespace

Convert

Syntax

```
bool SplitMultipageTiff ()
```

Parameters

None.

Returns

True if the file is successfully converted to a TIFF document.

False if the current page is not a TIFF or if there is a failure in the conversion.

If the number of input files/pages exceeds the maximum allowed or if there is a failure in the conversion, the batch is set to abort.

Level

Page level.

Details

If the current page is a TIFF, the file is converted to multiple TIFF files, one TIFF file for each page within the document. If the input page was a single page TIFF file, a single page TIFF is still be output.

Each new TIFF also has a new page created within the application environment which can be processed by subsequent rules. The original file name from which the page was extracted is stored in the *ParentImage*

variable, for possible future reference in your application.

If the input TIFF has a bit depth of 1 (black and white), then the output compression is set to group 4 fax. If the input TIFF has a bit depth greater than 1, then the output compression is uncompressed.

Example:

```
SplitMultipageTiff()
```

Parent topic: [Tiff actions](#)

SplitTIFFCompression

Sets the compression method used in the TIFF output by `SplitMultipageTiff`.

Member of namespace

Convert

Syntax

```
bool SplitTIFFCompression (int compressionTypeColor, int compressionTypeBW)
```

Parameters

`compressionTypeColor`

Type: int

`compressionTypeBW`

Type: int

Parameters

One of the following compression values are allowed.

- 0 : Source Image compression.
- 1 : No compression.
- 2 : CCITT modified Huffman RLE. (BW only)
- 3 : CCITT Group 3 fax. (BW only)
- 4 : CCITT Group 4 fax. (BW only)
- 5 : LZW Lempel-Ziv and Welch

Returns

True if the compression setting was successful.

False if the compression setting used is not a supported type.

Level

Page level.

Details

Sets the compression of the output image from SplitMultipageTiff. If this action is not called, the default value of CCITT4 is used for black and white pages and No compression for color pages.

Example:

```
SplitTIFFCompression(4,1)
plitMultipageTiff()
```

Parent topic: [Tiff actions](#)

Txt actions

Use the Tiff actions to convert an image file from TXT format to TIFF for recognition processing by Datacap.

The Tiff actions can specify the output resolution and the compression algorithm that is used when you convert from Text to TIFF.

- [TxtFontName](#)
Adjusts the font name of the text in the image that is output by the TxtToImage action.
- [TxtFontSize](#)
Adjusts the font size of the text in the image that is output by the TxtToImage action.
- [TxtPrintQuality](#)
Adjusts the resolution of the image output by TxtToImage.
- [TxtTiffCompression](#)
Sets the compression used in the TIFF output by TxtToImage.
- [TxtToImage](#)
Converts a page with *.txt file to a page or pages in TIFF format.
- [TxtToPdf](#)
Converts .txt files to PDF document format.

Parent topic: [Convert actions](#)

TxtFontName

Adjusts the font name of the text in the image that is output by the TxtToImage action.

Member of namespace

Convert

Syntax

```
bool TxtFontName(string fontName)
```

Parameters

fontName
Type: string
The font name to use in the output image.

Returns

False if the parameter is invalid. Otherwise, True.

Level

Page level.

Details

Sets the font name for the text in the output image for the TxtToImage action. If this action is not called, the default value of Times New Roman is used.

Example:

```
TxtFontName(Courier New)
TxtToImage()
```

Parent topic: [Txt actions](#)

TxtFontSize

Adjusts the font size of the text in the image that is output by the TxtToImage action.

Member of namespace

Convert

Syntax

```
bool TxtFontSize(int fontSize)
```

Parameters

fontSize

Type: int

The size of the font to use in the output image.

Returns

False if the parameter is invalid. Otherwise, True.

Level

Page level.

Details

Sets the font size for the text in the output image for the TxtToImage action. If this action is not called, the default value of 10 is used.

Example:

```
TxtFontSize(12)
TxtToImage()
```

Parent topic: [Txt actions](#)

TxtPrintQuality

Adjusts the resolution of the image output by TxtToImage.

Member of namespace

Convert

Syntax

```
bool TxtPrintQuality (int dpi)
```

Parameters

dpi

Type: int

A single positive numeric value for the dots per inch (dpi) of the output image.

Returns

False if the parameter is invalid. Otherwise, True.

Level

Page level.

Details

Sets the resolution of the output image for TxtToImage. If this action is not called, the default value of 200 dpi is used. Typically, input documents for recognition are 200 dpi.

Example:

```
TxtPrintQuality(200)  
TxtToImage()
```

Parent topic: [Txt actions](#)

TxtTiffCompression

Sets the compression used in the TIFF output by TxtToImage.

Member of namespace

Convert

Syntax

```
bool TxtTiffCompression (string tiffCompression)
```

Parameters

tiffCompression

Type: string

A parameter of one of the following values to set the TIFF compression:

Parameters

- NONE : A color image with no compression.
- LZW : A color image using LZW compression.
- CCITT4 : A black and white image with fax CCITT4 compression.

Returns

Always True.

Level

Page level.

Details

Sets the compression of the output image from `TxtToImage`. If this action is not called, the default value of CCITT4 is used. Typically, input documents for recognition are black and white with fax compression.

Example:

```
TxtTiffCompression (CCITT4)
TxtToImage ()
```

Parent topic: [Txt actions](#)

TxtToImage

Converts a page with *.txt file to a page or pages in TIFF format.

Member of namespace

Convert

Syntax

```
bool TxtToImage ()
```

Parameters

None.

Returns

True if the file is successfully converted to a TIFF document.

False if the current page is not a Txt Document or if there is a failure in the conversion.

If the number of input files/pages exceeds the maximum allowed or if there is a failure in the conversion, the batch is set to abort.

Level

Page level.

Details

If the current page is a Txt Document, the file are converted to multiple TIFF files, one TIFF file for each page within the Document, based on the settings of the other Txt actions that configure the conversion settings.

Each new TIFF also has a new page created within the application environment which can be processed by subsequent rules. The original file name from which the page was extracted is stored in the *ParentImage* variable, for possible future reference within your application.

If the configured output image format and compression only supports black and white, such as CCITT4, colored text is exported as black.

Example:

```
TxtPrintQuality(200)
TxtTiffCompression(CCITT4)
TxtToImage()
```

Parent topic: [Txt actions](#)

TxtToPdf

Converts .txt files to PDF document format.

Member of namespace

Convert

Syntax

```
bool TxtToPdf()
```

Returns

True if the file conversion succeeds. Otherwise, the action returns False if the current page is not an TXT document or some other conversion failure occurs..

Level

Page level.

Details

Use this action to convert TXT files to a single PDF file. For information about setting the compliance standard for the produced PDF document, see [PDF compliance standards](#).

This action sets the batch to abort in the following circumstances:

- The number of input files or pages exceeds the allowed maximum.
- The conversion fails.

Example:

```
TxtToPdf
```

Parent topic: [Txt actions](#)

Word actions

Use the Word actions to convert an image file from Microsoft Word format to TIFF for recognition processing by Datacap.

The Word actions can specify the output resolution and the compression algorithm that is used when you convert from Word to TIFF.

- [WordDocumentToImage](#)
Converts a page with *.doc or *.docx file to a page or pages in TIFF format.
- [WordDocumentToPdf](#)
Converts .doc or.docx files to PDF document format.
- [WordMonochromeQuality](#)
Adjusts binarization settings used by WordDocumentToImage.
- [WordPrintQuality](#)
Adjusts the resolution of the image output by WordDocumentToImage.
- [WordTiffCompression](#)
Sets the compression used in the TIFF output by WordDocumentToImage.

Parent topic: [Convert actions](#)

WordDocumentToImage

Converts a page with *.doc or *.docx file to a page or pages in TIFF format.

Member of namespace

Convert

Syntax

```
bool WordDocumentToImage ()
```

Parameters

None.

Returns

True if the file is successfully converted to a TIFF document.

False if the current page is not a Word Document or if there is a failure in the conversion.

If the number of input files/pages exceeds the maximum allowed or if there is a failure in the conversion, the batch is set to abort.

Level

Page level.

Details

If the current page is a Word Document, the file is converted to multiple TIFF files, one TIFF file for each page within the Document, based on the settings of the other Word actions that configure the conversion settings.

Each new TIFF also has a new page created within the application environment which can be processed by subsequent rules. The original file name from which the page was extracted is stored in the *ParentImage* variable, for possible future reference in your application. If the configured output image format and compression only supports black and white, such as CCITT4, colored text is exported as black.

Example:

```
WordPrintQuality(200)
WordTiffCompression("CCITT4")
WordDocumentToImage()
```

Parent topic: [Word actions](#)

WordDocumentToPdf

Converts .doc or.docx files to PDF document format.

Member of namespace

Convert

Syntax

```
bool WordDocumentToPdf ()
```

Returns

True if the file conversion succeeds. Otherwise, the action returns False if the current page is not a Word document or some other conversion failure occurs..

Level

Page level.

Details

Use this action to convert Word documents to a single PDF file. For information about setting the compliance standard for the produced PDF document, see [PDF compliance standards](#).

This action sets the batch to abort in the following circumstances:

- The number of input files or pages exceeds the allowed maximum.
- The conversion fails.

Example:

```
WordDocumentToPdf
```

Parent topic: [Word actions](#)
»

WordMonochromeQuality

Adjusts binarization settings used by WordDocumentToImage.

Member of namespace

Convert

Syntax

```
bool WordMonochromeQuality (int method, float threshold)
```

Parameters

method

Sets the binarization method to either `Threshold` or `FloydSteinbergDithering` by using one of the following values:

- 0 (for `Threshold`)
- 1 (for `FloydSteinbergDithering`)

threshold

A floating value between 0 and 1 for rendering brightness. Lower values are darker.

Returns

Always True.

Level

Any level.

Details

Defaults compression to `CCITT4` and sets the binarization settings used for black and white output. If this action is not called, the default values of `Threshold` and 0.5 will be used for monochrome compression.

Example:

```
WordMonochromeQuality(0, 0.45)  
WordDocumentToImage()
```

Parent topic: [Word actions](#)
«

WordPrintQuality

Adjusts the resolution of the image output by WordDocumentToImage.

Member of namespace

Convert

Syntax

```
bool WordPrintQuality (int dpi)
```

Parameters

dpi
Type: int

Parameters

dpi : A single positive numeric value for the dots per inch (dpi) of the output image.

Returns

False if the parameter is invalid. Otherwise, True.

Level

Page level.

Details

Sets the resolution of the output image for WordDocumentToImage. If this action is not called, the default value of 200 dpi is used. Typically, input documents for recognition are 200 dpi.

Example:

```
WordPrintQuality(200)  
WordDocumentToImage()
```

Parent topic: [Word actions](#)

WordTiffCompression

Sets the compression used in the TIFF output by WordDocumentToImage.

Member of namespace

Convert

Syntax

```
bool WordTiffCompression (string tiffCompression)
```

Parameters

tiffCompression
Type: string

Parameters

tiffCompression is one of the following values to set the TIFF compression:

- NONE : A color image with no compression.
- LZW : A color image using LZW compression.
- CCITT4 : A black and white image with fax CCITT4 compression.

Returns

Always True.

Level

Page level.

Details

Sets the compression of the output image from WordDocumentToImage. If this action is not called, the default value of CCITT4 is used. Typically, input documents for recognition are black and white with fax compression.

Example:

```
WordTiffCompression (CCITT4)
WordDocumentToImage ()
```

Parent topic: [Word actions](#)

Zip actions

Use the Zip actions to extract the images files in a compressed ZIP archive and convert them to separate TIFF files for recognition by Datacap.

The Zip actions can overwrite the files that exist when you extract from ZIP archives and sets the Password value that is used to extract files from password protected archives.

- [ZipOverwrite](#)
Controls overwriting files when extracting from ZIP archives.
- [ZipPassword](#)
Sets the password for Password protected archives that will be used by ZipUnPack.
- [ZipUnPack](#)
Extracts each file within a compressed file archive into separate files.

Parent topic: [Convert actions](#)

ZipOverwrite

Controls overwriting files when extracting from ZIP archives.

Member of namespace

Convert

Syntax

```
bool ZipOverwrite (bool overwrt)
```

Parameters

overwrt
Type: bool

Parameters

A Boolean value that indicates if a subsequent ZipUnPack action should overwrite existing files.

True: Overwrite files that already exist.

False: Do not overwrite files that already exist.

Returns

Always True.

Level

Page level.

Details

This action must be called before ZipUnPack. If this action is not called, then ZipUnPack uses the default value of True.

Example:

```
ChkDCOStatus ("49")
ZipOverwrite ("True")
ZipUnPack ()
SetDCOStatus ("75")
```

Parent topic: [Zip actions](#)

ZipPassword

Sets the password for Password protected archives that will be used by ZipUnPack.

Member of namespace

Convert

Syntax

```
bool ZipPassword (string pwd)
```

Parameters

pwd
Type: string

Parameters

pwd : The password for the archive. Smart parameters are supported.

Returns

Always True.

Level

Page level.

Details

The password provided is used to extract password protected archives. This action must be called before ZipUnPack.

Example:

```
ChkDCOStatus ("49")
ZipOverwrite ("True")
ZipPassword ("MySafePassword")
ZipUnPack ()
SetDCOStatus ("75")
```

Parent topic: [Zip actions](#)

ZipUnPack

Extracts each file within a compressed file archive into separate files.

Member of namespace

Convert

Syntax

```
bool ZipUnPack ()
```

Parameters

None.

Returns

True, if the contents of the compressed file is successfully extracted.

False, if the current page is not a PDF or if there is a failure in the extraction.

If the number of input files/pages exceeds the maximum that is allowed or if there is a failure in the extraction, the batch is set to abort.

Level

Page level.

Details

If the current page is compressed, the files that are contained in the archive are placed into the current batch directory. Each new file also has a new page that is created within the application environment that can be processed by subsequent rules. The original file name from which the page was extracted is stored in the *ParentImage* variable, for future reference within your application.

Example:

```
ChkDCOStatus ("49")
ZipUnPack ()
SetDCOStatus ("75")
```

In this example, the action checks if the current page is the type, Other, and tries to extract the page. If the extraction is successful, then the current page was a valid compressed file. The files are extracted from the compressed file and put in the batch directory. The next action sets the page status of the compressed file to Deleted. The action does not delete it from the batch, but stops further processing of the compressed file.

Parent topic: [Zip actions](#)

DatacapBOX actions

Use the DatacapBOX actions to move files between your Datacap system and Box.com.

Important:

During IBM Datacap installation, the installer places DatacapBOX connector standard rulesets and action library on the target system, at this location: C:\Datacap\RRS\Box

You cannot use the *DatacapBOX* connector directly from this location. You must manually copy the entire contents of this folder to the “Rules” folder of the Datacap application that is interacting with Box.

For example, if “TravelDocs” is the Datacap application that interacts with DatacapBOX connector, copy all the files from C:\Datacap\RRS\Box folder to C:\Datacap\TravelDocs\dco_TravelDocs\Rules

The word *Box* as used here refers to your account on Box.com. To use the DatacapBOX actions, configure the Datacap system with your Box.com account information. For information about this configuration, see the section [Box Connector actions](#).

DatacapBOX actions are associated with the following objects:

- Export
- Import
- [Export object](#)
To export files from the Datacap system to Box, configure settings on the Export object and call the Upload action to initiate the export process.
- [Import object](#)
To import files from Box into the Datacap system, configure settings on the Import object and call the Download action to initiate the import process.

Parent topic: [Global actions](#)

Export object

To export files from the Datacap system to Box, configure settings on the Export object and call the Upload action to initiate the export process.

Important: Box limits the number of API calls per second, which means that export failures are more likely to occur as the number of export threads increases. To avoid export failures, do not configure more than eight threads for a Box export ruleset. Decrease the thread number as necessary if your export logs indicate export failures that are caused by the Box call rate limitation. For information about Export task logs, see [Task log files](#). Also, the optimal number of threads can vary depending on your hardware, image or batch sizes, and network performance. For general information about configuring threads in Rulerunner, see [Rulerunner thread configuration](#).

The export settings govern the behavior of the export process in the following ways:

Category	Comment	Relevant settings
DCO objects	You export one of the following types of DCO objects: <ul style="list-style-type: none"> • Pages • Document-level PDF files 	<ul style="list-style-type: none"> • ProcessChildren • DocumentsToPDF
Metadata	You optionally export the following items as Box file metadata: <ul style="list-style-type: none"> • DCO variables • Fields 	<ul style="list-style-type: none"> • AddParentDataToPageMetadata • DCOVarsAreMetadata • FieldsAreMetadata
Location	You optionally specify the Box target folder in which the export process places the exported files. By default, the target folder is your Box root folder.	<ul style="list-style-type: none"> • TargetFolder • CreateBatchSubfolder
Existing file versions	You optionally specify how the export process handles any existing versions of a Box file that has the same name as an exported file. By default, any existing file versions are ignored.	<ul style="list-style-type: none"> • FailIfExists • OverwriteExistingFiles • ReplaceMetadata

- [AddParentDataToPageMetadata](#)
A setting that determines whether the export process includes parent data in the Box metadata for exported files.
- [CreateBatchSubfolder](#)
A setting that determines whether the export process creates a subfolder for each exported batch. A subfolder has the same name as the batch and contains the exported files for the batch.
- [DCOVarsAreMetadata](#)
A setting that determines whether the export process includes DCO variable values in the Box metadata for exported files.
- [DocumentsToPDF](#)
A setting that determines the type of DCO objects that are exported to Box: either document-level PDF files or pages.

- [FailIfFileExists](#)
A setting that determines whether the export process fails if the target folder has one or more existing versions of a file to be exported.
- [FieldsAreMetadata](#)
A setting that determines whether the export process includes field values in the Box metadata for exported files.
- [OverwriteExistingFiles](#)
A setting that determines whether the export process overwrites any existing Box versions of a file to be exported. This setting has no effect if the FailIfFileExists action setting is set to True.
- [ProcessChildren](#)
A setting that determines whether the export process exports child objects of the current DCO object to Box.
- [ReplaceMetadata](#)
A setting that determines whether the export process replaces the Box metadata for a file when exporting a new version of the file to Box. One set of metadata is associated with all versions of the same Box file.
- [TargetFolder](#)
A setting that specifies the Box folder (if any) in which the export process places exported files.
- [Upload](#)
Exports files to Box from the current DCO object based on the settings of the Export object.

Parent topic: [DatacapBOX actions](#)

AddParentDataToPageMetadata

A setting that determines whether the export process includes parent data in the Box metadata for exported files.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

The term *parent* refers to the parent objects of a page such as the parent document object and the parent batch object. This setting has two possible values:

True	Parent data is included in the Box metadata.
False	Parent data is not included in the Box metadata.

The default value for this setting is False. Smart parameters are supported.

The following settings affect the type of parent data included in the file metadata:

- FieldsAreMetadata
- DCOVarsAreMetadata

Member of namespace

DatacapBOX

Syntax

AddParentDataToPageMetadata (bool NewValue)

Level

Any level.

Example

```
AddParentDataToPageMetadata()  
Upload()
```

Parent topic: [Export object](#)

Related reference:

[FieldsAreMetadata](#)

[DCOVarsAreMetadata](#)

CreateBatchSubfolder

A setting that determines whether the export process creates a subfolder for each exported batch. A subfolder has the same name as the batch and contains the exported files for the batch.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

This setting has two possible values:

True	Batch subfolders are created. The exported files are placed in the subfolders.
False	Batch subfolders are not created. The exported files are placed in the Box target folder.

The default value for this setting is False.

The TargetFolder setting specifies the Box target folder in which the batch subfolders are created.

Member of namespace

DatacapBOX

Syntax

```
CreateBatchSubfolder (bool NewValue)
```

Level

Any level.

Example

```
CreateBatchSubfolder (True)  
Upload()
```

Parent topic: [Export object](#)

Related reference:

[TargetFolder](#)

DCOVarsAreMetadata

A setting that determines whether the export process includes DCO variable values in the Box metadata for exported files.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

This setting has two possible values:

True	DCO variable values are included in the Box metadata.
False	DCO variable values are not included in the Box metadata.

The default value for this setting is False.

By default, the exported DCO variable values belong to the exported object only (a page or document-level PDF file). This default behavior can be overridden by the `AddParentDataToPageMetadata` setting.

Member of namespace

DatacapBOX

Syntax

```
DCOVarsAreMetadata (bool NewValue)
```

Level

Any level.

Example

```
DCOVarsAreMetadata (True)  
Upload()
```

Parent topic: [Export object](#)

Related reference:

[AddParentDataToPageMetadata](#)

DocumentsToPDF

A setting that determines the type of DCO objects that are exported to Box: either document-level PDF files or pages.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

This setting has two possible values:

True	The document-level PDF files of the current batch are exported to Box. (The export process does not create any PDF files; it assumes that they were previously created.)
False	The pages of the current batch are exported to Box.

The default value for this setting is False.

Member of namespace

Syntax

```
DocumentsToPDF(bool NewValue)
```

Level

Any level.

Example

```
DocumentsToPDF(True)
Upload()
```

Parent topic: [Export object](#)

FailIfExists

A setting that determines whether the export process fails if the target folder has one or more existing versions of a file to be exported.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

This setting has two possible values:

True	The export process fails if it encounters an existing Box version of a file to be exported. Such a failure means that the export process does not continue. The failure does not affect the files that were exported before the process failed; they remain exported.
False	The export process does not fail if it encounters an existing Box version of a file to be exported. (The <code>OverwriteExistingFiles</code> setting determines whether any existing file versions are overwritten.)

The default value for this setting is `False`.

Member of namespace

DatacapBOX

Syntax

```
FailIfExists(bool NewValue)
```

Level

Any level.

Example

```
FailIfExists(True)
Upload()
```

Parent topic: [Export object](#)

Related reference:

FieldsAreMetadata

A setting that determines whether the export process includes field values in the Box metadata for exported files.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

This setting has two possible values:

True	Field values are included in the Box metadata.
False	Field values are not included in the Box metadata.

The default value for this setting is False.

By default, the exported field values belong to the exported object only (a page or document-level PDF file). This default behavior can be overridden by the `AddParentDataToPageMetadata` setting.

Member of namespace

DatacapBOX

Syntax

```
FieldsAreMetadata (bool NewValue)
```

Level

Any level.

Example

```
FieldsAreMetadata (True)  
Upload ()
```

Parent topic: [Export object](#)

Related reference:

[AddParentDataToPageMetadata](#)

OverwriteExistingFiles

A setting that determines whether the export process overwrites any existing Box versions of a file to be exported. This setting has no effect if the `FailIfExists` action setting is set to True.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

This setting has two possible values:

True	The last existing Box file version in the target folder is deleted.
-------------	---

	For example, suppose that three versions of file abc exist in Box, and you are exporting the abc file. The export process deletes version 3 of the file in Box.
False	None of the existing Box file versions are deleted.

In both cases, a new version of the file is added to Box.

The default value for this setting is False.

Member of namespace

DatacapBOX

Syntax

```
OverwriteExistingFiles (bool NewValue)
```

Level

Any level.

Example

```
OverwriteExistingFiles (true)
Upload()
```

Parent topic: [Export object](#)

Related reference:
[FailIfFileExists](#)

ProcessChildren

A setting that determines whether the export process exports child objects of the current DCO object to Box.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

This setting has two possible values:

True	Child DCO objects are exported in addition to the current DCO object.
False	Child DCO objects are not exported. Only the current DCO object is exported.

The default value for this setting is True.

Member of namespace

DatacapBOX

Syntax

```
ProcessChildren (bool NewValue)
```

Level

Any level.

Example

```
ProcessChildren (True)  
Upload ()
```

Parent topic: [Export object](#)

ReplaceMetadata

A setting that determines whether the export process replaces the Box metadata for a file when exporting a new version of the file to Box. One set of metadata is associated with all versions of the same Box file.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

This setting has two possible values:

True	The metadata for the exported Box file includes the newly exported metadata only. The previous Box metadata for the file is discarded.
False	The metadata for the exported Box file includes the following sets of metadata merged together: <ul style="list-style-type: none">• The newly exported metadata• The previous Box metadata for the file before the export If the same field exists in both sets of metadata, the value from the newly exported metadata is used.

The default value for this setting is True.

Member of namespace

DatacapBOX

Syntax

```
ReplaceMetadata (bool NewValue)
```

Level

Any level.

Example

```
ReplaceMetadata (True)  
Upload ()
```

Parent topic: [Export object](#)

TargetFolder

A setting that specifies the Box folder (if any) in which the export process places exported files.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

You can specify the target folder as a path. If the specified target folder does not exist, the export process creates it.

The default value for this setting is an empty string, which means that the target folder is your root Box folder. Smart parameters are supported.

The CreateBatchSubfolder setting affects the way that files are placed in the target folder.

Member of namespace

DatacapBOX

Syntax

```
TargetFolder (bool NewValue)
```

Level

Any level.

Example

```
TargetFolder ("Datacap")  
Upload ()
```

Parent topic: [Export object](#)

Related reference:

[CreateBatchSubfolder](#)

Upload

Exports files to Box from the current DCO object based on the settings of the Export object.

Member of namespace

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

DatacapBOX

Syntax

```
Upload ()
```

Returns

True if the export process succeeds. Otherwise, the action returns False.

For information about the causes of a failed export process, see the rulerunner log in the current batch folder. For more information, see [Analyze the Rulerunner log](#).

The FailIfExists setting partly determines what constitutes a successful export.

Level

Batch, document, or page level.

Details

Example:

```
// DCO objects
ProcessChildren(True)

// Metadata
AddParentDataToPageMetadata(True)
DCOVarsAreMetadata(True)
FieldsAreMetadata(True)

// Location
TargetFolder("Datacap")
CreateBatchSubfolder(True)

// Existing file versions
OverwriteExistingFiles(True)
ReplaceMetadata(True)

// Export process
Upload()
```

Parent topic: [Export object](#)

Related reference:

[FailIfFileExists](#)

Import object

To import files from Box into the Datacap system, configure settings on the Import object and call the Download action to initiate the import process.

Important: If any concurrently running threads might be using the same Box source folder, your Box-related tasks cannot be run in a multi-threaded configuration. Instead, use single-threaded tasks only. For information about configuring threads in Rulerunner, see [Rulerunner thread configuration](#). For information about the Box source folder, see [SourceFolder](#).

The import settings govern the behavior of the import process in the following ways:

Category	Comment	Relevant settings
Files	You determine the files that are imported from Box by specifying the following items: <ul style="list-style-type: none">The Box source folder from which files are importedThe allowed file extensions of imported filesThe number of files to import	<ul style="list-style-type: none">SourceFolderLookForExtensionsImportLimit

Category	Comment	Relevant settings
Reimport prevention	You specify a backup folder to prevent files from being imported again (by a later import process).	<ul style="list-style-type: none"> BackupFolder
DCO objects	You import files from Box as one of the following types of objects: <ul style="list-style-type: none"> Document-level pages Batch-level pages 	<ul style="list-style-type: none"> ImportAsDocumentType

- [BackupFolder](#)
 A setting that specifies the Box backup folder (if any) to which the import process moves the files that were imported from the source folder. The purpose of this file relocation is to prevent files from being imported more than once. All versions of an imported Box file are moved to the backup folder.
- [Download](#)
 Imports files from Box into the current batch based on the settings of the Import object.
- [ImportAsDocumentType](#)
 A setting that specifies the type for the document that the import process creates (if any) to hold imported files as child pages.
- [ImportLimit](#)
 A setting that specifies the maximum number of files that the import process imports from Box.
- [LookforExtensions](#)
 A setting that specifies a comma-delimited list of file extensions that the import process uses as a criterion for determining which files to import from Box. A file must have one of the specified extensions to be imported.
- [SourceFolder](#)
 A setting that specifies the Box source folder from which the import process imports files. The name of the source folder is case-sensitive. Subfolders within the source folder are not traversed; files are imported from the source folder only.

Parent topic: [DatacapBOX actions](#)

BackupFolder

A setting that specifies the Box backup folder (if any) to which the import process moves the files that were imported from the source folder. The purpose of this file relocation is to prevent files from being imported more than once. All versions of an imported Box file are moved to the backup folder.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

You can specify the backup folder as a path. If the specified backup folder does not exist, the import process creates it.

The default value for this setting is an empty string, which means that the import process does not move imported files to a backup folder. Smart parameters are supported.

Member of namespace

DatacapBOX

Syntax

```
BackupFolder(string NewValue)
```

Level

Any level.

Example

```
BackupFolder("InDatacap")  
Download()
```

Parent topic: [Import object](#)

Download

Imports files from Box into the current batch based on the settings of the Import object.

Member of namespace

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

DatacapBOX

Syntax

```
Download()
```

Returns

True in the following circumstances:

- One or more files are found in the Box source folder (as specified by the SourceFolder setting)
- All files in the Box source folder are successfully imported

Otherwise, the action returns False.

For information about the causes of a failed import process, see the rulerunner log in the current batch folder. For more information, see [Analyze the Rulerunner log](#).

Level

Batch level.

Details

Use this action to import files into the current batch from Box based on the settings of the Import object. Box data is converted in the following manner:

- Box files become page objects
- Box metadata becomes page DCO variables

If no files are found in the Box source folder, the status of the current batch is set to Pending.

Example:

```
// Files
SourceFolder("ToDatacap")
LookForExtensions("tif,tiff,jpg,jpeg")

// Reimport prevention
BackupFolder("InDatacap")

// DCO objects
ImportAsDocumentType("MyDocType")

// Import process
Download()
```

Parent topic: [Import object](#)

Related reference:

[SourceFolder](#)

ImportAsDocumentType

A setting that specifies the type for the document that the import process creates (if any) to hold imported files as child pages.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

The default value for this setting is an empty string, which means that the import process does not create a document to hold imported pages. Instead, files are imported as batch-level pages. Smart parameters are supported.

Member of namespace

DatacapBOX

Syntax

```
ImportAsDocumentType(string NewValue)
```

Level

Any level.

Example

```
ImportAsDocumentType("MyDocType")
Download()
```

Parent topic: [Import object](#)

ImportLimit

A setting that specifies the maximum number of files that the import process imports from Box.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

A setting value of -1 or 0 indicates that no maximum limit applies. This setting is the default setting.

Smart parameters are supported.

Member of namespace

DatacapBOX

Syntax

```
ImportLimit(string NewValue)
```

Level

Any level.

Example

Code	Comment
<pre>ImportLimit("-1") Download()</pre>	No maximum file limit applies to the import process.
<pre>ImportLimit("5") Download()</pre>	The import process imports no more than five files.

Parent topic: [Import object](#)

LookforExtensions

A setting that specifies a comma-delimited list of file extensions that the import process uses as a criterion for determining which files to import from Box. A file must have one of the specified extensions to be imported.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

The default value for this setting is an empty string, which means that imported files can have any file extension.

Member of namespace

DatacapBOX

Syntax

```
LookForExtensions(string NewValue)
```

Level

Any level.

Example

```
LookForExtensions ("tif,tiff,jpg,jpeg")
Download()
```

Parent topic: [Import object](#)

SourceFolder

A setting that specifies the Box source folder from which the import process imports files. The name of the source folder is case-sensitive. Subfolders within the source folder are not traversed; files are imported from the source folder only.

Important: You must configure the DatacapBOX action before you use this option. For more information, see [DatacapBOX actions](#).

The import process fails in the following circumstances:

- No source folder is specified
- The specified source folder does not exist

Smart parameters are supported.

Member of namespace

DatacapBOX

Syntax

```
SourceFolder(string NewValue)
```

Level

Any level.

Example

```
SourceFolder ("ToDatacap")
Download()
```

Parent topic: [Import object](#)

Related reference:

[Download](#)

Dcclip actions

Use the Dcclip action to clip a portion of each page image and save it as a separate TIFF file.

The Dcclip action uses the recognition zone coordinates of the current field and clips the specified region of each page to a separate TIFF file.

- [dci_clipfield](#)
During processing, clips the field on the Image file (.tif) of every source page represented by the bound Field object of the Document Hierarchy and generates a separate Image file (.tif) displaying the clipped field's contents.

Parent topic: [Global actions](#)

dci_clipfield

During processing, clips the field on the Image file (.tif) of every source page represented by the bound Field object of the Document Hierarchy and generates a separate Image file (.tif) displaying the clipped field's contents.

Syntax

```
bool dci_clipfield (strParam)
```

Parameters

Two comma-separated string values:

1. The Page Type that is to be assigned to the Image file containing the clipped field and its value.
Remember: The new Image file is represented by a new page in the current Page file. The Page Type value you assign will be used to identify pages with clipped fields.
2. The Page Status to be assigned to pages with clipped images of the bound Field object of the Document Hierarchy.
Attention: Be sure that the status you assign conforms to Page Status specifications used throughout your application.

Returns

False if either parameter is invalid. Otherwise True.

If the dci_clipfield action cannot locate the target field on a source page, the action will not generate an Image file for the clipped field and will not add a corresponding page to the current Page file (.xml).

Level

Field level only.

Details

During processing, clips the field on the Image file (.tif) of every source page represented by the bound Field object of the Document Hierarchy and generates a separate Image file (.tif) displaying the clipped field's contents.

The action also adds a page representing the new Image file to the current Page file.

Attention: If the Image ID assigned to the Image file representing the source page has this format: tm000001.tif. The Image ID of a clipped field's Image file adds one underscore character and a two digit index and has this format: tm000001_01.tif

The second pair in the batch will have these ID's: tm000002.tif and tm000002_01.tif. This assumes that a source page has only one clipped field.

Example

```
dci_clipfield(OfficePens_Page, 0)
```

Parent topic: [Dcclip actions](#)

DCImageFix actions

Use the DCImageFix actions to clean up and enhance page images.

The image INI settings indicate which processes are run by the ImageEnhance action. You configure these INI settings on the Zones tab in Datacap Studio.

- [ImageEnhance](#)
Runs image processing by using pre-configured image enhancement settings, typically from the imagefix.ini file.
- [LoadSettings](#)
Loads the image enhancement settings that are used by the ImageEnhance action to run image processing.
- [LoadSettings_FingerprintID](#)
Loads the specific ImageFix Settings file (.ini) that corresponds to the Fingerprint ID of the current page.

Parent topic: [Global actions](#)

ImageEnhance

Runs image processing by using pre-configured image enhancement settings, typically from the imagefix.ini file.

Member of namespace

DCImageFix

Syntax

```
bool ImageEnhance (string BackupFileExtension)
```

Parameters

String: BackupFileExtension

Parameters

The file extension that the action is to assign to the backup of the original Image file. For example: tio.

The extension must be at least one character. If the leading period is provided, at least one character must follow it. Long name file extensions are allowed.

Returns

False If the parameter is not 3 or 4 alphanumeric characters, or if an exception is encountered while the image is being enhanced. Otherwise, True.

Level

Page or Field Level.

Details

Initiates image processing to run a pre-configured set of image enhancements.

Include this action after a LoadSettings or LoadSettings_FingerprintID action.

Example:

```
LoadSettings (C:\ParentDir\Invoice\Process\ImageFix.ini)
ImageEnhance ("tio")
```

In this example, the ImageFix settings that are specified in ImageFix.ini are applied to every page in the batch. An example of the copied file name is "TM000001.tio".

```
LoadSettings (C:\ParentDir\Invoice\Process\ImageFix.ini)
ImageEnhance ("tio.tif")
```

This example uses a longer file extension, which preserves the original file type. This extension makes it easier to view the original file without renaming. An example of the copied file name is "TM000001.tio.tif".

Parent topic: [DCImageFix actions](#)

LoadSettings

Loads the image enhancement settings that are used by the ImageEnhance action to run image processing.

Member of namespace

DCImageFix

Syntax

```
bool LoadSettings (string BackupFileExtension)
```

Parameters

String: BackupFileExtension The value of the path to the ImageFix Settings file (.ini).

Attention: The action can also use Smart Parameter syntax, such as the '@PATH(string)' method, to specify the path.

Returns

False if the ImageFix Settings file that you specify as a parameter is not found. Otherwise, True.

Level

All.

Details

This action loads the settings that the ImageFix action uses to process all images in the current batch. The action's parameter includes the file's name and complete path to its location in the application's Process directory. As an alternative, the parameter can use a smart parameter such as @Path to designate the value of the path to the same Process directory.

Example:

```
LoadSettings (C:\ParentDir\Invoice\Process\ImageFix.ini)
ImageEnhance (tio)
```

Example:

This example loads the settings file using the path denoted by the ScanFixSettings key that is listed in the Paths.ini file. If the key points to a relative path, it would be converted to the appropriate full path and then use that path to find the settings:

```
LoadSettings (@PATH (ScanFixSettings) )
ImageEnhance (tio)
```

Parent topic: [DCImageFix actions](#)

LoadSettings_FingerprintID

Loads the specific ImageFix Settings file (.ini) that corresponds to the Fingerprint ID of the current page.

Member of namespace

DCImageFix

Syntax

```
bool LoadSettings_FingerprintID (string FingerprintsFolderPath)
```

Parameters

String: FingerprintsFolderPath The value of the path to the fingerprint folder.

Attention: The action can also use Smart Parameter syntax, such as the '@PATH(string)' method to specify the path.

Returns

False if a fingerprint-specific Settings file does not exist. Otherwise, True.

Level

Page level only.

Details

The action searches the fingerprint folder of the application for a fingerprint-specific ImageFix Settings file. The settings for these files are assigned during the Image Enhancement phase of Fingerprint Definition, using the tools in Rule Manager's Image Processing Setup dialog. (Chapter 3 of the Rule Manager Reference shows you how to define a fingerprint-specific ImageFix Settings file.)

Important: The name of a fingerprint-specific ImageFix Settings file is limited to the Fingerprint ID with the .ini extension: 1044.ini, for example.

Example:

```
LoadSettings_FingerprintID()
ImageEnhance (tio)
```

Parent topic: [DCImageFix actions](#)

DCO actions

Use the DCO actions to set up and modify the runtime batch hierarchy (runtime DCO) information.

The DCO actions can create documents, set up the status and type properties of an object, check the status of an object, and create a page data file for an object.

- [ChkConfidence](#)
Checks the confidence of all field data on child pages against a minimum acceptable confidence value (Parameter 1). If any fields in a page contain Low Confidence data, assigns the Page Status that is specified in Parameter 2 to the page.
- [ChkDCOStatus](#)
Confirms that the status of the Document Hierarchy's current object is identical to the status entered as the parameter.
- [ChkDCOType](#)
Confirms that the Type property of the Document Hierarchy's current object is identical to the type entered as the parameter.
- [ChkLastDCOTypeEx](#)
Checks that the Type property of the Document Hierarchy's previous object is identical to the type entered as the parameter.
- [ChkIntegrity](#)
Checks that the integrity of the batch, as detailed in the Page file of the current task, meets the integrity requirements set within the Document Hierarchy (Setup DCO).
- [ChkLastDCOType](#)
Checks that the Type property of the Document Hierarchy's previous object is identical to the type entered as the parameter.
- [ClearAltText](#)
Clears character and confidence values from the Character Array position specified by the parameter.
- [ClearDCO](#)
Clears all objects of the Document Hierarchy which are children of the bound object, and their variables.
- [CopyPD2DD](#)
Assigns the value in a Page object's PD (Page Data) variable to the Document object's DD (Doc Data) variable.
- [CountPagesToDocumentVar](#)
Counts the number of pages in the document.
- [CreateDocuments](#)
Arranges the contents of a task's Page file (for example, Recognition.xml) into documents based on the Document Integrity rules (min, max and order) specified in your application's Document Hierarchy, and assembles documents from the pages in the batch.
- [CreateFields](#)
Creates the Data file for a page in a batch. The Data file for the first page in the batch, tm000001, as an example, is tm000001.xml.
- [DeleteFields](#)
Deletes all child fields and characters from calling object of the Document Hierarchy.
- [IsDocumentCountMoreThan](#)
Compares the number of documents in a batch with a parameter that you specify to let you manage the document size of your batches.
- [IsFirstDocumentInBatch](#)
Checks to see if this document is the first document in a batch.
- [JoinPreviousDocument](#)
Specifies the document type to join with the current document.
- [PropagateToAltText](#)
Copies the character and confidence values from the first index of the Character Array (index 0) to the

- index specified by the parameter.
- [RemoveDocumentStructure](#)
Removes the document hierarchy from the batch.
 - [SaveImageInformation](#)
Gets the image information and stores it into the DCO.
 - [SetDCOStatus](#)
Assigns a value to the Status property of the current object of the Document Hierarchy.
 - [SetDCOType](#)
Assigns a value to the Type property of the current object of the Document Hierarchy.
 - [SetDocStatus](#)
Assigns a status to the current document.
 - [SetDocumentType](#)
The action assigns a Document Type to the current Document object of the Document Hierarchy.
 - [SetFldConfidence](#)
For a specific field, sets the confidence for all characters in the field to the same value.
 - [SetPageFingerprintID](#)
Assigns a value to the FingerprintID property of the selected Page object of the Document Hierarchy.
 - [SetPageStatus](#)
The action assigns a page status to an object of the Document Hierarchy.
 - [SetPageTemplateID](#)
Assigns a value to the FingerprintID property of the selected Page object of the Document Hierarchy.
 - [SetPageType](#)
The action assigns a Page Type to the current Page object of the Document Hierarchy.

Parent topic: [Global actions](#)

ChkConfidence

Checks the confidence of all field data on child pages against a minimum acceptable confidence value (Parameter 1). If any fields in a page contain Low Confidence data, assigns the Page Status that is specified in Parameter 2 to the page.

Syntax

```
bool ChkConfidence (StrParam)
```

Parameters

Two or three comma-separated values:

1. The Numeric value of the minimum confidence required. This value is superseded on a field-by-field basis, if the field's *ReqConf* variable is set.
2. The Numeric Page Status code to assign to any page that has one or more fields with Low Confidence data: if a field's *ConfidenceString* property contains a value lower than the first parameter. Subfields, line items, and so on, are included. Typically, "1" (Problem) is the value of this parameter. If only two parameters are specified, only pages with *Status=0* are checked by this action.
3. If a third parameter is supplied, these parameters specify the list of Page Statuses to be checked.

Returns

True, if all fields in all source pages are High Confidence. False, if any field has Low Confidence data, or if the parameters are not Numeric.

Level

All levels. This action operates on the entire batch regardless of the level to which its rule is bound.

Details

Checks the confidence of all field data on selected pages, which are selected by Page Status, against a minimum acceptable confidence value (Parameter 1). If any fields contain Low Confidence data, the page is marked with the status specified as a parameter.

Optionally, checks only pages of the status that is specified as Parameter 3.

Example:

```
ChkConfidence (8,1)
```

Parent topic: [DCO actions](#)

Related reference:

[ChkDCOStatus](#)

ChkDCOStatus

Confirms that the status of the Document Hierarchy's current object is identical to the status entered as the parameter.

Syntax

```
bool ChkDCOStatus (StrParam)
```

Parameters

The Numeric value of the status that you are checking.

Returns

True, if the DCO status matches the parameter value. Otherwise, False.

Level

All levels.

Details

Confirms that the status of the Document Hierarchy's current object is identical to the status entered as the parameter.

Example:

```
ChkDCOStatus(0)  
returns True, if the current object has a status equal to 0, and False, if it  
does not.
```

```
ChkDCOStatus(48)  
returns True, if the current object has a status equal to 48, and False, if it  
does not.
```

Parent topic: [DCO actions](#)

Related reference:

[SetDCOStatus](#)

[ChkDCOType](#)

ChkDCOType

Confirms that the Type property of the Document Hierarchy's current object is identical to the type entered as the parameter.

Syntax

```
bool ChkDCOType (StrParam)
```

Parameters

The String value of the Type property of the object you're checking.

Returns

True if the value of the DCO Type matches the parameter. Otherwise, False.

Level

All levels.

Details

Confirms that the Type property of the Document Hierarchy's current object is identical to the type entered as the parameter.

Example:

```
ChkDCOType (Invoice)  
SetPageStatus (1)
```

Applied at the Page level, the action returns True if the current object is an Invoices Page object (using the Invoices application as an example), and False if it is not.

This action will confirm the current DCO Type matches an expected type and take additional subsequent actions that follow this action. In this case, if the current DCO Type is Invoice, the page status is set to 1.

Parent topic: [DCO actions](#)

Related reference:

[SetDCOType](#)

[ChkDCOStatus](#)

[ChkLastDCOType](#)

ChkLastDCOTypeEx

Checks that the Type property of the Document Hierarchy's previous object is identical to the type entered as the parameter.

Member of namespace

DCO

Syntax

```
bool ChkLastDCOTypeEx (string prevPageToMatch, string chkObjLevel, string ignoreTypes)
```

Parameters

- prevPageToMatch - The previous object's DCO Type to compare, case sensitive.
- chkObjLevel - (Optional) Objects to compare:
 - 0 - All
 - 1 - Documents only
 - 2 - Pages only
 - 3 - Fields only
- ignoreTypes - (Optional) Type or comma-delimited list of Types to skip evaluation. If the prior object's Type is listed within the parameter then it will be skipped and if present, objects prior to it will be checked.

Returns

True if the Type property of the Document Hierarchy's previous non-skipped object matches the page type attempting to be matched. Otherwise, False.

Level

All.

Details

Checks that the Type property of the Document Hierarchy's previous object is identical to the type entered as the parameter. This action allows you to test the last DCO Type encountered so you can take specific subsequent steps based on that type.

Example:

```
ChkLastDCOTypeEx (Separator, ,)
```

Parent topic: [DCO actions](#)

ChkIntegrity

Checks that the integrity of the batch, as detailed in the Page file of the current task, meets the integrity requirements set within the Document Hierarchy (Setup DCO).

Syntax

```
bool ChkIntegrity ()
```

Parameters

None.

Returns

Returns True if no integrity problems are found. Otherwise, False.

Level

Batch and Document levels.

Details

Checks that the integrity of the batch, as detailed in the Page file of the current task, meets the integrity requirements set within the Document Hierarchy (Setup DCO).

Integrity refers to the correct types and numbers of pages within each document in the batch and the correct order of the pages in each document.

Example:

```
ChkIntegrity()
```

Parent topic: [DCO actions](#)

ChkLastDCOType

Checks that the Type property of the Document Hierarchy's previous object is identical to the type entered as the parameter.

Syntax

```
bool ChkLastDCOType (StrParam)
```

Parameters

The previous object's DCO Type to compare.

Returns:

True, if the Type property of the Document Hierarchy's previous object matches the parameter. Otherwise, False.

Level

All.

Details

Checks that the Type property of the Document Hierarchy's previous object is identical to the type entered as the parameter. You can use this action to test the last DCO Type that is encountered so you can take specific subsequent steps that are based on that type.

The example is applied at the Page level and checks to see whether the previous Page object's type matches the parameter (Separator).

Example:

```
ChkLastDCOType (Separator)
SetPageType (Invoice)
SetPageStatus (1)
```

Applied at the Page level, this sequence checks to see whether the previous Page object was a Separator page. If so, the type of the current page is set to Invoice, and its status is set to "1". If the previous document type was not a separator, the subsequent actions do not execute.

Parent topic: [DCO actions](#)

Related reference:

[SetDCOType](#)

[ChkDCOType](#)

ClearAltText

Clears character and confidence values from the Character Array position specified by the parameter.

Syntax

```
bool ClearAltText (strParam)
```

Parameters

The index in the Character Array where you want to clear the character and confidence values. 0 is the first index, followed by 1, etc.

Returns

Always True.

Level

Field level.

Details

Clears character and confidence values from the Character Array position specified by the parameter. When cleared, the confidence values are set to 10 (high confidence). (A field in the Data file can hold more than one representation of the field's value. Values other than the current, visible value are accessed via an index number. The current value is at index 0, the next value is at index 1. Each additional value also has corresponding character confidences.)

Note: Most actions only work with characters and confidence values located in the first position of the Character Array (position 0). The Cleartext action is used with User Application Web's Advanced Index task, for "Double Blind" data entry.

Example:

```
PropagateToAltText (1)
ClearAltText (0)
```

In this example, all characters at the first index (0) of the Character Array will be copied to the second index (1). The second action will then clear character and confidence values from the first index in the Character Array.

Parent topic: [DCO actions](#)

Related reference:

[PropagateToAltText](#)

ClearDCO

Clears all objects of the Document Hierarchy which are children of the bound object, and their variables.

Syntax

```
bool ClearDCO ()
```

Parameters

None.

Returns

True if all child objects and their variables are removed, otherwise False.

Level

All.

Details

Removes all DCO children and variable references from the bound object.

Example:

```
CreateFields ()  
ClearDCO ()
```

Applied at the Page level, the example will first add fields to the page and then remove them.

Parent topic: [DCO actions](#)

CopyPD2DD

Assigns the value in a Page object's PD (Page Data) variable to the Document object's DD (Doc Data) variable.

Syntax

```
bool CopyPD2DD ()
```

Parameters

None.

Returns

False if the action is not at the Document level, or if the PD variable at page level has no value. Otherwise, True.

Level

Document level.

Details

Assigns the value in a Page object's PD (Page Data) variable to the Document object's DD (Doc Data) variable.

Example:

```
CopyPD2DD ()
```

Parent topic: [DCO actions](#)

CountPagesToDocumentVar

Counts the number of pages in the document.

Syntax

```
bool CountPagesToDocumentVar (StrParam)
```

Parameters

None

Returns

Always True.

Level

Document level.

Details

This action counts the number of page objects in a document and writes the result in a document variable.

Example:

```
CountPagesToDocumentVar ("MyVarName")
```

Parent topic: [DCO actions](#)

CreateDocuments

Arranges the contents of a task's Page file (for example, Recognition.xml) into documents based on the Document Integrity rules (min, max and order) specified in your application's Document Hierarchy, and assembles documents from the pages in the batch.

Syntax

```
bool CreateDocuments ()
```

Parameters

None.

Returns

True if successful. Otherwise, False.

Level

Batch level only.

Details

Arranges the contents of a task's Page file (for example, Recognition.xml) into documents based on the Document Integrity rules for min, max, and order properties specified in your application's Document Hierarchy, and assembles documents from the pages in the batch.

Batches containing existing document structures will cause this action to return False, with no affect to the existing document structure.

Note: During document creation, temporary IDs are assigned (with a different format than real Document IDs), and if the action fails, these temporary IDs remain.

Important: This action is applied at the Batch level, and generally in its own Ruleset (in a CreateDocs ruleset, for example.)

Example:

```
CreateDocuments ()
```

Parent topic: [DCO actions](#)

CreateFields

Creates the Data file for a page in a batch. The Data file for the first page in the batch, tm000001, as an example, is tm000001.xml.

Syntax

```
bool CreateFields ()
```

Parameters

None.

Returns

True if successful. Otherwise, False.

Level

Page level.

Details

Creates the Data file for a page in a batch. The Data file for the first page in the batch, tm000001, as an example, is tm000001.xml.

This Data file lists all fields for the current page based on the fields listed in the setup Document Hierarchy. Each field has an ID (for an Invoices page, for example, the Date field's ID is Date), and three properties with default values: TYPE, Position, and Status.

Later, actions of various kinds (Locate, Zone, Validation, DCO, etc.) can assign other values to these properties. These actions can also add properties (variables) and values to the Data file, or remove properties and values.

Example:

```
AnalyzeImage ()
RotateImageRecognizePageOCR_S ()
SetSearchArea (0.5)
SetProblemValue (0.3)
SetTemplateDir (\ParentDirectory\Invoice\Template)
FindFingerprint (True)
CreateFields ()
```

This Invoices application sequence sets up the current page for processing, recognizes the words on the page, associates the page with a fingerprint, and finally creates a Data file with blank fields for the page.

Parent topic: [DCO actions](#)

DeleteFields

Deletes all child fields and characters from calling object of the Document Hierarchy.

Syntax

```
bool DeleteFields ()
```

Parameters

None.

Returns

True if successful, otherwise False.

Level

All.

Details

Deletes all fields and characters that are children of the bound object of the Document Hierarchy. This action will also remove the Data file (.xml) from the batch if called from a Page object.

Example:

```
DeleteFields()
```

Parent topic: [DCO actions](#)

IsDocumentCountMoreThan

Compares the number of documents in a batch with a parameter that you specify to let you manage the document size of your batches.

Syntax

```
bool IsDocumentCountMoreThan (string count , string returnTrueIfMore)
```

Parameters

`returnTrueIfMore`: determines whether the action returns True or False based on the results of the document count comparison.

Smart parameters are supported.

Returns

When set to True, returns True if the document count exceeds the value of the specified parameter. Otherwise, False.

When set to False, returns False if the document count exceeds the value of the specified parameter. Otherwise, True.

Level

All levels.

Details

This action compares the current batch document with the parameter that is provided and returns True or False depending on whether the count is exceeded by the provided parameter or not.

Example:

```
IsDocumentCountMoreThan(1, true)
```

This example returns True if there is more than 1 document in the batch

```
sDocumentCountMoreThan(1, false)
```

This example returns False if there is more than 1 document in the batch

Parent topic: [DCO actions](#)

IsFirstDocumentInBatch

Checks to see if this document is the first document in a batch.

Syntax

```
bool IsFirstDocumentInBatch()
```

Parameters

None

Returns

True if the action is on the first document, or an object in the first document. Otherwise False.

Level

Document level.

Details

This action checks to see if this action is on an object in the first document in a batch.

Parent topic: [DCO actions](#)

JoinPreviousDocument

Specifies the document type to join with the current document.

Syntax

```
bool JoinPreviousDocument (string DocTypeToCombine)
```

Parameters

None

Returns

Always True.

Level

Document, Page, or Field level.

Details

This action copies the pages of the previously named document into the front of the current document.

Example:

```
JoinPreviousDocument ("SeparatorDoc")
```

Parent topic: [DCO actions](#)

PropagateToAltText

Copies the character and confidence values from the first index of the Character Array (index 0) to the index specified by the parameter.

Syntax

```
bool PropagateToAltText (strParam)
```

Parameters

The index of the Character Array where you want to copy the character and confidence values. 0 is the first index, followed by 1, etc.

Returns

Always True.

Level

Field level.

Details

Copies the character and confidence values from the first index of the Character Array (index 0) to the index specified by the parameter. (The character "node" of a page's Data file is an array that can hold many recognized character values, and their corresponding confidence values.)

Note: Rules will only work with characters and confidence values located in the first position of the Character Array (index 0).

The PropagateToAltText action is used with the User Application Web's Advanced Index task, for "Double Blind" data entry.

Example:

```
PropagateToAltText (1)  
ClearAltText (0)
```

All characters in the first index of the Character Array will be copied to the second index. Then, the second action will clear the character and confidence values from the first index.

Parent topic: [DCO actions](#)

Related reference:

[ClearAltText](#)

RemoveDocumentStructure

Removes the document hierarchy from the batch.

Syntax

```
bool RemoveDocumentStructure ()
```

Parameters

None

Returns

Always True.

Level

Batch level.

Details

This action flattens the document and page hierarchy from the batch. If the batch consists of multiple documents, each with a set of pages, the document level is removed and all of the pages become a flat structure. Once complete, there is no distinction of sets of pages within a document.

Example:

```
RemoveDocumentStructure()
```

Parent topic: [DCO actions](#)

SaveImageInformation

Gets the image information and stores it into the DCO.

Syntax

```
bool SaveImageInformation(string ImageWidth, string ImageHeight, string ImageDPIX,  
string ImageDPIY, string PhysicalImageWidth, string PhysicalImageHeight, string  
BitDepth)
```

Parameters

string ImageWidth

string ImageHeight

string ImageDPIX

string ImageDPIY

string PhysicalImageWidth

string PhysicalImageHeight

string BitDepth

Parameters

ImageWidth: The input parameter is the name that user must specify to store the image width in pixels. If not specified, the DCO variable is not created for width.

ImageHeight: The input parameter is the name that user must specify to store the image height in pixels. If not specified, the DCO variable is not created for height.

ImageDPIX: The input parameter is the name that user must specify to store the DPIX in dots per inch. If not specified, the DCO variable is not created for DPIX.

ImageDPIY: The input parameter is the name that user must specify to store the DPIY in dots per inch. If not specified, the DCO variable is not created for DPIY.

PhysicalImageWidth: The input parameter is the name that user must specify to store the physical width in pixels. If not specified, the DCO variable is not created for physical width.

PhysicalImageHeight: The input parameter is the name that user must specify to store the physical height in pixels. If not specified, the DCO variable is not created for physical height.

BitDepth: The input parameter is the name that user must specify to store the depth in bit. If not specified, the DCO object is not created for Bit Depth.

Returns

True if the operation is successful, else False if any error occurred.

Level

Page level only, and the page must refer to a valid single page image file.

Details

This action gets the image information Height, Width, DPIX, DPIY, Physical Height, Physical Width, Bit Depth into respective parameters that are specified by user and stores it into the Document heirarchy.

Example 1:

```
SaveImageInformation("@P.Width", "@P.Height", "@P.DPIX", "@P.DPIY", "@P.PhysicalWidth", "@P.PhysicalHeight", "@P.BitDepth") RemoveDocumentStructure()
```

This example stores image information into variables that are specified by user at the page level.

Width = "2479"

Height = "3508"

DPIX = "300"

DPIY = "300"

PhysicalWidth = "743700"

PhysicalHeight = "1052400"

BitDepth = "1"

Example 2:

```
SaveImageInformation(" ", " ", " ", "@P.DPIX", "@P.DPIY", "@P.PhysicalWidth", "@P.PhysicalHeight", "@P.BitDepth")
```

This example stores image information DPIx, DPIy, PhysicalWidth, PhysicalHeight, BitDepth into respective variables that are specified at the page level.

```
DPIx = "300"
```

```
DPIy = "300"
```

```
PhysicalWidth = "743700"
```

```
PhysicalHeight = "1052400"
```

```
BitDepth = "1"
```

Example 3:

```
SaveImageInformation("@P\Field1.Width", "@P\Field1.Height", "@P\Field1.DPIx", "@P\Field1.DPIy", "@P\Field1.PhysicalWidth", "@P\Field1.PhysicalHeight", "@P\Field1.BitDepth")
```

This example stores image information into respective parameters that are specified by user at the field level.

```
Width = "2479"
```

```
Height = "3508"
```

```
DPIx = "300"
```

```
DPIy = "300"
```

```
PhysicalWidth = "743700"
```

```
PhysicalHeight = "1052400"
```

```
BitDepth = "1"
```

Parent topic: [DCO actions](#)

SetDCOStatus

Assigns a value to the Status property of the current object of the Document Hierarchy.

Syntax

```
bool SetDCOStatus (StrParam)
```

Parameters

An Integer representing the new status.

Returns

Always True.

Level

All.

Details

Assigns a value to the Status property of the current object of the Document Hierarchy.

Example:

```
ChkDCOType (Invoice)  
SetDCOStatus (1)
```

This sequence checks to see if the current object of the Document Hierarchy is a Page object - in this example, an Invoices page. If so, the value of the Page object's Status property is set to "1".

Parent topic: [DCO actions](#)

Related reference:

[SetDCOType](#)

[SetPageType](#)

SetDCOType

Assigns a value to the Type property of the current object of the Document Hierarchy.

Syntax

```
bool SetDCOType (StrParam)
```

Parameters

A String value you're assigning to the current object's Type property.

Returns

Always True.

Level

All.

Details

Assigns a value to the Type property of the current object of the Document Hierarchy.

Example:

```
ChkLastDCOType (Separator)  
SetDCOType (Invoice)
```

This sequence checks to see if the previous object of the Invoices application's Document Hierarchy was a Page object - in this case, a Separator page. If so, it sets Invoice as the Type property of the current object.

Parent topic: [DCO actions](#)

Related reference:

[SetDCOStatus](#)

[SetPageStatus](#)

[SetDocumentType](#)

SetDocStatus

Assigns a status to the current document.

Syntax

```
bool SetDocStatus (StrParam)
```

Parameters

String value representing the status to be assigned to the current document.

Typically:

- "0" = Complete.
- "1" = Incomplete.

Returns

False if the ruleset is not bound to a Document object, or the current object is not a document. Otherwise, True.

Level

Document level.

Details

Assigns a status to the current document.

Example:

```
SetDocStatus (DocOK)
```

Parent topic: [DCO actions](#)

SetDocumentType

The action assigns a Document Type to the current Document object of the Document Hierarchy.

Syntax

```
bool SetDocumentType (StrParam)
```

Parameters

The value you want to assign as the Document object's Type property.

You can also designate a field in a Page object's Data file, and use its text value to set the Document Type. Simply enter the name of a valid Field object and surround it with single quotes. For example: 'Number'.

Returns

False if there are no Document objects in the Data file, or if the parameter is invalid. Otherwise, True.

Level

Document, Page, and Field levels.

Details

Similar to the SetDCOType action but works at the Document, Page or Field level.

The action assigns the Document Type you enter as a parameter to the current Document object of the Document Hierarchy. You can also use a Field object's value to set the Document Type. (Refer to the Parameter section.)

Example:

```
SetDocumentType ('Number') \  
or  
SetDocumentType (Invoice_Document)
```

Parent topic: [DCO actions](#)

Related reference:

[SetDCOType](#)

[SetPageType](#)

SetFldConfidence

For a specific field, sets the confidence for all characters in the field to the same value.

Syntax

```
bool SetFldConfidence (StrParam)
```

Parameters

A comma-separated value that consists of:

1. The field name, or a Smart Parameter that designates the field.
2. The confidence value (1-10) to be assigned to the field's characters.

Returns

Always True. If an input parameter is invalid, no confidence levels are changed and a message is logged.

Level

Field level.

Details

This action unconditionally sets the confidence values for every character within a field to a specific level. This action can help change confidence levels when the preceding actions are all successful.

For example, a successful set of calculations that involves one or more fields might indicate that the confidence level of those fields' values ought to be high, regardless of the confidence set by the recognition engine. After

the success of the calculation, you can call `SetFldConfidence` to unconditionally reset the confidence values of the fields.

The first parameter is the name of the field that has its confidence level set. The second parameter is the wanted confidence level, between 1 and 10. If the second parameter is not passed in, 10 is used as the default.

Note: This function supports Smart parameters for the field name. See the following examples.

Example:

Example 1:

To set all characters in the field "GrossSalary" to a confidence of 9.
`SetFldConfidence(@P\GrossSalary,10)`

Example 2:

To set all characters in the field "AdjustedPay" to a confidence of 1.
`SetFldConfidence(@P\AdjustedPay,1)`

Example 3:

In the context of a test run before setting the confidence.

```
Calculate("'1TotalWages' + '2TaxableInterest' + '3Unemployment' =  
'4AdjustedGross'")
```

If this calculation works, the application can assume that all of the characters are read correctly and `SetFldConfidence` can adjust the fields to high confidence.

Note, you might also want to add a check that the values are all non-zero to eliminate a bad read.

```
SetFldConfidence("@P\1totalWages,10")  
SetFldConfidence("@P\2TaxableInterest,10")  
SetFldConfidence("@P\3Unemployment,10")  
SetFldConfidence("@P\4AdjustedGross,10")
```

Parent topic: [DCO actions](#)

SetPageFingerprintID

Assigns a value to the `FingerprintID` property of the selected Page object of the Document Hierarchy.

Syntax

```
bool SetPageFingerprintID (StrParam)
```

Parameters

The String value of the Fingerprint ID.

Returns

True if the rule is applied at the Page level. Otherwise, False.

Level

Page level.

Details

Assigns a value to the FingerprintID property of the selected Page object of the Document Hierarchy. Important: The SetPageFingerprintID action will create a FingerprintID property of the current Page object if it does not already exist.

Example:

```
WordFind (MQSW)  
SetPageFingerprintID (1010)
```

In this sequence, if the WordFind action locates "MQSW" on the current page, the SetPageFingerprintID action assigns "1010" as the page's Fingerprint ID. This links the page to a fingerprint with a Fingerprint ID of "1010".

Parent topic: [DCO actions](#)

SetPageStatus

The action assigns a page status to an object of the Document Hierarchy.

Syntax

```
bool SetPageStatus (StrParam)
```

Parameters

Numeric value that represents the status.

The Invoices application (as an example) employs three default Page Statuses:

- 49 = ScanOK
- 1 = Incomplete/Not validated
- 0 = Complete

You can define your own statuses by using the Filter tab of a task's Task Settings dialog.

Returns

Always True.

Level

Page or field level.

Details

The action assigns the page status that you enter to the page object of the Document Hierarchy. The current object can be the page or field. If the current object is a field object, it sets the page status for its parent page object.

Example:

A scan task might assign Other as the Page Type and 49 as the default Page Status for every successfully scanned image in the batch.

The following sequence is an example of a rule that converts Other pages to Invoices pages, and assigns a Page Status to each:

```
SetPageType (Invoice)  
SetPageStatus (1)
```

This combination establishes the page as an Invoices page, and gives it a status of 1. This means that the page is not validated and must be processed by a task that applies Validation rules (a Recognition or Verification task, for example).

Parent topic: [DCO actions](#)

Related reference:

[SetPageType](#)

[SetDCOStatus](#)

[SetDCOType](#)

[SetDocStatus](#)

SetPageTemplateID

Assigns a value to the FingerprintID property of the selected Page object of the Document Hierarchy.

Syntax

```
bool SetPageTemplateID (strParam)
```

Parameters

The String value of the Fingerprint ID.

Returns

True if the rule is applied at the Page level. Otherwise, False.

Level

Page level.

Details

The SetPageTemplateID action creates a FingerprintID property of the current Page object if one does not already exist.

Example:

```
WordFind (MQSW)  
SetPageTemplateID (1010)
```

In this sequence, if the WordFind action locates "MQSW" on the current page, the SetPageTemplateID action assigns "1010" as the page's Fingerprint ID. This links the page to a fingerprint with a Fingerprint ID of "1010".

Parent topic: [DCO actions](#)

SetPageType

The action assigns a Page Type to the current Page object of the Document Hierarchy.

Syntax

```
bool SetPageType (StrParam)
```

Parameters

A String value that represents the Page Type.

You can also designate a field in a Page object's Data file, and use its text value to set the Page Type. Enter the name of a valid Field object and surround it with single quotation marks. For example: 'PageCode'.

Returns

False, if there are no Page objects in the Page file, or if the parameter is invalid. Otherwise, True.

Level

Page and Field levels.

Details

Similar to the SetDCOType action, but works at the Page or Field level.

The action assigns the Page Type you enter as a parameter to the current Page object of the Document Hierarchy. You can also use a Field object's value to set the Page Type. (See the Parameter section.)

Example:

The application's scan task typically assigns Other as the Page Type and 49 as the default Page Status for every successfully scanned image in the batch.

The following sequence is an example of a rule that converts Other pages to Invoices pages, and assigns a Page Status to each:

```
SetPageType (Invoice)  
SetPageStatus (1)
```

This combination sets the page as an Invoices page, and gives it a status of 1. This means that the page is not validated and must be processed by a task that applies Validation rules (a Rulerunner Task, for example).

dcpdf actions

Use the dcpdf actions to convert PDF files to TIFF at the start of the workflow. You can also convert the TIFF files in a document into a PDF file.

The dcpdf actions can specify properties for PDF documents, set bits per pixel counts for images in PDF documents, and specify the compression method to use to convert PDF documents to TIFF.

- [dcpdf_CreateTiffFromPDF](#)
Converts each page of a PDF file into a TIFF file.
- [dcpdf_CreateTiffFromPDF_CreateDocs](#)
Converts each page of a PDF file into a TIFF file and creates a runtime hierarchy.
- [dcpdf_MakePDFDoc](#)
Creates a PDF document that contains one or more pages of the current document.
- [dcpdf_MaxSizeToReconvert](#)
Causes the dcpdf_CreateTiffFromPDF action to use a different conversion algorithm if the file that results from the default algorithm exceeds the specified size.
- [dcpdf_SetApplication](#)
Specifies the Application ID property for PDF documents that are generated by the dcpdf_MakePDFDoc action.
- [dcpdf_SetAuthor](#)
Specifies the Author property for PDF documents that are generated by the dcpdf_MakePDFDoc action.
- [dcpdf_SetImageBitcount](#)
Sets the bit count, bits per pixel, for images in the PDF document that is generated by the dcpdf_MakePDFDoc action.
- [dcpdf_SetImageCompression](#)
Specifies the compression method to use when you convert a PDF file to TIFF.
- [dcpdf_SetImageGrayscale](#)
Specifies how gray areas of a grayscale image are handled when you convert a PDF file to TIFF.
- [dcpdf_SetImageQuality](#)
Specifies the image quality to use when you convert a PDF file to TIFF.
- [dcpdf_SetImageResolution](#)
Specifies the output resolution to use when you convert a PDF file to TIFF.
- [dcpdf_SetKeywords](#)
Specifies a keyword to assign to PDF documents that are generated by the dcpdf_MakePDFDoc action.
- [dcpdf_SetProducer](#)
Specifies the Producer property for PDF documents that are generated by the dcpdf_MakePDFDoc action.
- [dcpdf_SetSubject](#)
Specifies the Subject property for PDF documents that are generated by the dcpdf_MakePDFDoc action.
- [dcpdf_SetTitle](#)
Specifies the Title property for PDF documents that are generated by the dcpdf_MakePDFDoc action.
- [dcpdf_UseAltConversionMethod](#)
Causes dcpdf_CreateTiffFromPDF to use an alternate conversion algorithm.

Parent topic: [Global actions](#)

dcpdf_CreateTiffFromPDF

Converts each page of a PDF file into a TIFF file.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_CreateTiffFromPDF ( )
```

Parameters

None.

Returns

False, if the action is not run at the Batch level; if there are no PDF files in the batch; or if an error occurs while TIFF files are being created. Otherwise, True.

Level

Batch only.

Details

This action looks for PDF files in the current batch; creates Image files (.tiff) for each page in the PDF file; and creates one document for the PDF file.

Attention: `dcpdf_MaxSizeToReconvert` can be used to control how this action creates a TIFF file. PDFs are converted to TIFF using a fast algorithm. With some occasional input documents, this may produce images that are large and may not recognize well, causing them to be automatically reconverted to TIFF using a cleaner but slightly slower algorithm. See the help for `dcpdf_MaxSizeToReconvert` for more information.

»

Important: The font mapping file, used by the convert actions to extract images from PDF, uses "Lucida Unicode" as the default font. The Lucida Unicode font is installed by default in the Microsoft Windows operating system, which makes it a reliable default font setting. It is possible that the font `Arial Sans Unicode` might perform better in some instances when converting from PDF to image. You can change the configuration file to use this font, or other fonts, instead of the default font. However, if the specified font is not installed on the machine that is performing the conversion, the text will render as blank on the final image.

To change the font that is used to render a PDF to image, modify the `fontfile.map` file, located in `\Datacap\dcshared\VeryPDF`, as follows:

1. Open `fontfile.map` in any text editor.
2. Change the `defaultwinfont` value from `L_10646.ttf` to `ARIALUNI.TTF`
3. Save the changes and exit.

This example will change the default font from `Lucida Unicode` to `Arial Sans Unicode`.«

»Previous versions of the Convert actions used `Arial Sans Unicode` as the default font. This default was changed in current versions since this font is not installed by default in the Windows operating system. «

Example:

```
dcpdf_CreateTiffFromPDF()
```

When the action in this example encounters a PDF file in the batch, it creates a corresponding Image file (.tiff) and gives the Image file the PDF file's name.

Parent topic: [dcpdf actions](#)

dcpdf_CreateTiffFromPDF_CreateDocs

Converts each page of a PDF file into a TIFF file and creates a runtime hierarchy.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_CreateTiffFromPDF_CreateDocs (strParam)
```

Parameters

The parameter can be True or False.

True: Causes a document hierarchy to be created when TIFF pages are created from a PDF file.

False: A document hierarchy will not be created, making this action operate exactly like dcpdf_CreateTiffFromPDF.

Returns

False, if the action is not run at the Batch level, or if the source PDF file does not have a minimum number of pages (0). Otherwise, True.

Level

Batch Level.

Details

This action converts the pages in a PDF file to TIFFs, like dcpdf_CreateTiffFromPDF. The difference is that if the parameter is True, a document hierarchy will be created for each PDF to group each of the pages from a single PDF into their own document.

Important: The font mapping file, used by the convert actions to extract images from PDF, uses "Lucida Unicode" as the default font. The Lucida Unicode font is installed by default in the Microsoft Windows operating system, which makes it a reliable default font setting. It is possible that the font `Arial Sans Unicode` might perform better in some instances when converting from PDF to image. You can change the configuration file to use this font, or other fonts, instead of the default font. However, if the specified font is not installed on the machine that is performing the conversion, the text will render as blank on the final image.

To change the font that is used to render a PDF to image, modify the `fontfile.map` file, located in `\Datacap\dcshared\VeryPDF`, as follows:

1. Open `fontfile.map` in any text editor.
2. Change the `defaultwinfont` value from `L_10646.ttf` to `ARIALUNI.TTF`
3. Save the changes and exit.

This example will change the default font from `Lucida Unicode` to `Arial Sans Unicode`.«

»Previous versions of the Convert actions used `Arial Sans Unicode` as the default font. This default was changed in current versions since this font is not installed by default in the Windows operating system. «

Example:

```
dcpdf_CreateTiffFromPDF_CreateDocs ("True")
```

In this example, the action uses a primary algorithm to establish a runtime Document for each source document in the PDF file, and assign pages to the runtime Documents according to their placement in the source PDF files.

Parent topic: [dcpdf actions](#)

dcpdf_MakePDFDoc

Creates a PDF document that contains one or more pages of the current document.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_MakePDFDoc(strParam)
```

Parameters

Comma-separated parameters: IncludeFieldText, PageTypes.

The IncludeFieldText parameter can be True or False.

True: stores recognized field data that is associated with the TIFF image of each page in the PDF file to make a searchable PDF. The text data is not visible, but it is searchable.

False: inserts the image of a page into the PDF file, the recognized text is not inserted.

The PageTypes parameter is a list of one or more page types to include in the PDF output. The page types in the list are separated by commas.

If no parameters are provided, IncludeFieldText defaults to False and all document pages are included in the PDF.

If only the IncludeFieldText parameter is provided, all document pages are included in the PDF.

Smart parameters are supported.

Returns

False if the action is not run at the Document level; if there are no pages in the document; or if an error occurs while the PDF file is being created. Otherwise, True. If there are pages in the document but none of them match the specified page type, the action does not create a PDF file and still returns True.

Level

Document Level.

Details

Creates a PDF document that contains one or more pages of a document. The PDF format can contain only the original image or it can contain the image along with the recognized text to make the PDF searchable.

Note: The "dcpdf_MakePDFDoc" action supports only the English language.

Only zoned field text is included if the input parameter is True and is searchable within the PDF. The searchable text might not accurately reflect the text position within the original input image. If you need the entire page

text to be included as searchable text, or more accurate alignment, use one of the recognition actions to create the PDF, such as `RecognizeDocToPDF` from the `OCR_S` library.

To exclude specific page types, set the variable `typesToExclude` to a comma delimited list of page types to exclude from the PDF.

To include specific page types, set the variable `typesToInclude` to a comma delimited list of page types to include in the PDF.

To exclude specific page status, set the variable `statusToExclude` to a comma delimited list of page status to exclude from the PDF.

When more than one filter is specified, the following order of precedence takes place:

- `statusToExclude` overrides `typesToInclude`
- `typesToInclude` overrides `typesToExclude`

If you are calling the action at the Document level, the types and status filters apply to both the documents and their child pages.

If you are calling the action at the Page level, the types and status filters apply to the page only.

These variables must be set before you call the `RecognizeToPDFOCR_A` action.

Example:

```
rrSet ("75", "@D.statusToExclude)
rrSet ("Blank", "@D.typesToExclude)
dcpdf_SetTitle ("MedicalClaims")
dcpdf_SetSubject ("Validated")
dcpdf_SetAuthor ("Steven Moffat")
dcpdf_SetProducer ("Russell Davies")
dcpdf_SetApplication ("MClaims")
dcpdf_MakePDFDoc ("True")
```

This example sets several properties of the PDF file and creates a PDF that contains the recognized text along with all of the page images for the current document. Pages whose type is "Blank" and status is "75" are skipped.

```
dcfpdf_MakePDFDoc ("False,Main_Page")
```

This example does not include the field text and exports only the page types of type `Main_Page`.

```
dcfpdf_MakePDFDoc ("True,Main_Page,Trailing_Page")
```

This example includes the field text and exports only the page types of type `Main_Page` or `Trailing_Page`.

Parent topic: [dcpdf actions](#)

dcpdf_MaxSizeToReconvert

Causes the `dcpdf_CreateTiffFromPDF` action to use a different conversion algorithm if the file that results from the default algorithm exceeds the specified size.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_MaxSizeToReconvert (strParam)
```

Parameters

A Numeric value representing the maximum image size in KB before attempting to convert with an alternate algorithm. If the value is 0, then the alternate algorithm will never be used.

Returns

False if the parameter is not Numeric. Otherwise, True.

Level

Batch or Document level.

Details

Causes `dcpdf_CreateTiffFromPDF` to use a different algorithm based on the configured file size.

The conversion of PDF to TIFF usually works fast and produces clean images. From time to time, the resulting TIFF may become unusually large. A reason for this has been due to the background becoming a dithered light gray background instead of a pure white. This leads to very large image sizes because compression is now less efficient. It also could lead to reduced recognition quality.

To compensate for these rare situations, this action can be used to produce a clean TIFF from a PDF that compresses well. When a TIFF is created from a PDF, the file size is checked to see if it exceeds the value set by this action. If the file size is smaller, then is considered a successful conversion. If the file size is larger, then this alternate method is performed.

This action must be called prior to `dcpdf_CreateTiffFromPDF`. If this action is not called, the default value of 2000KB is used. Calling `dcpdf_SetImageGrayscale(TRUE)` will cause `dcpdf_CreateTiffFromPDF(True)` to always use the alternate algorithm.

Example:

```
dcpdf_SetMaxImageSize("10000")
dcpdf_CreateTiffFromPDF("True")
```

This example will cause the alternate conversion algorithm to be used if the initial conversion produces a TIFF image that is larger than 10000KB.

Parent topic: [dcpdf actions](#)

dcpdf_SetApplication

Specifies the Application ID property for PDF documents that are generated by the `dcpdf_MakePDFDoc` action.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_SetApplication (strParam)
```

Parameters

String value of the Application ID.

Returns

Always True.

Level

Batch or Document level.

Details

This sets the Application ID property of a PDF document generated by a subsequent `dcpdf_MakePDFDoc` action.

If this action is not called, the value will default to "Application".

Example:

```
dcpdf_SetApplication("Invoices")  
dcpdf_SetAuthor("Harriet Jones")  
dcpdf_MakePDFDoc("True")
```

Parent topic: [dcpdf actions](#)

dcpdf_SetAuthor

Specifies the Author property for PDF documents that are generated by the `dcpdf_MakePDFDoc` action.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_SetAuthor (strParam)
```

Parameters

String value of the Author.

If you do not call this action, the value will default to Should be a Task Name.

Returns

Always True.

Level

Batch or Document level.

Details

This action attaches the Author's name (or a related value) to a PDF page or document generated by a subsequent `dcpdf_MakePDFDoc` action.

Example:

```
dcpdf_SetAuthor("Harriet Jones")
dcpdf_SetProducer("Russell Davies")
dcpdf_SetApplication("Invoices")
dcpdf_MakePDFDoc("True")
```

Parent topic: [dcpdf actions](#)

dcpdf_SetImageBitcount

Sets the bit count, bits per pixel, for images in the PDF document that is generated by the `dcpdf_MakePDFDoc` action.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_SetImageBitcount (strParam)
```

Parameters

Numeric value of the BitCount of any image in a PDF document. The action's acceptable values are:

- 1 for Black and White images (a typical value).
- 8 for Grayscale images.
- 24 for Color images.

Returns

False, if the parameter is not Numeric. Otherwise, True.

Level

Batch or Document level.

Details

Sets the BitCount of any image identified in a PDF file by an action such as `CreateTiffFromPDF`. The value of the parameter for the action typically reflects the nature of the images in the PDF file. The default value is 1 (Black and white images).

Attention: The BitCount is the standard number of bits per pixel throughout an image.

Example:

```
dcpdf_SetImageBitCount ("1")                black and white
images.
dcpdf_SetImageBitCount ("8")
```

```
grayscale images.  
dcpdf_SetImageBitCount ("24")
```

```
color images.
```

Parent topic: [dcpdf actions](#)

dcpdf_SetImageCompression

Specifies the compression method to use when you convert a PDF file to TIFF.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_SetImageCompression (strParam)
```

Parameters

A numeric value representing one the following Compressions:

- 1 = NONE (DUMP MODE)
- 2 = CCITTRLE (CCITT modified Huffman RLE)
- 3 = CCITTFAX3 (CCITT Group 3 fax encoding)
- 4 = CCITTFAX4 (CCITT Group 4 fax encoding)
- 5 = COMPRESSION_LZW (Lempel-Ziv and Welch)
- 7 = JPEG (%JPEG DCT compression)
- 32773 = PACKBITS (Macintosh RLE)

Returns

False, if the parameter is not *Numeric*. Otherwise, True.

Level

Batch or Document level.

Details

Sets the compression that will be used when converting a page from a PDF file to a TIFF file. Group 4 Fax is the most common compression used for text recognition. It produces a lossless compressed black and white image. The default compression value is 4 (CCITT Group 4 fax encoding).

Example:

```
dcpdf_SetImageCompression ("7")  
dcpdf_CreateTiffFromPDF ("True")
```

Parent topic: [dcpdf actions](#)

dcpdf_SetImageGrayscale

Specifies how gray areas of a grayscale image are handled when you convert a PDF file to TIFF.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_SetImageGrayscale (strParam)
```

Parameters

The parameter can be True or False.

- True: Gray areas of the image must not be dithered.
- False: Gray areas of the image must be dithered. This option is the default.

Returns

False, if the parameter is invalid. Otherwise, True.

Level

Batch or Document.

Details

Sets a Grayscale flag for images in a PDF file that is generated by an action such as `dcpdf_CreateTiffFromPDF`.

This action controls how gray areas of a grayscale image are handled when converted to black and white. For example, if you have a text document with a gray background, it is recommended to call this action and pass True. This option causes the gray area below a predefined tolerance to be converted to white, producing an image that can be recognized. If you have a grayscale image and this action is set to False, gray areas are dithered to simulate gray in the resulting TIFF image. The default value is False.

If this action is used, it must be called before `dcpdf_CreateTiffFromPDF` or `dcpdf_CreateTiffFromPDF_CreateDocs`.

Example:

```
dcpdf_SetImageGrayscale ("True")  
dcpdf_CreateTiffFromPDF ("True")
```

Parent topic: [dcpdf actions](#)

dcpdf_SetImageQuality

Specifies the image quality to use when you convert a PDF file to TIFF.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_SetImageQuality (strParam)
```

Parameters

Numeric value, between 1 and 100, of the Image Quality standard for images in the PDF file.

Returns

False, if the parameter is not Numeric. Otherwise, True.

Level

Batch or Document level.

Details

This action determines the resulting image quality when creating a TIFF from a PDF file. A higher number will produce a better looking image, but may require more processing time. The default value is 100.

Example:

```
dcpdf_SetImageQuality("75")
dcpdf_CreateTiffFromPDF("True")
```

Parent topic: [dcpdf actions](#)

dcpdf_SetImageResolution

Specifies the output resolution to use when you convert a PDF file to TIFF.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_SetImageResolution (strParam)
```

Parameters

Two comma-separated Numeric values specifying X resolution and Y resolution (in that order). The values are expressed in Dots (pixels) Per Inch (DPI).

Returns

False, if the parameters are not Numeric. Otherwise, True.

Level

Batch or Document level.

Details

This action sets the X and Y resolution for the pages of a PDF that is converted to TIFF. If this action is not called, the default of 200 x 200 will be used. It is strongly recommended that the X and Y resolutions are

always set the same to produce an isotropic image, which will allow for better fingerprinting and recognition.

This action must be called before the `dcpdf_CreateTiffFromPDF` or `dcpdf_CreateTiffFromPDF_CreateDocs` actions.

Example:

```
dcpdf_SetImageResolution("300,300")  
dcpdf_CreateTiffFromPDF()
```

Parent topic: [dcpdf actions](#)

dcpdf_SetKeywords

Specifies a keyword to assign to PDF documents that are generated by the `dcpdf_MakePDFDoc` action.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_SetKeywords (strParam)
```

Parameters

String value of the Keyword.

If you do not call this action, the keyword value is left blank.

Returns

Always True.

Level

Batch or Document level.

Details

This action assigns a single Keyword to a PDF page or document that is generated by a subsequent `dcpdf_MakePDFDoc` action.

Use this action repeatedly within a rule to assign more Keywords.

Important: This action must precede the `dcpdf_MakePDFDoc` action.

Example:

```
dcpdf_SetKeywords("Invoices")  
dcpdf_MakePDFDoc("True")
```

Parent topic: [dcpdf actions](#)

dcpdf_SetProducer

Specifies the Producer property for PDF documents that are generated by the `dcpdf_MakePDFDoc` action.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_SetProducer (strParam)
```

Parameters

String value of the Producer ID.

Returns

Always True.

Level

Batch or Document level.

Details

Sets the producer value of the PDF document. This action must be called prior to calling `dcpdf_MakePDFDoc`. If this action is not called, the value will default to Producer.

Example:

```
dcpdf_SetAuthor("Steven Moffat")
dcpdf_SetProducer("Russell Davies")
dcpdf_SetApplication("Invoices")
dcpdf_MakePDFDoc("True")
```

Parent topic: [dcpdf actions](#)

dcpdf_SetSubject

Specifies the Subject property for PDF documents that are generated by the `dcpdf_MakePDFDoc` action.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_SetSubject (strParam)
```

Parameters

String value of the Subject.

Returns

Always True.

Details

This action sets the Subject property of PDF generated by a subsequent `dcpdf_MakePDFDoc` action.

The Subject is a searchable value for the page or document. If this action is not called, the value of the subject is blank in the resulting document.

Example:

```
dcpdf_SetSubject("HealthClaimDoc")
dcpdf_SetAuthor("Harriet Jones")
dcpdf_MakePDFDoc("True")
```

Parent topic: [dcpdf actions](#)

dcpdf_SetTitle

Specifies the Title property for PDF documents that are generated by the `dcpdf_MakePDFDoc` action.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_SetTitle (strParam)
```

Parameters

String value of the Title.

Returns

Always True.

Level

Batch or Document level.

Details

This action sets the Title property of a PDF document generated by a subsequent `dcpdf_MakePDFDoc` action.

The Title is a searchable value for the page or document. If this action is not called prior to `dcpdf_MakePDFDoc`, the value will default to Untitled.

Example:

```
dcpdf_SetTitle("NewInvoice")
dcpdf_MakePDFDoc("True")
```

Parent topic: [dcpdf actions](#)

dcpdf_UseAltConversionMethod

Causes dcpdf_CreateTiffFromPDF to use an alternate conversion algorithm.

Member of namespace

dcpdf

Syntax

```
bool dcpdf_UseAltConversionMethod ()
```

Parameters

None.

Returns

Always True.

Level

Batch or Document level.

Details

There are two internal algorithms that are used to convert a PDF to a TIFF. This action enables the alternate algorithm. It is recommended that the alternate algorithm is used. Testing has shown that it produces cleaner TIFF images.

This action must be called prior to the dcpdf_CreateTiffFromPDF or dcpdf_CreateTiffFromPDF_CreateDocs actions.

Example:

```
dcpdf_UseAltConversionMethod()  
dcpdf_CreateTiffFromPDF()
```

Parent topic: [dcpdf actions](#)

DocumentAnalytics actions

Use the DocumentAnalytics actions to identify the content type of text blocks and extract data elements from the page layout file.

The DocumentAnalytics actions take advantage of the document's layout and font attributes to use analytics to extract data. These actions depend on a page or document level layout XML file such as tm000001._layout.xml. You use the OCR_A or OCR_S Recognize action to create a layout, then call DocumentAnalytics actions to identify the type of each block (AnalyzeLayout) and to extract data elements from the text.

The layout XML file groups text into blocks as a person would looking at the document. Each block can either have the default type of block or a specific type such as *title* or *table*. There are *Locate* actions available to

navigate the block structure (for example, `GoSiblingBlockNext`). This capability is in contrast to the CCO file produced by other actions that groups text into lines that span the width of the page. The layout XML file also retains font and color attributes, saved in CSS format, for the text. These retained attributes are used for extracting data and reconstructing the document in a new format.

Actions that can produce the layout XML include `OCR_SR.Recognize` and `OCR_A.Recognize`, both of which can process color images and PDF files. To use the *Locate* actions and perform *click 'n' key* during verification, use the `CreateCcoFromLayout` action from the `SharedRecognitionTools` library to create a CCO file for the page after producing the layout XML file.

- [FindLabelValuePairs](#)
Finds label value pairs in the document or page. Use `FindLabelValuePair` to extract a value after calling this action.
- [FindLabelValuePair](#)
Updates the target by finding a value that uses a regular expression to match its label.
- [CopyLabelValuePairs](#)
Copies all found pairs of labels and values to new fields in the DCO object.
- [CreateHTML](#)
Creates an HTML document based on the text and format captured in the layout XML file
- [CopyAllBlocks](#)
Copies all found blocks to DCO fields.
- [AnalyzeLayout](#)
Merges and splits blocks into logical groupings. Sets blocks to more specific types such as Title, Header, or Footer.
- [FindPatterns](#)
Finds patterns in the document or page.
- [ExtractText](#)
Finds entities such as names and addresses in the text by using text analytics. The results are saved and can then be used by subsequent actions, such as `FindExtractedText`.
- [ExtractTextAlchemyLanguage \(deprecated\)](#)
The action calls the AlchemyAPI Combined Call feature and passes in text from a single page at a time. The results are saved as entities in the page's layout XML file. Use the `FindExtractedText` action to populate fields with results of this action.
- [ExtractTextLogEnable](#)
Call this action to enable logging to the specified path and file name
- [ExtractTextNLP](#)
The action calls the Natural Language Processing (NLP) API and passes in text from a single page at a time. The results are saved as entities in the page's layout XML file. Use the `FindExtractedText` action to populate fields with results of this action. To extract from non-English-language text, set the page variable `hr_locale` to the wanted language before calling this action. For example, for the Japanese language, call `rrset("ja","@P.hr_locale")`.
- [FindExtractedText](#)
Finds patterns in the document or page.

[Recognize](#)

FindLabelValuePairs

Finds label value pairs in the document or page. Use FindLabelValuePair to extract a value after calling this action.

Syntax

```
bool FindLabelValuePairs ()
```

Parameters

None.

Returns

True.

Level

Page level

Details

FindLabelValuePairs analyzes the document or page, finding pairs of labels and their values, which can subsequently be used by other actions to populate fields. The label and values pairs are determined using font attributes and relative positioning of labels to values to identify what is a label and what is a value.

The prepared results can be used by FindLabelValuePair or CopyLabelValuePairs and can be used instead of or in conjunction with locate actions. The results are also saved to the layout XML file, allowing an application developer to easily review the identified pairs and then determine how they should be used within the application.

For example, if the document contains `Total: $100.00`, a label value pair will be created with the label `Total` and the value `$100`. You can then use the FindLabelValuePair action to populate specific fields with found values. You can call the CopyLabelValuePairs action to create a field and value for each match found.

FindLabelValuePairs requires a previously created layout file (for example: `tm000001_layout.xml`) where text is grouped into blocks. See [DocumentAnalytics actions](#) for information on the layout XML file.

Example

```
Recognize()  
  
FindLabelValuePairs()  
  
FindLabelValuePair(Total,@P\Total
```

Parent topic: [DocumentAnalytics actions](#)

FindLabelValuePair

Updates the target by finding a value that uses a regular expression to match its label.

Syntax

```
bool FindLabelValuePair (string Regex , string Target)
```

Parameters

string Regex

Smart parameter for the regular expression to find a matching label. For example, to search for the label `Total`, use `Total`.

string Target

Smart parameter for the target object to save the value to.
If you are using this action on a field, use `@F` to update the current field.

Returns

True if the keyword is found and the following node is a table or if the keyword is found in a table cell.
Otherwise, False.

Level

Page or Field level.

Details

Populates a field using a value that is found by using the FindLabelValuePairs action. The label and values are distinguished by using font attributes and relative positioning of labels to values to identify what is a label and what is a value. FindLabelValuePair is used instead of or in conjunction with *Locate* actions.

FindLabelValuePair requires a previously created layout file (for example: `tm000001_layout.xml`) where text is grouped into blocks. See [DocumentAnalytics actions](#) for information on the layout XML file.

Example

```
Recognize ()  
FindLabelValuePairs ()  
FindLabelValuePair (Total, @P\Total)
```

Parent topic: [DocumentAnalytics actions](#)

CopyLabelValuePairs

Copies all found pairs of labels and values to new fields in the DCO object.

Syntax

```
bool CopyLabelValuePairs ()
```

Parameters

None.

Returns

True.

Level

Page level.

Details

After calling `FindLabelValuePairs`, this action creates fields in the batch hierarchy for each pair that was found. The field ID is the identified label combined with a unique number (for example: `Last Name-1`). The field type is the block type (for example: `block` or `title`). The font and color attributes are saved in CSS format to the style variable. Use `CopyLabelValuePairs` during development to see if the `FindLabelValuePairs` and `FindLabelValuePair` actions can be used to find the fields to be extracted. You can also use this action to create an application where the unwanted fields will be deleted.

`CopyLabelValuePairs` requires a previously created layout file (for example: `tm000001_layout.xml`) where text is grouped into blocks. See [DocumentAnalytics actions](#) for information on the layout XML file.

Example

```
Recognize ()
```

```
FindLabelValuePairs ()
```

```
CopyLabelValuePairs ()
```

Parent topic: [DocumentAnalytics actions](#)

CreateHTML

Creates an HTML document based on the text and format captured in the layout XML file

Syntax

```
bool CreateHTML ()
```

Parameters

None

Returns

True if the HTML document is created. Otherwise, False.

Level

Page level

Details

Creates an HTML document using the text and format in the layout XML file. This is helpful in cases where a well-formatted HTML representation of the document is useful for processing or viewing the document in another product after capture is complete.

The HTML file name is constructed from the ID of the Page (the current object when the action is invoked), followed by the .html file extension. Images and other graphics in the original document are not included in this HTML file.

CreateHTML requires a previously created layout file (for example: tm000001_layout.xml) where text is grouped into blocks. See [DocumentAnalytics actions](#) for information on the layout XML file.

Example

```
Recognize ()
```

```
CreateHTML ()
```

Parent topic: [DocumentAnalytics actions](#)
»

CopyAllBlocks

Copies all found blocks to DCO fields.

Syntax

```
bool CopyAllBlocks ()
```

Parameters

None.

Returns

True.

Level

Page level.

Details

Creates fields in the batch document hierarchy for each block of text. The field ID is the type of block that was found combined with a unique number (for example: `block-1`). The field type is the block type (for example: `block` or `title`). The font and color attributes are saved in CSS format to the style variable. The text contents of the block will be the field's text value.

Entities found using the [FindExtractedText](#), [FindLabelValuePairs](#) and [ExtractTextAlchemyLanguage \(deprecated\)](#) actions are copied as new fields. AlchemyAPI entities fields are saved as field variables unless the field name is text.

CopyAllBlocks requires a previously created layout file (for example: tm000001_layout.xml) where text is grouped into blocks. See [DocumentAnalytics actions](#) for information on the layout XML file.

Example

```
Recognize()
```

```
CopyAllBlocks()
```

Parent topic: [DocumentAnalytics actions](#)
«

AnalyzeLayout

Merges and splits blocks into logical groupings. Sets blocks to more specific types such as Title, Header, or Footer.

Syntax

```
bool AnalyzeLayout ()
```

Parameters

None.

Returns

True.

Level

Page level

Details

AnalyzeLayout improves the grouping of text into blocks and changes the type of block to be more specific (for example: Changes the type from block to title). This action can be helpful for extracting data with FindLabelValuePairs where the value to be extracted spans multiple lines.

AnalyzeLayout requires a previously created layout file (for example: tm000001_layout.xml) where text is grouped into blocks. See [DocumentAnalytics actions](#) for information on the layout XML file.

Table 1. Block types vs XML node

Block type	Node in the layout XML file
Block	Block
Header	Header
Footer	Footer
Title	Title
Heading1	H1
Heading2	H2

Block type	Node in the layout XML file
Heading3	H3
Picture	Picture
Barcode	Barcode
Space	S
Tab	Tab
Table	Table
Row	Row
Cell	Cell
Paragraph	Para
Line	L
Sentence	Sent
Word	W
Character	C

After you identify the blocks, you can use the following *Locate* actions to navigate and select the blocks:

- GetSelectedBlockType
- GoSiblingBlockNext
- GoSiblingBlockPrevious
- IsSelectedBlockType
- RegExFind_InBlock
- RegExFindNext_InBlock
- SelectParentBlock
- SelectParentBlockOuterType
- SelectParentBlockType
- UpdateFieldWithBlock

Example

```
Recognize ()
```

```
AnalyzeLayout ()
```

Parent topic: [DocumentAnalytics actions](#)

FindPatterns

Finds patterns in the document or page.

Restriction: This action does not support regular expressions containing a line break nor tab expressions.

Syntax

```
bool FindPatterns (string patternsFilePath)
```

Parameters

patternsFilePath
Path to XML file containing patterns to match.

Returns

True.

Level

Page level

Details

Analyzes all blocks of text to determine if addresses, dates, or custom expressions are present. Regular expressions are stored in an XML file as a list of patterns with the properties listed at the end of this topic. Each pattern must have a unique `id` attribute. The pattern `type` attribute is the DCO field to populate. The pattern `value` is the regular expression.

FindPatterns requires a previously created layout file (for example: tm000001_layout.xml) where text is grouped into blocks. See [DocumentAnalytics actions](#) for information on the layout XML file.

Example

```
Recognize()  
  
FindPatterns("@APPVAR(values/gen/patternsPath)")
```

Format of a patter in the pattern XML file

```
<Pattern  
id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcacb148_un  
iqueString" type="documentHierarchyFieldType" enabled="true">

```

Parent topic: [DocumentAnalytics actions](#)

ExtractText

Finds entities such as names and addresses in the text by using text analytics. The results are saved and can then be used by subsequent actions, such as FindExtractedText.

Restriction: This action does not support regular expressions that contain a line break nor tab expressions.

Syntax

```
bool ExtractText (string extractors)
```

Parameters

extractors
Smart parameter for a comma-separated list of extractors to process.

Returns

True.

Level

Document or Page level

Details

Finds entities such as names and addresses in the text by using text analytics. The results are saved and can then be used by subsequent actions, such as FindExtractedText. To extract from non-English text, set the page variable `hr_locale` to the desired language before calling this action. For example, for Japanese call `rrset("ja", "@P.hr_locale")`.

The entities that are found are determined by AQL extractors. An initial set of pre-built extractors are provided and while they work in many instances they may not work in every case. See the IBM BigInsights documentation for pre-built extractors. Additional extractors may be created using the IBM BigInsights tools for creating AQL extractors.

Extractors are saved in compiled files with the extension `tam`. All `tam`, dictionary, and table files present in the `\rrs\aqf` folder will be loaded. The extractors provided by Datacap are exposed in `DatacapPreBuilt_BasicFeatures.tam`. You can add or remove `tam` files to the `\rrs\aqf` folder to control if they are executed or not.

All of the loaded extractors are run on the document or page.

Important: The results from ExtractText are saved to the layout XML file, for example `tm000001_layout.xml`, which can be opened in a text editor to see the available entities and the entity fields that can be copied into document hierarchy fields. You can search for an entity in the layout XML using its name such as `Address.Address`.

Important: This action requires a 32-bit Java runtime environment. The default location is `\Datacap\dcshared\jre` or else the path specified in the `JAVA_HOME` system variable is used.

ExtractText requires a previously created layout file (for example: `tm000001_layout.xml`) where text is grouped into blocks. See [DocumentAnalytics actions](#) for information on the layout XML file.

Example

The following example populates the city field with the first instance of an address where the state is California.

```
ExtractText (DateTime.DateTime, Address.Address)
FindExtractedText (@P\City, First, Address.Address, city, stateorprovince, (California) |
(CA))
```

Support for external dictionaries

The ExtractText action supports AQL external dictionary. Using this feature, you can write annotators that do not need to be recompiled when a change is needed.

You can export from the IBM® InfoSphere® BigInsights web tools and place the exported folders into `\rrs\aqf\src` location. The AQL is compiled at the run time.

Note: You need to manually copy any external dictionaries and tables to the `\rrs\aqf` location.

It is recommended that you keep a back up of RRS folder, in case a file or folder gets corrupted at the time of copying or due to misconfiguration.

Detailed steps to configure Custom annotators in Datacap:

Complete the following steps to configure Custom annotators in Datacap.

1. Once you create Custom Extractor using BigInsights Web tool, export the extractor as "Executables" with an option of including "Source files" . Export in a zip format.
2. Copy TAMs file from export to the `\rrs\aqf` folder. Do NOT copy the `InputDocumentProcessor.TAM` file. Leave the original in `\rrs\aqf` folder itself.
3. Copy the SRC folder from Export (one from exported zip) folder to `\rrs\aqf`.

4. Make sure to copy all the supported *.DICT files provided by BigInsights in rrs\aqf folder.

Custom extractors must be called with ExtractText action in the format Module.Viewname.

Verify the modulename from corresponding aql file.

For e.g. ZIPCODE_BasicFeatures.ZCView

After the compilation process completes, the compiled TAM files are saved in \rrs\aqf location. Ensure that you remove the rrs\aqf\src folders after the compilation process.

List of pre-built extractors

The following Datacap extractor names consist of the following two parts, separated by a period: the InfoSphere BigInsights extractor name followed by the InfoSphere BigInsights attribute name.

See the IBM InfoSphere BigInsights documentation for more information about pre-built extractors.

http://www.ibm.com/support/knowledgecenter/SSPT3X_3.0.0/com.ibm.swg.im.infosphere.biginsights.text.doc/doc/ana_txtan_extractor-libraries.html

ExtractTextAlchemyLanguage (deprecated)

The action calls the AlchemyAPI Combined Call feature and passes in text from a single page at a time. The results are saved as entities in the page's layout XML file. Use the FindExtractedText action to populate fields

with results of this action.

Important: This action is deprecated, and is scheduled to be removed in the future release. To read the announcement from IBM about retirement of *AlchemyAPI*, see <https://www.ibm.com/blogs/bluemix/2017/03/bye-bye-alchemyapi/>. According to the announcement, you no longer be able to provision new *AlchemyAPI* instances after April 7, 2017. However, all existing instances continue to be supported by *AlchemyAPI* until March 7, 2018.

Syntax

```
bool ExtractTextAlchemyLanguage (string options)
```

Parameters

- entity
- keyword
- taxonomy
- concept
- relation
- doc-sentiment
- doc-emotion
- dates

Variables

Timeout

The default timeout is 100 seconds. You can specify the timeout by saving a page variable that is called *alchTimeout* and specifying the time in milliseconds.

Save Response

The response from AlchemyAPI can be saved by setting the variable *alchSaveResponse* to 1.

Returns

True if the layout is loaded and there are no errors. Otherwise, False.

Level

Document or page.

Details

Important: You must have an AlchemyAPI license to use this action. This license is obtained by creating an account on bluemix.net and adding the AlchemyAPI service to a workspace. The URL and key are shown on the Service Credentials page. Enter the credentials in Datacap Application Manager:

- Save the URL in your application's general section in a variable called *AlchemyApiUrl*.
Note: The URL must end in `/calls/`. If the *AlchemyApiUrl* is not updated, the default URL is `https://gateway-a.watsonplatform.net/calls/`
- Save the license key in your application's advanced section in a variable called *AlchemyApiKey*.

Entities are named using the format *AlchemyFeature.ResponseNode*. For example, an entity result for a person will have the name *Entity.Person*. Most entity fields will be named using the node returned by AlchemyAPI.

Nested responses are flattened to one level. For example, the disambiguated sub type will be named *subTypes* and the results will be saved as a comma-separated list.

When called on the document or page, the text of the layout XML file specified in the calling object's layout variable will be sent to AlchemyAPI.

The results will be saved to the entities list of the page in the layout XML file.

Example

```
Recognize ()  
AnalyzeLayout ()  
ExtractTextAlchemyLanguage ()  
FindExtractedText ()
```

Parent topic: [DocumentAnalytics actions](#)
«

ExtractTextLogEnable

Call this action to enable logging to the specified path and file name

Syntax

```
bool ExtractTextLogEnable (string Target)
```

Parameters

Target
Smart parameter of the path and file name to log to.

Returns

True.

Level

Any

Details

Enables additional logging during text extraction. This is used for debugging during system configuration. The file will grow until it is deleted.

Example

```
ExtractTextLogEnable (c:\datacap\extract.log)  
ExtractText (DateTime.DateTime, Address.Address)
```

Parent topic: [DocumentAnalytics actions](#)
»

ExtractTextNLP

The action calls the Natural Language Processing (NLP) API and passes in text from a single page at a time. The results are saved as entities in the page's layout XML file. Use the FindExtractedText action to populate fields with results of this action. To extract from non-English-language text, set the page variable `hr_locale` to the

wanted language before calling this action. For example, for the Japanese language, call `rrset("ja","@P.hr_locale")`.

Syntax

```
bool ExtractTextNLP (string options, string model)
```

Parameter text features

No parameter - returns all results

- entities
- keywords
- categories
- concepts
- semantic_roles
- relations

Variables

Timeout

The default timeout is 150 seconds. You can specify the timeout by saving a page variable called `nlpTimeout` and specifying the time in milliseconds.

Save Response

The response from NLPAPI can be saved by setting the variable `nlpSaveResponse` to 1.

Returns

True if the layout is loaded and there are no errors. Otherwise, False.

Level

Document or page.

Details

Important: You must have an enterprise NLP license to use this action. This license is obtained by creating an account on bluemix.net and adding the NLP service to a workspace. The URL and key are shown on the Service Credentials page. Enter the credentials in Datacap Application Manager:

- Save the URL in your application's general section in a variable called `NLPApiUrl`.
Note: If the `NLPApiUrl` is not updated, the default URL is <https://gateway.watsonplatform.net/natural-language-understanding/api/v1/analyze?version=2017-02-27>
- Save the username in your application's gen section in a variable called `NLPApiUsername`.
- Save the password in your application's adv section in a variable called `NLPApiPassword`.

You can deploy Watson Knowledge Studio custom model to override default model.

Entities are named by using the format `NLPFeature.ResponseNode`. For example, an entity result for a person has the name `Entity.Person`. Most entity fields are named by using the node returned by NLPAPI. Nested responses are flattened to one level. For example, the disambiguated sub type is named `subTypes` and the results are saved as a comma-separated list.

When called on the document or page, the text of the layout XML file specified in the calling object's layout variable will be sent to NLPAPI.

The results will be saved to the entities list of the page in the layout XML file.

To populate a field with a result of this action, use the FindExtractedText action.

Example

```
Recognize ()
AnalyzeLayout ()
ExtractTextNLP ()
FindExtractedText ()
```

Parent topic: [DocumentAnalytics actions](#)

FindExtractedText

Finds patterns in the document or page.

Restriction: This action does not support regular expressions containing a line break nor tab expressions.

Syntax

```
bool FindExtractedText (string Target, string Scope, string Entity, string Source,
string SearchField, string SearchRegex)
```

Parameters

Target

Smart parameter for the target object to save the value to. If used on a field use @F to update the current field.

Scope

Smart parameter first|Last|All

Populates the target using the match or matches by using the specified entity type, search field, and search expression. If First is specified, the first match is used. If Last is specified the last match is used. If All is specified a sub field will be created for all matches. All is supported only when the target is a DCO object and is not supported for variables.

Entity

Smart parameter name of the entity to match. For example `Address.Address` for a result from the ExtractText action, or `Person` for a result from the ExtractTextAlchemyLanguage action. The format of the entity name is `Module.OutputView`.

SearchField

Optional. Smart parameter name of the entity field to match. For example `city`. If specified, matching will be limited to the specified field. If the Entity parameter is set to Field, this field's value will be used to update the target.

SearchRegex

Optional. Smart parameter regular expression to search for. To search for a word use `(SearchWord)`.

Returns

True when a match is found. Otherwise, False.

Level

Any

Details

Populates a field or variable with a value found using the `ExtractText` and `ExtractTextAlchemyLanguage` actions.

Important: The results from the `ExtractText` and `ExtractTextAlchemyLanguage` actions will be saved to the layout XML file (for example: `tm000001_layout.xml`), which can be opened in a text editor to see the available entities and the entity fields that can be copied into document hierarchy fields. You can search for an entity in the layout XML using its name such as `Address.Address`, or `Person`.

If the source is Entity: This can be used to create the line item detail structure in the run time hierarchy for capturing a list of items to be exported.

- If the Target has sub fields defined and the sub field types match the entity field names they will be populated.
- If the Target has sub fields and the sub fields have a variable named `entityMap` with a value that is the same as the entity field name in the layout.xml file the sub field of the target will be populated.
- If the Target does not have a sub field mapped to an entity field name a variable will be created using the entity field name.

`FindExtractedText` requires a previously created layout file (for example: `tm000001_layout.xml`) where text is grouped into blocks. See [DocumentAnalytics actions](#) for information on the layout XML file.

ExtractText example 1

This example will populate a page field called `City` with the first address in California.

```
Recognize()
ExtractText (Address.Address)
FindExtractedText (@P\City,First,Address.Address,city,stateorprovince,(California)|
(CA))
```

ExtractText example 2

This example will create a line item for each address found in the document.

The following document hierarchy is expected to be defined:

```
Field AddressDetail
  Field LineItem
    Field City
      Variable entityMap=city
    Field State
      Variable entityMap=stateorprovince

Recognize()
ExtractText (Address.Address)
FindExtractedText (@P\AddressDetail,All,Address.Address,, ,)
```

ExtractText example 3

This example will populate variables `city`, `stateorprovince`, `zip` and `address` on the target field `AddressDetail`.

```
Recognize()
ExtractText (Address.Address)
FindExtractedText (@P\AddressDetail,First,Address.Address,, ,)
```

ExtractTextAlchemyLanguage example 1

This example will populate a page field called Person with the first Person returned by AlchemyAPI.

```
Recognize ()
ExtractTextAlchemyLanguage (entity)
FindExtractedText (@P\Person, First, entity, text, type, Person)
```

Parent topic: [DocumentAnalytics actions](#)

DocumentAnalytics.VisualRecognitionClassifier actions

Visual Recognition Classifier is an IBM Watson service, which can be trained to classify image-based documents. The default instance name: DocumentAnalytics.Undoable-in-transactional.

You can use the default classifier to do the classification, or you can first create and train a custom classifier by using some representative set of training data. The uploaded training data must contain at least two compressed (.zip) files, each containing sample images of a particular classes.

Once the classifier has been trained, you can give it other similar documents and classifier attempts to classify them according to its training. The Classifier returns a confidence score that is associated with the classification.

Properties and methods:

- [VisualRecogClassify](#)
Classifies image by using IBM Watson Visual Recognition API.
- [VisualRecogSetCredentials](#)
Sets the credentials to be used to do the classification.
- [VisualRecogSetMinConfidence](#)
Sets the minimum confidence score for classification matching.
- [VisualRecogSetURL](#)
Updates the new URL to be used to do the classification.
- [VisualRecogTrain](#)
Creates or replaces a Visual Recognition Classifier.

Parent topic: [Global actions](#)

VisualRecogClassify

Classifies image by using IBM Watson Visual Recognition API.

Syntax

```
bool VisualRecogClassify (string ClassifierName)
```

Parameters

string ClassifierName - Name of the Classifier to be used

Returns

True, if the action succeeds. Otherwise, False

Level

Page level.

Details

This action identifies a page by using the Watson™ Recognition technology. This technology analyzes the image-based full page and attempts to find match within the classes that have been defined for the selected classifier. If a match is found, the Page type is populated with the ID of the category that was matched.

If a match is not found, the page type is set to "Other".

When classification is complete, a list of matches and their confidence values are stored in the "MatchingCategoryX" and "MatchingCategoryConfX" variables. The number of matches is stored in the variable "MatchingCategoriesCount".

To run classification without updating the page type, set the variable "UpdateDCOType" to "0" before calling this action. In this case, classification does not update the page type, but the variables that are mentioned above is populated.

Because this action supports image files (.jpg, .jpeg or .png) only. ConvertToJPEG must be called before using the Classify action for other types of files.

The ClassifierName can be a smart parameter.

Example

```
VisualRecogSetURL("@APPVAR(values/gen/url) ")
VisualRecogSetCredentials("@APPVAR(values/adv/VRAPIKey) ")
VisualRecogClassify("@APPVAR(values/gen/VRClassifierName) ")
```

Note: VisualRecogSetURL action is not included if your IBM Visual Recognition token is created before May 2018.

Parent topic: [DocumentAnalytics.VisualRecognitionClassifier actions](#)

VisualRecogSetCredentials

Sets the credentials to be used to do the classification.

Syntax

```
bool VisualRecogSetCredentials (string APIKey)
```

Parameters

string APIKey can be Smart Parameters.

Returns

True, if the action succeeds. Otherwise, False.

Level

Batch level.

Details

This action sets the credentials to be used to do the classification. The APIKey can be Smart Parameters.

Example

```
VisualRecogSetURL("@APPVAR(values/gen/url) ")
VisualRecogSetCredentials("@APPVAR(values/adv/VRAPIKey) ")
VisualRecogClassify("@APPVAR(values/gen/VRClassifierName) ")
```

Note: VisualRecogSetURL action is not included if your IBM Visual Recognition token is created before May 2018.

Parent topic: [DocumentAnalytics.VisualRecognitionClassifier actions](#)

VisualRecogSetMinConfidence

Sets the minimum confidence score for classification matching.

Syntax

```
bool VisualRecogSetMinConfidence (string MinScore)
```

Parameters

string MinScore - Minimum score for classification matching. Valid values are fractional values between zero and one (for example: 0.0 and 1.0).

Returns

True, if the parameter value is between the valid range of zero to one (0.0 and 1.0) Otherwise, False.

Level

All level.

Details

When Classify searches for a classification match, a score between zero (no match) and one (a positive match) is calculated. This action sets the minimum score that a match must be considered a match. Any matches with a score less than the value specified is rejected. With this action, you can control the tolerance for documents matching an existing example.

When setting up the parameter in your application, use the decimal character from the system locale that is defined for the application in the Taskmaster Application Manager. For example, when the decimal character is a period, use a value from 0.0 to 1.0. When the decimal character is a comma, use a value in the range 0,0 - 1,0.

The MinScore can be a Smart Parameter. This action must be called before the Classify action.

Example

```
VisualRecogSetCredentials("@APPVAR(values/adv/VRAPIKey) ")
VisualRecogSetMinConfidence(0.9)
VisualRecogClassify("@APPVAR(values/gen/VRClassifierName) ")
```

Parent topic: [DocumentAnalytics.VisualRecognitionClassifier actions](#)

VisualRecogSetURL

Updates the new URL to be used to do the classification.

Syntax

```
VisualRecogSetURL (string url)
```

Parameters

The URL can be Smart Parameters

Returns

True, if the action succeeds. Otherwise, False

Level

Batch level.

Details

This action updates the new URL to be used to do the classification. IBM Visual Recognition token created after May 2018 must apply this action before `VisualRecogSetCredentials()`.

Example

```
VisualRecogSetURL("@APPVAR(values/gen/url) ")
VisualRecogSetCredentials("@APPVAR(values/adv/VRAPIKey) ")
VisualRecogClassify("@APPVAR(values/gen/VRClassifierName) ")
```

Parent topic: [DocumentAnalytics.VisualRecognitionClassifier actions](#)

VisualRecogTrain

Creates or replaces a Visual Recognition Classifier.

Syntax

```
bool VisualRecogTrain (string ZIPDirectory, string Name, string deleteExisting)
```

Parameters

string ZIPDirectory - Directory where this action stores the zip file with the training data. the zip file has the name of the classifier. This parameter supports SmartParameters.

string Name - Name to give the classifier. This name is used when you later try to classify a page. This parameter supports SmartParameters.

string deleteExisting - Delete the classifier of the same name if it exists. If this flag is set to true, it deletes the classifier of the same name, if it exists. If this flag is set to false and a classifier with the same name exists, this

action adds the training data to the existing classifier. This parameter supports SmartParameters. The type of this parameter is string only to support SmartParameters. Internally, it is treated as a boolean. Specify '1' for true and '0' for false. Any other value is ignored and the action is default to false.

Returns

True, action is successful. Otherwise, False.

Level

Batch level.

Details

This action creates or replaces a Visual Recognition Classifier. Pages of the batch are used as the training data. It is expected that the batch is in a certain format. In particular, the batch needs to be divided into set documents, where the 'Type' associated with the document is class that is created in the Visual Recognition Service. All of pages in that document are treated as training data for that class. So, for example, if you wanted to train the classifier to recognize the main page and the trailing pages of a mortgage application, you would create a batch with two documents: Main_Page and Trailing_Page. Put all of the training page for the main page under the Main_Page document and the trailing pages under Trailing_Page document.

Example

```
VisualRecogSetURL("@APPVAR(values/gen/url) ")
VisualRecogSetCredentials("@APPVAR(values/adv/VRAPIKey) ")
VisualRecogTrain("@APPPATH(runtime)+\+..\+ZIP", "@APPVAR(values/gen/VRClassifierName)", 1)
```

Parent topic: [DocumentAnalytics.VisualRecognitionClassifier actions](#)

DocumentAnalytics.NaturalLanguageClassifier actions

Natural Language Classifier is an IBM Watson service, which can be trained to classify documents or sections of documents. That based on the text that is contained in the document or the section of a document. The default instance name: DocumentAnalytics.NaturalLanguageClassifierActions.

To do this, you must first create and train a classifier using some representative set of training data containing text from a set of sample documents. Once the classifier has been trained, you can give it other similar documents and classifier attempts to classify them according to its training. The Classifier returns a confidence score that is associated with the classification.

Because Natural Language Classifier works on the text of the document, you must first perform OCR on the document before calling the Classify action to do the classification.

Properties and methods:

- [NLCClassify](#)
Identifies a page by using the IBM Natural Language technology.
- [NLCClassifyText](#)
Classifies the specified text by using the IBM Natural Language technology.
- [NLCSetsCredentials](#)
Sets the credentials to be used to do the classification.
- [NLCSetsLanguage](#)
Sets the language of the page to be classified.

- [NLCSetsMinConfidence](#)
Sets the minimum confidence score for classification matching.
- [NLCTrain](#)
Creates or replaces an NLC Classifier.

Parent topic: [Global actions](#)

NLCClassify

Identifies a page by using the IBM Natural Language technology.

Syntax

```
bool NLCClassify (string ClassifierName)
```

Parameters

string ClassifierName - Name of the Classifier to be used.

Returns

True, action is successful. Otherwise, False..

Level

Page level.

Details

This action identifies a page by using the IBM Natural Language technology. This technology analyzes the full text of pages and attempts to find match within the classes that have been defined for the selected classifier. If a match is found, the Page type is populated with the ID of the category that was matched.

If a match is not found, the page type is set to "Other".

When classification is complete, a list of matches and their confidence values are stored in the "MatchingCategoryX" and "MatchingCategoryConfX" variables. The number of matches is stored in the variable "MatchingCategoriesCount" .

To run classification without updating the page type, set the variable "UpdateDCOType" to "0" before calling this action. In this case classification will not update the page type, but the variables that are mentioned above will still be populated.

Because the matching relies on a page's full text, a full page recognition action must be called before using the Classify action.

This action gets the text for the page in the following order:

- from the layout.xml that is file generated by the Recognize action
- from the .txt file that is generated by the RecognizeToFile action
- from the .cco file that is generated by the RecognizePage action

The ClassifierName can be a smart parameter.

Example

```
NLCSetLanguage("en")
NLCSetCredentials("@APPVAR(values/gen/NLCUserName)", "@APPVAR(values/adv/NLCPassword)")
NLCSetMinConfidence(0.9)
Recognize()
NLCClassify("@APPVAR(values/gen/NLCClassifierName)")
```

Parent topic: [DocumentAnalytics.NaturalLanguageClassifier actions](#)

NLCClassifyText

Classifies the specified text by using the IBM Natural Language technology.

Syntax

```
bool NLCClassifyText (string ClassifierName, string TextToClassify)
```

Parameters

string ClassifierName - Name of the Classifier to be used

string TextToClassify - Text to be classified by using the Natural Language Classifier. This parameter supports SmartParameters.

Returns

True, action is successful. Otherwise, False.

Level

Page level.

Details

This action classifies the specified text by using the IBM Natural Language technology. This technology analyzes the text that is specified and attempts to find match within the classes that have been defined for the selected classifier.

When classification is complete, a list of matches and their confidence values are stored in the "MatchingCategoryX" and "MatchingCategoryConfX" variables. The number of matches is stored in the variable "MatchingCategoriesCount".

Both ClassifierName and TextToClassify can be smart parameters.

Example

```
NLCSetCredentials("@APPVAR(values/gen/NLCUserName)", "@APPVAR(values/adv/nlcpassword)")
NLCSetMinConfidence(0.9)
NLCClassifyText("@APPVAR(values/gen/NLCClassifierName)", "Sample Text")
```

Parent topic: [DocumentAnalytics.NaturalLanguageClassifier actions](#)

NLCSetCredentials

Sets the credentials to be used to do the classification.

Syntax

```
bool NLCSetCredentials (string UserName , string Password)
```

Parameters

string UserName - UserName

string Password - Password

Returns

True, if the action succeeds. Otherwise, False.

Level

All level.

Details

This action sets the credentials to be used to do the classification. The UserName and password can be Smart Parameters. In order to protect the secrecy of the Password, it is recommended that you store it as an Advanced custom value in the Datacap Application Manager.

Example

```
NLCSetLanguage ("en")
NLCSetCredentials ("@APPVAR(values/gen/NLCUserName) ", "@APPVAR(values/adv/NLCPassword) ")
NLCSetMinConfidence (0.9)
Recognize ()
NLCClassify ("@APPVAR(values/gen/NLCClassifierName) ")
```

Parent topic: [DocumentAnalytics.NaturalLanguageClassifier actions](#)

NLCSetLanguage

Sets the language of the page to be classified.

Syntax

```
bool NLCSetLanguage (string LanguageCode)
```

Parameters

string LanguageCode - The two-letter code associate with the language of the page to be classified

Returns

True, if the action succeeds. Otherwise, False.

Level

All level.

Details

This action sets the language of the page to be classified. The LanguageCode can be a smart parameter. The possible values for the Language code are:

- 'en' : English
- 'ar' : Arabic
- 'fr' : French
- 'de' : German
- 'it' : Italian
- 'ja' : Japanese
- 'ko' : Korean
- 'pt' : Portuguese (Brazilian)
- 'es' : Spanish

This action must be called before the Classify action.

Example

```
NLCSetLanguage("en")
NLCSetCredentials("@APPVAR(values/gen/NLCUserName)", "@APPVAR(values/adv/NLCPassword)")
NLCSetMinConfidence(0.9)
Recognize()
NLCClassify("@APPVAR(values/gen/NLCClassifierName)")
```

Parent topic: [DocumentAnalytics.NaturalLanguageClassifier actions](#)

NLCSetMinConfidence

Sets the minimum confidence score for classification matching.

Syntax

```
bool NLCSetMinConfidence (string MinScore)
```

Parameters

string MinScore - Minimum score for classification matching. Valid values are fractional values between zero and one (for example: 0.0 and 1.0)

Returns

True, if the parameter value is between the valid range of zero to one (0.0 and 1.0) Otherwise, False.

Level

All level.

Details

When Classify searches for a classification match, a score between zero (no match) and one (a positive match) is calculated. This action sets the minimum score that a match must be considered a match. Any matches with a score less than the value specified is rejected. With this action, you can control the tolerance for documents matching an existing example.

When setting up the parameter in your application, use the decimal character from the system locale that is defined for the application in the Taskmaster Application Manager. For example, when the decimal character is a period, use a value from 0.0 to 1.0. When the decimal character is a comma, use a value in the range 0,0 - 1,0.

The MinScore can be a Smart Parameter. This action must be called before the Classify action.

Example

```
NLCSetLanguage("en")
NLCSetCredentials("@APPVAR(values/gen/NLCUserName)", "@APPVAR(values/adv/NLCPassword)")
NLCSetMinConfidence(0.9)
Recognize()
NLCClassify("@APPVAR(values/gen/NLCClassifierName)")
```

Parent topic: [DocumentAnalytics.NaturalLanguageClassifier actions](#)

NLCTrain

Creates or replaces an NLC Classifier.

Syntax

```
bool NLCTrain (string CSVDirectory, string Name, string deleteExisting, string
appendToCSV)
```

Parameters

string CSVDirectory - Directory where this action stores the csv file with the training data. CSV file has the name of the classifier. This parameter supports SmartParameters.

string Name - Name to give the classifier. This name is used when you later try to classify a page. This parameter supports SmartParameters.

string deleteExisting - Delete the classifier of the same name if it exists. If this flag is set to true, it deletes the classifier of the same name, if it exists. If this flag is set to false and a classifier with the same name exists, this action returns false. This parameter supports SmartParameters. The type of this parameter is string only to support SmartParameters. Internally, it is treated as a boolean. Specify '1' for true and '0' for false. Any other value is ignored and the action is default to false.

string appendToCSV - If an existing csv file found, this parameter indicates whether the training data from this batch should be appended to it or that it should be overwritten. If true, the classifier is trained with the data in the csv file and the new data from this batch. If false, the existing data in the csv file is overwritten and the classifier is trained with just the data in this batch. This parameter supports SmartParameters. The type of the parameter is string only to support SmartParameters. Internally, it is treated as a boolean. Specify '1' for true and '0' for false. Any other value is ignored and the action is default to true.

Returns

True, action is successful. Otherwise, False.

Level

Batch level.

Details

This action creates or replaces an NLC Classifier. Pages of the batch are used as the training data. It is expected that the batch is in a certain format. In particular, the batch needs to be divided into set documents where the 'Type' associated with the document is class that is created in NLC. All of pages in that document are treated as training data for that class. So, for example, if you wanted to train the classifier to recognize the main page and the trailing pages of a mortgage application, you would create a batch with two documents: Main_Page and Trailing_Page. Put all of the training page for the main page under the Main_Page document and the trailing pages under Trailing_Page document.

Example

```
NLCSetLanguage ("en")
NLCSetCredentials ("@APPVAR (values/gen/NLCUserName) ", "@APPVAR (values/adv/NLCPass
word) ")
NLCTrain ("@APPPATH (runtime)+\+..+\+CSV", "@APPVAR (values/gen/NLCClassifierName) "
, 0, 1)
```

Parent topic: [DocumentAnalytics.NaturalLanguageClassifier actions](#)

Documentum actions

Use the Documentum actions to upload documents to an EMC Documentum repository.

The Documentum Connector actions integrate Datacap applications with the Documentum repository. You run these actions to access the Documentum server, set up document attributes and folders on the server, and upload documents to the server for storage.

- [DM_Logon](#)
Creates the connection to the Documentum repository into which you can upload pages and documents.
- [DM_SetContentType](#)
Sets the content type to define in the repository for the object, for example TIFF, JPEG, DOC.
- [DM_SetFolderName](#)
Specifies the name of the Documentum folder where Datacap places the uploaded file on the Documentum system.
- [DM_SetObjectName](#)
Sets the name of the file that you are uploading as it appears in the Documentum repository.
- [DM_UploadDocument](#)
Uploads all of the pages in the document.
- [DM_UploadPage](#)
Uploads the selected page from the document.

Parent topic: [Global actions](#)

DM_Logon

Creates the connection to the Documentum repository into which you can upload pages and documents.

Syntax

```
bool DM_Logon (string sRepositoryDomain, string sRepositoryName, string sUserID,
string sPassword)
```

Parameters

string sRepositoryDomain

string sRepositoryName

string sUserID

String sPassword

Parameters

- sRepositoryDomain: The machine name for the repository.
- sRepositoryName: The name of the repository.
- sUserID: The userid for logon.
- sPassword: The password
-

The parameters cannot be blank. Smart parameters are supported.

Note: Use a Smart parameter to obtain the password from the application service instead of hardcoding it in the rules.

Returns

True, if the logon is successful. Otherwise, False.

Level

This action can be called at any level but is recommended to be called at the batch level. It must be called only once per task.

Details

Creates the connection to the repository where the pages are uploaded. This action must be called before DM_UploadPage or DM_UploadDocument. The user ID must have write permission or files cannot be uploaded.

It is recommended that you create an advanced value in the custom values tab in the Application Manager to store your password.

Example:

```
DM_Logon("machinename", "repository", "userid", "password")
```

```
DM_Logon("machinename", "repository", "userid",
"@APPVAR(values/adv/MyPassword) ")
```

This example uses the Smart parameter @APPVAR to obtain the password from the advanced value section of the application manager. The custom value name is "MyPassword".

Parent topic: [Documentum actions](#)

Related reference:

[DM_UploadPage](#)

[DM_UploadDocument](#)

DM_SetContentType

Sets the content type to define in the repository for the object, for example TIFF, JPEG, DOC.

Syntax

```
bool DM_SetContentType (StrParam)
```

Parameters

The repository defined type for this page. Smart parameters are supported.

Returns

Always True.

Level

Any level.

Details

Sets the type for the page to be uploaded. This type must be pre-defined in the repository. This action does not test that the specified type exists in the repository. If the specified content type is incorrect, the upload action will report the error.

This action must be called prior to `DM_UploadPage` or `DM_UploadDocument`.

Example:

```
DM_SetFolderName ("/folder1/folder2")
DM_SetContentType ("tiff")
DM_SetObjectName ("@ID")
DM_UploadDocument ()
```

Parent topic: [Documentum actions](#)

Related reference:

[DM_UploadPage](#)

[DM_UploadDocument](#)

DM_SetFolderName

Specifies the name of the Documentum folder where Datacap places the uploaded file on the Documentum system.

Syntax

```
bool DM_SetFolderName (StrParam)
```

Parameters

Repository folder where the file will be uploaded. Smart parameters are supported.

Returns

Always True.

Level

Any level.

Details

The name of the cabinet / folder that will hold the uploaded file. The path specification to the folder can be specified using a typical folder syntax separated by forward slashes, such as /folder/anotherfolder/finalfolder. Alternatively, the target folder can be specified by the object ID of the folder as defined in the repository, without any slashes.

This action does not confirm that the folder actually exists in the repository. If the specified content type is incorrect, the upload action will report the error. This action must be called prior to `DM_UploadPage` or `DM_UploadDocument`.

Example:

```
DM_SetFolderName("/folder1/folder2")
DM_SetContentType("tiff")
DM_SetObjectName("@ID")
DM_UploadPage()
```

This example shows the folder path as it exists in the repository.

```
DM_SetFolderName("0c0022538000252d")
DM_SetContentType("tiff")
DM_SetObjectName("@ID")
DM_UploadPage()
```

This example uses the object ID of the destination folder in the repository.

Parent topic: [Documentum actions](#)

Related reference:

[DM_UploadPage](#)

[DM_UploadDocument](#)

DM_SetObjectName

Sets the name of the file that you are uploading as it appears in the Documentum repository.

Syntax

```
bool DM_SetObjectName (StrParam)
```

Parameters

The name for the uploaded file as it will appear in repository. Smart parameters are supported.

Returns

Always True.

Level

Any level.

Details

This action is used to set the name of the uploaded file. This is not the file name as it exists in the batch, but the final name that will be used when viewed in the repository.

This action must be called prior to `DM_UploadPage` or `DM_UploadDocument`.

Example:

```
DM_SetFolderName("/folder1/folder2")
DM_SetContentType("tiff")
DM_SetObjectName("@ID")
DM_UploadDocument()
```

Parent topic: [Documentum actions](#)

Related reference:

[DM_UploadPage](#)

[DM_UploadDocument](#)

DM_UploadDocument

Uploads all of the pages in the document.

Syntax

```
bool DM_UploadDocument ()
```

Parameters

None.

Returns:

True, if all of the pages within the document are uploaded to the repository. Otherwise, False.

If any of the files for the document are missing from the batch, it is not considered an error and the batch will not abort. If the upload to Documentum fails due to a different reason, the document upload will stop and the batch will be set to abort.

Level

Document level.

Details

This action will upload all of the pages that are attached to a document. An XML file called `DM_Uploaded.xml` is created in the batch directory. This file lists all of pages that have been uploaded.

`DM_Logon` must have been previously called. Additionally, the destination folder, final object name and content type must have been previously set. When uploading a document using this action, all pages must be of the

same type.

Example:

```
DM_SetFolderName ("/folder1/folder2")
DM_SetContentType ("tiff")
DM_SetObjectName ("@ID")
DM_UploadDocument ()
```

Parent topic: [Documentum actions](#)

Related reference:

[DM_SetFolderName](#)

[DM_SetContentType](#)

[DM_SetObjectName](#)

DM_UploadPage

Uploads the selected page from the document.

Syntax

```
bool DM_UploadPage ()
```

Parameters

None.

Returns

True, if the page is uploaded to the repository. Otherwise, False.

If the file fails to upload or if the file is missing from the batch, the batch will be set to abort.

Level

Page level.

Details

This action uploads the current page to the repository. An XML file called DM_Uploaded.xml is created in the batch directory. This file lists all of pages that have been uploaded.

DM_Logon must have been previously called. Additionally, the destination folder, final object name and content type must have been previously set.

Example:

```
DM_SetFolderName ("/folder1/folder2")
DM_SetContentType ("tiff")
DM_SetObjectName ("@ID")
DM_UploadPage ()
```

Parent topic: [Documentum actions](#)

Related reference:

[DM_SetFolderName](#)

[DM_SetContentType](#)

Email actions

Use the email actions to compose and then send an email by using CDOSYS and an SMTP server. These actions also support Outlook, which requires the Outlook user to be logged on to the computer and security prompts might be displayed for each message.

Important: If any concurrently running threads might be using the same sending email address, your Email-related tasks cannot be run in a multi-threaded configuration. Instead, use single-threaded tasks only. For information about configuring threads in Rulerunner, see [Rulerunner thread configuration](#). For information about the sending email address, see [SetSender](#).

The Email actions specify path and file name for attachments, email recipients, and email subject.

- [SendEMail](#)
Sends an email.
- [SetAttachment](#)
Adds a file attachment to an email.
- [SetBlindCarbonCopyRcpts](#)
Sets Blind Carbon Copy recipients' email address(es).
- [SetCarbonCopyRcpts](#)
Set Carbon Copy recipients' email address(es).
- [SetEmailBody](#)
Sets the text of the email's body.
- [SetMailServer](#)
Configures the mail server to use for sending mail. Use this action only if you are sending emails with CDOSYS.
- [SetRecipients](#)
Sets email recipients' address(es).
- [SetSender](#)
Sets the sending email address.
- [SetSubject](#)
Sets the text for the email's Subject field.

Parent topic: [Global actions](#)

SendEMail

Sends an email.

Syntax

```
bool SendEMail ()
```

Parameters

None.

Returns

False, if the rule does not include a previous SetRecipients action, or if the email cannot be sent. Otherwise, True. If the email cannot be sent, the batch is set to abort.

Level

All levels.

Details

Sends an email that is assembled by previous actions. Typically, this is the final action in an email rule set. At a minimum, the `SetSender` and `SetRecipients` actions must be called before sending an email.

After the email is sent, this action will discard the contents of the email in memory. Calls to the email actions after `SendEmail` causes the creation of a new email message.

Example:

```
SetSender("paul@adomain.com")
SetRecipients("lisa@adomain.com,beth@adomain.com")
SetSubject("Document Integrity")
SetEMailBody("Document Page Types and counts are accurate. Thanks for your
help.")
SendEMail()
```

Parent topic: [Email actions](#)

SetAttachment

Adds a file attachment to an email.

Syntax

```
bool SetAttachment (StrParamMW)
```

Parameters

The file's path, name and extension. Smart Parameters are supported.

Returns

False if the file does not exist or cannot be attached. Otherwise, True.

Level

All levels.

Details

Attaches the specified file to the current email.

Example:

```
SetAttachment("h:\MyDir\MQSW\export\+@BATCHID+.txt")
```

This example attaches the Export file of the current batch to the email.

Parent topic: [Email actions](#)

SetBlindCarbonCopyRcpts

Sets Blind Carbon Copy recipients' email address(es).

Syntax

```
bool SetBlindCarbonCopyRcpts (StrParam)
```

Parameters

The email addresses to receive a copy of the email as a blind carbon copy. You can enter multiple email addresses separated by commas.

Returns

False if you do not enter an email addresses parameter, if the address is rejected by the mail system or if the email object cannot be initialized. Otherwise, True.

Invalid email addresses may not be reported until SendEMail is called.

Level

All levels.

Details

Adds addresses to the Bcc (Blind Carbon Copy) portion of the email's header.

Example:

```
SetRecipients("lisa@monarchy.com")  
SetBlindCarbonCopyRcpts("james@regency.com")
```

Parent topic: [Email actions](#)

Related reference:

[SetCarbonCopyRcpts](#)

[SetRecipients](#)

SetCarbonCopyRcpts

Set Carbon Copy recipients' email address(es).

Syntax

```
bool SetCarbonCopyRcpts (StrParam)
```

Parameters

Email addresses to receive a copy of the email as a carbon copy. You can enter multiple email addresses separated by commas.

Returns

False if you do not enter an email addresses parameter, if the address is rejected by the mail system or if the email object cannot be initialized. Otherwise, True.

Invalid email addresses may not be reported until SendEMail is called.

Level

All levels.

Details

Adds addresses to the Cc (Carbon Copy) portion of the email's header.

Example:

```
SetRecipients("lisa@adomain.com")
SetCarbonCopyRcpts("cindy@anotherdomain.org")
```

Parent topic: [Email actions](#)

Related reference:

[SetBlindCarbonCopyRcpts](#)

[SetRecipients](#)

SetEmailBody

Sets the text of the email's body.

Syntax

```
bool SetEmailBody (StrParamMW)
```

Parameters

The email message text. Smart Parameters are supported.

Returns

False if the mail object cannot be initialized. Otherwise, True.

Level

All levels.

Details

Sets the text of the email's body.

Example:

```
SetSubject("Document Integrity")
SetEmailBody("Document Page Types and counts are accurate. Thanks for your
help.")
```

Parent topic: [Email actions](#)

Related reference:

SetMailServer

Configures the mail server to use for sending mail. Use this action only if you are sending emails with CDOSYS.

Syntax

```
bool SetMailServer (StrParam)
```

Parameters

The IP or DNS address of the outgoing mail (SMTP) server.

Returns

Always True.

Level

All levels.

Details

Sets the address of the outgoing mail (SMTP) server. This server might be the same mail server that you configure in your mail program. The server must be accessible from the computer that runs the email actions. This action must be the first action in an email rule, if the CDOSYS object is being used.

Use this action only if you are sending emails with CDOSYS. To use CDOSYS, this action must be called before any of the other email actions. If this action is not called before other email actions, these actions use Outlook for sending emails.

You can use Email actions to direct a task to compose and send emails that contain information and attachments. Email actions use the Windows CDOSYS library to send email by your preferred SMTP mail server. The CDOSYS object is included with Windows 2000 and higher versions. Alternatively, Email actions can use the Outlook object but it is not recommended.

One of these two libraries (CDOSYS or Outlook) must be registered on the computer that runs the rules that employ email actions.

Outlook is primarily useful for demonstration purposes because it is not suitable for unattended operation. It requires the Outlook user to be logged in to the computer, and security prompts might be displayed for each message sent.

Example:

```
SetMailServer ("mail.YourISP.com")
SetSender ("paul@adomain.com")
SetRecipients ("lisa@adomain.com")
SetSubject ("Document Integrity")
SetEMailBody ("Document Page Types and counts are accurate. Thanks for your
help.")
SendEMail ()
```

Parent topic: [Email actions](#)

SetRecipients

Sets email recipients' address(es).

Syntax

```
bool SetRecipients (StrParam)
```

Parameters

Email address(es) of recipient(s). You can either call this action multiple times to add multiple recipients, or you can enter multiple email addresses separated by commas.

Returns

False if you do not enter an email addresses parameter, if the address is rejected by the mail system or if the email object cannot be initialized. Otherwise, True.

Invalid email addresses may not be reported until SendEMail is called.

Level

All levels.

Details

The email address of the email's primary recipients.

Example:

```
SetRecipients ("lisa@adomain.com, Joe@adomain.com")
```

Parent topic: [Email actions](#)

Related reference:

[SetCarbonCopyRcpts](#)

[SetBlindCarbonCopyRcpts](#)

SetSender

Sets the sending email address.

Syntax

```
bool SetSender (StrParam)
```

Parameters

The sender's email address.

Returns

False if the mail object cannot be initialized. Otherwise, False.

Invalid email addresses may not be reported until SendEMail is called.

Level

All levels.

Details

Sets the email address of the sender for the current email. When using the CDOSYS object, use this action. When using the Outlook object, the current email account is used as the sender.

Example:

```
SetRecipients("lisa@adomain.com")
SetSender("paul@adomain.com")
```

Parent topic: [Email actions](#)

SetSubject

Sets the text for the email's Subject field.

Syntax

```
bool SetSubject (StrParamMW)
```

Parameters

The subject line of the email. Smart Parameters are supported.

Returns

False if the mail object cannot be initialized. Otherwise, True.

Level

All levels.

Details

Sets the text for the email Subject field. It is recommended that the subject line be no longer than 78 characters as this is a common subject line length limitation. Some systems may support even shorter lengths, truncating the subject. Our testing has been successful with lengths up to 255 characters. It is recommended to test your settings and use lengths appropriate for your systems.

Example:

```
SetSubject("Document Integrity")
```

Parent topic: [Email actions](#)

Equalize actions

Use the Equalize action to equalize the x and y resolutions of an image.

The Equalize actions convert an image with different x and y resolutions to one with the same x and y resolutions.

- [EqualizeUnbalancedImage](#)
Resolves differences in the dpi (dots per inch) resolutions along the horizontal (X) and vertical (Y) planes of one or more faxed images in a batch.

Parent topic: [Global actions](#)

EqualizeUnbalancedImage

Resolves differences in the dpi (dots per inch) resolutions along the horizontal (X) and vertical (Y) planes of one or more faxed images in a batch.

Syntax

```
bool EqualizeUnbalancedImage (StrParam)
```

Parameters

Integer value which determines the cut-off point for the resolution which should be equalized:

EqualizeUnbalancedImage(0), for example, specifies that there is no cut-off point: all images will be subject to equalization.

EqualizeUnbalancedImage(20) establishes a cut-off point of 200(x)/180(y). This means that the action will equalize all images with this resolution ratio and more (200/180, 200/160 etc.) - but will ignore all images with balance ratios less than 200/180 (in this example.)

Attention: Standard Mode fax resolution in Dots per Inch (DPI) is 204/98; Fine Mode fax resolution is 204/196.

Returns

False if the parameter is not numeric or if the rule containing the action is not bound to a Page object of the Document Hierarchy. Otherwise, True.

Level

Page level only.

Details

Resolves differences in the dpi (dots per inch) resolutions along the horizontal (X) and vertical (Y) planes of one or more faxed images in a batch.

The action selects images from the batch in response to the parameter you enter, and produces new images with 200 x 200 dpi.

Example

```
EqualizeUnbalanceImage (0)
```

Parent topic: [Equalize actions](#)

Ewsmail actions

Use the Ewsmail actions to import image file attachments from an Exchange Server into the current batch by using Exchange Web Service (EWS).

Important: If any concurrently running threads might be using the same mail account, your Ewsmail-related tasks cannot be run in a multi-threaded configuration. Instead, use single-threaded tasks only. For information about configuring threads in Rulerunner, see [Rulerunner thread configuration](#). For information about the mail account, see [ex_login](#).

The `ex_scan` action polls the Exchange Server and imports image attachments until the batch reaches the specified size (`ex_max_docs`) or until the wait time (`ex_wait_time`) expires.

- [ex_abort_time](#)
Specifies how long to wait before you stop running the current batch if, for example, the Exchange Server is unavailable.
- [ex_done_folder](#)
Specifies the mailbox subfolder to which email messages are moved after the attachment was imported.
- [ex_EMLOption](#)
Creates a one page document per email containing an .eml file.
- [ex_ews_version](#)
Select the Exchange Server version.
- [ex_HTTP_timeout](#)
Specifies the maximum time to wait for an HTTP request or response from Exchange Server.
- [ex_load_properties_option](#)
Option to flag .
- [ex_login](#)
Specifies the Exchange Server and mail account
- [ex_logout](#)
Disconnect from the mail server
- [ex_max_docs](#)
Specifies maximum number of emails to include in a single batch.
- [ex_problem_folder](#)
Specifies folder for problem emails
- [ex_scan](#)
Poll the specified mail server for incoming email with image attachments
- [ex_types](#)
Specifies valid image attachment extensions
- [ex_wait_time](#)
Specifies the maximum time to wait for input emails for a single batch.

Parent topic: [Global actions](#)

ex_abort_time

Specifies how long to wait before you stop running the current batch if, for example, the Exchange Server is unavailable.

Member of namespace

Ewsmail

Syntax

```
bool ex_abort_time (int nSecs)
```

Parameters

nSecs
Type: int

Parameters

nSecs : The number of seconds to wait.

Returns

Always True.

Level

Batch level.

Details

The action will wait the specified time before returning when an abort occurs. This action can be useful to prevent a large number of aborted batches due to an abort condition. For example, if the email server should become unavailable for a time, the abort timeout will limit the amount of aborted batches until the mail server becomes available again.

If this action is not called, the default value of 30 seconds will be used.

Example:

```
ex_wait_time("20")  
ex_abort_time("60")  
ex_max_docs("200")  
ex_scan
```

Parent topic: [Ewsmail actions](#)

Related reference:

[ex_scan](#)

ex_done_folder

Specifies the mailbox subfolder to which email messages are moved after the attachment was imported.

Member of namespace

Ewsmail

Syntax

```
bool ex_done_folder (string folder)
```

Parameters

folder
Type: string
Destination folder for successfully imported emails

Parameters

folder : Destination folder for successfully imported emails

Returns

Always True.

Level

Batch level.

Details

Specifies the name of the email folder into which successfully imported emails are placed. This folder must be a subfolder of the email account's Inbox. When an email is processed and the attachment is imported, the email is moved to the folder name specified by this action.

If this action is not called, the default value of Done is used.

Example:

```
ex_done_folder("Imported")  
ex_problem_folder("Failed")
```

Parent topic: [Ewsmail actions](#)

Related reference:

[ex_scan](#)

ex_EMLOption

Creates a one page document per email containing an .eml file.

Member of namespace

Ewsmail

Syntax

```
bool ex_EMLOption (int folder)
```

Parameters

folder
Type: int
Optional - use a nonzero value to store one .eml file per email.

Parameters

folder : Optional - use a nonzero value to store one .eml file per email.

Returns

Always True.

Level

Batch level.

Details

If set, the `ex_scan` action creates a one page document containing the email and attachments in an .eml file; no attachment pages are created. When called with a non-zero parameter, the `ex_scan` function does not create pages for each attachment, instead one page is created per email document, containing an .eml file suitable for subsequent processing using eDocument Conversion actions.

When you use this action, pages for attachments are not created, and variables for those attachments are not set.

Example:

```
ex_EMLOption(1)
ex_scan()
```

Parent topic: [Ewsmail actions](#)

Related reference:

[ex_scan](#)

ex_ews_version

Select the Exchange Server version.

Member of namespace

Ewsmail

Syntax

```
bool ex_ews_version (int version)
```

Parameters

version

Type: int

Parameters

The value 0, 1 or 2, indicating the following:

- 1 = Exchange 2007 SP1
- 2 = Exchange 2010
- 0 = latest version (default)

Returns

Always True.

Level

Batch level, Open event.

Details

Each version of Exchange uses a slightly different communication protocol. Use this action to set the expected version.

In order to connect successfully with:

- Exchange 2007 SP1, call this action with parameter 1 before `im_login`.
- Exchange 2010, call action with parameter 2 before `im_login`.
- The latest version known by the .NET library in use, which is .NET 3.5 and is currently Exchange 2010. This action must be called with parameter 0.

If this action is not called at all it uses the default 0, the latest version.

Example:

```
ex_ews_version(1)
ex_login("myemailserver/Exchange.asmx", "Username@Org", "password")
```

Parent topic: [Ewsmail actions](#)

Related reference:

[ex_login](#)

ex_HTTP_timeout

Specifies the maximum time to wait for an HTTP request or response from Exchange Server.

Member of namespace

Ewsmail

Syntax

```
bool ex_HTTP_timeout (int nSecs)
```

Parameters

String nSecs

Parameters

nSecs : The maximum number of seconds to wait.

Returns

Always True.

Level

Batch level Open event only.

Details

The maximum time to wait for an HTTP request or response from Exchange Server. For example, this may be used by the `ex_scan` action while trying to ingest a very large email that may otherwise result in import failing due to the operation timing out. This timeout is in addition to any server-side timeout configuration settings.

If this action is not called, the timeout defaults to 100 seconds.

Example:

```
ex_HTTP_timeout("60")
ex_scan()
```

This example causes the timeout to be set to 60 seconds. When ingesting emails, any response exceeding this value may fail.

Parent topic: [Ewsmail actions](#)

Related reference:

[ex_login](#)

[ex_scan](#)

ex_load_properties_option

Option to flag .

Member of namespace

Ewsmail

Syntax

```
bool ex_load_properties_option (int nOption)
```

Parameters

nOption

Type: int

Parameters

nOption : 0 to load base properties, 1 to load limited extended base properties, 2 to load extended properties

Returns

Always True.

Level

Batch level Open event only.

Details

Used to optionally load certain properties at once. If this action is not called, the default of 0 will be used to load base properties.

Example:

```
ex_load_properties_option("1")
ex_scan()
```

This example reduces the number of times you have to access the Exchange Server because the additional properties are loaded once.

Parent topic: [Ewsmail actions](#)

Related reference:

[ex_scan](#)

ex_login

Specifies the Exchange Server and mail account

Member of namespace

Ewsmail

Syntax

```
bool ex_login (string hostname, string username, string password)
```

Parameters

hostname

Type: string

URL of Exchange Web Service, ends with /Exchange.asmx (Smart parameters are supported)

username

Type: string

Username@Org for mail account and organization (blank to use Windows Authentication, Smart parameters are supported)

password

Type: string

Password for mail account (blank if none or Windows Authentication, Smart parameters are supported)

Parameters

- hostname : URL of Exchange Web Service, ends with /Exchange.asmx
- username : Username@Org for mail account and organization (blank to use Windows Authentication)
- password : Password for mail account (blank if none or Windows Authentication)

All parameters support smart parameters.

Returns

True if the login succeeds. Otherwise, False.

Level

Batch level, open event.

Details

Connects to the mail server using the specified account information. Login credentials are for a Microsoft Exchange mail server.

The mail account must contain an Inbox folder and separate folders for messages imported (Done) and errors (Problem). The Done and Problem folders must be subfolders of the email account's Inbox. The names of these folders can be specified using the `ex_done_folder` and `ex_problem_folder` actions.

The Microsoft Exchange Email actions are designed to scan an email Inbox for incoming mail messages, and place selected messages into a new batch. It is possible to ignore all messages except those containing specific attachment types. The actions are typically assigned to a Task that is executed by an unattended Rulerunner station. Multiple Inboxes can be scanned by stringing together a set of login/scan/logout actions for each Inbox, or by assigning an Inbox to each input task.

Example:

```
ex_login("mymailserver/Exchange.asmx", "Username@Org", "password")
```

Parent topic: [Ewsmail actions](#)

Related reference:

[ex_logout](#)

ex_logout

Disconnect from the mail server

Member of namespace

Ewsmail

Syntax

```
bool ex_logout ()
```

Parameters

None.

Returns

Always True.

Level

Batch level Open or Close event only.

Details

Closes the connection to the mail server. Call once for each batch after `ex_login` and `ex_scan` have completed.

Example:

```
ex_logout()
```

Parent topic: [Ewsmail actions](#)

ex_max_docs

Specifies maximum number of emails to include in a single batch.

Member of namespace

Ewsmail

Syntax

```
bool ex_max_docs (int nDocs)
```

Parameters

nDocs

Type: int

The maximum number of emails in a batch.

Parameters

nDocs : The maximum number of emails in a batch.

Returns

Always True.

Level

Batch level Open event only.

Details

The import of emails into the batch will stop when this email limit is reached or when the maximum wait time has been reached. While waiting for new mail to arrive, the configured mailbox will be polled every two seconds to check for waiting mail.

If this action is not called, the default value of 100 is used. The actual amount of emails included in the batch could be less than this maximum.

Note: The value indicates the number of emails with expected attachments that will be processed. If a waiting email contains an unexpected attachment, it is not counted against the total maximum count.

It is also possible for an email to contain more than one valid attachment type. When this happens, it is possible for the number of items input to the batch can be greater than the number of configured emails. For example, if `ex_max_docs` is set to 5 and if there are 5 waiting emails and each email has 2 attachments, the total number of attachments that are included in the batch is 10.

Example:

```
ex_max_docs("50")
ex_scan()
```

This example causes the scan operation to limit the number of emails in a batch to a maximum of 50.

Parent topic: [Ewsmail actions](#)

Related reference:

[ex_scan](#)

ex_problem_folder

Specifies folder for problem emails

Member of namespace

Ewsmail

Syntax

```
bool ex_problem_folder (string folder)
```

Parameters

folder

Type: string

Destination folder for problem email

Parameters

folder : Destination folder for problem email

Returns

Always True.

Level

Batch level.

Details

When an email is processed and the attachment is not one of the expected types, the email is moved to the folder name specified by this action.

This folder must be a subfolder of the email account's Inbox.

If this action is not called, the default value of Problem is used.

Example:

```
ex_done_folder("Imported")
ex_problem_folder("Failed")
```

Parent topic: [Ewsmail actions](#)

Related reference:

[ex_scan](#)

ex_scan

Poll the specified mail server for incoming email with image attachments

Member of namespace

Ewsmail

Syntax

```
bool ex_scan ()
```

Parameters

None.

Returns

False if the operation fails, and the action will also pause before returning based on the configured abort time configured by `ex_abort_time`. Otherwise, True.

If no selected emails were available, the action returns True and also pauses before returning based on the wait time configured using `ex_wait_time`.

Level

Batch level Open event only.

Details

Scans emails in the Inbox for specified attachments, imports selected emails with attachments into the batch. Call once for each batch. A connection to the email server must have previously been established using the `ex_login` action.

Each input email (document) will contain the following variables set in the document hierarchy:

- `TYPE` : Always set to Document.
- `MessageID` : The email message ID.
- `Subject` : The email subject.
- `Body` : The text within the email.
- `DateSent` : The sent date stamp on the email.
- `From` : The email sender.
- `To` : The email recipients.
- `Priority` : The state of the email importance flag.
- `DateReceived` : The received date stamp on the email.

Each email attachment (page) will have the following variables set:

- `TYPE` : Always set to "Other".
- `IMAGEFILE` : The name of the attachment as saved on disk.

- ATTACHNAME : The name of the attachment.

The following batch level variable is created:

- EmailCount : The number of emails scanned into the batch.

Note: If the configured Done or Problem folders do not exist, the email will be moved to the Deleted Items folder.

Waiting emails are processed in blocks. The amount of emails processed in a block will be the number of waiting emails, or the number of emails remaining from the value set in `ex_max_docs`, up to a maximum of 50. After a block of emails are processed, the wait time is checked. If the wait time has not been reached and the maximum number of emails has not been reached, then another block of emails are processed. If the wait time has been reached, then no more emails are input to the batch.

It is recommended that the subject line be no longer than 78 characters as this is a common subject line length limitation. Some systems may support even shorter lengths, truncating the subject. Our testing has been successful with lengths up to 255 characters. It is recommended to test your settings and use lengths appropriate for your systems.

Use `ex_max_docs` to configure the number of emails processed per batch. The number of items included in the batch can be different than this amount, see `ex_max_docs` for more details.

Example:

```
ex_wait_time("20")
ex_abort_time("40")
ex_max_docs("50")
ex_types("jpg,tif")
ex_scan()
```

Parent topic: [Ewsmail actions](#)

Related reference:

[ex_login](#)

[ex_wait_time](#)

[ex_max_docs](#)

ex_types

Specifies valid image attachment extensions

Member of namespace

Ewsmail

Syntax

```
bool ex_types (string extensions)
```

Parameters

extensions

Type: string

Comma-separated list of file image file attachment extensions to import, with or without period. If a blank extension is supplied, `ex_scan` will import messages with no attachments.

Parameters

extensions : A comma-separated list of file image file attachment extensions to import, with or without period. If a blank extension is supplied, ex_scan will import messages with no attachments.

Returns

Always True.

Level

Batch level.

Details

This action specifies the allowable email attachment types.

If this action is not called, the default value of .pdf is used.

If this action is called and no attachment types are specified, all emails and any attachments are added to the batch.

If attachment types are specified and the email contains:

- Only the specified attachment types, the email and attachments are added to the batch
- Only unspecified attachment types, or if it contains a mix of specified and unspecified attachment types, the email is moved to the Problem folder
- No attachments, the email is moved to the Problem folder

Example:

```
ex_wait_time("20")
ex_abort_time("40")
ex_max_docs("200")
ex_types("jpg,tif")
```

Parent topic: [Ewsmail actions](#)

ex_wait_time

Specifies the maximum time to wait for input emails for a single batch.

Member of namespace

Ewsmail

Syntax

```
bool ex_wait_time (int nSecs)
```

Parameters

nSecs

Type: int

Parameters

nSecs : The maximum number of seconds to wait.

Returns

Always True.

Level

Batch level Open event only.

Details:

The maximum time to wait for input files for a single batch. Used by the `ex_scan` action after the first email has been processed to determine how long to wait for the batch to fill up.

The import of emails into the batch will stop when the wait limit is reached or when the maximum emails per batch has been reached. While waiting for new mail to arrive, the mailbox will be polled every two seconds to check for waiting mail. The action will continue to include new emails into the batch until this wait time is reached or the maximum number of emails per batch is reached.

If this action is not called, the default wait time of 5 seconds will be used.

Example:

```
ex_wait_time("20")
ex_scan()
```

This example causes the scan operation to wait for 20 seconds for additional email, after processing the first email, before finishing the scan operation.

[ex_scan](#)

Export actions

Use the Export actions to set up and write information to the export text file.

The Export actions can setup lineitem values, batch, document and page variables, path locations, before exporting the information.

- [BatchVariable_ExportValue](#)
Exports the value contained in the specified batch-level variable.
- [BlankFields](#)
Inserts n blank fields into the Export file, adjacent to the current field.
- [BlankLines](#)
Inserts n blank lines into the Export file.
- [BPilot](#)
Exports the value assigned to the Batch Pilot property designated as the parameter.
- [CloseExportFile](#)
Closes the currently opened Export file.

- [DCOProperty](#)
Exports the value assigned to the DCO property that you designate as the parameter.
- [DocumentVariable_ExportValue](#)
Exports the value that is contained in the specified Document-level variable.
- [ExportAllFields](#)
Exports all field values on the current page, including values of Line Item Detail sub-fields - with exceptions.
- [ExportFieldValue](#)
Exports the specified Field object's value to the Export file.
- [ExportMYValue](#)
Exports the current field value to the Export file.
- [ExportSmartParameter](#)
Exports an evaluated smart parameter value to the Export file.
- [ExportToBatchDir](#)
Specifies that the path for the current Export file (txt) is the Batch directory.
- [Filler](#)
Adds a string of identical filler characters to the Export.
- [FixedLenLJ](#)
Exports a specified number of characters from a field's left end (left-justified).
- [FixedLenRJ](#)
Exports a specified number of characters from a field's right end (right-justified).
- [GetDATE](#)
Exports today's Date in the format specified as the parameter.
- [GetProfileString](#)
Accesses a Settings file (.ini) and adds a value in that file to your Export file.
- [GetTime](#)
Exports the current Time in the format specified as the parameter.
- [LineItem_AddElement](#)
Includes the specified Line Item Field object as an element of a Line Item Array.
- [LineItem_BlankFields](#)
Includes the specified number of blank fields as elements of a Line Item Array.
- [LineItem_ClearElements](#)
Clears values in the Line Item Array.
- [LineItem_ExportElements](#)
Exports the captured values in a page's Line Item Array that have been populated with LineItem_AddElement actions.
- [LineItem_SmartParameter](#)
Add a smart parameter algorithm as an element of a Line Item Array.
- [NewLine](#)
Starts a new line in your Export file.
- [PageVariable_ExportValue](#)
Exports runtime values assigned to a variable of the bound Page object of the Document Hierarchy.
- [ResetFieldVariables](#)
Resets the variables of the bound Field object of the Document Hierarchy.
- [SaveFilePathAsVariable](#)
Saves the path and name of your Export file to the variable specified by the parameter.
- [SetCSV](#)
Ensures that all exported values are delimited by a comma separator.
- [SetElementSeparator](#)
Ensures that all exported values are delimited by a separator designated as the parameter.
- [SetExportFileEncodingAsASCII](#)
Determines if the Export file is created with ASCII or UNICODE encoding.

- [SetExportPath](#)
Specifies the path to the Export file's location. Alternatively, you can use a Smart Parameter to identify a Paths.ini file that has a set of path parameters for your application.
- [SetExtensionName](#)
Assigns an extension to the current Export file.
- [SetFileName](#)
Assigns a name to the current Export file.
- [SetFill](#)
Sets the filler character to be used to expand the current value of a field in a flat file, if the field's allowable length is greater than the length of its current export value.
- [SetFixedLength](#)
Uses the Numeric value you enter as a parameter to establish a fixed length of a value exported from the current field.
- [SetIgnoreFieldStatus](#)
Assigns a Numeric value to the application's SetIgnoreStatus variable. Any field with this status cannot export data to an Export file or database.
- [SetJustified](#)
Right-justifies or left-justifies a field's exported values.
- [SetOMR_Separator](#)
For multi-punch OMR fields, uses the parameter's value as the separator character.
- [SetSpaceFill](#)
Specifies the use of the ASCII 32 space as the global filler value to be used to expand the current value of a field in a flat file, if the field's allowable length is greater than the length of its current export value.
- [SetZeroFill](#)
Sets the ASCII 48 zero as the global filler value to be used to expand the current value of a field in a flat file, if the field's allowable length is greater than the length of its current export value.
- [Text](#)
Places a string into the Export file.
- [Variable_ExportValue](#)
Exports the value assigned to a variable of the current object of the Document Hierarchy.
- [Variable_IsValue](#)
Checks to see if the parameter value matches the value assigned to a variable of the current object of the Document Hierarchy.

Parent topic: [Global actions](#)

BatchVariable_ExportValue

Exports the value contained in the specified batch-level variable.

Syntax

```
bool BatchVariable_ExportValue (StrParam)
```

Parameters

The name of the Batch variable.

Returns

Always True.

Level

Any level.

Details

Exports the value contained in the specified batch-level variable.

Example

```
BatchVariable_ExportValue("ED")
```

This action will export the value located in the ED Batch variable to your Export file.

Parent topic: [Export actions](#)

BlankFields

Inserts n blank fields into the Export file, adjacent to the current field.

Syntax

```
bool BlankFields (StrParam)
```

Parameters

A number indicating how many blank fields to add to the Export file.

Returns

Always True.

Level

All levels.

Details

The BlankFields action adds the number of fields you specify. The fields are blank; other actions direct the Export task to fill the fields.

Attention: Make sure you call SetCSV, and optionally SetElementSeparator, to set the separator values as desired for your export file. If either of these actions are not called before the BlankFields action, blank fields cannot be exported into the file because the default separator is set to no separator.

Example

```
SetCSV("TRUE")  
BlankFields("12")
```

Parent topic: [Export actions](#)

Related reference:

[SetCSV](#)

[SetElementSeparator](#)

BlankLines

Inserts n blank lines into the Export file.

Syntax

```
bool BlankLines (StrParam)
```

Parameters

A number n that indicates how many blank lines to add after the current line.

Returns

Always True.

Level

All level.

Details

Inserts n blank lines into the Export file.

Example

```
BlankLines ("4")
```

This action inserts four empty lines, leaving the insertion point for the next output on the following line. Additional output begins on the fifth line.

Parent topic: [Export actions](#)

Related reference:

[NewLine](#)

BPilot

Exports the value assigned to the Batch Pilot property designated as the parameter.

Syntax

```
bool BPilot (StrParam)
```

Parameters

The name of the Batch Pilot Property whose value is to be included in the Export file.

- BatchDir: The name and location of the application's Batches directory.
- BatchID: The Batch Number of the current batch (20020072.003, for example.)
- JobName: The name of the current User Application job (Main, for example.)
- Operator: The User ID of the operator currently processing the batch.
- PagesInBatch: A count of all pages in the batch.
- DocsInBatch: A count of all documents in the batch. Remember: in most configurations, a Recognition task reorganizes a batch into a series of documents and their pages.
- Priority: The processing priority assigned to the current batch ("10" = Low, "1" = High, "5" = Default). A task selects batches from its queue first according to Priority.

- **Station:** The Station ID of the workstation currently processing the batch.
- **TaskName:** The name of the task with the batch in its queue.
- **XtraBatchFieldValue:** The value in a custom field you've added to the Job Monitor's Batch Information Table.

Returns

False if the parameter is not a Batch Pilot property. Otherwise, True.

Level

Any level.

Details

Exports the value assigned to the Batch Pilot property that designated as the parameter.

Example

```
NewLine ()
Text ("BatchID:")
BPilot ("BatchID"
```

This sequence adds "BatchID:" followed by the current Batch ID into the Export file. For example:
BatchID: 20050019.001

Parent topic: [Export actions](#)

CloseExportFile

Closes the currently opened Export file.

Syntax

```
bool CloseExportFile ()
```

Parameters

None.

Returns

Always True.

Level

Any level.

Details

Closes the currently opened Export file.

This action usually belongs to its own RuleSet (ExportClose, for example), and applies to the Batch object of the Document Hierarchy. However, it can be used at any level.

Example

```
CloseExportFile()
```

Parent topic: [Export actions](#)

Related reference:

[SetFileName](#)

DCOProperty

Exports the value assigned to the DCO property that you designate as the parameter.

Syntax

```
bool DCOProperty (StrParam)
```

Parameters

The name of the DCO Property whose value is to be included in the Export file.

- **ID:** The value of an object's ID property. For a Batch object, this might be 20020072.003. You can apply this action at any level(s).
- **ImageName:** The name and location of a Page object's Image file: for example, c:\ParentDirectory\Invoices\batches\20030145.001\TM000001.tif.
- **Status:** The value assigned to an object's Status property. You can apply this action at any level(s).
- **Type:** The value assigned to an object's Type property. You can apply this action at any level(s).

Returns

False if the parameter is not a valid DCO Property. Otherwise, True.

Level

All levels.

Details

Exports the value assigned to the DCO Property that you designate as the parameter.

Example

```
NewLine()  
Text("Document: ")  
DCOProperty("ID")
```

If this sequence is applied to a Document object, the Export file for document 01 in batch 20050219.057 will look like: Document: 20050219.057.01.

Parent topic: [Export actions](#)

[BPilot](#)

DocumentVariable_ExportValue

Exports the value that is contained in the specified Document-level variable.

Syntax

```
bool DocumentVariable_ExportValue (StrParam)
```

Parameters

Document Variable Name.

Returns

Always True.

Level

Document, Page or Field level.

Details

Exports the value that is contained in the specified Document-level variable.

Example

A number of techniques can add variables to a Document object of the Document Hierarchy. These variables are listed as properties of the object in the Document Hierarchy Setup window.

The following example reads the value that is assigned to the *PageCount Document* variable and places it in the Export file.

```
DocumentVariable_ExportValue ("PageCount")
```

Parent topic: [Export actions](#)

ExportAllFields

Exports all field values on the current page, including values of Line Item Detail sub-fields - with exceptions.

Syntax

```
bool ExportAllFields ()
```

Parameters

None.

Returns

False, if the action is not used at the Page level. Otherwise, True.

Level

Page level.

Details

This action exports all field values of the current page. However, the action does not export those values of Field objects of the Document Hierarchy with:

1. A setup *NOEXPORT* variable of "1", or
2. A value of a runtime SetIgnoreStatus, a field status equal to the Numeric field status defined by a previously-run SetIgnoreFieldStatus action. For details, see the description of that action.

Example

```
ExportAllFields ()
```

Parent topic: [Export actions](#)

ExportFieldValue

Exports the specified Field object's value to the Export file.

Syntax

```
bool ExportFieldValue (StrParam)
```

Parameters

The name of the Field object whose value you want to export.

Returns

False if the parameter is not a Field object's name. Otherwise, True.

Level

Page level.

Details

Exports the specified Field object's value to the Export file. Will only export the last Field if multiple fields of the same field type are found.

Example

```
ExportFieldValue ("Date")  
ExportFieldValue ("Number")  
ExportFieldValue ("Total")
```

This sequence exports the current values stored in the Date, Number and Total fields.

Parent topic: [Export actions](#)

ExportMYValue

Exports the current field value to the Export file.

Syntax

```
bool ExportMYValue ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Exports the current field value to the Export file.

Example

```
ExportMYValue ()
```

Parent topic: [Export actions](#)

ExportSmartParameter

Exports an evaluated smart parameter value to the Export file.

Syntax

```
bool ExportSmartParameter (StrParam)
```

Parameters

The value to export expressed with smart parameter syntax.

Returns

Always True.

Level

Any level.

Details

Exports an evaluated smart parameter value to the Export file. If the input parameter is not a smart parameter, it will export an empty field.

Example

The example will export the value of a variable named *Expired* on field *DueDate* which is a child field on the parent page (@P) of the calling node.

```
ExportSmartParameter("@P\DueDate.Expired")
```

Parent topic: [Export actions](#)

Related reference:

[SetCSV](#)

[SetElementSeparator](#)

ExportToBatchDir

Specifies that the path for the current Export file (txt) is the Batch directory.

Syntax

```
bool ExportToBatchDir ()
```

Parameters

None.

Returns

False, if the Batch Directory is not accessible. Otherwise, True.

Level

All levels.

Details

This action sets the path for the Export file to the current Batch directory.

Attention: Usually, an Export file is placed in the application's Export folder instead of in a Batch folder of the Batch directory.

Example

```
ExportToBatchDir ()
```

Parent topic: [Export actions](#)

Related reference:

[SetExportPath](#)

Filler

Adds a string of identical filler characters to the Export.

Syntax

```
bool Filler (StrParam)
```

Parameters

Two comma-separated values. The first is a number indicating the total length in characters of the filler. The second parameter is the filler's character.

The second parameter is optional: if you do not enter a value, the action will use the most recent Global character setting.

Returns

False if the first parameter is not numeric or if the second parameter is more than 1 character. Otherwise, True.

Level

All levels.

Details

Adds a single filler character to the Export, repeated by the number of times indicated in the first input parameter. The second parameter cannot be a space. The filler string is written regardless of the data in the current field. If you wish to use a space as a filler character, use `SetSpaceFill` and then call `Filler` without the optional second parameter.

Example

```
Filler("12,n")
```

The action in the example fills the current field with 12 instances of the character "n".

Parent topic: [Export actions](#)

FixedLenLJ

Exports a specified number of characters from a field's left end (left-justified).

Syntax

```
bool FixedLenLJ (StrParam)
```

Parameters

Two comma-separated values.

1. The field's name: The name of the corresponding Field object of the Document Hierarchy.
2. The number of characters that are to be exported, counting from the field's left end.

Returns

False, if either parameter is invalid or if the action is called at the wrong level. Otherwise, True.

Level

Page level.

Details

This action is similar to the FixedLenRJ. It exports a specified number of characters from a field's left end (left-aligned).

Example

```
FixedLenLJ("Volume, 8")
```

Parent topic: [Export actions](#)

FixedLenRJ

Exports a specified number of characters from a field's right end (right-justified).

Syntax

```
bool FixedLenRJ (StrParam)
```

Parameters

Two comma-separated values.

1. The field's name: The name of the corresponding Field object of the Document Hierarchy.
2. The number of characters that are to be exported, counting from the field's right end.

Returns

False, if either parameter is invalid or if the action is called at the wrong level. Otherwise, True.

Level

Page level.

Details

Similar to the FixedLenLJ action, this action exports a specified number of characters from a field's right end (right-aligned).

Example

The following example exports 12 characters from the right end of the InvoiceDate field.

```
FixedLenRJ("InvoiceDate, 12")
```

Parent topic: [Export actions](#)

GetDATE

Exports today's Date in the format specified as the parameter.

Syntax

```
bool GetDATE (StrParam)
```

Parameters

The Date's format.

"*" stipulates the default mm/dd/yyyy construction. However, you can combine any of the following String values to define a different format:

-
- d = day of the month, 1-31
- dd = two-digit day, 01-31
- yyyy = four-digit year
- yy = two-digit year
- m = month, 1-12
- mm = two-digit month, 01-12
- ccyy = four-digit year
- y = Julian day of the year

"." and "/" are valid separators.

Returns

Always True.

Level

All levels.

Details

Exports today's Date in the format specified as the parameter.

Example

```
GetDate("*") inserts today's date into the Export file with this format:  
11/16/2005
```

Parent topic: [Export actions](#)

Related reference:

[GetTime](#)

GetProfileString

Accesses a Settings file (.ini) and adds a value in that file to your Export file.

Syntax

```
bool GetProfileString (StrParam)
```

Parameters

1. The [Section] within the Settings file.
2. The Key entry within the section, with the value you want to retrieve.
3. The name of the Settings file.

Returns

False if the settings file cannot be found. Otherwise, True. If the settings file can be found but the key entry cannot be found within the file, this action will return True.

Level

All levels.

Details

Accesses a Settings file (.ini), locates the specified key and adds the value of the key to your Export file. If the key cannot be read from the settings file, an empty string will be written to the export. If the settings file cannot be found, nothing will be written to the export.

Important: The action assumes that the Settings file resides in the current batch directory. If you want the INI file to reside in the Batches directory, specify your file name with a relative path like this: ..\myfile.ini.

Example

```
GetProfileString("General,MyValue,Batch.ini")
```

Parent topic: [Export actions](#)

GetTime

Exports the current Time in the format specified as the parameter.

Syntax

```
bool GetTime (StrParam)
```

Parameters

The parameter specifies the display format for the current time.

* = A single asterisk will use the HH:MM:SS time format. However, you can combine any of the following String values to define a different format:

-
- m = minute 1-59
- s = second 1-59
- h = 1-23
- mm, min, minute = two-digit minute, 01-59
- ss, sec, second = two-digit second, 01-59
- hh, hr, hour = two-digit hour, 01-23

"/"- are the valid separators.

Returns

Always True.

Level

Any level.

Details

Exports the current Time in the format specified by the input parameter.

Example

```
GetTime("*")
inserts the current time into the Export file with this format: 07:08:16

GetTime("hh-mm-ss")
inserts the current time into the Export file with this format: 07-08-16

GetTime("ss:mm:hh")
inserts the current time into the Export file with this format: 16:08:07
```

Parent topic: [Export actions](#)

[GetDATE](#)

LineItem_AddElement

Includes the specified Line Item Field object as an element of a Line Item Array.

Syntax

```
bool LineItem_AddElement (strParam)
```

Parameters

The name of the child Field object of the Document Hierarchy.

Returns

Always True.

Level

The parent field that contains the child Line Item field.

Details

This action includes the specified Line Item field object as an element of a Line Item Array.

A Line Item Array accumulates and organizes captured line item values that are retrieved from the Data file of a particular page.

Note: A rule that uses this action must be applied to the LINEITEM fields of the Document Hierarchy.

This action is used for exporting Line Item values.

Example

The following action expands the Line Item Array by one field: Price.

LineItem_ExportElements populates this element and other elements of the array with the captured values that it finds in a page's Data file before exporting them.

```
LineItem_AddElement("Price")
LineItem_ExportElements()
```

Parent topic: [Export actions](#)

Related reference:

[LineItem_BlankFields](#)

[LineItem_ClearElements](#)

[LineItem_ExportElements](#)

LineItem_BlankFields

Includes the specified number of blank fields as elements of a Line Item Array.

Syntax

```
bool LineItem_BlankFields (strParam)
```

Parameters

The number of Blank fields to export as part of the Line Item Array.

Returns

Always True.

Level

The parent field that contains the child Line Item field.

Details

This action includes the specified number of Blank Line Item fields as elements of a Line Item Array.

A Line Item Array accumulates and organizes captured line item values that are retrieved from the Data file of a particular page.

Attention: A rule that uses this action must be applied to the LINEITEM fields of the Document Hierarchy.

This action is used for exporting Blank Line Item values.

Example

The following action expands the Line Item Array by six blank fields.

LineItem_ExportElements populates this element and other elements of the array with the captured values that it finds in a page's Data file before exporting them.

```
LineItem_BlankFields("6")
```

Parent topic: [Export actions](#)

Related reference:

[LineItem_AddElement](#)

[LineItem_ClearElements](#)

[LineItem_ExportElements](#)

[LineItem_SmartParameter](#)

LineItem_ClearElements

Clears values in the Line Item Array.

Syntax

```
bool LineItem_ClearElements ()
```

Parameters

None

Returns

Always True.

Level

The parent Field object of the Document Hierarchy that contains a child Line Item field, such as you may typically find in an invoice application.

Details

This is mainly a housekeeping function you can use to be sure the array does not contain leftover values.

Example

```
LineItem_ClearElements ()
```

Parent topic: [Export actions](#)

Related reference:

[LineItem_AddElement](#)

[LineItem_BlankFields](#)

[LineItem_ExportElements](#)

[LineItem_SmartParameter](#)

LineItem_ExportElements

Exports the captured values in a page's Line Item Array that have been populated with LineItem_AddElement actions.

Syntax

```
bool LineItem_ExportElements ()
```

Parameters

None.

Returns

Always True.

Level

The parent field that contains the child Line Item sub-fields.

Details

Exports the captured values in a page's Line Item Array that have been populated with `LineItem_AddElement` actions.

Example

```
LineItem_AddElement("Price")
LineItem_AddElement("LineTotal")
LineItem_ExportElements()
NewLine()
```

This example exports the values included in the Line Item Array to your Export file.

Parent topic: [Export actions](#)

Related reference:

[LineItem_AddElement](#)

[LineItem_BlankFields](#)

[LineItem_ClearElements](#)

[LineItem_SmartParameter](#)

LineItem_SmartParameter

Add a smart parameter algorithm as an element of a Line Item Array.

Syntax

```
bool LineItem_SmartParameter (strParam)
```

Parameters

Smart Parameter to be evaluated during processing of the Line Item array.

Returns

Always True.

Level

The parent field that contains the child Line Item field.

Details

This action permits adding a smart parameter as an element of a Line Item Array to be evaluated during the Array processing.

A Line Item Array accumulates and organizes captured line item values that are retrieved from the Data file of a particular page.

Important: A rule that uses this action must be applied to the LINEITEM fields of the Document Hierarchy.

This action is used for exporting Blank Line Item values.

Example

The following action places a child field Price of the calling field node (@F) appended with the current time in format HH:MM:SS to the export file.

LineItem_ExportElements populates this element and other elements of the array with the captured values that it finds in a page's Data file before exporting them.

```
LineItem_SmartParameter("@F\Price+@TIME (HH:MM:SS) ")  
LineItem_ExportElements()
```

Parent topic: [Export actions](#)

Related reference:

[LineItem_AddElement](#)

[LineItem_BlankFields](#)

[LineItem_ClearElements](#)

[LineItem_ExportElements](#)

NewLine

Starts a new line in your Export file.

Syntax

```
bool NewLine ()
```

Parameters

None.

Returns

Always True.

Level

Any level.

Details

Starts a new line in your Export file.

Example

```
NewLine()  
Text("Export Output")
```

This sequence starts a new line and adds "Export Output" to the beginning of the line.

Parent topic: [Export actions](#)

Related reference:

[BlankLines](#)

PageVariable_ExportValue

Exports runtime values assigned to a variable of the bound Page object of the Document Hierarchy.

Syntax

```
bool PageVariable_ExportValue (StrParam)
```

Parameters

String value of the variable's name.

Returns

Always True.

Level

Page level.

Details

Exports runtime values assigned to a variable of the bound Page object of the Document Hierarchy.

Example

```
PageVariable_ExportValue ("TemplateID")
```

Parent topic: [Export actions](#)

ResetFieldVariables

Resets the variables of the bound Field object of the Document Hierarchy.

Syntax

```
bool ResetFieldVariables ()
```

Parameters

None.

Returns

Always True.

Level

Any level.

Details

This action resets some of the export settings that can be independently set by other actions.

- The default field fill character is reset to a space.
- Field alignment is reset to left.
- The ignore field status is reset to not ignore any fields that are based on the status.
- Fields are no longer set to a specific length.

Example

```
ResetFieldVariables()
```

Parent topic: [Export actions](#)

Related reference:

[SetFixedLength](#)

[SetJustified](#)

[SetZeroFill](#)

[SetFill](#)

[SetSpaceFill](#)

[SetIgnoreFieldStatus](#)

SaveFilePathAsVariable

Saves the path and name of your Export file to the variable specified by the parameter.

Syntax

```
bool SaveFilePathAsVariable (strparam)
```

Parameters

Variable name specifying where the Export file name and path will be stored.

Returns

Always True.

Level

All levels.

Details

Saves the path and name of your Export file to the variable specified by the parameter. If the variable does not exist, it will be created.

Example

```
SaveFilePathAsVariable("Export_File")
```

Parent topic: [Export actions](#)

SetCSV

Ensures that all exported values are delimited by a comma separator.

Syntax

```
bool SetCSV (StrParam)
```

Parameters

TRUE or ON: Enables CSV formatted output using a comma separator.

FALSE: Uses a custom separator, as set by `SetElementSeparator()`, between output fields.

OFF: Causes no separator to be placed between output fields.

Smart parameters are supported.

Returns

Always True.

Level

All levels.

Details

Ensures that all exported values are delimited by a comma separator.

Example

```
SetCSV("TRUE")
ExportFieldValue("Date")
ExportFieldValue("Number")
ExportFieldValue("Total")
SetCSV("FALSE")
```

This sequence will export the captured values of the Date, Number, and Total Field objects into your Export file. A comma will be added after each value to separate the fields.

Parent topic: [Export actions](#)

Related reference:
[SetElementSeparator](#)

SetElementSeparator

Ensures that all exported values are delimited by a separator designated as the parameter.

Syntax

```
bool SetElementSeparator (StrParam)
```

Parameters

The input parameter can be one of the following:

- A field separator character: Uses the provided custom character as the separator between fields. Smart parameters are supported.

- ON or TRUE: Sets the field element separator to a single space. This is the default value.
- OFF or FALSE: No separator will be placed between fields.

Smart parameters are supported.

Returns

Always True.

Level

All levels.

Details

Ensures that all exported values are delimited by a separator designated as the parameter.
Attention: If you wish to set your own custom separator, `SetCSV(FALSE)` must be called prior to exporting fields. If `SetCSV(FALSE)` is not called, then your custom element separator will not be used for export.

Example

```
SetCSV("FALSE")
SetElementSeparator("|")
```

This action uses "|" to delimit the Export file's values.

```
SetElementSeparator("Off")
```

Turns off the action.

Parent topic: [Export actions](#)

Related reference:

[SetCSV](#)

SetExportFileEncodingAsASCII

Determines if the Export file is created with ASCII or UNICODE encoding.

Member of namespace

Export

Syntax

```
bool SetExportFileEncodingAsASCII (string ASCIIEncoding)
```

Parameters

- True - Create Export files with ASCII encoding.
- False - Create Export files with UNICODE encoding (Default)

Smart parameters are supported.

Returns

Always True.

Level

Any.

Details

Determines if the Export file is created with ASCII or UNICODE encoding.

Note: This action must be called before any actions that physically write to and create the Export file. If not called, then the file is created with UNICODE encoding.

Example:

```
SetExportFileEncodingAsASCII ("True")
```

Parent topic: [Export actions](#)

SetExportPath

Specifies the path to the Export file's location. Alternatively, you can use a Smart Parameter to identify a Paths.ini file that has a set of path parameters for your application.

Syntax

```
bool SetExportPath (strParam)
```

Parameters

The complete path to the application's Export folder. Smart parameters are supported.

Returns

True, if the path specified by the parameter exists. Otherwise, False.

Level

All

Details

The action's parameter specifies the path to the Export file's location, or uses a Smart Parameter to retrieve a path's value from the application's Paths.ini file.

Example

```
SetExportPath ("c:\ParentDirectory\Invoice\Export")
```

```
SetExportPath ("@APPPATH (export) ")
```

In the second example, a smart parameter is used to obtain the location of the Export Directory from the value that is configured in the Application Manager.

Parent topic: [Export actions](#)

SetExtensionName

Assigns an extension to the current Export file.

Syntax

```
bool SetExtensionName (StrParam)
```

Parameters

The file extension you want to use, including the leading period. If you do not want a file extension, do not pass any parameter to this action. Disallowed characters are `*><[]"/\|:?` and control characters.

Smart parameters are supported.

Returns

Always True.

Level

Any level.

Details

Assigns an extension to the current Export file. If this action is not called, the default value of .TXT will be used.

Example

```
SetFileName("Export_+@BATCHID")  
SetExtensionName(".dat")
```

In this example, the Export file will have a .dat extension.

Parent topic: [Export actions](#)

Related reference:

[SetFileName](#)

SetFileName

Assigns a name to the current Export file.

Syntax

```
bool SetFileName (StrParam)
```

Parameters

The file's name (without an extension).

Smart parameters are supported.

Returns

Always True.

Level

All levels.

Details

Assigns a name to the current Export file. If `SetExtensionName` is not called, the file extension defaults to `.TXT`. If you require a different file extension, use `SetExtensionName`.

Example

```
SetFileName("Export_+@BATCHID")  
SetExtensionName(".txt")
```

This sequence establishes a series of Export files with names such as
`Export_20021231.001.txt`
`Export_20021231.002.txt`

In contrast,
`SetFileName("@BATCHID")`
`SetExtensionName(".txt")`

will establish a series of Export files with Batch IDs only:
`20021231.001.txt`
`20021231.002.txt`

Parent topic: [Export actions](#)

Related reference:

[SetExtensionName](#)

SetFill

Sets the filler character to be used to expand the current value of a field in a flat file, if the field's allowable length is greater than the length of its current export value.

Syntax

```
bool SetFill (Strparam)
```

Parameters

Single String character to be used as the filler value.

Returns

False, if more than one character is entered as a parameter. Otherwise, True.

Level

Any level.

Details

Sets the filler character to be used to expand the current value of a field in a flat file, if the field's allowable length is greater than the length of its current export value.

Attention: When using SetFill, the action SetFixedLength, FixedLenRJ or FixedLenLJ must also be used to set the maximum length of the field. You can use SetSpaceFill if you wish to make the filler character a space. Use ResetFieldVariables to clear this setting.

Example

```
SetFixedLength("10")  
SetFill("$")
```

This example sets the fill character to a \$.

Parent topic: [Export actions](#)

SetFixedLength

Uses the Numeric value you enter as a parameter to establish a fixed length of a value exported from the current field.

Syntax

```
bool SetFixedLength (StrParam)
```

Parameters

Numeric value indicating the field's length.

Returns

False if the parameter is not Numeric. Otherwise, True.

Level

Any level.

Details

Uses the Numeric value you enter as a parameter to establish a fixed length of a value exported from the current field.

Use ResetFieldVariables to clear this setting.

Example

```
SetFixedLength("12")
```

Parent topic: [Export actions](#)

Related reference:
[ResetFieldVariables](#)

SetIgnoreFieldStatus

Assigns a Numeric value to the application's SetIgnoreStatus variable. Any field with this status cannot export data to an Export file or database.

Syntax

```
bool SetIgnoreFieldStatus (Strparam)
```

Parameters

A Numeric value that represents the status of fields to be ignored by Export tasks.

Returns

False if the parameter is not Numeric. Otherwise, True.

Level

Any level.

Details

This action establishes the status that determines if an Export task will export a field's value. If the status of the field being exported matches this set value, the field will not be exported.

Use ResetFieldVariables to clear this setting.

Example

```
SetIgnoreFieldStatus ("1")
```

This example ensures that runtime values for fields with a "1" status will not be added to an Export file or update an Export database. (Typically, "1" denotes a problem field.)

Parent topic: [Export actions](#)

SetJustified

Right-justifies or left-justifies a field's exported values.

Syntax

```
bool SetJustified (StrParam)
```

Parameters

An uppercase R (right-align) or L (left-align).

Returns

False, if the parameter is not an "R" or "L". Otherwise, True.

Level

Any level.

Details

Right-justifies or left-justifies a field's exported values according to the parameter you enter.

Use `ResetFieldVariables` to clear this setting. `SetFixedLength` must also be used to set the maximum length of the field.

Example

```
SetFixedLength("10")  
SetJustified("R")
```

Parent topic: [Export actions](#)

SetOMR_Separator

For multi-punch OMR fields, uses the parameter's value as the separator character.

Syntax

```
bool SetOMR_Separator (StrParam)
```

Parameters

The separator character you want to use.

Returns

Always True.

Level

All levels.

Details

For multi-punch OMR fields, uses the parameter's value as the separator character. When multi-punch fields are exported, you typically do not want to use the same separator that you are using for fields as these values are typically all within a single field. This action allows you to specify a custom separator to be used when exporting. If this action is not called, the default value is a space.

Example

```
SetOMR_Separator(";")
```

Parent topic: [Export actions](#)

SetSpaceFill

Specifies the use of the ASCII 32 space as the global filler value to be used to expand the current value of a field in a flat file, if the field's allowable length is greater than the length of its current export value.

Syntax

```
bool SetSpaceFill ()
```

Parameters

None.

Returns

Always True.

Level

Any level.

Details

Specifies the use of the ASCII 32 space as the global filler value to be used to expand the current value of a field in a flat file, if the field's allowable length is greater than the length of its current export value.

If you use `SetSpaceFill`, the action `SetFixedLength`, `FixedLenRJ` or `FixedLenLJ` must also be used to set the maximum length of the field. Use `ResetFieldVariables` to clear this setting.

Example

```
SetSpaceFill ()
```

Note that the action specifies the use of the ASCII 32 "space" as the filler character.

Parent topic: [Export actions](#)

SetZeroFill

Sets the ASCII 48 zero as the global filler value to be used to expand the current value of a field in a flat file, if the field's allowable length is greater than the length of its current export value.

Syntax

```
bool SetZeroFill ()
```

Parameters

None.

Returns

Always True.

Level

Any level.

Details

Sets the ASCII 48 zero as the global filler value to be used to expand the current value of a field in a flat file, if the field's allowable length is greater than the length of its current export value.

SetFixedLength, FixedLenRJ or FixedLenLJ must also be used to set the maximum length of the field. Use ResetFieldVariables to clear this setting.

Example

```
SetFixedLength("10")
SetZeroFill()
```

Note that the action specifies the use of the ASCII 48 "zero" filler.

Parent topic: [Export actions](#)

Text

Places a string into the Export file.

Syntax

```
bool Text (StrParam)
```

Parameters

The string to write to the export file.

Returns

Always True.

Level

Any level.

Details

This action unconditionally adds a string to the export file. No character padding will be performed on this value.

Example

```
SetFileName("Export_+@BatchID")
SetExtensionName(".txt")
Text("This line will appear in the export file.")
```

Parent topic: [Export actions](#)

Variable_ExportValue

Exports the value assigned to a variable of the current object of the Document Hierarchy.

Syntax

```
bool Variable_ExportValue (StrParam)
```

Parameters

The name of the variable with the value you want to export.

Returns

Always True.

Level

Any level.

Details

Exports the value assigned to a variable of the current object of the Document Hierarchy.

Example

```
Variable_ExportValue("ID")
```

This action exports the value assigned to the ID property of the current object of the Document Hierarchy.

Parent topic: [Export actions](#)

Variable_IsValue

Checks to see if the parameter value matches the value assigned to a variable of the current object of the Document Hierarchy.

Syntax

```
bool Variable_IsValue (strParam)
```

Parameters

1. The name of the variable with the value you want to compare.
2. The value you want to match with the variable's value.

Returns

True if the variable's value matches the parameter's value. Otherwise, False.

Level

Any level.

Details

Checks to see if the parameter value matches the value assigned to a variable of the current object of the Document Hierarchy.

Example

```
Variable_IsValue("Invoice, Yes")
```

This action returns True if the value of the current Page object's Invoice variable is Yes.

Parent topic: [Export actions](#)

ExportDB actions

Use the ExportDB actions to set up and write information to an export database. You build the record in memory before you commit it to the database by using AddRecord.

The ExportDB actions open a connection to the database, specify the table to which the data is exported, and write the batch values to the internal data record.

- [AddRecord](#)
Inserts assembled data into the database table specified by a previous SetTableName action.
- [ExportBatchIDToColumn](#)
Exports the current Batch ID to the database column specified by the parameter.
- [ExportCloseConnection](#)
Closes an open connection to your Export database.
- [ExportFieldToColumn](#)
A page-level action that extracts the captured value of a Field object from the Data file of the current page, and specifies its target location within a table of the Export database.
- [ExportNodeXMLToColumn](#)
Exports the value of the XML property of the bound object (node) of the Document Hierarchy to a column of the Export database.
- [ExportOpenConnection](#)
Opens a connection to the database specified as the parameter.
- [ExportPropertyToColumn](#)
Adds the value of a property (variable) of the selected object to a column of the Export database
- [ExportSmartParamToColumn](#)
Adds the evaluated value of a smart parameter to a column of the Export database
- [ExportToColumn](#)
A field-level action that exports the captured value of the current Field object from the page's Data file to a target column within a previously designated table of an open Export database.
- [SetTableName](#)
Sets the name of the table in your database to which the data is to be exported.

Parent topic: [Global actions](#)

AddRecord

Inserts assembled data into the database table specified by a previous SetTableName action.

Syntax

```
bool AddRecord ()
```

Parameters

None.

Returns

False if there is no connection to the database; if an error occurs when the action attempts to add the record to the database; or if a `SetTableName` action was not previously used. Otherwise, True.

Level

All, but generally used at the Page or Field level.

Details

Inserts assembled data into the database table specified by a previous `SetTableName` action.

Important: This action must be placed after earlier actions that gather data, open the database, and access the correct table.

Example:

```
SetTableName("Invoice")
ExportFieldToColumn("VendorID, db_Vendor")
ExportFieldToColumn("Number, db_Number")
ExportFieldToColumn("Total, db_Total")
AddRecord()
```

This `ExportDB` rule applies to a Page object of the Document Hierarchy.

The actions open the database and direct the rule's attention to the Invoice table. The rule then sets up a record with three values - Vendor ID, Invoice Number and Total. Afterwards, the `AddRecord` action updates the table with new information.

Note: A return of False means the record may not have been successfully exported, and needs to be followed by a failure check rule that typically would call `SetTaskStatus(0)` (or the runner action `rr_AbortBatch`) to ensure that the batch aborts.

Parent topic: [ExportDB actions](#)

Related reference:

[SetTableName](#)

[ExportFieldToColumn](#)

ExportBatchIDToColumn

Exports the current Batch ID to the database column specified by the parameter.

Syntax

```
bool ExportBatchIDToColumn (strParam)
```

Parameters

Three comma-separated values:

1. The name of the database column that will hold the value.
2. The name of the field whose value will be stored in the column.
3. Optional: Can be set to the numerical value of 1, 2, or 3.

If this parameter is not specified, quotes will be placed around the value in the SQL query to update the table.

Setting the value to 1 causes this action to return False if the Table name is invalid; otherwise the error will not be discovered until the action that performs the DB insert call, such as an AddRecord action, is called. This value would typically only be used in a development environment as it will increase processing time.

Setting this value to 2 allows NULL column values and inserts no quotes around values (for numeric) in the SQL query to update the database.

Setting the value to 3 allows NULL and if the column value is not NULL, the column value will be surrounded in quotes in the SQL query to update the database.

Returns

False if the second parameter is set to "1" and the parameters do not identify a valid database column. Otherwise, True.

Level

All, but generally at the Page or Field level.

Details

Exports the current Batch ID to the database column specified by the parameter. The action also has an optional Style parameter with two values.

Example:

```
SetTableName("Export_Results")
ExportBatchIDToColumn("db_BatchID,1,2")
ExportFieldToColumn("Date,db_Date")
ExportFieldToColumn("Total,db_Total")
AddRecord()
```

Parent topic: [ExportDB actions](#)

Related reference:

[AddRecord](#)

[ExportFieldToColumn](#)

[ExportPropertyToColumn](#)

ExportCloseConnection

Closes an open connection to your Export database.

Syntax

```
bool ExportCloseConnection ()
```

Parameters

None.

Returns

True, even if the connection is already closed.

Level

All, but generally used as part of a separate RuleSet at the Batch level.

Details

Closes an open connection to the previously opened Export database.

Usually, this action is placed in a RuleSet that is separate from the RuleSet that opens the connection and stores the data.

For example this action could be placed into a RuleSet called ExportDBCclose, and attached to a batch level close event which executes after all data has been exported from the batch to the specified database.

Example:

```
ExportCloseConnection()
```

This action closes the previously opened connection to the Export database.

This action is usually part of a separate RuleSet that prevents the need to repeatedly open the connection to the Export database. (You can open the connection once in the first RuleSet, export data from all documents and pages in the batch, then close the connection once in the second RuleSet.)

Parent topic: [ExportDB actions](#)

Related reference:

[ExportOpenConnection](#)

ExportFieldToColumn

A page-level action that extracts the captured value of a Field object from the Data file of the current page, and specifies its target location within a table of the Export database.

Syntax

```
bool ExportFieldToColumn (strParam)
```

Parameters

Three comma-separated values:

1. The name of the field whose value will be stored in the column.
2. The name of the database column that will hold the value.
3. Optional: Can be set to the numerical value of 1, 2, or 3.

If this parameter is not specified, quotes will be placed around the value in the SQL query to update the table.

Setting the value to 1 causes this action to return False if the Table name is invalid; otherwise the error will not be discovered until the action that performs the DB insert call, such as an AddRecord action, is called. This value would typically only be used in a development environment as it will increase processing time.

Setting this value to 2 allows NULL column values and inserts no quotes around values (for numeric) in the SQL query to update the database.

Setting the value to 3 allows NULL and if the column value is not NULL, the column value will be surrounded in quotes in the SQL query to update the database.

Returns

False if:

1. There is no connection to the database.
2. The database column specified as a parameter does not exist.
3. The Field object identified by the parameter does not exist.
4. A SetTableName action was not used previously.

Otherwise, True.

Level

Page level only.

Details

This is a page-level action that extracts the captured value of a Field object from the Data file of the current page, and specifies its target location within a table of the Export database.

Within a rule, this action should run before an AddRecord action, which commits the data to the database.

Example:

```
SetTableName("Export_Results")
ExportFieldToColumn("VendorID,db_Number,2")
ExportFieldToColumn("Date,db_Date")
ExportFieldToColumn("Total,db_Total")
AddRecord()
```

This action exports the captured value of three Field objects from the Data file of the current page, to corresponding columns of the Export_Results table, within the open Export database. It also provides the action with an optional Style value.

Important: Make sure you use the ExportOpenConnection action to establish a connection to your Export database. This is usually accomplished by a rule at the Batch level.

Parent topic: [ExportDB actions](#)

Related reference:

[SetTableName](#)

[ExportToColumn](#)

ExportNodeXMLToColumn

Exports the value of the XML property of the bound object (node) of the Document Hierarchy to a column of the Export database.

Syntax

```
bool ExportNodeXMLToColumn (strParam)
```

Parameters

Three comma-separated values:

1. The smart parameter path to the bound object of the Document Hierarchy. This object's XML property will be added to a designated column of the Export database.
2. The String value of the name of the target column in the Export database. The action will add the value of the calling object's XML property to this column.
3. Optional: Can be set to the numerical value of 1 or 3. If this parameter is not specified, quotes will be placed around the value in the SQL query to update the table.

Setting the value to 1 causes this action to return False if the Table name is invalid; otherwise the error will not be discovered until the action that performs the DB insert call, such as an AddRecord action, is called. This value would typically only be used in a development environment as it will increase processing time.

Setting the value to 3 allows NULL and if the column value is not NULL, the column value will be surrounded in quotes in the SQL query to update the database.

Returns

False if:

1. There is no connection to the database.
2. The column identified by the parameter does not exist.
3. A SetTableName action was not previously used.
4. The smart parameter path does not point to a valid object of the Document Hierarchy.

Otherwise, True.

Level

All, but generally at the Page or Field level.

Details

This action exports the value of the XML property of the bound object (node) of the Document Hierarchy to a column of the Export database.

Example:

```
ExportNodeXMLToColumn("@P\MyField,MYDBCOLUM")
```

Parent topic: [ExportDB actions](#)

ExportOpenConnection

Opens a connection to the database specified as the parameter.

Syntax

```
bool ExportOpenConnection (strParam)
```

Parameters

The Connection String of the target export database. Use Smart parameters to avoid clear text passwords in your application.

Returns

True, if the connection opens. Otherwise, False.

Level

All, but most often used at the Batch level.

Details

Opens a connection to the database specified as the parameter.

A rule that contains this action can apply to any object of the Document Hierarchy, but it is most often used at the batch level.

Example:

```
ExportOpenConnection ("@APPVAR (values/dsn/exportdb:cs) ")
```

Note: This action must come before any other ExportDB actions. This example uses smart parameters to obtain the connection string from the application service where the custom connection string key `exportdb` was created in the Custom Values tab. It provides a single location for the connection string and security for passwords.

Note: If the action is establishing a connection with an Oracle database, or a SQL Server database using SQL Server Authentication, be sure to expand the DSN parameter by adding the correct Provider, user ID and Password. For example:

- Oracle:

```
ExportOpenConnection ("PROVIDER=ODBCORACLE;DSN=1040Look;CATALOG=;DBNTA=;UID=Admin;PWD=Admin;")
```
- SQL Server Authentication:

```
ExportOpenConnection ("PROVIDER=ODBCMSSQL;DSN=1040Look;CATALOG=;DBNTA=;UID=Admin;PWD=Admin;")
```

Note: Although the Oracle and SQL Server examples show the connection string, it is recommended that a smart parameter is used to obtain the connection string from the application service, as shown in the first example, to provide password security and application portability.

Parent topic: [ExportDB actions](#)

Related reference:

[ExportCloseConnection](#)

ExportPropertyToColumn

Adds the value of a property (variable) of the selected object to a column of the Export database

Syntax

```
bool ExportPropertyToColumn (strParam)
```

Parameters

Three comma-separated values:

1. The property name whose value will be stored in the column.
2. The name of the database column that will hold the value.
3. Optional: Can be set to the numerical value of 1, 2, or 3. If this parameter is not specified, quotes will be placed around the value in the SQL query to update the table.

Setting the value to 1 causes this action to return False if the Table name is invalid; otherwise the error will not be discovered until the action that performs the DB insert call, such as an AddRecord action, is called. This value would typically only be used in a development environment as it will increase processing time.

Setting this value to 2 allows NULL column values and inserts no quotes around values (for numeric) in the SQL query to update the database.

Setting the value to 3 allows NULL and if the column value is not NULL, the column value will be surrounded in quotes in the SQL query to update the database.

Returns

False if:

1. There is no connection to the Export database.
2. The column of the database does not exist.
3. The property (variable) identified by the parameter does not exist.
4. A SetTableName action was not used previously.

Otherwise, True.

Level

All, but generally used at the Page or Field level.

Details

Adds the value of a property (variable) of the selected object to a column of the Export database.

Example:

```
SetTableName ("Export_Results")
ExportFieldToColumn ("VendorID, db_Number")
ExportPropertyToColumn ("Status, db_PageStatus, 2")
ExportFieldToColumn ("Total, db_Total")
AddRecord ()
```

This sequence updates the db_PageStatus column of the Export_Results table with the value of the selected object's Status property. It also uses the optional third parameter to define a Style for the action.

Parent topic: [ExportDB actions](#)

Related reference:

[ExportToColumn](#)

[ExportFieldToColumn](#)

[ExportBatchIDToColumn](#)

ExportSmartParamToColumn

Adds the evaluated value of a smart parameter to a column of the Export database

Syntax

```
bool ExportSmartParamToColumn (strParam)
```

Parameters

Three comma-separated values:

1. A smart parameter that specifies the value to be stored into the column.
2. The name of the database column that will hold the value.
3. Optional: Can be set to the numerical value of 1, 2, or 3. If this parameter is not specified, quotes will be placed around the value in the SQL query to update the table.

Setting the value to 1 causes this action to return False if the Table name is invalid; otherwise the error will not be discovered until the action that performs the DB insert call, such as an AddRecord action, is called. This value would typically only be used in a development environment as it will increase processing time.

Setting this value to 2 allows NULL column values and inserts no quotes around values (for numeric) in the SQL query to update the database.

Setting the value to 3 allows NULL and if the column value is not NULL, the column value will be surrounded in quotes in the SQL query to update the database.

Returns

False if:

1. There is no connection to the database.
2. The column identified by the parameter does not exist.
3. A SetTableName action was not previously used.

Otherwise, True.

Level

All, but generally at the Page or Field level.

Details

Using the database opened by an earlier ExportDB action, this action will store a value into the specified column for the current row.

The action allows the input value to be specified with a smart parameter.

Example:

```
ExportSmartParamToColumn("@P\MyField.TYPE,EXPDBCOLUMN")
```

Parent topic: [ExportDB actions](#)

ExportToColumn

A field-level action that exports the captured value of the current Field object from the page's Data file to a target column within a previously designated table of an open Export database.

Syntax

```
bool ExportToColumn (strParam)
```

Parameters

Two comma-separated values:

1. The name of the database column that will hold the value of the current field.
2. Optional: Can be set to the numerical value of 1, 2, or 3. If this parameter is not specified, quotes will be placed around the value in the SQL query to update the table.

Setting the value to 1 causes this action to return False if the Table name is invalid; otherwise the error will not be discovered until the action that performs the DB insert call, such as an AddRecord action, is called. This value would typically only be used in a development environment as it will increase processing time.

Setting this value to 2 allows NULL column values and inserts no quotes around values (for numeric) in the SQL query to update the database.

Setting the value to 3 allows NULL and if the column value is not NULL, the column value will be surrounded in quotes in the SQL query to update the database.

Returns

False if:

1. There is no connection to the database.
2. The column identified by the parameters does not exist.
3. A SetTableName action was not previously used.

Otherwise, True.

Level

Field level only.

Details

This field-level action exports the captured value of the current Field object from the page's Data file to a target column within a previously designated table of an open Export database. Optionally, it can assign a Style to the action.

Example:

```
Batch Level:  
ExportOpenConnection ("@APPVAR(values/dsn/exportdb:cs")  
SetTableName ("Export_Results")
```

```
Current field:  
ExportToColumn ("db_Date, 3")
```

```
Last Field:  
AddRecord ()
```

This example exports the captured value of the Field object to which the rule applies, from the Data file of the current page to the db_Date column of the Export_Results table, within the Export database.

It also uses the second, optional parameter value to assign a Style to the action.

Parent topic: [ExportDB actions](#)

Related reference:

[ExportFieldToColumn](#)

[ExportPropertyToColumn](#)

SetTableName

Sets the name of the table in your database to which the data is to be exported.

Syntax

```
bool SetTableName (strParam)
```

Parameters

Two comma separated parameters:

1. The name of the database table where the exported data will be inserted.
2. Optional: If the numeric value of 1 is specified, the action will immediately check the database to confirm that the supplied table name is valid.

If the table name is not valid, SetTableName will return False. Note that this value causes an extra database call so it is typically specified only during development, not in a production system as it will increase the number of database calls and running time.

If the second parameter is not specified, this action will always return True.

If the specified table name is in valid, an error will be returned when the current row is inserted to the database on the next AddRecord call.

Returns

Returns False only if the first parameter contains an invalid table name and a value of 1 is specified as a second parameter. Otherwise this action always returns True.

Level

All.

Details

Sets the name of the table in your database to which the data is to be exported. This action needs to be used before the AddRecord action.

Example:

```
SetTableName(Export_Results,1)
ExportFieldToColumn(MyDate, db_Date)
AddRecord()
```

Parent topic: [ExportDB actions](#)

Related reference:

[AddRecord](#)

ExportXML actions

Use the ExportXML actions to set up and write information to an export XML file.

The ExportXML actions can create nodes, assign attribute values to nodes, and specify the path to the storage location and the name of the export XML file.

- [xml_CommitNode](#)
Commits (closes) current xml node with the xml tag value of the parameter.
- [xml_NewNode](#)
Creates a child node under the specified parent node, creating the parent node if necessary.
- [xml_SaveFile](#)
Commits all unsaved nodes and saves the XML file to disk. Nodes that were not committed using the [xml_CommitNode](#) action will be committed to the parent node when [xml_SaveFile](#) is called, and will appear subsequent to nodes previously committed using the [xml_CommitNode](#) action.
- [xml_SetAttributeValue](#)
Assigns attributes to a specific node.
- [xml_SetExportPath](#)
Specifies the full path to the directory that will store the export XML file.
- [xml_SetFileEncodingAsASCII](#)
Determines if the Export file is created with ASCII or UNICODE encoding.
- [xml_SetFileName](#)
Specifies the name for the export XML file, which does not include the .xml extension.
- [xml_SetNodeValue](#)
Sets the value of the specified node.

Parent topic: [Global actions](#)

xml_CommitNode

Commits (closes) current xml node with the xml tag value of the parameter.

Syntax

```
bool xml_CommitNode (StrParam)
```

Parameters

String value of the xml Tag. Smart parameters are supported.

Returns

Always True.

Level

All.

Details

This action closes the specified node, which allows a new node with the same tag to be created at the same hierarchical level in the output xml. This action can use Smart Parameters.

Remember: Use of this action can change the expected order of xml nodes as they appear in the final xml, since this action commits the current xml to the parent xml node when it is called. Sibling xml nodes that were not committed using this action are later committed to the parent node when the `xml_SaveFile` action is called, so those xml nodes will appear after nodes previously committed using the `xml_CommitNode` action.

Example

```
xml_CommitNode("LineTotal")
```

Example commits (closes) the current xml node with a `Tag Line Total`.

Parent topic: [ExportXML actions](#)

xml_NewNode

Creates a child node under the specified parent node, creating the parent node if necessary.

Syntax

```
bool xml_NewNode (Strparam)
```

Parameters

Comma-separated String values of:

1. The NodeID (tag name) of a new child node.
2. The NodeID (tag name) of the parent node, if there is a parent.

Smart parameters are supported.

Returns

True, if parent node exists. False, if duplicate root node is declared, or parent NodeID does not exist.

Level

All.

Details

The new NodeID followed by the parent NodeID creates a new Node in the Export XML file. The action can use Smart Parameters.

The first `xml_NewNode` action in a rule set creates the root node of the XML file using the new child NodeID. The parent NodeID must be blank.

Example

```
xml_SetExportPath("C:\ParentDir\APT")
ml_SetFileName("@BATCHID")
xml_NewNode("B")
ml_SetAttributeValue("B, id, @BATCHID")
```

The example starts an export XML file that is named the same as the current batch ID. It has a root node `B` whose `id` is assigned the batch ID. It is expected that more rules continue to build the XML structure. The last action that was called must call `xml_SaveFile` to save the export file to disk.

```
xml_NewNode ("ClaimsData, HCFA")
```

Duplicated NodeIDs cause the previous node of the same ID to commit to its specific parent node and is no longer available for modification. Adding a second child NodeID with the same Tag name of the root node causes the action to return False.

Parent topic: [ExportXML actions](#)

Related reference:

[xml_SaveFile](#)

xml_SaveFile

Commits all unsaved nodes and saves the XML file to disk. Nodes that were not committed using the xml_CommitNode action will be committed to the parent node when xml_SaveFile is called, and will appear subsequent to nodes previously committed using the xml_CommitNode action.

Syntax

```
bool xml_SaveFile ()
```

Parameters

None.

Returns

True if the file is created successfully. Otherwise, False.

Level

Batch, Document or Page level.

Details

You must use this action to complete the creation of the export XML file.

Example

```
xml_SaveFile ()
```

Parent topic: [ExportXML actions](#)

xml_SetAttributeValue

Assigns attributes to a specific node.

Syntax

```
bool xml_SetAttributeValue (StrParam)
```

Parameters

Three comma-separated values:

1. The NodeID.
2. The attribute's name.
3. The value to be assigned to the attribute.

Smart parameters are supported.

Returns

False, if the node does not exist. Otherwise, True.

Level

All.

Details

Sets an attribute value within a specific node in the XML hierarchy.

Example

The following example assigns the current Page's Number field value to the Xpage node's Number attribute.

```
xml_SetAttributeValue ("Xpage, Number, @P\Number")
```

The following example shows how creation of an XML for invoice line items might look.

```
xml_NewNode ("LineItem, Invoice")
xml_SetAttributeValue ("LineItem, id, @ID")
xml_NewNode ("ItemID, LineItem")
xml_SetNodeValue ("ItemID, @F\ItemID")
xml_NewNode ("ItemDesc, LineItem")
xml_SetNodeValue ("ItemDesc, @F\ItemDesc")
xml_NewNode ("Qty, LineItem")
xml_SetNodeValue ("Qty, @F\Qty")
xml_CommitNode ("LineItem")
```

Parent topic: [ExportXML actions](#)

xml_SetExportPath

Specifies the full path to the directory that will store the export XML file.

Syntax

```
bool xml_SetExportPath (strParam)
```

Parameters

Specifies the full path to the directory that stores the export XML file. If this action is not called, the XML file is saved in the batch directory. Smart parameters are supported.

Returns

Always **True**.

Level

All.

Details

This action will only set the path. You will still need to use `xml_SetFileName` to set the name of the export file.

Example

```
xml_SetExportPath("C:\Invoice\ExportXML")
xml_SetFileName("@BatchID")
```

Parent topic: [ExportXML actions](#)

xml_SetFileEncodingAsASCII

Determines if the Export file is created with ASCII or UNICODE encoding.

Member of namespace

ExportXML

Syntax

```
bool xml_SetFileEncodingAsASCII ( string ASCIIEncoding)
```

Parameters

- True - Create Export files with ASCII encoding.
- False - Create Export files with UNICODE encoding (Default)

Smart parameters are supported.

Returns

Always True.

Level

Any.

Details

Determines if the Export file is created with ASCII or UNICODE encoding.

Note: This action must be called before any actions that physically write to and create the Export file. If not called, then the file is created with UNICODE encoding.

Example:

```
xml_SetFileEncodingAsASCII("True")
```

Parent topic: [ExportXML actions](#)

xml_SetFileName

Specifies the name for the export XML file, which does not include the .xml extension.

Syntax

```
bool xml_SetFileName (StrParam)
```

Parameters

The name of the XML export. Smart Parameters are supported.

Returns

Always True.

Level

All.

Details

This action is required to set the name of the XML Export file. This action can be called at any level, but it is usually called at the batch level. If the `xml_SetExportPath` action is not called, the file is saved in the batch folder.

Example

```
xml_SetExportPath("C:\Invoice\ExportXML")
xml_SetFileName("@BatchID")
```

Parent topic: [ExportXML actions](#)

Related reference:

[xml_SaveFile](#)

xml_SetNodeValue

Sets the value of the specified node.

Syntax

```
bool xml_SetNodeValue (StrParam)
```

Parameters

Two comma-separated values:

1. The NodeID.
2. The value to assign to the node.
3. The action defaults the current object's value.

Smart parameters are supported.

Returns

Always True.

Level

All.

Details

Assigns a value to a specific node. The action can use Smart Parameters.

Example

The following example shows how creation of an XML for invoice line items might look.

```
xml_NewNode("LineItem, Invoice")
xml_SetAttributeValue("LineItem, id, @ID")
xml_NewNode("ItemID, LineItem")
xml_SetNodeValue("ItemID, @F\ItemID")
xml_NewNode("ItemDesc, LineItem")
xml_SetNodeValue("ItemDesc, @F\ItemDesc")
xml_NewNode("Qty, LineItem")
xml_SetNodeValue("Qty, @F\Qty")
xml_CommitNode("LineItem")
```

Parent topic: [ExportXML actions](#)

Related reference:

[xml_NewNode](#)

FileIO actions

Use the FileIO actions to do various file system functions.

The FileIO actions can check for available disk space, copy or delete directories, and write file values to a specified variable.

- [CheckFreeDiskSpace](#)
Checks the size of the available disk space.
- [CopyDirectory](#)
Copies a directory and its subdirectories
- [CopyFile](#)
Copies a file.
- [DeleteDirectory](#)
Deletes a directory and optionally deletes subdirectories
- [DeleteFile](#)
Deletes a file.
- [GetFileSize](#)
Obtains the size of a file and stores it in the specified variable.
- [GetProfileString](#)
Reads a key value from a settings file.
- [IsDirectoryPresent](#)
Determines if the specified directory exists and optionally creates it.
- [IsFilePresent](#)
Determines if the specified file exists.

- [IsFileReadOnly](#)
Tests the read only attribute of a file.
- [IsProfilePresent](#)
Tests that a profile exists and that a specific section and key exists within it.
- [Readtextfile](#)
Reads a text file.
- [RenameFile](#)
Renames or moves the specified file.
- [SetFileReadOnly](#)
Sets or removes the read only attribute from a file or set of files.
- [SetProfileString](#)
Writes a value to a profile file, typically called an INI file.
- [SplitFileName](#)
Splits a file name into user specified variables.
- [ZipOcrResults](#)
Creates a .zip file to store recognition results for every page of the document.

Parent topic: [Global actions](#)

CheckFreeDiskSpace

Checks the size of the available disk space.

Member of namespace

FileIO

Syntax

```
bool CheckFreeDiskSpace (string DriveLetter, string Threshold, string  
TargetVariable)
```

Parameters

string DriveLetter

string Threshold

string TargetVariable

Parameters

DriveLetter: The drive letter to test for available disk space. UNC paths are not supported.

Threshold: Optional. The minimum amount of required disk space in bytes. If provided, this value must be a positive integer.

TargetVariable: Optional. The DCO variable to store the value of the available disk space.

Smart parameters are supported for each parameter.

Returns

False If the threshold is specified and the amount of free disk space is less than the specified value. If the target variable is provided but cannot be set or if the drive letter is invalid. Otherwise, True.

Level

Any level.

Details

Checks the available amount of free disk space in bytes.

Example

```
CheckFreeDiskSpace ("D", "1000", "@P.FreeSpace")
```

Checks that the amount of available disk space on drive D is at least 1000 bytes. It also stores the amount of free space in the page level runtime DCO variable *FreeSpace*.

```
CheckFreeDiskSpace ("D", "@B.MyLimit", "")
```

Only checks that the amount of available disk space on drive D is at least as much as the value specified in the batch level variable *MyLimit*.

```
CheckFreeDiskSpace ("D", "", "@P.FreeSpace")
```

Stores only the amount of free space in the page level runtime DCO variable *FreeSpace*.

Parent topic: [FileIO actions](#)

CopyDirectory

Copies a directory and its subdirectories

Member of namespace

FileIO

Syntax

```
bool CopyDirectory (string SourceDirectory, string DestDirectory, bool Recursive)
```

Parameters

SourceDirectory
Type: string
DestDirectory
Type: string
Recursive
Type: bool

Parameters

- SourceDirectory : The path of the directory to copy.
- DestDirectory : The path to the destination directory.

- Recursive : True copies the directory files and subdirectories. False only copies the files in the initial directory.

Smart parameters are supported for the directory paths.

Returns

False if a failure occurs when copying a directory. If some of the files have been copied prior to the failure, those files remain. Otherwise, True.

Level

Any level.

Details

Copies the source directory to the target directory. If the target directory does not exist, it will be created, however the parent directory does need to exist.

Example

```
CopyDirectory("C:\MyDir1\MyDir2", "C:\MyNewDir", True)
```

This example copies MyDir2 and all files and subdirectories to C:\MyNewDir.

Parent topic: [FileIO actions](#)

CopyFile

Copies a file.

Member of namespace

FileIO

Syntax

```
bool CopyFile (string sourcefile, string targetfile, bool overwrite)
```

Parameters

string sourcefile

string targetfile

bool overwrite

Parameters

sourcefile: The name and path of the file to copy. Smart parameters are supported.

targetfile: The target path and file name. Smart parameters are supported.

overwrite: If the target file exists, this parameter determines whether it is overwritten. True overwrites the target file.

Returns

True if the file is successfully copied. Otherwise, False.

Level

All levels.

Details

The file is copied from one location to the specified location. If a file of the same target name exists in the target directory, the overwrite parameter determines whether that file is overwritten by the new file. The output directory must exist for this action to succeed. You can use action `IsDirectoryPresent` to create the target directory.

If target file ends with a backslash, meaning only the target directory is specified, the same file name from the source string is used as the target file.

Because the target file name can be different from the source file, this action allows the copied file to be renamed in one step. If you want to do a "move" operation, call the `DeleteFile` action to remove the source file.

Smart parameters are supported in the source and target file name parameters. DOS * and ? wildcards are not supported.

Example

```
CopyFile("C:\MyFile.txt", "c:\temp\+@BATCHID+.txt", true)
```

This action copies `MyFile.txt` to the temp directory and give it a new name of the current batch ID.

```
CopyFile("@VAR(IMAGEFILE)", "c:\temp\", true)
```

This action copies the file that is specified by the variable `IMAGEFILE` and copies it to the temp directory.

Parent topic: [FileIO actions](#)

DeleteDirectory

Deletes a directory and optionally deletes subdirectories

Member of namespace

FileIO

Syntax

```
bool DeleteDirectory (string Directory, bool Recursive, bool FailureReturnValue)
```

Parameters

string Directory

bool Recursive

bool FailureReturnValue

Parameters

Directory: The path of the directory to delete.

Recursive: True deletes the directory and all files and subdirectories. False deletes only the directory and requires that the directory is empty.

FailureReturnValue: True causes the action to always return True, even if the delete fails. False causes the action to return False if the directory delete fails.

Smart parameters are supported for the directory path.

Returns

Always returns True if the directory is deleted.

If a failure occurs when you delete a directory, the action returns the value of FailureReturnValue. This result lets you determine whether the action returns True or False on a directory failure. Depending on the application, it might make sense to ignore a delete failure so this action can be set to always return True.

Level

Any level.

Details

Deletes the specified directory and can optionally delete subdirectories.

Example

```
DeleteDirectory("C:\MyDir1\MyDir2", True, True)
```

This example deletes MyDir2 and all files and subdirectories. If the delete fails, the action still returns True.

Parent topic: [FileIO actions](#)

DeleteFile

Deletes a file.

Member of namespace

FileIO

Syntax

```
bool DeleteFile (string filename)
```

Parameters

filename

Type: string

Parameters:

filename: The name and path of the file to delete. Smart parameters are supported.

Returns

Always True.

Level

All levels.

Details

Deletes the specified file. DOS wildcards are permitted in the file name.

Example

The following example deletes the specific file.

```
DeleteFile("C:\Temp\DeleteThis.txt")
```

The following example deletes all of the files in the Temp directory.

```
DeleteFile("C:\Temp\*. *")
```

The following example deletes the file name that matches the current batch ID and has an extension of TXT.

```
DeleteFile("C:\Temp\@BATCHID+.txt")
```

Parent topic: [FileIO actions](#)

GetFileSize

Obtains the size of a file and stores it in the specified variable.

Member of namespace

FileIO

Syntax

```
bool GetFileSize (string filename, string targetVariable)
```

Parameters

filename

Type: string

targetVariable

Type: string

Parameters

- filename : The name and path of the file.
- targetVariable : The name of the variable to store the file size. The variable level must be specified with a Smart Parameter.

Smart parameters are supported for each of the input parameters.

Returns

False if the target variable is blank. Otherwise, True.

Level

All levels.

Details

The size of the specified file will be stored into the specified variable. This can be helpful to test for problems, such as empty files. Subsequent actions can perform tests on the stored value and act upon it.

If the specified file is not found, the action will return True and a size of 0 will be stored into the variable. If any other kind of error occurs, the action will return False and the variable may or may not be set to 0.

Example

```
GetFileSize("C:\Temp\MyFile.txt", "@B.MyVariable")
```

This example sets the file size in the variable *MyVariable* at the batch level.

Parent topic: [FileIO actions](#)

GetProfileString

Reads a key value from a settings file.

Member of namespace

FileIO

Syntax

```
bool GetProfileString (string filename, string section, string key, string targetVariable)
```

Parameters

filename
Type: string

section
Type: string

key
Type: string

targetVariable
Type: string

Parameters

- filename : The INI file name.
- section : The section within the file.
- key : The key within the section.
- targetVariable : The variable where to store the value. The variable level must be specified with a smart parameter.

Smart parameters are supported for each of the input parameters.

Returns

True if the settings file exists and the target variable is valid. Otherwise, False.

Level

All levels.

Details

Reads the value from a settings file, typically a .INI file, and stores it into the variable specified. If the variable does not exist, it will be created. If the key does not exist but the file does exist, the action will still return true and an empty string will be stored in the variable. If you need to test for a blank key value, you can use the `IsProfilePresent` action.

If you are reading Unicode characters from an INI file, it is required that the file is in a format that supports Unicode. If the file is not a Unicode format, the Unicode characters may appear incorrectly when read by `GetProfileString` or displayed in an editor. Most file editors will let you choose the type of file encoding. See the help for your specific editor.

Example

```
GetProfileString("C:\Settings.ini", "MySection", "MyKey", "@B.MyVariable")
```

The value for MyKey is placed into the variable *MyVariable*.

Parent topic: [FileIO actions](#)

IsDirectoryPresent

Determines if the specified directory exists and optionally creates it.

Member of namespace

FileIO

Syntax

```
bool IsDirectoryPresent (string directoryName, bool create, bool testExistence)
```

Parameters

directoryName
Type: string

create
Type: bool
testExistence
Type: bool

Parameters

- `directoryName` : The directory path to test. Smart parameters are allowed.
- `create` : Specifies if the directory should be created. True creates the directory, if it does not exist.
- `testExistence` : Determines if True should be returned if the directory exists or does not exist.

Returns

If `testExistence` is True, the action will return True if the directory exists or if the directory did not exist but was successfully created.

If `testExistence` is False, the action will return True if the directory does not exist. This allows you to perform negative tests that will return true when a directory does not exist.

If an error occurs, the action will return False.

Level

All levels.

Details

Checks for the existence of a directory. Depending on the input parameters, if the directory does not exist, the action creates the directory. The meaning of the return value can be changed using the `testExistence` parameter. This allows rules to continue if a directory exists or rules can continue if a directory does not exist.

Example

```
IsDirectoryPresent("c:\temp", true, true)
```

This example creates the directory `C:\temp`, if it does not exist, and returns True if the directory exists or was created successfully.

```
IsDirectoryPresent("c:\temp", true, false)
```

This example creates the directory `C:\temp`, if it does not exist, and returns False if the directory exists or was created successfully.

Parent topic: [FileIO actions](#)

IsFilePresent

Determines if the specified file exists.

Member of namespace

FileIO

Syntax

```
bool IsFilePresent (string filename, bool testExistence)
```

Parameters

filename
Type: string
testExistence
Type: bool

Parameters

- filename : The file name and path. Smart parameters are allowed.
- testExistence : true tests that the file exists, false tests that the file does not exist.

Returns

If testExistence is True, the action will return True if the file exists. If testExistence is False the action will return True if the file does not exist. If an error occurs, the action will return False.

Level

All levels.

Details

Checks for the existence of a file. Depending on the testExistence parameter, the action can return true if a file exists or true if a file does not exist to provide flexibility when creating rules.

Example

```
IsFilePresent("C:\MyDir\MyFile.abc", false)
```

In this example, if the file does not exist, the action returns True and any subsequent actions are processed.

Parent topic: [FileIO actions](#)

IsFileReadOnly

Tests the read only attribute of a file.

Member of namespace

FileIO

Syntax

```
bool IsFileReadOnly (string filename, bool testForReadOnly)
```

Parameters

filename
Type: string

testForReadOnly
Type: bool

Parameters

- filename : The file name and path of the file to test. Smart parameters are allowed.
- testForReadOnly : Determines if the action should return true for read-only or read-write.

Returns

If testForReadOnly is True, the action returns True if the file is read only.

If testForReadOnly is False, the action returns True if the file is not read only.

If an error occurs, or if the file does not exist, the action returns False.

Level

All levels.

Details

This action will indicate if a file is set to read only.

Example

```
IsFileReadOnly("c:\mydir\myfile.txt", true)
```

if the file myfile.txt is set to read only, the action returns True.

```
IsFileReadOnly("c:\mydir\myfile.txt", false)
```

if the file myfile.txt is not set to read only, the action returns True.

Parent topic: [FileIO actions](#)

IsProfilePresent

Tests that a profile exists and that a specific section and key exists within it.

Member of namespace

FileIO

Syntax

```
bool IsProfilePresent (string filename, string section, string key, bool  
testExistence)
```

Parameters

filename
Type: string
section
Type: string

key
Type: string
testExistence
Type: bool

Parameters

- filename : The INI file name.
- section : The section within the file.
- key : The key within the section.
- testExistence : true tests that the it exists, false tests that it does not exist.

The filename, section, and key parameters can accept smart parameters.

Returns

True if testExistence is true and the section and key is found within the profile and the key has an assigned value. True if testExistence is false and the section or key is not found within the profile or the key value is blank. Otherwise, False.

Level

All levels.

Details

Checks that a specific section and key exists within a settings file, typically an INI file. It does not test the value of the key, only that a value exists.

Example

```
IsProfilePresent("C:\MyDir\settings.ini", "mysection", "mykey", true)
```

In this example, if settings.ini exists and contains *mysection*, *mykey* and if *mykey* has a non-blank value, it returns True.

Parent topic: [FileIO actions](#)

Readtextfile

Reads a text file.

Member of namespace

FileIO

Syntax

```
bool ReadTextFile (string filename, string target)
```

Parameters

- filename - The name and path of the text file to read.

- target - The DCO node to store the value of the text file.

Smart parameters are supported for each parameter.

Returns

True if the text file exists and was successfully read, otherwise False.

Level

All levels.

Details

Reads the specified text file.

Example:

```
ReadTextFile("C:\Temp\ReadThis.txt", "@P.text")
```

Parent topic: [FileIO actions](#)

RenameFile

Renames or moves the specified file.

Member of namespace

FileIO

Syntax

```
bool RenameFile (string oldName, string newName, bool overwrite)
```

Parameters

oldName
 Type: string
newName
 Type: string
overwrite
 Type: bool

Parameters

- oldName : The source file name and path. Allows smart parameters.
- newName : The destination file name and path. Allows smart parameters.
- overwrite : Specifies if the destination file should be overwritten. True overwrites an existing file.

Returns

True if the file is successfully renamed or moved. Otherwise, False.

Level

All levels.

Details

Renames the specified file to the new name. If the directories for the original and new file names are different, the file will be moved to the new directory. If the overwrite parameter is true, the file will overwrite an existing file. If overwrite is false, an existing file will not be overwritten.

Example

Code	Comment
<pre>RenameFile("C:\MyDir\File1.txt", "C:\MyDir\File2.txt", true)</pre>	Renames the file within the same directory. The renaming overwrites any existing file File2.txt.
<pre>RenameFile("C:\MyDir\File1.txt", "C:\New\File1.txt", true)</pre>	Moves the file from the MyDir directory to the New directory. The move overwrites any existing file File1.txt.
<pre>RenameFile("@DCO (BATCHDIR) +\+MyFile.pdf", "@APPATH (export) +\+MyFile.pdf", true)</pre>	Moves the PDF file from one directory to another.

Parent topic: [FileIO actions](#)

SetFileReadOnly

Sets or removes the read only attribute from a file or set of files.

Member of namespace

FileIO

Syntax

```
bool SetFileReadOnly (bool readonly, string filename)
```

Parameters

readonly

Type: bool

filename

Type: string

Parameters

- readonly : true turns on the read only attribute, false turns it off.
- filename : The path and filename. Smart parameters and DOS wildcards are allowed.

Returns

Always True.

Level

All levels.

Details

Sets the read only attribute of a file, or a group of files. The read only attribute can be set or cleared with this action. Standard DOS * and ? wildcards can be used to affect a change on multiple files at once.

Example

```
SetFileReadOnly(false, "C:\MyDir\*.*.*)
```

This example sets all of the files in MyDir as read-write.

Parent topic: [FileIO actions](#)

SetProfileString

Writes a value to a profile file, typically called an INI file.

Member of namespace

FileIO

Syntax

```
bool SetProfileString (string filename, string section, string key, string value)
```

Parameters

filename
Type: string

section
Type: string

key
Type: string

value
Type: string

Parameters

- filename : The profile file name.
- section : The section within the file.
- key : specifies if the destination file should be overwritten.
- value : The value to write. Smart parameters are supported for each of the input parameters.

Returns

True if the value is written to the profile. Otherwise, False.

Level

All levels.

Details

Writes a value to a settings profile, typically a file with an INI extension. The value is stored in the variable provided as a parameter. If the variable does not exist, it will be created. If the variable does exist, the current value will be replaced with the new value. If the file does not exist, the file will be created.

If you are writing Unicode characters to the INI file, it is required that the file exist and that it is in Unicode format. If the file is not a Unicode format, the Unicode characters may appear incorrectly when read by `GetProfileString` or displayed in an editor. Most file editors will let you chose the type of file encoding. See the help for your specific editor.

Example

```
SetProfileString("C:\MyDir\config.ini", "MySection", "MyKey", "Batch+@BATCHID")
```

Parent topic: [FileIO actions](#)

SplitFileName

Splits a file name into user specified variables.

Member of namespace

FileIO

Syntax

```
bool SplitFileName (string inputFilename, string rootPathVariable, string pathVariable, string fileVariable, string extVariable)
```

Parameters

inputFilename
 Type: string
rootPathVariable
 Type: string
pathVariable
 Type: string
fileVariable
 Type: string
extVariable
 Type: string

Parameters

- inputFilename : The input file name to break into its three logical parts.
- rootPathVariable : The name of the variable to store the root path.
- pathVariable : The name of the variable to store the file path.
- fileVariable : The name of the variable to store the file name without the extension.
- extVariable : The name of the variable to store the file extension.

Smart parameters are supported for each of the input parameters. For each of the parameters that accept a variable, the level must be specified with a Smart Parameter.

It is not necessary to specify a variable name for each part of the path that is split. Only destination variables for the desired values need to be specified. If you do not want to store a particular file name part, leave that parameter blank.

Returns

False if the structure of the file name or path is invalid. Otherwise, True. The file does not need to exist for this action to succeed.

Level

All levels.

Details

This action splits the input file name into its root path, path, file name and the extension, and place each of the parts into their own variables. The file does not need to exist.

If the file contains a file extension, the saved file extension will contain a preceding period.

Example

Code	Comment
<pre>SplitFileName("C:\Dir1\Dir2\MyFile.abc", " @B.FROOT", "@B.FPATH", " @B.FNAME", "@B.FEXT")</pre>	<p>Splits the file name and saves the information into four variables at the batch level:</p> <ul style="list-style-type: none">• FROOT = "C:\"• FPATH = "C:\Dir1\Dir2"• FNAME = "MyFile"• FEXT = ".abc"
<pre>SplitFileName("@VAR(IMAGEFILE)", "", "", "", " @B.EXT")</pre>	<p>Obtains the value that is stored in the variable IMAGEFILE and saves the file extension into a variable EXT.</p>
<pre>SplitFileName("@P.ScanSrcPath", "", "", "@P\ Fieldname.Text", "")</pre>	<p>Obtains the value that is stored in the page variable ScanSrcPath and saves the file name into the subfield Text.</p>

Parent topic: [FileIO actions](#)

ZipOcrResults

Creates a .zip file to store recognition results for every page of the document.

Member of namespace

FileIO

Syntax

Bool ZipOcrResults ()

Parameters

None

Returns

True if the .zip file is created successfully, otherwise False.

Level

Document level.

Details

This action creates a .zip file that contains all the files with recognition results from every page of the document. The name of the .zip file is based on the ID of the document object, and is in the DocumentID.ocr.zip format.

Example

If an action is called on a document with an ID 20160914.000000.01, which contains two pages, then a .zip file that is named as 20160914.000000.01.ocr.zip gets created. This .zip file contains files that store recognition results that are associated with each page. For example, -

tm000001.xml

tm000001_layout.xml

tm000001c.xml

tm000002.xml

tm000002_layout.xml

tm000002c.xml

Parent topic: [FileIO actions](#)

FileNetIDM actions

Use the FileNetIDM actions to upload documents into an FileNet® Image Services library

The FileNetIDM actions integrate Datacap applications with the FileNet Image Services library. You run these actions to access the FileNet Image Services server, set up document attributes and folders on the server, and upload documents to the server for storage.

- [AddAllImagesToDocument](#)
Adds all Document Page object images to the Image Services document object.
- [AddFileToDocument](#)
Adds a file to the current FileNet document.

- [AddPDFImageToDocument](#)
Adds a PDF image file to the new FileNet document.
- [AddTIFImageToDocument](#)
Adds a TIF image file to the new FileNet document.
- [CreateFolder](#)
Creates a top-level FileNet folder.
- [FileNetDB_ADOConnect](#)
Establishes an ActiveX Data connection object with FileNet.
- [FileNETDocID_SaveAsSmartParameter](#)
Assigns the ID of the FileNet document to a variable of the bound object in the Document Hierarchy.
- [FileNETDocID_SetValue](#)
Assigns the ID of the FileNet document to a child object of the bound object in the Document Hierarchy.
- [GetDocuments](#)
Logs the names of the documents in the FileNet collection.
- [GetTopFolders](#)
Lists the existing top-level folders in the log file of the task.
- [IndexProperty_ID_Component](#)
Links the property of the FileNet document to an object of the Document Hierarchy.
- [IndexProperty_ID_DateComponent](#)
Sets up the Date element of the processing index of the FileNet task.
- [IndexProperty_ID_Value](#)
Assigns a constant value to a particular property of a FileNet document.
- [IndexProperty_LeftJUSTIFY](#)
Left-justifies a value that is being assigned to a target property of the FileNet document.
- [IndexProperty_RightJUSTIFY](#)
Right-justifies a value that is being assigned to a target property of the FileNet document.
- [IndexProperty_SmartParameter](#)
Assigns a constant value to a particular property of a FileNet document.
- [Library_DMA_Initialize](#)
Initializes but does not open the FileNet DMA library.
- [Library_DS_Initialize](#)
Initializes a previously defined, active Document Services Library.
- [Library_IS_Initialize](#)
Initializes a previously defined, active Image Services library.
- [Library_LogIn](#)
Logs in to the Image Services library by using the user ID and Password parameter values.
- [Library_LogOff](#)
Closes the FileNet connection to the Image Services library.
- [NewDocument](#)
Sets up a new document and assigns a previously defined Document Class to it.
- [SaveDocToFolder](#)
Saves the document into an existing folder of the open FileNet library.
- [Upload](#)
Uploads the active FileNet document to the open FileNet library.
- [Upload_SetDelay](#)
Controls the delay between upload retries.
- [Upload_SetNumAttempts](#)
Sets the number of attempts to complete a failed Upload action.
- [UseIndexes_OFF](#)
Turns off the Rulerunner indexing feature.
- [UseIndexes_ON](#)
Allows the task to access the properties of the FileNet document and provide these values to the objects in the Document Hierarchy.

Parent topic: [Global actions](#)

AddAllImagesToDocument

Adds all Document Page object images to the Image Services document object.

Syntax

```
bool AddAllImagesToDocument ()
```

Parameters

None.

Returns

False if action is placed at the Batch level, if the current active FileNet® document has already been committed to the Library, or if no documents exist in the batch. Otherwise, True.

Attention: If the action cannot access the batch's image files, the action directs the Rulerunner task to finish with a status of Aborted.

Level

Document, Page or Field levels.

Details

Assigns all images associated within a Document object (or parent Document object) of the Document Hierarchy to the new FileNet document.

This action is valid for IS libraries only. DS libraries only permit a single associated file. This action solicits information from the Rulerunner task's Page file (upload.xml, for example) as it assigns Image files representing pages linked to a Document object or child Page objects of the Document Hierarchy to the FileNet document.

The images are not yet committed to the library.

Example

```
NewDocument ("1040EZtwo")  
AddAllImagesToDocument ()
```

Parent topic: [FileNetIDM actions](#)

AddFileToDocument

Adds a file to the current FileNet® document.

Syntax

```
bool AddFileToDocument (StrParamMW)
```

Parameters

String value of the File name to add to the document and its path. Smart Parameters are supported.

Returns

False if the specified file is not found, or if the active FileNet document has already been committed to the library. Otherwise, True.

Attention: If the action cannot access the batch's image files, the action directs the Rulerunner task to finish with a status of Aborted.

Level

All levels.

Details

Adds any file you designate as a parameter to the current FileNet document.

If the parameter does not include a path to a folder, the action will use the path to the current Batches directory as the default. You can also designate a variable of the bound object of the Document Hierarchy as the source of path's value by using the # character followed by the variable's name. For example: *#FilePath*.

Example

```
NewDocument ("1040EZtwo")
AddTIFFImageToDocument ()
AddFileToDocument ("C:\Datacap\MQSW\Process\FNLog.log")
```

This sequence assumes that Datacap logs its FileNet activities and that a resulting Log file is available for the document.

Parent topic: [FileNetIDM actions](#)

AddPDFImageToDocument

Adds a PDF image file to the new FileNet® document.

Syntax

```
bool AddPDFImageToDocument ()
```

Parameters

None.

Returns

False if no Page component of the calling object is found, batch images cannot be accessed, or if the active FileNet document has already been committed to the library. Otherwise, True.

Attention: If the action cannot access the batch's image files, the action directs the Rulerunner task to finish with a status of Aborted.

Level

Field or Page level.

Details

Adds a PDF Image file associated with a Page object of the Document Hierarchy to the new FileNet document. This action works only if the PDF file is in the appropriate folder of the application's Batches directory – and has the same name as an associated page's corresponding Tiff Image file.

Example

```
NewDocument ("1040EZtwo")  
AddPDFImageToDocument ()
```

This sequence associates calling components bound to the PDF file with a new FileNet '1040EZtwo' document.

Parent topic: [FileNetIDM actions](#)

AddTIFImageToDocument

Adds a TIF image file to the new FileNet® document.

Syntax

```
bool AddTIFImageToDocument ()
```

Parameters

None.

Returns

False, if no Page component of the calling object is found, batch images cannot be accessed, or if the active FileNet document is already committed to the library. Otherwise, True.

Attention: If the action cannot access the batch's image files, the action directs the Rulerunner task to finish with a status of Aborted.

Level

Field or Page level.

Details

Adds the Image file that is associated with a Page object of the Document Hierarchy to the new FileNet document.

If a rule that contains this action is bound to a Field object, it adds the Image file that is associated with the field's parent Page object. An Upload action must stay at any level lower than this action.

Example

```
NewDocument ("1040EZtwo")  
AddTIFImageToDocument ()
```

This sequence associates the calling component's bound Image file with a new FileNet 1040EZtwo document.

Parent topic: [FileNetIDM actions](#)

CreateFolder

Creates a top-level FileNet® folder.

Syntax

```
bool CreateFolder (StrParamMW)
```

Parameters

The name of the folder to create. Smart Parameters are supported.

Returns

False if the folder cannot be created. Otherwise, True.

Level

Document, Page or Field levels.

Details

Creates a top-level FileNet folder.

Example

```
CreateFolder("MQSW_Q601")
```

Parent topic: [FileNetIDM actions](#)

FileNetDB_ADOConnect

Establishes an ActiveX Data connection object with FileNet®.

Syntax

```
bool FileNetDB_ADOConnect ()
```

Parameters

None.

Returns

False if the FileNet library is not initialized. Otherwise, True.

Attention: If the action encounters an error connecting to the specified database, the action directs the Rulerunner task to finish with a status of Aborted.

Level

All levels.

Details

Establishes an ActiveX Data Connection object (ADO connection) with the specified FileNet database.

Example

```
Library_IS_Initialize("DefaultIMS:Domain:FileNet")
LibraryLogin("Admin,AdOK")
FileNetDB_ADOConnect()
```

Parent topic: [FileNetIDM actions](#)

FileNETDocID_SaveAsSmartParameter

Assigns the ID of the FileNet® document to a variable of the bound object in the Document Hierarchy.

Syntax

```
bool FileNETDocID_SaveAsSmartParameter ()
```

Parameters

None.

Returns

False, if no active FileNet document is found or if the active FileNet document has not been committed.
Otherwise, True.

Level

All levels.

Details

Assigns the FileNet document's ID to the TEXT variable of the bound object of the Document Hierarchy.

Example

```
NewDocument("1040EZtwo")
AddAllImagesToDocument()
Upload()
FileNETDocID_SaveAsSmartParameter()
```

Parent topic: [FileNetIDM actions](#)

FileNETDocID_SetValue

Assigns the ID of the FileNet® document to a child object of the bound object in the Document Hierarchy.

Syntax

```
bool FileNETDocID_SetValue (StrParamMW)
```

Parameters

The name of the Field object. Smart Parameters are supported.

Returns

False if an active FileNet document is not found; if the active FileNet document has not been committed; or if the child Field object was not found. Otherwise, True.

Level

Document level, Page level or Field with child fields.

Details

Assigns the FileNet Document's ID to a child Field object of the bound Document, Page or parent Field object of the Document Hierarchy.

Example

```
NewDocument ("1040EZtwo")  
AddAllImagesToDocument ()  
Upload ()  
FileNETDocID_SetValue ("DocID")
```

This sequence will set up a new FileNet document, commit it to the FileNet library, and assign its ID as the Text value of the specified child field value of the bound object.

Parent topic: [FileNetIDM actions](#)

GetDocuments

Logs the names of the documents in the FileNet® collection.

Syntax

```
bool GetDocuments ()
```

Parameters

None.

Returns

Always True.

Level

All levels.

Details

A utility action used to aid debugging, it logs the names of the documents in the collection. This action is used to help verify the FileNet connection and that documents have been created. It is recommended that this is used for debugging and not in a normal production environment.

Example

```
GetDocuments ()
```

Parent topic: [FileNetIDM actions](#)

GetTopFolders

Lists the existing top-level folders in the log file of the task.

Syntax

```
bool GetTopFolders ()
```

Parameters

None.

Returns

False if the top-level folder collection cannot be located. Otherwise, True.

Level

All levels.

Details

Lists existing top-level FileNet® folders in the current task's Log file.

Example

```
GetTopFolders ()
```

Parent topic: [FileNetIDM actions](#)

IndexProperty_ID_Component

Links the property of the FileNet® document to an object of the Document Hierarchy.

Syntax

```
()
```

Parameters

Comma-separated values of:

1. The name of a FileNet document's property;

2. The name(s) of one or more Document Hierarchy objects with values for the variable that will be transferred to the FileNet document's property;
3. The value of the maximum length of the subscript value.

Smart Parameters are supported.

Returns

False if the FileNet property specified is invalid, or the FileNet Property Collection does not exist. Otherwise, True.

Attention: If the action returns False, the action directs the Rulerunner task to finish with a status of Aborted.

Level

Page level or Field level with child Fields.

Details

This action links the property of the FileNet document to an object of the Document Hierarchy.

Example

```
IndexProperty_ID_Component("FNBatch,1040EZ,18")
IndexProperty_ID_Component("FNDoc,1040EZTwo,22")
IndexProperty_ID_Component("FNPageF,Front,12")
IndexProperty_ID_Component("FNPageB,Back,12")
IndexProperty_ID_Component("FNfldLast,Last,18")
IndexProperty_ID_Component("NFldFirst,First,18")
IndexProperty_ID_Component("NFldMI,MI,2")
```

This sequence defines seven elements of a processing index for a FileNet task. In each case, the first parameter is the name of a property of a FileNet document that has been previously assembled. The second parameter assigns the Name of a Document Hierarchy object to the FileNet document's property. The third parameter is the property's maximum length.

During task operations, runtime values for each object will become the FileNet document's Index values.

Parent topic: [FileNetIDM actions](#)

IndexProperty_ID_DateComponent

Sets up the Date element of the processing index of the FileNet® task.

Syntax

```
bool IndexProperty_ID_DateComponent (StrParamMW)
```

Parameters

String consisting of four comma-separated values:

1. The name of the FileNet document's Date property
2. The name of a Document Hierarchy object with a Date property
3. The format of the Date when supplied to the FileNet document

4. The format of the Date value that is being added to the task's processing index. See the example for acceptable Date values.

Smart Parameters are supported.

Returns

False if the FileNet property specified is invalid, or the FileNet Property Collection does not exist. Otherwise, True.

Attention: If the action returns False, the action directs the Rulerunner task to finish with a status of Aborted.

Level

Page level or Field level with child Fields.

Details

This element can supply Date information to a Date property of the FileNet document.

The parameters can use these Date formats: cc Century 20 yy Year 03 yyyy Year 2003 dd Day 29 mm Month 06 Julian Year/Day 03-145

Example

```
IndexProperty_ID_Date_Component ("FNStart,1040EZ,mm/dd/yy,yyyy/mm/dd")
```

This example re-formats the value of the Batch object's Start Date and assigns it to the FNStart property of the FileNet document.

Parent topic: [FileNetIDM actions](#)

IndexProperty_ID_Value

Assigns a constant value to a particular property of a FileNet® document.

Syntax

()

Parameters

String with two comma-separated values:

1. The name of the FileNet document's target property;
2. The constant's value.

Smart Parameters are supported.

Returns

False, if the FileNet property specified cannot be set. Otherwise, True.

Level

All levels.

Details

Assigns a constant value to a particular property of a FileNet document.

Example

The following action assigns “3” to the FNTaxQtr property of the FileNet document when the FileNet task processes the bound object of the Document Hierarchy, the object to which the action’s rule applies.

```
IndexProperty_ID_Value (FNTaxQtr, 3)
```

Parent topic: [FileNetIDM actions](#)

IndexProperty_LeftJUSTIFY

Left-justifies a value that is being assigned to a target property of the FileNet® document.

Syntax

```
bool IndexProperty_LeftJUSTIFY (StrParamMW)
```

Parameters

String with two comma-separated values:

1. The name of the property of the FileNet document; and
2. The maximum size of a value.

Smart Parameters are supported.

Returns

False if the FileNet property cannot be set. Otherwise, True.

Level

All levels.

Details

Left-justifies a value that is being assigned to a target property of the FileNet document.

Example

```
IndexProperty_ID_Variable ("FNFldData, Year+SSN+ Income+Deductions+Net, 256")  
IndexProperty_LeftJUSTIFY ("FNFldData, 256")
```

This sequence provides the FNFldData property with a value, then formats the value before it is actually assigned to the active FileNet document.

Parent topic: [FileNetIDM actions](#)

IndexProperty_RightJUSTIFY

Right-justifies a value that is being assigned to a target property of the FileNet® document.

Syntax

```
bool IndexProperty_RightJUSTIFY (StrParamMW)
```

Parameters

String with two comma-separated values:

1. The name of the property of the FileNet document; and
2. The maximum size of a value.

Smart Parameters are supported.

Returns

False if the FileNet property cannot be set. Otherwise, True.

Level

All levels.

Details

Right-justifies a value that is being assigned to a target property of the FileNet document.

Example

```
IndexProperty_ID_Variable("FNFldData,Year+SSN+ Income+Deductions+Net,256")  
IndexProperty_RightJUSTIFY("FNFldData,256")
```

This sequence provides the FNFldData property with a value, then formats the value before it is actually assigned to the active FileNet document.

Parent topic: [FileNetIDM actions](#)

IndexProperty_SmartParameter

Assigns a constant value to a particular property of a FileNet® document.

Syntax

```
bool IndexProperty_SmartParameter (string PropertyName, string Value, string Length)
```

Parameters

1. The name of the FileNet document's target property.
2. The value to assign to the property.
3. The length of the property value (space filled).

Smart Parameters are supported for all arguments.

Returns

False, if the FileNet property specified cannot be set. Otherwise, True.

Level

All levels.

Details

Assigns a constant value to a particular property of a FileNet document.

Example

The following action assigns the value of field Taxes to the FNTaxQtr property of the FileNet document.

```
IndexProperty_SmartParameter (FNTaxQtr, @P/Taxes, "")
```

The following action assigns the space filled value of page variable *LastName* to the FNNameLast property of the FileNet document, if the variable value exceeds 10 characters the value that is saved is right-truncated.

```
IndexProperty_SmartParameter (FNNameLast, @P.LastName, 10)
```

Parent topic: [FileNetIDM actions](#)

Library_DMA_Initialize

Initializes but does not open the FileNet® DMA library.

Syntax

```
bool Library_DMA_Initialize (StrParam)
```

Parameters

String value consisting of three colon-separated elements of the Library Name. Smart Parameters are supported.

Returns

False if there is a problem connecting to the FileNet DMA Library. Otherwise, True.

Note: If the action returns False, the action directs the Rulerunner task to finish with a status of Aborted.

Level

Any level, but the Batch level is recommended.

Details

Do not confuse the Library Name with the local FileNet Neighborhood label. In some cases, the formal three-part Library Name must be used to properly configure initialization. Please check your FileNet documentation

on how to discern your formal library name.

Example

```
Library_DMA_Initialize("DMALibrary:Datacap:FileNet")
```

This action initializes but does not open the library – see [Library_Login](#).

Parent topic: [FileNetIDM actions](#)

Library_DS_Initialize

Initializes a previously defined, active Document Services Library.

Syntax

```
bool Library_DS_Initialize (StrParam)
```

Parameters

String value consisting of the three colon-separated elements of the Library Name. Smart Parameters are supported.

Returns

False if there is a problem connecting to the FileNet® Document Services Library. Otherwise, **True**.

Note: If the action returns False, the action directs the Rulerunner task to finish with a status of Aborted.

Level

Any level, but the Batch level is recommended.

Details

Do not confuse the Library Name with the local FileNet Neighborhood label. In some cases, the formal three-part Library Name must be used to properly configure initialization. Please check your FileNet documentation for guidelines on designating a formal Library Name.

Example

```
Library_DS_Initialize("DSLlibrary:Datacap:FileNet")
```

This action initializes but does not open the library – see [Library_Login](#).

Parent topic: [FileNetIDM actions](#)

Library_IS_Initialize

Initializes a previously defined, active Image Services library.

Syntax

```
bool Library_IS_Initialize (StrParam)
```

Parameters

String value containing the Library name. The Library name will commonly consist of three, colon-separated elements of the Library Name. In some cases, the short name can be used. Smart Parameters are supported.

Returns

False if there is a problem connecting to the FileNet® Image Services Library. Otherwise, True.
Attention: If the action returns False, the action directs the Rulerunner task to finish with a status of Aborted.

Level

Any level, but the Batch level is recommended.

Details

Initializes a previously defined, active Image Services Library.

In some cases, the formal three-part Library Name should be used to properly configure initialization. However, there may be some cases where configuring the library through the IDM Configuration tool first and then passing the short name could be used. Please check your FileNet documentation for guidelines on designating a formal Library Name.

Example

```
Library_IS_Initialize("LibraryName")
```

This action initializes but does not open the library – see [Library_Login](#).

Parent topic: [FileNetIDM actions](#)

Library_Login

Logs in to the Image Services library by using the user ID and Password parameter values.

Syntax

```
bool Library_Login (StrParam)
```

Parameters

String values of the User ID and Password, with a comma separator. Smart Parameters are supported.

Returns

False if an active library is not found, the parameter values are incorrect, or an error occurs while logging into the library. Otherwise, True.
Attention: If the action returns False, the action directs the Rulerunner task to finish with a status of Aborted.

Level

Any level, but the Batch level is recommended.

Details

Logs into the initialized FileNet® library using the User ID and Password parameter values. You must include this action to access a library. Be sure the Library_Login action follows one of the Library_Initialize actions.

Example

```
Library_DS_Initialize("DefaultLib:Datacap:FileNet")
Library_Login("FileNet2, FN2")

Library_IS_Initialize("LibraryName")
Library_Login("@APPVAR(values/gen/ISUser), @APPVAR
(values/adv/ISPassword) ")

Library_IS_Initialize("LibraryName")
Library_Login("@STRING(@APPVAR
(values/gen/ISUser), @APPVAR(values/adv/ISPassword) ")")
```

Parent topic: [FileNetIDM actions](#)

Library_LogOff

Closes the FileNet® connection to the Image Services library.

Syntax

```
bool Library_LogOff ()
```

Parameters

None.

Returns

True, if the logoff was successful. Otherwise, False.

Level

Any level, but the Batch level is recommended.

Details

Closes the FileNet connection.

Example

```
Library_LogOff()
```

Parent topic: [FileNetIDM actions](#)

NewDocument

Sets up a new document and assigns a previously defined Document Class to it.

Syntax

```
bool NewDocument (string StrParam)
```

Parameters

String value of a previously defined FileNet® Document Class. Smart Parameters are supported.

Returns

False if a new document cannot be created. Otherwise, True.

Attention: If the action returns False, the action directs the Rulerunner task to finish with a status of Aborted.

Level

All Levels.

Details

Sets up a new FileNet document, and assigns the FileNet Document Class you specify as an argument to the new FileNet document.

After an Upload action commits the document to a FileNet library, FileNet immediately links a unique ID to the document.

Example

```
Library_DS_Initialize("DefaultIMS:Datacap:FileNet")
Library_Login("FileNet2, FN2")
NewDocument("1040EZtwo")
```

In this example, the NewDocument action instantiates a new FileNet document of Class:'1040EZtwo'. To populate the document, you'll probably follow this action with one of the AddImage actions.

Parent topic: [FileNetIDM actions](#)

SaveDocToFolder

Saves the document into an existing folder of the open FileNet® library.

Syntax

```
bool SaveDocToFolder (StrParam)
```

Parameters

String value of the Folder ID, beginning with a forward slash (/) - see the example. Smart Parameters are supported.

Returns

False if there is no active FileNet document, no active FileNet library, invalid parameter, or if the active FileNet document has not been committed. Otherwise, True.

Attention: If the action cannot access the specified folder, the action directs the Rulerunner task to finish with a status of Aborted.

Level

All Levels.

Details

Places the committed FileNet document in an existing folder of the open FileNet library. Although the forward slash (/) character is a standard element of this action's parameter, the setup of your FileNet library may mean that the forward slash is not used. Under exceptional circumstances, this action will have this syntax – note that a forward slash does not precede the Folder ID: `SaveDocToFolder("1074a")`.

Example

```
Library_DS_Initialize("1040Docs")
Library_Login("FileNet2, FN2")
NewDocument("1040EZtwo")
AddAllImagesToDocument()
Upload()
SaveDocToFolder("/1074a")
```

As the example shows, you can insert this action after adding images and successfully committing (uploading) the document to the FileNet library.

Parent topic: [FileNetIDM actions](#)

Upload

Uploads the active FileNet® document to the open FileNet library.

Syntax

```
bool Upload ()
```

Parameters

None.

Returns

False if the Document object does not exist; if the library object is missing; if all pages were previously committed; if the active FileNet document has already been committed to the library; or the upload is unsuccessful. Otherwise, True.

Attention: If the active FileNet document has already been committed, or the action encounters an error, the action directs the Rulerunner task to finish with a status of Aborted.

Level

All levels.

Details

Commits the active FileNet document to the open FileNet library.

Example

```
Upload()
```

Parent topic: [FileNetIDM actions](#)

Upload_SetDelay

Controls the delay between upload retries.

Member of namespace

FileNetIDM

Syntax

```
bool Upload_SetDelay (StrParamMW)
```

Parameters

The number of seconds to wait between each retry of the FileNet upload. Smart Parameters are supported

Returns

Always True.

Level

All levels.

Details

If an upload fails, the application will retry automatically to upload. Between each retry, the application will pause. You can use this action to set the length of the pause of the application. If this action is not called, the default value of 5 seconds is used.

Example:

```
Upload_SetDelay("15")
```

Parent topic: [FileNetIDM actions](#)

Upload_SetNumAttempts

Sets the number of attempts to complete a failed Upload action.

Syntax

```
bool Upload_SetNumAttempts (StrParamMW)
```

Parameters

The number of times to retry the FileNet upload upon failure. Smart Parameters are supported.

Returns

Always True.

Level

All levels.

Details

If the upload action fails, it will be automatically retried. The number of retries can be controlled with this action. If this action is not called, the default value of 3 will be used.

Example

```
Upload_SetNumAttempts ("5")
```

Parent topic: [FileNetIDM actions](#)

UseIndexes_OFF

Turns off the Rulerunner indexing feature.

Syntax

```
bool UseIndexes_OFF ()
```

Parameters

None.

Returns

Always True.

Level

All levels.

Details

Turns Off a Rulerunner task's Indexing feature. Because the feature is On by default, the task will continue to generate and assign index values until a rule with this action turns it Off.

A rule with action must be applied before a new FileNet® document is created.

Example

```
UserIndexes_OFF ()
```

Parent topic: [FileNetIDM actions](#)

UseIndexes_ON

Allows the task to access the properties of the FileNet® document and provide these values to the objects in the Document Hierarchy.

Syntax

```
bool UseIndexes_ON ()
```

Parameters

None.

Returns

Always True.

Level

All levels.

Details

This status allows the task to access the properties of the FileNet document, and to provide these properties with values of objects of the Document Hierarchy. True is the default value for using indexes.

Example

```
UserIndexes_ON()  
IndexProperty_ID_Component ("FNDoc,1040EZTwo,12")
```

A task cannot define or populate indices until a rule with this action activates the Indexing feature. However, the On status is a default status, and is in effect unless a UseIndexes_OFF action turns it Off.

Parent topic: [FileNetIDM actions](#)

FileNet P8 actions

Use the FileNet® P8 actions to export data to a FileNet P8 repository.

The FileNet P8 actions integrate Datacap applications with the IBM® FileNet P8 repository. You run these actions to access the FileNet P8 server, set up document attributes and folders on the server, and upload documents to the server for storage.

- [FNP8_AddRedactionsToP8Document](#)
Updates an existing FileNet P8 document to add redactions, if any of the fields have been redacted.
- [FNP8_CreateFolder](#)
Creates a subfolder on a specified target class and object.
- [FNP8_Login](#)
Sets the user ID and password for login to the FileNet P8 system.
- [FNP8_MultiPageDocs](#)
Sets the upload mode to create a multiple page FileNet P8 document.

- [FNP8_SearchAndDownload](#)
Executes a search for documents in FileNet P8 and downloads the content of the documents.
- [FNP8_SetSearchAndDownloadStatusProperty](#)
Sets the name of an integer property that the FNP8_SearchAndDownload action updates for the documents that are downloaded. This indicates that the document has been downloaded.
- [FNP8_SetSearchClass](#)
Sets the document class to be used for search.
- [FNP8_SetSearchCurrentVersionOnly](#)
Set to true to include only the current version of documents in the search results, false otherwise. Default is true.
- [FNP8_SetSearchDownloadDir](#)
Sets the directory path to the location at which the contents of the documents that are returned by search are downloaded.
- [FNP8_SetSearchFolderRestriction](#)
Sets a folder path to restrict the search results.
- [FNP8_SetSearchIncludeDocsWithoutContent](#)
Set to "True" to include documents without content in search results. By default it is set to "False".
- [FNP8_SetSearchIncludeSubClasses](#)
Set to "True" to include the subclasses of the search class in search results. Otherwise, "False". Default is "True".
- [FNP8_SetSearchMaxItems](#)
Sets the maximum number of search results.
- [FNP8_SetSearchOrderBy](#)
Sets the ORDERBY clause for the search results.
- [FNP8_SetSearchWhereClause](#)
Sets the search criteria (WHERE clause).
- [FNP8_SetDefineSecurityParentage](#)
Specifies whether the scanned documents that are exported from Datacap to the FileNet Content Manager inherit security from the parent folder.
- [FNP8_SetDestinationFolder](#)
Sets the destination folder for the documents to be uploaded.
- [FNP8_SetDocClassId](#)
Sets the FileNet P8 document class for the uploaded files.
- [FNP8_SetDocTitle](#)
Sets the document title for documents that you are uploading.
- [FNP8_SetFileMimeType](#)
Associates a custom MIME type with a file extension for documents that are uploaded to the FileNet P8 system.
- [FNP8_SetFileType](#)
Assigns the file type for the files that are uploaded.
- [FNP8_SetKeyProperty](#)
Sets the update key to a FileNet document property and its corresponding property value.
- [FNP8_SetLocale](#)
Identifies the locale on the target FileNet P8 system.
- [FNP8_SetMultiValueProperty](#)
Sets the values in a multi-value property.
- [FNP8_SetProperty](#)
Sets the designated FileNet P8 property to a specified value.
- [FNP8_SetPropertyEx](#)
Sets the designated FileNet P8 property to a specified value.
- [FNP8_SetRetry](#)
Sets the number of automatic upload retries.

- [FNP8_SetTargetClassID](#)
Sets the FileNet P8 document class for uploaded documents.
- [FNP8_SetTargetObjectID](#)
Sets the name of the Object Store in which documents are stored.
- [FNP8_SetTimeout](#)
Sets the timeout for the FileNet P8 web service in milliseconds.
- [FNP8_SetUploadMode](#)
Sets the upload mode.
- [FNP8_SetURL](#)
Sets the URL for the FileNet P8 Server that is used.
- [FNP8_UpdateProperties](#)
Updates the properties of an existing FileNet P8 document by using the data that is passed into the FNP8_SetProperty action.
- [FNP8_Upload](#)
Uploads the batch images to the FileNet P8 repository.
- [FNP8_UploadDir](#)
Uploads all of the images in the folder to the specified destination folder.

Parent topic: [Global actions](#)

FNP8_AddRedactionsToP8Document

Updates an existing FileNet P8 document to add redactions, if any of the fields have been redacted.

Syntax

```
bool FNP8_AddRedactionsToP8Document ()
```

Parameters

None. The page property "PageName" is used.

Returns

False if any issues occur during addition of redactions. Otherwise, True.

Level

Page level.

Details

This action updates an existing FileNet P8 document by adding redactions (if any of the fields have been redacted).

Important: This action can be used only for documents that were downloaded by FNP8_SearchAndDownload action, or those documents that have file names that begin with the FileNet P8 document ID. An example of the file name format is "{3054025F-0000-CE12-B41A-7B2661D28802}.APT008.tif".

Example

```
FNP8_SetSearchClass ("Invoice")  
FNP8_SetSearchDownloadDir ("C:/mylocaldir")  
FNP8_SetSearchWhereClause ("DocumentTitle LIKE '2017-Invoices%'  
FNP8_SearchAndDownload ()
```

```
Scan()  
RedactFields("CCPattern1", "Redact_CreditCard", "4,4,4,4", True)  
FNP8_AddRedactionsToP8Document()
```

Parent topic: [FileNet P8 actions](#)

FNP8_CreateFolder

Creates a subfolder on a specified target class and object.

Syntax

```
bool FNP8_CreateFolder(StrParam)
```

Parameters

A string value or a predefined Smart Parameter variable which specifies the name of the folder to create.

The allowed predefined variables are: *@BATCHID*, *@ID*, *@STATUS*, *@TYPE*, *@VALUE*, *@JOBID*, *@JOBNAME*, *@OPERATOR*, *@STATION*, *@TASKID*, and *@TASKNAME*. Please refer to the smart parameter documentation for more information on these values.

Returns

False if the parameter cannot be parsed, the set up information is invalid, or the folder cannot be created. Otherwise, True.

Attention: If the action returns False, the action directs the Rulerunner task to finish with a status of Aborted.

Level

All levels.

Details

This action creates a subfolder on a specified target class and object. Like the Upload actions, this action must be preceded by SetURL, Login and SetTargetClassID actions.

Example

```
FNP8_SetDestinationFolder("/1040EZ/Export/")  
FNP8_CreateFolder("@BATCHID")
```

This example creates a subfolder under the \1040EZ\Export\ folder and change the destination folder to the newly created folder. If the folder is created successfully, the action adds a variable *Folder_ID* to the current DCO with the folder ID returned from FileNet® Web Service.

Parent topic: [FileNet P8 actions](#)

FNP8_Login

Sets the user ID and password for login to the FileNet® P8 system.

Syntax

```
bool FNP8_Login(StrParam)
```

Parameters

Two comma-separated smart parameter supported string values:

1. Login Name.
2. Password.

Returns

False, if DC_P8_Server.dll was not successfully installed on this computer, or either parameter value is missing or not a string. Otherwise, True.

Level

All, but generally at the Batch level.

Details

This action provides the User ID and Password to use when logging in to IBM® FileNet P8.

Example

```
FNP8_Login("User1,Password1")
```

Parent topic: [FileNet P8 actions](#)

FNP8_MultiPageDocs

Sets the upload mode to create a multiple page FileNet® P8 document.

Syntax

```
bool FNP8_MultiPageDocs(StrParam)
```

Parameters

Specifies whether the FileNet_MultiPageDocs action creates in IBM® FileNet Content Manager a single content element for all the Datacap document pages or one content element per Datacap document page.

Returns

False if the parameter is blank or if the value of the parameter is invalid. Otherwise, True.

Level

All levels

Details

Set FNP8_MultiPageDocs to True to configure the upload actions to create one FileNet P8 document that contains multiple pages.

If the `FNFP8_MultiPageDocs` action is set to `True`, the `FNFP8_Upload` or `FNFP8_UploadDir` actions place all of the pages that are listed the DCO object into a single FileNet P8 document. The default behavior for these actions is to create a FileNet P8 document for each individual page that is listed in the document DCO object.

Example:

```
FNFP8_MultiPageDocs ("True")
FNFP8_Upload()
```

Parent topic: [FileNet P8 actions](#)

FNFP8_SearchAndDownload

Executes a search for documents in FileNet P8 and downloads the content of the documents.

Syntax

```
bool FNFP8_SearchAndDownload()
```

Parameters

Uses the parameters set in the `FNFP8_SetSearch*` methods for executing the search against FileNet P8 repository.

Returns

False if the actions `FNFP8_SetURL`, `FNFP8_Login`, `FNFP8_SetTargetObjectID`, `FNFP8_SetSearchClass`, and `FNFP8_SetSearchDownloadDir` are not successfully called before this action. Otherwise, True.

Level

All levels.

Details

Executes a search for documents in FileNet P8 and downloads the content of the documents that are returned by the search.

By default, the maximum number of search results is limited to 1000 documents. Use the action `FNFP8_SetSearchMaxItems` to set a different maximum limit.

The user or process that executes the action must have 'write' permissions for the directory. If a file exists in the directory with the same name as the content that gets downloaded, the existing file gets overwritten.

Important: To prevent downloading duplicate item content, the task that calls `FNFP8_SearchAndDownload` action should not be run in a multi-threaded configuration. Instead, use single-threaded tasks. For information about configuring threads in Rulerunner, see [Configuring Rulerunner to run tasks](#).

The following actions are *required* to be called before you call `FNFP8_SearchAndDownload`.

- [FNFP8_SetURL](#)
- [FNFP8_Login](#)
- [FNFP8_SetTargetObjectID](#)
- [FNFP8_SetSearchClass](#)
- [FNFP8_SetSearchDownloadDir](#)

The following actions can *optionally* be called before you call FNP8_SearchAndDownload.

Important: Use the following actions to filter the documents that are to be downloaded by the FNP8_SearchAndDownload action.

- [FNP8_SetSearchWhereClause](#)
- [FNP8_SetSearchFolderRestriction](#)
- [FNP8_SetSearchOrderBy](#)
- [FNP8_SetSearchMaxItems](#)
- [FNP8_SetSearchCurrentVersionOnly](#)
- [FNP8_SetSearchIncludeDocsWithoutContent](#)
- [FNP8_SetSearchIncludeSubClasses](#)
- [FNP8_SetSearchAndDownloadStatusProperty](#)

Example 1

```
FNP8_SetURL("http://myp8server:9080/wsi/FNCEWS40MTOM/")
FNP8_Login("User1,Password1")
FNP8_SetTargetObjectID("AP_ObjectStore")
FNP8_SetSearchClass("Invoice")
FNP8_SetSearchDownloadDir("@APPPATH(vscanimagedir)")
FNP8_SetSearchWhereClause("DocumentTitle LIKE '2017-Invoices%')")
FNP8_SetSearchMaxItems("100")
FNP8_SetSearchOrderBy("InvoiceDate ASC")
FNP8_SearchAndDownload()
Scan()
```

In this example following tasks are performed -

- It searches for documents of class "Invoice" that have a property DocumentTitle, that matches the wildcard string '2017-Invoice%'.
- It sorts the results in ascending order based on the InvoiceDate property.
- It takes the top 100 results and downloads the contents of those documents to the directory specified in the Smart Parameter for the VScan image directory.

The output file name is a concatenation of the FileNet P8 item ID and the name of original content file uploaded (if it exists). If the original file name does not exist, then the default file extension would be .tif if the mime type of the content is image/tiff An example of the filename is {3054025F-0000-CE12-B41A-7B2661D28802}.Flight1.tif..

When the Scan() action runs, the action checks the populated image directory, and processes as usual.

Example 2

```
FNP8_SetURL("http://myp8server:9080/wsi/FNCEWS40MTOM/")
FNP8_Login("User1,Password1")
FNP8_SetTargetObjectID("AP_ObjectStore")
FNP8_SetSearchClass("Invoice")
FNP8_SetSearchDownloadDir("@APPPATH(vscanimagedir)")
FNP8_SetSearchWhereClause("DocumentTitle LIKE '2017-Invoices%')")
FNP8_SetSearchMaxItems("100")
FNP8_SetSearchAndDownloadStatusProperty("myStatusProp")
FNP8_SearchAndDownload()
Scan()
```

This example is similar to earlier one. However, the main differences are as follows -

1. For each document that is downloaded, the property myStatusProp of the document is set to a value of 1.
2. During document search, the documents that have myStatusProp=1 are excluded from the search.

FNP8_SetSearchAndDownloadStatusProperty

Sets the name of an integer property that the FNP8_SearchAndDownload action updates for the documents that are downloaded. This indicates that the document has been downloaded.

Syntax

```
bool FNP8_SetSearchAndDownloadStatusProperty (StrParam)
```

Parameters

A name (symbolic name) of an existing integer property of the FileNet P8 document class specified by the action FNP8_SetSearchClass. Smart parameters are supported. The name of the property is not validated until the FNP8_SearchAndDownload action is executed.

Important: The FNP8_SearchAndDownload action updates the value of this specified property.

Returns

False if parameter is not a string. Otherwise, True. The existence of the property on the document class is not verified until FNP8_SearchAndDownload is run.

Level

All levels.

Details

This action is optional before you call action FNP8_SearchAndDownload.

Sets the name of an integer property that the FNP8_SearchAndDownload action updates for the documents that are downloaded. This indicates that the document has been downloaded (status property value is set to "1"). On subsequent executions of FNP8_SearchAndDownload(), the P8 documents that have been downloaded are not downloaded again.

If no status property is set, then properties on the P8 document are not updated by the FNP8_SearchAndDownload action when a P8 document is downloaded. Besides, no status property is checked when searching for documents. To reset a status property that was set earlier, set it to empty string""

Example 1

```
FNPN8_SetSearchClass ("Invoice")
FNPN8_SetSearchDownloadDir ("C:/mylocaldir")
FNPN8_SetSearchAndDownloadStatusProperty ("myStatusProp")
FNPN8_SearchAndDownload ()
```

In this example, FNP8_SearchAndDownload() downloads P8 documents of class "Invoice" and sets the property myStatusProp to "1" for each document that is downloaded. When FNP8_SearchAndDownload() action performs its search, any document with myStatusProp=1 gets excluded from the search and is not downloaded.

Example 2

```
Example:  
FNP8_SetSearchClass ("Invoice")  
FNP8_SetSearchDownloadDir ("C:/mylocaldir")  
FNP8_SetSearchAndDownloadStatusProperty ("")  
FNP8_SearchAndDownload ()
```

In this example, `FNP8_SetSearchAndDownloadStatusProperty("")` resets any previously set value for the download status property name. `FNP8_SearchAndDownload()` downloads P8 documents of class "Invoice", but does not set a status property on documents that have been downloaded. When `FNP8_SearchAndDownload()` action performs its search, there is no check of a status property, so P8 documents that may have been downloaded are included.

Parent topic: [FileNet P8 actions](#)

FNP8_SetSearchClass

Sets the document class to be used for search.

Syntax

```
bool FNP8_SetSearchClass (StrParam)
```

Parameters

A string value of the name (symbolic name) of the class of document to be searched in FileNet P8. The name must be the symbolic name of a FileNet P8 class. Smart parameters are supported. The name of the class is not validated until the `FNP8_SearchAndDownload` action is executed..

Returns

False if parameter is not a string. Otherwise, True.

Level

All levels.

Details

This action is required before you call action `FNP8_SearchAndDownload`.

Set the name (symbolic name in P8) of the class of document to be searched in FileNet P8.

By default, subclasses of the specified class are included in the search results. See action [FNP8_SetSearchIncludeSubClasses](#) to know how to include subclasses in search.

Example

```
FNP8_SetSearchClass ("Invoice")  
FNP8_SetSearchDownloadDir ("C:/mylocaldir")  
FNP8_SearchAndDownload ()  
Scan ()
```

Parent topic: [FileNet P8 actions](#)

FNP8_SetSearchCurrentVersionOnly

Set to true to include only the current version of documents in the search results, false otherwise. Default is true.

Syntax

```
bool FNP8_SetSearchCurrentVersionOnly (StrParam)
```

Parameters

A string representing a boolean value ("True" or "False") for whether or not to limit the search results to only the current version of documents. Smart parameters are supported.

Returns

True.

Level

All levels.

Details

This action is optional prior to calling action FNP8_SearchAndDownload.

Set to "True" to limit the search results to only the current version of documents.

Set to "False" to allow search results to include any version of documents.

If not set, the default is True.

If an invalid value is given for the parameter (i.e. not "True" or "False"), then the action has no effect on the setting and the setting stays the same value as it was prior to the action.

Example

```
FNP8_SetSearchClass ("Invoice")
FNP8_SetSearchDownloadDir ("C:/mylocaldir")
FNP8_SetSearchCurrentVersionOnly ("False")
FNP8_SearchAndDownload ()
```

Parent topic: [FileNet P8 actions](#)

FNP8_SetSearchDownloadDir

Sets the directory path to the location at which the contents of the documents that are returned by search are downloaded.

Syntax

```
bool FNP8_SetSearchDownloadDir (StrParam)
```

Parameters

A string value for the directory path to the location at which the contents of the documents that are returned by search are downloaded. Smart parameters are supported.

Returns

False if parameter is not a string. Otherwise, True.

Level

All levels.

Details

This action is *required* to be called before you call action FNP8_SearchAndDownload.

Sets the directory path to the location at which the contents of the documents that are returned by search are downloaded.

The user or process that runs the FNP8_SearchAndDownload action must have write permission to the directory specified by this action. This action does not validate the existence of the directory.

Example 1

```
FNP8_SetSearchClass("Invoice")
FNP8_SetSearchDownloadDir("@APPPATH(vscanimagedir)")
FNP8_SearchAndDownload()
Scan()
```

In this example, the action is called to download the content of the search documents to the directory specified by the Smart Parameter for the VScan image directory.

Example 2

```
FNP8_SetSearchClass("Invoice")
FNP8_SetSearchDownloadDir("C:/mylocaldir")
FNP8_SearchAndDownload()
Scan()
```

In this example, action is called to download the content of the search documents to the directory C:/mylocaldir.

Parent topic: [FileNet P8 actions](#)

FNP8_SetSearchFolderRestriction

Sets a folder path to restrict the search results.

Syntax

```
bool FNP8_SetSearchFolderRestriction (StrParam)
```

Parameters

A string of the folder path in FileNet P8 repository to restrict search results. Smart parameters are supported. The folder path is not validated until the FNP8_SearchAndDownload action is executed.

Returns

False if parameter is not a string. Otherwise, True.

Level

All levels.

Details

This action is *optional* before you call action FNP8_SearchAndDownload.

Set a FileNet P8 folder path to restrict the search results. The search results are not included in the subfolders of the folder. Set to empty string "" to reset a previously set value.

Note: Setting the folder restriction might result in including only document versions with version state value "Released", in search result.

Example

```
FNp8_SetSearchClass("Invoice")
FNp8_SetSearchDownloadDir("C:/mylocaldir")
FNp8_SetSearchFolderRestriction("/MyFolder/MySubfolderA")
FNp8_SearchAndDownload()
```

Parent topic: [FileNet P8 actions](#)

FNp8_SetSearchIncludeDocsWithoutContent

Set to "True" to include documents without content in search results. By default it is set to "False".

Syntax

```
bool FNp8_SetSearchIncludeDocsWithoutContent (StrParam)
```

Parameters

A string that represents a boolean value ("True" or "False") to indicate whether or not to include documents without content in the search results. Smart parameters are supported.

Returns

True.

Level

All levels.

Details

This action is *optional* before you call action FNP8_SearchAndDownload.

Set to "True" to include documents without content in search results.

Set to "False" to filter out documents without content from search results.

If not set, the default is "False".

If an invalid value is given for the parameter (that is, not "True" or "False"), then the action has no effect on the setting. The setting retains the value that was set before the action was called.

It is not required to change the default setting, since there is no content to download from content-less documents. This action is only provided in case of any unexpected behavior with the search clause that is used to filter out content-less documents, and a need to turn off the filtering is triggered.

Example

```
FNp8_SetSearchClass ("Invoice")
FNp8_SetSearchDownloadDir ("C:/mylocaldir")
FNp8_SetSearchIncludeDocsWithoutContent ("True")
FNp8_SearchAndDownload ()
```

Parent topic: [FileNet P8 actions](#)

FNp8_SetSearchIncludeSubClasses

Set to "True" to include the subclasses of the search class in search results. Otherwise, "False". Default is "True".

Syntax

```
bool FNp8_SetSearchIncludeSubClasses (StrParam)
```

Parameters

A string that represents a boolean value ("True" or "False") to indicate whether or not to include documents of the subclasses of the search class in the search results. Smart parameters are supported.

Returns

True.

Level

All levels.

Details

This action is *optional* before you call action FNp8_SearchAndDownload.

Set to "True" to include documents of the class that is specified by the action FNp8_SetSearchClass and all the subclasses of the search class in search results.

Set to "False" to include only documents of the class that is specified by the action FNp8_SetSearchClass in search results.

If not set, the default is "True".

If an invalid value is set for the parameter (that is not "True" or "False"), then the action has no effect on the setting. The setting retains the value that was set before the action was called.

Example

```
FNp8_SetSearchClass("Invoice")
FNp8_SetSearchDownloadDir("C:/mylocaldir")
FNp8_SetSearchIncludeSubClasses("False")
FNp8_SearchAndDownload()
```

Parent topic: [FileNet P8 actions](#)

FNp8_SetSearchMaxItems

Sets the maximum number of search results.

Syntax

```
bool FNp8_SetSearchMaxItems (StrParam)
```

Parameters

A string that represents an integer value for the maximum number of items to return in search results. Smart parameters are supported.

Returns

False if parameter is not a string numerical value. Otherwise, True.

Level

All levels.

Details

This action is *optional* before you call action FNp8_SearchAndDownload.

You can set the maximum number of search results. Set to "0" or any value less than "0" for no maximum. If not set, the default maximum is 1000.

Example

```
FNp8_SetSearchClass("Invoice")
FNp8_SetSearchDownloadDir("C:/mylocaldir")
FNp8_SetSearchMaxItems("100")
FNp8_SearchAndDownload()
```

Parent topic: [FileNet P8 actions](#)

FNp8_SetSearchOrderBy

Sets the ORDERBY clause for the search results.

Syntax

```
bool FNp8_SetSearchOrderBy (StrParam)
```

Parameters

A string value of the ORDERBY clause that sorts search results. Smart parameters are supported. The clause is not validated until the FNP8_SearchAndDownload action is executed. The expected format of the parameter is - PROPERTY_NAME ASC|DESC

Returns

False if parameter is not a string. Otherwise, True.

Level

All levels.

Details

This action is *optional* before you call action FNP8_SearchAndDownload.

Set the ORDERBY clause for the search results. Set to empty string "" to reset a previously set value.

The parameter is not validated until the SearchAndDownload is executed.

Example 1

```
FNP8_SetSearchClass("Invoice")
FNP8_SetSearchDownloadDir("C:/mylocaldir")
FNP8_SetSearchOrderBy("DocumentTitle ASC")
FNP8_SearchAndDownload()
```

In this example, the results are sorted by DocumentTitle in ascending order.

Example 2

```
FNP8_SetSearchClass("Invoice")
FNP8_SetSearchDownloadDir("C:/mylocaldir")
FNP8_SetSearchOrderBy("DocumentTitle DESC")
FNP8_SearchAndDownload()
```

In this example, the results are sorted by DocumentTitle in descending order.

Parent topic: [FileNet P8 actions](#)

FNP8_SetSearchWhereClause

Sets the search criteria (WHERE clause).

Syntax

```
bool FNP8_SetSearchWhereClause (StrParam)
```

Parameters

A string value of the SQL search criteria (that is, the WHERE clause). The criteria should follow the standard that is used by FileNet P8 query, which generally conforms to the SQL-92 standard. Smart parameters are supported. The clause is not validated until the FNP8_SearchAndDownload action is executed.

Returns

False if parameter is not a string. Otherwise, True.

Level

All levels.

Details

This action is *optional* before you call action FNP8_SearchAndDownload.

Set the SQL search criteria (that is, the WHERE clause). Set to empty string "" to reset a previously set WHERE clause.

Note: Only parametric search is supported, not content-based (full-text) search.

The syntax of the WHERE clause is not validated until the FNP8_SearchAndDownload action is executed. The SQL search criteria must follow the IBM FileNet standard, which generally conforms to SQL-92, with extensions for IBM FileNet specific constructs.

Example

```
FNP8_SetSearchClass("Invoice")
FNP8_SetSearchDownloadDir("C:/mylocaldir")
FNP8_SetSearchWhereClause("DocumentTitle LIKE '2017-Invoices%'")
FNP8_SearchAndDownload()
```

Parent topic: [FileNet P8 actions](#)

FNP8_SetDefineSecurityParentage

Specifies whether the scanned documents that are exported from Datacap to the FileNet Content Manager inherit security from the parent folder.

Syntax

```
bool FNP8_SetDefineSecurityParentage(StrParam)
```

Parameters

The FNP8_SetDefineSecurityParentage action takes a Boolean parameter: True Or False.

Returns

If the action is set to True, the security settings of the exported scanned documents are inherited from the parent folder. This is equivalent to the following API setting.

```
filenet.api.constant.DefineSecurityParentage=DEFINE_SECURITY_PARENTAGE
```

If the action is set to False, the security settings of the exported scanned documents are not inherited from the parent folder. This is equivalent to the following API setting.

```
filenet.api.constant.DefineSecurityParentage=DO_NOT_DEFINE_SECURITY_PARENTAGE
```

Level

All levels.

Details

By default, the `FNp8_SetDefineSecurityParentage` action is set to `False` and the security is not inherited from the parent folder.

Note: If the `FNp8_SetDefineSecurityParentage` action is not used, or if any invalid parameter is used, the default value `False` is used and security is not inherited from the parent folder.

Example

```
FNp8_SetDestinationFolder("@APPVAR(values/gen/P8Folder)")
FNp8_SetDefineSecurityParentage("True")
FNp8_Upload()
```

Parent topic: [FileNet P8 actions](#)

FNp8_SetDestinationFolder

Sets the destination folder for the documents to be uploaded.

Syntax

```
bool FNp8_SetDestinationFolder(StrParam)
```

Parameters

The path to the destination FileNet P8 folder in the selected Object Store where documents are to be uploaded. For example: `\1040EZ\`. The default value is the root folder of the specified target object. Smart parameters are supported.

Attention: The trailing backslash is optional. Subfolders of the root folder do not need to have a trailing backslash after the name. In some cases, a main folder of the object store requires a trailing backslash, if the object store is configured for it.

Returns

`False`, if `DC_P8_Server.dll` was not successfully installed on this computer, or either parameter value is missing or not a string. Otherwise, `True`.

Level

All levels.

Details

Sets the destination folder for the documents to be uploaded. See also `FNp8_CreateFolder`.

Note: This setting can be changed by a subsequent `FNp8_CreateFolder` action. If you call it with the folder name `Unfiled Documents` that is not case-sensitive, it uploads to the FileNet® special `Unfiled Documents` folder.

Example

```
FNp8_SetDestinationFolder("/1040EZ/")
```

Parent topic: [FileNet P8 actions](#)

FPN8_SetDocClassId

Sets the FileNet® P8 document class for the uploaded files.

Syntax

```
bool FNP8_SetDocClassId(StrParam)
```

»

Parameters

A string or Smart Parameter identifying the value of the Document Class ID.

The allowed predefined variables are: [@BATCHID](#), [@ID](#), [@STATUS](#), [@TYPE](#), [@VALUE](#), [@JOBID](#), [@JOBNAME](#), [@OPERATOR](#), [@STATION](#), [@TASKID](#), [@TASKNAME](#) and [@name](#).

«

Returns

False if DC_P8_Server.dll was not successfully installed on this computer, or if parameter is not a string. Otherwise, True.

Level

All levels.

Details

Sets the Document Class to be used in FileNet P8 for the documents being uploaded. If this action is not called, the default value of Document is used.

Example

```
FPN8_SetDocClassId("Document")
```

Parent topic: [FileNet P8 actions](#)

FPN8_SetDocTitle

Sets the document title for documents that you are uploading.

Syntax

```
bool FNP8_SetDocTitle(StrParam)
```

Parameters

String value of a Document Title or a predefined Smart Parameter variable. *Title* is an acceptable default parameter.

Smart parameters are supported.

Returns

False if DC_P8_Server.dll was not successfully installed on this computer, or if parameter is not a string. Otherwise, True.

Level

All levels.

Details

Sets the Document Title for documents being uploaded.

Example

```
FNp8_SetDocTitle("1040ez")  
or  
FNp8_SetDocTitle("@ID")
```

Parent topic: [FileNet P8 actions](#)

FNp8_SetFileMimeType

Associates a custom MIME type with a file extension for documents that are uploaded to the FileNet P8 system.

Member of namespace

FileNet P8

Syntax

```
bool FNp8_SetFileMimeType (StrParam)
```

Parameters

StrParam

The file extension and the associated MIME type separated by a comma.

Returns

Always True.

Level

All levels.

Details

Use this action to set the MIME (Multipurpose Internet Mail Extensions) type for uploaded documents with the specified file extension. This action overrides the library's default mapping of the file extension to a MIME type.

The following table shows the default mappings of file extension to MIME type. Any unlisted file type is mapped to the generic MIME type *application/octet-stream*.

ai	application/illustrator
avi	video/x-msvideo
bmp	image/bmp
doc	application/msword
docx	application/vnd.openxmlformats-officedocument.wordprocessingml.document
dwg	image/vnd.dwg
dxf	image/vnd.dxf
gif	image/gif
htm	text/html
html	text/html
ico	image/x-icon
jpe	image/jpeg
jpeg	image/jpeg
jpg	image/jpeg
jpgv	video/jpeg
m4v	video/x-m4v
mov	video/quicktime
mp4	video/mp4
mpeg	video/mpeg
mpg	video/mpeg
mpp	application/vnd.ms-project
mpv	video/mpv
msg	application/msoutlook
ogg	application/ogg
pcx	image/x-pcx
pdf	application/pdf
pic	image/x-pict
png	image/png
ppt	application/vnd.ms-powerpoint
pptx	application/vnd.openxmlformats-officedocument.presentationml.presentation
qt	video/quicktime
rgb	image/x-rgb
rtf	text/richtext
tif	image/tiff

tiff	image/tiff
txt	text/plain
vsd	application/vnd.visio
wmd	application/x-ms-wmd
wmv	video/x-ms-wmv
wmx	video/x-ms-wmx
xls	application/vnd.ms-excel
xlsx	application/vnd.openxmlformats-officedocument.spreadsheetml.sheet
xml	text/xml

Example:

```
FNP8_SetFileMimeType(".rar, application/x-rar-compressed")
```

Parent topic: [FileNet P8 actions](#)

FNP8_SetFileType

Assigns the file type for the files that are uploaded.

Syntax

```
bool FNP8_SetFileType (StrParam)
```

Parameters

StrParam

A string that identifies the file type. The valid values are as follows:

- doc
- docx
- gif
- jpe
- jpeg
- jpg
- msg
- pdf
- ppt
- tif
- xls
- xlsx
- zip

The default file type is TIF.

Returns

Always returns True.

Level

Batch or Document level.

Details

Use this action to identify the file type of the files that will be uploaded to FileNet® P8.

Example

```
 FNP8_SetFileType ("jpg")
 FNP8_Upload ()
```

Parent topic: [FileNet P8 actions](#)

FNP8_SetKeyProperty

Sets the update key to a FileNet® document property and its corresponding property value.

Syntax

```
bool FNP8_SetKeyProperty (StrParam)
```

Parameters

Strings values identify a FileNet document class property and its corresponding property value. The document class property name and its value must exist on the destination FileNet P8 Object Store. The property value must also be unique because the call to the FNP8_UpdateProperties action returns only one value. Smart parameters are allowed for the second parameter.

Returns

False if either parameter is blank or if the value parameter is invalid. Otherwise, True.

Level

Batch, Document or Page level.

Details

This action sets a key that is used by the UpdateProperties action. The key is a FileNet document property id and its corresponding value. The UpdateProperties action uses the key to search for an existing FileNet document. If the document is found, the properties on the document are updated with the values specified in the SetProperty actions.

Example

```
 FNP8_SetKeyProperty ("DCKey,@DCKey")
 FNP8_SetProperty ("FNProperty,@SomeValue")
 FNP8_SetKeyProperty ("@FNProperty2,@SomeValue2")
 FNP8_UpdateProperties ()
```

This example uses the parameters of FNP8_SetKeyProperty("DCKey,@DCKey") to search for a FileNet document on an object store. If the FileNet document is found, it is assigned the values that are

specified in the SetProperty action when the UpdateProperties action is called. The UpdateProperties action performs actions only on the first document that is returned. If more than one document matches the criteria that is specified in the SetKeyProperty action, only the first document is updated.

Parent topic: [FileNet P8 actions](#)

FNP8_SetLocale

Identifies the locale on the target FileNet® P8 system.

Syntax

```
bool FNP8_SetLocale(StrParam)
```

Parameters

Locale value accepted by the FileNet P8 Web Service. The default value is en_US.

Locales are represented by 2-letter ISO 639 Language Codes and 2-letter ISO 3166 Country Codes separated by a _ character. For example: en_US or de_DE.

Please consult these ISO documents to determine your locale value.

Returns

False, if DC_P8_Server.dll was not successfully installed on this computer, or either parameter value is missing or not a string. Otherwise, True.

Level

All, but generally at the Batch level.

Details

Sets the Locale (the language and language conventions such as date format) used on the P8 server. This action is only required if the FileNet P8 repository uses a locale other than US English.

Example

```
FNP8_SetLocale("en_US")
```

Parent topic: [FileNet P8 actions](#)

FNP8_SetMultiValueProperty

Sets the values in a multi-value property.

Syntax

```
bool FNP8_SetMultiValueProperty(StrParam)
```

Parameters

A comma separated string consisting of these three values:

1. Property ID
2. Property Value. Smart parameters are supported for this parameter only.
3. An optional Property Type. The default is a String. Refer to the FileNet® P8 documentation for a list of Property Types.

Returns

False if the ID or Value parameters are missing or if the specified property is not a multi-value property. Otherwise True.

Level

All levels.

Details

This action sets the property of a FileNet P8 multi-value property. It can be called multiple times.

Example

```
FNP8_SetDocClassId("MyFilenetClass")
FNP8_SetDocTitle("MyFilenetClass Documents")
FNP8_SetProperty("CustomerName,@D.CustomerName")
FNP8_SetMultiValueProperty("InvoiceList,@D.InvoiceList")
FNP8_SetProperty("ScanStation,@STATION")
FNP8_SetProperty("ScanOperator,@OPERATOR")
FNP8_SetFileType("pdf")
FNP8_Upload()
```

Parent topic: [FileNet P8 actions](#)

FNP8_SetProperty

Sets the designated FileNet® P8 property to a specified value.

Syntax

```
bool FNP8_SetProperty(StrParam)
```

Parameters

The following comma-separated string values:

1. Property ID: the name of an existing document property in the FileNet library (equivalent to a document index field).
2. Property Value: the value to assign to the associated Property ID.
3. Optional property type. If this parameter is not specified, the property type will default to a 'string'. Supported types are: Binary, Boolean, DateTime, Float, ID, Integer, Object and String.

Smart Parameters are supported for values.

Returns

False if either parameter is blank or if the value parameter is invalid. Otherwise True.

Attention: If the action returns False, the action directs the Rulerunner task to finish with a status of Abort. The task will also abort if more than one value is assigned to the Smart Parameter variable. If a ruleset calls the FNP8_SetProperty action more than once, using the same Property ID as the opening parameter, FileNet P8 assumes that the second parameter is multi-value and assigns that value to the property.

Level

All levels.

Details

Sets the designated FileNet property to a specified value. This is equivalent to setting an index value for a document in other document management systems.

Example

```
FNP8_SetProperty("DocumentTitle, @ID")
FNP8_Upload()
```

Parent topic: [FileNet P8 actions](#)

FNP8_SetPropertyEx

Sets the designated FileNet® P8 property to a specified value.

Syntax

```
bool FNP8_SetPropertyEx(StrParam)
```

Parameters

The following comma-separated string values:

1. Property ID: the name of an existing document property in the FileNet P8 library (equivalent to a document index field).
2. Property Value: the value to assign to the associated Property ID.
3. Optional property type. If this parameter is not specified, the property type defaults to a string. Supported types are: Binary, Boolean, DateTime, Float, ID, Integer, Object and String.

Smart Parameters are supported for values.

Returns

False if either parameter is blank or if the value of the parameter is invalid. Otherwise True.

Attention: If the action returns False, the action directs the Rulerunner task to finish with a status of Abort. The task will also abort if more than one value is assigned to the Smart Parameter variable.

Important: Any ruleset that calls the FNP8_SetPropertyEx action more than once, using the same Property ID as the opening parameter, the property value will not create a multivalued property. Unlike the behavior of the FNP8_SetProperty action, it replaces the existing property value that was set up by any previous ruleset.

Level

All levels.

Details

Sets the designated FileNet property to a specified value. This is equivalent to setting an index value for a document in other document management systems.

Example

```
FNp8_SetPropertyEx("DocumentTitle, @ID")
FNp8_Upload()
```

Parent topic: [FileNet P8 actions](#)

FNp8_SetRetry

Sets the number of automatic upload retries.

Syntax

```
bool FNp8_SetRetry(StrParam)
```

Parameters

A integer value identifies the amount of retries performed if the upload failed. Smart parameters are supported.

Returns

False if non-numeric parameter specified. Otherwise True.

Level

Batch, Document or Page level.

Details

Use this action to set the amount of retries for the FileNet® P8 upload actions. If the upload to FileNet fails, the upload action will immediately be retried the number of times specified by the FNp8_SetRetry action.

If this action is not called prior to a FileNet P8 upload action, the default amount of retries is 0.

Example

```
FNp8_SetRetry("3")
NP8_Upload()
```

FNp8_SetRetry("3") causes the FNp8_Upload to initiate 3 upload attempts if the upload to FileNet fails.

Parent topic: [FileNet P8 actions](#)

FNp8_SetTargetClassID

Sets the FileNet® P8 document class for uploaded documents.

Syntax

```
bool FNP8_SetTargetClassID(StrParam)
```

Parameters

Specifies the repository type. The valid values are ObjectStore and FileStore.

Returns

False, if DC_P8_Server.dll was not successfully installed on this computer, or either parameter value is missing or not a string. Otherwise, True.

Level

All levels.

Details

Sets the top-level repository type. If this action is not called, the default value of ObjectStore is used. FileStore is an alternative repository type.

Example

```
FNP8_SetTargetClassID("ObjectStore")
```

Parent topic: [FileNet P8 actions](#)

FNP8_SetTargetObjectID

Sets the name of the Object Store in which documents are stored.

Syntax

```
bool FNP8_SetTargetObjectID (StrParam)
```

Parameters

String value of the Object ID. Smart parameters are supported.

Returns

False, if DC_P8_Server.dll was not successfully installed on this computer, or either parameter value is missing or not a string. Otherwise, True.

Level

All, but generally at the Batch level.

Details

Provides the name of the Object Store that you wish to store your documents in.

Example

```
FNP8_SetTargetObjectID("AP_ObjectStore")
```

Parent topic: [FileNet P8 actions](#)

FNP8_SetTimeout

Sets the timeout for the FileNet® P8 web service in milliseconds.

Syntax

```
bool FNP8_SetTimeout (StrParam)
```

Parameters

A single parameter identifying the timeout in milliseconds for the FileNet P8 Web Service. The default timeout is 600000 milliseconds (600 seconds).

Returns

False if DC_P8_Server.dll was not successfully installed on this computer, or if the parameter is not formatted as a valid integer value. Otherwise, True.

Level

All, but generally at the Batch level.

Details

This action sets the timeout in milliseconds for the FileNet P8 Web Service. This action should be called before the FNP8_Upload action.

Example

```
FNP8_SetTimeout (90000)
```

Parent topic: [FileNet P8 actions](#)

FNP8_SetUploadMode

Sets the upload mode.

Syntax

```
bool FNP8_SetUploadMode (StrParam)
```

Parameters

A string or Smart Parameter identifying the page level variable where file name is stored. If this action is not called the value defaults to blank and regular upload logic applied. Smart parameters are supported.

For example FNP8_SetUploadMode("ParentImage") uploads a file with the name stored in *ParentImage* variable on the page level.

Returns

Always True.

Level

Batch, Document or Page level.

Details

Use this action to identify the files that will be uploaded to FileNet® P8.

Example

```
 FNP8_SetUploadMode ("ParentImage")
 FNP8_Upload ()
```

Parent topic: [FileNet P8 actions](#)

FNP8_SetURL

Sets the URL for the FileNet® P8 Server that is used.

Syntax

```
bool FNP8_SetURL (StrParam)
```

Parameters

A single parameter that identifies the URL for the IBM® FileNet P8 Server. The IP port is typically :9080 (IBM WebSphere®) and the URL typically ends in /WSDL.

Returns

False, if DC_P8_Server.dll was not successfully installed on this computer, or if the parameter is not formatted as a valid URL. Otherwise, True.

Attention: This action returns True whether the URL is to an operating IBM FileNet P8 Server or not. If not, an error is reported when the Upload or UploadDir action runs. You can check that the URL is correct and operating by displaying it in any web browser.

Level

All, but generally at the Batch level.

Details

This action sets the URL for the IBM FileNet P8 IBM FileNet P8 Server. This action must be called before any other FileNet P8 upload actions.

Example

```
 FNP8_SetURL ("http://myp8server:9080/wsi/FNCEWS40MTOM/")
```

Important: The address can be case-sensitive and the trailing forward-slash "/" must be present. To confirm that the address reaches a working IBM FileNet P8 Server, browse to the address after you add

wsdl to the end of the URL address, as in the following example,
<http://myp8server:9080/wsi/FNCEWS40MTOM/wsdl>

Parent topic: [FileNet P8 actions](#)

FNP8_UpdateProperties

Updates the properties of an existing FileNet® P8 document by using the data that is passed into the FNP8_SetProperty action.

Syntax

```
bool FNP8_UpdateProperties()
```

Parameters

Uses the key specified in the FNP8_SetKeyProperty action to search for an existing document within a FileNet P8 Case Manager Object Store and updates the P8 document's properties as specified by the FNP8_SetProperty action.

Returns

True if the update is successful, False if the action is unable to update the document.

Level

Batch, Document or Page level.

Details

Use this action to update an existing FileNet P8 document's properties. The UpdateProperties action should only be used to update properties for an existing document. If a new document is created use the Upload action.

Example

```
FNP8_SetKeyProperty ("DCKey,@DCKey)  
FNP8_SetProperty("AGIncome, @AGIncome")  
FNP8_SetProperty("TaxYear,@TaxYear)  
FNP8_UpdateProperties()
```

This example will first set the key document property name and value to search for a document, the next two actions indicate which properties and values that the FileNet P8 document should be updated with. The FNP8_UpdateProperties will invoke the actual update. If more than one document matches the criteria specified in the SetKeyProperty action, only the first document will be updated.

Parent topic: [FileNet P8 actions](#)

FNP8_Upload

Uploads the batch images to the FileNet® P8 repository.

Syntax

```
bool FNP8_Upload()
```

Parameters

None.

Returns

False if the upload is not successful, or the action was applied to the Field level. Otherwise, True. If successful, each page uploaded will have a variable *Doc_ID* set to the FileNet document identifier.

Attention: The action directs the Rulerunner task to finish with a status of Aborted.

Level

Batch, Document or Page level.

Details

Uploads image files from the Datacap batch to the specified destination folder in the FileNet library.

When called at the Batch or Document level, attempts to upload a multipage TIF image file named ObjID.tif, where ObjID is the DCO Object ID of the Batch or Document. If such a file does not exist, tries to upload all page images in the Batch or Document.

When called at the Page level, uploads the image file for that page. It is important that any required properties are set before calling FNP8_Upload such as FNP8_SetDocTitle otherwise an upload error could occur.

Example

```
FNP8_SetURL("http://server:port//wsi/FNCEWS40MTOM/")
FNP8_Login("user,password")
FNP8_SetLocale("en-us")
FNP8_SetDocClassId("MyFileNetDocClass")
FNP8_SetDocTitle("Document Title")
FNP8_SetProperty("CustomerName,@D.CustomerName")
FNP8_SetMultiValueProperty("InvoiceList,@D.InvoiceList")
FNP8_SetProperty("ScanStation,@STATION")
FNP8_SetProperty("ScanOperator,@OPERATOR")
FNP8_SetFileType("pdf")
FNP8_Upload()
```

Parent topic: [FileNet P8 actions](#)

FNP8_UploadDir

Uploads all of the images in the folder to the specified destination folder.

Syntax

```
bool FNP8_UploadDir(StrParam)
```

Parameters

Two comma-separated String values:

1. The full path of the source folder that contains the images to be uploaded. For example: C:\images.

2. A Boolean value to indicate whether images must be deleted from the source folder. False: images will not be deleted from the source folder after they are uploaded. True: images will be deleted from the source folder after they are uploaded.

Returns

False, if the upload is not successful. Otherwise, True.

Attention: If the action returns False, the action directs the Rulerunner task to finish with a status of `Aborted`.

Level

Batch or Document level.

Details

Uploads all images in the folder you enter as the first parameter to the specified destination folder.

This action is an alternative to `FNP8_Upload` if you want to upload images that are not within a Datacap batch.

Example

```
FNP8_UploadDir("C:\images,False")
```

This example leaves the images in the source folder after they are uploaded.

```
FNP8_UploadDir("C:\images,True")
```

This example deletes the images in the source folder after they are uploaded.

Parent topic: [FileNet P8 actions](#)

FingerprintMaintenance actions

Use the `FingerprintMaintenance` actions to delete fingerprints from the fingerprint library of the application.

The `FingerprintMaintenance` actions open and close connections to the fingerprint database, specify the folder that contains the fingerprints to be deleted, and deletes those fingerprints.

- [CloseDatabase](#)
Closes connection to the fingerprint database and saves the Setup DCO.
- [DeleteFingerprint](#)
Deletes specified fingerprint.
- [DeleteFingerprints](#)
Deletes all fingerprints that are returned by the SQL statement in the parameter
- [OpenDatabase](#)
Opens a connection to the fingerprint database.
- [SetFingerprintFolder](#)
Specifies the folder containing the fingerprint files.

Parent topic: [Global actions](#)

CloseDatabase

Closes connection to the fingerprint database and saves the Setup DCO.

Member of namespace

FingerprintMaintenance

Syntax

```
bool CloseDatabase ()
```

Parameters

None.

Returns

Always True.

Level

Any level.

Details

Closes the open database connection and saves the Setup DCO if position information was deleted. The Setup DCO is not modified if FPXML files are used, or if no fingerprints were deleted.

Example:

```
CloseDatabase ()
```

Parent topic: [FingerprintMaintenance actions](#)

DeleteFingerprint

Deletes specified fingerprint.

Member of namespace

FingerprintMaintenance

Syntax

```
bool DeleteFingerprint (string ID)
```

Parameters

ID

Type: string

ID of fingerprint to delete

Parameters

The ID of the fingerprint to delete.

Returns

Always True.

Level

Any level.

Details

Deletes the CCO, TIFF and FPXML files for the specified fingerprint. Also deletes the database record and position information from the DCO. A smart parameter may be used.

Example:

```
DeleteFingerprint ("1002")
```

Parent topic: [FingerprintMaintenance actions](#)

DeleteFingerprints

Deletes all fingerprints that are returned by the SQL statement in the parameter

Member of namespace

FingerprintMaintenance

Syntax

```
bool DeleteFingerprints (string SQL)
```

Parameters

SQL

Type: string

SQL statement to return a recordset of fingerprints to be deleted.

Parameters

SQL statement that is used to return a recordset of fingerprints that must be deleted.

Returns

Always True.

Level

Any level.

Details

Deletes all fingerprints that are returned by the query that is specified in the parameter. A smart parameter can be used.

Example:

```
Access - DeleteFingerprints("SELECT * FROM Template WHERE tp_LastHit <
dateadd("d",-30,NOW) ")
SQL - DeleteFingerprints("SELECT * FROM Template WHERE tp_LastHit <
dateadd(d,-2,GETDATE()) ")
Oracle- DeleteFingerprints("SELECT * FROM Template WHERE tp_LastHit <
TRUNC(SYSDATE) - 30")
```

Parent topic: [FingerprintMaintenance actions](#)

OpenDatabase

Opens a connection to the fingerprint database.

Member of namespace

FingerprintMaintenance

Syntax

```
bool OpenDatabase (string ConnectionString)
```

Parameters

ConnectionString
Type: string
Fingerprint database connection string.

Parameters

Fingerprint database connection string.

Returns

True, if the connection is established. False, if the connection is not established.

Level

Any level.

Details

Opens a connection to the fingerprint database by using the connection string provided in the parameter. A smart parameter can be used.

Example:

```
OpenDatabase ("provider=microsoft.jet.oledb.4.0;
data source=c:\datacap\apt\APTFingerprint.mdb;
persist security info=false")
```

This example obtains the connection string set in the Application Manager.

```
OpenDatabase("@APPVAR(*/*dco_*[1]/fingerprintconn:cs)")
```

Parent topic: [FingerprintMaintenance actions](#)

SetFingerprintFolder

Specifies the folder containing the fingerprint files.

Member of namespace

FingerprintMaintenance

Syntax

```
bool SetFingerprintFolder (string Folder)
```

Parameters

Folder

Type: string

Folder containing the fingerprints.

Parameters

Folder path where the fingerprints are located.

Returns

Always True.

Level

Any level.

Details

Specifies the folder containing the fingerprint files. A smart parameter may be used.

Example:

```
SetFingerprintFolder("C:\Datacap\APT\fingerprint")
```

This example obtains the path set in the Application Manager.

```
SetFingerprintFolder("@APPPATH(*/*fingerprint)")
```

Parent topic: [FingerprintMaintenance actions](#)

FPXML actions

Use the FPXML actions to store zone coordinates in an external XML file instead of the document hierarchy (setup DCO). These actions are useful for porting fingerprints between systems or to avoid making frequent

modifications to the document hierarchy.

The FPXML actions can load zone information for a fingerprint, set the type of Details and LineItem fields, and set the location for the fingerprint XML files.

- [ReadZonesFPX](#)
Loads position information for current fingerprint
- [SetDetailsAndLineitemPairFPX](#)
Sets the type of the special Details and Lineitem fields.
- [SetDirectoryFPX](#)
Sets the directory in which fingerprint xml files should be read and written to.
- [WriteZoneFPX](#)
Writes the positions of a field to Fingerprint XML
- [WriteZonesFPX](#)
Writes position information for all fields of the page

Parent topic: [Global actions](#)

ReadZonesFPX

Loads position information for current fingerprint

Member of namespace

FPXML

Syntax

```
bool ReadZonesFPX ()
```

Parameters

None.

Returns

False, if the fingerprint.xml cannot be loaded or if SetDirectoryFPX has not been called to set the location of the fingerprint XML files. Otherwise, True.

Level

Page or Field level.

Details

This action reads the field zone information from the fingerprint XML file associated with the fingerprint for the current page object. This action is similar to the ReadZones action in the Zones library. The primary difference is that ReadZones reads the zone information stored in the setup DCO and ReadZonesFPX reads the zone information from the associated fingerprint XML file. Typically this action is called after the CreateFields action but before field recognition. ReadZonesFPX loads position information for each node in the calling object and it's children. Pre-adjusts these values based on offset information stored in the *Image_Offset* variable at any node level.

The offset value is applied to all child objects of a node where an *Image_Offset* variable is found; unless overwritten by a child node also having an *Image_Offset* value to apply.

Position information is based on the Fingerprint XML position for the parent page's fingerprint ID.

If Enable FPXML setting is checked in the application settings Main tab in the Datacap Application Manager, Datacap Studio places field zone information into a fingerprint XML file instead of placing the zone information into the applications setup DCO. One FPXML file is created per fingerprint. Depending on application needs, using fingerprint XML files might have advantages. Refer to Datacap documentation for more information about using fingerprint XML files.

If the application is using FPXML files, then use this action to load the zones.

Example:

```
SetDirectoryFPX("@APPPATH(* /fingerprint) ")
ReadZonesFPX()
```

Parent topic: [FPXML actions](#)

SetDetailsAndLineitemPairFPX

Sets the type of the special Details and Lineitem fields.

Member of namespace

FPXML

Syntax

```
bool SetDetailsAndLineitemPairFPX (StrParam)
```

Parameters

Two comma separated parameters:

- Detail field type: type of the field that is the parent to the line item field, often called Details.
- LineItem field type: type of the line item field which is the parent of the fields to be captured, often called Lineitem.

Smart parameters are supported.

Returns

False if one of the parameters is missing. Otherwise True.

Level

Any level.

Details

Use this action if your page contains Details and Lineitems fields, as is common with an invoice page. The action sets the type of the special Details and Lineitem fields. These fields, unlike other field types, are handled

by the ReadZonesFPX and WriteZonesFPX actions in a special way that is compatible with the Locate actions framework.

If your page has Details and Lineitems, then this action is required to identify the types so the position information is properly saved. Using SetDetailsAndLineitemPairFPX prior to calling WriteZonesFPX causes WriteZonesFPX to save line item field positions to the fingerprint file. The second parameter is the type of the line item field which is the parent of the fields to be captured and is often called Lineitem.

If your page contains Detail and Lineitem fields, this action also must be used prior to calling ReadZonesFPX.

Details are the parent object of the line item fields. Details are a collection of lineitems and each line item has a collection of fields. For example, in a typical invoice application a single lineitem can contain the fields: quantity, item number, description, unit price, and total.

Example:

```
SetDetailsAndLineitemPairFPX("Details,Lineitem")
```

```
ReadZonesFPX()
```

In this example, the details field is called "Details" and the line items are called "Lineitem".

An example DCO hierarchy may look something like this:

```
- Details
--- Lineitem
----- Qty
----- ItemID
----- ItemDesc
----- Price
----- LineTotal
```

Parent topic: [FPXML actions](#)

SetDirectoryFPX

Sets the directory in which fingerprint xml files should be read and written to.

Member of namespace

FPXML

Syntax

```
bool SetDirectoryFPX (StrParam)
```

Parameters

A string identifying the Fingerprint directory. This is the directory that contains the FPXML files.

Smart parameters are supported.

Returns

False if the parameter is missing. Otherwise True.

Level

Any level.

Details

This action sets the directory from which fingerprint XML files will be written or read.

This action must be called to identify the FPXML directory before calling ReadZonesFPX or WriteZonesFPX.

Example:

```
SetDirectoryFPX("@APPPATH(* /fingerprint)")  
ReadZonesFPX()
```

This example uses the @APPPATH smart parameter to obtain the directory from the application service.

```
SetDirectoryFPX("C:\Datacap\APT\fingerprint")  
ReadZonesFPX()
```

This example hard codes the directory, which is fine but could make the application less portable.

Parent topic: [FPXML actions](#)

WriteZoneFPX

Writes the positions of a field to Fingerprint XML

Member of namespace

FPXML

Syntax

```
bool WriteZoneFPX (StrParam)
```

Parameters

Field name (required only when the action is called at the page level)

Returns

False if there is there is not a fingerprint directory set, or the fingerprint ID cannot be determined, if the field in the parameter cannot be found, if called at the page level without a parameter, or if there is a problem opening or saving the fingerprint XML file. Otherwise True.

Level

Page and Field

Details

When called at the field level, writes position information for each node in the calling object and its children.

When called at the page level, writes position information the specified field and its sub fields.

Parent topic: [FPXML actions](#)

WriteZonesFPX

Writes position information for all fields of the page

Member of namespace

FPXML

Syntax

```
bool WriteZonesFPX (StrParam)
```

Parameters

Three comma separated parameters:

- Fingerprint host name: This is the fingerprint class name and can be seen in the Zones tab of Datacap Studio. It is used to group or classify fingerprints. If this value is not provided, then a blank class name will be used.
- Fingerprint host id: This is an internal numeric value that is associated with the fingerprint class name. If a value is not provided, a blank value is used.
- Fingerprint page type: This is the page type that corresponds to the fingerprint for the page. If this value is not provided, it uses the page type of the current page.

Smart parameters are supported. All parameters are optional. If you provide only the second or third parameter, you must supply an empty value for the previous parameters.

Returns

False, if there is a problem saving to fingerprint XML file or if not called at the page level, if the page does not have a fingerprint assigned, or a fingerprint directory has not been set. Otherwise True.

Level

Page level only.

Details

This action writes out all of the field positions for the current page to the fingerprint XML file. Typically this action is used for applications that are using fingerprint XML files and new pages are dynamically zoned at runtime. After the zoning of the page has been completed, then this action is used to write out the zone information to the FPXML file, allowing subsequent pages of this type to be processed using the saved zone information.

If the fingerprint directory that had been previously specified using SetDirectoryFPX does not exist, it is created, providing that the parent directory already exists.

Fields with empty positions are not written to the fingerprint XML file.

Example:

```
SetDirectoryFPX("@APPPATH(* /fingerprint) ")
WriteZonesFPX("MyFPClass,,MyPageType")
```

This example writes out the zones for the current page and sets the fingerprint class to "MyFPClass" and the page type to "MyPageType".

```
SetDirectoryFPX("@APPPATH(* /fingerprint) ")
WriteZonesFPX("MyFPClass,,@P.MyType")
```

This example writes out the zones for the current page and sets the fingerprint class to "MyFPClass" and the page type to the value contained by the page variable "MyType".

Parent topic: [FPXML actions](#)

Grayscale actions

Use the Grayscale action to convert grayscale TIFF images to black-and-white.

The ConvertGraytoBW action can convert color dropout forms, including medical claims, scanned in grayscale to black and white. The action categorizes each pixel in the image as either foreground (black), dropout (red / light gray), or background (white), to produce a final black and white image without the dropout color.

- [ConvertGraytoBW](#)
Converts Grayscale TIFF files to black and white TIFF files.

Parent topic: [Global actions](#)

ConvertGraytoBW

Converts Grayscale TIFF files to black and white TIFF files.

Syntax

```
bool ConvertGraytoBW ()
```

Parameters

None.

Returns

False, if a rule set with this action is bound to a Field object of the Document Hierarchy. Otherwise, True.

If the input image is not grayscale, or if there is an error in processing, the image is not converted and the action returns False.

Level

Batch, Document or Page level. If called at the batch level, all images will be converted.

If called at the document level all of the pages within the document will be converted.

If called at the page level, the single page will be converted.

Details

This action converts grayscale TIFF files into Black and White TIFF files.

The ConvertGraytoBW action is especially good at converting color dropout forms, including medical claims, scanned in grayscale to black and white. The action categorizes each pixel in the image as either foreground (black), dropout (red / light gray), or background (white), to produce a final black and white image without the dropout color.

Attention: The action renames the original grayscale image using the same base file name, but replaces the .tif filename extension with .tis.

Example

```
ConvertGraytoBW ()
```

Parent topic: [Grayscale actions](#)

HandwritingRecognition actions

Use the Handwriting Recognition actions to perform cursive recognition of the configured fields using the Parascript FormXtra Recognition Engine.

The Handwriting Recognition actions are described in the following table.

- [Recognize](#)
Recognizes the content within the configured fields.
- [SetAddressApartmentZone](#)
Sets the name of the field that contains the zone for the apartment part of the address.
- [SetAddressCityStateZipZone](#)
Sets the name of the field that contains the zone for the City, State, and Zip part of the address.
- [SetAddressCityStateZone](#)
Sets the name of the field that contains the zone for the City and State part of the address.
- [SetAddressCityZone](#)
Sets the name of the field that contains the zone for the City part of the address.
- [SetAddressStateZone](#)
Sets the name of the field that contains the zone for the State part of the address.
- [SetAddressZipZone](#)
Sets the name of the field that contains the zone for the Zip code (postal code) part of the address.
- [SetAmountFormat](#)
Sets the format of the amount fields.
- [SetBoxRemovalMode](#)
Sets the type of box removal to be performed on the field.
- [SetCreditCardFormat](#)
Sets the format of credit card number fields.
- [SetDateFormat](#)
Sets the date format for date fields.
- [SetDeskew](#)
Turns on or off the deskew on the field snippet prior to recognition.
- [SetFieldType](#)
Sets the type of the field to read.
- [SetFullNameFormat](#)
Sets the format of full name fields.
- [SetLanguage](#)
Sets the recognition language for the fields.
- [SetLineRemovalMode](#)
Sets the type of line removal to be performed on the field.

- [SetMultiLineMode](#)
Sets which lines to extract from multi-line fields.
- [SetNoiseRemoval](#)
Turns on or off the noise removal on the field snippet prior to recognition.
- [SetPostalDatabase](#)
Sets the path of the postal database for address recognition.
- [SetProcessingMode](#)
Sets whether to favor speed or accuracy when performing recognition.
- [SetSpecialCharacterSet](#)
Sets additional characters to add to the default field character set.
- [SetTemplate](#)
Sets the format of the field text to read.
- [SetValidLength](#)
Sets the length range for the field.
- [SetValidValues](#)
Sets the length range for the field.
- [SetVocabulary](#)
Sets the vocabulary file to use for recognizing fields.
- [SetWritingStyle](#)
Sets the writing style of the field.

Parent topic: [Global actions](#)

Recognize

Recognizes the content within the configured fields.

Member of namespace

HandwritingRecognition

Syntax

```
bool Recognize ()
```

Returns

True always.

Level

Page.

Details

Performs recognition of the configured fields. After you have configured all the fields to be recognized, you must call this action to produce recognition results.

Example:

```
Field Level ruleset
```

```
SetFieldType  
SetWritingStyle
```

Page Level Ruleset

Recognize ()

The page level ruleset in this example is attached to the page's "Close" to ensure that all fields are configured before calling Recognize. Alternatively, the Recognize action could also be called in a separate ruleset, after the page fields have been configured.

Parent topic: [HandwritingRecognition actions](#)

SetAddressApartmentZone

Sets the name of the field that contains the zone for the apartment part of the address.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetAddressApartmentZone (string param)
```

Parameters

The string value representing name of the field that contains the zone for the apartment part of the address. Smart parameters are supported.

Returns

True always.

Level

Field.

Details

Sets the name of the field that contains the zone for the apartment part of the address. This is required when recognizing fields of type "Address" and multiple zones are used to recognize the address.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType (8)  
SetAddressApartmentZone ("ApartmentField")
```

The example above sets the field type to address. The field containing the apartment zone, ApartmentField in this example, is set using the SetAddressApartmentZone action. Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset)

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetAddressCityStateZipZone

Sets the name of the field that contains the zone for the City, State, and Zip part of the address.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetAddressCityStateZipZone (string param)
```

Parameters

The string value representing name of the field that contains the zone for the City, State, and Zip part of the US address. Smart parameters are supported.

Returns

True always.

Level

Field.

Details

Sets the name of the field that contains the zone for the City, State, and Zip part of the address. This is required when recognizing fields of type "Address" and multiple zones are used to recognize the address.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType(8)  
SetAddressCityStateZipZone("CityStateZipField")
```

The example above sets the field type to address. Assuming the field zoned for the City, State, and Zip zone is called CityStateZipField, this field is then specified using the SetAddressCityStateZipZone action. When recognition runs, the field CityStateZipField is recognized and its text value is set with the City, State and Zip value. The original field configured as the address field has DCO variables created that contain the City, State, Zip and ZipFull.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetAddressCityStateZone

Sets the name of the field that contains the zone for the City and State part of the address.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetAddressCityStateZone (string param)
```

Parameters

The string value representing name of the field that contains the zone for the City and State part of the address. Smart parameters are supported.

Returns

True always.

Level

Field.

Details

Sets the name of the field that contains the zone for the City and State part of the address. This is required when recognizing fields of type "Address" and multiple zones are used to recognize the address.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType(8)
SetAddressCityStateZone("CityStateField")
SetAddressZipZone("ZipCodeField")
```

The example above sets the field type to address. The field containing the City, State zone is configured. Finally the field containing the Zip zones is set.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetAddressCityZone

Sets the name of the field that contains the zone for the City part of the address.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetAddressCityStateZone (string param)
```

Parameters

The string value representing name of the field that contains the zone for the City part of the address. Smart parameters are supported.

Returns

True always.

Level

Field.

Details

Sets the name of the field that contains the zone for the City part of the address. This is required when recognizing fields of type "Address" and multiple zones are used to recognize the address.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType(8)
SetAddressCityZone("CityField")
SetAddressStateZone("StateField")
SetAddressZipZone("ZipCodeField")
```

The example above sets the field type to address. The field containing the City, State, and Zip zones are identified using the SetAddress actions.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

Recognize()

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetAddressStateZone

Sets the name of the field that contains the zone for the State part of the address.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetAddressStateZone (string param)
```

Parameters

The string value representing name of the field that contains the zone for the State part of the address. Smart parameters are supported.

Returns

True always.

Level

Field.

Details

Sets the name of the field that contains the zone for the State part of the address. This is required when recognizing fields of type "Address" and multiple zones are used to recognize the address.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType(8)
SetAddressCityZone("CityField")
SetAddressStateZone("StateField")
SetAddressZipZone("ZipCodeField")
```

The example above sets the field type to address. The field containing the City, State, and Zip zones are identified using the SetAddress actions.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetAddressZipZone

Sets the name of the field that contains the zone for the Zip code (postal code) part of the address.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetAddressZipZone (string param)
```

Parameters

The string value representing name of the field that contains the zone for the Zip code part of the address. Smart parameters are supported.

Returns

True always.

Level

Field.

Details

Sets the name of the field that contains the zone for the Zip code (postal code) part of the address. This is required when recognizing fields of type "Address" and multiple zones are used to recognize the address.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType (8)
SetAddressCityZone ("CityField")
SetAddressStateZone ("StateField")
SetAddressZipZone ("ZipCodeField")
```

The example above sets the field type to address. The field containing the City, State, and Zip zones are identified using the SetAddress actions.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetAmountFormat

Sets the format of the amount fields.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetAmountFormat (string param)
```

Parameters

The integer value representing the amount format. The following values are supported:

- 0 - Positive (default)
- 1 - Positive or negative

Returns

True always.

Level

Field.

Details

Sets the format of the amount fields.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType (32)  
SetFullNameFormat (1)
```

The example above sets the field type to amount, and sets the amount format to positive or negative amount.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetBoxRemovalMode

Sets the type of box removal to be performed on the field.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetBoxRemovalMode (string param)
```

Parameters

The integer value representing the type of box removal. The following are the valid values:

- 0 - None (default)
- 1 - Remove box
- 2 - Remove box and around
- 3 - Remove combs

Returns

True always.

Level

Field.

Details

Sets the type of box removal to be performed on the field.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetBoxRemovalMode (1)
SetFieldType (1)
SetMultiLineMode (2)
```

The example above sets line removal to remove boxes, then sets the field type to alpha, and finally sets the recognition to read only the second line.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetCreditCardFormat

Sets the format of credit card number fields.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetCreditCardFormat (string param)
```

Parameters

The integer value representing the format of credit card number fields. The following values are supported:

- 0 - Number (default)
- 1 - Number and expiration date

Returns

True always.

Level

Field.

Details

Sets the format of credit card number fields.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType (256)
SetCreditCardFormat (1)
```

The example above sets the field type to credit card number, and sets the format to read number and expiration date.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetDateFormat

Sets the date format for date fields.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetDateFormat (string param)
```

Parameters

The integer value representing the date format. The following values are supported:

- 0 - MMDDYYYY. The numeric month/day/year format. For example, 12/31/2010 or 12/31/10.
- 1 - MMMMDDYYYY. The mixed alpha-numeric month/day/year format. For example, 12/31/2010, 12/31/10 or December 31, 2010.
- 2 - DDMMYYYY. The European day/month/year format. For example, 31/12/2010 or 31/12/10.
- 3 - DDMMMYYYY. The European mixed alpha-numeric day/month/year format. For example, 31/12/2010, 31/12/10, or 31 December 2010.
- 4 - YYYY. The numeric year format. For example, 2010 or 10.
- 5 - MM. The numeric month format. For example, 12.
- 6 - DD. The numeric day format. For example, 31.
- 7 - MYYYYY. The numeric month/year format. For example, 12/2010 or 12/10.
- 8 - MMDD. The numeric month/day format. For example, 12/31.
- 9 - YYYYMMDD. The numeric year/mm/day format. For example, 2010/12/31 or 10/12/31.

- 10 - GenericUS. The combination of date formats generally used in the United States. This is a combination of date formats MMDDYYYY, YYYYMMDD, and MMMMDDYYYY.

Returns

True always.

Level

Field.

Details

Sets the date format for date fields. The date type supports the following languages: English, German, Portuguese (Brazil), or Spanish (Latin America). The date formats DD MMMM YYYY and MMMM DD, YY are not supported for German language.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType (512)
SetDateFormat (1)
```

The example above sets the field type to Date, and sets the expected date format.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetDeskew

Turns on or off the deskew on the field snippet prior to recognition.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetDeskew (string param)
```

Parameters

The boolean value specifying whether or not to perform deskew on the field snippet prior to recognition. The following are the valid values:

- True - Deskew is performed (default).
- False - Deskew is not performed.

Returns

True always.

Level

Field.

Details

This action turns the deskew on or off on the field snippet prior to recognition.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetDeskew("False")
SetFieldType(2)
SetValidValues("1000,2000")
```

The example above turns off deskew on this field, sets the field type to numeric, and finally sets the minimum value to 1000, maximum value to 2000.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetFieldType

Sets the type of the field to read.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetFieldType (string param)
```

Parameters

The integer value representing field type. The following values are supported:

- **1 - Alpha** - Describes a field containing alpha characters. Fields of type Alpha or Alpha numeric are intended to recognize a field that would contain 1, 2 or 3 words. The supported character set includes the letters A to Z (upper, lower, or mixed case) as well as the following special characters:

space; apostrophe; dash; comma; period; slash; pound sign; plus; dollar sign; parentheses; asterisk; quotation marks.

You can use the following actions to improve recognition of this field type:

- SetVocabulary
 - SetWritingStyle
 - SetLanguage
 - SetSpecialCharacterSet
 - SetValidValues
 - SetProcessingMode
- **2 - Numeric** - Describes a field containing numbers. The supported character set includes the numerals 0 to 9 as well as the following special characters:

space; apostrophe; dash; comma; period; slash; pound sign; plus; dollar sign; parentheses; asterisk; quotation marks.

The selected language must match the expected format of the characters. For example, a 7 with a stroke through it is considered European and would recognize better with the language set to French instead of English. The Numeric type supports the languages English, German, Portuguese (Brazil), or Spanish (Latin America).

You can use the following actions to improve recognition of this field type:

- SetVocabulary
 - SetWritingStyle
 - SetLanguage
 - SetSpecialCharacterSet
 - SetValidValues
 - SetProcessingMode
- **4 - Alphanumeric** - Describes a field containing a combination of alpha and numeric characters. This Field Type combines the attributes of an Alpha Field Type and a Numeric Field Type. Fields of type Alpha or Alpha numeric are intended to recognize a field that would contain 1, 2 or 3 words.

Note: You must set a vocabulary or template for this field type. If the vocabulary or template is not set, an error may occur. To set the template, use the SetTemplate or SetVocabulary actions.

You can use the following actions to improve recognition of this field type:

- SetTemplate (*required if SetVocabulary is not called)
 - SetVocabulary (*required if SetTemplate is not called)
 - SetWritingStyle
 - SetLanguage
 - SetSpecialCharacterSet
 - SetValidValues
 - SetProcessingMode
- **8 - Address** - The Address type has the following formats:
 - Address Block
 - Street + City, State, ZIP
 - Street + City
 - State + ZIP
 - Street + City + State + ZIP
 - Street + Apt + City, State, ZIP
 - Street + Apt + City, State + ZIP
 - Street + Apt + City + State + ZIP
 - City, State, ZIP; City, State + ZIP
 - City + State + ZIP

Note: The comma defines the parts of the fields as being joined into one entity. The “+” sign indicates that the parts are separate entities. Only US addresses are supported.

Important: In order to get address recognition results, you must set the postal database path using the SetPostalDatabase action.

When the address is recognized, for each component of the address that is recognized a DCO variable is created in the field object and the variable contains the respective portion of the address. The following DCO variables can be created: Primary, Street, City, State, Zip, ZipFull.

You need to configure the Address field for the following scenarios:

Scenario 1: The address is to be recognized and parsed from a single zone containing the street address (apartment, if present) and city, state, zip. For this scenario, it suffices to create the zone around the entire address and set the field type to address. No additional fields or setup is needed, beyond specification of the postal database. The multiple line mode must be set to **None** via the SetMultiLineMode action (parameter of 0). If this value is not set the results may only contain text for only a single line of the address block. Upon completion of the recognition, the field value is set to the text of entire address and the variables specified above are created containing the respective portions of the address.

Scenario 2: Use this scenario when the address is to be recognized and parsed from multiple zones because it is not written in a standard contiguous format. For example, street address, city, state, and zip are in different zones. For this scenario, the following actions are available to configure the different zones for each part of the address as needed:

SetAddressCityStateZip, SetAddressCityState, SetAddressApartment, SetAddressCity, SetAddressState, SetAddressZip

For this scenario, each of the fields called out in the SetAddress actions above must be zoned on the page area that contains each of the respective portions of the address. For example, the field specified for SetAddressCityState must be zoned to include both the city and state and the field specified for SetAddressCity must be zoned just for the city text. It is not required that all actions and zones are created. If the city and state are written in the contiguous form "city, state", then it makes sense to zone them as one field and use SetAddressCityState to identify the field. If the city and state do not appear as contiguous on the page, then the city and state can be zoned separately using two fields and use the actions SetAddressCity and SetAddressState to identify each field. This scenario uses a set of fields to recognize the address. One main field is configured with SetFieldType(8) and then uses the set actions to identify the other fields that comprise the address to be recognized. The main field zone does not need to be surrounding the entire address as the address is obtained from the identified address parts. When recognition is complete, the text value of each of the fields specified by SetAddress is filled with the recognized text. Additionally the main field that is configured with SetFieldType(8) contains DCO variables mentioned above that contain the respective portions of the recognized address. The field text is not updated with any of the recognized text unless it has been zoned around an address field.

For both the scenarios, you can use the following actions to improve recognition of this field type:

- SetPostalDatabase (*required)
- SetWritingStyle
- **16 - Age** - Describes a field containing age data. This Field Type supports:
 - A numeric value, for example 37.
 - An alpha-numeric representation, for example 14 years old.

The supported value units include the following words and abbreviations:

- Day, Days, Dys

- o Mo, Month, Months, Mos, Mths, Mth, Month Old, Months Old, Mos Old, Mths Old
- o Week, Weeks, Wk, Wks
- o Year, Years, Years Old, Yr, Yrs, Yrs Old

You can use the following actions to improve recognition of this field type:

- o SetWritingStyle
- o SetSpecialCharacterSet
- o SetValidValues
- o SetProcessingMode

- **32 - Amount** - Describes a field containing a dollar amount and/or a cent amount. The supported character set includes numerals as well as the following:

space; dash; comma; period; dollar sign

You can use the following actions to improve recognition of this field type:

- o SetAmountFormat
- o SetWritingStyle
- o SetValidValues
- o SetProcessingMode

- **64 - Barcode** - Not supported. For barcode recognition please use the actions in the [Barcode_P actions](#) library.

- **128 - CheckBox** - Not supported. For check box recognition please use the action `RecogOMRThreshold` in the [Barcode_P actions](#) library.

- **256 - Credit Card Number** - Describes a field containing credit card number.

You can use the following actions to improve recognition of this field type:

- o SetWritingStyle
- o SetValidValues
- o SetProcessingMode
- o SetCreditCardFormat

- **512 - Date** - The date type has the following formats:

MM/DD/YY (MM/DD/YYYY); YYYY; MM; DD; MM/YY; MMMM DD, YYYY; DD/MM/YY (DD/MM/YYYY)

The date type supports the languages English, German, Portuguese (Brazil), or Spanish (Latin America). The date formats DD MMMM YYYY and MMMM DD, YY are not supported for German language.

You can use the following actions to improve recognition of this field type:

- o SetDateFormat
- o SetWritingStyle
- o SetProcessingMode

- **1024 - Empty** - Use to skip recognition of the field. This field type can be used to skip recognition on fields used only to hold zone information for address fields.

- **2048 - First name** - Describes a field that contains first name of a person. Often the first name is written together with the middle initial. In this situation it is still possible to assign a First name type to the field.

You can use the following actions to improve recognition of this field type:

- SetVocabulary
 - SetWritingStyle
 - SetLanguage
 - SetSpecialCharacterSet
 - SetValidValues
 - SetProcessingMode
- **4096 - Full name** - Describes a field on a form that contains first name of a person, middle initial and last name written within one box. It is recommended that you define a field as Full name when it is impossible to reliably separate first name, middle initial, and last name and define them as separate fields with individual field types.

You can use the following actions to improve recognition of this field type:

- SetFullNameFormat
 - SetVocabulary
 - SetWritingStyle
 - SetLanguage
 - SetSpecialCharacterSet
 - SetProcessingMode
- **8192 - Last name** - Describes a field that contains last name of a person.

You can use the following actions to improve recognition of this field type:

- SetVocabulary
 - SetWritingStyle
 - SetLanguage
 - SetSpecialCharacterSet
 - SetProcessingMode
- **16384 - Middle Initial** - Describes a field that contains middle initial of a person.

You can use the following actions to improve recognition of this field type:

- SetVocabulary
 - SetWritingStyle
 - SetLanguage
 - SetSpecialCharacterSet
 - SetProcessingMode
- **32768 - Phone number** - Describes a field containing an area code, a telephone number, or both. The possible format of the field is defined by Field Properties and includes the following:

(000); 000-0000; (000) 000-0000; [(000)] 000-0000

You can use the following actions to improve recognition of this field type:

- SetVocabulary
- SetWritingStyle
- SetLanguage
- SetSpecialCharacterSet
- SetValidValues
- SetProcessingMode

- **65536 - PostNet Barcode** - Not supported. For barcode recognition please use the actions in the [Barcode_P actions](#) library.
- **131072 - Social security number** - Describes a field containing a social security number. The supported character set includes the numerals 0 to 9 as well as the special characters:

space; dash; period; slash

You can use the following actions to improve recognition of this field type:

- SetVocabulary
 - SetWritingStyle
 - SetLanguage
 - SetSpecialCharacterSet
 - SetValidValues
 - SetProcessingMode
- **262144 - Length** - Describes a field containing length measurement expressed in feet, inches, or both. The supported character set includes Numeric and the following special characters:

dash; apostrophe; quotation marks

The supported formats include:

NN' - NN"; NN' NN"; NN NN; NN-NN; NN'NN"

You can use the following actions to improve recognition of this field type:

- SetWritingStyle
 - SetValidValues
 - SetProcessingMode
- **524288 - Measure** - Describes a field containing a numerical value and an abbreviation, for example 115 lbs.. The supported character set includes letters and numbers as well as the following special characters:

period; pound sign

The measurement units (lbs., oz., kg., mm., and so on) should not exceed four characters.

You can use the following actions to improve recognition of this field type:

- SetWritingStyle
 - SetValidValues
 - SetProcessingMode
- Note:
- French language is only supported for the following field types: Alpha, Alpha-numeric, and Numeric for Cursive writing style
 - Russian language is supported for the following field types: Alpha, Alpha-numeric, First Name, Last Name, Middle Initial, and Numeric

Returns

True always.

Level

Field.

Details

Sets the type of the field to read.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldTtype (8)  
SetAddressCityStateZipZone ("fieldCZS")
```

The example above sets the field type to Address. Then sets the zone for the city, state, and zip text in the image. This assumes that the zones for field FieldCSZ are populated previously by an action such as ReadZones.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetFullNameFormat

Sets the format of full name fields.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetFullNameFormat (string param)
```

Parameters

The integer value representing the full name format. The following values are supported:

- 0 - First name followed by last name (default)
- 1 - Last name followed by first name

Returns

True always.

Level

Field.

Details

Sets the format of full name fields.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType (4096)
SetFullNameFormat (1)
```

The example above sets the field type to full name, and sets the full name format to first,last.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetLanguage

Sets the recognition language for the fields.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetLanguage (string param)
```

Parameters

The integer value representing the recognition language. The following values are supported:

- 1 - English (default)
- 2 - German
- 4 - French
- 8 - Russian
- 16 - Brazilian Portuguese
- 32 - Latin American Spanish

Returns

True always.

Level

Field.

Details

Sets the recognition language for the fields.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType (1)  
SetLanguage (2)
```

The example above sets the field type to alpha, and sets the language to German.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetLineRemovalMode

Sets the type of line removal to be performed on the field.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetLineRemovalMode (string param)
```

Parameters

The integer value representing the type of line removal to perform on the field. The following are the valid values:

- 0 - None
- 1 - Vertical lines
- 2 - Horizontal lines
- 3 - Vertical and horizontal lines (default)
- 4 - Vertical and horizontal dash lines

Returns

True always.

Level

Field.

Details

Sets the type of line removal to be performed on the field.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetLineRemovalMode (1)  
SetFieldType (1)  
SetMultiLineMode (2)
```

The example above set line removal to only remove vertical lines, then sets the field type to alpha, and finally sets the recognition to read only the second line.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset)

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetMultiLineMode

Sets which lines to extract from multi-line fields.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetMultiLineMode (string param)
```

Parameters

The integer value representing the way to read the lines, in fields, which have multiple lines. The following are the valid values:

- 0 - None
- 1 - Top line
- 2 - Second line
- 3 - Third line
- 4 - Fourth line
- 5 - Bottom line
- 6 - Second from bottom line
- 7 - Third from bottom line
- 8 - Fourth from bottom line
- 9 - All beneath top
- 10 - All above bottom
- 11 - Default or All above bottom
- 12 - All (default)

Returns

True always.

Level

Field.

Details

Sets which lines to extract from multi-line fields.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType (1)  
SetMultiLineMode (2)
```

The example above sets the field type to alpha, and sets the recognition to read only the second line.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetNoiseRemoval

Turns on or off the noise removal on the field snippet prior to recognition.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetNoiseRemoval (string param)
```

Parameters

A boolean value specifying whether or not to perform noise removal on the field snippet prior to recognition. The following are the valid values:

- True - Noise removal is performed (default)
- False - Noise removal is turned off

Returns

True always.

Level

Field.

Details

This action turns the noise removal on or off on the field snippet prior to recognition.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetNoiseRemoval ("False")  
SetFieldType (2)  
SetValidValues ("1000,2000")
```

The example above turns off noise removal on this field, sets the field type to numeric, and finally sets the minimum value to 1000, maximum value to 2000.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetPostalDatabase

Sets the path of the postal database for address recognition.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetPostalDatabase (string param)
```

Parameters

Smart parameters are supported.

Returns

True always.

Level

Field.

Details

Sets the full path of the postal database file ads_database.cfg, required for address recognition. An address must exist in the postal database for it to be recognized correctly.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType(8)
SetPostalDatabase("c:\PostalDatabase\ads_database.cfg")
```

The example above sets the field type to address, and sets the path to the postal database.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetProcessingMode

Sets whether to favor speed or accuracy when performing recognition.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetProcessingMode (string param)
```

Parameters

The integer value representing whether to favor speed or accuracy when performing recognition. The following are the valid values:

- 0 - Favor Accuracy (slower, default)
- 1 - Speed (Faster)

Returns

True always.

Level

Field.

Details

Sets whether to favor speed or accuracy when performing recognition.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetProcessingMode(1)
SetFieldType(1)
SetMultiLineMode(2)
```

The example above sets recognition to favor speed, then sets the field type to alpha, and finally sets the recognition to read only the second line.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetSpecialCharacterSet

Sets additional characters to add to the default field character set.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetSpecialCharacterSet (string param)
```

Parameters

The additional characters to add to the default field character set.

Returns

True always.

Level

Field.

Details

Sets additional characters to add to the default field character set. If spaces should be included in the results, use an underscore "_" as the character to specify a space. A special character set can be provided for the Alpha, Alphanumeric, and Numeric field types.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType (1)  
SetSpecialCharacterSet ("12345")
```

The example above sets the field type to alpha, and adds the digits 1-5 to the alpha character set to use during recognition. To allow recognition of spaces, use an underscore _ in the special character set.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

SetTemplate

Sets the format of the field text to read.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetTemplate (string param)
```

Parameters

The string value representing the format of the field text.

- # matches numerals
- @ matches alpha characters
- \$ matches special symbols
- * matches any symbol
- | separates multiple formats for the template

None

Returns

True always.

Level

Field.

Details

Sets the format of the field text to read. If the recognized text does not match the template, then no result is returned.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType (4)  
SetTemplate ("@@#####")
```

The example above sets the field type to AlphaNumeric and sets the field template to two alpha characters, followed by four numbers.

```
SetTemplate ("@@##### | ***")
```

The example above allows two alpha followed by four numbers or any three characters. Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

Recognize ()

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetValidLength

Sets the length range for the field.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetValidLength (string param)
```

Parameters

A comma separated value of two integers. The first one representing the minimum length, and the second one representing the maximum length.

Returns

True always.

Level

Field.

Details

Sets the length range for the field.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType(1)  
SetValidLength("3,5")
```

The example above sets the field type to alpha, and sets the minimum length to 3, and maximum length to 5.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetValidValues

Sets the length range for the field.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetValidValues (string param)
```

Parameters

A comma separated value of two integers. The first one representing the minimum value and the second one representing the maximum value.

Returns

True always.

Level

Field.

Details

Sets the length range for the field.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType (2)  
SetValidValues ("1000,2000")
```

The example above sets the field type to numeric, and sets the minimum value to 1000, and maximum value to 2000.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize ()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetVocabulary

Sets the vocabulary file to use for recognizing fields.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetVocabulary (string param)
```

Parameters

A string value representing the vocabulary file to use for recognizing this field.

Returns

True always.

Level

Field.

Details

Sets the vocabulary file to use for recognizing fields. A vocabulary is required when recognizing fields of type AlphaNumeric. You can create vocabularies using the VocabularyEditor.exe in the FormXtra directory. A vocabulary is a list of all of the expected words to be recognized, and weights are assigned to each word. Words that are expected often should be given a higher weight and words expected less often should be given a lower weight.

If a vocabulary is not specified for the AlphaNumeric fields, you must set a template using the SetTemplate action. A vocabulary can provide more accurate results than a template.

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType(4)  
SetVocabulary("c:\temp\vocab.fvx")
```

The example above sets the field type to AlphaNumeric and the vocabulary file to use to c:\temp\vocab.fvx.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

SetWritingStyle

Sets the writing style of the field.

Member of namespace

HandwritingRecognition

Syntax

```
bool SetWritingStyle (string param)
```

Parameters

The integer value representing the writing style of the field. The following values are supported:

- 1 - Cursive - It is only supported for field types: Address, Alpha, First name, Middle name, Last name, and Full name. Setting the writing styles of other field types to cursive may result in an error.
- 2 - Handprint
- 4 - BoxedHandprint (The text is hand-printed within the confines of special boxes or combs)

Returns

True always.

Level

Field.

Details

Sets the writing style of the field. The language support is different for each field type. The following is the list of the languages supported for each field type for the styles Cursive and Handprint:

- **Alpha:** English, French, Russian, Portuguese (Brazil), Spanish (Latin America)
- **Numeric:** English, German, French, Russian, Portuguese (Brazil), Spanish
- **Alpha-numeric:** English, French, Russian
- **Address:** English
- **Age:** English
- **Amount:** English
- **Credit card number:** English, French (Handprint only), Russian, Portuguese (Brazil), Spanish (Latin America)
- **Date:** English, French (Handprint only), Russian, Portuguese (Brazil), Spanish (Latin America)
- **First name:** English, Russian
- **Full name:** English, Russian
- **Last name:** English, Russian
- **Middle name:** English, Russian
- **Phone number:** English
- **Social security number:** English
- **Length:** English
- **Measure:** English

Example:

Field level ruleset (can be run either when entering a field, Open node, or leaving a field, Close node):

```
SetFieldType(1)  
SetWritingStyle(2)
```

The example above sets the field type to alpha, and sets the writing style to handprint.

Page level ruleset (must be run after ALL fields to be recognized have been configured, either at the Close of the page, or in a separate subsequent ruleset).

```
Recognize()
```

This ruleset performs recognition of the configured fields.

Parent topic: [HandwritingRecognition actions](#)

IBMCM actions

Use the IBMCM actions to upload documents into an IBM® Content Manager Connector repository.

The IBM Content Manager Connector actions integrate Datacap applications with the IBM Content Manager Connector repository. You run these actions to access the IBM Content Manager Connector server, set up document attributes and folders on the server, and upload documents to the server for storage.

- [IBMCM_AddPages](#)
Adds new pages to an existing document in the IBM Content Manager repository. The new pages are appended to the existing pages in the IBM Content Manager document.
- [IBMCM_CreateFolder](#)
Creates an IBM Content Manager folder in the parent folder that is based on the specified item type.
- [IBMCM_CreateItem](#)
Creates an IBM Content Manager document that is based on a specified item type.
- [IBMCM_SetAttributeValue](#)
Sets the attribute value on an IBM Content Manager document or folder.
- [IBMCM_CreateChildItem](#)
Creates a child component under the current document that was created by using IBMCM_CreateItem.
- [IBMCM_SetChildAttributeValue](#)
Assigns a child attribute value for a child item (child component attribute value).
- [IBMCM_DeletePages](#)
Deletes pages from an existing document in the IBM Content Manager repository.
- [IBMCM_Logon](#)
Logs on to an IBM Content Manager Server.
- [IBMCM_ReplacePage](#)
Replaces a page in an existing IBM Content Manager document with a new page in the runtime DCO hierarchy.
- [IBMCM_SearchItem](#)
Searches for the existing item in the IBM Content Manager repository.
- [IBMCM_SetSearchOnlyFolderItems](#)
Prepares the IBMCM_SearchItem action to limit the searches to only folder items. You use this action to search folder and non-folder from Datacap into IBM Content Manager.
- [IBMCM_SetMimeType](#)
Sets the mime type for the upload document.
- [IBMCM_SetDestinationFolder](#)
Sets the destination folder for uploading images to the IBM Content Manager repository.
- [IBMCM_SetDestinationFolderEx](#)
Sets the destination folder for uploading image files to IBM Content Manager repository.
- [IBMCM_StoreItemIDinDCO](#)
Stores the Item ID of the most recently created folder or the most recently uploaded IBM Content Manager item into a variable of the current object of the Document Hierarchy.
- [IBMCM_UploadDCO_DOC](#)
Uploads the set of Images files that are associated with the current document object of the Document Hierarchy to the IBM Content Manager Server.
- [IBMCM_UploadDCO_Page](#)
Uploads image files that are associated with the current Page object of the Document Hierarchy to IBM Content Manager.

- [IBMCM_SearchAndDownload](#)
Searches and downloads item content from IBM Content Manager repository.
- [IBMCM_SetSearchAndDownloadCriteria](#)
Sets the search criteria for IBMCM_SearchAndDownload action.
- [IBMCM_SetSearchAndDownloadDirectory](#)
Sets the download directory for SearchAndDownload action.
- [IBMCM_SetSearchAndDownloadMaximum](#)
Sets the maximum number of downloads for SearchAndDownload action.
- [IBMCM_SetSearchAndDownloadSort](#)
Sets the sortBy and sortOrder for SearchAndDownload action.
- [IBMCM_SetSearchAndDownloadStatusAttribute](#)
Sets the status attribute to update after a successful SearchAndDownload action.

Parent topic: [Global actions](#)

IBMCM_AddPages

Adds new pages to an existing document in the IBM® Content Manager repository. The new pages are appended to the existing pages in the IBM Content Manager document.

Syntax

```
bool IBMCM_AddPages(int newPage)
```

Parameters

Int newPage: the new page to add to the IBM Content Manager document.

Parameters

newpage is required when you call the action at the document level.

If newpage=0, all of the new pages in the runtime DCO are added to the existing IBM Content Manager document.

If newpage>0, only the new page that is specified by newpage is added.

Returns

True, if the new page or pages are successfully added. Otherwise, False.

Level

Doc and Page levels.

Details

You must retrieve the existing IBM Content Manager document from the IBM Content Manager repository before you call this action to add new pages to it.

You can use the IBMCM_SearchItem action to retrieve the existing IBM Content Manager document.

Example

```
IBMCM_SearchItem("", "A1001001A14B04B12546D00215")
IBMCM_AddPages (2)
```

This example searches the IBM Content Manager repository for the existing document with the unique ID of A1001001A14B04B12546D00215.

If the document is found, this action adds a second page (TM000002) in the runtime Document DCO to this document.

```
IBMCM_SearchItem("EmployeeID", "14B04B12")
IBMCM_AddPages (0)
```

This example searches the IBM Content Manager repository for the existing document with the unique ID of EmployeeID=14B04B12.

If the document is found, this action adds all of the pages in the runtime Document DCO object to this document.

Parent topic: [IBMCM actions](#)

IBMCM_CreateFolder

Creates an IBM® Content Manager folder in the parent folder that is based on the specified item type.

Syntax

```
bool IBMCM_CreateFolder(string itemType, string attribute, string attributeValue,
bool hasParent)
```

Parameters

String itemType: the item type (classification) that is used to create the IBM Content Manager folder. This parameter is required.

String attribute: the attribute name.

String attributeValue: the unique attribute value or folder ID.

bool hasParent: if True the new folder has a parent folder.

Parameters

If hasParent is False, the new folder is created without a parent folder and the action ignores the attribute and attributeValue parameters.

If hasParent is True, it is expected that this folder is the child of an existing folder and that the attribute and attributeValue parameters specify the parent folder.

If hasParent is True and both attribute and attributeValue are not provided, the parent folder is set to the most recently created folder.

If the folder ID is used in the attributeValue parameter, leave the attribute parameter empty ("").

Smart parameters are supported for the string parameters.

Returns

True, if the folder is successfully created. Otherwise, False. The action fails if the a folder with the specified attribute or ID is not found.

Level

All levels.

Details

Creates a folder in the IBM Content Manager repository. The `IBMCM_SetAttributeValue` action can be called following this action to set the attributes of the newly created folder.

Example:

```
IBMCM_CreateFolder("NOINDEX", "", "", False)
```

This example creates an IBM Content Manager folder that is based on the NOINDEX item type. The new folder has no parent and is placed in the root directory.

```
IBMCM_CreateFolder("NOINDEX", "",  
"A1001001A14B04B12546D00215", True)
```

This example creates an IBM Content Manager folder that is based on the NOINDEX item type. The folder is placed inside the parent folder with the ID "A1001001A14B04B12546D00215".

```
IBMCM_CreateFolder(@MyItemType, @MyAttribute,  
@MyAttributeValue, True)  
IBMCM_SetAttributeValue("name, @BATCHID")
```

This example creates an IBM Content Manager folder that is based on the information that is stored in the smart parameter *@ MyItemType*. This folder is a child that is identified by the values from the batch level smart parameters *@ MyAttribute*, and *@ MyAttributeValue*.

```
IBMCM_CreateFolder(@B.MyItemType, "", "", False)  
IBMCM_SetAttributeValue("Name, MyFolder1")  
IBMCM_CreateFolder(@B.MyItemType, "", "", True)  
IBMCM_SetAttributeValue("Name, MyFolder2")
```

This example creates the folders "MyFolder1" and "MyFolder2" based on the type that is identified by `@B.MyItemType`.

The "MyFolder1" folder has no parent folder. The parent folder of "MyFolder2" is the "MyFolder1" folder.

Parent topic: [IBMCM actions](#)

IBMCM_CreateItem

Creates an IBM® Content Manager document that is based on a specified item type.

Member of namespace

ibmcm

Syntax

```
bool IBMCM_CreateItem(string itemtype)
```

Parameters

itemtype: Creates an IBM Content Manager document that is based on the item type.

Parameters

itemtype: a string value of a valid IBM Content Manager Item Type, for example NOINDEX. An `IBM Content Manager Item Type is equivalent to a Document Class (Index Class).

Smart parameters are supported, such as `@BATCHID`, `@ID`, `@STATUS`, `@TYPE`, `@VALUE`, `@JOBID`, `@JOBNAME`, `@OPERATOR`, `@STATION`, `@TASKID`, and `@TASKNAME`. For more information, refer to the smart parameter documentation.

Returns

True If the document is successfully created. Otherwise, False.

Level

Document or Page level.

Details

Creates an IBM Content Manager based on the item type. This action must be called before the document and page upload actions.

Example:

```
IBMCM_CreateItem("NOINDEX")
IBMCM_SetMimeType("image/tiff")
IBMCM_UploadDC)_DOC()
```

This example creates an IBM Content Manager document that is based on the NOINDEX item type. It sets the mime type of the uploaded document, and then runs the upload action.

```
IBMCM_CreateItem(@P.name)
```

This example creates an IBM Content Manager document that is based on the value that is contained inside the Smart Parameter `@P.name` at the Page level.

Typically, there is one item for each processed document that is represented by a Document object of the Document Hierarchy, or for a processed page that is represented by a Page object.

Parent topic: [IBMCM actions](#)

IBMCM_SetAttributeValue

Sets the attribute value on an IBM® Content Manager document or folder.

Member of namespace

ibmcm

Syntax

```
bool IBMCM_SetAttributeValue (string attributesvalues)
```

Parameters

String *attributesvalues*: Sets the attribute value on an IBM Content Manager document or folder.

Parameters

attributesvalues is a string value of two comma separated variables:

Name: The name of the variable to set.

Value: The value of the variable to set.

A IBM Content Manager Item Type is equivalent to a Document Class (Index Class).

Smart parameters are supported, such as *@BATCHID*, *@ID*, *@STATUS*, *@TYPE*, *@VALUE*, *@JOBID*, *@JOBNAME*, *@OPERATOR*, *@STATION*, *@TASKID*, and *@TASKNAME*. Refer to the smart parameter documentation for more information and usage.

Returns

True if the document is successfully created. Otherwise, False.

Level

All levels.

Details

Sets the attribute value on a IBM Content Manager document or folder. The specified attribute must already be defined on the IBM Content Manager server. The attribute can be applied to a document or a folder. This action must follow a previous action that created the new folder or that identifies a document. This action can be called multiple times to set multiple processes.

Example:

```
IBMCM_CreateFolder("MyItemType")
IBMCM_SetAttributeValue("Name,@BATCHID")
```

This example creates an IBM Content Manager folder and sets the *Name* property of the folder to the ID of the current batch.

```
IBMCM_CreateItem("@B.name")
IBMCM_SetAttributeValue("Author,@D.TheAuthor")
IBMCM_SetAttributeValue("Date,@DATE")
```

When running on the document level, this example creates a new document by using the batch level value that is stored in the DCO variable *Name* and sets the *Author* attribute to the value that is stored in the DCO document level variable named *TheAuthor*. Then it stores the current date in the *Date* property.

```
IBMCM_SearchItem("employeeID","3F1234D")
IBMCM_SetAttributeValue("FirstName,Thomas")
```

This example searches the IBM Content Manager repository for an existing IBM Content Manager document with the EmployeeID that is 3F1234D. If the existing IBM Content Manager document is found, then its attribute *FirstName* is set to *Thomas*.

Parent topic: [IBMCM actions](#)

IBMCM_CreateChildItem

Creates a child component under the current document that was created by using IBMCM_CreateItem.

Member of namespace

ibmcm

Syntax

```
bool IBMCM_CreateChildItem(string attributeInfo)
```

Parameters

attributeInfo: String in the format of *child item name, count*.

Returns

True, if the child item is created is successfully created. Otherwise, False.

Level

Document or Page level.

Details

Creates a child component under the current document that was created by using IBMCM_CreateItem. A comma-separated string that consists of two values:

childItemName

Defines a child component under the IBM® Content Manager item that was created by IBMCM_CreateItem.

The parameter is a string value that specifies the name of a child component.

count

The number of child component attribute values that will be set.

The count is the number of child component attributes values that will be set by IBMCM_SetChildAttributeValue.

This action needs to be called after IBMCM_CreateItem.

Example:

```
IBMCM_CreateItem("ABCInsPlc")
IBMCM_CreateChildItem("Automobiles,1")
IBMCM_SetChildAttributeValue("Automobiles,ABCVIN,vin123")
IBMCM_UploadDCO_DOC()
```

This example creates an IBM Content Manager Child Item based on the name `Automobiles`.

Parent topic: [IBMCM actions](#)

IBMCM_SetChildAttributeValue

Assigns a child attribute value for a child item (child component attribute value).

Member of namespace

ibmcm

Syntax

```
bool IBMCM_SetChildAttributeValue(string attributeInfo)
```

Parameters

attributeInfo: String in the format of *child item name, attribute name, attribute value*.

Returns

True, if the child attribute value is set successfully. Otherwise, False.

Level

All levels.

Details

Assigns a child attribute value for a child item. (child component attribute value)

A comma-separated string that consists of three values:

childItemName

Defines a child component under the IBM® Content Manager item that was created by IBMCM_CreateItem.

The parameter is a string value that specifies the name of a child component.

attributeName

The attribute name of the child.

attributeValue

The attribute value.

IBMCM_CreateChildItem must be called before this action can be called.

IBMCM_SetChildAttributeValue must be called the same number of times that is specified in IBMCM_CreateChildItem otherwise the child attributes will not be saved

Smart parameters are supported.

Example:

```
IBMCM_CreateItem("ABCInsPlc")
IBMCM_CreateChildItem("Automobiles,2")
IBMCM_SetChildAttributeValue("Automobiles,ABCVIN,vin123")
IBMCM_SetChildAttributeValue("Automobiles,ABCLicensePlate,carlic123")
IBMCM_UploadDCO_DOC()
```

This example creates an IBM Content Manager Child Item based on the name `Automobiles` and assigns two attributes.

IBMCM_DeletePages

Deletes pages from an existing document in the IBM® Content Manager repository.

Syntax

```
bool IBMCM_DeletePages(int existingPage)
```

Parameters

Int existingPage: the existing page to delete from the document. This parameter is required.

Parameters

existingPage: required when you call this action at the Document level.

If existingPage = 0, all of the existing pages in the IBM Content Manager document are deleted. Otherwise, only the existing page that is specified by existingPage is deleted from the document.

Returns

True, if the page or pages are successfully deleted. Otherwise, False.

Level

All levels.

Details

You must retrieve the existing IBM Content Manager document from the IBM Content Manager repository before you call this action to delete pages from it.

The IBMCM_SearchItem action can be used to retrieve the existing IBM Content Manager document.

Important: Be careful with this destructive action. It should be used at the Batch level to make sure that it is run one time per batch. If you must use it at the Document or Page level, make sure that you set filters and conditions to keep this action from being called repeatedly.

Example

```
IBMCM_SearchItem("EmployeeID", "14B04B12")  
IBMCM_DeletePages(2)
```

This example searches the IBM Content Manager repository for the existing IBM Content Manager document with the unique attribute EmployeeID=14B0B12.

If the existing IBM Content Manager document is found, it deletes the second page from the existing IBM Content Manager document.

```
IBMCM_SearchItem("EmployeeID", "14B04B12")  
IBMCM_DeletePages(0)
```

This example searches the IBM Content Manager repository for the existing IBM Content Manager document with the unique attribute EmployeeID=14B0B12.

If the existing IBM Content Manager document is found, it deletes all of the pages from the existing IBM Content Manager document.

Parent topic: [IBMCM actions](#)

IBMCM_Logon

Logs on to an IBM® Content Manager Server.

Member of namespace

ibmcm

Syntax

```
bool IBMCM_Logon(string connectioninfo)
```

Parameters

connectioninfo

Type: string

A comma-separated string consisting of three values:

1. The ID of the IBM Content Manager Server
2. A valid Content Manager User ID
3. The user's Password

Smart parameters are supported for each parameter.

Returns

True if the logon succeeds. False if the logon is unsuccessful. The logon is unsuccessful if the action cannot find the specified server, or if the user ID or password is invalid.

Level

Any level. Usually at the Batch level.

Details

Performs the logon to the IBM Content Manager system. This action must be called before the actions that communicate with the IBM Content Manager repository. Connectivity, based on the requirements of the IBM Content Manager Server, must be setup on the machine that runs the Datacap rules.

Example:

```
IBMCM_Logon("ibmcmserver,user1,password")
```

```
IBMCM_Logon("ibmcmserver,user1,@APPVAR(values/adv/MyPassword)")
```

This example uses the smart parameter @APPVAR to get the password from the advanced value section of the Application Manager. The custom value name is "MyPassword".

Parent topic: [IBMCM actions](#)

IBMCM_ReplacePage

Replaces a page in an existing IBM® Content Manager document with a new page in the runtime DCO hierarchy.

Syntax

```
bool IBMCM_ReplacePage(int existingPage, int newPage)
```

Parameters

Int existingPage: the existing page in the IBM Content Manager document.

Int newPage: the new page in the DCO hierarchy.

Parameters

When you call this action at the Document level, both existingPage and newPage parameters are required.

When you call this action at the Page level, the newPage parameter is ignored.

Returns

True, if the existing page in the IBM Content Manager document is replaced with the new page in the runtime DCO. Otherwise, False.

Level

Document and Page level.

Details

You must retrieve the existing IBM Content Manager document from the IBM Content Manager repository before you call this action.

The IBMCM_SearchItem action can be used to retrieve the existing IBM Content Manager document.

Example

```
IBMCM_SearchItem("EmployeeID", "14B04B12")  
IBMCM_ReplacePage(2, 3)
```

This example searches the IBM Content Manager repository for the existing IBM Content Manager document with the unique attribute EmployeeID=14B0B12.

If the existing IBM Content Manager document is found, it replaces the second page in the existing IBM Content Manager document with the third page (TM000003) in the runtime Document DCO.

Parent topic: [IBMCM actions](#)

IBMCM_SearchItem

Searches for the existing item in the IBM® Content Manager repository.

Syntax

```
bool IBMCM_SearchItem (string attribute, string attributeValue)
```

Parameters

String attribute: the attribute name.

String attributeValue: the unique attribute value or folder ID.

Parameters

Both attribute and attributeValue are required parameters. If folder ID is used in the second parameter, leave the first parameter empty ("").

Smart parameters are supported.

Returns

True, if the item is found. Otherwise, False.

Level

All levels.

Details

Searches for the existing item in the IBM Content Manager repository that matches the specified attribute and value. If an item is found, the current item is set to it. Otherwise the current item is set to NULL.

IBMCM_SearchItem is used to retrieve an existing IBM Content Manager item before calling other actions such as IBMCM_AddPages, IBMCM_DeletePages, IBMCM_ReplacePage, and IBMCM_SetAttributeValue to update the attributes of the item or the contents of the item.

Example

```
IBMCM_SearchItem("Department", "Human Resource")
IBMCM_SetAttributeValue("Department", "Operations")
```

This example searches for an item with the attribute name *Department* and the attribute value *Human Resources*. It then changes the attribute value to *Operations*.

```
IBMCM_SearchItem("", "A1001001A14B04B12546D00215")
```

This example searches for an item with the ID equal to *A1001001A14B04B12546D00215*.

Parent topic: [IBMCM actions](#)

IBMCM_SetSearchOnlyFolderItems

Prepares the IBMCM_SearchItem action to limit the searches to only folder items. You use this action to search folder and non-folder from Datacap into IBM® Content Manager.

Syntax

```
bool IBMCM_SetSearchOnlyFolderItems (string strParam)
```

Parameters

String strParam: True or False

A string or smart parameter value is True or False, whether the subsequent IBMCM_SearchItem actions limit the result to folder items.

Smart parameters are supported.

Returns

False, if parameter is not a string. Otherwise, True.

Level

All levels.

Details

If True, the subsequent IBMCM_SearchItem actions search for folder items. If False, the subsequent IBMCM_SearchItem actions search for all items that match the search criteria.

If this action is not called or the parameter is not True or False, the default value of True is used, and IBMCM_SearchItem actions only return folder items. This action should be called before IBMCM_SearchItem.

Example

```
IBMCM_SetSearchOnlyFolderItems ("False")
IBMCM_SearchItem ("", "A1001001A17E08B00210C00000")
```

This example demonstrates the search for an item with item ID A1001001A17E08B00210C00000. If an item is found, regardless of whether it is a folder item or not, the current item is set to it. Otherwise, if the item is not found, the current item is set to NULL.

```
IBMCM_SetSearchOnlyFolderItems ("True")
IBMCM_SearchItem ("", "@P.PageName")
```

This example demonstrates the search only for a folder item. If a folder item is found, the current item is set to it. Otherwise, if the item is not found or the item is not a folder item, the current item is set to NULL.

This example demonstrates the use of the predefined special page variable @PageName. The VScan.Scan action populates @P.PageName to be the file name of the image file without the file extension. For example, the image file A1001001A17E08B00210C00000.tif has a PageName of "A1001001A17E08B00210C00000". This page variable can be used to identify the IBM Content Manager item ID if the image file name conforms to the convention.

Member of object Datacap.Libraries.IBMCM.Actions.

Parent topic: [IBMCM actions](#)

IBMCM_SetMimeType

Sets the mime type for the upload document.

Syntax

```
bool IBMCM_SetMimeType(string mimeType)
```

Parameters

String mimeType: the mime type.

Parameters

Smart parameter is supported.

Returns

True, if the mime type is successfully set. Otherwise, False.

Level

All levels.

Details

Set the mime type for the upload document. This action is needed when you are uploading non-tiff files.

When you call this action at the batch or document level, the same mime type is applied to all of the files in the batch or document DCO.

This action must be called before the document and page upload actions.

Table 1. Supported mime types

MIME Types	File Extensions
application/msword	dod, dot, rtf
application/octet-stream	bin, dms, lha, lzh, exe, class
application/pdf	pdf
application/rtf	rtf
application/lotus-1-2-3	123, wk4, wk3, wk1, wks, wg1
application/lotus-freelance	prz, pre
application/vnd.ms-excel	xls, xlt, xlm, xld, xla, xlc, xlw, xll
application/vnd.ms-powerpoint	ppt, pot, ppa, pps, pwz
application/vnd.visio	vsd
audio/basic	au, snd, ulw
audio/mpeg	mpeg, mpg, m1s, m1a, mp2, mp3, mpm, mpa, mpga
audio/x-aiff	aif, aiff, aifc
audio/x-midi	midi, mid, smf, kar
audio/x-wav	wav

MIME Types	File Extensions
image/bmp	bmp, dib
image/gif	gif
image/jpeg	jpeg, jpg, jpe, jfif, pjpeg, pip
image/tiff	tiff, tif
text/html	html, htm, shtml, plg
text/plain	txt, text
text/xml	xml, dtd
video/mpeg	mpeg, mpg, mpe, m1s, m1v, m1a, m75, m15, mp2
video/quicktime	mov, qt

Example:

```
IBMCM_ SetMimeType ("image/tiff")
```

This example sets the mime type to "image/tiff".

Parent topic: [IBMCM actions](#)

IBMCM_SetDestinationFolder

Sets the destination folder for uploading images to the IBM® Content Manager repository.

Syntax

```
bool IBMCM_SetDestinationFolder(string attribute, string attributeValue)
```

Parameters

String attribute: the attribute name.

String attributeValue: the unique attribute value or folder ID.

Parameters

If both parameters are not provided, the destination folder is set to the most recently created folder.

If the folder ID is used in the second parameter, leave the parameter empty ("").

Smart parameters are supported.

Returns

True, if the destination folder is successfully set. Otherwise, False. The action fails if a folder with the specified attribute or ID is not found.

Level

All levels.

Details

Sets the upload destination folder in the IBM Content Manager repository. To set the destination to a newly created folder, first create the folder by using the `IBMCM_CreateFolder` action. Then, call the `IBMCM_SetDestinationFolder` action with empty ("") parameters.

Example:

```
IBMCM_SetDestinationFolder("Department", "Human Resource")
IBMCM_CreateItem("NOINDEX")
IBMCM_SetMimeType("image/tif")
IBMCM_UploadDCO_DOC()
```

This example sets the destination folder to the folder with the attribute name "Department" and the attribute value "Human Resource" to upload images to it.

```
IBMCM_SetDestinationFolder("", "A1001001A14B04B12546D00215")
IBMCM_CreateItem("NOINDEX")
IBMCM_SetMimeType("image/tif")
IBMCM_UploadDCO_DOC()
```

This example sets the destination folder to folder with the ID "A1001001A14B04B12546D00215" to upload images to it.

```
IBMCM_CreateFolder("NOINDEX", "", "A1001001A14B04B12546D00215", true)
IBMCM_SetDestinationFolder("", "")
IBMCM_CreateItem("NOINDEX")
IBMCM_SetMimeType("image/tif")
IBMCM_UploadDCO_DOC()
```

This example sets the destination folder to the most currently created folder to upload images to it.

Parent topic: [IBMCM actions](#)

IBMCM_SetDestinationFolderEx

Sets the destination folder for uploading image files to IBM® Content Manager repository.

Syntax

```
bool IBMCM_SetDestinationFolderEx (string itemType, string attribute, string
attributeValue)
```

Parameters

string itemType - The item type.

string attribute - The attribute name.

string attributeValue - The unique attribute value or folder ID.

Parameters

If all parameters are not provided then destination folder is set to the most recently created folder.

Returns

True, if the destination folder is successfully set. Otherwise, False. The action fails if a folder with the specified attribute or ID is not found.

Level

All levels.

Details

Sets the upload destination folder in IBM Content Manager repository. To set the destination to a newly created folder, first create the folder using `IBMCM_CreateFolder` and then call `IBMCM_SetDestinationFolder` with empty ("") parameters.

Example

```
IBMCM_SetDestinationFolderEx("NOINDEX", "SOURCE", "Human Resource")
IBMCM_CreateItem("NOINDEX")
IBMCM_SetMimeType("image/tiff")
IBMCM_UploadDCO_DOC()
```

This example demonstrates the setting up the destination folder to the folder with attribute `Department="Human Resource"` to upload images to it.

Example

```
IBMCM_SetDestinationFolder("", "A1001001A14B04B12546D00215")
IBMCM_CreateItem("NOINDEX")
IBMCM_SetMimeType("image/tiff")
IBMCM_UploadDCO_DOC()
```

This example demonstrates the setting up the destination folder to the folder with folder ID=`A1001001A14B04B12546D00215` to upload images to it.

Example

```
IBMCM_CreateFolder("NOINDEX", "", "A1001001A14B04B12546D00215", true)
IBMCM_SetDestinationFolder("", "")
IBMCM_CreateItem("NOINDEX")
IBMCM_SetMimeType("image/tiff")
IBMCM_UploadDCO_DOC()
```

This example demonstrates the setting up the destination folder to the most recently created folder to upload images to it

Parent topic: [IBMCM actions](#)

IBMCM_StoreItemIDinDCO

Stores the Item ID of the most recently created folder or the most recently uploaded IBM® Content Manager item into a variable of the current object of the Document Hierarchy.

Member of namespace

ibmcm

Syntax

```
bool IBMCM_StoreItemIDinDCO(string itemID)
```

Parameters

String itemID: sets the attribute value on an IBM Content Manager document or folder.

Returns

True, if the Item ID is returned successfully. Otherwise, False.

Level

All levels.

Details

Stores the Item ID of the most recently created folder or the most recently uploaded IBM Content Manager document into a variable of the current object of the Document Hierarchy. If the variable does not exist, it is created on the current DCO Hierarchy object.

It might be useful to store the item ID if the object is referenced in the following action, such as setting the upload directory.

Example:

```
IBMCM_CreateFolder("NOINDEX", "", "", False)
IBMCM_StoreItemIDinDCO("ItemID")
```

This example stores the ID of the new IBM Content Manager folder in a variable that is called *ItemID* in the current object of the DCO Hierarchy.

```
IBMCM_CreateItem("NOINDEX")
IBMCM_MimeType("image/tiff")
IBMCM_UploadDCO_DOC()
IBMCM_StoreItemIDinDCO("ItemID")
```

This example stores the ID of the new IBM Content Manager document in a variable that is called *ItemID* in the current object of the DCO Hierarchy.

Parent topic: [IBMCM actions](#)

IBMCM_UploadDCO_DOC

Uploads the set of Images files that are associated with the current document object of the Document Hierarchy to the IBM® Content Manager Server.

Member of namespace

ibmcm

Syntax

```
bool IBMCM_UploadDCO_DOC ()
```

Parameters

None

Returns

True if the document is successfully created. Otherwise, False.

Level

Document level

Details

Uploads the Image files that are associated with current Document object of the Document Hierarchy to IBM Content Manager Server.

Example:

```
IBMCM_Logon("cmserver,adminPWD,adminUID")
IBMCM_CreateItem("NOINDEX")
IBMCM_SetAttributeValue("USERID, @OPERATOR")
IBMCM_SetMimeType("image/tiff")
IBMCM_UploadDCO_DOC()
```

This sequence uploads the set of Images files that are associated with the current document object of the Document Hierarchy to the IBM Content Manager server. Additionally, all attributes set by using IBMCM_SetAttributeValue action are also persisted.

Parent topic: [IBMCM actions](#)

IBMCM_UploadDCO_Page

Uploads image files that are associated with the current Page object of the Document Hierarchy to IBM® Content Manager.

Member of namespace

ibmcm

Syntax

```
bool IBMCM_UploadDCO_Page ()
```

Returns

True if the action successfully sends the image to the server. False if the action is unable to save the image.

Level

Page level

Details

Uploads the Image file associated with current Page object of the Document Hierarchy to the IBM Content Manager server. Additionally, all attributes set using IBMCM_SetAttributeValue are also persisted.

Example:

```
IBMCM_Logon (cmserver, adminPWD, adminUID)
IBMCM_CreateItem (NOINDEX)
IBMCM_SetAttributeValue (USERID, @OPERATOR)
IBMCM_UploadDCO_Page ()
```

This sequence uploads Image files associated with the current Page object of the Document Hierarchy to IBM Content Manager, and assigns the name of the object – the value of its Type property.

Parent topic: [IBMCM actions](#)

IBMCM_SearchAndDownload

Searches and downloads item content from IBM® Content Manager repository.

Syntax

```
bool IBMCM_SearchAndDownload ()
```

Returns

True, if one or more items are downloaded. False, if zero items were downloaded or if any errors occurred during parameter validation or searching or downloading.

Level

All levels.

Details

The parameters are used to search for items in IBM Content Manager repository that matches the specified search criteria from the IBMCM_SetSearchAndDownloadCriteria action. For each matching item found, if the corresponding ICMBase parts have content, the content file is written to the directory set from IBMCM_SetSearchAndDownloadDirectory. The output file name is the IBM Content Manager item ID, and the file extension is the same as the original file extension.

To limit the number of downloads for each IBMCM_SearchAndDownload action, you can set a limit with IBMCM_SetSearchAndDownloadMaximum action. The default maximum is 1000.

To change the default sorting, call IBMCM_SetSearchAndDownloadSort.

See the related actions for more details and examples:

- IBMCM_SetSearchAndDownloadCriteria
- IBMCM_SetSearchAndDownloadDirectory
- IBMCM_SetSearchAndDownloadMaximum
- IBMCM_SetSearchAndDownloadSort

Example

```
IBMCM_SetSearchAndDownloadCriteria ("APT", , , ,)
IBMCM_SetSearchAndDownloadMaximum ("100")
IBMCM_SetSearchAndDownloadDirectory ("C:\datacap\APT\images\input")
IBMCM_SetSearchAndDownloadSort ("True", "Date", "ASCENDING")
IBMCM_SearchAndDownload ()
```

This example demonstrates the search and download up to 100 APT IBM Content Manager items' content to the directory, C:\datacap\APT\images\input. The IBM Content Manager query syntax is "/APT SORTBY(@Date ASC)". Each item content has the item ID as the file name. For example, A1001001A17E08B00210C00000.tif .

Member of object Datacap.Libraries.IBMCM.Actions.

Parent topic: [IBMCM actions](#)

IBMCM_SetSearchAndDownloadCriteria

Sets the search criteria for IBMCM_SearchAndDownload action.

Syntax

```
bool IBMCM_SetSearchAndDownloadCriteria (string itemType , string attributeName  
, string comparisonOperator , string attributeValue , string dataType)
```

Parameters

string itemType - Name of the item type

string attributeName - Name of the attribute

string comparisonOperator - Comparison operator

string attributeValue - Comparison value of the attribute

string dataType - Data type of the attribute

Parameters

Item type name is mandatory. The search is limited to the specified item type. The rest of the parameters are optional. If they are not provided, then the search returns all items from the specified item type.

If the attribute name is specified, the item attribute must exist in the IBM® Content Manager repository schema.

If the comparison operator is not specified, but the attribute name and value are specified, then the comparisonOperator defaults to the equal operator, "=". Supported comparison operators are: "=", "<", "<=", ">", ">=", "!=", "LIKE", "NOT LIKE", "IS NULL", "IS NOT NULL", "IN", "NOT IN".

The **comparison value of the attribute** is mandatory if the **attribute name** is specified. For "IS NULL" and "IS NOT NULL" operations, the attribute value and the data type are ignored. For "LIKE" and "NOT LIKE" operations, the attribute value should include the wildcard character "%". For "IN" and "NOT IN" operations, the attribute value should be enclosed in parentheses "()" and delimited by commas. See examples below.

The **data type of the attribute** is optional. Supported data types are: "STRING", "DATE", "NUMBER". The default is "STRING".

Smart parameters are supported.

Returns

False, if parameters are not strings or parameter validations failed. Otherwise, True. Some parameter validations are done in this action, others are done in the IBMCM_SearchAndDownload() action

Level

All levels.

Details

The parameters are used in `IBMCM_SearchAndDownload` action to construct the IBM Content Manager query.

If this action is not called and the search criteria has not been set before `IBMCM_SearchAndDownload()` that returns `False`. This action should be called before `IBMCM_SearchAndDownload`.

Example

```
IBMCM_SetSearchAndDownloadCriteria("APT",,,,)  
IBMCM_SetSearchAndDownloadMaximum("100")  
IBMCM_SetSearchAndDownloadDirectory("C:\datacap\APT\images\input")  
  IBMCM_SetSearchAndDownloadSort("True","ITEMID","ASCENDING")  
IBMCM_SearchAndDownload()
```

This example demonstrates the search and download up to 100 APT IBM Content Manager items' content to the directory, `C:\datacap\APT\images\input`, sorted by the IBM Content Manager item ID. The IBM Content Manager query syntax is `/APT SORTBY(@ITEMID,ASC)`. Each item content has the item ID as the file name. For example, `A1001001A17E08B00210C00000.tif`.

Example

```
IBMCM_SetSearchAndDownloadCriteria("APT", "DCStatus", "=", "NA", )  
IBMCM_SetSearchAndDownloadDirectory("@APPPATH(vscanimagedir) ")  
IBMCM_SetSearchAndDownloadSort("False", , )  
IBMCM_SearchAndDownload()
```

This example demonstrates the search and download up to the default maximum number of APT IBM Content Manager items' content that have not been processed by Datacap into the Smart Parameter VScan image directory. The IBM Content Manager query syntax is `/APT[@DCStatus="NA"]`. Each item content has the item ID as the file name. The file extension is the same as the file extension of the original file. For example, `A1001001A17E08B00210C00000.tif`

Example

```
IBMCM_SetSearchAndDownloadCriteria("APT", "Quantity", ">", "5", "NUMBER")  
IBMCM_SetSearchAndDownloadCriteria("APT", "DCStatus", "IS NULL", , )  
IBMCM_SetSearchAndDownloadCriteria("APT", "DCStatus", "LIKE", "start%", )  
IBMCM_SetSearchAndDownloadCriteria("APT", "DCStatus", "IN", "  
("started", "stopped")", , )  
IBMCM_SetSearchAndDownloadCriteria("APT", "Date", ">", "2017-01-01", "DATE")
```

These are usage examples of the supported data type and comparison operators.

Member of object `Datacap.Libraries.IBMCM.Actions`

Parent topic: [IBMCM actions](#)

IBMCM_SetSearchAndDownloadDirectory

Sets the download directory for `SearchAndDownload` action.

Syntax

```
bool IBMCM_SetSearchAndDownloadDirectory (string path)
```

Parameters

string path - The directory where the downloaded files reside

Parameters

The parameter is used as the download directory in IBMCM_SearchAndDownload action. The output directory is mandatory. You must verify that the directory is valid and has write permissions. Smart parameters are supported.

Returns

True, if parameter is a string. Otherwise, False. The directory is not verified until the IBMCM_SearchAndDownload attempts to write to the directory

Level

All levels.

Details

If this action is not called and the download directory has not been set before IBMCM_SearchAndDownload() that returns False. This action must be called before IBMCM_SearchAndDownload to set the output directory.

Example

```
IBMCM_SetSearchAndDownloadCriteria("APT",,,)
IBMCM_SetSearchAndDownloadMaximum("100")
IBMCM_SetSearchAndDownloadDirectory("C:\datacap\APT\images\input")
IBMCM_SetSearchAndDownloadSort("True","ITEMID","ASCENDING")
IBMCM_SearchAndDownload()
```

This example demonstrates the search and download up to 100 APT IBM® Content Manager items' content to the directory, C:\datacap\APT\images\input. The IBM Content Manager query syntax is "/APT SORTBY(@ITEMID,ASC)". Each item content has the item ID as the file name. For example, A1001001A17E08B00210C00000.tif.

Example

```
IBMCM_SetSearchAndDownloadCriteria("APT", "DCStatus","=","NA")
IBMCM_SetSearchAndDownloadDirectory("@APPPATH(vscanimagedir)")
IBMCM_SetSearchAndDownloadSort("True","Date","ASCENDING")
IBMCM_SearchAndDownload()
```

This example demonstrates the search and download up to the default maximum number of APT IBM Content Manager items' content that have not been processed by Datacap into the Smart Parameter VScan image directory. The IBM Content Manager query syntax is "/APT[@DCStatus='NA'] SORTBY(@Date,ASC)". Each item content has the item ID as the file name. The file extension is the same as the file extension of the original file. For example, A1001001A17E08B00210C00000.tif

Member of object Datacap.Libraries.IBMCM.Actions

Parent topic: [IBMCM actions](#)

IBMCM_SetSearchAndDownloadMaximum

Sets the maximum number of downloads for SearchAndDownload action.

Syntax

```
bool IBMCM_SetSearchAndDownloadMaximum (string strParm)
```

Parameters

string strParm - The maximum number of downloads

Parameters

The strParm sets the maximum number of downloads in the IBMCM_SearchAndDownload action. Smart parameters are supported.

Returns

True, if parameter is a number. Otherwise, False.

Level

All levels.

Details

If this action is not called and the download maximum has not been set before IBMCM_SearchAndDownload() that uses the default maximum, which is 1000. Specify a number less than 1 to have no maximum, and IBMCM_SearchAndDownload() returns all matching items. This action should be called before IBMCM_SearchAndDownload to change the maximum download.

Example

```
IBMCM_SetSearchAndDownloadCriteria("APT",,,)
IBMCM_SetSearchAndDownloadMaximum("100")
IBMCM_SetSearchAndDownloadDirectory("C:\datacap\APT\images\input")
IBMCM_SearchAndDownload()
```

This example demonstrates the search and download up to 100 APT IBM® Content Manager items' content to the directory, C:\datacap\APT\images\input.

Example

```
IBMCM_SearchAndDownload()
```

Since this action was not called, the default maximum is used. This example demonstrates the search and download up to 1000 of content matching the IBMCM_SetSearchAndDownloadCriteria parameters.

Example

```
IBMCM_SetSearchAndDownloadMaximum("0")
IBMCM_SearchAndDownload()
```

Since the maximum is zero, there is no limit to the search. This example demonstrates the search and download all content matching the IBMCM_SetSearchAndDownloadCriteria parameters.

Member of object Datacap.Libraries.IBMCM.Actions

Parent topic: [IBMCM actions](#)

IBMCM_SetSearchAndDownloadSort

Sets the sortBy and sortOrder for SearchAndDownload action.

Syntax

```
bool IBMCM_SetSearchAndDownloadSort (string doSort , string sortBy , string
sortOrder)
```

Parameters

string doSort - True or False to sort

string sortBy - Item attribute name to sort by

string sortOrder - Sort order ASCENDING or DESCENDING

Parameters

The doSort parameter takes True or False and determines whether to sort the search results during the IBMCM_SearchAndDownload action. The sortBy parameter is the name of the item attribute to sort by. The item attribute must exist in the IBM® Content Manager repository schema. The sortOrder parameter takes "ASCENDING" or "DESCENDING" and determines the sort order of the sort by attribute. Smart parameters are supported.

Returns

False, if parameters are missing or invalid. Otherwise, True.

Level

All levels.

Details

If this action is not called and the sort information has not been set before IBMCM_SearchAndDownload() that does not sort the returned results.

This action should be called before IBMCM_SearchAndDownload to change the sort information.

Example

```
IBMCM_SetSearchAndDownloadCriteria("APT","Date","IS NULL",)
IBMCM_SetSearchAndDownloadMaximum("100")
IBMCM_SetSearchAndDownloadDirectory("C:\datacap\APT\images\input")
IBMCM_SetSearchAndDownloadSort("True","Date","ASCENDING")
IBMCM_SearchAndDownload()
```

This example demonstrates the search and download up to 100 APT IBM Content Manager items' content to the directory, C:\datacap\APT\images\input, sorted by the "Date" attribute in ascending order.

Example

```
IBMCM_SearchAndDownload()
```

Since this action was not called, no sorting is done. This example demonstrates the search and download content matching the `IBMCM_SetSearchAndDownloadCriteria` parameters.

Member of object `Datacap.Libraries.IBMCM.Actions`

Parent topic: [IBMCM actions](#)

IBMCM_SetSearchAndDownloadStatusAttribute

Sets the status attribute to update after a successful `SearchAndDownload` action.

Member of namespace

ibmcm

Syntax

```
bool IBMCM_SetSearchAndDownloadStatusAttribute (string checkStatus, string  
attributeName) ()
```

Parameters

string `checkStatus`: True or False whether to add checking for download status.

string `attributeName`: The Datacap download status attribute name.

The `checkStatus` parameter takes True or False and determines whether to check the download status of an item during the `IBMCM_SearchAndDownload` action.

The attribute must exist and should be defined for the `SearchAndDownload` item type as a short integer, with no default. The attribute name is case-sensitive and should be the same as defined in the IBM® Content Manager System Administration Client.

The default behavior is `IBMCM_SetSearchAndDownloadStatusAttribute(False)`. Setting a status attribute is not required for the `IBMCM_SearchAndDownload` action.

Smart parameters are supported.

Returns

True, if parameters are string. Otherwise, False. The attribute is not verified until the `IBMCM_SearchAndDownload` attempts to update the status attribute value.

Level

All level.

Details

The status attribute is used two times during the `IBMCM_SearchAndDownload` action. First, the search criteria is appended to search for the attribute being 0 or NULL. Second, when an item has been downloaded, the

attribute is updated to 1.

Having a status attribute for the download is beneficial to avoid downloading duplicates with the same search criteria between batches.

Example:

```
IBMCM_SetSearchAndDownloadCriteria("APT",,,,)  
IBMCM_SetSearchAndDownloadMaximum("100")  
IBMCM_SetSearchAndDownloadDirectory("C:\datacap\APT\images\input")  
IBMCM_SetSearchAndDownloadStatusAttribute("True", "DCStatus")  
IBMCM_SearchAndDownload()
```

In this example, the IBM Content Manager query syntax is `"/APT[ICMPARTS AND (@DCStatus IS NULL OR @DCStatus=0)]"`. During each batch, 100 items are downloaded and their attributes changed to `@DCStatus=1`. Subsequent batches using the `IBMCM_SearchAndDownload` action does not return any items that have already been downloaded, since the `DCStatus` is no longer null.

Example:

```
IBMCM_SetSearchAndDownloadCriteria("APT", "Date", " < ", "2017-01-01", "DATE")  
IBMCM_SetSearchAndDownloadStatusAttribute("True", "DCStatus")  
IBMCM_SearchAndDownload()
```

In this example, the IBM Content Manager query syntax is `"/APT [ICMPARTS AND @Date < "2017-01-01" AND (@DCStatus IS NULL OR @DCStatus=0)]"`.

Example:

```
IBMCM_SetSearchAndDownloadCriteria("APT", "APT_Date", " < ", "2017-01-01", "DATE")  
IBMCM_SetSearchAndDownloadStatusAttribute("False",)  
IBMCM_SearchAndDownload()
```

In this example, the IBM Content Manager query syntax is `"/APT[ICMPARTS AND @APT_Date < "2017-01-01-01"]"`. No checking is done whether the item has been downloaded by Datacap before. It is recommend that the application calls `IBMCM_SetAttributeValue()` to update the `@APT_Date` value to prevent the item from matching the criteria next time.

Member of object `Datacap.Libraries.IBMCM.Actions`.

Parent topic: [IBMCM actions](#)

ICR_C actions

Use the `ICR_C` actions to recognize constrained (unconnected) hand or computer printed characters. These actions use the OpenText RecoStar engine.

The `ICR_C` actions can recognize characters in fields, page, and zones that are configured for `ICR_C` recognition and store the results in a PDF file.

- [EnableLoggingICR_C](#)
Enables or disables event logging for the ICR/C engine.
- [RecognizeFieldICR_C](#)
Performs character recognition for a specific field.
- [RecognizeFieldVoteICR_C](#)
Recognizes characters based on results from two recognition engines.
- [RecognizePageFields2CCO_ICR_C](#)
Performs recognition for all of the zoned fields on a page.

- [RecognizePageFieldsICR_C](#)
Performs recognition on all fields that have been configured for ICR/C in Datacap Studio.
- [RecognizePageFieldsICR_CEx](#)
Recognizes all fields on the page that have been configured for ICR/C recognition.
- [RecognizePageICR_C](#)
Performs full page recognition using the ICR/C Engine.
- [RecognizePageToPDFICR_C](#)
Performs recognition on the current page and places the results in a PDF file.

Parent topic: [Global actions](#)

EnableLoggingICR_C

Enables or disables event logging for the ICR/C engine.

Member of namespace

icr_c

Syntax

```
bool EnableLoggingICR_C (strParam)
```

Parameters

A boolean value. True enables ICRC logging and False disables ICRC logging. If no parameter is passed in, it uses the default value of True.

Returns

True if the logging state is successfully changed. Otherwise, False.

Level

All levels.

Details

This action enables or disables event logging for the ICR/C engine. Logs are written to the System event log under the entry Datacap.Recognition.Recostar. This action is intended for debugging ICRC recognition problems. If this action is never called, no logging will occur.

Example:

```
EnableLoggingICR_C("true")
```

Parent topic: [ICR_C actions](#)

RecognizeFieldICR_C

Performs character recognition for a specific field.

Member of namespace

icr_c

Syntax

```
bool RecognizeFieldICR_C ()
```

Parameters

None.

Returns

False, if called at the wrong level or if there is a failure in the recognition process. Otherwise, True.

Level

Field level.

Details

Recognition is performed on the current field. The field must have the proper settings in the ICR/C tab in Datacap Studio. This field-level action recognizes characters based on the settings in the ICR/C tab in Datacap Studio and the value is stored in the current field object.

Important: When recognizing an area that contains hand printed characters only, a country, not language, should be selected from the Country dropdown in the ICR/C tab of Datacap Studio for optimal recognition results. If the zoned area contains both hand printed and machine printed characters, then a language, and not a country, should be selected from the Country dropdown in the ICR/C tab of Datacap Studio for optimal recognition results.

Example:

```
RecognizeFieldICR_C()
```

Parent topic: [ICR_C actions](#)

RecognizeFieldVoteICR_C

Recognizes characters based on results from two recognition engines.

Member of namespace

icr_c

Syntax

```
bool RecognizeFieldVoteICR_C ()
```

Parameters

None.

Returns

False, if called at the wrong level or if there is a failure in the recognition process. Otherwise, True.

Level

Field level.

Details

Voting adjusts the assigned confidence of recognized characters based on the results from two different recognition engines. This action is expected to be called after field level recognition is performed on the same field by a different engine.

When this action stores the results of recognition, it first determines if the corresponding Field object of the Document Hierarchy already contains a value. If a value is present, indicating recognition had previously been performed on the field, the action compares the existing value with the field's new recognition results - character by character. If a character's values match the existing value, the Confidence Rating for the character is raised to the maximum level.

Note that when using voting actions, the recognition results are never assigned to the field. Instead, the action changes the Confidence Ratings on the basis of results provided by the first Recognition engine. However, if there are no previous recognition results in the field when this action is called, it will perform like the RecognizeFieldICR_C action.

Example:

```
RecognizeFieldOCR_S()  
RecognizeFieldVoteICR_C()
```

This example first uses the OCR/S engine to recognize the text and store it in the field object. Then it votes on the confidence of the character by comparing it to the ICR/C engine result.

Parent topic: [ICR_C actions](#)

RecognizePageFields2CCO_ICR_C

Performs recognition for all of the zoned fields on a page.

Member of namespace

icr_c

Syntax

```
bool RecognizePageFields2CCO_ICR_C ()
```

Parameters

None.

Returns

False if called at the wrong level or if the CCO does not already exist. Otherwise, True.

Level

Page level.

Details

This action recognizes all of the zoned fields on a page and puts the recognition results for each field in both the Datacap Object Hierarchy and in an already existing CCO. To create a CCO, call either a Full Page OCR action or the AnalyzeImage action before this action.

Example:

```
AnalyzeImage ()  
RecognizePageFields2CCO_ICR_C ()
```

Parent topic: [ICR_C actions](#)

[AnalyzeImage](#)

[Cco2cco actions](#)

RecognizePageFieldsICR_C

Performs recognition on all fields that have been configured for ICR/C in Datacap Studio.

Member of namespace

icr_c

Syntax

```
bool RecognizePageFieldsICR_C ()
```

Parameters

None.

Returns

False, if called at the wrong level or if there is a failure in the recognition process. Otherwise, True.

Level

Page level.

Details

This page-level action recognizes all fields on the page that have been configured for ICR/C recognition in Datacap Studio. Individual field-level recognition actions will overwrite the results from this page-level action. This action will not recognize a zoned field if the Skip Recognition checkbox is selected in the ICR/C tab in Datacap Studio.

Important: The recognition settings must be set individually for each field being recognized. When recognizing an area that contains hand printed characters only, a country, not language, should be selected from the Country dropdown in the ICR/C tab of Datacap Studio for optimal recognition results. If the zoned area contains

both hand printed and machine printed characters, then a language, and not a country, should be selected from the Country dropdown in the ICR/C tab of Datacap Studio for optimal recognition results.

Example:

```
AnalyzeImage ()  
RotateImage ()  
RecognizePageFieldsICR_C ()
```

Parent topic: [ICR_C actions](#)

RecognizePageFieldsICR_CEx

Recognizes all fields on the page that have been configured for ICR/C recognition.

Member of namespace

icr_c

Syntax

```
bool RecognizePageFieldsICR_CEx ()
```

Parameters

None.

Returns

False, if called at the wrong level or if there is a failure in the recognition process. Otherwise, True.

Level

Page level.

Details

This page-level action recognizes all fields on the page that have been configured for ICR/C recognition. Individual field-level recognition actions will overwrite the results from this page-level action. This action will not recognize a zoned field if the Skip Recognition checkbox is selected in the ICR/C tab in Datacap Studio. Important: The recognition settings must be set individually for each field being recognized. When recognizing an area that contains hand printed characters only, a country, not language, should be selected from the Country dropdown in the ICR/C tab of Datacap Studio for optimal recognition results. If the zoned area contains both hand printed and machine printed characters, then a language, and not a country, should be selected from the Country dropdown in the ICR/C tab of Datacap Studio for optimal recognition results.

Example:

```
RecognizePageFieldsICR_CEx ()
```

Parent topic: [ICR_C actions](#)

RecognizePageICR_C

Performs full page recognition using the ICR/C Engine.

Member of namespace

icr_c

Syntax

```
bool RecognizePageICR_C ()
```

Parameters

None.

Returns

False, if called at the wrong level or if there is a failure in the recognition process. Otherwise, True.

Level

Page level.

Details

Performs full page character recognition on the current page based on the settings in the ICR/C tab in Datacap Studio. The action will recognize all characters on the page, and populate the page's CCO file with the recognition results. If a CCO file does not exist at the time this action is called, the action will create one.

Example:

```
AnalyzeImage ()  
RotateImage ()  
RecognizePageICR_C ()
```

This sequence creates a CCO file and checks to see if rotation of the image is needed. Full-page recognition then takes place based on the settings in the ICR/C tab in Datacap Studio. The recognition results are stored in the page's CCO file.

Parent topic: [ICR_C actions](#)

RecognizePageToPDFICR_C

Performs recognition on the current page and places the results in a PDF file.

Member of namespace

icr_c

Syntax

```
bool RecognizePageToPDFICR_C ()
```

Parameters

None.

Returns

False, if called at the wrong level or if there is a failure in the recognition process. Otherwise, True.

Level

Page level.

Details

Performs full page character recognition on the current page based on the settings in the ICR/C tab in Datacap Studio. The action will create a PDF that contains the original page image and the recognized text.

Example:

```
AnalyzeImage ()  
RotateImage ()  
RecognizePageToPDFICR_C ()
```

Parent topic: [ICR_C actions](#)

ImageConvert actions

Use the ImageConvert actions to combine image files or to convert image files to JPEG or TIFF.

The ImageConvert actions can combine multiple pages into a single document, specify both the compression format for file conversion as well as the luminance and color of the output.

- [AppendAllImages](#)
Appends all of the images in the document to the first page.
- [AppendAllImages_ByType](#)
Appends all of the images of a specific type within a document.
- [AppendImage](#)
Concatenates the current image to the bottom of an existing image.
- [AppendImage_StartAsNew](#)
Sets the current page as the first page for a concatenated file.
- [ConvertToJPEG](#)
Converts the current image to a JPEG.
- [ConvertToTIFF](#)
Converts the current image to a TIFF.
- [RescaleImage](#)
Adjusts image for the current page to the specified size.
- [SetChrominanceFactor](#)
Set Compression for JPEG Output Files.
- [SetDeleteOriginal](#)
Controls deletion of file after conversion.
- [SetGrayScale](#)
Controls the grayscale output for JPEG images.
- [SetImageDPIByWidth](#)
Adjusts the DPI of the image and resizes the image based on the expected physical size.
- [SetLuminanceFactor](#)
Sets the image luminance or grayscale quality.

- [SetTIFFCompression](#)
Controls the compression format when saving a TIFF.

Parent topic: [Global actions](#)

AppendAllImages

Appends all of the images in the document to the first page.

Syntax

```
bool AppendAllImages ()
```

Parameters

None.

Returns

True, if all of the TIFF images within the document have been appended to the end of the first TIFF image. Otherwise, False.

Level

Document level.

Details

This action will append (concatenate) all of the images within the document to the first image of the document, creating one long image. The result of the action will modify the first image in the document to become a single continuous image like this:

- Page 1
- Page 2
- Page 3

If images are appended prior to recognition, the entire page area will be recognized and click-n-key enabled.

It is highly recommended that this action be used only documents that have a small number of pages, such as two or three pages per document. The size of the final composite image can quickly become larger than can be handled by some image viewers and possibly subsequent actions. To keep memory usage to a minimum, it is also recommended that 1-bit Black and White images are used.

Note: This action only operates on TIFF images.

Example:

```
AppendAllImages ()
```

Parent topic: [ImageConvert actions](#)

AppendAllImages_ByType

Appends all of the images of a specific type within a document.

Syntax

```
bool AppendAllImages_ByType (StrParam)
```

Parameters

A string that matches the *Type* variable of the page.

Returns

True, if all of the TIFF images that match the specified type within the document have been appended to the end of the first matching TIFF image. Otherwise, False.

Level

Document level.

Details

This action will append (concatenate) all of the images, that are of the type specified by the input parameter, that are all within the same document to the first image of that type, creating one long image. Images are not appended across documents. Assuming you have a document where the first three pages are all the same matching type, the result of the action will modify the first image in the document to become a single continuous image like this:

- Page 1
- Page 2
- Page 3

If images are appended prior to recognition, the entire page area will be recognized and click-n-key enabled.

It is highly recommended that this action be used only documents that have a small number of pages, such as two or three pages per document. The size of the final composite image can quickly become larger than can be handled by some image viewers and possibly by subsequent actions. To keep memory usage to a minimum, it is also recommended that 1-bit Black and White images are used.

Note: This action only operates on TIFF images.

Example:

```
AppendAllImages_ByType ("PO")
```

This example will append all of the images within a document that have a page type of PO.

Parent topic: [ImageConvert actions](#)

AppendImage

Concatenates the current image to the bottom of an existing image.

Syntax

```
bool AppendImage ()
```

Parameters

None.

Returns

True, if the current page is successfully concatenated with the previous page. Otherwise, False.

Level

Page level.

Details

This action concatenates the image for the current page to the bottom of the previous image that is processed by a call to `AppendImage_StartAsNew` or `AppendImage`. If `AppendImage_StartAsNew` is not called, then the first image that is encountered is treated as the starting image.

If images are appended before recognition, the entire page area is recognized and click-n-key enabled.

The image must be a TIFF. See `AppendImage_StartAsNew` for details.

Example:

```
AppendImage ()
```

Parent topic: [ImageConvert actions](#)

Related reference:

[AppendImage_StartAsNew](#)

AppendImage_StartAsNew

Sets the current page as the first page for a concatenated file.

Syntax

```
bool AppendImage_StartAsNew ()
```

Parameters

None.

Returns

True, if the image file exists for the current page and if it is a TIFF file. Otherwise, False.

Level

Page level.

Details

Sets the current page as the start of a new concatenated document. This action is used with `AppendImage` to create a single image that is created by concatenating images to the bottom of the first image. `AppendImage_StartAsNew` identifies the first page and `AppendImage` identifies all subsequent pages. The result of the action modifies the first image in the document to become a single continuous image like this:

- Page 1
- Page 2
- Page 3

If images are appended before recognition, the entire page area is recognized and click-n-key enabled.

It is recommended to use this action only for documents that have a few pages, such as two or three pages per document. The size of the final composite image can quickly become larger than can be handled by some image viewers and possibly subsequent actions. To keep memory usage to a minimum, you can use 1-bit Black and White images.

Attention: This action operates only on TIFF images.

Example:

```
AppendImage_StartAsNew()
```

Parent topic: [ImageConvert actions](#)

Related reference:

[AppendImage](#)

ConvertToJPEG

Converts the current image to a JPEG.

Syntax

```
bool ConvertToJPEG ()
```

Parameters

None.

Returns

True, if the image is converted to a JPEG. False, if the input image is a JPEG or if a failure occurs during the conversion.

Level

Page level.

Details

Converts the current image to a JPEG. The output file name will have a JPG extension.

Supported input file formats: BMP (1, 4, 8, or 24-bit), GIF (1, 4 or 8-bit), PNG (1, 4, 8 and 24-bit), and TIFF (1, 4, 8 and 24-bit) with compression (RLE, Group 3 fax, and Group 4 fax, Pack Bits, LZW, JPEG).

Note: Not all actions that manipulate images support the same input file formats as this action.

Example:

```
SetLuminanceFactor ("24")  
SetChrominanceFactor ("10")  
SetGrayScale ("True")  
ConvertToJPEG ()
```

Parent topic: [ImageConvert actions](#)

ConvertToTIFF

Converts the current image to a TIFF.

Syntax

```
bool ConvertToTIFF ()
```

Parameters

None.

Returns

True, if the image is converted to a TIFF. False, if the input image is a TIFF or if a failure occurs during the conversion.

Level

Page Level.

Details

Converts the current image to a TIFF. The output file name will have a TIF extension.

Supported input file formats: BMP (1, 4, 8, or 24-bit), GIF (1, 4 or 8-bit), JPG or JPEG (8 and 12-bit grayscale and 24-bit color), and PNG (1, 4, 8 and 24-bit).

Note: Not all actions that manipulate images support the same input file formats as this action.

Example:

```
SetTiffCompression ("3")  
ConvertToTIFF ()
```

Parent topic: [ImageConvert actions](#)

RescaleImage

Adjusts image for the current page to the specified size.

Syntax

```
bool RescaleImage (string ImageHeight, string ImageWidth, string ImageDPI)
```

Parameters

Smart parameters are supported.

ImageHeight

Output Height of the page in pixels. If blank, defaults to 3300 pixels.

ImageWidth

Output Width of the page in pixels. If blank, defaults to 2550 pixels.

ImageDPI

The new DPI of the image. If blank, defaults to 300 dpi.

Returns

True, if the operation is successful, else False, if any error occurs.

Level

Page level only, and the page must refer to a valid single page image file.

Details

Scales the image and sets the DPI to the specified values.

Example

```
RescaleImage (3300, 2550, 300)
```

Parent topic: [ImageConvert actions](#)

SetChrominanceFactor

Set Compression for JPEG Output Files.

Syntax

```
bool SetChrominanceFactor (StrParam)
```

Parameters

A value of 0 to 255, with a value of 0 meaning minimum compression (best quality) and 255 meaning maximum image compression. Smart Parameters are supported.

Returns

Always True.

Level

All levels.

Details

JPEG images are stored in a compressed format. This action controls the amount of compression that is used when you are converting an image to a JPEG image using the `ConvertToJPEG` action.

Data loss is the result of JPEGs ability to achieve high compression ratios. Higher-quality settings result in less compression, while lower quality settings result in higher compression. Quality versus compression is a trade-off. Adjust image compression ratio by setting the `SetLuminanceFactor` and `SetChrominanceFactor` actions. The `SetLuminanceFactor` action adjusts the luminance or gray scale quality, while the `SetChrominanceFactor` action adjusts the chrominance or color quality. Lower settings for these properties result in higher-quality images with less compression. Higher settings for these properties result in lower quality images with more compression.

If this action is not called, a default value of 10 is used.

Example:

```
SetLuminanceFactor ("24")
SetChrominanceFactor ("10")
SetGrayScale ("True")
ConvertToJPEG ()
```

Parent topic: [ImageConvert actions](#)

Related reference:

[ConvertToJPEG](#)

SetDeleteOriginal

Controls deletion of file after conversion.

Syntax

```
bool SetDeleteOriginal (StrParam)
```

Parameters

True: After the new image is created, the original will be deleted. False: After the new image is created, the original will remain.

Smart Parameters are supported.

Returns

Always True.

Level

All levels.

Details

Use this action to control the deletion of the source image file when using the actions `ConvertToJPEG` and `ConvertToTIFF`. If this action is not called, the default value of False will be used, the source image will not be deleted after conversion.

Example:

```
SetDeleteOriginal ("True")
ConvertToJPEG ()
```

Parent topic: [ImageConvert actions](#)

Related reference:

[ConvertToJPEG](#)

[ConvertToTIFF](#)

SetGrayScale

Controls the grayscale output for JPEG images.

Syntax

```
bool SetGrayScale (StrParam)
```

Parameters

True: Saves the image as a grayscale image. False: Saves the image as color.

Smart Parameters are supported.

Returns

Always True.

Level

All Levels.

Details

This action will determine if a JPEG image will be output as grayscale or color. If SetGrayScale is True, all images will be saved as 8 bit grayscale. If SetGrayScale is False, color images will be saved as 24 bit color and if the original image is 1 bit black and white, the new image will be 8 bit grayscale. If this action is not called, the value will default to False (color).

Example:

```
SetLuminanceFactor ("24")
SetChrominanceFactor ("10")
SetGrayScale ("True")
ConvertToJPEG ()
```

Parent topic: [ImageConvert actions](#)

Related reference:

[ConvertToJPEG](#)

SetImageDPIByWidth

Adjusts the DPI of the image and resizes the image based on the expected physical size.

Syntax

```
bool SetImageDPIByWidth (string PageWidth, string ImageDPI, string Rescale)
```

Parameters

Smart parameters are supported.

PageWidth

Physical width of the page in inches. If not specified, the value defaults to 8.5 inches.

ImageDPI

The target DPI for the updated image. If not specified, the value defaults to 300 dpi.

Rescale

Indicates whether the image must be rescaled or not.

- True - Rescale image width and height to match the specified DPI and physical size.
- False - Do not rescale the page, set the DPI only.

Returns

True, if the operation is successful, else False, if any error occurs.

Level

Page level only, and the page must refer to a valid single page image file.

Details

This action adjusts the DPI and width of the image to the specified DPI. The image can also be resized to the correct logical size based on the expected physical width in inches. This action is useful for images that do not have a correctly specified DPI or needs to be resized based on the expected width.

When the rescale parameter is true, the image size is adjusted. The image is scaled proportionally in the horizontal and vertical directions based on the width that is specified for the image. The final image has the specified DPI and the pixel width and height is scaled to the specified logical size.

Example

```
SetImageDPIByWidth ("6", "", "True")
```

Parent topic: [ImageConvert actions](#)

SetLuminanceFactor

Sets the image luminance or grayscale quality.

Syntax

```
bool SetLuminanceFactor (StrParam)
```

Parameters

A value of 0 to 255, with a value of 0 meaning minimum compression (best quality) and 255 meaning maximum image compression. Smart Parameters are supported.

Returns

Always True.

Level

All levels.

Details

JPEG images are stored in a compressed format. This action controls the amount of compression that is used when you are converting an image to a JPEG image using the `ConvertToJPEG` action.

Data loss is the result of JPEGs ability to achieve high compression ratios. Higher-quality settings result in less compression, while lower quality settings result in higher compression. Quality versus compression is a trade-off. Adjust image compression ratio by setting the `SetLuminanceFactor` and `SetChrominanceFactor` actions. The `SetLuminanceFactor` action adjusts the luminance or gray scale quality, while the `SetChrominanceFactor` action adjusts the chrominance or color quality. Lower settings for these properties result in higher-quality images with less compression. Higher settings for these properties result in lower quality images with more compression.

If this action is not called, a default value of 24 is used.

Example:

```
SetLuminanceFactor ("24")
SetChrominanceFactor ("10")
SetGrayScale ("True")
ConvertToJPEG ()
```

Parent topic: [ImageConvert actions](#)

Related reference:

[ConvertToJPEG](#)

SetTIFFCompression

Controls the compression format when saving a TIFF.

Syntax

```
bool SetTIFFCompression (StrParam)
```

Parameters

One of the following values:

- 0 : No compression.
- 1 : Run length encoding (RLE).
- 2 : CCITT Group 3 fax compression.
- 3 : CCITT Group 4 fax compression.
- 4 : LZW compression.
- 5 : Apple Macintosh PackBits compression.
- 6 : JPEG compression format.
- 7 : Lossless compression standard derived from LZ77.

- 8 : CCITT Group 3 two-dimensional standard fax compression.

Smart Parameters are supported.

Returns

Always True.

Level

All levels.

Details

This action sets the compression type of the TIFF that is output from the action `ConvertToTIFF`. Typically Group 4 compression is used for performing recognition on images.

All of these possible output formats may not be supported by other image processing actions. If this action is not called, Group 4 compression will be used.

Example:

```
SetTiffCompression("3")
ConvertToTIFF()
```

Parent topic: [ImageConvert actions](#)

Related reference:

[ConvertToTIFF](#)

ImageFix actions

The ImageFix actions are older versions of the DCImageFix action. Use the DCImageFix actions instead.

Parent topic: [Global actions](#)

Imail actions

Use the Imail actions to import image attachments from a mail server into the current batch by using IMAP.

Important: If any concurrently running threads might be using the same mail account, your Imail-related tasks cannot be run in a multi-threaded configuration. Instead, use single-threaded tasks only. For information about configuring threads in Rulerunner, see [Rulerunner thread configuration](#). For information about the mail account, see [im_login](#).

The Imail scan action polls the server and imports image attachments until the batch reaches the specified size or until the wait time expires.

- [im_abort_time](#)
Specifies the delay time before it returns when a batch stops running.
- [im_AcceptMixedAttachments](#)
Ingest emails with selected attachment types, even if non-selected attachment types are included
- [im_AcceptNoAttachments](#)
Ingest emails without attachments, even if attachment types are specified

- [im_done_folder](#)
Specifies the IMAP folder for successfully imported emails.
- [im_login](#)
Specifies the IMAP mail server URL and login credentials.
- [im_logout](#)
Disconnect from the mail server.
- [im_max_docs](#)
Specifies maximum number of emails to include in a single batch.
- [im_problem_folder](#)
Specifies the IMAP folder for problem emails.
- [im_reject_types](#)
Specifies file extensions for attachments to reject.
- [im_scan](#)
Poll the specified mail server for incoming emails with image attachments.
- [im_SetProxy](#)
Specifies the settings for a proxy service that can be used to connect to the email server.
- [im_SortByDate](#)
Sort emails by received date
- [im_StoreEML](#)
Store one .eml file per message, rather than one file per attachment
- [im_types](#)
Specifies valid file extensions for image attachments.
- [im_UseSSL](#)
Connect to IMAP Server by using an SSL encrypted channel
- [im_wait_time](#)
Specifies the maximum time to wait for input emails for a single batch.

Parent topic: [Global actions](#)

im_abort_time

Specifies the delay time before it returns when a batch stops running.

Member of namespace

Imail

Syntax

```
bool im_abort_time(int nSecs)
```

Parameters

nSecs
Type: int

Parameters

nSecs: The number of seconds to wait.

Returns

Always True.

Level

Batch level.

Details

The action waits the specified time before it returns when an abort occurs. This action can be useful to prevent many aborted batches due to an abort condition. For example, if the email server can become unavailable for a time, the abort timeout limits the number of aborted batches until the mail server becomes available again.

If this action is not called, the default abort time value of 30 seconds is used.

Example:

```
im_wait_time("20")
im_abort_time("60")
im_max_docs("200")
im_types("jpg,tif")
```

Parent topic: [Imail actions](#)

im_AcceptMixedAttachments

Ingest emails with selected attachment types, even if non-selected attachment types are included

Member of namespace

Imail

Syntax

```
bool im_AcceptMixedAttachments(bool bMixedOK)
```

Parameters

bMixedOK

Type: bool

A boolean value that enables ingestion of emails with both allowed and disallowed attachment types.

Parameters

True An email message with an attachment type not specified by `im_types` is ingested when it contains a required attachment.

False An email message with any disallowed attachment is rejected, which is the default process if this action is never called.

Returns

Always True.

Level

Batch level.

Details

If this action is never called, the presence of any attachment that is not specified by `im_types` causes `im_scan` to treat that email message as a Problem.

If this action is called with parameter `True`, messages with disallowed attachment types are ingested when they contain at least one allowed attachment.

If `im_types` is called with a blank parameter before `im_scan`, all emails are ingested, so this action has no effect.

Parent topic: [Iemail actions](#)

im_AcceptNoAttachments

Ingest emails without attachments, even if attachment types are specified

Member of namespace

Iemail

Syntax

```
bool im_AcceptNoAttachments (bool bNoAttachOK)
```

Parameters

`bNoAttachOK`

Type: bool

A boolean value that enables ingestion of emails with no attachments.

Parameters

True: An email message with no attachments is ingested by `im_scan`.

False: An email message no attachments are rejected by `im_scan`, unless `im_types` was called with a blank parameter, which is the default behavior if this action is never called.

Returns

Always True.

Level

Batch level.

Details

If this action is never called, the absence of an attachment causes `im_scan` to treat that email message as a Problem.

If this action is called with parameter True, a message with no attachments are ingested.

If `im_types` is called with a blank parameter before `im_scan`, all emails are ingested, so this action has no effect.

Parent topic: [Iml actions](#)

im_done_folder

Specifies the IMAP folder for successfully imported emails.

Member of namespace

Iml

Syntax

```
bool im_done_folder(string folder)
```

Parameters

folder
Type: string

Parameters

folder: Destination IMAP folder for successfully imported emails.

Returns

Always True.

Level

Batch level.

Details

When an email is processed and the attachment is imported, the email is moved to the folder name specified by this action. The folder is expected to be on the root level, the same level as the inbox folder in the mail account that is specified by the `im_login` action. If the folder exists in a subfolder, then use a forward slash to separate the folder names.

If this action is not called, the default value of Done is used.

Example:

```
im_done_folder("Imported")  
im_problem_folder("Failed")
```

This example changes the default names of the Done and Problem folders and also requires the Imported and Failed folders to be on the same level as the Inbox folder.

```
im_done_folder("Inbox/Imported")
im_problem_folder("Inbox/Failed")
```

This example requires the folders to be a subfolder of the Inbox folder.

Parent topic: [Email actions](#)

im_login

Specifies the IMAP mail server URL and login credentials.

Member of namespace

Email

Syntax

```
bool im_login(string hostname, string username, string password)
```

Parameters

Smart parameters are supported for all parameters.

hostname

A string that specifies the following attributes of the IMAP mail server:

String inclusion	Attribute
Required	The URL or IP address.
Optional	The port number. This number is at the end of the string and preceded by a colon.

username

The username for the mail account.

password

The password for the mail account.

Returns

True If the login succeeds. Otherwise, False.

Level

Batch level Open event only.

Details

Connects to the mail server by using the specified account information. Specifies the mail server URL and login credentials. Login credentials are for a mail server that supports the IMAP protocol (such as MS Exchange, and many others). Call one time for each batch.

The password can be encrypted by storing it in the Advanced section of the Custom tab in the Datacap Application Manager. The URL and user name parameters can be stored in the General section of the Application Manager but they cannot be encrypted. To retrieve the password that is stored in the Advanced section, use a smart parameter for the action's password parameter similar to

@APPVAR(values/adv/mailPassword) where mailPassword is the name that is entered for the value in the Application Manager.

You can affect the behavior of this action by first calling the following actions:

To connect on an encrypted channel by using the SSL / HTTPS protocol	Call im_useSSL(True).
To connect by using a proxy service	Call im_SetProxy.

Example:

```
im_login("mymailserver.com","theuser","password")
im_login("mymailserver.com:9080","theuser","password")
```

Parent topic: [Iemail actions](#)

Related reference:

[im_SetProxy](#)

[im_UseSSL](#)

im_logout

Disconnect from the mail server.

Member of namespace

Iemail

Syntax

```
bool im_logout ()
```

Parameters

None.

Returns

Always True.

Level

Batch level Open or Close event only.

Details

Closes the connection to the mail server. Call one time for each batch after im_login and im_scan are completed.

Example:

```
im_logout ()
```

Parent topic: [Iemail actions](#)

im_max_docs

Specifies maximum number of emails to include in a single batch.

Member of namespace

Imail

Syntax

```
bool im_max_docs(int nDocs)
```

Parameters

nDocs
Type: int

Parameters

nDocs: The maximum number of emails in a batch.

Returns

Always True.

Level

Batch level.

Details

The import of emails into the batch stops when this email limit is reached or when the maximum wait time is reached. While it is waiting for new mail to arrive, the configured mailbox is polled every 2 seconds to check for waiting mail.

If this action is not called, the default value of 100 is used. The actual amount included in the batch might be less than this maximum.

Example:

```
im_wait_time("20")
im_abort_time("60")
im_max_docs("50")
im_types("jpg,tif")
```

This example causes the scan operation to limit the number of emails in a batch to a maximum of 50.

Parent topic: [Imail actions](#)

im_problem_folder

Specifies the IMAP folder for problem emails.

Member of namespace

Iemail

Syntax

```
bool im_problem_folder(string folder)
```

Parameters

folder
Type: string

Parameters

folder: Destination IMAP folder for problem emails.

Returns

Always True.

Level

Batch level.

Details

When an email is processed and the attachment is not one of the expected types, the email is moved to the folder specified by this action.

The folder is expected to be on the root level, the same level as the inbox folder of the mail account that is specified by the `im_login` action. If the folder exists in a subfolder, then use a forward slash to separate the folder names.

If this action is not called, the default value of Problem is used.

Example:

```
im_done_folder("Imported")
im_problem_folder("Failed")
```

This example changes the default name of the Problem folder to Failed and requires the Imported and Failed folders to be on the same level as the Inbox folder.

```
im_done_folder("Inbox/Imported")
im_problem_folder("Inbox/Failed")
```

This example specifies the folder, which is a subfolder of the Inbox folder.

Parent topic: [Iemail actions](#)

im_reject_types

Specifies file extensions for attachments to reject.

Member of namespace

Email

Syntax

```
bool im_reject_types (string extensions)
```

Parameters

extensions - Comma-separated list of file image file extensions to ignore, with or without period. Use in conjunction with `im_AcceptMixedAttachments(True)` to reject emails with specific attachment types. Attachments specified in `im_types` are ingested, attachment types not specified in `im_types` or `im_reject_types` are ignored. Smart parameters are supported.

Returns

Always True.

Level

Batch level.

Details

This action specifies disallowed attachment types.

Example:

```
im_types("jpg,tif")
im_AcceptMixedAttachments("True")
im_reject_types(".eml")
```

Parent topic: [Email actions](#)

im_scan

Poll the specified mail server for incoming emails with image attachments.

Member of namespace

Email

Syntax

```
bool im_scan ()
```

Parameters

None.

Returns

False If the operation fails, and pauses before it returns. Otherwise, True.

If no selected emails were available, the action returns True and pauses before it returns.

Action returns when timeout is reached, or the requested number of emails are processed.

Level

Batch level Open event only.

Details

Scans emails in the Inbox for specified attachments, imports selected emails with attachments into the batch. Call one time for each batch. A connection to the email server must be previously established by using the `im_login` action.

Each input email contains the following variables set in the document hierarchy:

- **TYPE:** Always set to "Document".
- **Subject:** The email subject.
- **Body:** The text within the email.
- **DateSent:** The sent date stamp on the email.
- **From:** The email sender.
- **User:** The email user who is specified in the `im_login` action.
- **To:** The email recipients.
- **Priority:** The state of the email importance flag.

Attachments are ingested as individual pages within the email document, unless `im_StoreEML(true)` is called before `im_scan`. With individual attachments, each attachment page has the following variables set.

- **TYPE:** Always set to "Other".
- **IMAGEFILE:** The name of the attachment as saved on disk.

The following batch level variable is created:

- **EmailCount:** The number of emails that are scanned into the batch.

It is recommended that the subject line is no longer than 78 characters because this length is a common subject line length limitation. Some systems might support even shorter lengths, truncating the subject. Testing was successful with lengths up to 255 characters. It is recommended to test your settings and use lengths appropriate for your systems.

Example:

```
im_wait_time("20")
im_abort_time("40")
im_max_docs("200")
im_types("jpg,tif")
im_scan()
```

Parent topic: [Iml actions](#)

Related reference:

[im_abort_time](#)

[im_AcceptMixedAttachments](#)

[im_AcceptNoAttachments](#)

[im_done_folder](#)

[im_problem_folder](#)

[im_SortByDate](#)

im_StoreEML
im_UseSSL
im_wait_time

im_SetProxy

Specifies the settings for a proxy service that can be used to connect to the email server.

Member of namespace

Imail

Syntax

```
bool im_SetProxy(string hostname, string proxyPort, string proxyType, string proxyUsername, string proxyPassword)
```

Parameters

Smart parameters are supported for all parameters.

hostname

The URL or IP address of the proxy service.

You can store the passed parameter value in the General section of the Datacap Application Manager.

proxyPort

The proxy service connection port.

proxyType

The type of proxy service. The following values are possible:

- HTTP
- SOCKS4
- SOCKS5
- NONE

Any unsupported type is treated as NONE.

proxyUsername

The username for the proxy server.

You can store the passed parameter value in the General section of the Application Manager.

proxyPassword

The password for the proxy server.

You can store the passed parameter value in the Advanced section of the Custom tab in the Application Manager. A smart parameter such as @APPVAR(values/adv/<mailProxyPassword>) retrieves the value, where <mailProxyPassword> is the name that you entered for the value in the Application Manager.

Returns

False if the proxyPort parameter value is not numeric. Otherwise, the action returns True.

Important: This action does not attempt to log on to the proxy service. The value True is returned regardless of the validity of the passed proxy service settings. If the settings are invalid, this condition is detected when you

call `im_login`.

Level

Any level but typically batch level.

Details

Use this action to optionally specify a proxy service that connects to the email server. The `im_login` action uses the specified proxy service settings to connect to the proxy service. If you do not call this action before the call to `im_login`, no proxy service is used.

Example:

```
im_SetProxy("theHostName", "1234", "SOCKS4",  
"MyUser", "@APPVAR(values/adv/mailProxyPassword)")  
im_login("mymailserver.com", "theuser", "password")
```

In this example, the call to `im_SetProxy` specifies the settings for a proxy service, which the `im_login` action then uses to connect to that service. As illustrated, the smart parameter `APPVAR` can be used to pass in the `proxyPassword` parameter value for `im_SetProxy`.

Parent topic: [Imail actions](#)

Related information:

[Smart parameters](#)

im_SortByDate

Sort emails by received date

Member of namespace

Imail

Syntax

```
bool im_SortByDate (bool bSort)
```

Parameters

`bSort`

Type: `bool`

A boolean value that enables or disables sorting of emails before ingestion.

Parameters

True: Causes `im_scan` to sort email messages by date they are received and ingested the oldest messages first. This sorting is the default behavior if `im_SortByDate` is never called.

False: Disables sorting of email messages. This sorting greatly increases performance of `im_scan` when many emails are pending in the inbox.

Returns

Always True.

Level

Batch level.

Details

When you enable sorting, all pending emails are sorted and the oldest is ingested first. This process can take a significant amount of time for each batch. When the inbox might contain many emails (for example, more than 100), call `im_SortByDate(False)` to speed up the process. In this case, messages are processed in the order that the email server presents them to Datacap.

Parent topic: [Iemail actions](#)

im_StoreEML

Store one .eml file per message, rather than one file per attachment

Member of namespace

Iemail

Syntax

```
bool im_StoreEML(bool bStoreEML)
```

Parameters

bStoreEML

Type: bool

A boolean value that enables storing each email message as an .eml file.

Parameters

True: Store each ingested email message, formatted together with all attachments, in a single .eml file and attach it as a page to the document.

False: Add each ingested email message as a document, with associated variables, and add each attachment as a page within the document. This process is the default if `im_StoreEML` is not called.

Returns

Always True.

Level

Batch level.

Details

If set, the `im_scan` action creates a one page document that contains the email and attachments in an .eml file. No attachment pages are created and no variables are set in the document.

im_types

Specifies valid file extensions for image attachments.

Member of namespace

Iemail

Syntax

```
bool im_types(string extensions)
```

Parameters

extensions
Type: string

Parameters

extensions: Comma-separated list of file image file extensions to import, with or without period. If the parameter is blank, all emails with or without attachments are processed.

Returns

Always True.

Level

Batch level.

Details

This action specifies the allowable email attachment types.

If this action is not called, the default value of .pdf is used.

If this action is called and no attachment types are specified, all emails and any attachments are added to the batch. Emails that are processed without attachments result in documents without any pages.

If attachment types are specified and the email contains:

- Only the specified attachment types, the email, and attachments are added to the batch
- Only unspecified attachment types, or if it contains a mix of specified and unspecified attachment types, the email is moved to the Problem folder
- No attachments, the email is moved to the Problem folder

Example:

```
im_wait_time("20")
im_abort_time("40")
im_max_docs("200")
im_types("jpg,tif")
```

Parent topic: [Iemail actions](#)

im_UseSSL

Connect to IMAP Server by using an SSL encrypted channel

Member of namespace

Iemail

Syntax

```
bool im_UseSSL(bool bUseSSL)
```

Parameters

bUseSSL

Type: bool

A boolean value that enables or disables SSL communication.

Parameters

True: Use SSL to encrypt communication with the mail server.

False: Communicate with the email server without encryption, which is the default method if im_UseSSL is not called.

Returns

Always True.

Level

Batch level.

Details

When SSL is enabled, subsequent im_login and im_scan actions communicate with the email server over IMAPS protocol by using SSL encryption on port 993. When SSL is not in use, these actions communicate with the email server over IMAP protocol on port 143.

Parent topic: [Iemail actions](#)

im_wait_time

Specifies the maximum time to wait for input emails for a single batch.

Member of namespace

Iemail

Syntax

```
bool im_wait_time(int nSecs)
```

Parameters

nSecs
Type: int

Parameters

nSecs: The maximum number of seconds to wait.

Returns

Always True.

Level

Batch level.

Details

The maximum time to wait for input emails for a single batch, when there is at least one pending email. Used by the `im_scan` action after the first email is processed to determine how long to wait for the batch to fill up. If no emails are pending, the `im_scan` action does not wait regardless of the wait time value.

The import of emails into the batch stops when the wait limit is reached or when the maximum email per batch is reached. While it is waiting for new mail to arrive, the configured mailbox is polled every 2 seconds to check for waiting mail. The action continues to include new files into the batch until this wait time is reached or the maximum number of emails per batch is reached.

If this action is not called, the default wait time of 5 seconds is used.

Example:

```
im_wait_time("20")
im_abort_time("60")
im_max_docs("200")
im_types("jpg,tif")
```

Parent topic: [Email actions](#)

Imprint actions

Use the Imprint actions to imprint text over an image, or for blackout or whiteout redactions.

The Imprint actions can specify the width, font style, and font size of the imprinted text as well as whether overlay rectangles are opaque or transparent.

- [AnnotateImage](#)
Imprints the text that you specify onto the current page image.
- [RedactByRegEx](#)
Searches the entire page and redacts all occurrences of the phrase that matches the RegEx expression.
- [RedactParameters](#)
Overlays a black or white rectangle on the image to redact the current field or the specified region of a page.

- [SetAdjustedWidth](#)
Specifies the width of the imprinted text.
- [SetFontName](#)
Specifies the font style to use for the imprinted text.
- [SetFontSize](#)
Specifies the font size to use for the imprinted text.
- [SetOpaque](#)
Specifies whether the transparency of the overlay rectangles are opaque (1) or transparent (0).

Parent topic: [Global actions](#)

AnnotateImage

Imprints the text that you specify onto the current page image.

Syntax

```
bool AnnotateImage (string displayText, string xCoordinate, string yCoordinate)
```

Parameters

string displayText

string xCoordinate

string yCoordinate

Parameters

Three parameters:

- displayText smart parameter supported string to be placed onto the image. The displayText can combine plain text along with smart parameters.
- xCoordinate The X coordinate for the starting position of the text on the image. Smart parameter supported.
- yCoordinate The Y coordinate for the starting position of the text on the image. Smart parameter supported.

Returns

False, if parameters are missing, or the X or Y parameters are not Numeric. Otherwise, True.

Level

Page level only.

Details

Imprints the text you specify onto the current page's image file. By default, the text's font size is 12, and font's style Times New Roman, with an adjusted width of 30.

Example:

```
SetFontName("Arial")
SetFontSize("10")
SetAdjustedWidth("100")
AnnotateImage("@BATCHID+ Page:+@ID", "0", "0")
```

This example places the Batch ID followed by `Page:` and the calling object ID at the top of the image using the Arial font with a point size of 10 and a width of 100.

Parent topic: [Imprint actions](#)

RedactByRegEx

Searches the entire page and redacts all occurrences of the phrase that matches the RegEx expression.

Syntax

```
bool RedactByRegEx (string RegEx, string VariableBase)
```

Parameters

string RegEx

string VariableBase

Parameters

- RegEx The expression to search for on the page. Smart parameters are supported.
- VariableBase A variable to create in the runtime DCO to track each redaction.

Returns

Always True.

Level

Page Level.

Details

This action searches the entire page and redacts all occurrences of the phrase that matches the RegEx expression. This action must be called at a field level, however the coordinates of the field will change during the operation and will remain on the last found occurrence of the found text, so it may be necessary to use a zoned but unused field for this action.

The VariableBase parameter specifies a variable name to use as a history of redacted words. For each redaction, a variable of the form "VariableBasen", where n is an incrementing number, is created in the runtime DCO with the coordinates of the redacted word. For example, if the parameter was "Hello", the variables created would be named: "Hello1", "Hello2", "Hello3", etc. for each redaction. An example value of the variable: "TM000001,159,1085,242,1115".

Example:

```
RedactByRegEx("[Hh]istory", "Location")
```

This example will redact all areas on the page where the word "History" or "history" exists. The redactions will be tracked in the runtime DCO in a variable called Location0, Location1, etc.

Parent topic: [Imprint actions](#)

Related reference:
[Redact \(deprecated\)](#)

RedactParameters

Overlays a black or white rectangle on the image to redact the current field or the specified region of a page.

Syntax

```
bool RedactParameters (string FillColor, string NewText, string TopLeftX, string TopLeftY, string BottomRightX, string BottomRightY)
```

Parameters

string

string FillColor

string NewText

string TopLeftX

string TopLeftY

string BottomRightX

string BottomRightY

Parameters

- FillColor The fill color to use. Must be either White, or Black.
- NewText Optional - The text to include in the overlay.
- TopLeftX The upper left X coordinate in pixels.
- TopLeftY The upper left Y coordinate in pixels.
- BottomRightX The lower right X coordinate in pixels.
- BottomRightY The lower right Y coordinate in pixels.

Smart parameters are supported for all parameters.

Returns

True, if the area is redacted. Otherwise, False.

Level

Page and Field level.

Details

This action overlays a black, or white rectangle on the image. A default text value might optionally be applied to the overlay.

If run on the field level, the entire field is redacted and the last four X/Y parameters are ignored.

If run on the page level the last four parameters to specify the location must be provided.

Example:

```
Redact("black", "", "0", "0", "100", "100")
```

Called at the page level, this applies a black square overlay on the upper left of the image.

```
Redact("White", "Hello", "", "", "", "")
```

Called at the field level, this applies a white square overlay on the coordinates for the current field, and imprint the word "Hello".

Parent topic: [Imprint actions](#)

SetAdjustedWidth

Specifies the width of the imprinted text.

Syntax

```
bool SetAdjustedWidth (StrParam)
```

Parameters

Numeric value for a length adjustment of the string to be imprinted. Smart parameters are supported.

Returns

False if the parameter is not numeric. Otherwise, True.

Level

Page level only.

Details

This actions adjusts the maximum width of the imprinted text. It is possible that the calculation of the string length may not allow for the entire string in the specified font and point size. This is an adjustment factor which will lengthen the area for the string to imprint on the image.

This action is optional. If the action is not used, the adjusted width will default to 30. If your text is being cut off, increase the parameter value. If you use this action it must be called prior to the AnnotateImage action.

Example:

```
SetFontName("Arial")
SetFontSize("10")
SetAdjustedWidth("100")
AnnotateImage("@BATCHID+ Page:+@ID", "0", "0")
```

Parent topic: [Imprint actions](#)

SetFontName

Specifies the font style to use for the imprinted text.

Syntax

```
bool SetFontName (StrParam)
```

Parameters

String value of the font's name. Smart parameters are supported.

Returns

False if the parameter is missing. Otherwise True.

Level

Page level only.

Details

Specifies the font style that is used.

This action is optional. If not used, the font style will default to Times New Roman. If you use this action, it must be called prior to the AnnotateImage action.

Example:

```
SetFontName("Arial")
SetFontSize("10")
SetAdjustedWidth("100")
AnnotateImage("@BATCHID+ Page:+@ID", "0", "0")
```

Parent topic: [Imprint actions](#)

SetFontSize

Specifies the font size to use for the imprinted text.

Syntax

```
bool SetFontSize (StrParam)
```

Parameters

Numeric value of the font's size. Smart parameters are supported.

Returns

False if the parameter is not Numeric. Otherwise True.

Level

Page level only.

Details

Specifies the font size that will be used.

This action is optional. If you do not use the action, the font size will default to 12. If you use this action, it must be called prior to the AnnotateImage action.

Example:

```
SetFontName("Arial")
SetFontSize("10")
SetAdjustedWidth("100")
AnnotateImage("@BATCHID+ Page:@ID", "0", "0")
```

Parent topic: [Imprint actions](#)

SetOpaque

Specifies whether the transparency of the overlay rectangles are opaque (1) or transparent (0).

Syntax

```
bool SetOpaque (StrParam)
```

Parameters

- Integer value: 1 or 0.
- SetOpaque(1) indicates full opacity / black.
- SetOpaque(0) results in subsequent rectangles that are white.

Smart parameters are supported.

Returns

False if the parameter is not an Integer. Otherwise, True.

Level

All, but generally used at the Page level.

Details

Sets the transparency of the background of the imprint text. This is the background that is added behind the imprinted text. If you use this action it must be called prior to the AnnotateImage action.

If this action is not called, then the default value of 0, white, will be used for the background of the annotation text.

Example:

```
SetOpaque ("1")
AnnotateImage ("@BATCHID+ Page:+@ID", "0", "0")
```

Parent topic: [Imprint actions](#)

Intellocate actions

Use the Intellocate actions to update the existing field position information in the document hierarchy (setup DCO) or to add position information for a new fingerprint.

The Intellocate actions can generate fingerprints automatically by using a page image and the recognition zones that are specified manually during verification.

- [iloc_AdjustZones](#)
Updates fingerprint-specific position coordinates for Field objects in the Document Hierarchy based on the locations listed for the current source page's Data file (.xml).
- [iloc_AssignPageType](#)
Assigns a required Page Type value to a newly created fingerprint.
- [iloc_SetDetailZones](#)
Writes the position coordinates of a new fingerprint's Detail Line fields from a page's Data file to the Pos properties of the corresponding Detail Line Field objects of the application's Document Hierarchy.
- [iloc_SetZones](#)
Writes the position coordinates of a new fingerprint's zoned fields from a page's Data file to the Pos properties of the corresponding Field objects in the Document Hierarchy file (.xml).
- [IsPageDataMissing](#)
Checks to see that the current page data exists.

Parent topic: [Global actions](#)

iloc_AdjustZones

Updates fingerprint-specific position coordinates for Field objects in the Document Hierarchy based on the locations listed for the current source page's Data file (.xml).

Member of namespace

Intellocate

Syntax

```
bool iloc_AdjustZones ()
```

Parameters

None.

Returns

False if a fingerprint match has not occurred and a Template ID value has not been assigned to the current page, or if the Document Hierarchy file cannot be saved. Otherwise, True.

Level

Page level only.

Details

Updates fingerprint-specific position coordinates for Field objects in the Document Hierarchy based on the locations listed for the current source page's Data file (.xml).

This action is designed to be used on existing fingerprints only. It will only update fields that do not have position information. Existing fields will not be updated, even if the position information for those fields has changed.

Example:

```
iloc_AdjustZones()
```

Parent topic: [Intellocate actions](#)

iloc_AssignPageType

Assigns a required Page Type value to a newly created fingerprint.

Member of namespace

Intellocate

Syntax

```
bool iloc_AssignPageType (strParam)
```

Parameters

The value of the page type to assign to the current page. The input parameter must be one of the following:

1. A numeric value that corresponds to the Page Type.
2. A string value of the page type name.

Returns

False if the numeric value cannot be retrieved from the fingerprint database or if there is no connection to the fingerprint database. Otherwise, True.

Level

Page level only.

Details

Assigns a required Page Type value to a newly created fingerprint. The assigned value corresponds to the values configured in the PageType table within the fingerprint database. These values are custom defined for each application. If a string value is passed as a parameter, this action will look up the corresponding numeric value within the database.

Example:

```
Iloc_AssignPageType ("2")
```

This example assigns a page type of 2 to the new fingerprint.

```
Iloc_AssignPageType ("PageSeparator")
```

This example assigns a page type of "PageSeparator" to the new fingerprint.

Parent topic: [Intellocate actions](#)

iloc_SetDetailZones

Writes the position coordinates of a new fingerprint's Detail Line fields from a page's Data file to the Pos properties of the corresponding Detail Line Field objects of the application's Document Hierarchy.

Member of namespace

Intellocate

Syntax

```
bool iloc_SetDetailZones ()
```

Parameters

None.

Returns

Always True.

Level

Page level only.

Details

Writes the position coordinates of a new fingerprint's Detail Line fields from a page's Data file to the Pos properties of the corresponding Detail Line Field objects of the application's Document Hierarchy.

Example:

```
iloc_SetDetailZones ()
```

Parent topic: [Intellocate actions](#)

iloc_SetZones

Writes the position coordinates of a new fingerprint's zoned fields from a page's Data file to the Pos properties of the corresponding Field objects in the Document Hierarchy file (.xml).

Member of namespace

Intellocate

Syntax

```
bool iloc_SetZones ()
```

Parameters

None.

Returns

False if a fingerprint match has not occurred, or if the Document Hierarchy file (.xml) cannot be saved. Otherwise, True.

Level

Page level only.

Details

Writes the position coordinates of a new fingerprint's zoned fields from a page's Data file to the Pos properties of the corresponding Field objects in the Document Hierarchy file (.xml).

Example:

```
iloc_SetZones ()
```

Parent topic: [Intellocate actions](#)

IsPageDataMissing

Checks to see that the current page data exists.

Member of namespace

Intellocate

Syntax

```
bool IsPageDataMissing ()
```

Parameters:

None.

Returns

True if the current page does not have page data. Otherwise, False.

Level

Page level only.

Details

Checks to see that the current page data exists. This action does not physically check for the existence of a data file. It confirms that a valid page data is loaded into memory.

Example:

```
IsPageDataMissing()
```

Parent topic: [Intellocate actions](#)

Invoice actions

Use the Invoice actions to process invoices by using the Datacap Accounts Payable application.

The Invoice actions can configure date, fingerprint, format, and vendor settings on invoice pages before export.

- [AddToDetailErrorMsg](#)
Appends extra text to the existing error message.
- [AddToErrorMsg](#)
Appends the supplied text to any existing error message string.
- [AllMixedCase](#)
Changes the value of the current field to be Title case. The first letter of each word is capitalized.
- [AlterDatebyDay](#)
Adds the specified number of days to the date contained in the current field. The original character confidence is not changed.
- [CalculateNotesZone](#)
Creates a zone between detail lines to recognize the text between lines.
- [CaptureOpInfo](#)
Captures the Operator, Station ID, and current time and place them into variables. The variables are named based on the provided variable prefix, such as, *prefix Operator*, *prefix Station*, and *prefix Time*. When, a prefix is not provided the task name is used as the prefix by default.
- [CheckAndFixDecimal](#)
Replaces the space or comma with a decimal point. This action is used to fix errors where the decimal is not recognized and leaves a blank in that area.
- [CheckForSticky](#)
For new fingerprints, checks whether there is another matching fingerprint within the same batch that was already verified. It can be used to obtain zone information.
- [CheckFreeDiskSpace](#)
Reads the LowDiskSpaceThreshold setting from the [Notifications] section of the INI file that is specified in the first parameter.
- [ClearErrorMsg](#)
Use this action to clear the current error message.
- [CreateFingerprint](#)
Creates a fingerprint for the current page, even when there is an existing fingerprint.
- [DetailFix](#)
Calculates the quantity, price, and line total when one of them is blank within a detail field. This calculation is done for all detail lines on the page.
- [FindExportImage](#)
Searches the batch directory for a file that corresponds to the current page that contains the current field. The file extension must match the extension that is specified with the input parameter.
- [FPXMLUsed](#)
Indicates when FPXML format fingerprint files are being used. Call this action when you are using fingerprints from FPXML with Invoice.rrx.

- [GenerateDetails](#)
Sets up a field in APT and puts a detail subfield on every page. This extra detail subfield appears on all pages of a multi-page invoice, allowing every page to be viewed.
- [iloc_SetDetailSimple](#)
Fills the Setup DCO from Runtime Data file.
- [IncrementBatchVar](#)
Increments a batch level variable by 1. When the variable does not exist, it is created. When the variable exists but the value is not a number, the variable is set to 1.
- [IsFingerPrintClass](#)
Connects to the fingerprint database and verifies that the specified fingerprint class contains the fingerprint ID of the current page.
- [IsInINI](#)
Reads and returns to the action the value of the specified key in the INI file.
- [IsInList](#)
Validates that the value of a field is contained within a string.
- [IsMultipageDocument](#)
Determines whether the current object is a document with multiple pages attached.
- [IsSinglePageDocument](#)
Determines whether the current object is a document with only 1 page attached.
- [IsStationIDSuffix](#)
Tests the current station ID by checking that the specified parameter matches the rightmost portion of the station ID.
- [Is_JobNamePrefix](#)
Tests the leftmost portion of the job name to determine if it matches the provided prefix.
- [LoadCCOFromField](#)
Loads the DCO from a field object. The verify panels do not load the CCO into the scripting engine so this action accomplishes that task.
- [PopulateZNLineItemFieldDynamic](#)
This action is like the [PopulateZNLineItemField](#) except that it uses the CCO that was loaded into memory by [LoadCCOFromField](#), instead of the global CCO.
- [ReadFPXMLZones](#)
Reads the zones from the FPXML into the objects for the page and stores the specified fields. When it creates detail lines, it knows the positions of the fields of these detail lines.
- [ScanLineItemDynamic](#)
Scans the line items from the CCO that was loaded into the field. This action is like [ScanLineItem](#) except that it uses the CCO loaded for the field and reads position variables from the line item level.
- [SendOutlookNotification](#)
Uses Outlook to send a notification to specified email addresses. The message within the email is determined by previous calls to actions with a set notification, such as [CheckFreeDiskSpace](#).
- [SetDynamicDetailZones](#)
Takes the position of the line items and builds the line coordinates. It sets the details zones from the first line to the end of the CCO.
- [SetStickyNo](#)
Sets the Sticky indicator to No to indicate that there are no sticky fingerprints. Sticky fingerprints identify a page within a single verification session when another form of the same type appears after a previous form was zoned.
- [SwapImages](#)
Interchanges the TIF for the current page with another TIF that has the same file name but a different extension.
- [SwitchMMDD](#)
Switches US Month and Day date values. It swaps the first 2 characters of the field value with the 2 characters that follow the separator.

- [UpdateFPStats](#)
Updates the fingerprint statistics in the fingerprint database. This action keeps track of the last accessed fingerprint and the number of times a fingerprint is accessed.
- [ValidateVendor](#)
Checks whether the current vendor, vendor number, and postal code exist on the same record in the lookup database.
- [WriteErrorMessage](#)
Writes the message to field level variable message that appears in the status bar. The message is stored in the *MESSAGE* variable.

Parent topic: [Global actions](#)

AddToDetailErrorMsg

Appends extra text to the existing error message.

Syntax

```
bool AddToDetailErrorMsg (StrParam)
```

Parameters

The error message text.

Returns

Always False.

Level

Field level.

Details

Appends additional text to the existing error message.

Example

```
AddToDetailErrorMsg("Description cannot be blank.")
```

Parent topic: [Invoice actions](#)

AddToErrorMsg

Appends the supplied text to any existing error message string.

Syntax

```
bool AddToErrorMsg (StrParam)
```

Parameters

The error message text.

Returns

Always False.

Level

Field level.

Details

Appends the supplied text to any existing error message string.

Example

```
AddToErrorMsg("Vendor Number cannot be blank.")
```

Parent topic: [Invoice actions](#)

AllMixedCase

Changes the value of the current field to be Title case. The first letter of each word is capitalized.

Syntax

```
bool AllMixedCase ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

This action will change the value of the current field to be Title case. The first letter of each word will be capitalized.

Example

```
AllMixedCase ()
```

If the field in this example is "hello, i MUST be going.", the text will be changed to "Hello, I Must Be Going."

Parent topic: [Invoice actions](#)

AlterDatebyDay

Adds the specified number of days to the date contained in the current field. The original character confidence is not changed.

Syntax

```
bool AlterDatebyDay (StrParam)
```

Parameters

The number of days to add.

Returns

False if called at the wrong level or if the input is not numeric. Otherwise, True.

Level

Field level.

Details

This action will add the specified number of days to the date contained in the current field. The original character confidence is not changed.

Example

```
AlterDatebyDay("7")
```

This example adds one week to the date contained in the field. If the date crosses over a month or year boundary, they will be adjusted appropriately.

Parent topic: [Invoice actions](#)

CalculateNotesZone

Creates a zone between detail lines to recognize the text between lines.

Syntax

```
bool CalculateNotesZone ()
```

Parameters

None.

Returns

Always True.

Level

Field level, on the detail field.

Details

This action creates a zone between detail lines, so the text between lines can be recognized.

Example

```
CalculateNotesZone()
```

Parent topic: [Invoice actions](#)

CaptureOpInfo

Captures the Operator, Station ID, and current time and place them into variables. The variables are named based on the provided variable prefix, such as, *prefix Operator*, *prefix Station*, and *prefix Time*. When, a prefix is not provided the task name is used as the prefix by default.

Syntax

```
bool CaptureOpInfo (StrParam)
```

Parameters

An optional prefix to the variable name.

Returns

Always True.

Level

Any level.

Details

This action will capture the Operator, Station ID and current time and place them into variables. The variables are named based on the provided variable prefix, like this: *prefix Operator*, *prefix Station*, and *prefix Time*. If a prefix is not provided, the task name is used as the prefix by default.

Example

```
Status_Preserve_OFF()  
ClearErrorMsg()  
CaptureOpInfo("Production")  
rrCompare("@P\Routing_Instructions", "None")
```

In this example, the variables created will be *Production Operator*, *Production Station*, and *Production Time*.

Parent topic: [Invoice actions](#)

CheckAndFixDecimal

Replaces the space or comma with a decimal point. This action is used to fix errors where the decimal is not recognized and leaves a blank in that area.

Syntax

```
bool CheckAndFixDecimal ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Replaces the space or , with . to fix errors where the decimal is not recognized and leaves a blank in that area. This action can also be used for conversion for European numbers that use a comma to separate dollars from cents so \$100,00 becomes \$100.00 or \$100 00 becomes \$100.00.

Example

```
CheckAndFixDecimal()  
Is_InCharSet("0123456789.,-$")  
AllowOnlyChars("0123456789.-")  
IsFieldCurrency()
```

Parent topic: [Invoice actions](#)

CheckForSticky

For new fingerprints, checks whether there is another matching fingerprint within the same batch that was already verified. It can be used to obtain zone information.

Syntax

```
bool CheckForSticky ()
```

Parameters

None.

Returns

Always True.

Level

Page level.

Details

An example of this action is when a batch contains two similar invoices, which have never been processed by the system before. Once the first invoice is zoned during verify, the same new fingerprint can be used on the second invoice. This is only needed on new matching fingerprints within the same batch because a fingerprints zones are saved at export time and are available for subsequent batches.

Example

```
CheckForSticky()
```

Parent topic: [Invoice actions](#)

CheckFreeDiskSpace

Reads the LowDiskSpaceThreshold setting from the [Notifications] section of the INI file that is specified in the first parameter.

Syntax

```
bool CheckFreeDiskSpace (StrParam)
```

Parameters

Two comma separated parameters:

1. The path to .ini file that contains the LowDiskSpaceThreshold setting.
2. The letter drive of the drive to check. The letter drive must be accompanied by a colon, for example, C:.

Returns

False if called at the wrong level, if parameters are missing or if the settings.ini file cannot be found. Otherwise, True.

Level

Batch level.

Details

If the available disk space is less than the value specified in the .ini file, then a notification will be created in the .ini file. The notification is created under the [Notifications] section of the .ini file, under the LowDiskNotification setting. This setting will be set to Yes.

If the LowDiskSpaceThreshold is missing from the .ini file, the default value of 3000 bytes will be used.

If a notification has been previously created, and the disk space has been increased since the last time the action ran, then the notification will be removed from the .ini file and LowDiskNotification is set to No.

Example

```
CheckFreeDiskSpace ("C:\Datacap\APT\dco_APT\settings.ini,C:")  
Scan()
```

Parent topic: [Invoice actions](#)

ClearErrorMsg

Use this action to clear the current error message.

Syntax

```
bool ClearErrorMsg ()
```

Parameters

None.

Returns

Always True.

Level

Any level.

Details

This action clears the current error message.

Example

```
Status_Preserve_OFF()  
ClearErrorMsg()  
CaptureOpInfo()  
rrCompare("@P\Routing_Instructions", "None")
```

Parent topic: [Invoice actions](#)

CreateFingerprint

Creates a fingerprint for the current page, even when there is an existing fingerprint.

Syntax

```
bool CreateFingerprint ()
```

Parameters

None.

Returns

True if a new fingerprint has been created. Otherwise, False.

Level

Page level.

Details

This action will create a fingerprint for the current page. Forces the creation of a new fingerprint using the current image, even if there is an existing fingerprint. A typical scenario is when there is a very similar fingerprint that incorrectly matches the current image, such as two invoices that are very similar. When the new invoice is received in the future, it should now match on this new fingerprint.

Example

```
IsChildFieldValue("Add_New_Fingerprint,YES")
SetFingerprintDir("@APPPATH(fingerprint)")
SetFingerprintRecogPriority("True")
RecognizePageOCR_S()
CreateFingerprint()
SetFingerprint("@P\Vendor")
iloc_SetDetailSimple("Details")
IncrementBatchVar("Verify requested Add Fingerprint")
```

Parent topic: [Invoice actions](#)

DetailFix

Calculates the quantity, price, and line total when one of them is blank within a detail field. This calculation is done for all detail lines on the page.

Syntax

```
bool DetailFix ()
```

Parameters

None.

Returns

False if called at the wrong level.

False if any of following fields do not exist or are not numeric: Qty, Price, and LineTotal.

Otherwise, True.

Level

Field level.

Details

A typical scenario is a similar fingerprint incorrectly matches the current image, such as two similar invoices. When a new invoice is received in the future, it now matches this new fingerprint.

Example

```
DetailFix()
```

Parent topic: [Invoice actions](#)

FindExportImage

Searches the batch directory for a file that corresponds to the current page that contains the current field. The file extension must match the extension that is specified with the input parameter.

Syntax

```
bool FindExportImage (StrParam)
```

Parameters

One of the following values:

1. Document Level TIFF
2. Document Level PDF
3. Page Level TIO
4. Page Level TIF

Returns

False if called at the wrong level or if the input parameter is invalid. True if the correctly named file with the specified extension exists in the batch directory.

Level

Field level.

Details

Example

```
FindExportImage ("1")
```

Parent topic: [Invoice actions](#)

FPXMLUsed

Indicates when FPXML format fingerprint files are being used. Call this action when you are using fingerprints from FPXML with Invoice.rrx.

Syntax

```
bool FPXMLUsed ()
```

Parameters

None.

Returns

True if a FPXML fingerprint file exist for the current page object. Otherwise, False.

Level

Page level.

Details

Call this action if you are using fingerprints from FPXML with Invoice.rrx.

Example

```
FPXMLUsed()  
ZoneBOTTOM_ImageBottom()  
ScanDetails()
```

Parent topic: [Invoice actions](#)

GenerateDetails

Sets up a field in APT and puts a detail subfield on every page. This extra detail subfield appears on all pages of a multi-page invoice, allowing every page to be viewed.

Syntax

```
bool GenerateDetails ()
```

Parameters

None.

Returns

False if called on the wrong level. Otherwise, True.

Level

Field level.

Details

This action sets up a field in APT and puts a detail subfield on every page. This extra detail subfield appears on all pages of a multi-page invoice, allowing every page to be viewed.

Example

```
GenerateDetails()
```

Parent topic: [Invoice actions](#)

iloc_SetDetailSimple

Fills the Setup DCO from Runtime Data file.

Syntax

```
bool iloc_SetDetailSimple (sDetailName)
```

Parameters

The detail Datacap Object (DCO) Type.

Returns

False if called at the wrong level, if the DCO node cannot be found, if the fingerprint ID is not found, or if the setup DCO cannot be saved. Otherwise, True.

Level

Page level.

Details

This action fills the Setup DCO from Runtime Data file.

Example

```
SetFingerprint("@P\Vendor")
iloc_SetZones()
iloc_SetDetailSimple("Details")
IncrementBatchVar("Intellocate Fingerprint")
```

Parent topic: [Invoice actions](#)

IncrementBatchVar

Increments a batch level variable by 1. When the variable does not exist, it is created. When the variable exists but the value is not a number, the variable is set to 1.

Syntax

```
bool IncrementBatchVar (StrParam)
```

Parameters

The name of the variable to increment.

Returns

Always True.

Level

Any level.

Details

This action increments a batch level variable by 1. If the variable does not already exist, it will be created. If the variable exists but the value is not numeric, the variable is set to 1.

Example

```
rrCompareNot("@P.RecogStatus","1")
SetDocStatus("128")
IncrementBatchVar("Recog - Deleted Document")
```

Parent topic: [Invoice actions](#)

IsFingerPrintClass

Connects to the fingerprint database and verifies that the specified fingerprint class contains the fingerprint ID of the current page.

Syntax

```
bool IsFingerPrintClass (StrParam)
```

Parameters

Two comma separated parameters:

1. The database connection string. Smart parameters are supported.
2. Fingerprint class.

Returns

False if called with the wrong number of parameters, on the wrong level, if the fingerprint ID does not exist in the specified class.

Level

Page Level.

Details

Example

```
ChkDCOStatus("75")
IsFingerPrintClass("@APPVAR(* /fingerprintconn:cs)+, [New]")
DeleteFingerprint()
IncrementBatchVar("Deleted New Fingerprint")
```

A parameter of [New] checks to see if the fingerprint exists in the new class, and if it does, follow on actions can perform further processing.

Parent topic: [Invoice actions](#)

IsInINI

Reads and returns to the action the value of the specified key in the INI file.

Syntax

```
bool IsInINI (StrParam)
```

Parameters

A comma separated string of:

1. The INI Filename.
2. The section within the INI file.
3. The keyword to find in the section.

Returns

True if the value of the current field is a substring within the string specified in the INI file. Otherwise, False.

Level

Field Level.

Details

When possible it is recommended to use the generic actions that read and write INI files in the FileIO action library. Reads and returns to the action the value of the specified key in the INI file. It compares the value of the current field with the with the string in the INI file. The field must be a substring of the string in the INI file.

Example

```
IsInINI("C:\MyDir\settings.ini", "mysection", "mykey")
```

Parent topic: [Invoice actions](#)

IsInList

Validates that the value of a field is contained within a string.

Syntax

```
bool IsInList (StrParam)
```

Parameters

A string that is a substring of the expected Text value.

Returns

True if the value of the *Text* variable of the current field is contained within the specified list.

Level

Field Level.

Details

Example

```
IsInList("Hello Larry")
```

In this example, if the field Text value is *Larry*, the action returns True.

Parent topic: [Invoice actions](#)

IsMultipageDocument

Determines whether the current object is a document with multiple pages attached.

Syntax

```
bool IsMultipageDocument ()
```

Parameters

None.

Returns

False if called at the Batch level, the document object cannot be found, or if the document does not have more than 1 child. Otherwise, True.

Level

Document level.

Details

This action is used to determine if the current object is a document with multiple pages attached.

Example

```
IsMultipageDocument ()
```

Parent topic: [Invoice actions](#)

IsSinglePageDocument

Determines whether the current object is a document with only 1 page attached.

Syntax

```
bool IsSinglePageDocument ()
```

Parameters

None.

Returns

False if not called on a document object or if the document does not contain exactly one page. True if the document contains one page.

Level

Document level.

Details

This action is used to determine if the current object is a document with only 1 page attached.

Example

```
IsSinglePageDocument()  
PopulateZNField()
```

Parent topic: [Invoice actions](#)

IsStationIDSuffix

Tests the current station ID by checking that the specified parameter matches the rightmost portion of the station ID.

Syntax

```
bool IsStationIDSuffix (StrParam)
```

Parameters

The expected Station ID suffix.

Returns

False if the suffix is longer than the current Station ID or if the specified suffix does not match the Station ID. Otherwise, True.

Level

Any level.

Details

This action checks that the specified parameter matches the right most portion of the station ID. This action is useful if you have stations with different suffixes and you want to control actions based on the station name.

Example

```
IsStationIDSuffix("-Test")  
CloseConnection()  
OpenConnection("@APPVAR(*/*lookupdb:cs) ")
```

In this example, If the station name is Validate-Test, the action returns True and continues executing the following actions.

Parent topic: [Invoice actions](#)

Is_JobNamePrefix

Tests the leftmost portion of the job name to determine if it matches the provided prefix.

Syntax

```
bool Is_JobNamePrefix (StrParam)
```

Parameters

The prefix you are expecting for the current job.

Returns

True if the left most portion matches. Otherwise, False.

Level

Any level.

Details

Example

```
Is_JobNamePrefix("Test")
```

If the current job name is TestRecognition, the action returns True.

Parent topic: [Invoice actions](#)

LoadCCOFromField

Loads the DCO from a field object. The verify panels do not load the CCO into the scripting engine so this action accomplishes that task.

Syntax

```
bool LoadCCOFromField ()
```

Parameters

None.

Returns

False if this action is not called on a field or if the CCO file does not exist. Otherwise, True.

Level

Field Level.

Details

This action is required for any invoice action that uses the CCO.

Example

```
LoadCCOFromField()  
SetDynamicDetailZones("Zone Bottom,Notes")  
ZoneBOTTOM_ImageBottom()  
ScanDetails()
```

Parent topic: [Invoice actions](#)

PopulateZNLineItemFieldDynamic

This action is like the `PopulateZNLineItemField` except that it uses the CCO that was loaded into memory by `LoadCCOFromField`, instead of the global CCO.

Syntax

```
bool PopulateZNLineItemFieldDynamic ()
```

Parameters

None

Returns

True if there is no field position or if the data was found in a zone. False if there is a zone defined but it is blank.

Level

Page level.

Details

This action populates the data file of the Fingerprint with the recognized value contained inside the zone of a child Field object of a LINEITEM parent field. This action should only be used with sub-fields of the LINEITEM field - ItemID, ItemDesc, Quantity, Price in the Invoices application.

Example

```
FPXMLUsed()  
PopulateZNLineItemFieldDynamic()
```

Parent topic: [Invoice actions](#)

ReadFPXMLZones

Reads the zones from the FPXML into the objects for the page and stores the specified fields. When it creates detail lines, it knows the positions of the fields of these detail lines.

Syntax

```
bool ReadFPXMLZones (StrParam)
```

Parameters

Comma-separated parameters:

1. The fingerprint directory. Smart parameters are supported.
2. A comma-separated list of the detail lines.

Returns

False if called at the wrong level or if the FPXML does not exist. Otherwise, True.

Level

Page level.

Details

Example

```
ReadFPXMLZones("@APPPATH(fingerprint), details, lineid, itemdesc, qty, price, linetotal")
rrSet("FPXML", "@P.ZoneRead")
IsMultipageDocument()
SetEOL("|")
```

Parent topic: [Invoice actions](#)

ScanLineItemDynamic

Scans the line items from the CCO that was loaded into the field. This action is like ScanLineItem except that it uses the CCO loaded for the field and reads position variables from the line item level.

Syntax

```
bool ScanLineItemDynamic (StrParam)
```

Parameters

A comma separated list of any fields that should be ignored.

Returns

Always True.

Level

Field Level.

Details

This action is required for Find Details functionality. It saves the positions of the line and of the fields at the detail level so all of the line items can be erased and recreated.

Example

```
FPXMLUsed()  
ScanLineItemDynamic("ZoneBottom,Notes")
```

Parent topic: [Invoice actions](#)

SendOutlookNotification

Uses Outlook to send a notification to specified email addresses. The message within the email is determined by previous calls to actions with a set notification, such as [CheckFreeDiskSpace](#).

Syntax

```
bool SendOutlookNotification (StrParam)
```

Parameters

The extension of the attachment. The attachment is expected to be named the same as the current document ID.

Returns

False if called at the wrong level, if the connection to Outlook could not be established, or if email addresses could not be found in [Settings.ini](#).

Level

Document level.

Details

This action requires Outlook to be installed on the computer and logged in with an ID that has the appropriate permissions to send emails.

Example

```
SendOutlookNotification(".pdf")
```

Parent topic: [Invoice actions](#)

Related reference:
[CheckFreeDiskSpace](#)

SetDynamicDetailZones

Takes the position of the line items and builds the line coordinates. It sets the details zones from the first line to the end of the CCO.

Syntax

```
bool SetDynamicDetailZones (StrParam)
```

Parameters

The parameter is the Zone Bottom field. If more than one field is listed, Zone Bottom must be the first field and other fields are ignored.

Returns

False, if no children exist. Otherwise, True.

Level

Page level.

Details

Example

```
LoadCCOFromField()  
SetDynamicDetailZones("Zone Bottom,Notes")  
ZoneBOTTOM_ImageBottom()  
ScanDetails()
```

Parent topic: [Invoice actions](#)

SetStickyNo

Sets the Sticky indicator to No to indicate that there are no sticky fingerprints. Sticky fingerprints identify a page within a single verification session when another form of the same type appears after a previous form was zoned.

Syntax

```
bool SetStickyNo ()
```

Parameters

None.

Returns

Always True.

Level

Any level.

Details

Example

```
IsCurrentObjVariable("Sticky,Yes")  
SetStickyNo()
```

Parent topic: [Invoice actions](#)

SwapImages

Interchanges the TIF for the current page with another TIF that has the same file name but a different extension.

Syntax

```
bool SwapImages (StrParam)
```

Parameters

Two extensions:

1. The extension to be saved as TIF.
2. The current tif file's extension.

Returns

False if called at the wrong level, if the wrong number of parameters are specified, or if the original file cannot be found. True if the file extensions are interchanged.

Level

Page level.

Details

One possible use for this action is if you want to export the original version of the TIF file instead of the converted version of the image used to process the document. The original version of the TIF file had previously been renamed using the extension .TIO (where the O stands for *Original*). So in the example, the SwapImages action will be used to change the current .TIF file to instead have an extension of .TIB (where the B can stand for *Backup*), and then take the original file (.TIO) and give it the .TIF extension.

Example

```
SwapImages ("TIB,TIO")
```

The action renames the current image TM00000n.TIF to TM00000n.TIB. It then copies TM00000n.TIO to TM00000n.TIF and that becomes the new current image.

Parent topic: [Invoice actions](#)

SwitchMMDD

Switches US Month and Day date values. It swaps the first 2 characters of the field value with the 2 characters that follow the separator.

Syntax

```
bool SwitchMMDD (StrParam)
```

Parameters

A list of separators.

Returns

True if two separators are found and the separators are swapped. Otherwise, False.

Level

Field level.

Details

Example

```
SwitchMMDD("/")
```

In this example, the value "03/09/10" becomes "09/03/10".

Parent topic: [Invoice actions](#)

UpdateFPStats

Updates the fingerprint statistics in the fingerprint database. This action keeps track of the last accessed fingerprint and the number of times a fingerprint is accessed.

Syntax

```
bool UpdateFPStats ()
```

Parameters

None.

Returns

False if called at the wrong level or if the fingerprint does not exist. Otherwise, True.

Level

Page level.

Details

Example

```
UpdateFPStats ()
```

Parent topic: [Invoice actions](#)

ValidateVendor

Checks whether the current vendor, vendor number, and postal code exist on the same record in the lookup database.

Syntax

```
bool ValidateVendor (StrParam)
```

Parameters

The connection string to the lookup database. Smart Parameters are supported.

Returns

False if the connection cannot be opened or if the settings file cannot be found.

False if these fields cannot be found: Vendor, Vendor_Number, or Remittance_Zip.

False if the vendor cannot be found in the database.

Otherwise, True.

Level

Page level.

Details

The fields that are validated are in the validate vendor check are Vendor, Vendor_Number, and Remittance_Zip.

Example

```
SetIsOverrideable("False")
ValidateVendor("@APPVAR(*/*lookupdb:cs) ")
```

Parent topic: [Invoice actions](#)

WriteErrorMessage

Writes the message to field level variable message that appears in the status bar. The message is stored in the *MESSAGE* variable.

Syntax

```
bool WriteErrorMessage (StrParam)
```

Parameters

The error message.

Returns

Always False.

Level

All levels.

Details

Example

```
GetDCOStatus("75")
WriteErrorMessage("The page is set to a deleted status.")
```

Parent topic: [Invoice actions](#)

IOverlay actions

Use the IOverlay actions to combine the current page image with a background image. You can use this action to reapply a form background that dropped out during scanning.

The IOverlay actions enable dithering of a background image and haloing with white pixels around the black pixels on an image. These actions make the image easier to read.

- [Overlay](#)
Combines the current image with the image file specified by the SetBackgroundImage action into a new image replacing the current image. This action is used to reinstate a form background that was dropped out during scanning.
- [SetBackgroundImage](#)
Designates the Image file that will overlay the image of the current page.
- [SetDitheringBackground](#)
Enables or disables dithering of the background image. Dithering makes the background image appear lighter than the information of the current image so that visually it appears less prominent.
- [SetHaloBackground](#)
Enables or disables a halo of white pixels around any black pixels from the current image where they would otherwise touch pixels from the background. This makes the foreground information easier to read.

Parent topic: [Global actions](#)

Overlay

Combines the current image with the image file specified by the SetBackgroundImage action into a new image replacing the current image. This action is used to reinstate a form background that was dropped out during scanning.

Syntax

```
bool Overlay ()
```

Parameters

None.

1. The parameter of the preceding SetBackgroundImage action can be a smart parameter that locates a file.
2. Looks for a field type called Image_Offset or IMAGEOVERLAYOFFSET containing a comma separated value containing the amount of X and Y pixel offset for the overlay image.

These fields are automatically generated by running FindFingerprint, CalculateOffset, WordFind_Offset, CalculateLocalOffset, Autofield(), and most of the PatternMatch.rxx actions.

Returns

False if the action is not applied to a Page object; if it cannot locate the Background Image file; or if the action encounters an error of a different kind. Otherwise, True.

Level

Page level only.

Details

Example:

```
SetBackgroundImage (c:\ParentDir\mclaims\process\hcfa\hcfa.tif)
Overlay()
```

In this example, the Overlay action uses the file name and path in the parameter of the SetBackgroundImage action to locate the Background Image file.

```
SetBackgroundImage (@APPPATH(formdir)+\+ub04.tif)
Overlay()
```

Here, the SetBackgroundImage action uses a smart parameter to load the file name with the directory path coming from the application service.

Note: SetBackgroundImage must be called before Overlay. Other actions such as SetHaloBackground and SetDithering are optional and, if used, should precede the call to the Overlay action.

Parent topic: [IOverlay actions](#)

SetBackgroundImage

Designates the Image file that will overlay the image of the current page.

Syntax

```
bool SetBackgroundImage (StrParam)
```

Parameters

Full path to the overlay Image file.

Returns

False if image does not exist, otherwise True.

Level

All.

Details

Designates the Image file that will overlay the image of the current page. Smart Parameters supported.

Example:

```
SetBackgroundImage(c:\ParentDir\mclaims\process\hcfa\hcfat.tif)
SetDitheringBackground(True)
SetHaloBackground(True)
Overlay()
```

Parent topic: [IOverlay actions](#)

SetDitheringBackground

Enables or disables dithering of the background image. Dithering makes the background image appear lighter than the information of the current image so that visually it appears less prominent.

Syntax

```
bool SetDitheringBackground (StrParam)
```

Parameters

String value to enable dithering (True) or disable dithering (False).

Returns

Always True.

Level

All.

Details

Example:

```
SetBackgroundImage(c:\ParentDir\mclaims\process\hcfa\hcfat.tif)
SetDitheringBackground(True) SetHaloBackground(True)
Overlay()
```

Parent topic: [IOverlay actions](#)

SetHaloBackground

Enables or disables a halo of white pixels around any black pixels from the current image where they would otherwise touch pixels from the background. This makes the foreground information easier to read.

Syntax

```
bool SetHaloBackground (StrParam)
```

Parameters

String value to enable a halo (True) or prevent a halo (False).

Returns

Always True.

Level

All.

Details

Example:

```
SetBackgroundImage(c:\ParentDir\mclaims\process\hcfa\hcfat.tif)
SetDitheringBackground(True)
SetHaloBackground(True)
Overlay()
```

Parent topic: [IOverlay actions](#)

Locate actions

Use the Locate actions in combination with full text recognition to locate words or regular expressions on the page. And to move around the page by line or word.

The Locate library also includes a few format validation actions, such as `IsCurrency` and `IsDateValue`. Most of the validation actions are located in the `Validate` library.

- [AddKeyList](#)
Adds a list of keywords or phrases that can be used for matching.
- [AggregateKeyList](#)
Toggles the Key list searches to merge all words or phrases in the list into a single query.
- [CreateVirtualPage](#)
This action creates a new page that is a subset of an existing page or a subset of merged pages.
- [CreateVirtualZone](#)
Creates a field zone at runtime based on the identified text locations.
- [DefaultValue](#)
Sets the text value of the current field in the page data file to the value that is specified.
- [FilterIt](#)
Removes all instances of the specified characters from the word that is located.
- [FindDBList](#)
Locates a word that matches one of a list of words that are obtained from a SQL query.
- [FindDBList_InZone](#)
Locates a word that matches a word from the current field.
- [FindKeyList](#)
Locates the first or next occurrence of a word or phrase that matches one of the entries in a keyword file.
- [FindKeyList_InZone](#)
Locates the first (or next) occurrence of a word or phrase that matches one of the entries in the current field.
- [FindLastKeyList](#)
Locates the last occurrence of a word or phrase that matches one of the entries in a keyword file.
- [FindLastKeyList_InZone](#)
Locates the last occurrence of a word or phrase that matches one of the current field.
- [FindLastRegEx](#)
Same as the `FindLastWord` action, except that it supports regular expressions.

- [FindLastRegEx_InZone](#)
Same as the FindLastWord_InZone action, except that it supports regular expressions.
- [FindLastRegExList](#)
Same as the FindLastKeyList action, except that it supports regular expressions.
- [FindLastRegExList_InZone](#)
Same as the FindLastRegExList action, except that it searches the current field only.
- [FindLastWord](#)
Locates the last occurrence of the specified word or phrase on the current page.
- [FindLastWord_InZone](#)
Locates the last occurrence of the specified word or phrase on the current field.
- [FindNextDBList](#)
Same as the FindDBList action, except that it locates the next instance.
- [FindNextDBList_InZone](#)
Same as the FindNextDBList action, except that it searches the current field only.
- [FindNextKeyList](#)
Same as the FindKeyList action, except that it locates the next instance.
- [FindNextKeyList_InZone](#)
Same as the FindNextKeyList action, except that it searches the current field only.
- [FindNextRegExList](#)
Same as the FindRegExList action, except that it locates the next instance.
- [FindNextRegExList_InZone](#)
Same as the FindNextRegExList action, except that it searches the current field only.
- [FindRegExList](#)
Same as the FindKeyList action, except that it supports regular expressions.
- [FindRegExList_InZone](#)
Same as the FindRegExList action, except that it searches the current field only.
- [GetSelectedBlockType](#)
Obtains the type of the currently selected block and stores it in the DCO location indicated by the target parameter. This action uses the document block layout that is created by the DocumentAnalytics actions.
- [GoAboveWord](#)
Moves up the specified number of lines from the previously found word or phrase.
- [GoBelowWord](#)
Moves down the specified number of lines from the previously found word or phrase.
- [GoDownLine](#)
Moves down the specified number of lines from the previously found word or phrase and selects the first word.
- [GoFirstLine](#)
Moves to the first line of the page when you are running full page recognition.
- [GoFirstWord](#)
Moves to the first word on the current line.
- [GoLastLine](#)
Moves to the last line of the page when you are running full page recognition.
- [GoLastWord](#)
Moves to the last word on the current line.
- [GoLeftWord](#)
Moves the specified number of words to the left of the previously found word or phrase.
- [GoRightWord](#)
Moves the specified number of words to the right of the previously found word or phrase.
- [GoSiblingBlockNext](#)
The currently selected block in the document layout is changed to the next sibling block at the same level in the structure. The number of siblings that are moved is determined by the input parameter. This action uses the document block layout that is created by the DocumentAnalytics actions.

- [GoSiblingBlockPrevious](#)
The currently selected block in the document layout is changed to the previous sibling block at the same level in the structure. The number of siblings moved is determined by the input parameter. This action uses the document block layout that is created by the DocumentAnalytics actions.
- [GoUpLine](#)
Moves up the specified number of lines from the previously found word or phrase and selects the first word.
- [GroupWords](#)
Groups words to the left and right of the previously found word if they are no more than the specified number of character widths apart.
- [GroupWordsLEFT](#)
Groups words to the left of the previously found word if they are no more than the specified number of character widths apart.
- [GroupWordsRIGHT](#)
Groups words to the right of the previously found word if they are no more than the specified number of character widths apart.
- [IsAlpha](#)
Determines whether the specified percentage of characters in a located word is letters (defaults to 100%)
- [IsCurrency](#)
Determines whether the value of the located word is a currency value. The value contains numbers and includes a two-digit decimal amount.
- [IsDateValue](#)
Determines whether the value of the located word is in one of the supported date formats.
- [IsNumber](#)
Determines whether the specified percentage of characters in a located word is numbers (defaults to 100%)
- [IsSelectedBlockType](#)
Compares the provided block type to the type of the currently selected block. This action uses the document block layout that is created by the DocumentAnalytics actions.
- [IsValue](#)
Determines whether the value of the located word matches the value that is specified.
- [IsValue_RegEx](#)
Determines whether the value of the located word matches the regular expression specified.
- [LocatePositionRestore](#)
LocatePositionRestore returns the internal locate word pointer to the word position it was on when LocatePositionSave was called.
- [LocatePositionSave](#)
LocatePositionSave creates a restore point for the current word position of the locate pointer.
- [MaxLength](#)
Determines whether the number of characters in the located word is greater than or equal to the number specified.
- [MergeWordLF](#)
Merges the located word with one or more words to the left, on the same line.
- [MergeWordRT](#)
Merges the located word with one or more words to the right, on the same line.
- [MinLength](#)
Determines whether the number of characters in the located word is less than or equal to the number specified.
- [RegExFind](#)
Same as the WordFind action, except that it supports regular expressions.
- [RegExFind_InBlock](#)
RegExFind_InBlock will look for the first occurrence of a word or phrase that matches the regular

expression. This action uses the document block layout that is created by the DocumentAnalytics actions.

- [RegExFind_InZone](#)
Same as the RegExFind action, except that it searches the current field only.
- [RegExFindNext](#)
Same as the WordFindNext action, except that it supports regular expressions.
- [RegExFindNext_InBlock](#)
Starting from the location of a previously found word or phrase, this action locates the first occurrence of a word or phrase in the currently selected block where the input search term is specified as a regular expression. Once the regular expression has been matched, the location of the found word or phrase will be remembered so the result can be used by subsequent actions. This action uses the document block layout that is created by the DocumentAnalytics actions.
- [RegExFindNext_InZone](#)
Same as the RegExFindNext action, except that it searches the current field only.
- [ScanRT](#)
Moves the specified number of words to the right of the current word. Expands the search area up and down slightly in case the word is a little above or below the current word.
- [SelectParentBlock](#)
Looks for the first occurrence of a word or phrase that matches the regular expression. If a match is found, the next action will change the currently selected block from the found word to the entire line that contains the word. SelectParentBlock is then called again to change the selected block to the parent of the current line, then the current field zone is updated to contain the entire set of lines contained in the current block and the field value is set to all of the text within the current block. This action utilizes the document block layout created by the DocumentAnalytics actions.
- [SelectParentBlockOuterType](#)
Selects the outermost parent of the current block of the type that is specified. If the currently selected block has multiple parent blocks of the same type, then the parent farthest from the current block is selected. This action uses the document block layout that is created by the DocumentAnalytics actions.
- [SelectParentBlockType](#)
Selects the parent of the current block of the type that is specified. If the currently selected block has multiple parent blocks of the same type, then the parent nearest to the current block would be selected. Uses the document block layout created by the DocumentAnalytics actions.
- [SelectSnippet](#)
Populates a snippet field with the recognized value of the located word. Used with directional actions.
- [SetKeyFileEncodingAsUnicode](#)
Determines if the Locate key files are opened as ASCII or UNICODE.
- [SetRect](#)
Sets the position and size of the current field in the page data file to the values specified.
- [SetVirtualPageEndPosition](#)
Use this action after you use the Locate commands that identify the last word of a new virtual page.
- [SetVirtualPageStartPosition](#)
Use this action after you use the Locate commands that identify the first word of a new virtual page.
- [UpdateDCOField](#)
Updates the position coordinates for the specified field in the page data file with the position of the located word.
- [UpdateField](#)
Updates the current field in the page data file with the value and position of the located word.
- [UpdateFieldWithBlock](#)
Updates the current DCO object's field zone coordinates with the coordinates of the currently selected block. The text of the field will be set with the contents of the text bound by the currently selected block in the document layout. Uses the document block layout created by the DocumentAnalytics actions.
- [ValueInField](#)
Determines whether any part of the located word matches the value that is specified.

- [ValueInField_Fuzzy](#)
Uses fuzzy matching to determine whether any part of the located word matches the value that is specified.
- [ValueInField_RegEx](#)
Determines whether any character or series of characters in the located word matches the specified regular expression.
- [WordFind](#)
Locates the first or next occurrence of the specified word or phrase on the current page.
- [WordFind_InZone](#)
Same as the WordFind action, except that it searches the current field only.
- [WordFindNext](#)
Same as the WordFind action, except that it locates the next occurrence.
- [WordFindNext_InZone](#)
Same as the WordFindNext action, except that it searches the current field only.
- [WordFind_Offset](#)
Sets the value of the page's Image_Offset variable. The variable is based on the difference in the position of the specified word on the current page and on the matched fingerprint image.

Parent topic: [Global actions](#)

AddKeyList

Adds a list of keywords or phrases that can be used for matching.

Syntax

```
bool AddKeyList (string KeyName, string KeyWord_01, string KeyWord_02, string
KeyWord_03, string KeyWord_04, string KeyWord_05, string KeyWord_06, string
KeyWord_07, string KeyWord_08, string KeyWord_09, string KeyWord_10, string
KeyWord_11, string KeyWord_12, string KeyWord_13, string KeyWord_14, string
KeyWord_15, string KeyWord_16, string KeyWord_17, string KeyWord_18, string
KeyWord_19, string KeyWord_20, string KeyWord_21, string KeyWord_22, string
KeyWord_23, string KeyWord_24, string KeyWord_25)
```

Parameters

1. String value used as a reference name for other actions to call this list of keywords or phrases.
2. Up to twenty five keywords or phrases to be used for matching.

Returns

False if no keywords or phrases are entered. Otherwise, True.

Level

Any.

Details

Adds a list of keywords or phrases that can be used for matching.

This action complements the List search actions that can load a Keyword text file which contains a list of words or phrases, separated by new lines, that are used for matching.

AddKeyList adds a list of up to 25 words or phrases without having to read or edit a file.
Attention: You can not redefine or overwrite an existing key list

Example

```
AddKeyList("InvNum","Invoice Number","Inv. Num.,""Invoice #:")  
FindKeyList("InvNum")
```

This action searches the current page, from first word to the last word of the current page, for the first occurrence of all keywords in the Invoices Number Keyword list "InvNum".

If successful, the search stops and remembers the location of that word for subsequent actions.

If not successful, the action continues searching for the next keyword in the InvNum list, starting from first word of the current page, repeating this search pattern until a match is found, or until there are no more keywords.

[AggregateKeyList](#)

AggregateKeyList

Toggles the Key list searches to merge all words or phrases in the list into a single query.

Syntax

```
bool AggregateKeyList (bool SearchAll)
```

Parameters

Toggles Key list searches to merge all words or phrases in the list into a single query.

Returns

Always True.

Level

Any.

Details

Use of this action changes the search behavior for all 'List' type key word search actions. Default behavior is to search each keyword in the list sequentially. This action with the parameter set to True changes the search behavior to check for all the keywords in a single aggregate keyword search. To change back to the default behavior use this action with the False parameter.

Example

```
AggregateKeyList (True)  
FindKeyList ("InvNum")
```

This action searches the current page, from first word to the last word of the current page, for the first occurrence of all keywords in the Invoices Number Keyword file (InvNum.key). If successful, the search stops and remembers the location of that word for subsequent actions; if not, the action continues searching for the next word in InvNum.key, starting from first word of the current page, repeating this search pattern until a match is found, or until there are no more keywords.

[AddKeyList](#)

CreateVirtualPage

This action creates a new page that is a subset of an existing page or a subset of merged pages.

Syntax

```
bool CreateVirtualPage (string sPageType)
```

Parameters

The new page type for the created page can be provided as a parameter to this action. The provided name is assigned as the type for the new DCO page that is created by this action. If no parameter is provided, the new page type is default to "Other". Smart parameters are supported.

Returns

True, if the new page is created. False, if an error occurs or if the start and end points for the block are not set.

Level

Page level.

Details

Using the actions SetVirtualPageStartPosition and SetVirtualPageEndPosition, a segment of text from within the current page can be duplicated into a unique page. This approach can be useful to separate out a required area of text to allow subsequent actions to work solely on the required area.

A layout file is needed to use this action and the CCO must be loaded from the layout file by using the CreateCcoFromLayout action. The recognition of the layout file and creation of the CCO for the page might be performed in the same ruleset or in an earlier ruleset. Multiple pages within the same document can be merged

together by using the action MergeLayoutByType action to create a multi-page segment of text to be extracted into a new page. For example, it is possible to merge together three pages of text. You can create a new page that starts with text from the bottom of page 1, all of the text in page 2, and text from the start of page 3. When you create a new page, all of the text must be continuous.

It is possible to create multiple new page subsets from a single page or single merged page. Use the Start and End actions to define the start and end of a page and create the new virtual page. Then, define new start and end points, create another new page, and so on.

The new pages that are created are no different than any other page. Actions that work on a page object can be used on the new pages, allowing processing on these new pages as needed. For example, these new pages can be combined into their own new document and then processed with extra searches or exported.

When a new page is created, the image for the current page is copied to the name for the new page object. The new page object is then added to the application's runtime DCO. The new page ID and associated image, and layout file use the name of the existing page with an underscore added and a number. This number is incremented if CreateVirtualPage is called multiple times on the same page. For example, "TM000001_0". CreateCcoFromLayout can be called on the new page and have extra rules run on it as needed.

Example

```
Recognize ()
CreateCcoFromLayout ()
WordFind ("Hello")
SetVirtualPageStartPosition ()
WordFindNext ("Good bye")
GoUpLine ("1")
GoLastWord ()
SetVirtualPageEndPosition ()
CreateVirtualPage ("MyNewPageType")
```

This example recognizes a page, creating a layout file. The CCO is created from the layout file and then Locate actions are used to find the first word to include in the new page. The start of the new page's text segment is identified by calling SetVirtualPageStartPosition. The end of the text segment is located. In this example, the word "Good bye" indicates it is the end of the desired text. Because the word "Good bye" should not be included in the new page, the located word position is moved to the last word of the line above the word "Good bye". SetVirtualPageEndPosition then identifies this new position as the end of the new page segment. Finally, the action CreateVirtualPage is called to create the new page. After this action completes, the new page will exist in the document hierarchy and can be acted upon by subsequent rules and actions.

Parent topic: [Locate actions](#)

CreateVirtualZone

Creates a field zone at runtime based on the identified text locations.

Member of namespace

Locate

Syntax

```
bool CreateVirtualZone (string sFieldName)
```

Parameters

sFieldName

Type: String

Name of the field that has its zone assigned based on the previously set virtual start and end positions. If the field does not exist, it is created. Smart parameters are supported.

Returns

True if the zone is set on the field. Otherwise, returns False if there is an error or if the start and end points for the zone are not set.

Level

Page or Field level.

Details

This action assigns zone coordinates to a field based on previously set start and end positions that were identified using locate actions. Using the actions SetVirtualPageStartPosition and SetVirtualPageEndPosition, a rectangular segment of text from within the current page can be identified at run time and set as a zoned area. This approach can be useful to set the zone position of a field that is not a fixed location but can be determined by searching the recognized text to find the top-left corner and bottom-right corner of the zone area.

A layout file is required to use this action and the CCO must be loaded from the layout file by using the CreateCcoFromLayout action. The recognition of the layout file and creation of the CCO for the page can be performed in the same ruleset or in an earlier ruleset.

Once the zone is set, it can be used just like a zone that is created from a fingerprint. Subsequent actions can be used to process the zoned text.

A field with coordinates set based on the contents of the recognized page can have many uses. A less obvious use is for table identification when the table boundary is not determined by grid lines or the engine is not properly determining the table area even if grid lines exist. In this scenario, use the locate actions to determine the top-left and bottom-right coordinates of the table with steps similar to the example below. This will find the table location based on the text that exists on the page. There would need to be expected text or positions to identify the table boundaries. After calling CreateVirtualZone, then the field can be identified with the variable `y_TableZone` as described in the help for the OCR/A Recognize action to provide table boundaries for better table identification by making a second call to the Recognize action.

Example:

```
Recognize ()
CreateCcoFromLayout ()
WordFind ("Hello")
SetVirtualPageStartPosition ()
WordFindNext ("Good bye")
GoUpLine ("1")
GoLastWord ()
SetVirtualPageEndPosition ()
CreateVirtualZone ("MyField")
```

This example recognizes a page, creating a layout file. The CCO is created from the layout file and then Locate actions are used to find the first word to include in the new page. The start of the new page's text segment is identified by calling SetVirtualPageStartPosition. This location is used at the left-top coordinate for the zone. The end of the text segment is located. In this example, the word "Good bye" indicates it is the end of the desired text. Because the word "Good bye" should not be included in the

new page, the located word position is moved to the last word of the line above the word "Good bye". The SetVirtualPageEndPosition then identifies this new position as the bottom-right position for the zone. Finally, the action CreateVirtualZone is called to set the zone for the specified field based on the found text.

Parent topic: [Locate actions](#)

DefaultValue

Sets the text value of the current field in the page data file to the value that is specified.

Syntax

```
bool DefaultValue (strParam)
```

Parameters

The String value assigned to the bound Field object of the Document Hierarchy that represents the current field.

Returns

Always True.

Level

Field level only.

Details

Sets the captured value of the current field to the String value you enter as a parameter.

Example:

```
DefaultValue("Bill Paid")
DefaultValue("Past Due")
```

Parent topic: [Locate actions](#)

FilterIt

Removes all instances of the specified characters from the word that is located.

Syntax

```
bool FilterIt (StrParam)
```

Parameters

A string containing the characters to remove.

Important: This action removes every instance of the character or characters.

Returns

Always True.

Level

Field level only.

Details

Removes all instances of each character you enter as a parameter from the located word or phrase.

Example

```
FilterIt("-")
31-Dec-01 becomes 31Dec01
FilterIt("1")
31-Dec-01 becomes 3-Dec-0
FilterIt("1-")
31-Dec-01 becomes 3Dec0
```

Parent topic: [Locate actions](#)

FindDBList

Locates a word that matches one of a list of words that are obtained from a SQL query.

Syntax

```
bool FindDBList (StrParam)
```

Parameters

An SQL statement whose result returns a word or phrase, or a list of words or phrases.

Returns

True if the word or phrase is located on the page. Otherwise, False.

Level

Page or field level.

Details

This action issues an SQL query against the lookup database, returning a list of words or phrases that will be located on the current page. The search is performed from the first word of the current page. Initially, the first listed word or phrase is searched for on the page. If there is no match, it will search for the next word or phrase returned from the database. This continues until a match is found or none of the returned words are contained on the page. The location of the found word or phrase will be remembered so the result can be used by subsequent actions. The search is case sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes "will" and the recognition read "wi11", a match will still occur.

Common substitutions include characters: B8, Z2, S5, oO0 and iItl1.

Example

```
FindDBList("Select LastName from Providers")
```

This example gets a list of last names from a provider table and find the first matching occurrence on the page.

Parent topic: [Locate actions](#)

Related reference:

[FindDBList_InZone](#)

[FindNextDBList](#)

FindDBList_InZone

Locates a word that matches a word from the current field.

Syntax

```
bool FindDBList_InZone (StrParam)
```

Parameters

An SQL statement whose result returns a word or phrase, or a list of word or phrases.

Returns

True, if the word or phrase is on the page. Otherwise, False.

Level

Page or field level.

Details

This action generates an SQL query against the Lookup database, returning a list of words or phrases that are in the current field. The search is performed from the first word of the current field. Initially, the first listed word or phrase is searched for in the field. If there is no match, it will search for the next word or phrase that is returned from the database. The search continues until a match is found or none of the returned words are contained on the page. The location of the found word or phrase is remembered so the result can be used by subsequent actions. The search is case-sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes `will` and the recognition that is read is `wi11`, a match still occurs.

Common substitutions include characters: B8, Z2, S5, o00, and iTt1.

Example

```
FindDBList("Select LastName from Providers")
```

This example obtains a `LastName` list from a provider table and finds the first matching occurrence on the page.

Parent topic: [Locate actions](#)

Related reference:[FindNextDBList](#)[FindNextDBList_InZone](#)

FindKeyList

Locates the first or next occurrence of a word or phrase that matches one of the entries in a keyword file.

Syntax

```
bool FindKeyList (StrParam)
```

Parameters

The name of the Keyword text file. The file will contain a list of words or phrases, separated by new lines, that will be used for matching.

The file name can be provided in one of two ways:

1. A full path name of the file, including the .key extension.
2. The file name only, with no extension specified. The application will look in the process directory and the file must have a .key extension.

Returns

True if at least one word on the page matches any word or pattern in the Keyword file. Otherwise, False.

Level

Field level only.

Details

Opens the Keyword file you specify as a parameter, then checks the words or phrases on the current page against the keywords in the list to find a match. The location of the found word or phrase that matches an entry in the keyword file will be remembered so the result can be used by subsequent actions. Matching is case sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes "will" and the recognition read "wi11", a match will still occur.

Common substitutions include characters: B8, Z2, S5, o00 and iIt1.

Example

```
FindKeyList ("InvNum")
```

This action searches the current page, from first word to the last word of the current page, for the first keyword in the Invoices Number Keyword file (InvNum.key). If successful, the search stops and remembers the location of that word for subsequent actions; if not, the action continues searching for the next word in InvNum.key, starting from first word of the current page, repeating this search pattern until a match is found, or until there are no more keywords.

FindKeyList_InZone

Locates the first (or next) occurrence of a word or phrase that matches one of the entries in the current field.

Syntax

```
bool FindKeyList_InZone (StrParam)
```

Parameters

The name of the Keyword text file. The file will contain a list of words or phrases, separated by new lines, that will be used for matching.

The file name can be provided in one of two ways:

1. A full path name of the file, including the .key extension.
2. The file name only, with no extension specified. The application will look in the process directory and the file must have a .key extension.

Returns

True if at least one word in the current bound zone matches any word or pattern in the Keyword file. Otherwise, False.

Level

Field level.

Details

Opens the Keyword file you specify as a parameter, then checks the words or phrases in the current field of the source page's .cco file against the keywords in the key file list to find a match. The location of the found word or phrase that matches an entry in the keyword file will be remembered so the result can be used by subsequent actions. Matching is case sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes "will" and the recognition read "wi11", a match will still occur.

Common substitutions include characters: B8, Z2, S5, oO0 and iItl1.

Example

```
FindKeyList_InZone("Line_Items")
```

This action searches the current bound zone for the first keyword in the Keyword file (Line_Items.key). If successful, the search stops and remembers the location of that word for subsequent actions; if not, the action continues searching for the next word in Line_Items.key, from the beginning of the current bound zone, repeating this search pattern until a match is found, or until there are no more keywords.

Parent topic: [Locate actions](#)

Related reference:

[FindNextKeyList](#)
[FindLastKeyList](#)
[AddKeyList](#)

FindLastKeyList

Locates the last occurrence of a word or phrase that matches one of the entries in a keyword file.

Syntax

```
bool FindLastKeyList (StrParam)
```

Parameters

The name of the Keyword text file. The file will contain a list of words or phrases, separated by new lines, that will be used for matching.

The file name can be provided in one of two ways:

1. A full path name of the file, including the .key extension.
2. The file name only, with no extension specified. The application will look in the process directory and the file must have a .key extension.

Returns

True if at least one word on the page matches any word or pattern in the Keyword file. Otherwise, False.

Level

Page level.

Details

Opens the Keyword file you specify as a parameter, then checks the words or phrases on the current page against the keywords in the list to find a match. The current page will be searched to find the last occurrence of word or phrase. The location of the last occurrence word or phrase that matches an entry in the keyword file will be remembered so it can be utilized by subsequent actions. Word matching is case sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes "will" and the recognition read "wi11", a match will still occur.

Common substitutions include characters: B8, Z2, S5, o00 and iIt1.

Example

```
FindLastKeyList ("InvNum")
```

This action searches the current page for the last instance of a match with the first keyword in the Keyword file (InvNum.key). If successful, the search stops and remembers the location of that word for subsequent actions; if not, the action continues searching using the next word in InvNum.key, matching the last occurrence of the word, repeating this search pattern until a match is found, or until there are no more keywords.

Parent topic: [Locate actions](#)

Related reference:

[FindNextKeyList](#)
[FindKeyList](#)
[AddKeyList](#)

FindLastKeyList_InZone

Locates the last occurrence of a word or phrase that matches one of the current field.

Syntax

```
bool FindLastKeyList_InZone (StrParam)
```

Parameters

The name of the Keyword text file. The file will contain a list of words or phrases, separated by new lines, that will be used for matching.

The file name can be provided in one of two ways:

1. A full path name of the file, including the .key extension.
2. The file name only, with no extension specified. The application will look in the process directory and the file must have a .key extension.

Returns

True if at least one word on the page matches any word or pattern in the Keyword file. Otherwise, False.

Level

Field level.

Details

Opens the Keyword file you specify as a parameter, then checks the words or phrases in the current bound zone against the keywords in the list to find a match. The location of the found word or phrase will be remembered so the result can be used by subsequent actions. Word matching is case sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes "will" and the recognition read "wi11", a match will still occur.

Common substitutions include characters: B8, Z2, S5, oO0 and iItl1.

Example

```
FindLastKeyList_InZone ("ClaimsData")
```

This action searches the current bound zone for the last instance of a match with the first keyword in the Keyword file (ClaimsData.key). If successful, the search stops and remembers the location of that word for subsequent actions; if not, the action continues searching using the next word in ClaimsData.key, matching the last occurrence of the word, repeating this search pattern until a match is found, or until there are no more keywords.

FindLastRegEx

Same as the FindLastWord action, except that it supports regular expressions.

Syntax

```
bool FindLastRegEx (StrParam)
```

Parameters

A word or phrase to find on the current page. The parameter is expected to be a Regular Expression.

Returns

True if the word or phrase is located on the page. Otherwise, False.

Level

Page level.

Details

Locates the last occurrence of a word or phrase on the current page where the input search term is specified as a regular expression. The search is started from the first word of the current page. The location of the found word or phrase will be remembered so the result can be used by subsequent actions. The search is case sensitive.

Example

```
FindLastRegEx ("Da?e")  
GoRightWord ("1")  
IsDateValue ()  
UpdateField ()
```

FindLastRegEx will look for the last occurrence of a word that matches the regular expression. If it match is found, it will continue processing by moving one word right to the result of RegExFind and act on that word. In this example, if it is a date format, UpdateField will place the value into the current field.

[RegExFindNext](#)

FindLastRegEx_InZone

Same as the FindLastWord_InZone action, except that it supports regular expressions.

Syntax

```
bool FindLastRegEx_InZone (StrParam)
```

Parameters

A word or phrase to find in the current field. The parameter is expected to be a Regular Expression.

Returns

True if the word or phrase is located in the field. Otherwise, False.

Level

Field level.

Details

Locates the last occurrence of a word or phrase in the current field where the input search term is specified as a regular expression. The search is started from the first word of the current field. The location of the found word or phrase will be remembered so the result can be used by subsequent actions. The search is case sensitive.

Example

```
FindLastRegEx_InZone ("Da?e")
GoRightWord ("1")
IsDateValue ()
UpdateField ()
```

FindLastRegEx will look for the last occurrence of a word that matches the regular expression. If it match is found, it will continue processing by moving one word right to the result of RegExFind and act on that word. In this example, if it is a date format, UpdateField will place the value into the current field.

[RegExFindNext](#)

FindLastRegExList

Same as the FindLastKeyList action, except that it supports regular expressions.

Syntax

```
bool FindLastRegExList (StrParam)
```

Parameters

The name of the Keyword text file. The file will contain a list of words or phrases, separated by new lines, that will be used for matching. The entries in the keyword file are expected to be regular expressions.

The file name can be provided in one of two ways:

1. A full path name of the file, including the .key extension.

2. The file name only, with no extension specified. The application will look in the process directory and the file must have a .key extension.

Returns

True if at least one word on the page matches any word or pattern in the Keyword file. Otherwise, False.

Level

Page level.

Details

Opens the Keyword file you specify as a parameter, then checks the words or phrases on the current page against the keywords in the list to find a match. The entries in the keyword file are expected to be regular expressions. To perform the action, the search first looks for the last occurrence of the first word or phrase in the keyword file. If the word is found on the page, the search stops at the last occurrence of the word. If no match is found, the next line from the keyword file is read and again the entire page is searched. This process continues until a match is found or all of the lines in the keyword file have been read. The location of the last occurrence of a found word or phrase will be remembered so the result can be used by subsequent actions. Word matching is case sensitive.

Example

```
FindLastRegExList("InvoiceNum")
```

This action searches the current page, from the first word of the current page, for the last occurrence of the first keyword in the Keyword file (InvoiceNum.key). If successful, the search stops and remembers the location of that word for subsequent actions; if not, the action continues searching for the last occurrence of the next word in InvoiceNum.key, starting from starting of the current page, repeating this search pattern until a match is found, or until there are no more keywords.

FindLastRegExList_InZone

Same as the FindLastRegExList action, except that it searches the current field only.

Syntax

```
bool FindLastRegExList_InZone (StrParam)
```

Parameters

The name of the Keyword text file. The file will contain a list of words or phrases, separated by new lines, that will be used for matching. The entries in the keyword file are expected to be regular expressions.

The file name can be provided in one of two ways:

1. A full path name of the file, including the .key extension.

2. The file name only, with no extension specified. The application will look in the process directory and the file must have a .key extension.

Returns

True if at least one word in the field matches any word or pattern in the Keyword file. Otherwise, False.

Level

Field level.

Details

Opens the Keyword file you specify as a parameter, then checks the words or phrases in the current field against the keywords in the list to find a match. The entries in the keyword file are expected to be regular expressions.

To perform the action, the search first looks for the last occurrence of the first word or phrase in the keyword file. If the word is found on the page, the search stops at the last occurrence of the word. If no match is found, the next line from the keyword file is read and again the entire field is searched. This process continues until a match is found or all of the lines in the keyword file have been read. The location of the last occurrence of a found word or phrase will be remembered so the result can be used by subsequent actions. Word matching is case sensitive.

Example

```
FindLastRegExList_InZone ("InvoiceNum")
```

This action searches the current page, from the first word of the current page, for the last occurrence of the first keyword in the Keyword file (InvoiceNum.key). If successful, the search stops and remembers the location of that word for subsequent actions; if not, the action continues searching for the last occurrence of the next word in InvoiceNum.key, from starting of the current page, repeating this search pattern until a match is found, or until there are no more keywords.

[FindNextRegExList](#)

[AddKeyList](#)

FindLastWord

Locates the last occurrence of the specified word or phrase on the current page.

Syntax

```
bool FindLastWord (StrParam)
```

Parameters

A word or phrase to find on the page.

Returns

True, if the word or phrase is on the page. Otherwise, False.

Level

Page level.

Details

The current page is searched to find the last occurrence of a word or phrase. The location of the last word or phrase that matches the parameter is remembered and it can be used by subsequent actions.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes `will` and the recognition that is read is `wi11`, a match still occurs.

Common substitutions include characters: B8, Z2, S5, o00, and iIt1

Example

```
FindLastWord("Total")
GoRightWord("1")
IsCurrency()
```

In this example, the action finds the last instance of `Total` on the current page. Then, it moves right one word and checks to be sure that the word has a `Currency` value.

Parent topic: [Locate actions](#)

Related reference:

[WordFind](#)

[WordFindNext](#)

FindLastWord_InZone

Locates the last occurrence of the specified word or phrase on the current field.

Syntax

```
bool FindLastWord_InZone (StrParam)
```

Parameters

The word or phrase to locate within the current zone.

Returns

True if the word or phrase is located in the field. Otherwise, False.

Level

Page level.

Details

The current field will be searched to find the word or phrase. The location of the last occurrence of the word or phrase that matches the parameter will be remembered so it can be utilized by subsequent actions. Word matching is case sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes "will" and the recognition read "wi11", a match will still occur.

Common substitutions include characters: B8, Z2, S5, oO0 and iItl1.

Example

```
FindLastWord_InZone ("Total")
GoRightWord ("1")
IsCurrency ()
```

This sequence attempts to find the last occurrence of "Total" in the current zone. It then locates and validates a Currency amount for the Total field, assuming the currency amount is to the right of the word "Total".

[WordFindNext_InZone](#)

FindNextDBList

Same as the FindDBList action, except that it locates the next instance.

Syntax

```
bool FindNextDBList (StrParam)
```

Parameters

An SQL statement whose result returns a word or phrase, or a list of word or phrases.

Returns

True, if the word or phrase is on the page. Otherwise, False.

Level

Page level.

Details

This action generates an SQL query against the Lookup database, returning a list of words or phrases that are on the current page. Starting from the location of a previously found word, the search is performed. Initially, the first listed word or phrase from the SQL query is searched for on the page. If there is no match, it will search for the next word or phrase that is returned from the database. The search continues until a match is found or none of the returned words are contained on the page. The location of the found word or phrase is remembered so the result can be used by subsequent actions. The search is case-sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes `will` and the recognition that is read is `wi11`, a match still

occurs.

Common substitutions include characters: B8, Z2, S5, o00, and iItl1.

Example

```
WordFind("Hello")
FindNextDBList("Select LastName from Providers")
```

In this example, when the first word `Hello` is found, the `LastName` list is obtained from a provider table. Then, the first matching occurrence on the page that occurs after the word `Hello` is found.

Parent topic: [Locate actions](#)

FindNextDBList_InZone

Same as the `FindNextDBList` action, except that it searches the current field only.

Syntax

```
bool FindNextDBList_InZone (StrParam)
```

Parameters

An SQL statement whose result returns a word or phrase, or a list of word or phrases.

Returns

True, if the word or phrase is in the field. Otherwise, False.

Level

Field level.

Details

This action generates an SQL query against the lookup database, returning a list of words or phrases that are in the current field. Starting from the location of a previously found word, the search is performed. Initially, the first listed word or phrase from the SQL query is searched for on the page. If there is no match, it will search for the next word or phrase that is returned from the database. The search continues until a match is found or none of the returned words are contained on the page. The location of the found word or phrase is remembered so the result can be used by subsequent actions. The search is case-sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes `will` and the recognition that is read is `wi11`, a match still occurs.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions.

Common substitutions include characters: B8, Z2, S5, o00, and iItl1

Example

```
WordFind_InZone("Hello")
FindNextDBList("Select LastName from Providers")
```

In this example, when the first word `Hello` is found in the current field, the `LastName` list is obtained from a provider table. Then, the first matching occurrence in the field that occurs after the word `Hello` is found.

[FindDBList](#)

FindNextKeyList

Same as the `FindKeyList` action, except that it locates the next instance.

Syntax

```
bool FindNextKeyList (StrParam)
```

Parameters

The name of the Keyword text file. The file will contain a list of words or phrases, separated by new lines, that will be used for matching.

The file name can be provided in one of two ways:

1. A full path name of the file, including the `.key` extension.
2. The file name only, with no extension specified. The application will look in the process directory and the file must have a `.key` extension.

Returns

True if at least one word or phrase on the page, starting from the previously located word, matches any word or pattern in the Keyword file. Otherwise, False.

Level

Field level.

Details

Opens the Keyword file you specify as a parameter, then checks the words or phrases on the current page against the keywords in the list to find a match. The search starts from the last word that had been found using an action such as `FindKeyList` or `FindNextKeyList`. The location of the found word or phrase that matches an entry in the keyword file will be remembered so the result can be used by subsequent actions. Matching is case sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes "will" and the recognition read "wi11", a match will still occur.

Common substitutions include characters: B8, Z2, S5, oO0 and iItl1.

Example

```
FindKeyList("Tax")  
FindNextKeyList("IRS")
```

Starting from the word or phrase that was located in the FindKeyList action, this action searches the current page, starting from that previously found word, for the first word or phrase in the first line of the Keyword file (IRS.key). If successful, the search stops and remembers the location of that new word for subsequent actions; if not, the action continues searching using the next word or phrase in IRS.key, starting again from the location of the word previously found by FindKeyList(Tax), repeating this search pattern until a match is found, or until there are no more keywords in the file.

Parent topic: [Locate actions](#)

[AddKeyList](#)

[FindKeyList_InZone](#)

[FindNextKeyList_InZone](#)

FindNextKeyList_InZone

Same as the FindNextKeyList action, except that it searches the current field only.

Syntax

```
bool FindNextKeyList_InZone (StrParam)
```

Parameters

The name of the Keyword text file. The file will contain a list of words or phrases, separated by new lines, that will be used for matching.

The file name can be provided in one of two ways:

1. A full path name of the file, including the .key extension.
2. The file name only, with no extension specified. The application will look in the process directory and the file must have a .key extension.

Returns

False if the Fingerprint file (.cco) of the current source page has not been loaded, or is empty. Otherwise, True.

Level

Field level.

Details

Opens the Keyword file you specify as a parameter, then checks the words or phrases in the current field against the keywords in the list to find a match. The search starts from the last word that had been found using an action such as FindKeyList_InZone or FindNextKeyList_InZone. The location of the found word or phrase that matches an entry in the keyword file will be remembered so the result can be used by subsequent actions. Matching is case sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes "will" and the recognition read "wi11", a match will still occur.

Common substitutions include characters: B8, Z2, S5, o00 and iIt1.

Example

```
FindKeyList_InZone("Inventory")
FindNextKeyList_InZone("Parts")
```

This action searches the current field, starting from the first word of the zone, for the first occurrence of a word or phrase in the Keyword file "Inventory.key". If a match is found, the application will then look for a word from within the Keyword file "Parts.key", starting from the previously found word from the FindKeyList_InZone action and using the first word or phrase in the "Parts.key" file. If successful, the search stops and remembers the location of the new word for subsequent actions; if not, the action continues searching using the next word in "Parts.key", starting again from the location of previously found word in the zone, repeating this search pattern until a match is found, or until there are no more keywords in the file.

Parent topic: [Locate actions](#)

FindNextRegExList

Same as the FindRegExList action, except that it locates the next instance.

Syntax

```
bool FindNextRegExList (StrParam)
```

Parameters

The name of the Keyword text file. The file will contain a list of words or phrases, separated by new lines, that will be used for matching.

The file name can be provided in one of two ways:

1. A full path name of the file, including the .key extension.
2. The file name only, with no extension specified. The application will look in the process directory and the file must have a .key extension.

Returns

True if at least one word on the page, that follows the result of a previous find, matches any word or pattern in the Keyword file. Otherwise, False.

Level

Field level only.

Details

Opens the Keyword file you specify as a parameter, starting from the location of a previous find, this action checks the words or phrases on the current page against the keywords in the list to find a match. The entries in the keyword file are expected to be regular expressions.

To perform the action, the search first looks for the first word or phrase in the keyword file. Starting from the location of the last find, if the word is found, the search stops. If no match is found, the next line from the keyword file is read and again the search starts from the result of a previous find. This process continues until a match is found or all of the lines in the keyword file have been read. The location of the found word or phrase that matches an entry in the keyword file will be remembered so the result can be used by subsequent actions. Word matching is case sensitive.

Example

```
FindRegExList ("InvoiceNum")  
FindNextRegExList ("InvoiceNum")
```

This action searches the current page, starting from the result of the FindRegExList action, for the first keyword in the Keyword file (InvoiceNum.key). If successful, the search stops and remembers the location of that word for subsequent actions; if not, the action continues searching for the next word in InvoiceNum.key, repeating this search pattern until a match is found, or until there are no more keywords. Although this example shows FindNextRegExList using the same keyword file, it is allowed to use a different keyword file.

[FindNextRegExList](#)

FindRegExList_InZone

Same as the FindRegExList action, except that it searches the current field only.

Syntax

```
bool FindRegExList_InZone (StrParam)
```

Parameters

The name of the Keyword text file. The file will contain a list of words or phrases, separated by new lines, that will be used for matching.

The file name can be provided in one of two ways:

1. A full path name of the file, including the .key extension.
2. The file name only, with no extension specified. The application will look in the process directory and the file must have a .key extension.

Returns

True if at least one word on the page matches any word or pattern in the Keyword file. Otherwise, False.

Level

Field level only.

Details

Opens the Keyword file you specify as a parameter, then checks the words or phrases on the current page against the keywords in the list to find a match. The entries in the keyword file are expected to be regular expressions.

To perform the action, the search first looks for the first word or phrase in the keyword file. If the word or phrase is found in the current field zone, the search stops. If no match is found, the next line from the keyword file is read and again the current field zone is searched. This process continues until a match is found or all of the lines in the keyword file have been read. The location of the found word or phrase that matches an entry in the keyword file will be remembered so the result can be used by subsequent actions. Word matching is case sensitive.

Example

```
FindRegExList_InZone ("InvoiceNum")
```

This action searches the current page, from the first word of the current field, for the first keyword in the Keyword file (InvoiceNum.key). If successful, the search stops and remembers the location of that word for subsequent actions; if not, the action continues searching for the next word in InvoiceNum.key, starting from first word of the current field, repeating this search pattern until a match is found, or until there are no more keywords.

GetSelectedBlockType

Obtains the type of the currently selected block and stores it in the DCO location indicated by the target parameter. This action uses the document block layout that is created by the DocumentAnalytics actions.

Important: This action is currently released as a preview. If you use this action in your application, you might need to make updates to your application if a new version of this action released.

Syntax

```
bool GetSelectedBlockType (string varTarget)
```

Parameters

string varTarget

Target

A smart parameter that defines the target variable to store the type of the currently selected block.

Returns

True if the type was successfully stored, otherwise False.

Level

Page or field.

Details

Obtains the type of the currently selected block and stores it in the DCO location indicated by the target parameter. This action uses the document block layout created by the DocumentAnalytics actions.

Example

```
RegExFind_InBlock("Da.e")
GetSelectedBlockType("@X.SelectedBlock")
```

Finds the block that contains the matching expression and then stores the name of the currently selected block in a variable called `SelectedBlock` on the current DCO object.

If the variable does not exist, it will be created. In this example, the name of the stored block would be `Word` because the currently selected block is the found word block.

Parent topic: [Locate actions](#)

[DocumentAnalytics actions](#)

GoAboveWord

Moves up the specified number of lines from the previously found word or phrase.

Syntax

```
bool GoAboveWord (strParam)
```

Parameters

An integer indicating the number of lines to move up.

Returns

True if a word is found. Otherwise, False.

Level

Page or field level.

Details

Starting from a word or phrase found by a previous Locate action, the location position is moved to a word directly above it by the number of lines indicated by the input parameter. Subsequent Locate actions can then perform additional operations on this located word. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Attention: If the action is added with an empty or non-numeric parameter, the action will default the argument to '1'.

Example

```
WordFind("Total")
GoAboveWord("1")
GoRightWord("1")
UpdateField()
```

This sequence finds the word which is the Tax field's entered value ("29.78") when a fingerprint has these fields and values:

```
Tax 29.78
Total 234.70
```

Parent topic: [Locate actions](#)

[GoBelowWord](#)

GoBelowWord

Moves down the specified number of lines from the previously found word or phrase.

Syntax

```
bool GoBelowWord (strParam)
```

Parameters

An integer indicating the number of lines to move down.

Returns

True if the word or phrase is found. Otherwise, False.

Level

Page or field level.

Details

Starting from a word or phrase found by a previous Locate action, the location position is moved to a word directly below it by the number of lines indicated by the input parameter. Subsequent Locate actions can then perform additional operations on this located word. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Attention: If the action is added with an empty or non-numeric parameter, the action will default the argument to '1'. This action is always called after a search action has been used.

Example

```
WordFind("Tax")
GoBelowWord("1")
GoRightWord("1")
UpdateField()
```

This sequence finds the word which is the Total field's entered value ("234.70") when a fingerprint has these fields:

```
Tax 29.78
Total 234.70
```

GoDownLine

Moves down the specified number of lines from the previously found word or phrase and selects the first word.

Syntax

```
bool GoDownLine (strParam)
```

Parameters

An integer indicating the number of lines to move down below the current line.

Returns

True if a line is found. Otherwise, False.

Level

Page or field level.

Details

Starting from the current position, the location position is moved down by the number of lines indicated in the input parameter and is moved to the first word of that line.

Attention: If the action is added with an empty or non-numeric parameter, the action will default the argument to '1'. This action is always called after a search action has been used.

Example

```
FindKeyList("Invoice")
GoDownLine("1")
GoRightWord("1")
UpdateField()
```

This sequence finds the word which is the Number field's entered value ("10034") when a fingerprint has these fields:

```
INVOICE Number: 10034
```

Level

Page or field level.

Details

Starting from the current position, the location position is moved to the first line of the current zone, or to the first line on the page if a zone is not present. Subsequent Locate actions can then perform additional operations from this position. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Example

```
GoFirstLine ()
```

Parent topic: [Locate actions](#)

Related reference:

[WordFind](#)

[FindKeyList](#)

[RegExFind](#)

GoFirstWord

Moves to the first word on the current line.

Syntax

```
bool GoFirstWord ()
```

Parameters

None.

Returns

False if the page's Fingerprint file (.cco) is not available or if it is empty. Otherwise, True.

Level

Page or field level.

Details

Starting from a word or phrase found by a previous Locate action, the location position is moved to the first word on the current line. If the page's Fingerprint file (.cco) does not have a line position, the action defaults to the first word on the first line of the current zone, or on the first line of the current page if a zone is not present. Subsequent Locate actions can then perform additional operations on this located word. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Example

```
GoFirstWord()
```

Parent topic: [Locate actions](#)

[WordFind](#)

[FindKeyList](#)

[RegExFind](#)

GoLastLine

Moves to the last line of the page when you are running full page recognition.

Syntax

```
bool GoLastLine ()
```

Parameters

None.

Returns

False if the source page's Fingerprint file (.cco) is not available, or if it is empty. Otherwise, True.

Level

Page or field.

Details

Starting from the current position, the location position is moved to the last line and word of the current zone, or to the last line and word on the page if a zone is not present. Subsequent Locate actions can then perform additional operations from this position. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Example

```
GoLastLine()
```

Parent topic: [Locate actions](#)

Related reference:

[WordFind](#)

GoLastWord

Moves to the last word on the current line.

Syntax

```
bool GoLastWord ()
```

Parameters

None.

Returns

False if the Fingerprint file (.cco) is not available, or if it is empty. Otherwise, True.

Level

Page or field level.

Details

Starting from a word or phrase found by a previous Locate action, the location position is moved to the last word on the current line. If the page's Fingerprint file (.cco) does not have a line position, the action defaults to the last word on the first line of the current zone, or on the first line of the current page if a zone is not present. Subsequent Locate actions can then perform additional operations on this located word. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Example

```
GoLastWord ()
```

Parent topic: [Locate actions](#)

Related reference:

[WordFind](#)
[FindKeyList](#)
[RegExFind](#)

GoLeftWord

Moves the specified number of words to the left of the previously found word or phrase.

Syntax

```
bool GoLeftWord (strParam)
```

Parameters

An integer indicating the number of words to move to the left.

Returns

True if a word is found. Otherwise, False.

Level

Page or field level.

Details

Starting from a word or phrase found by a previous Locate action, the location position is moved to the left on the current line by the number of words indicated by the input parameter. Subsequent Locate actions can then perform additional operations on this located word. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Attention: If the action is added with an empty or non-numeric parameter, the action will default the argument to '1'. This action is always called after a search action has been used.

Example

```
WordFind("Total")
GoLeftWord("1")
GoBelowWord("1")
UpdateField()
```

If the fingerprint has a table with columns such as Total and Tax, the actions above will locate the Tax amount below ("344.76"):

```
Tax Total
344.76 13,774.00
```

Parent topic: [Locate actions](#)

Related reference:

[GoRightWord](#)

[WordFind](#)

[FindKeyList](#)

GoRightWord

Moves the specified number of words to the right of the previously found word or phrase.

Syntax

```
bool GoRightWord (strParam)
```

Parameters

An integer indicating the number of words to move to the right.

Returns

True if a word is found. Otherwise, False.

Level

Page or field level.

Details

Starting from a word or phrase found by a previous Locate action, the location position is moved to the right on the current line by the number of words indicated by the input parameter. Subsequent Locate actions can then perform additional operations on this located word. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Attention: If the action is added with an empty or non-numeric parameter, the action will default the argument to '1'. This action is always called after a search action has been used.

Example

```
WordFind("Tax") GoRightWord("1")
GoBelowWord("1")
UpdateField()
```

If the fingerprint has a table with columns such as Total and Tax, the actions above will locate the Total amount below ("13,774.00"):

```
Tax Total 344.76 13,774.00
```

Parent topic: [Locate actions](#)

GoSiblingBlockNext

The currently selected block in the document layout is changed to the next sibling block at the same level in the structure. The number of siblings that are moved is determined by the input parameter. This action uses the document block layout that is created by the DocumentAnalytics actions.

Important: This action is currently released as a preview. If you use this action in your application, you might need to make updates to your application if a new version of this action released.

Syntax

```
bool GoSiblingBlockNext (string count)
```

Parameters

string count

count

The number of sibling blocks to move. Smart parameters are supported.

Returns

True if the sibling is found at the location that is specified from the currently selected block. Otherwise, False.

Level

Page or field.

Details

When a sibling block is selected, the currently selected block becomes the sibling block and the currently selected word is changed to the first word in the new block and that word might be in a nested block. Any searches that look for the next instance will start from the location of this selected word.

For example, if the currently selected block is a line and the parameter is two, then the currently selected block moves down two lines in the structure and the currently selected block will be the sibling line and the selected word will be the first word in the new line. If there is no sibling at that location, then the current block is not changed and the action returns false.

Example

```
RegexFind_InBlock("Da.e")
SelectParentBlockType("Block")
GoSiblingBlockNext("2")
RegexFind_InBlock("Qty")
```

This example finds the matching text for the regular expression `Da.e`, then select the parent block of type `Block`. It then moves down two blocks of type `Block`. Now, the currently selected block is a type block and the currently selected word is the first word in that block. Then, another search is run within that new block for `Qty`. If `Qty` does not exist within the bounds of that new block, the action returns false.

Parent topic: [Locate actions](#)

Related reference:

[GoSiblingBlockPrevious](#)

GoSiblingBlockPrevious

The currently selected block in the document layout is changed to the previous sibling block at the same level in the structure. The number of siblings moved is determined by the input parameter. This action uses the document block layout that is created by the DocumentAnalytics actions.

Important: This action is currently released as a preview. If you use this action in your application, you might need to make updates to your application if a new version of this action released.

Syntax

```
bool GoSiblingBlockPrevious (string count)
```

Parameters

string count

count

The number of sibling blocks to move. Smart parameters are supported.

Returns

True if the sibling is found at the location specified from the currently selected block. Otherwise, False.

Level

Page or field.

Details

When a sibling block is selected, the currently selected block becomes the sibling block and the currently selected word is changed to the first word in the new block, and that word might be in a nested block. Any searches that look for the next instance will start from the location of this selected word.

For example, if the currently selected block is a line and the parameter is two, then the currently selected block will move up two lines in the structure. If there is no sibling at that location, then the current block is not changed and the action returns false.

Example

```
RegExFind_InBlock("Da.e")
SelectParentBlockType("Block")
GoSiblingBlockPrevious("2")
RegExFind_InBlock("Qty")
```

This example will find the matching text for the regular expression `Da.e`, then select the parent block of type `Block`. The example then moves up two blocks of type `Block`. Now, the currently selected block is a type block and the currently selected word is the first word in that block. Then another search is performed within that new block for `Qty`. If `Qty` does not exist within the bounds of that new block, the action will return false.

Parent topic: [Locate actions](#)

GoUpLine

Moves up the specified number of lines from the previously found word or phrase and selects the first word.

Syntax

```
bool GoUpLine (strParam)
```

Parameters

An integer indicating the number of lines to move up above the current line.

Returns

True if a line is found. Otherwise, False.

Level

Page or field level.

Details

Starting from the current position, the location position is moved up by the number of lines indicated in the input parameter and is moved to the first word of that line.

Attention: If the action is added with an empty or non-numeric parameter, the action will default the argument to '1'. This action is always called after a search action has been used.

Example

```
FindKeyList("Invoice")
GoUpLine("1")
```

```
GoRightWord("1")
UPdateField()
```

This sequence finds and extracts the entered value of the Date field ("2/13/03"), in a fingerprint with these words:

```
Date: 2/13/03
INVOICE
```

Parent topic: [Locate actions](#)

GroupWords

Groups words to the left and right of the previously found word if they are no more than the specified number of character widths apart.

Syntax

```
bool GroupWords (nSpaces)
```

Parameters

Long value of the maximum character width separating words to the right and left of the current word.

Returns

Always True.

Level

Page or field level.

Details

Groups any words to the left and right of a located word if the target words are themselves separated by a character width equal to or less than the character width you specify as a parameter. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Example

```
WordFind("Treasury")
GroupWords("1.5")
```

```
If a line contains these words:
20 000 U S Treasury 7 33
```

the GroupWords action merges "20" with "000"; "U" with "S" and "7" with "33" to produce:

```
20 000 U S Treasury 7 33
```

Parent topic: [Locate actions](#)

Related reference:

[GroupWordsLEFT](#)

[GroupWordsRIGHT](#)

GroupWordsLEFT

Groups words to the left of the previously found word if they are no more than the specified number of character widths apart.

Syntax

```
bool GroupWordsLEFT (nSpaces)
```

Parameters

Long value of the maximum character width separating words to the left of the current word.

Returns

Always True.

Level

Page or field level.

Details

Groups only words to the left of the located word if the target words are separated by a character width equal to or less than the character width you specify as a parameter. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Example

```
WordFind("000")  
GroupWordsLeft("2")
```

```
If a line contains these words:  
Found 20 000 US Treasury bills.
```

the GroupWordsLeft action merges "20" with "000" to produce:

```
20 000
```

Parent topic: [Locate actions](#)

Related reference:

[GroupWords](#)

[GroupWordsRIGHT](#)

GroupWordsRIGHT

Groups words to the right of the previously found word if they are no more than the specified number of character widths apart.

Syntax

```
bool GroupWordsRIGHT (nSpaces)
```

Parameters

Long value of the maximum character width separating words to the right of the current word.

Returns

Always True.

Level

Page or field level.

Details

Groups words to the right of the located word if the target words are separated by a character width equal to or less than the character width you specify as a parameter. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Example

```
WordFind("US")
GroupWordsRight("2")
```

```
If a line contains these words:
Found 20 000 US Treasury bills.
```

the GroupWordsRight action merges "US" with "Treasury" to produce:

```
US Treasury
```

Parent topic: [Locate actions](#)

[GroupWords](#)

[GroupWordsLEFT](#)

IsAlpha

Determines whether the specified percentage of characters in a located word is letters (defaults to 100%)

Syntax

```
bool IsAlpha (StrParam)
```

Parameters

An integer (0-100) indicating the minimum percentage of characters that must be alphabetic. If no value is provided, the percentage defaults to 100; all characters must be alphabetic.

Returns

True if the minimum percentage of characters specified by the parameter is alphabetic. Otherwise, False.

Level

Page or field level.

Details

Using the current location of a previously located word or phrase, this action determines if the characters are alphabetic. By testing the type of characters recognized in the current word or phrase, it is possible for an application to determine it has located the type of data that is required, and then take subsequent actions based on the result of the test. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Example

```
FindKey (Name)  
GoRightWord ("1")  
IsAlpha ("100")
```

If the located word's recognized value is: ABC1

```
IsAlpha ("75") returns True
```

```
IsAlpha ("80") returns False
```

Parent topic: [Locate actions](#)

Related reference:

[IsCurrency](#)

[IsDateValue](#)

[IsNumber](#)

IsCurrency

Determines whether the value of the located word is a currency value. The value contains numbers and includes a two-digit decimal amount.

Syntax

```
bool IsCurrency ()
```

Parameters

None.

Returns

True if the located value is currency. Otherwise, False.

Level

Page or field level.

Details

Using the current location of a previously located word or phrase, this action determines if the characters are in a valid currency format and are a valid currency value. By testing the type of characters recognized in the current word or phrase, it is possible for an application to determine it has located the type of data that is required, and then take subsequent actions based on the result of the test. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Attention: This action is NOT dynamic locale aware and uses a simple regex and separator character test.

Example

```
If the recognized value of the word or phrase is: 12.00  
IsCurrency() returns TRUE
```

```
If the recognized value of the word or phrase is: 12,00  
IsCurrency() returns TRUE
```

```
If the recognized value of the word or phrase is: 1200  
IsCurrency() returns FALSE
```

```
If the recognized value of the word or phrase is: 1,200.00  
IsCurrency() returns TRUE
```

```
If the recognized value of the word or phrase is: $12.00  
IsCurrency() returns TRUE
```

Parent topic: [Locate actions](#)

Related reference:

[IsAlpha](#)

[IsDateValue](#)

[IsNumber](#)

IsDateValue

Determines whether the value of the located word is in one of the supported date formats.

Syntax

```
bool IsDateValue ()
```

Parameters

None.

Returns

True if the located value is an acceptable Date. Otherwise, False.

Level

Page or field level.

Details

Using the current location of a previously located word or phrase, this action determines if the characters are in a valid date format and are a valid date. By testing the type of characters recognized in the current word or phrase, it is possible for an application to determine it has located the type of data that is required, and then

take subsequent actions based on the result of the test. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Attention: This action is dynamic locale aware.

Example

```
If the located word's recognized value is: 01/01/2003  
IsDateValue() returns TRUE
```

```
If the located word's recognized value is: January 01,2003  
IsDateValue() returns TRUE
```

```
If the located word's recognized value is: 13/13/2003  
IsDateValue() returns FALSE
```

[IsAlpha](#)

[IsCurrency](#)

[IsNumber](#)

[WordFind](#)

[FindKeyList](#)

[RegExFind](#)

IsNumber

Determines whether the specified percentage of characters in a located word is numbers (defaults to 100%)

Syntax

```
bool IsNumber (StrParam)
```

Parameters

An integer (0-100) indicating the minimum percentage of characters that must be numeric. If no parameter is specified, the value defaults to 100 percent; all characters must be numeric.

Returns

True if the located value meets the parameter's requirement for an integer. Otherwise, False.

Level

Page or field level.

Details

Using the current location of a previously located word or phrase, this action determines if the characters are numeric. By testing the type of characters recognized in the current word or phrase, it is possible for an application to determine it has located the type of data that is required, and then take subsequent actions based on the result of the test. This action does not consider the decimal symbol, digit grouping symbol or a currency symbol to be numeric. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Example

```
WordFind("Total")
GoRightWord("1")
IsNumber("100")
```

If the located word's recognized value is: #755

```
IsNumber("75") returns TRUE
IsNumber("80") returns FALSE
```

IsSelectedBlockType

Compares the provided block type to the type of the currently selected block. This action uses the document block layout that is created by the DocumentAnalytics actions.

Important: This action is currently released as a preview. If you use this action in your application, you might need to make updates to your application if a new version of this action released.

Syntax

```
bool IsSelectedBlockType (string StrParam)
```

Parameters

string StrParam

Type

The name of the expected block type. Smart parameters are supported.

Returns

True if the provided parameter matches the name of the currently selected block. Otherwise, False.

Level

Page or field.

Details

This action uses the document block layout that is created by the DocumentAnalytics actions. IsSelectedBlockType compares the provided block type to the type of the currently selected block.

Example

```
RegExFind_InBlock("Da.e")
SelectParentBlock()
IsSelectedBlockType("Line")
```

This example finds a word, selects the parent of the word and then confirms that the parent is of type `Line`.

Parent topic: [Locate actions](#)

Related reference:

[GetSelectedBlockType](#)

IsValue

Determines whether the value of the located word matches the value that is specified.

Syntax

```
bool IsValue (strParam)
```

Parameters

The value to be compared to the object's recognized value.

Returns

True if the located value matches the parameter's value. Otherwise, False.

Level

Page or field level.

Details

Using the current location of a previously located word or phrase, this action determines if the value matches the value of the input parameter. By testing the value recognized in the current word or phrase, it is possible for an application to determine it has located the data that is required, and then take subsequent actions based on the result of the test. If you want to check the value of a subset of the word or phrase, use the `ValueInWord` action. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Attention: Match test is not case sensitive and does not include leading and trailing spaces.

Example

```
WordFind("Houston")  
GoRightWord("2")  
IsValue("77770")
```

This sequence confirms that the current page's recognized value for Houston's ZIP code is "77770".

The action returns a Boolean value: True if the values are the same, False if they are not.

Parent topic: [Locate actions](#)

Related reference:

[ValueInField](#)

[WordFind](#)

[FindKeyList](#)

[RegExFind](#)

IsValue_RegEx

Determines whether the value of the located word matches the regular expression specified.

Syntax

```
bool IsValue_RegEx (strParam)
```

Parameters

A Regular Expression that will be used for comparison with the recognized value of the word or phrase.

Returns

True if the located value matches the parameter's value. Otherwise, False.

Level

Page or field level.

Details

Using the current location of a previously located word or phrase, this action determines if the regular expression provided in the input parameter finds a match in the value. By testing the value recognized in the current word or phrase, it is possible for an application to determine it has located the data that is required, and then take subsequent actions based on the result of the test. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Example

```
WordFind("Houston")  
GoRightWord("2")  
IsValue_RegEx("Total")
```

Parent topic: [Locate actions](#)

LocatePositionRestore

LocatePositionRestore returns the internal locate word pointer to the word position it was on when LocatePositionSave was called.

Syntax

```
bool LocatePositionRestore ()
```

Parameters

None

Returns

False if called on the wrong level or if the COO does not exist. Otherwise, True.

Level

Page or field level.

Details

LocatePositionRestore returns the internal locate word pointer to the word position it was on when LocatePositionSave was called.

Using LocatePositionSave and LocatePositionRestore together provides an efficient way to reset the position to a located word, when the subsequent locate actions have moved the pointer to a located word. For example, when rules need to look for text in multiple directions based on a found word, these actions efficiently reset the internal locate pointer to a saved position instead of performing the original locate action a second time, which can require more processing time.

Example

This example shows two functions. The first performs a locate, saves the location, moves to the right and tests the word. If the word does not match the IsNumber criteria, then control falls to the next function which restores the saved locate position to the word found in the previous FindKeyList action and then looks in a different direction for a numeric value. Alternatively, the second function can call FindKeyList again, but the action to restore the last position is much more efficient.

```
Key List Right 1 Function
+ FindKeyList ("InvNum")
+ LocatePositionSave ()
+ GoRightWord ("1")
+ IsNumber ("60")
+ UpdateField ()
Key List Down 1 Function
+ LocatePositionRestore ()
+ GoBelowWord ("1")
+ IsNumber ("60")
+ UpdateField ()
```

Parent topic: [Locate actions](#)

Related reference:
[LocatePositionSave](#)

LocatePositionSave

LocatePositionSave creates a restore point for the current word position of the locate pointer.

Syntax

```
bool LocatePositionSave ()
```

Parameters

None

Returns

False if called on the wrong level or if the COO does not exist. Otherwise, True.

Level

Page or field level.

Details

LocatePositionSave creates a restore point for the current word position of the locate pointer. After calling additional locate actions that change the word location of locate pointer, the previously saved position can be restored using the LocatePositionRestore action.

Using LocatePositionSave and LocatePositionRestore together provides an efficient way to reset the position to a located word, when the subsequent locate actions have moved the pointer to a located word. For example, when rules need to look for text in multiple directions based on a found word, these actions efficiently reset the internal locate pointer to a saved position instead of performing the original locate action a second time, which can require more processing time.

Example

This example shows two functions. The first performs a locate, saves the location, moves to the right and tests the word. If the word does not match the IsNumber criteria, then control falls to the next function which restores the saved locate position to the word found in the previous FindKeyList action and then looks in a different direction for a numeric value. Alternatively, the second function could call FindKeyList again, but the action to restore the last position is much more efficient.

```
Key List Right 1 Function
+ FindKeyList ("InvNum")
+ LocatePositionSave ()
+ GoRightWord ("1")
+ IsNumber ("60")
+ UpdateField ()
Key List Down 1 Function
+ LocatePositionRestore ()
+ GoBelowWord ("1")
+ IsNumber ("60")
+ UpdateField ()
```

Parent topic: [Locate actions](#)

[LocatePositionRestore](#)

MaxLength

Determines whether the number of characters in the located word is greater than or equal to the number specified.

Syntax

```
bool MaxLength (StrParam)
```

Parameters

An integer specifying the maximum number of characters the word or phrase can contain.

Returns

False if the parameter is not Numeric, or if the actual number of characters exceeds the parameter. Otherwise, True.

Level

Page or field level.

Details

Compares the number of characters in the located word or phrase to a maximum number you supply as the parameter. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Example

```
If the recognized value of the located word or phrase is: ANYTHING
MaxLength("14") returns TRUE
MaxLength("8") returns TRUE
MaxLength("3") returns FALSE
```

Parent topic: [Locate actions](#)

Related reference:

[MinLength](#)

MergeWordLF

Merges the located word with one or more words to the left, on the same line.

Syntax

```
bool MergeWordLF (StrParam)
```

Parameters

An integer that indicates the number of words or phrases to the left of the previously found field that is to be placed into the current object field.

Returns

Always True.

Level

Page or field level.

Details

Merges the located word or phrase with one or more words to the left, on the same line. A "word" in this context is a string of characters that might include spaces. This action is used when the value searched for might have spaces in it. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Example

```
WordFind("2000")
MergeWordLF("1")UpdateField()
```

Given the following cco string:
Invoice Date: Jan 2000

```
FindWord("2000") locates the highlighted value:
Invoice Date: Jan 2000
```

```
MergeWordLF("1") consolidates it with the text "Jan":
Invoice Date: Jan 2000
```

so that the UpdateField action will save the entire value,
"Jan 2000" into the current object's field.

Parent topic: [Locate actions](#)

Related reference:

[MergeWordRT](#)

MergeWordRT

Merges the located word with one or more words to the right, on the same line.

Syntax

```
bool MergeWordRT (StrParam)
```

Parameters

An integer indicating the number of words to the right, starting from the previously found word or phrase, to be placed into a field.

Returns

Always True.

Level

Page or field level.

Details

Places the located word or phrase with one or more words to the right, on the same line, into the current object field. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Example

```
WordFind("Jan")
MergeWordRT("1")
UpdateField()
```

For the cco string, Invoice Date: Jan 2000 , the result of `WordFind("Jan")` is to locate the highlighted word, Jan, in Invoice Date: Jan. `MergeWordRt("1")` consolidates that value with the year value to its right, which is Invoice Date: Jan 2000. `UpdateField` saves the entire value, Jan 2000, which is saved to the calling object field.

Parent topic: [Locate actions](#)

Related reference:

[MergeWordLF](#)

MinLength

Determines whether the number of characters in the located word is less than or equal to the number specified.

Syntax

```
bool MinLength (StrParam)
```

Parameters

An integer specifying the minimum number of characters the word or phrase can contain.

Returns

False if the parameter is not Numeric, or if the actual number of characters is less than the parameter. Otherwise, True.

Level

Page or field level.

Details

Compares the number of characters in the located word or phrase to a minimum number you supply as the parameter. Regardless of being called at the page or field level, this action operates on the recognized text for the current page.

Example

```
If the recognized value of the word or phrase is: ABC1  
MinLength("4") returns TRUE  
MinLength("3") returns TRUE  
MinLength("6") returns FALSE
```

Parent topic: [Locate actions](#)

Related reference:

[MaxLength](#)

RegExFind

Same as the WordFind action, except that it supports regular expressions.

Syntax

```
bool RegExFind (StrParam)
```

Parameters

A word or phrase to find on the current page. The parameter is expected to be a Regular Expression.

Returns

True if the word or phrase is located on the page. Otherwise, False.

Level

Page level.

Details

Locates the first occurrence of a word or phrase on the current page where the input search term is specified as a regular expression. The search is started from the first word on the current page. The location of the found word or phrase will be remembered so the result can be used by subsequent actions. The search is case sensitive.

Example

```
RegExFind("Da?e")
GoRightWord("1")
IsDateValue()
UpdateField()
```

RegExFind will look for the first occurrence of a word or phrase that matches the regular expression. If a match is found, it continues processing by moving one word to the right of the result of RegExFind and acts on that word. If it is a date format, UpdateField will place the value into the current field.

[RegExFindNext](#)

RegExFind_InBlock

RegExFind_InBlock will look for the first occurrence of a word or phrase that matches the regular expression. This action uses the document block layout that is created by the DocumentAnalytics actions.

Important: This action is currently released as a preview. If you use this action in your application, you might need to make updates to your application if a new version of this action released.

Syntax

```
bool RegExFind_InBlock (StrParam)
```

Parameters

A word or phrase to find on the current page. The parameter is expected to be a Regular Expression. The search is case sensitive.

Returns

True if the word or phrase is located within the currently selected block. Otherwise, False.

Level

Page or field level.

Details

The action locates the first occurrence of a word or phrase on the current page where the input search term is specified as a regular expression, respecting the currently selected block of the document layout. The search is started from the first word within the currently selected block.

When the document layout is created, the entire page is set as the currently selected block, making the initial search area the entire page. Once the regular expression has been matched, the location of the found word or phrase will be remembered so the result can be used by subsequent actions.

Additionally, the found word will become the currently selected word and the block region of that word becomes the currently selected block area within the document block layout. Subsequent block actions will act upon the currently selected block, allowing the area of interest to be changed to control the area of the page that is the target of subsequent actions.

Example

```
RegExpFind_InBlock("Da.e")
SelectParentBlock()
GoRightWord("1")
IsDateValue()
UpdateField()
```

RegExpFind_InBlock will look for the first occurrence of a word or phrase that matches the regular expression. If a match is found, the next action will change the currently selected block from the found word to the entire line that contains the word, then move to the right of the word. If it is a date format, UpdateField will place the value into the current field.

Parent topic: [Locate actions](#)

RegExpFind_InZone

Same as the RegExpFind action, except that it searches the current field only.

Syntax

```
bool RegExpFind_InZone (StrParam)
```

Parameters

A word or phrase to find in the current field. The parameter is expected to be a Regular Expression.

Returns

True if the word or phrase is located in the current field. Otherwise, False.

Level

Field level.

Details

Locates the first occurrence of a word or phrase in the current field where the input search term is specified as a regular expression. The search is started from the first word of the current field. The location of the found word or phrase will be remembered so the result can be used by subsequent actions. The search is case sensitive.

Example

```
RegExpFind_InZone ("Da?e") GoRightWord ("1")
IsDateValue ()
UpdateField ()
```

RegExpFind_InZone will look for the first occurrence of a word or phrase that matches the regular expression. If a match is found, it will continue processing by moving one word right of the result of RegExpFind and act on that word. If it is a date format, UpdateField places the value into the current field.

Parent topic: [Locate actions](#)

Related reference:

[FindRegExpList](#)

[RegExpFindNext_InZone](#)

RegExpFindNext

Same as the WordFindNext action, except that it supports regular expressions.

Syntax

```
bool RegExpFindNext (StrParam)
```

Parameters

A word or phrase to find on the current page. The parameter is expected to be a Regular Expression.

Returns

True if the word or phrase is located on the page. Otherwise, False.

Level

Page level.

Details

Starting from the location of a previously found word or phrase, this action locates the first occurrence of a word or phrase on the current page where the input search term is specified as a regular expression. The search is started from the location of a previously found word or phrase. The location of the found word or phrase will now be remembered so the result can be used by subsequent actions. The search is case sensitive.

Example

```
RegExpFind ("ItemID")
RegExpFindNext ("Desc")
```

In this sequence, the first action looks for ItemID. If the search succeeded, RegExFindNext looks for the first occurrence of Desc that comes after ItemID.

Parent topic: [Locate actions](#)

Related reference:

[FindRegExList](#)

[RegExFind_InZone](#)

[RegExFindNext](#)

RegExFindNext_InBlock

Starting from the location of a previously found word or phrase, this action locates the first occurrence of a word or phrase in the currently selected block where the input search term is specified as a regular expression. Once the regular expression has been matched, the location of the found word or phrase will be remembered so the result can be used by subsequent actions. This action uses the document block layout that is created by the DocumentAnalytics actions.

Important: This action is currently released as a preview. If you use this action in your application, you might need to make updates to your application if a new version of this action released.

Syntax

```
bool RegExFindNext_InBlock (StrParam)
```

Parameters

A word or phrase to find in the current field. The parameter is expected to be a Regular Expression. The search is case sensitive.

Returns

True if the word or phrase is located within the currently selected block. Otherwise, False.

Level

Page or field level.

Details

Starting from the location of a previously found word or phrase, this action locates the first occurrence of a word or phrase in the currently selected block where the input search term is specified as a regular expression. Once the regular expression has been matched, the location of the found word or phrase will be remembered so the result can be used by subsequent actions. Additionally, the found word becomes the currently selected word and the block region of that word becomes the currently selected block area within the document block layout. Subsequent block actions act upon the currently selected block, allowing the area of interest to be changed to control the area of the page that is the target of subsequent actions.

Example

```
RegExFind_InZone("ItemID")
SelectParentBlock()
GoParentBlockNext()
RegExFindNext_InZone("Description")
```

```
GoRightWord("1")
UpdateField()
```

In this sequence, the first action looks for `ItemID` starting from the beginning of the currently selected block. If the search succeeded, the selected block is changed to the containing line, then changed to the following line. `RegExFindNext_InZone` looks for the first occurrence of `Description` within the line that follows `ItemID`, selects the word that follows `ItemID`, and updates the current field.

Parent topic: [Locate actions](#)

Related reference:
[RegExFind_InBlock](#)

RegExFindNext_InZone

Same as the `RegExFindNext` action, except that it searches the current field only.

Syntax

```
bool RegExFindNext_InZone (StrParam)
```

Parameters

A word or phrase to find in the current field. The parameter is expected to be a Regular Expression.

Returns

True if the word or phrase is located on the page. Otherwise, False.

Level

Page level.

Details

Starting from the location of a previously found word or phrase, this action locates the first occurrence of a word or phrase in the current field where the input search term is specified as a regular expression. The search is started from the location of a previously found word or phrase in the current field. The location of the found word or phrase will be remembered so the result can be used by subsequent actions. The search is case sensitive.

Example

```
RegExFind_InZone ("ItemID")
RegExFindNext_InZone ("Desc")
```

In this sequence, the first action looks for `ItemID`. If the search succeeded, `RegExFindNext` looks for the first occurrence of `Desc` that comes after `ItemID`.

Parent topic: [Locate actions](#)

[RegExFind_InZone](#)
[RegExFindNext](#)

ScanRT

Moves the specified number of words to the right of the current word. Expands the search area up and down slightly in case the word is a little above or below the current word.

Syntax

```
bool ScanRT (StrParam)
```

Parameters

Numeric value of the number of words to be evaluated to the right of the current word or phrase.

Returns

True, if a word is found. Otherwise, False.

Level

Field level only.

Details

ScanRT (scan right) looks for a word in positions that are slightly above or below the line on which the current word or phrase is located.

Example

```
WordFind("Number")
ScanRT("1")
```

In this example, the action finds the `Number` on the current page. Then, it moves one word to the right as it searches for a value.

To compensate for the possibility that this value might be printed slightly above or below the line on which `Number` was printed, the ScanRT action expands the area for the target value. When a page is recognized, then skewing or data layout might cause alignment problems. Words might not be recognized as being on the same line and might be recognized as being slightly above or below the current line.

This action compensates for alignment problems at the current word location. The action uses a calculation adjustment to determine which of the words to the right of the current word can be considered to be on the same line. It then remembers the location of the word that best fits this criteria. This new remembered location can then be used by subsequent actions.

Parent topic: [Locate actions](#)

Related reference:

[GoRightWord](#)

SelectParentBlock

Looks for the first occurrence of a word or phrase that matches the regular expression. If a match is found, the next action will change the currently selected block from the found word to the entire line that contains the

word. SelectParentBlock is then called again to change the selected block to the parent of the current line, then the current field zone is updated to contain the entire set of lines contained in the current block and the field value is set to all of the text within the current block. This action utilizes the document block layout created by the DocumentAnalytics actions.

Important: This action is currently released as a preview. If you use this action in your application, you might need to make updates to your application if a new version of this action released.

Syntax

```
bool SelectParentBlock ()
```

Parameters

None.

Returns

True if the word or phrase is located on the page. Otherwise, False.

Level

Page or field level.

Details

The currently selected block, which denotes an area on the page, is changed to the containing block. This effectively makes the new area of interest larger than the previous area.

For example, if the currently selected block is a word, when SelectParentBlock is called, the selected word remains the same, but the area of interest is changed to the parent block, which would be the entire line. Subsequent actions that act on the current block now respects the line as the area of interest on the page.

Calling SelectParentBlock again moves the selected block to the parent of the line. Determining which block gets selected depends on the layout of the page. One scenario is that the selected block will now be a paragraph that contains multiple lines, including the word that was previously found. Any block actions, such as additional searches, will be run within the boundaries of this newly selected paragraph block.

While the block nesting layout often follows the same pattern, the layout of blocks will depend on the layout of text on the page. For predictable results, the application rules might need to work on expected layouts based on the page types that are supported by the application.

Example

```
RegexFind_InBlock("Da.e")  
SelectParentBlock()  
SelectParentBlock()  
UpdateFieldWithBlock()
```

RegexFind_InBlock will look for the first occurrence of a word or phrase that matches the regular expression. If a match is found, the next action will change the currently selected block from the found word to the entire line that contains the word. SelectParentBlock is then called again to change the selected block to the parent of the current line, then the current field zone is updated to contain the entire set of lines contained in the current block and the field value is set to all of the text within the current block.

Parent topic: [Locate actions](#)

SelectParentBlockOuterType

Selects the outermost parent of the current block of the type that is specified. If the currently selected block has multiple parent blocks of the same type, then the parent farthest from the current block is selected. This action uses the document block layout that is created by the DocumentAnalytics actions.

Important: This action is currently released as a preview. If you use this action in your application, you might need to make updates to your application if a new version of this action released.

Syntax

```
bool SelectParentBlockOuterType (string selectType)
```

Parameters

string selectType

selectType

The type of the outer most parent block to select.

Smart parameters are supported.

Returns

True if the word or phrase is located on the page. Otherwise, False.

Level

Field or page level.

Details

This action is usually the last rule of a Locate RuleSet, and is used when the probable area of the sought after value has been found.

Example

```
RegExFind_InBlock("Da.e")  
SelectParentBlockOuterType("Block")
```

In this example the selected block will be the one of type `Block` that is the farthest parent to the block containing the found word. The available block types are: Document, Page, Title, Block, Table, Row, Cell, Paragraph, Header, and Footer. Consider a page that contains the following nested block layout:

```
[Page]  
[Block]  
[Block]  
[Line]  
[Word] "Date" [/Word]  
[/Line]  
[/Block]  
[/Block]  
[/Page]
```

In this example, the selected block would be the `Block` that is the first child to the `Page` block.

Parent topic: [Locate actions](#)

Related reference:

[SelectParentBlock](#)

[SelectParentBlockType](#)

SelectParentBlockType

Selects the parent of the current block of the type that is specified. If the currently selected block has multiple parent blocks of the same type, then the parent nearest to the current block would be selected. Uses the document block layout created by the DocumentAnalytics actions.

Important: This action is currently released as a preview. If you use this action in your application, you might need to make updates to your application if a new version of this action released.

Syntax

```
bool SelectParentBlockType (string selectType)
```

Parameters

string selectType

selectType

The type of the parent block to select.

Smart parameters are supported.

Returns

True the specified parent block is found and selected. If the current block is of the specified type, then true will be returned. Otherwise, False.

Level

Page or field level.

Details

If the current block is of the specified type, then the action will return true and the selected block will remain at the current block. When starting a new search after performing previous searches, it may be useful to call this action with type `Page` to reset the selected block to the page block so the entire page block area can be searched again using the block actions.

Example

```
RegexFind_InBlock("Da.e")  
SelectParentBlockType("Block")
```

In this example the selected block will be the one of type `Block` that is the nearest parent to the block containing the found word. The available block types are: Document, Page, Title, Block Table, Row, Cell, Paragraph, Header, and Footer. Consider a page that contains the following nested block layout:

```
[Page]
[Block]
[Block]
[Line]
[Word] "Date" [/Word]
[/Line]
[/Block]
[/Block]
[/Page]
```

In this example, the selected block would be the `Block` that is the parent to the `Line` block.

`SelectParentBlockType("Page")`

Specifying `Page` selects the page block as the currently selected block. When a previous `Locate` action has been run, reselecting the `Page` block will reset the block to the page so that the next action that searches within the selected block will search the entire page.

Parent topic: [Locate actions](#)

Related reference:

[SelectParentBlock](#)

[SelectParentBlockOuterType](#)

SelectSnippet

Populates a snippet field with the recognized value of the located word. Used with directional actions.

Syntax

```
bool SelectSnippet (strParam)
```

Parameters

1. The character that is to appear in the Snippet field if a value is not available. "~" is the default.
2. The size of the captured value's snippet image. "1" is 1x of the actual word area, and is the default. "2" is 2x of the actual word area, the zone is twice the size of the selected target word. ".5" is 1/2 the actual word area, not recommended as only a portion of the target word would display in the snippet at verify time.

Returns

Always True.

Level

Field level only.

Details

Used in conjunction with directional actions, this action will populate a Snippet field with the recognized value of the located word or phrase.

This action is usually the last rule of a `Locate RuleSet`, and is used when the probable area of the sought after value has been found.

Example

```
FindKeyInList ("InvNum")
GoRightWord ("1")
SelectSnippet ("~",1")
```

This sequence first tries to locate an Invoices Number keyword in the current page. If successful, the next action attempts to lock onto a word or phrase to the right of the located word or phrase.

If that word is present, the SelectSnippet action will place the image of the word's recognized value into the Snippet of the applicable Field object. The Data Entry operator can then determine if the Snippet contains the correct value and can enter the data into the accompanying Data Edit field in the Data Entry Panel.

Parent topic: [Locate actions](#)

SetKeyFileEncodingAsUnicode

Determines if the Locate key files are opened as ASCII or UNICODE.

Member of namespace

Locate

Syntax

```
bool SetKeyFileEncodingAsUnicode (StrParam)
```

Parameters

- True - Key files open as UNICODE encoding.
- False - Key files opens as ASCII encoding and is Default.

Smart parameters are supported.

Returns

Always True.

Level

Any.

Details

Determines if the Locate key files are opened as ASCII or UNICODE. This action must be called before any Locate action that uses a key file. If not called, then the key files are opened as ASCII.

Example:

```
SetKeyFileEncodingAsUnicode ("True")
```

Parent topic: [Locate actions](#)

SetRect

Sets the position and size of the current field in the page data file to the values specified.

Syntax

```
bool SetRect (strParam)
```

Parameters

Four comma separated coordinates designating the rectangle's size and location: X, Y, Width and Height.

Returns

Always True.

Level

Field level only.

Details

Updates the zone of the current field.

Example

```
SetRect ("0,0,100,200")
```

This action changes the field's zone position to a rectangle at coordinates 0, 0, which is 100 wide and 200 high.

This action is useful if you wish to change the zone to a specific area of the image where you know your value resides.

Parent topic: [Locate actions](#)

SetVirtualPageEndPosition

Use this action after you use the Locate commands that identify the last word of a new virtual page.

Syntax

```
bool SetVirtualPageEndPosition()
```

Parameters

None.

Returns

True, if the action is successful. False, if an error occurs.

Level

Page level or field level.

Details

This action requires that the page has an associated layout file and the CCO populated by using the `CreateCcoFromLayout` action. This action is expected to be used with `CreateVirtualPage` to build a new page by using a subset of text from the current page. For more information, see [CreateVirtualPage](#).

Example

```
Recognize ()
CreateCcoFromLayout ()
WordFind ("Hello")
SetVirtualPageStartPosition ()
WordFindNext ("Good bye")
GoUpLine ("1")
GoLastWord ()
SetVirtualPageEndPosition ()
CreateVirtualPage ("MyNewPageType")
```

Parent topic: [Locate actions](#)

SetVirtualPageStartPosition

Use this action after you use the Locate commands that identify the first word of a new virtual page.

Syntax

```
bool SetVirtualPageStartPosition ()
```

Parameters

None.

Returns

True, if the action is successful. False, if an error occurs.

Level

Page level or field level.

Details

This action requires that the page has an associated layout file and the CCO populated by using the `CreateCcoFromLayout` action. This action is expected to be used with `CreateVirtualPage` to build a new page by using a subset of text from the current page. For more information, see [CreateVirtualPage](#).

Example

```
Recognize ()
CreateCcoFromLayout ()
WordFind ("Hello")
SetVirtualPageStartPosition ()
WordFindNext ("Good bye")
GoUpLine ("1")
GoLastWord ()
```

```
SetVirtualPageEndPosition()  
CreateVirtualPage("MyNewPageType")
```

Parent topic: [Locate actions](#)

UpdateDCOField

Updates the position coordinates for the specified field in the page data file with the position of the located word.

Syntax

```
bool UpdateDCOField (StrParam)
```

Parameters

String value of the target field's name (Smart Parameter enabled), as a Field object of the Document Hierarchy.

Returns

False if the source page's Fingerprint file (.cco) is not available or is empty; if the target field cannot be found; or if there is no information about the target field's starting and ending sizes and locations. Otherwise, True.

Level

Page or Field level.

Details

This action updates the size and position coordinates of the Field object representing the field identified by the parameter. Typically, the action follows earlier actions and events which modify the field's width and height, or its precise placement on the current source page.

Do not confuse this action with the UpdateField action, which updates Text values. This action does not update a field's Text value. Instead, it modifies the size and location parameters of a field or zone.

Example

```
To find a sibling field 'Preparer_Name':  
UpdateDCOField("../Preparer_Name")
```

```
To find a child field 'Preparer_Name':  
UpdateDCOField("Preparer_Name")
```

Parent topic: [Locate actions](#)

UpdateField

Updates the current field in the page data file with the value and position of the located word.

Syntax

```
bool UpdateField ()
```

Parameters

None.

Returns

Always True.

Level

Field level only.

Details

Updates the appropriate field in the current page's Data file with the recognized (and possibly formatted) value of the located word or phrase.

Important: An entered value that the UpdateField action places in a Data file becomes a captured value, and can be processed by Validation and Export RuleSets.

Example

```
FindKeyList("Date")
GoRightWord("1")
IsDateValue()
UpdateField()
```

The first action in the sequence finds a word or phrase that identifies the Date Field object of the current page. This is the field's static value - probably its title.

The next action moves right one word or phrase to locate the field's entered value, a recognized date such as 12/31/2002. The third action checks to be sure the value has an acceptable Date format.

The concluding UpdateField action takes place only if the others are successful. It adds the field's entered value to the current page's Data file, where it is a captured value awaiting the attention of upcoming rules with Validate and Export actions.

Parent topic: [Locate actions](#)

UpdateFieldWithBlock

Updates the current DCO object's field zone coordinates with the coordinates of the currently selected block. The text of the field will be set with the contents of the text bound by the currently selected block in the document layout. Uses the document block layout created by the DocumentAnalytics actions.

Important: This action is currently released as a preview. If you use this action in your application, you might need to make updates to your application if a new version of this action released.

Syntax

```
bool UpdateFieldWithBlock ()
```

Parameters

None.

Returns

True if the word or phrase is located on the page. Otherwise, False.

Level

Field level only.

Details

UpdateFieldWithBlock updates the current DCO object's field zone coordinates with the coordinates of the currently selected block. The text of the field will be set with the entire text within the currently selected block in the document layout.

Example

```
RegExFind_InBlock("Da.e")
SelectParentBlock()
SelectParentBlock()
UpdateFieldWithBlock()
```

RegExFind_InBlock looks for the first occurrence of a word or phrase that matches the regular expression. If a match is found, the next action will change the currently selected block from the found word to the entire line that contains the word. SelectParentBlock is then called again to change the selected block to the parent of the current line, likely a paragraph. Then the current field zone is updated to contain the entire set of lines contained in the current block and the field value is set to all of the text within the current block.

[SelectParentBlock](#)

[SelectParentBlockType](#)

ValueInField

Determines whether any part of the located word matches the value that is specified.

Syntax

```
bool ValueInField (StrParam)
```

Parameters

The value that is to be matched with a portion of the value in the current field.

Returns

False if no match occurs. Otherwise, True.

Level

Field level.

Details

Checks if the parameter you enter is within the value of the current field represented by the bound Field object of the Document Hierarchy. Only a portion of the field's value needs to match the parameter. If the entire field must match, use `IsValue`. Case insensitive.

Example

```
ValueInField("Invoice")
```

Parent topic: [Locate actions](#)

Related reference:

[IsValue](#)

[ValueInField_RegEx](#)

ValueInField_Fuzzy

Uses fuzzy matching to determine whether any part of the located word matches the value that is specified.

Syntax

```
bool ValueInField_Fuzzy (StrParam)
```

Parameters

String value to be matched to the current field's value, using fuzzy matching procedures.

Returns

False if no match occurs. Otherwise, True.

Level

Field level only.

Details

Checks if there is a "fuzzy" match of the parameter's value with the value in the current field. Only a portion of the field's value needs to match. The match is performed by allowing for common substitutions that can occur during recognition. These substitutions include characters: B8, Z2, S5, oO0 and iItl1. Case insensitive.

Example

```
ValueInField_Fuzzy("Invoice")
```

Parent topic: [Locate actions](#)

ValueInField_RegEx

Determines whether any character or series of characters in the located word matches the specified regular expression.

Syntax

```
bool ValueInField_RegEx (StrParam)
```

Parameters

The portion of the value to find in the field. The parameter is expected to be expressed as a regular expression.

Returns

False if no match occurs. Otherwise True.

Level

Field level only.

Details

This action checks if the Regular Expression you specify as the parameter is equivalent to the value of the current field. Only a part of the field must match the parameter. To match the entire value of the field, use `IsValueRegEx`.

Example

```
ValueInField_RegEx("[\^\b\s\n\r]Inv[oO][iItl1]ce[\b\s]*")
```

Parent topic: [Locate actions](#)

Related reference:

[IsValue](#)

[IsValue_RegEx](#)

[ValueInField](#)

WordFind

Locates the first or next occurrence of the specified word or phrase on the current page.

Syntax

```
bool WordFind (StrParam)
```

Parameters

A word or phrase to find on the page.

Returns

True, if the word or phrase is on the page. Otherwise, False.

Level

Field level only.

Details

The current page is searched to find the whole word or phrase. The location of the first word or phrase that matches the parameter is remembered and can be used by subsequent actions. Matching is case-sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes `will` and the recognition that is read is `wi11`, a match still occurs.

This action matches whole word values and does not search for parts of words or characters within words.

Common substitutions include characters: B8, Z2, S5, o00, and i1t1

Example

```
WordFind("Sales Tax")
GoRightWord("1")
IsCurrency()
UpdateField
```

In this example, the `WordFind` action looks for the first occurrence of `Sales Tax` within the current page, always starting at the first word of the page. If the phrase `Sales Tax` is found, the subsequent actions operate based on the location of the found phrase.

Parent topic: [Locate actions](#)

Related reference:

[WordFindNext](#)

[FindKeyList](#)

[AddKeyList](#)

WordFind_InZone

Same as the `WordFind` action, except that it searches the current field only.

Syntax

```
bool WordFind_InZone (StrParam)
```

Parameters

A word or phrase to find in the current zoned field.

Returns

True if the word or phrase is located in the field. Otherwise, False.

Level

Page or Field

Details

The current field will be searched to find the word or phrase. The location of the first word or phrase that matches the parameter will be remembered so it can be utilized by subsequent actions. Matching is case sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes "will" and the recognition read "wi11", a match will still occur.

Common substitutions include characters: B8, Z2, S5, oO0 and iIt1.

Example

```
WordFind_InZone("Sub Total")
GoRightWord("1")
IsCurrency()
```

In this example, the WordFind action looks for the first occurrence of Sub Total within the current field, always starting at the first word of the zone. If the phrase Sub Total is found, the subsequent actions will operate based on the location of the found phrase.

Parent topic: [Locate actions](#)

Related reference:

[WordFind](#)

[WordFindNext](#)

[WordFindNext_InZone](#)

WordFindNext

Same as the WordFind action, except that it locates the next occurrence.

Syntax

```
bool WordFindNext (StrParam)
```

Parameters

A word or phrase to find on the page, following a previously found word or phrase.

Returns

True if the parameter is located. Otherwise, False.

Level

Field level only.

Details

The current page will be searched to find the word or phrase, starting from the location remembered from the last search, such as from WordFind. The location of the first word or phrase that matches the parameter will now be remembered so it can be utilized by subsequent actions. Matching is case sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes "will" and the recognition read "wi11", a match will still occur.

Common substitutions include characters: B8, Z2, S5, oO0 and iIt1.

Example

```
WordFindNext ("Total")
WordFindNext ("Total")
GoRightWord ("1")
IsCurrency ()
UpdateField
```

In this sequence, the Locate rule locates the third instance of the word Total in the current page.

Parent topic: [Locate actions](#)

Related reference:

[WordFind](#)

[FindLastWord](#)

WordFindNext_InZone

Same as the WordFindNext action, except that it searches the current field only.

Syntax

```
bool WordFindNext_InZone (StrParam)
```

Parameters

A word or phrase to find in the current field, following a previously found word or phrase.

Returns

True if the parameter is located. Otherwise, False.

Level

Field level.

Details

The current field will be searched to find the word or phrase, starting from the remembered location of a previous find. The new location of the first word or phrase in the field that matches the parameter will now be remembered so it can be utilized by subsequent actions. Matching is case sensitive.

To improve matching, this action automatically adjusts the search criteria to allow for common character substitutions. For example, if the list includes "will" and the recognition read "wi11", a match will still occur.

Common substitutions include characters: B8, Z2, S5, o00 and i1t1.

Example

```
WordFind_InZone (ItemID)
WordFindNext_InZone (Desc)
```

In this example, the WordFind_InZone action looks for the first occurrence of ItemID within the current field, always starting at the first word of the zone. If the phrase ItemID is found, the word Desc will be looked for in the current field, starting after the location of ItemID. If Desc is found, any subsequent actions will operate based on the location of that found phrase.

Parent topic: [Locate actions](#)

[WordFind_InZone](#)
[FindLastWord_InZone](#)

WordFind_Offset

Sets the value of the page's Image_Offset variable. The variable is based on the difference in the position of the specified word on the current page and on the matched fingerprint image.

Syntax

```
bool WordFind_Offset (StrParam)
```

Parameters

1. String value of a keyword that the action is to find on both the fingerprint and recognized image.
2. An optional parameter that specifies the offset threshold. If not specified, the default value is 100 pixels.

Returns

Always True.

Level

Page level.

Details

This action locates a word or phrase on both the recognized page and on the fingerprint. The positioning of both locations are compared to determine an offset value. The calculated difference is stored in the DCO of the current page in the variable Image_Offset. This value will be used by subsequent actions, such as ReadZones, to compensate for the difference so the field data is properly located.

For best results, the word or phrase should appear only once or the first instance of the word or phrase should always appear in the same location.

The threshold is the maximum distance between keywords found on the Live image and the fingerprint. The Default value is 100 pixels. If the keywords are more than 100 pixels apart no Offset is generated; preventing matches of keywords where there is more than one instance of the word to be found on an image. A successful matched pair will update the Image_Offset variable at the page level.

This action requires the FingerPrint CCO to have full page recognition results. Otherwise, there will be nothing to match against.

This action should not be located in the same ruleset where full page recognition is done. It needs to exist in a ruleset that is performed afterwards.

Example

```
WordFind_Offset ("Invoice")
```

Parent topic: [Locate actions](#)

Lookup actions

Use the Lookup actions to validate field values by using database lookups and populate fields with lookup results.

The Lookup actions opens a connection to the Lookup database and populates the current field with a value returned by the previous ExecuteSQL or LookupReturnValue action.

- [ClearLookupResults](#)
Clears the results that are returned by the previous Lookup action.
- [CloseConnection](#)
Closes an open connection to the Lookup database.
- [ExecuteSQL](#)
Runs a SQL statement on the Lookup database. If a SELECT statement returns one or more values, these values are stored in an internal data record that you can access by using the PopulateWithResult action.
- [ExecuteSQLEx](#)
Executes the SQL statement you enter in the first parameter.
- [OpenConnection](#)
Uses a data source name or connection string to open a connection to a Lookup database.
- [PopulateWithResult](#)
Populates the current field with a value returned by the previous ExecuteSQL or LookupReturnValue action. If the previous action returned multiple values, you can specify the value that you want to use.
- [SmartSQL](#)
Runs a SQL statement that supports smart parameters.
- [SmartSQLEx](#)
Executes the SQL statement you enter in the first parameter.

Parent topic: [Global actions](#)

ClearLookupResults

Clears the results that are returned by the previous Lookup action.

Syntax

```
bool ClearLookupResults ()
```

Parameters

None.

Returns

Always True.

Level

All.

Details

This action clears the stored results returned from a previous Lookup action such as PopulateWithResult.

Example:

```
OpenConnection("@APPVAR(* /lookupdb:cs)")
ExecuteSQL("SELECT NAME, ADDRESS FROM Vendor;")
PopulateWithResult("1")
ClearLookupResults()
```

Here, ClearLookupResults() clears the stored results of the Vendor Name and Address.

Parent topic: [Lookup actions](#)

CloseConnection

Closes an open connection to the Lookup database.

Syntax

```
bool CloseConnection ()
```

Parameters

None.

Returns

True, even if the connection is already closed.

Level

All, but generally used as part of a separate RuleSet at the Batch level.

Details

Closes an open connection to your Lookup database.

Usually, this action is placed in a RuleSet that is separate from the RuleSet that opens the connection and stores the data.

LookupDBCclose RuleSet, for example, is run at the Batch level after all data has been exported from the batch to the specified database.

Example:

```
CloseConnection()
```

This action closes the previously opened connection to the Lookup database. This action is usually part of a separate RuleSet that prevents the need to repeatedly open the connection to the database. You can open the connection once in the first RuleSet, use the database from all documents and pages in the batch, then close the connection once in the second RuleSet.

Parent topic: [Lookup actions](#)

Related reference:

[OpenConnection](#)

ExecuteSQL

Runs a SQL statement on the Lookup database. If a SELECT statement returns one or more values, these values are stored in an internal data record that you can access by using the `PopulateWithResult` action.

Syntax

```
bool ExecuteSQL (sStringIn)
```

Parameters

1. The SQL expression that you want to run surrounded by quotation marks (" "). '%s' or %s can be substituted in the SQL expression to represent a field value.
 - o If %s represents a text field, it must be surrounded by ' '.
 - o If %s represents a numeric field, it appears without surrounding apostrophe characters.
2. , 3+ Field names whose captured values you want to use in the SQL expression (see the example).

Returns

True, if the SQL statement runs successfully, select statements must also return a value. False, if it does not.

Level

All.

Details

Runs the SQL statement that you enter in the first parameter. Field values can be substituted for "%s" in the statement.

Example:

This sequence opens a connection to the InvoiceLook database. Next, it inserts values into the `CompanyCode` and `Type` columns of the `Vendor` table:

```
OpenConnection("@APPVAR(* /lookupdb:cs)")
ExecuteSQL("INSERT INTO Vendor (CompanyCode,Type) VALUES ('MQSW','New')")
```

Here, `dbVendorID` is a numeric field, while `dbVendorname` is a text field.

```
OpenConnection("@APPVAR(* /fingerprintconn:cs)")
ExecuteSQL("""SELECT CompanyCode FROM Vendor WHERE dbVendorID = %s AND
dbVendorName = '%s';",VendorID,VendorName")
```

Parent topic: [Lookup actions](#)

ExecuteSQLEx

Executes the SQL statement you enter in the first parameter.

Member of namespace

Lookup

Syntax

```
bool ExecuteSQLEx (string sStringIn, bool sPopulate, string sTarget)
```

Parameters

- **sStringIn** - The SQL expression you want to execute surrounded by quotation marks (" ")
%s' or %s can be substituted in the SQL expression to represent a field value.
If %s represents a text field, it must be surrounded by ' '.
If %s represents a numeric field, it appears without surrounding apostrophe characters **2,3+**.
Field names whose captured values you want to use in the SQL expression (see the example).
- **sPopulate** - True/False value to enable or suppress populating value of any record returned from the SQL expression.
- **sTarget** - Smart Parameter destination for value population, leave blank for current object's Text property.

Returns

True if the SQL statement executes successfully, selected statements must also return a value.

False, if it does not.

Level

All.

Details

Executes the SQL statement you enter in the first parameter. Field values can be substituted for "%s" in the statement.

Example:

```
ExecuteSQLEx("INSERT INTO Vendor (CompanyCode,Type) VALUES ('MQSW','New')",  
"False", "")
```

Parent topic: [Lookup actions](#)

OpenConnection

Uses a data source name or connection string to open a connection to a Lookup database.

Syntax

```
bool OpenConnection (strParam)
```

Parameters

The Database Connection String, using an OLEDB or ODBC database provider.

If the action is establishing a connection with DB2, Oracle database, or SQL Server database, you must specify the user ID and Password. Some database providers support integrated authentication, which use the credentials of the running process.

Smart parameters are supported and recommended to prevent plain text credentials in the application rules.

Returns

True if the action results in a connection to the database. Otherwise, False.

Level

All.

Details

This action uses the Connection String that you provide as the parameter to open a connection to your LookUp database.

Example:

```
OpenConnection("@APPVAR(* /fingerprintconn:cs ")
```

This example opens the fingerprint database and obtains the connection information from the Application Service. It is recommended to use the application service so passwords are kept hidden.

Access:

```
OpenConnection("Provider=MSACCESS;DSN=C:\Datacap\1040EZ\1040ezLook.mdb;UID=;PWD=;")
```

Oracle:

```
OpenConnection("Provider=OraOLEDB.Oracle.1;Password=myspassword;Persist Security Info=True;User ID=myuserid;Data Source=TM2")
```

SQL Server (Standard authentication):

```
OpenConnection("Provider=SQLOLEDB;Data Source=SQLServerName;Initial Catalog=myDatabase;User ID=myuserid;Password=myPassword;")
```

SQL Server (Integrated authentication):

```
OpenConnection("Provider=SQLOLEDB;Data Source=SQLServerName;Initial Catalog=myDatabase;Integrated Security=SSPI;")
```

DB2:

```
OpenConnection("Provider=IBMDADB2;Hostname=1.22.333.444;Port=50000;Data Source=DB2;Database=myDatabase;User ID=myuserid;Password=myPassword;")
```

Parent topic: [Lookup actions](#)

Related reference:

[CloseConnection](#)

PopulateWithResult

Populates the current field with a value returned by the previous ExecuteSQL or LookupReturnValue action. If the previous action returned multiple values, you can specify the value that you want to use.

Syntax

```
bool PopulateWithResult (StrParam)
```

Parameters

1. A number that indicates the value in a record that is retrieved by an earlier ExecuteSQL or SmartSQL action is to be assigned to the current Field object (and added to the Data file of the current page.)
 - o "1" refers to the first column in a recordset, "2" refers to the second column, and so on.
2. True or False. True causes the action to fail, if the action returns a recordset with multiple lines. False permits the action to accept a record set with multiple lines but to use values in the first record of the record set.

Returns

True, if the second parameter is True and a previous ExecuteSQL or SmartSQL action finds a recordset with only one record.

True, if the second parameter is "False" and a previous ExecuteSQL (or SmartSQL) action finds a recordset with one or more records.

Otherwise, False.

Level

Field level only.

Details

Populates a Field object with a database value retrieved by a ExecuteSQL or SmartSQL action.

This action allows multiple rules to populate multiple Field objects with data from a single database record (see the following example.)

Example:

```
(Field #1)
OpenConnection("@APPVAR(* /lookupdb:cs) ")
ExecuteSQL("Select * From Vendor Where VendorID = %s;", VendorID")
PopulateWithResult("1, FALSE")
```

```
(Field #2)
PopulateWithResult("2, FALSE")
```

In the example, the ExecuteSQL action of the RuleSet applied to Field #1 retrieves the recordset (if it exists).

The PopulateWithResult action places the value of the first record's first column into the field where the rule applied. The PopulateWithResult action of a rule that is applied to Field #2 populates the field with the value of the first record's second column.

False means that the action can accept a recordset with multiple records but extracts values from the first record only.

Parent topic: [Lookup actions](#)

Related reference:

[ExecuteSQL](#)

[SmartSQL](#)

SmartSQL

Runs a SQL statement that supports smart parameters.

Syntax

```
bool SmartSQL (string sStringIn, string sPopulate)
```

Parameters

1. The SQL expression that you want to run. Smart parameters are supported within the expression.
2. True/False value to enable or suppress populating value of any record that is returned from the SQL expression.

Returns

True, if the SQL statement runs successfully, select statements must also return a value. False, if the SQL statement does not execute successfully.

Level

All.

Details

Runs the SQL statement that you enter in the first parameter.

Example:

This sequence opens a connection to the InvoiceLook database. Next, it inserts values into the CompanyCode and Type columns of the Vendor table:

```
OpenConnection("@APPVAR(* /lookupdb:cs ")
SmartSQL("INSERT INTO Vendor (CompanyCode,Type) VALUES ('MQSW','New')")
```

Here, dbVendorID is a numeric field, while dbVendorname is the calling text field.

```
OpenConnection("@APPVAR(* /lookupdb:cs ")
SmartSQL("SELECT CompanyCode FROM Vendor WHERE dbVendorID =+@P\VendorID+ AND
dbVendorName = '+@F+';", YES)
```

Parent topic: [Lookup actions](#)

SmartSQLEx

Executes the SQL statement you enter in the first parameter.

Member of namespace

Lookup

Syntax

```
bool SmartSQLEx (string sStringIn, bool sPopulate, string sTarget)
```

Parameters

- **sStringIn** - The SQL expression you want to execute. Smart parameters are supported within the expression.
- **sPopulate** - True/False value to enable or suppress populating value of any record returned from the SQL expression.
- **sTarget** - Smart Parameter destination for value population, leave blank for current object's Text property.

Returns

True if the SQL statement executes successfully, selected statements must also return a value.

False, if the SQL statement does not execute successfully.

Level

All.

Details

Executes the SQL statement you enter in the first parameter.

Example:

```
SmartSQLEx("INSERT INTO Vendor (CompanyCode,Type) VALUES ('MQSW','New')",  
"False", "")
```

Parent topic: [Lookup actions](#)

MC_Identify

Use the MC_Identify actions to identify claim forms in a batch.

The MC_Identify actions identify the medical claim forms that are processing in the batch.

- [AutoField](#)
Identifies red HCFA-1500 or red UB04 forms.
- [FindFields](#)
Sets up a data file for the current page and provides field position information to the data file.
- [ReadDCOSetup](#)
Designates the file name of the document hierarchy.
- [ReadPageSetup](#)
Designates the file name and path of the document hierarchy.
- [SetFormType](#)
Set the value of the Form Type that is used by the AutoField action.
- [SetMaxTolerantDistance](#)
Set the tolerance level that the AutoField action uses to match HCFA-1500 or red UB04 forms.

Parent topic: [Global actions](#)

Parent topic: [Medical Claims actions](#)

AutoField

Identifies red HCFA-1500 or red UB04 forms.

Member of namespace:

MC_Identify

Syntax:

```
bool AutoField()
```

Parameters

None

Returns

False, if the action is not applied at the page level. Otherwise, True.

Level

Page level.

Details

This action Identifies red HCFA-1500 or red UB04 forms.

This action must be placed in the rule after the SetMaxToleranceDistance, SetFormType, ReadDCOSetup, and SetWritePosFile actions.

Example:

```
SetMaxToleranceDistance(60)
SetFormType(0)
ReadDCOSetup(HFCA.xml, POS 1052)
AutoField()
```

Parent topic: [MC_Identify](#)

FindFields

Sets up a data file for the current page and provides field position information to the data file.

Member of namespace:

MC_Identify

Syntax:

```
bool FindFields()
```

Parameters

None

Returns

False, if the rule with this action is not bound to a page object of the document hierarchy or if a source page that is represented by the page object is not available. Otherwise, True.

Level

Page level.

Details

This action sets up a data file (.xml) for the current page and supplies the data field with field position information.

This action is usually part of a Medical Claims ID_PageFix rule.

Example:

```
SetMaxToleranceDistance (60)
SetFormType (0)
ReadDCOSetup (HCFA.xml, POS 1052)
FindFields`()
```

Parent topic: [MC_Identify](#)

ReadDCOSetup

Designates the file name of the document hierarchy.

Member of namespace:

MC_Identify

Syntax:

```
bool ReadDCOSetup (StrParam)
```

Parameters

A comma-separated string value that is made up of a smart parameter that designates the file name of the document hierarchy followed by a variable name that indicates the position of the fingerprint. The file name is usually the application ID with an .xml extension. For example, HCFA.xml is name of document hierarchy file of the HCFA application. POS 1052 specifies a previously assembled HCFA-1500 fingerprint with details of the form's Field IDs, locations, and data types. For use with the Application Service, the syntax of the first parameter changes to include the smart parameter that points to the Setup DCO. For example, it uses @APPPATH(setupdco) instead of HCFA.xml.

Returns

False, if the document hierarchy is not found. Otherwise, True.

Level

All levels, but usually the Batch level.

Details

Example:

```
ReadDCOSetup (HFCA.xml, POS 1052)
```

For use with the Application Manager with the @APPPATH smart parameter to locate the Setup DCO:

```
ReadDCOSetup (@APPPATH (setupdco) , POS 1052)
```

This action is used with almost every other MC_Identify action.

Parent topic: [MC_Identify](#)

ReadPageSetup

Designates the file name and path of the document hierarchy.

Member of namespace:

MC_Identify

Syntax:

```
bool ReadPageSetup (string DCOSetupPath, string FPPosition, string PageType)
```

Parameters

string DCOSetupPath

string FPPosition

string PageType

Parameters

1. PageType: A smart parameter enabled argument that designates the file name and path of the document hierarchy.
2. FPPosition: The fingerprint position variable, usually Pos followed by the ID of the desired fingerprint.
3. PageType: The page type of the page to identify, usually PClaim or IClaim.

Returns

False, if the document hierarchy file is not found. Otherwise, True.

Level

All levels.

Details

Example:

```
ReadPageSetup (@APPPATH (setupdco) , POS 1059, PClaim)
```

This action is used with almost every other MC_Identify action.

Parent topic: [MC_Identify](#)

SetFormType

Set the value of the Form Type that is used by the AutoField action.

Member of namespace:

MC_Identify

Syntax:

```
bool SetFormType (StrParam)
```

Parameters

String value that indicates the Form Type:

- For HCFA-1500 or CMS-1500, use 0 or hcfa.
- For UB-04, use 2 or ub04.

Returns

False, if the parameter is invalid. Otherwise, True.

Level

All levels.

Details

This action sets the Form Type value that is used by the AutoField action.

Example:

```
SetMaxToleranceDistance (60)
SetFormType (0)
ReadDCOSetup (HFCA.xml, POS 1052)
SetWritePosFile (True)
AutoField ()
```

Parent topic: [MC_Identify](#)

SetMaxTolerantDistance

Set the tolerance level that the AutoField action uses to match HCFA-1500 or red UB04 forms.

Member of namespace:

MC_Identify

Syntax:

```
bool SetMaxTolerantDistance (StrParam)
```

Parameters

The Maximum Tolerance Distance: an integer from 1 for the lowest tolerance to 100 for the highest tolerance.

Returns

False, if the parameter is not an integer from 1 to 100. Otherwise, True.

Level

All levels.

Details

This action sets the tolerance level that is used by the AutoField action to match HCFA-1500 or red UB04 forms based on the form that is specified in the SetFormType action.

Example:

```
SetMaxToleranceDistance (60)
SetFormType (0)
ReadDCOSetup (HFCA.xml, POS 1052)
AutoField ()
```

Parent topic: [MC_Identify](#)

MC_Validation

Use the MC_Validation actions to validate medical claim form information.

The MC_Identify actions validates the information in the medical claim forms that are processing in the batch.

- [AddCenturyTo2YearDigit](#)
Converts two-digit Year values to four-digit Year values.
- [AddToDetailErrorMsg](#)
Adds the specified value to the existing value for the page variable *ErrorMessage*.
- [AddToErrorMsg](#)
Adds the specified value to the existing value for the page variable *ErrorMessage*.
- [CalculateHCFALineCharges](#)
Calculates charges for HCFA service lines.
- [CalculateUBLLineCharges](#)
Calculates charges for UB service lines.
- [CheckDocID](#)
Checks the document IDs and updates them to the proper format.
- [ClearErrorMsg](#)
Clears the value of the page variable *ErrorMessage*.
- [CommonParseAddress](#)
Parses the addresses in the HCFA and UB04 fields into appropriate subfields.
- [CommonValAddress](#)
Validates the address values first name, last name, street, city, state, zip code, and phone number.
- [ConvertHyphen](#)
Removes spaces, commas, hyphens, and invalid characters.

- [FilterPID](#)
Filters the qualifier from the attending physician for UB04 claims.
- [FormatFieldLengths](#)
Truncates the length of the field and sets the last character of the field to low confidence.
- [InheritSnippets](#)
Assigns the snippet position information of the current Field object to the Field objects that are specified in the parameter.
- [MC_ReadZones](#)
Adjusts the autofield that is based on the OMR field zone positions on the calling page.
- [Parse31aPhSig](#)
Parses the 31aPhSig field of the HFCA application.
- [Parse58ainsnm](#)
Parses the 58ainsnm field of the UB04 application.
- [Parse58binsnm](#)
Parses the 58binsnm field of the UB04 application.
- [Parse58cinsnm](#)
parses the 58cinsnm field of the UB04 application.
- [ParseConditionCodes](#)
Detects and parses Condition Code data elements from the calling field value.
- [ParseEPSDT](#)
Detects and parses an ESDT Reason Code from the calling field value.
- [ParseLastFirstIniNames](#)
Parses the name information in the first line of an address superfield.
- [ParseNDC](#)
Detects and parses NDC data elements from the calling field value.
- [PopulateFromField](#)
Copies the value from field that is specified by the parameter into the current field.
- [SetConf](#)
Set a confidence string for a field.
- [SetOriginalTIF](#)
Replaces the current TIF file with the original TIF image that was previously renamed with a TI1 extension.
- [StripTrailingAlpha](#)
Removes all alpha characters from the captured value, except from the first character position.
- [TransformLI](#)
Assigns values to the fields in the lines of the Line Item Table.
- [UpdateCredentialList](#)
Updates the default list of abbreviations that are used by the parsing actions to extract credential strings from names.
- [ValidateNPI](#)
Validates the NPI value by evaluating the 10 digits in the value that use a modified LUHN checkdigit algorithm.
- [ValProcedureCode](#)
Validates the Procedure Code fields in a HCFA-1500 form.
- [ValRequiredGroup](#)
Checks that all of the fields in a designated group are filled with data.

Parent topic: [Global actions](#)

AddCenturyTo2YearDigit

Converts two-digit Year values to four-digit Year values.

Member of namespace:

MC_Validation

Syntax:

```
bool AddCenturyTo2YearDigit()
```

Parameters

None.

Returns

False, if the value is not a valid date in the mmddyy format or if the action is not applied at the Field level. Otherwise, True.

Level

Field level.

Details

This action converts two-digit Year values to four-digit Year values.

All dates are assumed to be before today's date with a format of mmddyy. If today is 051507 and this action is applied to a field with a value of 102295, the date is assumed to be 10221995.

Example:

```
AddCenturyTo2YearDigit()
```

Parent topic: [MC_Validation](#)

AddToDetailErrorMsg

Adds the specified value to the existing value for the page variable *ErrorMessage*.

Member of namespace:

MC_Validation

Syntax:

```
bool AddToDetailErrorMsg(StrParam)
```

Parameters

1. A smart parameter or regular string to add to the error message variable.
2. Optional comma separated second parameter to trigger the action to return True.

Returns

True, if the optional second comma separated parameter is used. Otherwise, False.

Level

Field level.

Details

This action adds the specified value to the existing value for the page variable *ErrorMessage*.

Example:

```
AddToDetailErrorMsg("Description cannot be blank")
```

Parent topic: [MC_Validation](#)

AddToErrorMsg

Adds the specified value to the existing value for the page variable *ErrorMessage*.

Member of namespace:

MC_Validation

Syntax:

```
bool AddToErrorMsg(StrParam)
```

Parameters

1. A smart parameter or regular string to add to the error message variable.
2. Optional comma separated second parameter to trigger the action to return True.

Returns

True, if the optional second comma separated parameter is used. Otherwise, False.

Level

Field level.

Details

This action adds the specified value to the existing value for the page variable *ErrorMessage*.

Example:

```
AddToErrorMsg("Invoice Number must be 60% numeric with a  
minimum length of 2.")
```

Parent topic: [MC_Validation](#)

CalculateHCFALineCharges

Calculates charges for HCFA service lines.

Member of namespace:

MC_Validation

Syntax:

```
bool CalculateHCFALineCharges ()
```

Parameters

None.

Returns

True, if the line charges equal the charges field. Otherwise, False.

Level

Field level.

Details

This action calculates charges for HCFA service lines.

Example:

```
CalculateHCFALineCharges ()
```

Parent topic: [MC_Validation](#)

CalculateUBLLineCharges

Calculates charges for UB service lines.

Member of namespace:

MC_Validation

Syntax:

```
bool CalculateUBLLineCharges ()
```

Parameters

None.

Returns

True, if the line charges equal the charges field. Otherwise, False.

Level

Field level.

Details

This action calculates charges for UB service lines.

Example:

```
CalculateUBLLineCharges ()
```

Parent topic: [MC_Validation](#)

CheckDocID

Checks the document IDs and updates them to the proper format.

Member of namespace:

MC_Validation

Syntax:

```
bool CheckDocID ()
```

Parameters

None.

Returns

True, if the docid is formatted without an error. Otherwise, False.

Level

Document level.

Details

This action checks the document IDs and updates them to the proper format.

Example:

```
CheckDocID ()
```

Parent topic: [MC_Validation](#)

ClearErrorMsg

Clears the value of the page variable *ErrorMessage*.

Member of namespace:

MC_Validation

Syntax:

```
bool ClearErrorMsg()
```

Parameters

None.

Returns

Always True.

Level

Page level.

Details

This action clears the value of the page variable *ErrorMessage*.

Example:

```
ClearErrorMsg()
```

Parent topic: [MC_Validation](#)

CommonParseAddress

Parses the addresses in the HCFA and UB04 fields into appropriate subfields.

Member of namespace:

MC_Validation

Syntax:

```
bool CommonParseAddress(StrParam)
```

Parameters

For Professional Claim, string value of:

1. HCField32Object: for parsing the Facility Address field (field 32).
2. HCField33Object: for parsing the Physician Address field (field 33).

For Institutional Claim, string value of:

1. UBField1Object: for parsing the Provider Address field (field 1).
2. UBField2Object: for parsing the Pay-To Address field (field 2).
3. UBField38Object: for parsing the Responsible Party Name and Address field (field 38).

Returns

False, if the parameter is invalid or if the action is not on the Page level. Otherwise, True.

Level

Page level.

Details

This action parses the addresses in the following fields into appropriate subfields:

- Professional Claims - Facility Address (field 32) or Physician Address (field 33)
- Institutional Claims - Provider Address (field 1), Pay-To Address (field 2), or Responsible Party Name and Address (field 38).

Example:

```
CommonParseAddress (HCField32Object)
```

Parent topic: [MC_Validation](#)

CommonValAddress

Validates the address values first name, last name, street, city, state, zip code, and phone number.

Member of namespace:

MC_Validation

Syntax:

```
bool CommonValAddress (StrString)
```

Parameters

Comma-delimited String that contains a list of name with addresses to be validated.

Returns

False, if the action is not run at the Page level. Otherwise, True.

Level

Page level.

Details

This action validates the following address values:

1. First Name: value can start with Ms, Mr, Miss, Dr salutations. The remaining values must be alphanumeric with no special characters. Punctuation is allowed only after the salutation.
2. Last Name: same requirements as the first name.
3. Street: alphanumeric, upper or lower case. Can include punctuation and the # character.
4. City: characters from A to Z, upper or lower case, comma, period, space, and the & character.
5. State: must be 2 alphanumeric characters.
6. Zip Code: must be between 5 and 9 characters. This value is checked against the State value above.

7. Phone Number: the area code is checked against the State and Zip Code values above.

Example:

```
CommonValAddress (Insured, 4InsFNam, 4InsLNam, 7|AddStr, 7|AddCity,  
7|AddSta, 7|AddZip)  
or  
CommonValAddress (Description, 12plname, 12pfname, 13paddr1, 13paddr2,  
13padcit, 13padsta, 13padzip)
```

Parent topic: [MC_Validation](#)

ConvertHyphen

Removes spaces, commas, hyphens, and invalid characters.

Member of namespace:

MC_Validation

Syntax:

```
bool ConvertHyphen ()
```

Parameters

None.

Returns

False, if the parameter is not called at the Field level. Otherwise, True.

Level

Field level.

Details

This action removes spaces, commas, hyphens, and invalid characters.

"1,2,3,4" becomes "1234", "1-2-3" becomes "123". Valid characters for this field are {1,2,3,4}.

Characters other than 1,2,3,4, space, commas, or hyphens will lower the field confidence level.

Example:

```
ConvertHyphen ()
```

Parent topic: [MC_Validation](#)

FilterPID

Filters the qualifier from the attending physician for UB04 claims.

Member of namespace:

MC_Validation

Syntax:

```
bool FilterPID(StrParam)
```

Parameters

The name of the field to filter.

Returns

False, if not called at the Field level. Otherwise, True.

Level

Field level.

Details

This action filters the qualifier from the attending physician for UB04 claims.

Example:

```
FilterPID(76apqual)
```

Parent topic: [MC_Validation](#)

FormatFieldLengths

Truncates the length of the field and sets the last character of the field to low confidence.

Member of namespace:

MC_Validation

Syntax:

```
bool FormatFieldLengths()
```

Parameters

None.

Returns

Always True.

Level

Page level.

Details

This action truncates the length of the field and sets the last character of the field to low confidence.

Example:

```
FormatFieldLengths()
```

Parent topic: [MC_Validation](#)

InheritSnippets

Assigns the snippet position information of the current Field object to the Field objects that are specified in the parameter.

Member of namespace:

MC_Identify

Syntax:

```
bool InheritSnippets(StrParam)
```

Parameters

The names of the fields that will inherit the same snippet information as the current Field object.

For example, 2paLname, 2PaFname, aPaMInit.

Returns

False, if the action is not called at the Field level or if a parameter is incorrect. Otherwise, True.

Level

Field level.

Details

This action assigns the snippet position information of the current Field object to the Field objects that are specified in the parameter.

Example:

```
InheritSnippets(2paLname, 2PaFname, aPaMInit)
```

Parent topic: [MC_Validation](#)

MC_ReadZones

Adjusts the autofield that is based on the OMR field zone positions on the calling page.

Member of namespace:

MC_Validation

Syntax:

```
bool MC_ReadZones ()
```

Parameters

None.

Returns

False, if the action is not called at the Page level. Otherwise, True.

Level

Page level.

Details

This action adjusts the autofield that is based on the OMR field zone positions on the calling page. Important: This action handles Autofield-based OMR zone detection for Medical Claims application. This action is not compatible with standard rules-based OMR zone detection procedures.

Example:

```
MC_ReadZones ()
```

Parent topic: [MC_Validation](#)

Parse31aPhSig

Parses the 31aPhSig field of the HFCA application.

Member of namespace:

MC_Validation

Syntax:

```
bool Parse31aPhSig ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

This action parses the 31aPhSig field of the HFCA application.

Example:

```
Parse31aPhSig()
```

Parent topic: [MC_Validation](#)

Parse58ainsnm

Parses the 58ainsnm field of the UB04 application.

Member of namespace:

MC_Validation

Syntax:

```
bool Parse58ainsnm()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

This action parses the 58ainsnm field of the UB04 application.

Example:

```
Parse58ainsnm()
```

Parent topic: [MC_Validation](#)

Parse58binsnm

Parses the 58binsnm field of the UB04 application.

Member of namespace:

MC_Validation

Syntax:

```
bool Parse58binsnm()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

This action parses the 58binsnm field of the UB04 application.

Example:

```
Parse58binsnm()
```

Parent topic: [MC_Validation](#)

Parse58cinsnm

parses the 58cinsnm field of the UB04 application.

Member of namespace:

MC_Validation

Syntax:

```
bool Parse58cinsnm()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

This action parses the 58cinsnm field of the UB04 application.

Example:

Parse58cinsnm()

Parent topic: [MC_Validation](#)

ParseConditionCodes

Detects and parses Condition Code data elements from the calling field value.

Member of namespace:

MC_Validation

Syntax:

```
bool ParseConditionCodes()
```

Parameters

None.

Returns

False, if the action generates an error or an invalid code is detected. Otherwise, True.

Level

Field level that contains Condition Code data to detect and parse to fields CCode 1 through CCode4.

Details

This action detects and parses Condition Code data elements from the calling field value.

Valid codes are: AA, AB, AC, AD, AE, AF, AG, AH, AI, W2, W3, W4, or W5.

Example:

```
ParseConditionCodes()
```

Parent topic: [MC_Validation](#)

ParseEPSDT

Detects and parses an ESDT Reason Code from the calling field value.

Member of namespace:

MC_Validation

Syntax:

```
bool ParseEPSDT(string EPSDTCode)
```

Parameters

A Smart Parameter enabled value that represents the target field where the parsed data is to be saved.

Returns

False, if the action generates an error. Otherwise, True.

Level

Field level that contains the Reason Code data.

Details

This action detects and parses an ESDT Reason Code from the calling field value. Parsing looks for "AV", "S2", "ST", or "NU" as a single word at the end of the field value.

Example:

```
ParseEPSDT ("..\EPSDTCode")
```

Parent topic: [MC_Validation](#)

ParseLastFirstIniNames

Parses the name information in the first line of an address superfield.

Member of namespace:

MC_Validation

Syntax:

```
bool ParseLastFirstIniNames (StrParam)
```

Parameters

These comma separated parameters:

1. The name of the Last Name Field object.
2. The name of the First Name Field object.
3. The name of the Middle Name or Middle Initial object.
4. The name of the Credential Field object.
5. The name of the Suffix Field object.

Returns

False, if the parameter values are invalid. Otherwise, True.

Level

Field level.

Details

This action parses the name information in the first line of an address superfield.

The action parses the value of the full name into the Last, First, and MiddleName/Initial fields that are specified by the parameter. In the absence of any explicit pattern, such as a punctuation mark or a middle initial, parsing defaults to First Middle Last. A parameter value of -1 in the argument changes this default in the absence of any explicit pattern to Last First.

Example:

For form fields where the instructions specify First Middle Last:

```
ParseLastFirstIniNames (8plname, 8pfname, 8pminit)
```

For form fields where the instructions specify Last First Middle:

```
ParseLastFirstIniNames (17RelLNam, 17RelFNam, 17RelMini,  
17RelCred, 17RelSufx, -1)
```

Parent topic: [MC_Validation](#)

ParseNDC

Detects and parses NDC data elements from the calling field value.

Member of namespace:

MC_Validation

Syntax:

```
bool ParseNDC(string NDCField, string TypeField, string QuantityField)
```

Parameters

Three Smart Parameters that represent the target path from the calling object to the field's parsed data that is to be saved.

Returns

False, if the action generates an error. Otherwise, True.

Level

Field level that contains NDC data to detect and parse.

Details

This action detects and parses NDC data elements from the calling field value. NDC value parsing looks for "N4" followed by 11 numbers. The NDC Type and Quantity parameters look for "F2", "GR", "ML", or "UN" followed by 1 to 9 numbers.

Example:

```
ParseNDC ("..\NDC", "..\NDCType", "..\NDCQty")
```

Parent topic: [MC_Validation](#)

PopulateFromField

Copies the value from field that is specified by the parameter into the current field.

Member of namespace:

MC_Validation

Syntax:

```
bool PopulateFromField(StrParam)
```

Parameters

The name of the field whose value is to be assigned to the current field

Returns

False, if the parameter is invalid or if the action is not applied at the Field level. Otherwise, True.

Level

Field level.

Details

This action copies the value from field that is specified by the parameter into the current field.

Example:

```
PopulateFromField(24aDtFr1)
```

Parent topic: [MC_Validation](#)

SetConf

Set a confidence string for a field.

Member of namespace:

MC_Validation

Syntax:

```
bool SetConf(StrParam)
```

Parameters

The value of the new confidence for each character in the field, 0 to 9.

Returns

Always True.

Level

Field level.

Details

This action sets a confidence string for a field.

Example:

```
SetConf(9)
```

This example sets the confidence for each character in the field to 9, which is the highest confidence.

Parent topic: [MC_Validation](#)

SetOriginalTIF

Replaces the current TIF file with the original TIF image that was previously renamed with a TI1 extension.

Member of namespace:

MC_Validation

Syntax:

```
bool SetOriginalTIF(StrParam)
```

Parameters

The extension of the original image file.

Returns

False, if the original image does not exist. Otherwise, True.

Level

Page level.

Details

This action replaces the current TIF file with the original TIF image that was previously renamed with a TI1 extension. It is assumed that the original file name was copied to a file name that uses a different extension for safe keeping.

Example:

```
SetOriginalTIF(TI1)
```

This example replaces the current TIF file with the original TIF image that was previously renamed with a TIF extension.

Parent topic: [MC_Validation](#)

StripTrailingAlpha

Removes all alpha characters from the captured value, except from the first character position.

Member of namespace:

MC_Validation

Syntax:

```
bool StripTrailingAlpha()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

This action removes all alpha characters from the captured value, except from the first character position.

Example:

```
StripTrailingAlpha()
```

Parent topic: [MC_Validation](#)

TransformLI

Assigns values to the fields in the lines of the Line Item Table.

Member of namespace:

MC_Validation

Syntax:

```
bool TransformLI()
```

Parameters

None.

Returns

True if the assignment of values is successful for all of the fields in all of the lines of the Line Item Table.

False, if the transfer of values for one or more of the fields fails.

Level

Document or Page level.

Details

Each line in the table is remapped into a repeating set of fields. These fields have a parent field with a unique ID. All of the data in a source field is retained in the new target field, with the exception of the new fields type and ID. The linear field structure is replaced with a structure that is based on a parent field in the claim page called DETAILS.

Each set of fields in the row of table data is then placed in a LINEITEM type field. The ID of the field is patterned on the index of its insertion in the DETAILS field. The first Line Item field is called LINEITEM1, the second is LINEITEM2, and so on. Each Line Item field contains an identical set of Field Type and ID as outlined in the following values list.

For example, the HCFA Line Item Table has 12 24nDtfr fields. During processing, the TransformLI action assigns recognized values for these fields to a Field object named DateFrom that is a child of the Line Item Table Details new parent Field object. So, 12 recognized values can be assigned to the Field object DateFrom.

Values that are associated with rows of the HCFA-1500 table are assigned to the Field types where n is value from 1 to 12:

- 24aDtn = DateFrom
- 24aDtTon = DateThru
- 24bPlacn = PlaceOfService
- 24cTypen = TypeOfService
- 24cEMG_n = EMG_C
- 24dCPT_n = CPT_Code
- 24dModin = Modifiers
- 24eDiagn = DiagPointer
- 24fChgsn = Charges
- 24gDaysn = Days_Units
- 24hEPDn = EPD
- 24iQualn = Qualifier
- 24jReflDn = ReferenceId
- 24jEMG_n = EMG_I
- 24jCOBn = COB
- 24kLocn = LocalUse
- 24lInfn = Info

Values that are associated with the rows of a UB04 table are assigned to the child Field objects where n is a value from a to z:

- 42nrevcd = RevCode
- 43ndscrt = Description
- 44nhcpcs = HCPCS

- 44nMod = Modifiers
- 45nsrvdt = ServiceDate
- 46nsrvun = Units
- 47nttchg = Charges
- 48nncchg = NotCovered
- 49n = LocalUse

Note: This action converts all of the pages in a document if it called from a Document object. The expected page types are HCFA, 1500 and UB04_Page.

Parent topic: [MC_Validation](#)

UpdateCredentialList

Updates the default list of abbreviations that are used by the parsing actions to extract credential strings from names.

Member of namespace:

MC_Validation

Syntax:

```
bool UpdateCredentialList(string sCredential,string AddRemove)
```

Parameters

string sCredential

string AddRemove

Parameters

A two parameter specification of a list of credential abbreviations and a Add or Remove from the list indicator.

sCredential is a comma separated list of credential abbreviations. Smart parameters are supported.

AddRemove indicator is an Add or Remove Condition from the list command. Defaults to Add. The keywords for setting the remove from the list mode are: "OFF", "REMOVE", "0", "FALSE", "-1", "NO", and "DELETE".

Returns

False, if the action generates an error. Otherwise, True.

Level

All levels.

Details

This action updates the default list of abbreviations that are used by the following name parsing actions to extract credential strings from names: ParseLastFirstIniNames(), Parse58ainsnm(), Parse58binsnm(), Parse58cinsnm(), Parse82name(), Parse83aname(), Parse83bname(), Parse31aPhSig(),

Example:

```
UpdateCredentialList (MD, Add)
```

Parent topic: [MC_Validation](#)

ValidateNPI

Validates the NPI value by evaluating the 10 digits in the value that use a modified LUHN checkdigit algorithm.

Member of namespace:

MC_Validation

Syntax:

```
bool ValidateNPI ()
```

Parameters

None.

Returns

True, if the field contains a valid NPI value. Otherwise, False.

Level

Field level.

Details

This action validates the NPI value by evaluating the 10 digits in the value that use a modified LUHN checkdigit algorithm.

Example:

```
ValidateNPI ()
```

Parent topic: [MC_Validation](#)

ValProcedureCode

Validates the Procedure Code fields in a HCFA-1500 form.

Member of namespace:

MC_Validation

Syntax:

```
bool ValProcedureCode ()
```

Parameters

None.

Returns

False, if the action is not applied at the Field level or if the Procedure Code is invalid. Otherwise, True.

Level

Field level.

Details

This action validates the Procedure Code fields in a HCFA-1500 form.

Example:

```
ValProcedureCode ()
```

Parent topic: [MC_Validation](#)

ValRequiredGroup

Checks that all of the fields in a designated group are filled with data.

Member of namespace:

MC_Validation

Syntax:

```
bool ValRequiredGroup (StrParam)
```

Parameters

The names of fields in the group.

Returns

False, if the parameters are invalid or if any of the parameter fields do not contain data. Otherwise, True.

Level

Field level.

Details

This action checks that all of the fields in a designated group are filled with data.

Example:

```
ValRequiredGroup (24aDtFr1,24aDtTo1,24adCPT_1,24fChg1,24gdays1)
```

mvscan actions

Use mvscan actions in place of the vscan actions to create batches from files that are stored on your local disk. The mvscan actions can handle large numbers of files that are stored in the input folder.

The mvscan actions can run simultaneously on multiple stations, in multiple threads. These actions can read from a single folder or multiple folders to provide high availability and throughput. The mvscan actions can also read metadata and include it in the batch with the input files. Refer to the [set_metadata_types](#) action for details.

Note: If a batch aborts, and the files are not moved; for example, if there is no problem folder, then the batch aborts repeatedly, and the Rulerunner does not process normally.

- [mv_retain_folder](#)
Indicates whether to retain the directory tree structure of a file's input folder when the file is placed in the copy or problem folder.
- [scan](#)
Polls the folder that is specified by the [set_folder](#) action and scans the images into a batch folder.
- [set_abort_time](#)
Specifies the length of time in seconds to delay processing if the scan action encounters an unrecoverable error and sets the batch status to aborted.
- [set_copy_folder](#)
Optional, sets a folder to contain a copy of each ingested file.
- [set_delete_empty_folders](#)
Determines whether to delete the empty subdirectories.
- [set_folder](#)
Specifies the folder or folders in which to search for the image files that you want to scan.
- [set_image_validation](#)
Causes the Scan action to validate that the specified input files are all valid image files. Invalid files are moved to the problem folder.
- [set_max_docs](#)
Specifies maximum number of pages in each batch when used with the [set_types](#) action.
- [set_metadata_types](#)
Specifies the input file name extensions of XML files that contain the names of the files to ingest and the metadata to include in the batch for each file.
- [set_min_age](#)
Specifies the minimum time in seconds to wait after the file was modified before ingesting the file.
- [set_move_wait_time](#)
Specifies the time to wait for a source file to be deleted after it is moved from to the batch folder.
- [set_multipage_burst](#)
Forces multipage TIFF images to be split into single pages during ingestion.
- [set_problem_folder](#)
Sets the folder into which the files that cannot be ingested are placed.
- [set_sort_method](#)
Selects method to use for sorting files for ingestion.
- [set_tree_mode](#)
Determines whether subdirectories are included in the scan for files to ingest.
- [set_types](#)
Specifies the extensions of the file types to ingest in a comma-separated list of file extensions.
- [set_wait_time](#)
For batch creation purposes, specifies the maximum interval that the scan action waits for the arrival of more input files to add to a batch.

mv_retain_folder

Indicates whether to retain the directory tree structure of a file's input folder when the file is placed in the copy or problem folder.

Member of namespace

mvscan

Syntax

```
mv_retain_folder(bool bRetainFolders)
```

Parameters

bRetainFolders

Whether to retain the directory tree structure of a file's input folder. Here are the possible values:

True	Within the copy and problem folders, the scan action places files in a directory structure that partly replicates the file's original input folder. Also, the scan action creates several variables that indicate various folder and file paths. For further explanation, see the Details section.
False	Input files are placed directly in the copy or problem folders.

By default, if you do not call this action, the directory tree structure of a file's input folder is not retained.

Returns

Always True.

Level

Batch level.

Details

Use this action to retain a file's input folder structure in the copy or problem folder. For an explanation of the specific manner in which folder structure is retained, see the example.

This action sets the following variables:

Variable	Description	Example
ScanSrcInputFolder	The full path of the input folder for this file. For more information, see ScanSrcInputFolder .	c:\shared\group1
ScanSrcSubFolder	The relative path of the input folder in which the file was found, which includes the root input folder name but not the root folder path. For more information, see ScanSrcSubFolder .	\shared\group1\batch1

Variable	Description	Example
ScanSrcFile Name	The original filename without the path. For more information, see ScanSrcFileName .	invoice_0001.tif

You can see the values of these variables in the VScan.xml file. For information about this file, see [Examining the files in the runtime batch folder](#).

Example:

```
set_folder("c:\shared\group1|c:\shared\group2|d:\shared\group3")
set_copy_folder("InProgress")
set_problem_folder("Error")
mv_retain_folder(True)
scan()
```

In this example, the set_folder action specifies three input folders. The following table shows the copy and problem folders for each input folder:

Input folder	Root input folder	Copy folder	Problem folder
c:\shared\group1	c:\shared	c:\shared\InProgress	c:\shared\Error
c:\shared\group2	c:\shared	c:\shared\InProgress	c:\shared\Error
d:\shared\group3	d:\shared	d:\shared\InProgress	d:\shared\Error

Within the copy or problem folder, files are placed in a directory structure that replicates the file's original input folder except for the root input folder. The following table shows some examples:

Input folder file placement	Copy folder placement	Problem folder placement
c:\shared\group1\batch1	c:\shared\InProgress\group1\batch1	c:\shared\Error\group1\batch1
d:\shared\group3\batch99	c:\shared\InProgress\group3\batch99	d:\shared\Error\group3\batch99

Parent topic: [mvscan actions](#)

scan

Polls the folder that is specified by the set_folder action and scans the images into a batch folder.

Member of namespace

mvscan

Syntax

```
bool scan ()
```

Parameters

None.

Returns

False, if the operation fails, and pauses before the return. Otherwise, True.

Action returns when timeout is reached, or the requested number of files is ingested.

Level

Batch level Open event only.

Details

Scans the source folder for files with the extensions that you want, then ingests them into a batch. Call one time for each batch. All options must be set before this action is called. If no files are present for ingestion, the batch is set to pending status, and the action returns immediately. The files in each batch folder are ingested by the order of the date the file was last modified.

Each input file generates one or more "pages" in the batch with the following page variables set:

- TYPE : Always set to "Other".
- IMAGEFILE : The file name within the batch, for example TM000002.tif.

Example:

```
set_folder("@APP_PATH(vscaimagedir)+@STRING(\mvscan folder)")
set_types("jpg,pdf,tif")
set_max_docs("2")
scan()
```

Parent topic: [mvscan actions](#)

set_abort_time

Specifies the length of time in seconds to delay processing if the scan action encounters an unrecoverable error and sets the batch status to aborted.

Member of namespace

mvscan

Syntax

```
bool set_abort_time (int nSecs)
```

Parameters

nSecs

Type: int

Time to wait before continuing when a serious error occurs.

Parameters

nSecs : Time to wait before continuing when a serious error occurs.

Returns

Always True.

Level

Batch level.

Details

The scan action waits the specified time before returning if a fatal error is detected that would cause the batch to abort. This action can be useful to prevent a large number of aborted batches due to an abort condition. For example, if the source folder should become unavailable for some time, the abort timeout will limit the number of aborted batches until the folder becomes available again.

This delay restricts the number of aborted batches if the problem persists.

If this action is not called, the default abort time value of 5 seconds is used.

Example:

```
set_abort_time("60")
scan()
```

Parent topic: [mvscan actions](#)

set_copy_folder

Optional, sets a folder to contain a copy of each ingested file.

Member of namespace

mvscan

Syntax

```
bool set_copy_folder (string folderpath)
```

Parameters

Smart parameters are supported.

folderpath

The folder, if any, to which the scan action copies files that it successfully ingested. Specify a full or relative folder path. If you specify a relative path, the path is relative to the root input folder. For information about the root input folder, see [set_folder](#).

Here are the possible values:

Same as input folder	For demonstration purposes, you might want to set the copy folder to be the same as the input folder. In this case, ingested files are left in place.
Empty string	Ingested files are moved to the batch folder without making copies.
Any other folder	Ingested files are copied to the specified folder.

If you do not call this action, the scan action behaves by default the same as if you specified an empty string for the copy folder.

The location of the copy folder is affected by the `mv_retain_folder` action. For more information, see [mv_retain_folder](#).

Returns

Always True.

Level

Batch level.

Details

If the specified folder does not exist, the scan action generates an error.

This action must be called before `scan()` to take effect.

Example:

```
set_folder("@APPPATH(vscanimagedir)+@STRING(\input folder)")
set_copy_folder(@APPPATH(vscanimagedir)+@STRING(\copy folder))
scan()
```

Parent topic: [mvscan actions](#)

set_delete_empty_folders

Determines whether to delete the empty subdirectories.

Member of namespace

mvscan

Syntax

```
bool set_delete_empty_folders (bool bParam)
```

Parameters

bParam
Type: bool

Parameters

bParam : A Boolean value that enables or disables deleting sub-folders if they are empty. The root folder specified for ingestion is never deleted. Subfolders are only deleted if both this setting and tree mode are enabled.

True: Delete subfolders of the main ingestion folder if they are empty. This is the default if the action is not called.

False: Leave empty subfolders intact.

Details

If tree mode is not enabled, this setting has no effect. For this action to take effect, it must be called before the Scan action.

Example:

```
set_types("tif")
set_min_age("10")
set_tree_mode(True)
set_delete_empty_folders(False)
scan()
```

Parent topic: [mvscan actions](#)

set_folder

Specifies the folder or folders in which to search for the image files that you want to scan.

Member of namespace

mvscan

Syntax

```
bool set_folder (string folderpath)
```

Parameters

Smart parameters are supported.

folderpath

One or more input folders that are separated with a vertical bar (“|”). Specify the full path for each folder.

The scan action polls the specified input folders for files, which are incorporated into batches for processing.

Returns

Always True.

Level

Batch level.

Details

Use this action to specify the input folders for the scan action. To indicate that the subfolders of the input folders are also to be polled by the scan action, use the `set_tree_mode` action.

For any particular input folder, the root input folder is the parent folder of the input folder. For example, if the input folder is `c:\shared\group1`, the input root folder is `c:\shared`. The root input folder might be significant for other actions when you specify relative folder paths.

A batch contains files from one input folder only.

This action must be called before `scan()`.

Example:

```
set_folder("@APPPATH(vscanimagedir)+@STRING(\input folder)")
scan()

set_folder("c:\shared\group1|c:\shared\group2|d:\shared\group3")
scan()
```

Parent topic: [mvscan actions](#)

Related reference:

[scan](#)

[set_tree_mode](#)

set_image_validation

Causes the Scan action to validate that the specified input files are all valid image files. Invalid files are moved to the problem folder.

Member of namespace

mvscan

Syntax

```
bool set_image_validation (bool bValidate)
```

Parameters

bValidate
Type: bool

Parameters

bValidate : A Boolean value that enables or disables validating image files during ingestion.

True: Check to confirm that each file ingested contains a valid TIFF or JPG image.

False: Copy input files regardless of type or contents. This is the default if the action is not called.

Returns

Always True.

Level

Batch level.

Details

Enables testing that each file ingested is a valid image file. If enabled, converts black and white TIF files to G4 compression. This action should not be called against invalid file types such as PDFs due to incompatibility.

For this action to take effect, it must be called before the Scan action.

Example:

```
set_types("tif")
set_image_validation("True")
scan()
```

Parent topic: [mvscan actions](#)

set_max_docs

Specifies maximum number of pages in each batch when used with the set_types action.

Member of namespace

mvscan

Syntax

```
bool set_max_docs (int nDocs)
```

Parameters

nDocs

Type: int

Number of documents in a batch. Default 100.

Parameters

nDocs : An integer value which specifies the maximum number of input files to place into a batch.

If Metadata files are used, set_metadata_types() is called instead of set_types(), this specifies the maximum number of metadata files to ingest. All files referenced in each metadata file are included in the batch, there is no limit on the number of pages in the batch in this case. The default value is 100.

Returns

Always True.

Level

Batch level.

Details

For this action to take effect, it must be called before the Scan action.

Example:

```
set_tree_mode(false)
set_max_docs("1")
scan()
```

Parent topic: [mvscan actions](#)

set_metadata_types

Specifies the input file name extensions of XML files that contain the names of the files to ingest and the metadata to include in the batch for each file.

Member of namespace

mvscan

Syntax

```
bool set_metadata_types (string extensions)
```

Parameters

extensions

Type: string

Metadata image file extensions. If specified, XML metadata files (trigger files) control ingestion of files into batches, along with associated metadata. See more documentation for syntax and usage of metadata trigger files. If specified, these extensions override any prior call to `set_types()`.

Parameters

String value of extensions of input files that contain pointers to files to be ingested along with metadata to be included in the batch for each file. For multiple types, separate each one with a comma. Any files with extensions not in this list are ignored.

It is optional to include a period before each extension. The parameter is not case-sensitive.

Returns

Always True.

Level

Batch level Open event only.

Details

The format of the metadata file is documented here. This action overrides any previous call to `set_types()`, and forces the action to read properly formatted XML from the metadata trigger file. Then, the action determines which files get ingested, rather than ingesting individual files into the batch. Other settings such as `set_min_age()` are applied to the metadata files.

You must set up the XML file in the correct format to use the `set_metadata_type` action to scan metadata files into batches.

The following example illustrates a sample XML file:

```
<input>
  <item name="Invoice1" vendor_number="TS265329"
    vendor_name="Busy Car Repair" invoice_number="28100">
    <filename>C:\Datacap\APT\images\Input\
      Invoice_0001S1.tif</filename>
```

```

        <filename>C:\Datacap\APT\images\Input\
        Invoice_0002S1.tif</filename>
    </item>
    <item name="Invoice2" vendor_number="TS23785354"
        vendor_name="Trucking Co." invoice_number="876-3456">
        <filename>C:\Datacap\APT\images\Input\
        Invoice_0003S1.tif</filename>
        <filename>C:\Datacap\APT\images\Input\
        Invoice_0004S1.tif</filename>
    </item>
</input>

```

The XML file must follow this format.

1. The tag name of the XML root node must be `<input>`.
2. The `<item>` nodes represent a group of input files or images that share metadata.
3. The `<item>` nodes must contain at least one attribute, but can have a number of attributes. In this example, the `<item>` nodes contain the attributes `name=`, `vendor_number=`, `vendor_name=`, `invoice_number=`.
4. The `<item>` attribute names are entered in the item as text that follows the `=`.
5. These name values are prepended with `Meta_Item_` when they are written to the DCO to define the metadata variable names that are placed on each page. The attribute values populate the variable values.
6. The inner most nodes must be `<filename>` and contain items that represent single input files.
7. A `<filename>` can be either a fully qualified path, for example `\\server\folder\filename`, or a partial path relative to the location of the metadata file such as `folder\filename`. The number of file names in each repeating item is only limited to the practical limit of how many files you want to ingest in a single batch.
8. Each file is ingested as a Page in the batch, regardless of the file type or contents.

All of the items in a metadata file are ingested into the same batch. For example, if a metadata file contains 1 node with 50 file names, 50 files are ingested for that single metadata file. If the metadata file contains 5 nodes with 50 file names in each of them, then 250 files are ingested. The external system that creates the metafile must create all of the files to be ingested before it writes the metafile that refers to them.

Example:

```

set_metadata_types ("xml")
Scan ()

```

This sequence scans for metadata trigger files that end in ".xml".

Parent topic: [mvscan actions](#)

set_min_age

Specifies the minimum time in seconds to wait after the file was modified before ingesting the file.

Member of namespace

mvscan

Syntax

```
bool set_min_age (int nSecs)
```

Parameters

nSecs

The number of seconds since a file or group of files was last modified before the scan action ingests the file or files. As shown in the following table, the specific meaning of this parameter depends on the way that the scan action checks the minimum age of files:

Checking type	Parameter meaning	When
Individual	The number of seconds since a file was modified before the scan action ingests the file.	Non-tree mode or when the wait time is zero as set by the <code>set_wait_time</code> action
Collective	The number of seconds since any file was modified within a particular folder before the scan action ingests any file from that folder.	Tree mode except when the wait time is zero as set by the <code>set_wait_time</code> action

You set tree mode by calling `set_tree_mode`. For more information, see [set_tree_mode](#). For information about setting the wait time, see [set_wait_time](#).

By default, if you do not call this action, the default number of seconds that the scan action waits is zero. In this case, files are ingested as soon as they are present.

Returns

Always True.

Level

Batch level.

Details

This setting can be used to prevent premature ingestion of a file which may be incomplete. For example, a network scanner or multifunction device might create the image file and write contents over a period of time, rather than all at once. In that case ingesting the file immediately could cause errors, whereas waiting for 5 or 10 seconds would provide sufficient time for the file to be completed. If required, the appropriate value must be determined experimentally.

For this action to take effect, it must be called before the Scan action.

Example:

```
set_types("tif")
set_min_age("10")
scan()
```

Parent topic: [mvscan actions](#)

set_move_wait_time

Specifies the time to wait for a source file to be deleted after it is moved from to the batch folder.

Syntax

```
bool set_move_wait_time (int nSecs)
```

Parameters

int nSecs - Number of seconds to wait for the source file to be deleted before the action fails.

Returns

Always True.

Level

Batch level

Details

Over a slow network, and especially with large input files, moving files from the source folder to batch folder can take a significant length of time. The scan action checks that the source file was deleted after it was moved. If the source folder still exists, the scan action waits for a length of time periodically checking to see if the file was deleted.

If the folder still exists at the end of this time period, the copy in the batch folder is renamed with the extension .failed and it is not included in the batch. It is assumed that the original source file will be ingested by a subsequent scan task.

Example:

```
set_move_wait_time("120")
scan()
```

Parent topic: [mvscan actions](#)

set_multipage_burst

Forces multipage TIFF images to be split into single pages during ingestion.

Member of namespace

mvscan

Syntax

```
bool set_multipage_burst (bool bBurst)
```

Parameters

bBurst

Type: bool

Nonzero to force bursting of TIFF image files. Default = 0, no bursting.

Parameters

bBurst : A Boolean value that enables or disables bursting multipage image files during ingestion.

True: Any multipage TIFF file is separated into multiple pages in the batch, one per image.

False: One page is output per input file. This is the default if the action is not called.

Returns

Always True.

Level

Batch level.

Details

Enables splitting or bursting multipage source image files into one image per page in the batch. For this action to take effect, it must be called before the Scan action.

This action requires that `set_types()` be called with only one extension of TIF, TIFF, JPG or JPEG.

Example:

```
set_types(".tif")
set_multipage_burst(1)
scan()
```

If the scan action in this sequence encounters a multipage .tif file, it reads each one into the current batch as a separate image, thereby bursting the multipage file into individual images.

Parent topic: [mvscan actions](#)

set_problem_folder

Sets the folder into which the files that cannot be ingested are placed.

Member of namespace

mvscan

Syntax

```
bool set_problem_folder (string folderpath)
```

Parameters

folderpath

The folder to which the scan action moves files that it could not ingest. Specify a full or relative folder path. If you specify a relative path, the path is relative to the root input folder. For information about the root input folder, see [set_folder](#).

The location of the problem folder is affected by the `mv_retain_folder` action. For more information, see [mv_retain_folder](#).

Returns

Always True.

Level

Batch level.

Details

This action must be called before `scan()`. If this action is not called, and `scan` is unable to ingest a file, the batch is aborted. Files that are already ingested into the batch remain in the batch. The file that cannot be ingested might be in a locked state. Manual intervention is required.

Example:

```
set_folder("@APPPATH(vscanimagedir)+@STRING(\input folder)")
set_problem_folder(@APPPATH(vscanimagedir)+@STRING(\problem folder))
scan()
```

Parent topic: [mvscan actions](#)

set_sort_method

Selects method to use for sorting files for ingestion.

Member of namespace

mvscan

Syntax

```
bool set_sort_method (string method)
```

Parameters

method

Type: string

Sort method can be either DATE (default) or NAME. The parameter is not case sensitive.

Returns

Always True.

Level

Batch level Open event only.

Details

The scan action takes snapshots of the input folder, sorts the files by either date last modified (default) or by filename, and then tries to ingest the files in that order. This action allows you to override the default sort order.

Example:

```
set_sort_method("NAME")
Scan()
```

This sequence ingests files in alphabetical order.

Parent topic: [mvscan actions](#)

set_tree_mode

Determines whether subdirectories are included in the scan for files to ingest.

Member of namespace

mvscan

Syntax

```
bool set_tree_mode (bool bTreeFlag)
```

Parameters

bTreeFlag
Type: bool

Parameters

bTreeFlag : A Boolean value that enables or disables ingesting files from sub-folders within the top-level scan folder.

True: Search for files in subfolders to any depth under the scan folder. This is the default if the action is not called.

False: Ingest files that are located in the scan folder only. Ignore subfolders.

Details

If tree mode is enabled, each batch contains files from only one folder. Files from multiple folders are never ingested into the same batch.

For this action to take effect, it must be called before the Scan action.

Example:

```
set_types("tif")
set_tree_mode(True)
scan()
```

Parent topic: [mvscan actions](#)

set_types

Specifies the extensions of the file types to ingest in a comma-separated list of file extensions.

Member of namespace

mvscan

Syntax

```
bool set_types (string extensions)
```

Parameters

extensions

Type: string

Comma-separated list of file image file extensions to import

Parameters

String value of extension(s) of input files that should be ingested. For multiple types, separate each one with a comma. Any files with extensions not in this list are ignored. A smart parameter that evaluates to a file extension or list of extensions is accepted.

It is optional to include a period before each extension. The parameter is not case-sensitive.

Returns

Always True.

Level

Batch level Open event only.

Details

Uses the value of a file extension(s) to specify the type of files the task will scan.

This is an optional action: the task will scan .tif files by default. For this action to take effect, it must be called before the scan action.

This action overrides any previous call to `set_metadata_types()`, and causes files to be ingested without metadata.

Example:

```
set_types("tif,tiff,pdf")
scan()
```

This sequence ingests files ending with .tif, .tiff, and .pdf.

Parent topic: [mvscan actions](#)

set_wait_time

For batch creation purposes, specifies the maximum interval that the scan action waits for the arrival of more input files to add to a batch.

Important: This action can also affect the behavior of `set_min_age`. For more information, see [set_min_age](#).

Member of namespace

mvscan

Syntax

```
bool set_wait_time (int nSecs)
```

Parameters

nSecs

The maximum number of seconds to wait for files to complete a batch.

If you do not call this action, the default wait interval is 2 seconds.

Returns

Always True.

Level

Batch level.

Details

The maximum time to wait for input files to arrive, if at least one file was ingested, no more files are available, and the batch has not reached capacity. Ingestion of files into the batch stops when the wait limit is reached or when the maximum number of files per batch has been reached. If no files are available during the scan() action, and this time is reached, the scan action returns and the batch status remains pending.

Example:

```
set_wait_time("60")
scan()
```

Parent topic: [mvscan actions](#)

Maintenance Manager actions

The Maintenance Manager actions are divided into setup, batch processing, logging, and reporting categories.

The Maintenance Manager actions get connections to Datacap application databases and build query strings that run against these databases. These actions can also write logging information to Windows log files and send email messages that contain the log file. Maintenance Manager actions also write information to report tables in the Engine database for use by Datacap Report Viewer.

Embedded help is provided in Datacap Studio for all of the Maintenance Manager actions. To access the embedded help, select an action in the Actions Library tab and click information.

- [Application setup actions](#)
Use the Application setup actions to set up a connection from a Datacap application to Maintenance Manager.

- [Query setup actions](#)
Use the Query setup actions to build the query string that is run against the application databases that you connected to in the application setup.
- [Batch processing actions](#)
Use the Batch processing actions to run the SQL query and complete actions on the selected database records and, optionally, the corresponding batches.
- [Logging actions](#)
Use the Logging actions to write information to the Maintenance Manager and Windows log files and to send emails that contain the internal log file.
- [Reporting actions](#)
Use the Reporting actions to write information to the report tables in the Engine database for use by Datacap Report Viewer.

Parent topic: [Global actions](#)

Application setup actions

Use the Application setup actions to set up a connection from a Datacap application to Maintenance Manager.

The Application setup actions identify the name of the application and the Datacap Server to be used by Maintenance Manager. These actions also specify the login credentials, database information, and connection information that you need to connect a Datacap application to Maintenance Manager.

- [SetAdminDB](#)
Specifies the Administration database.
- [SetApplication](#)
Specifies the name of the Application used by Maintenance Manager.
- [SetEngineDB](#)
Specifies the Engine database.
- [SetPassword](#)
Action to set password to connect to the Server.
- [SetServer](#)
Specifies the name of the Datacap Server.
- [SetStation](#)
Action to set the station ID that is used to connect to the Server.
- [SetupDisconnectAll](#)
Disconnect from all Datacap servers.
- [SetupOpenApplication](#)
Creates connection to the application based on default settings.
- [SetupOpenApplicationEx](#)
Creates connection to the application based on the parameters provided.
- [SetUser](#)
Action to set a user name to login to the Server.

Parent topic: [Maintenance Manager actions](#)

SetAdminDB

Specifies the Administration database.

Member of namespace

Maintenance Manager

Syntax

```
bool SetAdminDB (string adminDB)
```

Parameters

adminDB
Type: string

Parameters

adminDB: Administration Database key in the Application Service. Smart parameters are supported.

Returns

Always True.

Level

Batch level.

Details

Obtains the Administrator database connection information from the application service. This is the default value used for the action SetupOpenApplication.

Example:

```
SetApplication("APT")
SetServer("Server 1")
SetAdminDB("*/tmadmin:cs")
SetEngineDB("*/tmengine:cs")
SetupOpenApplication("")
```

Parent topic: [Application setup actions](#)

Related reference:

[SetupOpenApplication](#)

[SetupOpenApplicationEx](#)

SetApplication

Specifies the name of the Application used by Maintenance Manager.

Member of namespace

Maintenance Manager

Syntax

```
bool SetApplication (string application)
```

Parameters

string application

Parameters

application: The application name. Smart parameters are supported.

Returns

False if the application name is missing. Otherwise, True.

Level

Batch level.

Details

Sets the name of the application, as defined in the application service, which are used by Maintenance Manager. The application determines the rules and databases that are used by subsequent actions. This will be the default value that is used for the SetupOpenApplication action.

Example:

```
SetApplication("APT")
SetServer("Server 1")
SetupOpenApplication("")
```

Parent topic: [Application setup actions](#)

Related reference:

[SetupOpenApplication](#)

[SetupOpenApplicationEx](#)

SetEngineDB

Specifies the Engine database.

Member of namespace

Maintenance Manager

Syntax

```
bool SetEngineDB (string engineDB)
```

Parameters

engineDB
Type: string

Parameters

engineDB: Engine Database key in the Application Service.

Returns

Always True.

Level

Batch level.

Details

Obtains the Engine database connection information from the application service. This will be the default value used for the action `SetupOpenApplication`.

Example:

```
SetApplication("APT")
SetServer("Server 1")
SetAdminDB("*/tmadmin:cs")
SetEngineDB("*/tmengine:cs")
SetUser("Admin")
```

Parent topic: [Application setup actions](#)

Related reference:

[SetupOpenApplication](#)

[SetupOpenApplicationEx](#)

SetPassword

Action to set password to connect to the Server.

Member of namespace

Maintenance Manager

Syntax

```
bool SetPassword (string password)
```

Parameters

String password

Parameters

password: Password. Smart parameters are supported.

Returns

Always True.

Level

Batch level.

Details

Specifies the password for the previously specified user ID. This will be the default value used for the SetupOpenApplication action.

When using LDAP or ADSI authentication, use the SetUser, SetStation, and SetApplication to login.

Example:

```
SetApplication("APT")
SetServer("Server 1")
SetAdminDB("*/tmadmin:cs")
SetEngineDB("*/tmengine:cs")
SetUser("Admin")
SetPassword("@APPVAR(values/adv/MyNENUPassword)")
SetupOpenApplication("")
```

This example uses the Smart Parameter @APPVAR to obtain the value of the password from the value name MyNENUPassword in the Custom Values tab of the Application Service Manager. The value name is configurable.

Parent topic: [Application setup actions](#)

Related reference:

[SetupOpenApplication](#)

[SetupOpenApplicationEx](#)

SetServer

Specifies the name of the Datacap Server.

Member of namespace

Maintenance Manager

Syntax

```
bool SetServer (string server)
```

Parameters

server

Type: string

Parameters

server: Server name. Smart parameters are supported.

Returns

False if a server name is not specified. Otherwise, True.

Level

Batch level.

Details

The name of the Datacap server as it is defined in the application service, which will be the server used by subsequent Maintenance Manager actions. This will be the default value used for the action SetupOpenApplication.

Example:

```
SetApplication("APT")
SetServer("Server 1")
SetupOpenApplication("")
```

Parent topic: [Application setup actions](#)

Related reference:

[SetupOpenApplication](#)

[SetupOpenApplicationEx](#)

SetStation

Action to set the station ID that is used to connect to the Server.

Member of namespace

Maintenance Manager

Syntax

```
bool SetStation (string station)
```

Parameters

string station

Parameters

station: Station ID. Smart parameters are supported.

Returns

Always True.

Level

Batch level.

Details

Specifies the station ID for login. This will be the default value that is used for the SetupOpenApplication action.

When using LDAP or ADSI authentication, use the SetUser, SetStation, and SetApplication to login.

Example:

```
SetApplication("APT")
SetServer("Server 1")
SetAdminDB("*/tmadmin:cs")
```

```
SetEngineDB ("*/tmengine:cs")
SetStation ("1")
SetupOpenApplication ("")
```

Parent topic: [Application setup actions](#)

Related reference:

[SetupOpenApplication](#)

[SetupOpenApplicationEx](#)

SetupDisconnectAll

Disconnect from all Datacap servers.

Member of namespace

Maintenance Manager

Syntax

```
bool SetupDisconnectAll ()
```

Parameters

None.

Returns

Always True.

Level

Any level.

Details

Closes the connections to all Datacap databases that were opened by Maintenance Manager actions. Some Maintenance Manager actions automatically close the connection to the database after a query has been performed.

Example:

```
SetupDisconnectAll ()
```

Parent topic: [Application setup actions](#)

SetupOpenApplication

Creates connection to the application based on default settings.

Member of namespace

Maintenance Manager

Syntax

```
bool SetupOpenApplication ()
```

Parameters

None.

Returns

True if the application exists in the application service the connection was successful. Otherwise, False.

Level

Batch level.

Details

A simplified version of `SetupOpenApplicationEx`. It is identical in operation with the difference that all of the default parameters are used. The default values can be set independently by individual actions, such as `SetApplication`, `SetServer`, etc. See `SetupOpenApplicationEx` for more information.

When using LDAP and LLDAP authentication the User, Password, and Station values must be blank.

Example:

```
SetApplication("APT")
SetServer("Server 1")
SetUser("user")
SetPassword("password")
SetAdminDB("* /tmadmin:cs")
SetEngineDB("* /tmengine:cs")
SetStation("1")
SetupOpenApplication()
```

Parent topic: [Application setup actions](#)

Related reference:

[SetupOpenApplicationEx](#)

[SetApplication](#)

[SetServer](#)

[SetAdminDB](#)

[SetEngineDB](#)

[SetUser](#)

[SetPassword](#)

[SetStation](#)

SetupOpenApplicationEx

Creates connection to the application based on the parameters provided.

Member of namespace

Maintenance Manager

Syntax

```
bool SetupOpenApplicationEx (string application, string server, string admin, string engine, bool debugFlag, string user, string password, string station)
```

Parameters

application
Type: string

server
Type: string

admin
Type: string

engine
Type: string

debugFlag
Type: bool

user
Type: string

password
Type: string

station
Type: string

Parameters

All parameters, except for debugFlag, support Smart parameters.

- application: Application name (Optional). Default value: the name of the application that is running this action.
- server: Server name (Optional). Default value: first available server in the application.
- admin: Administration database name (Optional). Default value: first available Admin DB.
- engine: Engine database name (Optional). Default value: first available Engine DB.
- debugFlag: Debug Flag (Optional). Default value: false.
- user: User name (Optional). Default value: current user credentials. Leave Blank for LDAP authentication.
- password: Password (Optional). Default value: current user credentials. Leave Blank for LDAP authentication.
- station: Station ID (Optional). Default value: Current station name. Leave Blank for LDAP authentication.

Returns

True, if the application exists in the application service the connection was successful. Otherwise, False.

Level

Batch level.

Details

Similar to SetupOpenApplication, this action connects Maintenance Manager to a specific application. The difference between the two actions is that here the default parameters can be overridden in one single action. These parameters determine what application is to be monitored by Maintenance Manager. This action, or

SetupOpenApplication, must be called first, then the Maintenance Manager actions can be used to run queries on the application and do required actions that are based on the results.

When you are using LDAP or ADSI authentication, use the SetUser, SetStation, and SetApplication actions instead of SetupOpenApplicationEx.

Example:

```
SetupOpenApplicationEX("Survey", "", "SurveyAdm.mdb", "SurveyEng.mdb", "False",  
"", "", "1")
```

Parent topic: [Application setup actions](#)

Related reference:

[SetupOpenApplication](#)

[SetApplication](#)

[SetServer](#)

[SetAdminDB](#)

[SetEngineDB](#)

[SetUser](#)

[SetPassword](#)

[SetStation](#)

SetUser

Action to set a user name to login to the Server.

Member of namespace

Maintenance Manager

Syntax

```
bool SetUser (string user)
```

Parameters

string user

Parameters

user: User name. Smart parameters are supported.

Returns

Always True.

Level

Batch level.

Details

Specifies the name of the user for the login to the Administrator and Engine databases. This will be the default value that is used for the SetupOpenApplication action.

When using LDAP or ADSI authentication, use the SetUser, SetStation, and SetApplication to login.

Example:

```
SetApplication("APT")
SetServer("Server 1")
SetAdminDB("*/tmadmin:cs")
SetEngineDB("*/tmengine:cs")
SetUser("Admin")
SetupOpenApplication("")
```

Parent topic: [Application setup actions](#)

Query setup actions

Use the Query setup actions to build the query string that is run against the application databases that you connected to in the application setup.

Before, you can run a query against the application databases, you must build an SQL query string. When you run the actions in this category, Maintenance Manager appends the corresponding SQL code to the current query string. For example, running `QuerySetStatus("hold")` followed by `QuerySetOperator("admin")` generates the following query string.

```
Select * FROM JobMonitor WHERE queue.qu_status IN ('hold') AND qstats.qs_op IN ('admin')
```

- [QueryClear](#)
Clears the SQL query.
- [QuerySetAge](#)
Selects batches based on age using a date or number of seconds.
- [QuerySetBatchRange](#)
Sets range of batches for SQL query.
- [QuerySetBranch](#)
Sets the minimum number of children for the SQL query.
- [QuerySetDateFormat](#)
Sets custom Date format for SQL queries.
- [QuerySetDateRange](#)
Sets Date range for SQL query.
- [QuerySetDateTimeFormat](#)
Sets custom DateTime format for SQL queries.
- [QuerySetGeneric](#)
Builds an SQL query using the provided column name and value.
- [QuerySetJobID](#)
Sets the Job ID for the SQL query.
- [QuerySetOperator](#)
Sets the operator for the SQL query.
- [QuerySetPriority](#)
Sets the Priority for the SQL query.
- [QuerySetSeparator](#)
Sets SQL Date and Time Separator for SQL queries.

- [QuerySetStation](#)
Sets the station for the SQL query.
- [QuerySetStatus](#)
Sets the Task status for the SQL query.
- [QuerySetTaskID](#)
Sets the Task ID for the SQL query.

Parent topic: [Maintenance Manager actions](#)

QueryClear

Clears the SQL query.

Member of namespace

Maintenance Manager

Syntax

```
bool QueryClear ()
```

Parameters

None.

Returns

True if the query is cleared. Otherwise, False.

Level

Any level.

Details

Clears any SQL query that may be in memory. This action can be called to ensure that any Maintenance Manager query that you build is not building on any previous information.

Example:

```
QueryClear ("")
```

Parent topic: [Query setup actions](#)

Related reference:
[ProcessRunSqlQuery](#)

QuerySetAge

Selects batches based on age using a date or number of seconds.

Member of namespace

Syntax

```
bool QuerySetAge (string age, bool queryAgeStart)
```

Parameters

age
Type: string

queryAgeStart
Type: bool

Parameters

- age: All dates prior or within this date will be selected. Smart parameters are supported.
- queryAgeStart: If True, age will use the start time of the batch. If False, age will use the end time of the batch.

Returns

True if the query has been successfully set. It does not mean the query has been performed. Otherwise, False.

Level

Any level.

Details

Builds a query that selects batches based on the age of a batch. The age can be specified using a date or in seconds. The queryAgeStart parameter determines if the age is based on the start of the batch, the qs_start column, or based on the end of the batch, the qu_done column. If a date is specified, all batches will be selected based on the date. If a number is specified, all batches will be selected based on the number of seconds.

To control the age range use the exclamation point '!'. When the exclamation point is not specified, the age between now and the specified value will be selected. When the exclamation point is specified, the ages that are older than the value specified will be selected.

Example:

```
QuerySetAge ("300", "True")  
ProcessRunSqlQuery ("")
```

This example selects all batches started within last 300 seconds.

```
QuerySetAge ("!300", "true")  
ProcessRunSqlQuery ("")
```

This example selects all batches started prior to 300 seconds ago. Use the same pattern when using dates.

QuerySetBatchRange

Sets range of batches for SQL query.

Member of namespace

Maintenance Manager

Syntax

```
bool QuerySetBatchRange (string start, string end)
```

Parameters

start

Type: string

end

Type: string

Parameters

- start: BatchID of the first batch in the range. Default value 00000000.000".
- end: BatchID of the last batch in the range. Default value zzzzzzzz.zzz".

Returns

True if the query has been successfully set. It does not mean the query has been performed. Otherwise, False.

Level

Any level.

Details

Allows selecting batch range based on the BatchID.

Example:

```
QuerySetBatchRange ("20110059.001", "20110059.010")  
InjectBatches ("20110059.001")
```

Parent topic: [Query setup actions](#)

Related reference:

[ProcessInjectBatches](#)

QuerySetBranch

Sets the minimum number of children for the SQL query.

Member of namespace

Maintenance Manager

Syntax

```
bool QuerySetBranch (int children)
```

Parameters

children
Type: int

Parameters

children: The minimum number of children for the batch.

Returns

True if the query has been successfully set. It does not mean the query has been performed. Otherwise, False.

Level

Any level.

Details

Selects all of the batches that have at least the minimum number of specified children.

Example:

```
QuerySetBranch ("3")  
ProcessRunSqlQuery ("")
```

Parent topic: [Query setup actions](#)

Related reference:
[ProcessRunSqlQuery](#)

QuerySetDateFormat

Sets custom Date format for SQL queries.

Member of namespace

Maintenance Manager

Syntax

```
bool QuerySetDateFormat (string dateFormat)
```

Parameters

dateFormat
Type: string

Parameters

dateFormat: Date format. Smart parameters are supported.

Returns

Always True.

Level

Any level.

Details

Configures the Date format used by the database. If this action is not called, the value for the Date format will be "yyyy/MM/dd". Detailed description of available values are:

- **d** Represents the day of the month as a number from 1 through 31. A single-digit day is formatted without a leading zero
- **dd** Represents the day of the month as a number from 01 through 31. A single-digit day is formatted with a leading zero
- **ddd** Represents the abbreviated name of the day of the week (Mon, Tues, Wed etc.)
- **dddd** Represents the full name of the day of the week (Monday, Tuesday etc.)
- **h** 12-hour clock hour (e.g. 7)
- **hh** 12-hour clock, with a leading 0 (e.g. 07)
- **H** 24-hour clock hour (e.g. 19)
- **HH** 24-hour clock hour, with a leading 0 (e.g. 19)
- **m** Minutes
- **mm** Minutes with a leading zero
- **M** Month number
- **MM** Month number with leading zero
- **MMM** Abbreviated Month Name (e.g. Dec)
- **MMMM** Full month name (e.g. December)
- **s** Seconds
- **ss** Seconds with leading zero
- **t** Abbreviated AM / PM (e.g. A or P)
- **tt** AM / PM (e.g. AM or PM)
- **y** Year, no leading zero (e.g. 2001 would be 1)
- **yy** Year, leading zero (e.g. 2001 would be 01)
- **yyy** Year (e.g. 2001 would be 001)
- **yyyy** Year (e.g. 2001 would be 2001)
- **K** Represents the time zone information of a date and time value (e.g. +05:00)
- **z** With DateTime values, represents the signed offset of the local operating system's time zone from Coordinated Universal Time (UTC), measured in hours. (e.g. +6)
- **zz** As z but with leading zero (e.g. +06)
- **zzz** With DateTime values, represents the signed offset of the local operating system's time zone from UTC, measured in hours and minutes. (e.g. +06:00)
- **f** Represents the most significant digit of the seconds fraction; that is, it represents the tenths of a second in a date and time value.
- **ff** Represents the two most significant digits of the seconds fraction; that is, it represents the hundredths of a second in a date and time value.
- **fff** Represents the three most significant digits of the seconds fraction; that is, it represents the milliseconds in a date and time value.
- **ffff** Represents the four most significant digits of the seconds fraction; that is, it represents the ten thousandths of a second in a date and time value. While it is possible to display the ten thousandths of a

second component of a time value, that value may not be meaningful. The precision of date and time values depends on the resolution of the system clock. On Windows NT 3.5 and later, and Windows Vista operating systems, the clock's resolution is approximately 10-15 milliseconds.

- **ffff** Represents the five most significant digits of the seconds fraction; that is, it represents the hundred thousandths of a second in a date and time value. While it is possible to display the hundred thousandths of a second component of a time value, that value may not be meaningful. The precision of date and time values depends on the resolution of the system clock. On Windows NT 3.5 and later, and Windows Vista operating systems, the clock's resolution is approximately 10-15 milliseconds.
- **ffffff** Represents the six most significant digits of the seconds fraction; that is, it represents the millionths of a second in a date and time value. While it is possible to display the millionths of a second component of a time value, that value may not be meaningful. The precision of date and time values depends on the resolution of the system clock. On Windows NT 3.5 and later, and Windows Vista operating systems, the clock's resolution is approximately 10-15 milliseconds.
- **fffffff** Represents the seven most significant digits of the seconds fraction; that is, it represents the ten millionths of a second in a date and time value. While it is possible to display the ten millionths of a second component of a time value, that value may not be meaningful. The precision of date and time values depends on the resolution of the system clock. On Windows NT 3.5 and later, and Windows Vista operating systems, the clock's resolution is approximately 10-15 milliseconds.
- **F** Represents the most significant digit of the seconds fraction; that is, it represents the tenths of a second in a date and time value. Nothing is displayed if the digit is zero.
- **:** Represents the time separator defined in the current `DateTimeFormatInfo...:TimeSeparator` property. This separator is used to differentiate hours, minutes, and seconds.
- **/** Represents the date separator defined in the current `DateTimeFormatInfo...:DateSeparator` property. This separator is used to differentiate years, months, and days.
- **"** Represents a quoted string (quotation mark). Displays the literal value of any string between two quotation marks ("). Your application should precede each quotation mark with an escape character (\).
- **'** Represents a quoted string (apostrophe). Displays the literal value of any string between two apostrophe (') characters.
- **%c** Represents the result associated with a c custom format specifier, when the custom date and time format string consists solely of that custom format specifier. That is, to use the d, f, F, h, m, s, t, y, z, H, or M custom format specifier by itself, the application should specify %d, %f, %F, %h, %m, %s, %t, %y, %z, %H, or %M. For more information about using a single format specifier, see [Using Single Custom Format Specifiers](#).

Example:

```
QuerySetDateFormat ("dd-MMM-yy")
```

[QuerySetDateTimeFormat](#)

QuerySetDateRange

Sets Date range for SQL query.

Member of namespace

Maintenance Manager

Syntax

```
bool QuerySetDateRange (string start, string end, bool queryAgeStart)
```

Parameters

start
Type: string

end
Type: string

queryAgeStart
Type: bool

Parameters

- start: Date Range Start. Smart parameters are supported.
- end: Date Range End. Smart parameters are supported.
- queryAgeStart: True will use the batch start date. False will use the batch end date.

Returns

True if the query has been successfully set. It does not mean the query has been performed. Otherwise, False.

Level

Any level.

Details

Selects all of the batches that match the specified priority. If queryAgeStart is set to True, the query uses the batch start date, qs_start. If queryAgeStart is set to False, the query uses the batch end date, qu_done.

An exclamation point can be prefixed to the value to find all values except the ones specified.

Example:

```
QuerySetDateRange ("03/16/2010", "05/26/2010", "True")  
ProcessRunSqlQuery ("")
```

This example selects all of the batches that were created between the two specified dates.

```
QuerySetDateRange ("03/16/2010", "@DATE (mm/dd/yyyy) ", "True")  
ProcessRunSqlQuery ("")
```

This example uses a Smart parameter to obtain the current date. The query selects all batches that have been created between 03/16/2010 and the current date.

Parent topic: [Query setup actions](#)

Related reference:
[ProcessRunSqlQuery](#)

QuerySetDateTimeFormat

Sets custom DateTime format for SQL queries.

Member of namespace

Syntax

```
bool QuerySetDateTimeFormat (string dateTimeFormat)
```

Parameters

dateTimeFormat
Type: string

Parameters

dateTimeFormat: DateTime format. Smart parameters are supported.

Returns

Always True.

Level

Any level.

Details

Configures the Date and Time format used by the database. If this action is not called, the value for the Date format is yyyy/MM/dd HH:mm:ss. Detailed description of available values are:

- **d** Represents the day of the month as a number from 1 through 31. A single-digit day is formatted without a leading zero
- **dd** Represents the day of the month as a number from 01 through 31. A single-digit day is formatted with a leading zero
- **ddd** Represents the abbreviated name of the day of the week (Mon, Tues, Wed etc.)
- **dddd** Represents the full name of the day of the week (Monday, Tuesday etc.)
- **h** 12-hour clock hour (e.g. 7)
- **hh** 12-hour clock, with a leading 0 (e.g. 07)
- **H** 24-hour clock hour (e.g. 19)
- **HH** 24-hour clock hour, with a leading 0 (e.g. 19)
- **m** Minutes
- **mm** Minutes with a leading zero
- **M** Month number
- **MM** Month number with leading zero
- **MMM** Abbreviated Month Name (e.g. Dec)
- **MMMM** Full month name (e.g. December)
- **s** Seconds
- **ss** Seconds with leading zero
- **t** Abbreviated AM / PM (e.g. A or P)
- **tt** AM / PM (e.g. AM or PM)
- **y** Year, no leading zero (e.g. 2001 would be 1)
- **yy** Year, leading zero (e.g. 2001 would be 01)
- **yyy** Year (e.g. 2001 would be 001)
- **yyyy** Year (e.g. 2001 would be 2001)
- **K** Represents the time zone information of a date and time value (e.g. +05:00)

- **z** With DateTime values, represents the signed offset of the local operating system's time zone from Coordinated Universal Time (UTC), measured in hours. (e.g. +6)
- **zz** As z but with leading zero (e.g. +06)
- **zzz** With DateTime values, represents the signed offset of the local operating system's time zone from UTC, measured in hours and minutes. (e.g. +06:00)
- **f** Represents the most significant digit of the seconds fraction; that is, it represents the tenths of a second in a date and time value.
- **ff** Represents the two most significant digits of the seconds fraction; that is, it represents the hundredths of a second in a date and time value.
- **fff** Represents the three most significant digits of the seconds fraction; that is, it represents the milliseconds in a date and time value.
- **ffff** Represents the four most significant digits of the seconds fraction; that is, it represents the ten thousandths of a second in a date and time value. While it is possible to display the ten thousandths of a second component of a time value, that value may not be meaningful. The precision of date and time values depends on the resolution of the system clock. On Windows NT 3.5 and later, and Windows Vista operating systems, the clock's resolution is approximately 10-15 milliseconds.
- **fffff** Represents the five most significant digits of the seconds fraction; that is, it represents the hundred thousandths of a second in a date and time value. While it is possible to display the hundred thousandths of a second component of a time value, that value may not be meaningful. The precision of date and time values depends on the resolution of the system clock. On Windows NT 3.5 and later, and Windows Vista operating systems, the clock's resolution is approximately 10-15 milliseconds.
- **ffffff** Represents the six most significant digits of the seconds fraction; that is, it represents the millionths of a second in a date and time value. While it is possible to display the millionths of a second component of a time value, that value may not be meaningful. The precision of date and time values depends on the resolution of the system clock. On Windows NT 3.5 and later, and Windows Vista operating systems, the clock's resolution is approximately 10-15 milliseconds.
- **fffffff** Represents the seven most significant digits of the seconds fraction; that is, it represents the ten millionths of a second in a date and time value. While it is possible to display the ten millionths of a second component of a time value, that value may not be meaningful. The precision of date and time values depends on the resolution of the system clock. On Windows NT 3.5 and later, and Windows Vista operating systems, the clock's resolution is approximately 10-15 milliseconds.
- **F** Represents the most significant digit of the seconds fraction; that is, it represents the tenths of a second in a date and time value. Nothing is displayed if the digit is zero.
- **:** Represents the time separator defined in the current DateTimeFormatInfo / TimeSeparator property. This separator is used to differentiate hours, minutes, and seconds.
- **/** Represents the date separator defined in the current DateTimeFormatInfo / DateSeparator property. This separator is used to differentiate years, months, and days.
- **"** Represents a quoted string (quotation mark). Displays the literal value of any string between two quotation marks ("). Your application should precede each quotation mark with an escape character (\).
- **'** Represents a quoted string (apostrophe). Displays the literal value of any string between two apostrophe (') characters.
- **%c** Represents the result associated with a c custom format specifier, when the custom date and time format string consists solely of that custom format specifier. That is, to use the d, f, F, h, m, s, t, y, z, H, or M custom format specifier by itself, the application should specify %d, %f, %F, %h, %m, %s, %t, %y, %z, %H, or %M. For more information about using a single format specifier, see Using Single Custom Format Specifiers.

Example:

```
QuerySetDateFormat("dd-MMM-yy hh:mm:ss tt")
```

Parent topic: [Query setup actions](#)

[ProcessRunSqlCommand](#)

QuerySetGeneric

Builds an SQL query using the provided column name and value.

Member of namespace

Maintenance Manager

Syntax

```
bool QuerySetGeneric (string column, string value)
```

Parameters

column

Type: string

value

Type: string

Parameters

- column: Column in the database table to query. Smart parameters are supported.
- value: Value to match within the specified column. Smart parameters are supported.

Returns

True if the query has been successfully set. It does not mean the query has been performed. Otherwise, False.

Level

Any level.

Details

Allows building of a query where the column and value of the tmbatch, queue or qstats table are explicitly specified.

Any wild card specified in the value parameter would need to be appropriate for your target database. The column value is not validated until the query is run using ProcessRunSqlQuery.

Example:

```
QuerySetGeneric("pb_userid", "admin")  
ProcessRunSqlQuery("")
```

Parent topic: [Query setup actions](#)

Related reference:

[ProcessRunSqlQuery](#)

QuerySetJobID

Sets the Job ID for the SQL query.

Member of namespace

Maintenance Manager

Syntax

```
bool QuerySetJobID (string jobid)
```

Parameters

jobid
Type: string

Parameters

jobid: Job name. Smart parameters are supported.

Returns

True, if the query is successfully set. It does not mean that the query has been performed. Otherwise, True.

Level

Any level.

Details

When you are building a query, this action sets the job ID that is selected in the result set. If you want to match multiple job IDs, use commas to separate values. An exclamation point can be used to negate the query.

Example:

```
QuerySetJobID("Demo Job, Web Job")  
ProcessRunSqlQuery("")
```

This example creates a result set that contains batches with job ID of `Demo Job` and `Web Job`.

```
QuerySetJobID("Demo Job")  
QuerySetJobID("Web Job")  
ProcessRunSqlQuery("")
```

This example creates an empty result set.

```
QuerySetJobID("!Demo Job")  
ProcessRunSqlQuery("")
```

This example creates a result set that contains all batches except for the job ID of `Demo Job`.

Parent topic: [Query setup actions](#)

Related reference:
[ProcessRunSqlQuery](#)

QuerySetOperator

Sets the operator for the SQL query.

Member of namespace

Maintenance Manager

Syntax

```
bool QuerySetOperator (string operator)
```

Parameters

operator
Type: string

Parameters

operator: The operator ID. Smart parameters are supported.

Returns

True if the query has been successfully set. It does not mean the query has been performed. Otherwise, False.

Level

Any level.

Details

Selects all of the batches that match the specified operator ID.

To find multiple values, separate them with commas. An exclamation point can be prefixed to the value to find all values except the ones specified.

Example:

```
QuerySetOperator ("Admin")  
ProcessRunSqlQuery ("")
```

Parent topic: [Query setup actions](#)

Related reference:
[ProcessRunSqlQuery](#)

QuerySetPriority

Sets the Priority for the SQL query.

Member of namespace

Maintenance Manager

Syntax

```
bool QuerySetPriority (string priority)
```

Parameters

priority
Type: string

Parameters

priority: Batch Priority.

Returns

True if the query has been successfully set. It does not mean the query has been performed. Otherwise, False.

Level

Any level.

Details

Selects all of the batches that match the specified priority.

To find multiple values, separate them with commas. An exclamation point can be prefixed to the value to find all values except the ones specified.

Example:

```
QuerySetPriority("1")  
ProcessRunSqlQuery("")
```

Parent topic: [Query setup actions](#)

Related reference:
[ProcessRunSqlQuery](#)

QuerySetSeparator

Sets SQL Date and Time Separator for SQL queries.

Member of namespace

Maintenance Manager

Syntax

```
bool QuerySetSeparator (string separator)
```

Parameters

separator
Type: string

Parameters

separator: Date separator. Smart parameters are supported.

Returns

Always True.

Level

Any level.

Details

Configures the Date and Time separator that is used by the database. If this action is not called, the value for the separator is selected based on the connection string. Some database separators are MS SQL " ' ", Oracle " ' ", Access "#".

Example:

```
QuerySetSeparator("#")
```

Parent topic: [Query setup actions](#)

Related reference:
[ProcessRunSqlQuery](#)

QuerySetStation

Sets the station for the SQL query.

Member of namespace

Maintenance Manager

Syntax

```
bool QuerySetStation (string station)
```

Parameters

station
Type: string

Parameters

station: The station ID. Smart parameters are supported.

Returns

True if the query has been successfully set. It does not mean the query has been performed. Otherwise, False.

Level

Any level.

Details

Selects all of the batches that match the specified station.

To find multiple values, separate them with commas. An exclamation point can be prefixed to the value to find all values except the ones specified.

Example:

```
QuerySetStation("1")
ProcessRunSqlQuery("")
```

Parent topic: [Query setup actions](#)

Related reference:

[ProcessRunSqlQuery](#)

QuerySetStatus

Sets the Task status for the SQL query.

Member of namespace

Maintenance Manager

Syntax

```
bool QuerySetStatus (string status)
```

Parameters

status

Type: string

Parameters

status: The batch status: aborted, cancelled, finished, hold, job done, pending, running. Smart parameters are supported.

Returns

True if the query has been successfully set. It does not mean the query has been performed. Otherwise, False.

Level

Any level.

Details

Selects all of the batches that match the specified status.

To find multiple values, separate them with commas. An exclamation point can be prefixed to the value to find all values except the ones specified.

Example:

```
QuerySetStatus("finished")
ProcessRunSqlQuery("")
```

Parent topic: [Query setup actions](#)

Related reference:

[ProcessRunSqlQuery](#)

QuerySetTaskID

Sets the Task ID for the SQL query.

Member of namespace

Maintenance Manager

Syntax

```
bool QuerySetTaskID (string taskid)
```

Parameters

taskid

Type: string

Parameters

taskid: Task ID. Smart parameters are supported.

Returns

True if the query has been successfully set. It does not mean the query has been performed. Otherwise, False.

Level

Any level.

Details

When building a query, this action sets the task ID that is selected in the result set. The current task batches selected will match the supplied value.

To find multiple values, separate them with commas. An exclamation point can be prefixed to the value to find all values except the ones specified.

Example:

```
QuerySetTaskID("Verify")
ProcessRunSqlQuery("")
```

This example queries all batches for the survey application that are at the verify task.

```
QuerySetTaskID("@B.MyQueryTask")
ProcessRunSqlQuery("")
```

This example uses Smart parameters to retrieve the name of the task to query from a batch level variable called *MyQueryTask*.

Parent topic: [Query setup actions](#)

Related reference:
[ProcessRunSqlQuery](#)

Batch processing actions

Use the Batch processing actions to run the SQL query and complete actions on the selected database records and, optionally, the corresponding batches.

The ProcessRunSqlQuery action runs the current query string and generates a recordset that contains information about all matching batches. For example, if you build a query by using `QuerySetStatus("hold")` and your query locates one batch with status hold. The returned recordset contains the following information that is aggregated from the tmbatch, qstats, and queue tables.

```
<rs:data xmlns:rs="urn:schemas-microsoft-com:rowset"><z:row pb_adjustdocs="0"
pb_adjustpages="0" pb_batch="20100260.001"
pb_batchdir="C:\Datacap\APT\batches\20100260.001" pb_expectdocs="0" pb_expectpgs="8"
pb_headertable=" " pb_ndocs="0" pb_needMeet="0" pb_pagefile="rrsvscan.xml"
pb_pages="8" qs_elaps="8" qs_op="admin"
qs_gid="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcaca00
4_3" qs_start="2010-09-17T07:35:26"
qs_station="2" qs_stop="2010-09-17T07:35:34"
qs_taskid="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcac
a004_VScan" qs_tsorder="0"
qu_admDB="156" qu_batch="20100260.001" qu_counter="0" qu_done="2010-09-17T07:35:34"
qu_elaps="8"
qu_id="_dcs_markdown_workspace_Transform_htmlout_0_com.ibm.dc.reference.doc_dcaca004
_3" qu_job="Demo" qu_lock="none" qu_parent="0" qu_priority="5"
qu_spawntype="0" qu_start="2010-09-17T07:35:26" qu_status="hold" qu_task="VScan"
qu_tsorder="0" xmlns:z="#RowsetSchema" /></rs:data>
```

The other actions in the batch processing category can manipulate the batches that are identified in the query results record set.

- [ProcessChangeBatchStatus](#)
Changes the status of one or more batches.
- [ProcessChangeBatchStatusOrder](#)
Changes batch status and order.
- [ProcessChangeBatchStatusTaskOrder](#)
Changes batch status, task and order.
- [ProcessClearAuditTable](#)
Clears the Audit table located in the admin database.
- [ProcessClearDebugTable](#)
Clears the Debug table located in the engine database.
- [ProcessDeleteBatchesEx](#)
Delete selected batches.
- [ProcessInjectBatches](#)
Injects the data from master batch to all batches selected and updates DB.
- [ProcessMoveBatchesEx](#)
Move selected batches to folder specified in the parameter.
- [ProcessMoveDBRecords](#)
Creates connection to the application based on the parameters that are provided and moves selected database data to this application.

- [ProcessResetPendingOrNotify](#)
Resets all selected batches to `Pending` status.
- [ProcessRunSqlQueryEx](#)
Runs the previously defined Maintenance Manager query. Use this action as an alternative to `ProcessRunSqlQuery`.

Parent topic: [Maintenance Manager actions](#)

ProcessChangeBatchStatus

Changes the status of one or more batches.

Member of namespace

Maintenance Manager

Syntax

```
bool ProcessChangeBatchStatus (string newStatus)
```

Parameters

`newStatus`
Type: string

Parameters

`newStatus`: The new batch status: aborted, cancelled, finished, hold, job done, pending, running. Smart parameters are supported.

Returns

True if the batch status is successfully changed. Otherwise, False.

Level

Batch level.

Details

Using the results from a previous query performed by Maintenance Manager actions, the selected batches have their status attribute changed.

The database connection is closed by this action.

Example:

```
QuerySetStation("1")  
QuerySetJobID("!Demo Job")  
ProcessRunSqlQuery("")  
ProcessChangeBatchStatus("hold")
```

Parent topic: [Batch processing actions](#)

ProcessChangeBatchStatusOrder

Changes batch status and order.

Member of namespace

Maintenance Manager

Syntax

```
bool ProcessChangeBatchStatusOrder (string newStatus, int newOrder)
```

Parameters

newStatus
Type: string
newOrder
Type: int

Parameters

- newStatus: The new batch status: aborted, cancelled, finished, hold, job done, pending, running. Smart parameters are supported.
- newOrder: New task order, zero-based index of task inside its job.

Returns

True if the batch status is successfully changed. Otherwise, False.

Level

Batch level.

Details

Using the results from a previous query performed by Maintenance Manager actions, the selected batches have their status and order attributes changed.

The database connection is closed by this action.

Example:

```
ProcessChangeBatchStatusOrder("hold", "1")
```

Parent topic: [Batch processing actions](#)

ProcessChangeBatchStatusTaskOrder

Changes batch status, task and order.

Member of namespace

Syntax

```
bool ProcessChangeBatchStatusTaskOrder (string newStatus, int newOrder, string newTask)
```

Parameters

newStatus
Type: string

newOrder
Type: int

newTask
Type: string

Parameters

- newStatus: The new batch status: aborted, cancelled, finished, hold, job done, pending, running. Smart parameters are supported.
- newOrder: The order of the new task, zero-based index of task inside its job.
- newTask: The name of the new task.

Returns

True if the batch status is successfully changed. Otherwise, False.

Level

Batch level.

Details

Using the results from a previous query performed by Maintenance Manager actions, the selected batches have their status, order and task attributes changed.

The database connection will be closed by this action.

Example:

```
QuerySetStation("1")  
QuerySetJobID("!Demo Job")  
ProcessRunSqlQuery("")  
ProcessChangeBatchStatusTaskOrder("hold", "1", "Verify")
```

Parent topic: [Batch processing actions](#)

ProcessClearAuditTable

Clears the Audit table located in the admin database.

Member of namespace

Maintenance Manager

Syntax

```
bool ProcessClearAuditTable ()
```

Parameters

None.

Returns

True if the table is cleared. Otherwise, False.

Level

Any level.

Details

Clears the Audit table located in the admin database. This action can be called to ensure that Audit table is cleared when information is moved from one database to another.

Example:

```
ProcessClearAuditTable ("")
```

Parent topic: [Batch processing actions](#)

Related reference:

[ProcessClearDebugTable](#)

ProcessClearDebugTable

Clears the Debug table located in the engine database.

Member of namespace

Maintenance Manager

Syntax

```
bool ProcessClearDebugTable ()
```

Parameters

None.

Returns

True if the table is cleared. Otherwise, False.

Level

Any level.

Details

Clears the Debug table located in the engine database. This action can be called to ensure that Debug table is cleared when information is moved from one database to another.

Example:

```
ProcessClearDebugTable ("")
```

Parent topic: [Batch processing actions](#)

Related reference:

[ProcessClearAuditTable](#)

ProcessDeleteBatchesEx

Delete selected batches.

Member of namespace

Maintenance Manager

Syntax

```
bool ProcessDeleteBatchesEx (bool deleteSubFolders, bool preserveEngineDBRecords)
```

Parameters

deleteSubFolders

Type: bool

preserveEngineDBRecords

Type: bool

Parameters

- deleteSubFolders: True deletes any sub-folders within batch directories regardless of creation source.
- preserveEngineDBRecords: True retains engine database records (only batch directories are deleted).

Returns

True if the batches are deleted. Otherwise False.

Level

Any level.

Details

Using the results from a previous query performed by Maintenance Manager actions, the selected batches are deleted from disk.

A previous query must have been run to identify the batches to delete. The database connection is closed by this action.

Example:

```
QuerySetStation("1")
QuerySetJobID("!Demo Job")
ProcessRunSqlQuery("")
ProcessDeleteBatchesEx("false, false")
```

Parent topic: [Batch processing actions](#)

Related reference:

[ProcessMoveBatchesEx](#)

[ProcessMoveDBRecords](#)

ProcessInjectBatches

Injects the data from master batch to all batches selected and updates DB.

Member of namespace

Maintenance Manager

Syntax

```
bool ProcessInjectBatches (string masterBatchID)
```

Parameters

masterBatchID
Type: string

Parameters

masterBatchID: Master batch to copy data from.

Returns

True if all the all the batches were successfully set. Otherwise, False.

Level

Any level.

Details

Allows creating large set of batches at some predefined state.

Example:

```
QuerySetBatchRange("20110059.001", "20110059.010")
InjectBatches("20110059.001")
```

Parent topic: [Batch processing actions](#)

Related reference:

[QuerySetBatchRange](#)

ProcessMoveBatchesEx

Move selected batches to folder specified in the parameter.

Member of namespace

Maintenance Manager

Syntax

```
bool ProcessMoveBatchesEx (string pathTo, bool moveSubFolders, bool preserveEngineDBPaths, bool continueOnError)
```

Parameters

pathTo
Type: string

moveSubFolders
Type: bool

preserveEngineDBPaths
Type: bool

continueOnError
Type: bool

Parameters

- pathTo: The destination directory for the batches. Smart parameters are supported.
- moveSubFolders: True moves any subfolders within batch directories regardless of creation source. This parameter is required if the batches contain subfolders or else operations, including database updates, will fail.
- preserveEngineDBPaths: True preserves original batch directory paths inside the engine database.
- continueOnError: True continues processing if any single batch fails to be moved with non-fatal error.

Returns

True, if the batches are successfully moved. Otherwise, False.

Level

Any level.

Details

Using the results from a previous query that is performed by Maintenance Manager actions, the selected batches are moved to the specified destination directory. A previous query must first be run to identify the batches to move to the new directory. The destination directory must exist. The database connection is closed by this action.

If you are moving batches from one location to another and also moving database records from one database to another, move the batches first. The movement of the database records must be done last.

Examples

The following example runs a query to select all batches from station "1" where the Job ID does not equal "Demo Job", then moves the batches to a directory called "My Old Batches".

```
QuerySetStation("1")
QuerySetJobID("!Demo Job")
ProcessRunSqlQuery("")
ProcessMoveBatchesEx("@STRING(C:\My Old Batches\), false, false, false")
```

This following example selects the same set of batches but it uses a Smart parameter to obtain the full path to directory from the Application Service. A key called BatchArchiveDirectory must exist in the Application Service. If these rules are used for multiple applications, each application can have a unique definition of this value within the Application Service, making these rules flexible.

One benefit of this approach is that in an environment where there is a test system and a production system, each system will have unique values stored in the Application Service. Each of the environments can have a different physical directory specified within the Application Service, allowing the rules in each system to remain identical.

```
QuerySetStation("1")
QuerySetJobID("!Demo Job")
ProcessRunSqlQuery("")
ProcessMoveBatchesEx("@APPPATH(BatchArchiveDirectory), false, false, false")
```

Parent topic: [Batch processing actions](#)

Related reference:

[ProcessDeleteBatchesEx](#)

[ProcessMoveDBRecords](#)

ProcessMoveDBRecords

Creates connection to the application based on the parameters that are provided and moves selected database data to this application.

Member of namespace

Maintenance Manager

Syntax

```
bool ProcessMoveDBRecords (string application, string server, string admin, string engine, bool debugFlag, string user, string password, string station, bool deleteOriginal, string targetDBSQLSeparator)
```

Parameters

application
Type: string

server
Type: string

admin
Type: string

engine
Type: string

debugFlag
Type: bool

user
Type: string
password
Type: string
station
Type: string
deleteOriginal
Type: bool
targetDBSQLSeparator
Type: string

Parameters

- application: Application name (Optional). Default value: the name of the application that is running this action.
- server: Server name (Optional). Default value: first available server in the application.
- admin: Administration database name (Optional). Default value: first available Admin DB.
- engine: Engine database name (Optional). Default value: first available Engine DB.
- debugFlag: Debug Flag (Optional). Default value: false.
- user: User name (Optional). Default value: current user credentials.
- password: Password (Optional). Default value: current user credentials.
- station: Station ID (Optional). Default value: Current station name
- deleteOriginal: Delete database records in source database.
- targetDBSQLSeparator: Target database date and time separator (Optional). If blank, that action tries to detect the correct separator that is based on the connection string.

Returns

Always True.

Level

Any level.

Details

Creates connection to the application based on the parameters that are provided and moves selected database data to this application. When you are performing operations on a batch and you are moving the database records from one database to another, do the database move operation last. When database records are moved, the database connection is still connected to the original database. Subsequent operations are on the original database, not the records in the new database.

Example:

```
ProcessMoveDBRecords("APTBack","tms","admin","engine","false","admin","admin","1","true","")
```

In this example, the source database is Oracle and the target is Access.

Parent topic: [Batch processing actions](#)

Related reference:

[ProcessMoveBatchesEx](#)

[ProcessDeleteBatchesEx](#)

ProcessResetPendingOrNotify

Resets all selected batches to `Pending` status.

Member of namespace

Maintenance Manager

Syntax

```
bool ProcessResetPendingOrNotify (int threshold, bool asattachment, string addressFrom, string addressTo, string subject, string user, string password, string domain, string server, string port)
```

Parameters

`threshold`
Type: int

`asattachment`
Type: bool

`addressFrom`
Type: string

`addressTo`
Type: string

`subject`
Type: string

`user`
Type: string

`password`
Type: string

`domain`
Type: string

`server`
Type: string

`port`
Type: string

Parameters

All parameters, except for `threshold`, support Smart parameters.

- `threshold`: Maximum number of attempts to reset the batch to status 'Pending'.
- `asattachment`: Send the log as attachment to the email.
- `addressFrom`: Address From (Optional). Default value: `currentUser@currentDomain`.
- `addressTo`: The email recipient. If multiple recipients, separate by using a comma.
- `subject`: Email subject (Optional). Default value: `'NENU notification current_date_and_time'`.
- `user`: Mail user name (Optional). Default value: current user credentials.
- `password`: Mail user password (Optional). Default value: current user credentials.
- `domain`: Mail user domain (Optional). Default value: current domain.
- `server`: Mail Server name (Optional). Default value: `mail.current_domain`.
- `port`: Mail Server Port number (Optional). Default value: 25.

Returns

True, if the email is sent. Otherwise, False.

Level

Any level.

Details

Resets the status of all batches that are selected by a previous SQL query to Pending status. The action attempts to reset the batch by the amount that is specified in the threshold parameter. If the maximum reset attempts are reached, the action sends an email, along with the log, to the provided list of recipients.

Example:

```
QuerySetStation("1")
QuerySetJobID("!Demo Job")
ProcessRunSqlQuery("")
ProcessResetPendingOrNotify("3", "rrodrig@somewhere.com",
"tom@somewhere.com,john@somewhere.com","","","","","","")
```

Parent topic: [Batch processing actions](#)

ProcessRunSqlQueryEx

Runs the previously defined Maintenance Manager query. Use this action as an alternative to ProcessRunSqlQuery.

Member of namespace

Maintenance Manager

Syntax

```
bool ProcessRunSqlQueryEx (int minRecords, int maxRecords)
```

Parameters

minRecords

The minimum number of record results that are required for this action to return True.

maxRecords

The maximum number of record results that are required for this action to return True. To indicate no maximum, specify -1 for the parameter value.

Returns

True in the following circumstances:

- The query is successful.
- The number of record results is within the specified range.

Otherwise, this action returns False.

Level

Any level.

Details

Use this action as an alternative to `ProcessRunSqlQuery` for finding batches. Unlike `ProcessRunSqlQuery`, this action can return `False` if the number of found batches is not as expected. The behavior of this action is the same as `ProcessRunSqlQuery` in the following ways:

Query definition	Use the query setup actions to define the SQL query that this action runs. For example, use <code>QueryClear</code> to clear the SQL query. To output the query statement, use <code>LogWriteSQLQuery</code> .
Result set processing	Use other batch processing actions to act upon the records that are returned by this action. To write out the result set for debugging purposes, use <code>LogWriteRecordSet</code> .

Example:

```
QuerySetStation("1")
QuerySetJobID("!Demo Job")
ProcessRunSqlQueryEx(1,-1)
```

In this example, the query results consist of the batches that were run on station “1” except for any “Demo Job” batches. If at least one such batch is found, the `ProcessRunSqlQueryEx` action returns `True`.

Parent topic: [Batch processing actions](#)

Related reference:

[Batch processing actions](#)

[LogWriteRecordSet](#)

[LogWriteSQLQuery](#)

[Query setup actions](#)

Logging actions

Use the Logging actions to write information to the Maintenance Manager and Windows log files and to send emails that contain the internal log file.

During rule execution, Maintenance Manager writes status messages to an internal log file and the Rulerunner log file.

- The internal log file is maintained in memory and is used by the `SendEmail` action.
- The Rulerunner log file is stored in the `application_name > batches > Maintenance Manager` folder.
- [LogClear](#)
Clears current Log.
- [LogConfigure](#)
Configures features of aTM logging.
- [LogSendEmail](#)
Sends email with log to comma-separated list of recipients.
- [LogWriteEventLog](#)
Writes a message to the Event Log.
- [LogWriteRecordSet](#)
Outputs the results of `ProcessRunSqlQuery` to the error log.

- [LogWriteSQLQuery](#)
Outputs the constructed SQL query to the error log.

Parent topic: [Maintenance Manager actions](#)

LogClear

Clears current Log.

Member of namespace

Maintenance Manager

Syntax

```
bool LogClear ()
```

Parameters

None.

Returns

Always True.

Level

Any level.

Details

Clears current log.

Example:

```
LogClear ()
```

Parent topic: [Logging actions](#)

LogConfigure

Configures features of aTM logging.

Member of namespace

Maintenance Manager

Syntax

```
bool LogConfigure (int severity, string filePath, bool overwrite, bool reflash, bool showTime, bool showDate, bool showSeverity)
```

Parameters

severity

Type: int

The log severity limit [0-9]. 0 = maximum logging. 4 or 5 = typically informational or error logging.

filePath

Type: string

Log file path name or blank to disable logging. Smart parameters are supported.

overwrite

Type: bool

True overwrites any existing file.

reflash

Type: bool

True flushes the error message buffer to disk after every write.

showTime

Type: bool

True adds the current time to each log message.

showDate

Type: bool

True adds the current date to each log message.

showSeverity

Type: bool

True adds the severity to the log.

Returns

True if logging is successfully configured. Otherwise, False.

Level

Any level.

Details

Configures aTM logging. The severity controls verbosity of the log; logging only severe errors will provide the best performance at expense of reduced debugging information, should a debug trace be required.

This will not change logging as configured for each of the tasks in the target application (i.e. RRS logs). If this action is not called, no aTM log file will be created. aTM logging can be evaluated to see which requests were transmitted to the Maintenance Manager Server.

Example:

```
LogConfigure("5", "@STRING(C:\ParentDir\NENU\Logs\NENU.aTM)")
```

In this example, rolling 'NENU.aTM.#.log' logs is placed into the custom directory.

```
LogConfigure("5", "@APPPATH(export)")
```

In this example, the output directory is retrieved from the application service using Smart parameters. The path is the export directory for the current application.

Parent topic: [Logging actions](#)

LogSendEmail

Sends email with log to comma-separated list of recipients.

Member of namespace

Maintenance Manager

Syntax

```
bool LogSendEmail (bool asattachment, string addressFrom, string addressTo, string subject, string user, string password, string domain, string server, string port)
```

Parameters

asattachment
 Type: bool
addressFrom
 Type: string
addressTo
 Type: string
subject
 Type: string
user
 Type: string
password
 Type: string
domain
 Type: string
server
 Type: string
port
 Type: string

Parameters

All parameters support Smart parameters.

- asattachment: Send the log as attachment to the email.
- addressFrom: Address From (Optional). Default value: currentUser@currentDomain.
- addressTo: Comma-separated list of recipients.
- subject: email subject (Optional). Default value: 'NENU notification current_date_and_time'.
- user: Mail user name (Optional). Default value: current user credentials.
- password: Mail user password (Optional). Default value: current user credentials.
- domain: Mail user domain (Optional). Default value: current domain.
- server: Mail Server name (Optional). Default value: mail.current_domain.
- port: Mail Server Port number (Optional). Default value: 25.

Returns

True, if the email is sent. Otherwise, False.

Level

Any level.

Details

Sends an email by using the SMTP protocol. As Maintenance Manager actions run, an in-memory log tracks each of the Maintenance Manager actions that are called and their parameters. The LogSendEmail action places the action activity information into an email and send it.

Example:

```
LogSendEmail("jsmith@somewhere.com", "jdoe@somewhere.com,mmoore@somewhere.com",  
            "", "", "", "", "", "", "")
```

Parent topic: [Logging actions](#)

LogWriteEventLog

Writes a message to the Event Log.

Member of namespace

Maintenance Manager

Syntax

```
bool LogWriteEventLog (string message, int level, int eventID)
```

Parameters

message
 Type: string
level
 Type: int
eventID
 Type: int

Parameters

- message: Message to write to the Event Log and the local log. Smart parameters are supported.
- level: Integer value. 0 - informational, 1 - Warning, 2 - Error.
- eventID: Integer value. Desired Event ID.

Returns

True if the event is successfully logged. Otherwise, False.

Level

Any level.

Details

Unconditionally writes out a message to the Windows Event Log and to the application log file for the running task. Set the level and event ID to the values that is appropriate for the message being logged.

Example:

```
LogWriteEventLog("This is an informational message.", "0", "10")
```

This example writes the message `This is an informational message.` to the event log.

```
LogWriteEventLog("@B.MyMessage", "0", "10")
```

This example uses Smart parameters to write out the value of the batch level variable `MyMessage`.

Parent topic: [Logging actions](#)

LogWriteRecordSet

Outputs the results of `ProcessRunSqlQuery` to the error log.

Member of namespace

Maintenance Manager

Syntax

```
bool LogWriteRecordSet ()
```

Parameters

None.

Returns

True if the write is successful. Otherwise, False.

Level

Any level.

Details

Writes out the result of the last call to `ProcessRunSqlQuery` to the error file. This action can be useful for debugging an application.

Example:

```
QuerySetStation("1")  
QuerySetJobID("!Demo Job")  
ProcessRunSqlQuery("")  
LogWriteRecordSet("")
```

Parent topic: [Logging actions](#)

Related reference:

[ProcessRunSqlQuery](#)

[LogWriteSQLQuery](#)

LogWriteSQLQuery

Outputs the constructed SQL query to the error log.

Member of namespace

Maintenance Manager

Syntax

```
bool LogWriteSQLQuery ()
```

Parameters

None.

Returns

True if the log is successfully written. Otherwise, False.

Level

Any level

Details

Writes out the result of the previous calls to the "QuerySet" actions to the error file. This action can be useful for debugging an application, allowing you to view the exact SQL that was constructed and used in ProcessRunSqlQuery.

Example:

```
QuerySetStation("1")  
QuerySetJobID("!Demo Job")  
LogWriteSQLQuery("")  
ProcessRunSqlQuery("")
```

Parent topic: [Logging actions](#)

Related reference:

[ProcessRunSqlQuery](#)

[LogWriteRecordSet](#)

Reporting actions

Use the Reporting actions to write information to the report tables in the Engine database for use by Datacap Report Viewer.

The Reporting actions can query the active users on an application and set the database tables that contain the reports for processed batches and users.

- [ReportQueryTMUsage](#)
Update the ReportUser Database with the current users.
- [ReportSetReportingTable](#)
Sets database that contains reports on all processed batches
- [ReportSetUsageDBTable](#)
Sets database that contains reports on users that are logged in to Datacap.

Parent topic: [Maintenance Manager actions](#)

ReportQueryTMUsage

Update the ReportUser Database with the current users.

Member of namespace

Maintenance Manager

Syntax

```
bool ReportQueryTMUsage ()
```

Parameters

None.

Returns

True if the database update was successful. Otherwise, False.

Level

Any level.

Details

This action will query the number of users current logged on and place the information into the reportUser. This information is statistical information that can later be used to generate usage reports with the Report Viewer reporting system.

Example:

```
ReportQueryTMUsage ("")
```

Parent topic: [Reporting actions](#)

ReportSetReportingTable

Sets database that contains reports on all processed batches

Member of namespace

Maintenance Manager

Syntax

```
bool ReportSetReportingTable (string tbName, string batchColumn, string attemptColumn, string doneColumn, string actionColumn)
```

Parameters

tbName

Type: string

Table name in Engine database.

batchColumn

Type: string

Optional. Name of the column that contains Batch ID.

attemptColumn

Type: string

Optional. Name of the column that contains attempts.

doneColumn

Type: string

Optional. Name of the column that contains completion result.

actionColumn

Type: string

Optional. Name of the column that contains last action that is performed.

Returns

Always True.

Level

Batch level.

Details

Sets database that contains reports on all processed batches. Table must exist in the engine database.

Example:

```
ReportSetReportingTable("NENU", "nn_batch", "nn_attempt", "nn_done", "nn_action")
```

Parent topic: [Reporting actions](#)

Related reference:

[ReportSetUsageDBTable](#)

ReportSetUsageDBTable

Sets database that contains reports on users that are logged in to Datacap.

Member of namespace

Maintenance Manager

Syntax

```
bool ReportSetUsageDBTable (string tbName, string ipAddressColumn, string jobIDColumn, string portColumn, string processedBathcesColumn, string stationColumn, string taskIDColumn, string userIDColumn, string queryTimeColumn)
```

Parameters

tbName

Type: string
Table name in Engine database.

ipAddressColumn
Type: string
IP address column.

jobIDColumn
Type: string
Job ID column.

portColumn
Type: string
Port column.

processedBatchesColumn
Type: string
Processed batches column.

stationColumn
Type: string
Station ID column.

taskIDColumn
Type: string
Task ID column.

userIDColumn
Type: string
User ID column.

queryTimeColumn
Type: string
Query time column.

Returns

Always True.

Level

Batch level.

Details

Sets database that contains reports on users that are logged in to Datacap. Table must exist in the engine database.

Example:

```
ReportSetUsageDBTable("reportUsers","ru_ip","ru_job","ru_port","ru_bathces","ru_station","ru_task","ru_user","ru_time")
```

Parent topic: [Reporting actions](#)

[ReportSetReportingTable](#)

OCR_J actions

The OCR_J actions use the Rosetta Stone Japanese OCR engine to perform OCR for Japanese machine print and Japanese handwriting.

- [InitializeEngine](#)
Initializes the Datacap interface for the Rosetta Stone Japanese OCR engine. Call this action before you call other actions in the OcrRose library.
- [Recognize](#)
Performs field-zone OCR for Japanese machine print and Japanese handwriting.
- [ReleaseEngine](#)
Releases the Datacap interface for the Rosetta Stone Japanese OCR engine so that all interface resources are freed. Do not call other actions in the OCR_J library after you call this action.

Parent topic: [Global actions](#)

InitializeEngine

Initializes the Datacap interface for the Rosetta Stone Japanese OCR engine. Call this action before you call other actions in the OcrRose library.

Member of namespace

OCR_J

Syntax

```
bool InitializeEngine ()
```

Returns

True if the action succeeds. Otherwise, the action returns False.

Level

All levels.

Details

Example:

```
InitializeEngine ()
```

Parent topic: [OCR_J actions](#)

Recognize

Performs field-zone OCR for Japanese machine print and Japanese handwriting.

Member of namespace

OCR_J

Syntax

```
bool Recognize ()
```

Returns

True if the action succeeds. Otherwise, the action returns False.

Level

Field level.

Details

Use this action to perform field-zone OCR for Japanese machine print and Japanese handwriting. As indicated by the following tables, you can configure this action's OCR behavior by setting the specified DCO variables before you call this action.

Example:

```
InitializeEngine ()
rrSet ("3", "@F.rsFrameType")
rrSet ("8", "@F.rsOcrType")
Recognize ()
ReleaseEngine ()
```

Frame type

The DCO variable `rsFrameType` specifies the frame type of the fields for which OCR is to be performed. The frame type is the way that fields are framed on the form by boxes, ticks, vertical lines, or other marks. Here are the valid values:

0	None (unconstrained field)
1	Normal
2	Individual
3	Field
4	Box
5	Ladder
6	Solid ladder

The default frame type is "0".

OCR type

The DCO variable `rsOcrType` specifies the type of the characters for which OCR is to be performed. Here are the valid values:

1	Machine printed Japanese alpha characters
2	Machine printed numbers
4	Machine printed alpha-numeric characters
8	Handwritten numbers
16	Handwritten alpha-numeric characters
32	Handwritten Japanese alpha characters

The default OCR type is “1”.

Parent topic: [OCR_J actions](#)

ReleaseEngine

Releases the Datacap interface for the Rosetta Stone Japanese OCR engine so that all interface resources are freed. Do not call other actions in the OCR_J library after you call this action.

Member of namespace

OCR_J

Syntax

```
bool ReleaseEngine ()
```

Returns

True if the action succeeds. Otherwise, the action returns False.

Level

All levels.

Details

Example:

```
ReleaseEngine ()
```

Parent topic: [OCR_J actions](#)

OCR_A actions

Use the OCR_A actions to do text recognition by using the FineReader OCR engine.

- [EnableEngineLogsOCR_A](#)
Enables OCR_A Engine logging
- [OCRA_ConvertImage2BW](#)
This action converts a Color or Grayscale image to Black and White.
- [Recognize](#)
Recognize refers to settings in the OCR/A tab of the Recognition Options Setup dialog to recognize all characters on a page, and populates the page's Fingerprint file (.cco) with the recognition results.
- [RecognizeBarcodeOCR_A](#)
A field/page level action that retrieves barcodes.
- [RecognizeFieldOCR_A](#)
A field-level action that retrieves a zoned field's settings from the OCR/A tab of the Recognition Options Setup dialog, and uses these settings to recognize the field's value.
- [RecognizeFieldVoteOCR_A](#)
A field-level action that initiates a voting procedure that first uses specifications in the OCR/A tab of the Recognition Options Setup dialog to recognize the field's characters.

- [RecognizePageFieldsOCR_A](#)
A page-level action that recognizes all fields on the page that have been configured for OCR/A recognition (see the OCR/A tab of the Recognition Options Setup dialog.)
- [RecognizePageOCR_A](#)
Refers to settings in the OCR/A tab of the Recognition Options Setup dialog to recognize all characters on a page, and populates the page's Fingerprint file (.cco) with the recognition results.
- [RecognizeToALTOOCR_A](#)
Converts a scanned Images (.tif) to an ALTO electronic Document Format (XML) file.
- [RecognizeToPDFOCR_A](#)
Converts a scanned Images (.tif) to an Adobe Portable Document Format (PDF) file.
- [ReleaseEngineOCR_A](#)
This action releases the OCR_A engine.
- [RotateImageOCR_A](#)
Use with `Recog_Shared > RotateTIO` to update the CCO file with the correct position coordinates after image rotation.
- [SetAutoRotationOCR_A](#)
This action set to False turns off automatic image orientation detection and rotation.
- [SetConfCalculationParamsOCR_A](#)
Specifies the values to use for OCR_A->Datacap confidence mapping.
- [SetFastModeOCR_A](#)
This action set to TRUE provides 2-2.5 times faster recognition speed at the cost of a moderately increased error rate (1.5-2 times more errors).

Parent topic: [Global actions](#)

EnableEngineLogsOCR_A

Enables OCR_A Engine logging

Member of namespace

ocr_a

Syntax

```
bool EnableEngineLogsOCR_A ()
```

Parameters

None.

Returns

True, if logging is successfully enabled. Otherwise, False.

Level

Any level.

Details

This action enables OCR_A Engine logging. The log file is created in the batch folder with the name engine.log.

Example:

```
RecognizePageOCR_A()  
EnableEngineLogsOCR_A()
```

This sequence creates a log file in the batch folder with the name engine.log.

Parent topic: [OCR_A actions](#)

OCRA_ConvertImage2BW

This action converts a Color or Grayscale image to Black and White.

Member of namespace

ocr_a

Syntax

```
bool OCRA_ConvertImage2BW (StrParam)
```

Parameters

The file extension that the action is to assign to the backup of the original Image file. For example: tio.

The extension should be 3 or 4 alphanumeric characters.

Returns

False if called at a level other than the Page. False if the parameter is not 3 or 4 alphanumeric characters. Otherwise, True.

Level

Page.

Details

This action converts a Color or Grayscale image to Black and White.

Example:

```
OCRA_ConvertImage2BW()
```

Parent topic: [OCR_A actions](#)

Recognize

Recognize refers to settings in the OCR/A tab of the Recognition Options Setup dialog to recognize all characters on a page, and populates the page's Fingerprint file (.cco) with the recognition results.

The *Recognize* action performs document layout analysis and OCR, generating a layout XML file such as TM000001_layout.xml. The layout file groups text into blocks as a person would be looking at the document.

Each block might have the default type of block or a specific type such as title or table. There are *locate* actions available in the *DocumentAnalytics* action library to navigate the block structure such as "GoSiblingBlockNext". This is in contrast to the CCO file produced by other actions that groups text into lines that span the width of the page. The layout XML file also retains font and color attributes, which are saved in CSS format, for the text that is used for extracting data and reconstructing the document in a new format. To use the Locate actions and perform click "n" key during verification, use the *CreateCcoFromLayout* action in the *SharedRecognitionTools* action library. This action creates a CCO file for the page after producing the layout XML file.

Member of namespace

ocr_a

Syntax

```
bool Recognize ()
```

Parameters

None.

Returns

False if the ruleset with this action is not bound to a **Page** object of the Document Hierarchy. Otherwise, **True**.

Level

Page level.

Details

The following are the types of elements that might be present in the layout XML file:

Table 1. Block types versus XML node

Block type	Node in the layout XML file
Block	Block
Header	Header
Footer	Footer
Title	Title
Heading1	H1
Heading2	H2
Heading3	H3
Picture	Picture
Barcode	Barcode
Space	S
Tab	Tab
Table	Table

Block type	Node in the layout XML file
Row	Row
Cell	Cell
Paragraph	Para
Line	L
Sentence	Sent
Word	W
Character	C

Supported File Formats

The Recognize action can process color images and PDF files. When processing PDF documents, the action extracts embedded text within the PDF document, and performs recognition only on those areas that contain data but do not contain embedded text. This improves the processing speed and overall performance of the processing of PDF documents.

Tip: It is also possible to process Microsoft Excel, Microsoft Word, Html, Rtf, and Txt documents by first converting those documents to searchable PDFs via the Convert library. For example, a Microsoft Excel document can be converted to PDF by calling the action *ExcelWorkbookToPdf*. After the PDF document is created, it can be processed through the Recognize action.

Language detection

Language detection helps improve recognition results. Instead of using the default English setting, it detects the language and results in more accurate OCR results. When the OCR process is complete, a report on the number of languages detected (and total number of words that are detected for each language) is generated. This report is stored in the runtime DCO as variables, and can also be found in the layout XML file. To enable automatic language detection:

1. Use *rrSet* or a similar action to set the *y_lg* variable to a list of comma-separated list of **at least** three supported auto-detection languages.
2. After specifying the list of languages, call the *Recognize* action.

Important: The list of languages must be minimized to the languages expected to be processed by the application. More languages slow down the processing. However, if an application process only two languages, you must still provide at least three languages to enable automatic language detection.

Languages Supported by Auto Detection

Important: When you set the comma-separated list of languages, make sure that the languages are entered exactly as written in this list. An invalid language name causes the action to abort.

Note: Text that follows the colon ":" is informational only and must not be included.

The language can be bound to the DCO object by selecting it in the OCR_A tab in the Zones tab of Datacap Studio. When selected in the OCR_A tab, the variable `y_lg` is set to the language. The language also can be set within rules by using the `rrSet` action to set the `y_lg` variable to the wanted language.

For example: `rrSet("Italian", "@X.y_lg")` Sets the language to Italian.

If the `s_lg` variable is not set for the current DCO object, the recognized language is determined by the current locale set with the `hr_locale` variable. For example, if the locale is set for Germany, `rrSet("de-DE", "@X.hr_locale")`, then the text is recognized as German.

If both the `hr_locale` and `y_lg` variables are set, the value in `y_lg` takes precedence over the locale setting. If `y_lg` is set but the engine should use the value set for `hr_locale` instead, setting the variable `dco_uselocale` to "1" gives precedence to `hr_locale`.

If the page you are recognizing is formatted for right-to-left text, such as Arabic or Hebrew, then the variable "`hr_bidi`" must be set to "`rtl`" to indicate that the page is right to left.

Example:

```
rrSet("English,French,German", @P.y_lg) - Auto detection of English, French or German
rrSet("English,German,GermanNewSpelling,Norwegian", @P.y_lg) - Auto detection of
English, German, or Norwegian
rrSet("ChinesePRC+@CHR(43)+English", "@P.y_lg") - An exception for specification of
Simplified Chinese and English
```

Custom Parameters

The following variables can be used to set custom parameters for recognition:

`y_userProfile`

Reserved for Internal use only.

`y_predefinedProfile`

Set this variable to the name of a predefined profile to use during recognition. Valid values are:

- *DocumentConversion_Accuracy*
- *DocumentConversion_Speed*
- *DocumentArchiving_Accuracy*
- *DocumentArchiving_Speed*
- *BookArchiving_Accuracy*
- *BookArchiving_Speed*
- *TextExtraction_Accuracy*
- *TextExtraction_Speed*
- *EngineeringDrawingsProcessing*
- *BusinessCardsProcessing*

Text Extraction versus Text Recognition

When a PDF is recognized, by default, the text included in the recognition results is obtained from a combination of automatic recognition that is run on the PDF and from searchable text that is embedded within the PDF.

Any images that are embedded on the page have the text that is recognized by the engine. If areas of the page contain both an image and searchable text that is associated with the image, the engine decides whether the engine must use the searchable text or recognize the text from the matching image.

Because the engine performs recognition, the confidence of the text might vary even if the same searchable text is embedded in the PDF.

The variable `y_contentReuseMode` can be used to force the engine only to use the recognized text on the page or only to use the embedded text on the page. One reason why you might decide only to use the embedded text is to prevent recognition and produce high confidence results.

A drawback of only using the embedded text is that if the embedded text is wrong or incomplete, recognition is not performed to capture that missing data that results in a layout XML that is incomplete compared to what the user sees when the user views the PDF. Do not use this setting if the source PDF file is of the image-on-text type because in this case, the text layer is not extracted.

If a text line contains characters that are not included in the alphabet of the selected recognition languages, this text is not written to the result and mode 0 or 1 must be used.

These settings of `y_contentReuseMode` can be set on the DCO node that is being converted:

`rrSet("0", "@X.y_contentReuseMode")` - The default auto mode that uses a combination of recognition and embedded text.

`rrSet("1", "@X.y_contentReuseMode")` - Only recognition is used to create the layout XML.

`rrSet("2", "@X.y_contentReuseMode")` - Only embedded text is used to create the layout XML.

Example:

This sequence creates a layout XML file, and subsequently, a CCO file for the current page. Auto detection is enabled for English, French, and Japanese documents. The CCO file that is produced is ready for use by navigation and pattern match actions.

```
rrSet("English,French,Japanese", "@P.y_lg")
Recognize()
CreateCcoFromLayout()
```

Table Identification

Some recognition engines can identify a table on a document when performing full page recognition when using layout files produced by the *Recognize* action. When text is recognized as a table, it means that additional metadata is internally stored about the words that have been recognized. This extra metadata stores the cell information, row and column position, for the text. This table metadata can be used by subsequent actions that support table functions. This is an alternative approach to using the "line items" feature that processes recognized data as tables without a table being identified by the recognition engine.

The *Recognize* action attempts to detect tables on a page, identifying the rows and columns. If a table is detected, then the table structure can be used by subsequent actions that manipulate the recognized tables. As with character recognition, 100% accuracy of a table's rows and columns is not guaranteed. If this feature is needed, it is advisable to test on various tables that you expect to be processing in your application, and determine whether the accuracy is good enough to provide the functions that you need. If table recognition accuracy is not good enough for your wanted approach, it is recommended that you change your approach.

It is possible that parts of a table might not be recognized as expected even if they visually look good to the human eye. For example, parts of your table might be left outside of the table structure or rows and columns might be combined in ways that might not be expected from visually looking at the table. If the tables in your documents are not being identified well by the engine, then you might consider a different approach, such as using line items, to process tabular data within your documents.

The following tips can help to improve the recognition of your table:

- Tables must be well-defined with grid lines that identify the rows and columns of the table.
- Do not perform line removal if you are attempting to detect table structures.
- Cells cannot intersect each other.
- All cells must have a rectangular shape.

Forcing single lines per table cell

If your table contains only a single row but the engine recognizes multiple rows per table cell, the engine can be instructed to recognize the multiple rows as a single row by setting the DCO variable *y_SingleLinePerCell* to "1".

Example: `rrSet("1", "@X.y_SingleLinePerCell")`

Splitting table by separators

While identifying a table layout, the engine uses grid lines and its own heuristics to determine the rows and columns for the table. Sometimes this can cause the cells created by the engine to be different from what is defined by grid lines on the page. For example, your table may have grid lines that show multiple lines in a cell but instead those lines are interpreted as single line cells. The DCO variable *y_SplitOnlyBySeparators* can be set to "1" which tells the engine to use grid lines only while identifying the layout of a table. For example: `rrSet("1", "@X.y_SplitOnlyBySeparators")`. When enabled, the setting tells the engine to use the grid lines to guide the identification, providing a table layout that closely matches the visible grid lines. This setting is off by default.

If *y_SplitOnlyBySeparators* is enabled, the engine does not attempt to recognize a table without grid lines.

Disabling table detection

Table detection is enabled by default. You can disable it by setting the page level variable *y_DetectTables* to "0".

Example: `rrSet("0", "@X.y_DetectTables")`.

However, typically, it is not necessary to disable table detection. However, the setting is provided in the case it gives better results for your document types.

Zoning the table location

In some cases, the table identification can be improved by identifying the table location / zone. This might improve table identification when the engine is not detecting the table boundaries well or when the table does not have gridlines to identify the table boundaries.

If the page can be fingerprinted so that the location of the table is always known, then the table area can be zoned to identify the table boundaries. To identify the table zone to the recognition engine, specify the name of the field that contains the table zone by using the variable *y_TableZone*. For example, if the current page has a field that is called "MyTable" and the zone for that field identifies the table location on the page then the action `rrSet("MyTable", "@X.y_TableZone")` allows the engine to use the zone to identify the table.

If a table is recognized by using the user-provided zone, sub-fields are created off of the *y_TableZone* specified field with the table contents. If there are multiple tables on the page, only one table can be identified by using this method.

If you need to identify multiple tables on a page, then you must use auto detection, process the page multiple times with different zones for each table or take a different approach. If the location of the table cannot be predicted or identified before recognition, then you would need to use auto detection or take a different approach.

Providing the engine with the table zone gives better results in situations where table auto detect is making mistakes, as in the case when there are no grid lines. Be aware that this technique still cannot guarantee 100% accuracy and you might need to take additional custom steps to massage the recognized data for your needs. It is a similar situation as to the need to correct standard character recognition.

Parent topic: [OCR_A actions](#)

Related reference:

[Recognize](#)

RecognizeBarcodeOCR_A

A field/page level action that retrieves barcodes.

Member of namespace

ocr_a

Syntax

```
bool RecognizeBarcodeOCR_A ()
```

Parameters

None.

Returns

False if the ruleset with this action is not bound to a Field object or Page object of the Document Hierarchy. Otherwise, True.

Level

Field and Page levels.

Details

A field/page level action that retrieves barcodes.

Example:

```
TaxpayerSSN Rule 1  
RecognizeBarcodeOCR_A
```

Parent topic: [OCR_A actions](#)

RecognizeFieldOCR_A

A field-level action that retrieves a zoned field's settings from the OCR/A tab of the Recognition Options Setup dialog, and uses these settings to recognize the field's value.

Member of namespace

ocr_a

Syntax

```
bool RecognizeFieldOCR_A ()
```

Parameters

None.

Returns

False if the ruleset with this action is not bound to a Field object of the Document Hierarchy. Otherwise, True.

Level

Field level.

Details

This field-level action retrieves a zoned field's settings from the OCR/A tab of the Recognition Options Setup dialog, and uses these settings to recognize the field's value.

Example:

```
TaxpayerSSN Rule 1  
RecognizeFieldOCR_A()
```

In the example, the rule uses the action to retrieve and apply settings in the OCR/A tab of the Recognition Options Setup dialog, settings that were previously assigned to a Document Hierarchy's zoned field.

Parent topic: [OCR_A actions](#)

RecognizeFieldVoteOCR_A

A field-level action that initiates a voting procedure that first uses specifications in the OCR/A tab of the Recognition Options Setup dialog to recognize the field's characters.

Member of namespace

ocr_a

Syntax

```
bool RecognizeFieldVoteOCR_A ()
```

Parameters

None.

Returns

False if the ruleset with this action is not bound to a Field object of the Document Hierarchy. Otherwise, True.

Level

Field level.

Details

This field-level action initiates a voting procedure that first uses specifications in the OCR/A tab of the Recognition Options Setup dialog to recognize the field's characters.

When this action stores the results of recognition, it first determines if the corresponding Field object of the Document Hierarchy contains a value. If a value is present, the action compares the field's existing value with the recognition results - character by character.

If a particular character's values match, the Confidence Rating for the character is raised to the maximum level. If the values do not match, the Confidence Rating for the character is lowered to the minimum.

Note: When using this voting procedure, the second Recognition engine is secondary and its results are never assigned. Instead, the action changes the Confidence Ratings on the basis of results provided by the first Recognition engine. If there are no recognition results previous to this action, it will act just like the RecognizeFieldOCR_A action.

Example:

```
RecognizeFieldICR_C()  
RecognizeFieldVoteOCR_A()
```

Parent topic: [OCR_A actions](#)

RecognizePageFieldsOCR_A

A page-level action that recognizes all fields on the page that have been configured for OCR/A recognition (see the OCR/A tab of the Recognition Options Setup dialog.)

Member of namespace

ocr_a

Syntax

```
bool RecognizePageFieldsOCR_A ()
```

Parameters

None.

Returns

False if the ruleset with this action is not bound to a Page object of the Document Hierarchy. Otherwise, True.

Level

Page level.

Details

OCR/A This page-level action recognizes all fields on the page that have been configured for OCR/A recognition (see the OCR/A tab of the Recognition Options Setup dialog.)

Note: Individual field-level recognition actions will overwrite the results from this page-level action. The action will not recognize a zoned field if the Skip Recognition checkbox in the OCR/A tab of the Recognition Options Setup dialog has been selected.

Example:

```
ReadZones ()  
RecognizePageFieldsOCR_A ()
```

Parent topic: [OCR_A actions](#)

RecognizePageOCR_A

Refers to settings in the OCR/A tab of the Recognition Options Setup dialog to recognize all characters on a page, and populates the page's Fingerprint file (.cco) with the recognition results.

Member of namespace

ocr_a

Syntax

```
bool RecognizePageOCR_A ()
```

Parameters

None.

Returns

False if the ruleset with this action is not bound to a Page object of the Document Hierarchy. Otherwise, True.

Level

Page level.

Details

This action responds to settings in the OCR/A tab of the Recognition Options Setup dialog to recognize all characters on a page, and populates the page's CCO file with the recognition results. If a CCO file does not exist at the time this action is called, the action will create one.

Example:

```
AnalyzeImage ()  
RotateImage ()  
RecognizePageOCR_A ()
```

This sequence creates a CCO file for the current page, and checks to see if rotation of the image is needed. Full-page recognition then takes place in response to settings in the OCR/A tab of the Recognition Options Setup dialog. The recognition results are stored in the CCO file.

Parent topic: [OCR_A actions](#)

RecognizeToALTOOCR_A

Converts a scanned Images (.tif) to an ALTO electronic Document Format (XML) file.

Member of namespace

ocr_a

Syntax

```
bool RecognizeToALTOOCR_A()
```

Parameters

None.

Returns

False If called at an invalid level. Otherwise, True.

Level

Document or Page Level.

Details

Converts a scanned Images (.tif) to an ALTO Document Format (XML) file.

When placed at Page level, the action recognizes and converts the current tif page to an ALTO file.

When placed at Document level, the action recognizes and converts all tif pages in the existing doc into one ALTO file.

Document Format

The following variables can be used to set the properties of the ALTO xml file.

y_AltoFontFormattingMode

Specifies the character attributes that are saved to the ALTO xml file.

Valid values are.

- 0 - The only saved attribute is whether characters are subscript or superscript. This value is the default.
- 1 - The following attributes are saved, whether characters are subscript, superscript, bold, italic, underlined, strikethrough. Font size and font name are not saved.
- 2 - All font attributes are saved.

y_AltoWriteNondeskedCoordinates

Specifies whether character, word, block coordinates that are written into files in ALTO format are defined on an original image. Or are defined on an image that is used for recognition to which different modifications, such as deskewing, were applied. This property is True by default, which means that the coordinates are defined on the original page.

If you set this property to False, export to ALTO is run faster because there is no need to convert the coordinates between the modified image and the original image, which takes a long time. If this property is set to the default True value, the baseline position is not written during export. If it is set to False, the baseline position is written into the resulting ALTO file because ALTO format requires the baseline position be defined by

only one number. In the original coordinates, the baseline might not be strictly horizontal or vertical. In this case, it is impossible to define its position by a single number.

Document Contents

To exclude specific page types, set the variable *typesToExclude* to a comma delimited list of page types to exclude from the ALTO xml file.

To include specific page types, set the variable *typesToInclude* to a comma delimited list of page types to include in the ALTO xml file.

To exclude specific page status, set the variable *statusToExclude* to a comma delimited list of page status to exclude from the ALTO xml file.

When more than one filter is specified, the following order of precedence takes place:

- *statusToExclude* overrides *typesToInclude*
- *typesToInclude* overrides *typesToExclude*

If you are calling the action at the Document level, the types and status filters apply to both the documents and their child pages.

If you are calling the action at the Page level, the types and status filters apply to the page only.

The variables in the previous three sections must be set before you call the RecognizeToALTOOCR_A action.

Example

```
rrset ("75", "@D.statusToExclude")
rrSet ("Blank", "@D.typesToExclude")
RecognizeToALTOOCR_A()
```

This example creates an ALTO XML document with all of the pages that are contained in the DCO Document object except those pages with type "Blank" and status "75".

Parent topic: [OCR_A actions](#)

RecognizeToPDFOCR_A

Converts a scanned Images (.tif) to an Adobe Portable Document Format (PDF) file.

Member of namespace

ocr_a

Syntax

```
bool RecognizeToPDFOCR_A()
```

Parameters

None.

Returns

False if called at an invalid level. Otherwise, True.

Level

Document or Page Level.

Details

Converts one or more scanned Images (.tif) to an Adobe Portable Document Format (PDF) file. The PDF is searchable as it also includes the text as read directly by the recognition engine.

When placed at Page level, the action recognizes and converts the current TIF page to a PDF file.

When placed at document level, the action recognizes and converts all TIF pages in the existing doc into one PDF file. If the pages are PDF files, the action builds a new PDF that combines the page level PDFs into a single PDF.

Document Format

To create PDF/A1A documents, set the *y_pdfA* variable to "1" before you call `RecognizeToPDFOCR_A`.

To create PDF/A1B documents, set the *y_pdfA* variable to "1" and the *y_pdfA1B* variable to "1" before you call `RecognizeToPDFOCR_A`.

To set the MRC (Mixed Raster Content) Mode for conversion to PDF/A, set the *y_pdfMRCMode* variable to one of the following values:

- 0 - Engine decides whether MRC is to be used. Default.
- 1 - MRC is always used.
- 2 - MRC is never used. MRC technology uses a lossy compression algorithm. Some unimportant information from the source image (background texture, garbage, and so on) can be lost. Disable MRC if even insignificant information from the source image cannot be lost. Using a parameter of 2 helps to address issues where the text in the PDF document is too dark.

Document Contents

To exclude specific page types, set the variable *typesToExclude* to a comma-delimited list of page types to exclude from the PDF.

To include specific page types, set the variable *typesToInclude* to a comma-delimited list of page types to include in the PDF.

To exclude specific page status, set the variable *statusToExclude* to a comma-delimited list of page status to exclude from the PDF.

When more than one filter is specified, the following order of precedence takes place:

- *statusToExclude* overrides *typesToInclude*.
- *typesToInclude* overrides *typesToExclude*.

If you are calling the action at the Document level, the types and status filters apply to both the documents and their child pages.

If you are calling the action at the Page level, the types and status filters apply to the page only.

By default, recognition is performed on images, creating searchable text in the PDF. To prevent recognition, creating an image only PDF, set the variable *y_PDFImageOnly* to 1 in the current DCO object.

If you are creating a searchable PDF, for more information, on the supported languages and how to configure them, refer the OCR_A action, [Recognize](#).

Document Attributes

The following variables can be used to set the corresponding PDF document attributes:

- *y_PDFKeys*
- *y_PDFAuthor*
- *y_PDFTitle*
- *y_PDFSubject*
- *y_PDFProducer*
- *y_pdfCreator*
- *y_PDFQuality*
- *y_pdfDelTmp*

Memory or Disk Processing

By default the conversion is performed in memory. If you are creating PDF with many pages, it is possible for the conversion to run out of memory. The disk can be used for processing by setting the DCO variable *y_maxPagesForInMemoryProcessing* to the maximum number of pages for in-memory processing. If the document contains more pages than this value, the disk is used instead of memory.

The variables in the previous three sections must be set before you call the `RecognizeToPDFOCR_A` action.

Including PDF Annotations

By default, when you convert PDF to PDF, annotations in the source PDF file are not included in the output PDF. "Free Text" annotations in source PDF can be included in the output PDF by setting the page DCO variable *y_IncludeAnnotation* to "1". Other types of PDF annotations are not supported, such as popup and ink annotations. This feature does not cause the text of a "Sticky note" to be displayed on the image and a sticky note icon might display on the final image regardless of this setting.

PDF Export Optimization

The variable *y_pdfExportScenario* can be used to set the scenario of export to PDF (PDF/A) format, which optimizes export for some parameters. This impacts the size and quality of the output PDF.

It takes the following values:

- 0 - Optimize the PDF (PDF/A) export in order to receive the best quality of the resulting file.(This is default)
- 1 - The PDF (PDF/A) export will be balanced between the quality of the resulting file, its size and the time of processing.
- 2 - Optimize the PDF (PDF/A) export in order to receive the minimum size of the resulting file.
- 3 - Optimize the PDF (PDF/A) export in order to receive the highest speed of processing.

Example

```
rrset("IBM", "@D.y_PDFProducer")
rrSet("75", "@D.statusToExclude)
rrSet("Blank", "@D.typesToExclude)
RecognizeToPDF_A()
```

This example creates a PDF document with all of the pages that are contained in the DCO Document object except those pages with type "Blank" and status "75".

Parent topic: [OCR_A actions](#)

ReleaseEngineOCR_A

This action releases the OCR_A engine.

Member of namespace

ocr_a

Syntax

```
bool ReleaseEngineOCR_A ()
```

Returns

Always True.

Level

All.

Details

This action releases the OCR_A engine.

Example:

```
ReleaseEngineOCR_A()
```

Parent topic: [OCR_A actions](#)

RotateImageOCR_A

Use with `Recog_Shared > RotateTIO` to update the CCO file with the correct position coordinates after image rotation.

Member of namespace

ocr_a

Syntax

```
bool RotateImageOCR_A ()
```

Parameters

None.

Returns

False if the ruleset with this action is not bound to a Page object of the Document Hierarchy, or if the action cannot locate the Image file representing the current page. Otherwise, True.

Level

Page only.

Details

This action checks if the scanned Image file needs to be rotated by 90, 180, or 270 degrees to be in the upright position. If rotation is necessary, the action saves the Image file in the new, correct position.

Note: You can specify a target language (for example, "Hebrew") so that the engine can properly rotate the text according to that language.

Example:

```
RotateImageOCR_A ()  
AnalyzeImage ()
```

Parent topic: [OCR_A actions](#)

SetAutoRotationOCR_A

This action set to False turns off automatic image orientation detection and rotation.

Member of namespace

ocr_a

Syntax

```
bool SetAutoRotationOCR_A (StrParam)
```

Parameters

True: Forces image orientation detection and rotation. This is the default value.

False: Image orientation and rotation will not be performed.

Returns

Always True.

Level

All.

Details

This action set to True forces image orientation detection and rotation. If this action is not called, the value will default to True. If used, this action must be called prior to recognition and both actions must be called at the same level.

Example:

```
SetAutoRotationOCR_A ("True")  
RecognizePageOCR_A
```

Parent topic: [OCR_A actions](#)

SetConfCalculationParamsOCR_A

Specifies the values to use for OCR_A->Datacap confidence mapping.

Member of namespace

ocr_a

Syntax

```
bool SetConfCalculationParamsOCR_A (StrParam)
```

Parameters

The M and C values for the following formula:

$$\text{Datacap Confidence} = \text{MAX}(10, (M/100) * (\text{OCR_A Confidence} + C))$$

The default values for M is 10. The default value for C is 60.

Returns

False if both parameters are not passed or are not numeric. Otherwise, True.

Level

Any level.

Details

Specifies the values to use for OCR_A->Datacap confidence mapping.

Example:

```
SetConfCalculationParamsOCR_A(0.1,70)
```

Parent topic: [OCR_A actions](#)

SetFastModeOCR_A

This action set to TRUE provides 2-2.5 times faster recognition speed at the cost of a moderately increased error rate (1.5-2 times more errors).

Member of namespace

ocr_a

Syntax

```
bool SetFastModeOCR_A (StrParam)
```

Parameters

True Enables Fast Mode which sacrifices recognition quality over speed.

False: Disables Fast Mode causing the recognition to run slower, but provides more accurate results.

If no parameter is specified, the value defaults to False.

Returns

Always True.

Level

All.

Details

This action set to TRUE provides 2-2.5 times faster recognition speed at the cost of a moderately increased error rate (1.5-2 times more errors).

It is recommended to disable fast mode if you are performing field level recognition because you will sacrifice quality yet see negligible speed increase at the field level.

If you use this action, it must be called prior to recognition.

Example:

```
SetFastModeOCR_A("True")
```

Parent topic: [OCR_A actions](#)

OCR_N actions

Use the OCR_N actions to do recognition by using the NovoDynamics engine. The OCR_N actions can run recognition on a full page or on all of the field zones that are defined for the current page.

If you plan to use the NovoDynamics engine for Arabic recognition, you must separately license the engine directly from the vendor and then install the engine on the machine that is running the recognition rules. In addition, you must complete these steps:

1. Copy the contents of the NovoDynamics bin folder into the Datacap\DCShared\OCRN folder.
Tip: The default location of the bin folder is C:\Program Files (x86)\NovoDynamics\NovoVerus\bin.
2. Use a command line to register the Datacap connector DLL:

```
C:\WINDOWS\Microsoft.NET\Framework\v2.0.50727\RegAsm.exe  
datacap.libraries.novodynamics.dll /codebase
```

You can ignore a warning that the DLL is not signed.

Arabic language recognition works optimally when the scanned image has at least a 300-DPI resolution.

- [RecognizePageFieldsOCR_N](#)
Does full page recognition and populates the fingerprint (CCO) file of the page with the results.
- [RecognizePageOCR_N](#)
Does recognition on all field zones that are defined for the current page and writes the results to the runtime page data file.

Parent topic: [Global actions](#)

RecognizePageFieldsOCR_N

Does full page recognition and populates the fingerprint (CCO) file of the page with the results.

Member of namespace

Datacap.Libraries.NovoDynamics

Syntax

```
bool RecognizePageFieldsOCR_N ()
```

Parameters

None.

Returns

False if the ruleset with this action is not bound to a Page object of the Document Hierarchy. Otherwise, True.

Level

Page only.

Details

This page-level action recognizes all fields on the page that have been configured for OCR/N recognition (see the action library help text for available settings via runtime\setup variables).

Important: Page level recognition settings are used to recognized the fields\zones. Per zone recognition settings are not supported.

Example:

```
ReadZones ()  
RecognizePageFieldsOCR_N ()
```

Parent topic: [OCR_N actions](#)

RecognizePageOCR_N

Does recognition on all field zones that are defined for the current page and writes the results to the runtime page data file.

Member of namespace

Datacap.Libraries.NovoDynamics

Syntax

```
bool RecognizePageOCR_N ()
```

Parameters

None.

Returns

False if the ruleset with this action is not bound to a Page object of the Document Hierarchy. Otherwise, True.

Level

Page only.

Details

This action performs full page recognition.

The NormalizeCCO action from the CCO2CCO action library should be called after RecognizePageOCR_N if the application will be using the navigation and pattern match actions to find recognized text on a page or perform pattern matching.

If a CCO file does not exist at the time this action is called, the action will create one.

Example:

```
RotateImage ()
RecognizePageOCR_N ()
NormalizeCCO ("")
```

This sequence creates a CCO file for the current page, and checks to see if rotation of the image is needed. Full-page recognition then takes place in response to settings (see the action library help text for available settings via runtime\setup variables).

The recognition results are stored in the CCO file. The words and lines in the CCO are then sorted for use by navigation and pattern match actions.

Parent topic: [OCR_N actions](#)

OCR_SR actions

Use the OCR_SR actions to do recognition and image rotation by using the updated Nuance OmniPage OCR engine. You can run recognition actions on field zones and pages. The results can be processed by actions in other libraries and ultimately displayed to the user for verification. The results can also be written out to files in several possible file formats.

OCR/SR actions perform automatic retries when a recognition operation takes longer than expected. For information about the logic of the automatic retry mechanism and how to override the default settings that govern that logic, see [SetupAutomaticRetry](#).

After a recognition operation completes, the variable RecogStatus is set to indicate the success or failure of recognition. For page-level recognition, here are the possible RecogStatus values and their meanings:

0	Success.
1	Success but no results. The page was empty.
2	Success. Additional processing such as RotateImage was performed.
Any other value	Failure.

- [Recognize](#)
Performs document layout analysis and OCR and also generates a layout XML file such as TM000001_layout.xml.
- [RecognizeFieldOCR_S](#)
Does recognition on the zone of the current field and writes the result to the runtime page file.
- [RecognizeFieldVoteOCR_S](#)
Does recognition on the zone of the current field and compares the result to the existing field value, character by character. Raises the confidence level when the characters match and lowers it when they do not match.
- [RecognizePageFieldsOCR_S](#)
Does recognition on all field zones that are defined for the current page and writes the results to the runtime page data file.
- [RecognizePageOCR_S](#)
Does full page recognition and populates the fingerprint (CCO) file of the page with the results.
- [RecognizeToFileOCR_S](#)
Does full page recognition and writes the recognition results to one of several available output file types, such as .doc, .rtf, .html.
- [RecognizeToPDFOCR_S](#)
Does full page recognition and saves the current page as a PDF file. You can also create the file in PDF/A format.
- [RotateImageExOCR_S](#)
Rotates an image.
- [RotateImageOCR_S](#)
Use with the RotateTIO action from the Recog_Shared library to update the CCO file with the correct position coordinates after image rotation.
- [SetContinueOnFailureOCR_S](#)
Sets a value indicating whether a recognition action will abort or continue after it has encountered an error.
- [SetEngineTimeoutOCR_S](#)
Specifies the number of seconds to wait before it is determined that an OCR/S recognition action is not running properly.
- [SetOutOfProcessLoggingOCR_S](#)
Writes logs for the out-of-process process for debugging.
- [SetOutOfProcessTimeoutOCR_S](#)
Sets the number of seconds to wait to determine that an out-of-process action has stalled.
- [UseOutOfProcessRecogOCR_S](#)
Sets whether recognition will run out-of-process or in process. Running out of process improves stability of the application.

Parent topic: [Global actions](#)

Recognize

Performs document layout analysis and OCR and also generates a layout XML file such as TM000001_layout.xml.

Member of namespace

OCR_SR

Syntax

```
bool Recognize ()
```

Returns

False if the ruleset with this action is not bound to a page object of the document hierarchy. Otherwise, this action returns True.

Level

Page level.

Details

Performs document layout analysis and OCR and also generates an XML layout file such as TM000001_layout.xml.

The layout file groups text into blocks similar to how a person would see and identify the structure in the document. (In contrast, other actions produce a CCO file that groups text into lines that span the width of the page.) For example, a page can have items such as tables, paragraphs, and lines, which are all a type of a block. For information about the block types, see [DocumentAnalytics actions](#). A block might be of the default type or of a specific type such as title or table. The type depends on how the recognition engine interprets the block. Locate actions, such as GoSiblingBlockNext, are available in the Locate action library to navigate the block structure.

The layout XML file also retains the font and color attributes for the extraction text in CSS format. This text is used for extracting data and reconstructing the document in a new format.

Example:

In the following example, the Recognize action first creates an XML layout file, and then the CreateCcoFromLayout action creates a CCO file from that layout file. Both files are created for the current page.

```
Recognize ()
CreateCcoFromLayout ()
```

Supported File Formats

This action can process color images and PDF files. It processes PDF documents in the following manner:

- Extracts embedded text within the PDF document
- Performs recognition only on those areas that contain data but do not contain embedded text

This behavior improves the processing speed and overall performance of PDF document processing.

Tip: You can also process the following types of documents by first converting the documents to searchable PDFs with Convert library actions:

- Microsoft Excel
- Microsoft Word
- HTML
- RTF
- Txt

For example, you can convert a Microsoft Excel document to PDF by calling the action ExcelWorkbookToPdf. Once the PDF document is created, it can be processed with the Recognize action.

Language Detection

The Recognize action does not support language detection. However, this feature is available in the Recognize action of the OCR_A action library.

Parent topic: [OCR_SR actions](#)

Related reference:

[CreateCcoFromLayout](#)

[Recognize](#)

[DocumentAnalytics actions](#)

RecognizeFieldOCR_S

Does recognition on the zone of the current field and writes the result to the runtime page file.

Member of namespace

OCR_SR

Syntax

```
bool RecognizeFieldOCR_S ()
```

Parameters

None

Returns

False if the ruleset with this action is not bound to a Field object of the Document Hierarchy. Otherwise, True.

Level

Field level.

Details

This field-level action is a shortcut to zonal recognition procedures that are carried out in response to settings in the OCR/S tab of Datacap Studio.

This action supports the automatic retry mechanism.

Example

```
RecognizeFieldOCR_S ()
```

Parent topic: [OCR_SR actions](#)

Related reference:

[SetupAutomaticRetry](#)

RecognizeFieldVoteOCR_S

Does recognition on the zone of the current field and compares the result to the existing field value, character by character. Raises the confidence level when the characters match and lowers it when they do not match.

Member of namespace

OCR_SR

Syntax

```
bool RecognizeFieldVoteOCR_S ()
```

Parameters

None.

Returns

False if the ruleset with this action is not bound to a Field object of the Document Hierarchy. Otherwise, True.

Level

Field only.

Details

This field-level action initiates a voting procedure that first uses specifications in the OCR/S tab of the Recognition Options Setup dialog to recognize the characters of the field.

When this action stores the results of recognition, it first determines if the corresponding Field object of the Document Hierarchy contains a value. If a value is present, the action compares the field's existing value with the recognition results, character by character.

If a particular character's values match, the Confidence Rating for the character is raised to 9 if the original confidence is smaller than 9. Otherwise the confidence of matching characters is raised to the maximum level (10).

When using this voting procedure, the second Recognition engine is secondary and its results are never assigned. Instead, the action changes the Confidence Ratings on the basis of results provided by the first Recognition engine. If there are no recognition results previous to this action, it acts like the RecognizeFieldOCR_S action.

This action supports the automatic retry mechanism.

Example

```
RecognizeFieldICR_C()  
RecognizeFieldVoteOCR_S()
```

Parent topic: [OCR_SR actions](#)

Related reference:

[SetupAutomaticRetry](#)

RecognizePageFieldsOCR_S

Does recognition on all field zones that are defined for the current page and writes the results to the runtime page data file.

Member of namespace

OCR_SR

Syntax

```
bool RecognizePageFieldsOCR_S ()
```

Parameters

None.

Returns

False if the ruleset with this action is not bound to a Page object of the Document Hierarchy. Otherwise, True.

Level

Page only.

Details

This page-level action recognizes all fields on the page that have been configured for OCR/S recognition, see the OCR/S tab of the Recognition Options Setup dialog.

Note: Individual field-level recognition actions will overwrite the results from this page-level action.

The action does not recognize a zoned field if the Skip Recognition checkbox in the OCR/S tab of the Recognition Options Setup dialog is selected.

Example

```
ReadZones ()
RecognizePageFieldsOCR_S ()
```

Parent topic: [OCR_SR actions](#)

RecognizePageOCR_S

Does full page recognition and populates the fingerprint (CCO) file of the page with the results.

Member of namespace

OCR_SR

Syntax

```
bool RecognizePageOCR_S ()
```

Parameters

None.

Returns

False if the ruleset with this action is not bound to a Page object of the Document Hierarchy. Otherwise, True.

Level

Page only.

Details

This action responds to settings in the OCR/S tab of the Recognition Options Setup dialog to recognize all characters on a page, and populates the page's CCO file with the recognition results.

Attention: The NormalizeCCO action from the CCO2CCO action library should be called after RecognizePageOCR_S if the application is using the navigation and pattern match actions to find recognized text on a page or perform pattern matching. If a CCO file does not exist when this action is called, the action creates one.

This action supports the automatic retry mechanism.

The DCO variable *s_charReplace* can be used to indicate characters that need to be replaced with an alternate character during the recognition step. This procedure can be used when replacing a specific character in a post-processing step is not feasible. Using this technique provides a way to limit the characters with full-page recognition as can be done with field-level recognition. The replacement string must contain pairs of comma-separated decimal values that represent the characters to replace, such as:

"original,new,original,new,original,new" and so on. It is recommended that this feature is used only if absolutely necessary. It is usually better to adjust characters later in a follow-on step.

The *s_charReplace* variable is only used during full-page recognition. It is not used for field-level recognition.

Attention: If a CCO file does not exist at the time when this action is called, the action will create one. If a CCO file already exists, it will be replaced.

Example

```
AnalyzeImage ()  
RotateImage ()  
RecognizePageOCR_S ()  
NormalizeCCO ("")
```

This sequence creates a CCO file for the current page, and checks to see whether the rotation of the image is needed. Full-page recognition then takes place in response to settings in the OCR/S tab of the Recognition Options Setup dialog. The recognition results are stored in the CCO file. The words and lines in the CCO are then sorted for use by navigation and pattern match actions.

Example

This example shows how to use the character replacement string.

```
rrSet ("8212,45", "@X.s_charReplace")  
RecognizePageOCR_S ()
```

In this case, any dashes that are recognized as a Unicode dash ("8213" in decimal) are converted to a standard minus sign character ("45" in decimal).

If there are more characters to filter, you should continue with more pairs in the same string.

Parent topic: [OCR_SR actions](#)

Related reference:
[SetupAutomaticRetry](#)

RecognizeToFileOCR_S

Does full page recognition and writes the recognition results to one of several available output file types, such as .doc, .rtf, .html.

Member of namespace

OCR_SR

Syntax

```
bool RecognizeToFileOCR_S (int FileType)
```

Parameters

FileType
Type int

Parameters

fileType - The action requires a Numeric parameter from 1-22 to specify a combination of recognition targets and output formats.

Important: Image refers to the image of the bound Page object of the Document Hierarchy. Filename is the string portion of a file's name that precedes its extension.

The output for all of these parameters will produce a file name that is identical to the original file name and will have the extension specified for that parameter.

1. A PDF document with the original image in the foreground with the recognized text hidden in the background (but in the correct position). Perfect for archiving and indexing documents.
2. A general PDF document where the text in the original image is replaced by the corresponding text recognized by the engine.
3. A special type of PDF document, where the suspect words are covered by their images cut out from the original image.
4. A non-searchable PDF document.
5. Recognize an HTML image of the bound Page object of the Document Hierarchy. Output .html (HTML 140).
6. Recognize an image of the bound Page object of the Document Hierarchy in an Excel file. Output .xls (Excel 2000.)
7. Recognize any image of the bound Page object of the Document Hierarchy in a WordML file. Output .doc (Word ML).
8. Recognize any image of the bound Page object of the Document Hierarchy in an RTF2000 file. Output .rtf (RTF 2000).
9. Recognize the image of the bound Page object of the Document Hierarchy in a Text file with an .RTF6 extension. Output .rtf (Rich Text).
10. Recognize the image of the Page object of the Document Hierarchy in a Text file with an .RTF6 extension. Output .rtf (Rich Text).
11. Recognize the image of the Page object of the Document Hierarchy in a Text file with an .Text extension. Output .txt (Text).
12. Recognize the image of the Page object of the Document Hierarchy in a Text file with an Csv extension. Output .txt (CSV - Comma Separated Variable).
13. Recognize the image of the Page object of the Document Hierarchy in a Text file with a .FormattedTxt extension. Output .txt (Formatted Text).

14. Recognize the image of the Page object of the Document Hierarchy in a Text file with a .UText extension. Output .txt (Text).
15. Recognize the image of the Page object of the Document Hierarchy in a Text file with a .UCSV extension. Output .CSV (Comma Separated Variable).
16. Recognize the image of the Page object of the Document Hierarchy in a Text file with a .UFormattedText extension. Output .txt (Text).
17. Recognize the image of the Page object of the Document Hierarchy in a Text file with an .Audio extension. Output aud (Text).
18. Recognize the image of the Page object of the Document Hierarchy in a Text file with a .WordPad extension. Output .rtf (Rich Text for WordPad).
19. Recognize the image of the Page object of the Document Hierarchy in a Text file with an .XML extension. Output .xml (XML).

Returns

False if a ruleset with this action is bound to a Field object of the Document Hierarchy, or if the parameter is not numeric. Otherwise, True.

Level

Page or Document.

Details

Performs OCR recognition on the image of a source page, and stores the output of the OCR/S recognition engine in a file. The output file is in one of 22 alternative formats. Because the files are not actually processed in the format you specify, this action is useful primarily for debugging the engine, or if you need raw (unverified) OCR output in that format.

By default, PDF documents created by this action are compatible with PDF Version 1.6.

However, it is possible to change the default compatibility by setting the *s_pdfVersion* variable to one of the following values:

```
2 = PDF Version 1.5
3 = PDF Version 1.4
4 = PDF Version 1.3
5 = PDF Version 1.2
6 = PDF Version 1.1
7 = PDF Version 1.0
8 = PDF Version A
9 = PDF Version 1.6
10 = PDF Version 1.7
11 = PDF Version A2B
12 = PDF Version A2U
13 = PDF Version A1A
14 = PDF Version A2A
```

To exclude specific page types, set the variable *typesToExclude* to a comma delimited list of page types to exclude from the pdf.

To exclude specific page status, set the variable *statusToExclude* to a comma delimited list of page status to exclude from the pdf.

These variables must be set before calling the action `RecognizeToPDFOCR_S`.

This action supports the automatic retry mechanism.

Example

The following example creates a PDF document with all pages contained in the dco document object except for pages with type `Blank` and status of 75:

```
rrSet ("75", "@D.statusToExclude")
rrSet ("Blank", "@D.typesToExclude")
RecognizeToFileOCR_S (1)
```

Parent topic: [OCR_SR actions](#)

Related reference:

[SetupAutomaticRetry](#)

RecognizeToPDFOCR_S

Does full page recognition and saves the current page as a PDF file. You can also create the file in PDF/A format.

Member of namespace

OCR_SR

Syntax

```
bool RecognizeToPDFOCR_S (int OutputPDFType)
```

Parameters

OutputPDFType
Type int

Parameters

A number value that indicates the PDF output type

1. A PDF document with the original image in the foreground with the recognized text hidden in the background (but in the correct position). Perfect for archiving and indexing documents.
2. A general PDF document where the text in the original image is replaced by the corresponding text that is recognized by the engine.
3. A special type of PDF document, where the suspect words are covered by their images cut out from the original image.
4. A non-searchable PDF document.

Returns

False if the rule with this action is not applied to a document or page object or if the parameters are not in the valid range. Otherwise, True.

Level

Document and Page only.

Details

This action converts a scanned Image file (.tif) to an Adobe Portable Document Format (PDF) file.

By default, PDF documents created by this action are compatible with PDF Version 1.6.

However, it is possible to change the default compatibility by setting the *s_pdfVersion* variable to one of the following values:

2 = PDF Version 1.5
3 = PDF Version 1.4
4 = PDF Version 1.3
5 = PDF Version 1.2
6 = PDF Version 1.1
7 = PDF Version 1.0
8 = PDF Version A
9 = PDF Version 1.6
10 = PDF Version 1.7
11 = PDF Version A2B
12 = PDF Version A2U
13 = PDF Version A1A
14 = PDF Version A2A

To exclude specific page types, set the variable *typesToExclude* to a comma delimited list of page types to exclude from the PDF.

To include specific page types, set the variable *typesToInclude* to a comma delimited list of page types to include in the PDF.

To exclude specific page status, set the variable *statusToExclude* to a comma delimited list of page status to exclude from the PDF.

When more than one filter is specified, the following order of precedence takes place:

- *statusToExclude* overrides *typesToInclude*
- *typesToInclude* overrides *typesToExclude*

If you are calling the action at the Document level, the types and status filters apply to both the documents and their child pages.

If you are calling the action at the Page level, the types and status filters apply to the page only.

To create a PDF in PDF/A format, set the variable *s_pdfVersion* to one of the following supported PDF/A formats:

- IMF_PDFA1B = 8
- IMF_PDFA2B = 11
- IMF_PDFA2U = 12
- IMF_PDFA1A = 13
- IMF_PDFA2A = 14

Important:

If you want to apply any of these variables (*typesToExclude*, *typesToInclude*, *statusToExclude*, *s_pdfVersion*), you must set the variables that you want before you call the RecognizeToPDFOCR_A action.

This action supports the automatic retry mechanism.

Example 1

```
rrSet ("75", "@D.statusToExclude")  
rrSet ("Blank", "@D.typesToExclude")
```

RecognizeToPDF(3)

This example creates a PDF document with all of the pages that are contained in the DCO Document object except those pages with type "Blank" and status "75".

Example 2

```
rrSet("8", "@P.s_pdfVersion")  
RecognizeToPDFOCR_S(1)
```

This example creates a PDF document in PDF/A-1b format. You can find `RecognizeToPDFOCR_S(1)` in the following area in the action library: `ocr_sr > Datcap.Libraries.ScansoftR.Actions > RecognizeToPDFOCR_S`.

Parent topic: [OCR_SR actions](#)

Related reference:

[SetupAutomaticRetry](#)

RotateImageExOCR_S

Rotates an image.

Member of namespace

OCR_SR

Syntax

```
bool RotateImageExOCR_S (string ImagePath, string RotationMode)
```

Parameters

ImagePath

The image file to rotate. If left blank, the current page image file is used by default. Smart parameters are supported.

RotationMode

The type of rotation to apply to the image. Here are the valid values:

0	Auto
1	No rotation
2	90-degree rotation, clockwise
3	180-degree rotation, clockwise
4	90-degree rotation, counter-clockwise

If left blank, Auto is used by default.

Returns

False if any of the following conditions apply:

- The ruleset with this action is not bound to a page object of the document hierarchy

- The action cannot locate the image file that you specified in the first parameter
- The rotation mode that you specified is not within the valid range of values

Otherwise, this action returns True.

Level

Page level.

Details

Use this action to rotate an image. After the action runs and the image is rotated, the applied rotation mode is saved in the page level variable OCRSRotMod.

If you do not specify the rotation mode, the automatic image rotation algorithm is used. This algorithm relies on and works best with images that have a good quality machine printed text. The algorithm does not fully work with images that contain nine-pin dot-matrix text or other non-machine printed text. Also, if an image contains text with various orientations, such as vertical and horizontal text, the image might be rotated in an undesirable way.

To avoid the possibility of the recognition engine not releasing the image until ruleset completion, call this action in a separate ruleset after recognition.

This action supports the automatic retry mechanism.

Example:

In the following example, the first instance of this action rotates the current page image file automatically and saves the applied rotation mode in the variable OCRSRotMod. The second instance applies a 90-degree rotation to the current image.

```
RotateImageExOCR_S ("", "")  
RotateImageExOCR_S ("", "2")
```

Parent topic: [OCR_SR actions](#)

RotateImageOCR_S

Use with the RotateTIO action from the Recog_Shared library to update the CCO file with the correct position coordinates after image rotation.

Member of namespace

OCR_SR

Syntax

```
bool RotateImageOCR_S ()
```

Parameters

None

Returns

False if the ruleset with this action is not bound to a Page object of the Document Hierarchy, or if the action cannot locate the image file representing the current page. Otherwise, True.

Level

Page only.

Details

This action performs automatic rotation of black and white .TIF (or .TIFF) files. The automatic image rotation algorithm relies on, and works best with, images with good quality machine printed text. If an image contains text with various orientations, for example vertical and horizontal, the image might be rotated undesirably. The automatic rotation algorithm does not fully work with images containing 9-pin dot-matrix text or other non-machine printed text.

It is recommended that this action be called in a separate ruleset after recognition due to instances where the recognition engine will not release the image until the ruleset has completed. This problem can manifest as a `cco does not exist` error in the log file.

This action supports the automatic retry mechanism.

Example

```
RotateImageOCR_S ()  
RecognizePageICR_C ()
```

In this example, automatic image rotation is performed prior to full page recognition via the ICR_C actions.

Parent topic: [OCR_SR actions](#)

Related reference:

[SetupAutomaticRetry](#)

SetContinueOnFailureOCR_S

Sets a value indicating whether a recognition action will abort or continue after it has encountered an error.

Member of namespace

OCR_SR

Syntax

```
bool SetContinueOnFailureOCR_S (bool ContinueOnFailure)
```

Parameters

ContinueOnFailure - A value indicating whether a recognition action will abort or continue after it has encountered an error. If this action is not called, the default value of True is used.

Returns

Always True.

Level

Page or Field.

Details

This action sets a value indicating whether a recognition action will abort or continue after it has encountered an error. If this action is not called, the default behavior is for the recognition actions to continue on error. This action is provided for legacy support of rules that manually perform a retry of recognition failures and is provided for backwards compatibility. It is recommended that you allow OCR_SR actions to automatically handle retries of recognition failures. When automatic mode is used, this action does not need to be called.

Example:

```
SetContinueOnFailureOCR_S(true)
```

Parent topic: [OCR_SR actions](#)

SetEngineTimeoutOCR_S

Specifies the number of seconds to wait before it is determined that an OCR/S recognition action is not running properly.

Important:

- If legacy mode is not currently enabled, calling this action enables legacy mode and disables automatic retry mode.
- In legacy mode, rules must be configured to retry recognition operations that fail. To avoid unnecessary rule configuration, use automatic retry instead of calling this action. For more information, see [SetupAutomaticRetry](#).

Member of namespace

OCR_SR

Syntax

```
bool SetEngineTimeoutOCR_S (int Seconds)
```

Parameters

Seconds
Type int

Parameters

Seconds: The value that indicates the number of seconds to wait before it is determined that an OCR/S recognition action is stalled or exited.

Returns

False, if the parameter is not numeric or is less than 1. Otherwise, True.

Level

Page or Field.

Details

This action sets the number of seconds to wait before it is assumed that an OCR/S recognition action is no longer running correctly. When the timeout is reached, the recognition process is removed from memory.

If a recognition action does not complete within the specified number of seconds indicated by a `SetOutOfProcessRecogTimeout` action or a `SetEngineTimeout` action, it is assumed that the recognition engine encountered a severe error. It is removed from memory, and recognition is automatically restarted one more time. If the recognition action completes successfully within the specified time on either the first or second attempt, that recognition action is successful. If the recognition action does not complete by the specified time on the second attempt, the recognition action is set to abort, if the `RecogContinueOnFailure(False)` action was used.

If `SetEngineTimeout` is not called, the default value of 180 seconds is used. In normal conditions, the default value is sufficient and does not need to be changed. This value must be increased only if a single page consistently takes more than 3 minutes to complete, which is not a typical situation. The programmer can choose to shorten this time to reduce the time to detect failures earlier, provided there is time to perform recognition in worst case scenarios. For best results, this timeout can be set the same or longer than the value specified in a `SetOutOfProcessRecogTimeout` action.

Example

```
SetEngineTimeoutOCR_S(180)
RecognizeFieldOCR_S
```

Parent topic: [OCR_SR actions](#)

SetOutOfProcessLoggingOCR_S

Writes logs for the out-of-process process for debugging.

Member of namespace

OCR_SR

Syntax

```
bool SetOutOfProcessLoggingOCR_S (bool EnableLogging)
```

Parameters

EnableLogging - A value indicating whether to write logs for the out-of-process process for debugging.

Returns

Always True.

Level

Page or Field.

Details

Writes logs for the out-of-process process for debugging. This log file is written to the batch folder. Multiple logs are created and they are named, `dcoprocessor.logdcoproc XX_XX_XX.log`, where X is numeric.

Example:

```
SetOutOfProcessLoggingOCR_S(true)
```

Parent topic: [OCR_SR actions](#)

SetOutOfProcessTimeoutOCR_S

Sets the number of seconds to wait to determine that an out-of-process action has stalled.

Member of namespace

OCR_SR

Syntax

```
bool SetOutOfProcessTimeoutOCR_S (int Seconds)
```

Parameters

Seconds - A value indicating the number of seconds to wait to determine that an out-of-process recognition action has stalled.

Returns

False, if the parameter is not numeric or less than 1. Otherwise, True.

Level

Page or Field.

Details

This action sets the number of seconds to wait to determine that an out-of-process action has stalled. If a recognition action does not complete within the specified number of seconds indicated by a *SetOutOfProcessTimeoutOCR_S* action or a *SetEngineTimeoutOCR_S* action, it is assumed that the recognition engine has encountered a severe error, and the recognition is removed from memory. A variable with *RecogStatus* of -1 is created in the calling object in this situation. If *SetOutOfProcessTimeoutOCR_S* is not called, the default value of 600 seconds is used. In normal scenario, the default value is sufficient and does not need to be changed. You may need to increase this value only if a single page consistently takes more than 10 minutes to complete, which is a very atypical situation.

Example:

```
SetOutOfProcessTimeoutOCR_S(180)
```

Parent topic: [OCR_SR actions](#)

UseOutOfProcessRecogOCR_S

Sets whether recognition will run out-of-process or in process. Running out of process improves stability of the application.

Member of namespace

OCR_SR

Syntax

```
bool UseOutOfProcessRecogOCR_S (bool UseOutOfProcessRecog)
```

Parameters

UseOutOfProcessRecog - A value indicating whether recognition will run out-of-process. Set to **True** for out-of-process recognition, and **False** for in-process recognition. By default, the recognition actions run out-of-process.

Returns

Always True.

Level

Page or Field.

Details

This action indicates whether recognition will run out-of-process or in process. Running out of process improves stability of the application.

Example:

```
UseOutOfProcessRecogOCR_S(true)
```

Parent topic: [OCR_SR actions](#)

OpenTextFaxServer actions

Use the OpenTextFaxServer actions to import faxes from an OpenTextFaxServer.

You can use the OpenTextFaxServer actions to create Datacap document batches from incoming faxes. You can also use these actions send the contents of a document to a specified fax number.

- [Connect](#)
Creates the connection to the Fax server.
- [ContinueOnConnectionError](#)
Specifies whether the batch should continue if there is an error connecting to the server.
- [ContinueOnFaxImportError](#)
Specifies whether the batch should abort if there is an error importing a fax.
- [Disconnect](#)
Disconnects the connection from the Fax server.

- [ImportFaxes](#)
Imports the faxes from the Fax server into the document batch.
- [SendAsFax](#)
Faxes the contents of the document or page to the specified Fax number.
- [SetAbortTimeout](#)
Sets the amount of time to wait before you stop running a batch.
- [SetFaxRemovalAfterImport](#)
Sets whether to remove processed faxes from the Fax server. This action must be set to True to enable the import of new faxes.
- [SetInputFolder](#)
Sets the name of the input folder where faxes are to be imported from.
- [SetMaxNumberOfFaxes](#)
Sets the maximum number of faxes that are allowed per batch.
- [SetNumberOfRetries](#)
Sets the number of times to attempt a connection to the Fax server after a connection error occurs.
- [SetPollingInterval](#)
Sets the number of milliseconds to wait before the OpenTextFaxServer resumes fax polling from the Fax server.
- [SetProcessedFaxesFolder](#)
Sets the name of the folder where faxes are to be moved to after they are imported.
- [SetProtocol](#)
Sets the protocol to use to connect to the Fax server.
- [SetRetryTimeout](#)
Sets the number milliseconds to wait before attempting a connection to the fax server after a connection error occurs.
- [SetServerName](#)
Sets the name of the Fax server to which you can upload faxes.
- [SetUserID](#)
Sets the user ID used to log in to the Fax server.
- [SetUserPassword](#)
Sets the password used to log in to the Fax server.
- [SetWindowsAuthentication](#)
Sets whether to use Windows Authentication to connect to the Fax server.

Parent topic: [Global actions](#)

Connect

Creates the connection to the Fax server.

Member of namespace

OpenTextFaxServer

Syntax

```
bool Connect ()
```

Returns

False if the action is not called at the batch level or if the connection to fax server cannot be established. Otherwise, True.

Level

Batch Level.

Details

Connects to the fax server. This action should be called after setting the server connection parameters via the following actions:

- `SetServerName("myserver")`
- `SetUserID("myuser")`
- `SetUserPassword("mypassword")`
- `SetProtocol(4)`
- `SetWindowsAuthentication(True)`

Example

```
SetServerName ("myserver")
SetUserID ("myuser")
SetUserPassword ("mypassword")
SetProtocol (4)
Connect ()
```

Parent topic: [OpenTextFaxServer actions](#)

ContinueOnConnectionError

Specifies whether the batch should continue if there is an error connecting to the server.

Member of namespace

OpenTextFaxServer

Syntax

```
bool ContinueOnConnectionError (bool Continue)
```

Parameters

Continue
Type: bool

Parameters

A boolean value specifying whether or not the batch should abort if there is an error connecting to the server.

Returns

Always True.

Level

Any level.

Details

When the parameter is set to True, the batch finishes with Pending status, avoiding the creation of more batches that will result in an aborted status.

If this action is not called, the default value of False is used and the batch is aborted at the end of processing.

Include this action before the Connect() action.

Example

```
ContinueOnConnectionError(true)
SetNumberOfRetries(3)
SetServerName("myserver")
SetWindowsAuthentication(True)
SetProtocol(4)
Connect()
ImportFaxes()
```

Parent topic: [OpenTextFaxServer actions](#)

ContinueOnFaxImportError

Specifies whether the batch should abort if there is an error importing a fax.

Member of namespace

OpenTextFaxServer

Syntax

```
bool ContinueOnFaxImportError (bool Continue)
```

Parameters

Continue
Type: bool

Parameters

A boolean value specifying whether or not the batch should abort if there is an error importing a fax.

Returns

Always True.

Level

Any level.

Details

Sets a boolean value specifying whether or not the batch should abort if there is an error importing a fax. When the parameter is set to True the batch finishes with Pending status, and contains all faxes that were imported

successfully, up to the last one that failed to be imported.

If `ContinueOnFaxImportError` is never called, the `ImportFaxes` action continue processing after an error. Call `ContinueOnFaxImportError(False)` to stop ingestion of faxes after an error.

Include this action before the `Connect()` action.

Example

```
ContinueOnFaxImportError (true)
SetNumberOfRetries (3)
SetServerName ("myserver")
SetWindowsAuthentication (True)
SetProtocol (4)
Connect ()
ImportFaxes ()
```

Parent topic: [OpenTextFaxServer actions](#)

Disconnect

Disconnects the connection from the Fax server.

Member of namespace

`OpenTextFaxServer`

Syntax

```
bool Disconnect ()
```

Returns

False if the action is not called at the batch level or if the connection to fax server cannot be closed. Otherwise, True.

Level

Batch Level.

Details

Disconnects to the fax server. This action should be called after the `Import()` or `Connect()` actions. Typically this action would be called at the Batch's close node, after the connection to the fax server is made and faxes are imported.

Example

```
SetServerName ("myserver")
SetUserID ("myuser")
SetUserPassword ("mypassword")
SetProtocol (4)
Connect ()
ImportPages ()
Disconnect ()
```

Parent topic: [OpenTextFaxServer actions](#)

ImportFaxes

Imports the faxes from the Fax server into the document batch.

Member of namespace

OpenTextFaxServer

Syntax

```
bool ImportFaxes ()
```

Returns

False if the action is not called at the batch level or if an exception is encountered while importing faxes. Otherwise, True.

Level

Batch Level.

Details

This action imports faxes from the fax server. Each fax that is imported is stored in a document inside the Datacap batch. The following fax information will be stored in the document's variables (some of these variables can be empty):

- FaxUniqueID
- FaxStatus
- TotalPages
- LastHistoryChangeDateTime
- FromFaxNumber
- FromName
- FromVoiceNumber
- FromGeneralFaxNumber
- FromGeneralVoiceNumber
- Attachments
- ToFaxNumber
- ToVoiceNumber

Attention: Setting the batch variable *WriteFaxXMLData* to "1" causes the action to write all possible fax properties to an XML file. The XML is named based on the created document ID for a fax, for example, 20120109.000008.01.xml.

Include this action after a `Connect()` action.

Example

```
SetServerName ("myserver")
SetUserID ("myuser")
SetUserPassword ("mypassword")
SetProtocol (4)
Connect ()
ImportFaxes ()
```

Note: If the `Connect()` action is not called prior to calling `ImportFaxes()`, `ImportFaxes()` automatically calls the `Connect()` action. However, the actions that set the connection parameters need to be called prior to `ImportFaxes()`.

Parent topic: [OpenTextFaxServer actions](#)

SendAsFax

Faxes the contents of the document or page to the specified Fax number.

Member of namespace

OpenTextFaxServer

Syntax

```
bool SendAsFax (string ToFaxNumber, string ToName)
```

Parameters

ToFaxNumber
Type: string
ToName
Type: string

Parameters

- ToFaxNumber: Recipient's fax number. This parameter is required. Smart parameters are supported.
- ToName: Recipient's name. This parameter is optional. If empty, the default ToName configured for the logged in user (on the server) is used. Smart parameters are supported.

Returns

False, if the action is not called at the document or page levels, or the fax number is not specified, or the document does not contain pages (attachments), or if a connection cannot be made to the fax server, or if the fax server returns an exception while attempting to send the fax. Otherwise, True.

Level

Document and Page levels.

Details

Faxes the document contents to the specified fax number.

Example

```
SendAsFax ("123-456-8971", "John Doe")
```

A connection to the Fax server must be established via actions before you can use the SendAsFax action.

Parent topic: [OpenTextFaxServer actions](#)

SetAbortTimeout

Sets the amount of time to wait before you stop running a batch.

Member of namespace

OpenTextFaxServer

Syntax

```
bool SetAbortTimeout (int Milliseconds)
```

Parameters

Milliseconds
Type: int

Parameters

Milliseconds : The amount of time, in milliseconds, to wait before aborting a batch. The default value is 10000 ms (10 seconds).

Returns

False if the action is not called at the batch level. Otherwise, True.

Level

Batch Level.

Details

Sets the amount of time to wait before aborting a batch.

The action waits the specified time before returning when an abort occurs. This action can be useful to prevent a large number of aborted batches due to an abort condition. For example, if the fax server should become unavailable for a time, the abort timeout will limit the amount of aborted batches until the fax server becomes available again.

If this action is not called, the default value of 10 seconds is used.

Include this action before a ImportFaxes() action.

Example

```
SetServerName ("myserver")
SetUserID ("myuser")
SetUserPassword ("mypassword")
SetProtocol (4)
SetAbortTimeout (5000)
Connect ()
ImportFaxes ()
```

Parent topic: [OpenTextFaxServer actions](#)

SetFaxRemovalAfterImport

Sets whether to remove processed faxes from the Fax server. This action must be set to True to enable the import of new faxes.

Member of namespace

OpenTextFaxServer

Syntax

```
bool SetFaxRemovalAfterImport (bool RemoveFaxes)
```

Parameters

RemoveFaxes
Type: bool

Parameters

A boolean that sets whether or not to remove processed faxes from the server. The default value is False.

- True : Faxes will be removed from the fax server once they are imported into a Datacap batch.
- False : Faxes will remain in the fax server once they are imported into a Datacap batch.

The default value is False.

Returns

False if the action is not called at the batch level. Otherwise, True.

Level

Batch Level.

Details

Sets whether or not to remove processed faxes from the server after they have been imported into the Datacap batch.

If this action is not called, the default value of False is used.

Include this action before a ImportFaxes() action.

Example

```
SetServerName ("myserver")
SetUserID ("myuser")
SetUserPassword ("mypassword")
SetProtocol (4)
SetFaxRemovalAfterImport (True)
Connect ()
ImportFaxes ()
```

Parent topic: [OpenTextFaxServer actions](#)

SetInputFolder

Sets the name of the input folder where faxes are to be imported from.

Member of namespace

OpenTextFaxServer

Syntax

```
bool SetInputFolder (string FolderName)
```

Parameters

FolderName
Type: string

Parameters

An string value representing the name of the user folder where faxes are to be imported from.

Returns

Always True.

Level

Any level.

Details

If this action is not called, the faxes are imported from the default user folder.

Include this action before a `ImportFaxes()`.

Example

```
SetNumberOfRetries (3) >  
SetRetryTimeout (3000)  
SetServerName ("myserver")  
SetWindowsAuthentication (True)  
SetProtocol (4)  
Connect ()  
SetInputFolder (INPUT)  
ImportFaxes ()
```

Parent topic: [OpenTextFaxServer actions](#)

SetMaxNumberOfFaxes

Sets the maximum number of faxes that are allowed per batch.

Member of namespace

Syntax

```
bool SetMaxNumberOfFaxes (int MaxFaxes)
```

Parameters

MaxFaxes
Type: int

Parameters

MaxFaxes : The maximum number of faxes allowed per batch. The default value is 100.

Returns

False if the action is not called at the batch level. Otherwise, True.

Level

Batch Level.

Details

Sets the maximum number of faxes allowed per batch.

If this action is not called, the default value of 100 faxes per batch is used.

Include this action before a ImportFaxes() action.

Example

```
SetServerName ("myserver")  
SetUserID ("myuser")  
SetUserPassword ("mypassword")  
SetProtocol (4)  
SetMaxNumberOfFaxes (5)  
Connect ()  
ImportFaxes ()
```

Parent topic: [OpenTextFaxServer actions](#)

SetNumberOfRetries

Sets the number of times to attempt a connection to the Fax server after a connection error occurs.

Member of namespace

OpenTextFaxServer

Syntax

```
bool SetNumberOfRetries (int NumberOfRetries)
```

Parameters

NumberOfRetries
Type: int

Parameters

An integer value representing the number of times to attempt a connection to the fax server after a connection error occurs.

Returns

Always True.

Level

Any level.

Details

Sets the number of times to attempt a connection to the fax server after a connection error occurs.

If this action is not called, the default value of 3 is used.

Include this action before the Connect() action.

Example

```
SetNumberOfRetries (3)
SetServerName ("myserver")
SetWindowsAuthentication (True)
SetProtocol (4)
Connect ()
ImportFaxes ()
```

Parent topic: [OpenTextFaxServer actions](#)

SetPollingInterval

Sets the number of milliseconds to wait before the OpenTextFaxServer resumes fax polling from the Fax server.

Member of namespace

OpenTextFaxServer

Syntax

```
bool SetPollingInterval (int Milliseconds)
```

Parameters

Milliseconds
Type: int

Parameters

Milliseconds : The amount of time, in milliseconds, to wait before polling the fax server again. The default value is 2000 ms (2 seconds).

Returns

False if the action is not called at the batch level. Otherwise, True.

Level

Batch Level.

Details

Sets the amount of time to wait before resuming fax polling from the server.

If this action is not called, the default value of 2 seconds is used.

Include this action before a `ImportFaxes()` action.

Example

```
SetServerName ("myserver")
SetUserID ("myuser")
SetUserPassword ("mypassword")
SetProtocol (4)
SetPollingInterval (5000)
Connect ()
ImportFaxes ()
```

Parent topic: [OpenTextFaxServer actions](#)

SetProcessedFaxesFolder

Sets the name of the folder where faxes are to be moved to after they are imported.

Member of namespace

OpenTextFaxServer

Syntax

```
bool SetProcessedFaxesFolder (string FolderName)
```

Parameters

FolderName
Type: string

Parameters

A string value that represents the name of the user folder where faxes are to be moved to after they are imported.

Returns

Always True.

Level

Any level.

Details

If this action is not called, the faxes remain in the input folder.

Include this action before a `ImportFaxes()`.

Example

```
SetNumberOfRetries (3) >
SetRetryTimeout (3000)
SetServerName ("myserver")
SetWindowsAuthentication (True)
SetProtocol (4)
Connect ()
SetProcessedFaxesFolder (OUTPUT)
ImportFaxes ()
```

Parent topic: [OpenTextFaxServer actions](#)

SetProtocol

Sets the protocol to use to connect to the Fax server.

Member of namespace

OpenTextFaxServer

Syntax

```
bool SetProtocol (int Protocol)
```

Parameters

Protocol
Type: int

Parameters

The protocol to be used to connect to the fax server. The default value is 4 (TCPIP).
Valid parameter values are:

- 1 : Named Pipes
- 2 : IPXOS2
- 3 : SPX
- 4 : TCPIP
- 5 : IPX

- 6 : SecTCPIP
- 7 : SecSPX

Returns

False if the action is not called at the batch level or if the parameter is invalid. Otherwise, True.

Level

Batch Level.

Details

Sets the protocol to be used to connect to the fax server.

If this action is not called, the default value of 4 (TCPIP protocol) is used.

Include this action before a `ImportFaxes()` or `Connect()` action.

Example

```
SetServerName ("myserver")
SetUserID ("myuser")
SetUserPassword ("mypassword")
SetProtocol (4)
Connect ()
ImportFaxes ()
```

Parent topic: [OpenTextFaxServer actions](#)

SetRetryTimeout

Sets the number milliseconds to wait before attempting a connection to the fax server after a connection error occurs.

Member of namespace

OpenTextFaxServer

Syntax

```
bool SetRetryTimeout (int Milliseconds)
```

Parameters

Milliseconds
Type: int

Parameters

An integer value representing the number milliseconds to wait before attempting a connection to the fax server after a connection error occurs.

Returns

Always True.

Level

Any level.

Details

If this action is not called, the default value of 3000 milliseconds is used.

Include this action before a `ImportFaxes()` or `Connect()` action.

Example

```
SetNumberOfRetries (3) >  
SetRetryTimeout (3000)  
SetServerName ("myserver")  
SetWindowsAuthentication (True)  
SetProtocol (4)  
Connect ()  
ImportFaxes ()
```

Parent topic: [OpenTextFaxServer actions](#)

SetServerName

Sets the name of the Fax server to which you can upload faxes.

Member of namespace

OpenTextFaxServer

Syntax

```
bool SetServerName (string ServerName)
```

Parameters

ServerName
Type: string

Parameters

ServerName : The name of the fax server. Smart parameters are supported.

Returns

False if the action is not called at the batch level. Otherwise, True.

Level

Batch Level.

Details

Sets the name of the fax server to connect to.

Include this action before an ImportFaxes() or Connect() action

Example

```
SetServerName ("myserver")
SetUserID ("myuser")
SetUserPassword ("mypassword")
SetProtocol (4)
Connect ()
ImportFaxes ()
```

Parent topic: [OpenTextFaxServer actions](#)

SetUserID

Sets the user ID used to log in to the Fax server.

Member of namespace

OpenTextFaxServer

Syntax

```
bool SetUserID (string UserID)
```

Parameters

UserID
Type: string

Parameters

UserID : The user ID to be used to connect to the fax server. Smart parameters are supported.

Returns

False if the action is not called at the batch level. Otherwise, True.

Level

Batch Level.

Details

Sets the user ID to connect to the fax server.

Include this action before a ImportFaxes() or Connect() action.

Example

```
SetServerName ("myserver")
SetUserID ("myuser")
SetUserPassword ("mypassword")
```

```
SetProtocol (4)
Connect ()
ImportFaxes ()
```

Parent topic: [OpenTextFaxServer actions](#)

SetUserPassword

Sets the password used to log in to the Fax server.

Member of namespace

OpenTextFaxServer

Syntax

```
bool SetUserPassword (string UserPassword)
```

Parameters

UserPassword
Type: string

Parameters

UserPassword : The user ID password to connect to the fax server. Smart parameters are supported.

Returns

False if the action is not called at the batch level. Otherwise, True.

Level

Batch Level.

Details

Sets the user ID password to connect to the fax server.

Include this action before a `ImportFaxes()` or `Connect()` action.

It is recommended that you create an advanced value in the custom values tab in the Application Manager to encrypt your password instead of hard coding it in the action parameter. The password can be retrieved using smart parameters.

Example

```
SetServerName ("myserver")
SetUserID ("myuser")
SetUserPassword ("mypassword")
SetProtocol (4)
Connect ()
ImportFaxes ()
```

Parent topic: [OpenTextFaxServer actions](#)

SetWindowsAuthentication

Sets whether to use Windows Authentication to connect to the Fax server.

Member of namespace

OpenTextFaxServer

Syntax

```
bool SetWindowsAuthentication (bool UseWindowsAuthentication)
```

Parameters

UseWindowsAuthentication
Type: bool

Parameters

Sets whether or not to use Windows Authentication to connect to the fax server. The default value is False.

- True : Windows Authentication will be used. The actions SetUserID() and SetUserPassword() are not required when UseWindowsAuthentication is set to True.
- False : Fax Server user authentication will be used. The actions SetUserID() and SetUserPassword() are required when UseWindowsAuthentication is set to False.

The default value is False.

Returns

False if the action is not called at the batch level. Otherwise, True.

Level

Batch Level.

Details

Include this action before a ImportFaxes() or Connect() action.

Example

```
SetServerName ("myserver")
SetWindowsAuthentication (True)
SetProtocol (4)
Connect ()
ImportFaxes ()
```

Parent topic: [OpenTextFaxServer actions](#)

PatternMatch actions

Use the `PatternMatch` actions for pattern-based page identification and for page registration (alignment). Page registration is important when you are working with OMR check boxes.

`PatternMatch` actions look for a match to specified anchor patterns, identifies the page, sets the page type, and sets the confidence level for pattern matching.

- [MatchPattern](#)
Align the image of this field on the current page with the fingerprint
- [pat_RecogMatch_Id](#)
Identifies the current page type by matching OCR results in any fingerprint Anchor zone with OCR results for the corresponding zone on the current page.
- [pat_RegisterZones](#)
Registers and adjusts the positions of all fields on the current source page, based on the positions of the page's designated Anchor field(s).
- [pat_ReleasePageAnchors](#)
An action that can be called at the end of a batch to release information about the identity and location of a page's Anchor field(s).
- [PatternMatch_Fingerprint](#)
Identifies a page from a specified list of fingerprints.
- [PatternMatch_Identify](#)
Identifies a page by using image pattern matching.
- [PatternMatch_PageType](#)
Identifies a page according to its Page Type.
- [SetMatchConfidence](#)
Sets the confidence threshold for pattern matching.

Parent topic: [Global actions](#)

MatchPattern

Align the image of this field on the current page with the fingerprint

Member of namespace

`PatternMatch`

Syntax

```
bool MatchPattern ()
```

Parameters

None.

Returns

False, if any of the follow conditions occur.

- The Anchor position that is returned is not Numeric.
- No image is found.
- The accuracy of the match is below the set Confidence Value.
- An Anchor match does not occur.

Otherwise, True.

Level

Field level.

Details

Searches on the current image in a zone that is associated with the current field for a match to the pattern specified for this field in a fingerprint. The zoned area from the original fingerprint is matched against a larger zone in the current image. The search area is controlled by the METRIC variable. METRIC=200,100 means search from 200 pixels to the left and right, and 100 pixels above and below the expected location. If METRIC is not specified, the default is 500 pixels horizontal and vertical.

The fingerprint is determined by the current image's Fingerprint ID, or the Global Fingerprint ID if the current image is not identified.

MatchPattern can be called on any field and if matched, an offset variable is saved for that field. If called before ReadZones, then ReadZones uses the offset for that field when its position is set. Other fields are unaffected.

If the field is matched to the fingerprint with a confidence equal to or greater than the required confidence, the position of the field is set to the found location. If the field is not matched, the function returns false. If not found and the field's Required variable is non-zero, the field status is set to 1 (Error or Validation failed).

This action operates on black and white images, grayscale or color images cause the action to fail. The fingerprint image must have the same resolution (DPI) as the current page image. The geometric shape that is contained in the Anchor field must be bold and well-defined with clear edges, with crisp, black and white markings that product a distinct shape. The shape must be thick and compact, not composed of long thin lines. To avoid false positive matches, the shape must not match other shapes or black areas that might exist nearby within the same image.

Example

```
MatchPattern ()
```

Parent topic: [PatternMatch actions](#)

pat_RecogMatch_Id

Identifies the current page type by matching OCR results in any fingerprint Anchor zone with OCR results for the corresponding zone on the current page.

Member of namespace

PatternMatch

Syntax

```
bool pat_RecogMatch_Id ()
```

Parameters

None.

Returns

True if the ruleset is bound to a Page, and a fingerprint matching the text of at least one Anchor field is found. Otherwise, and in case of any errors, False. In addition, the page variable *TemplateID* is set to the matching Fingerprint ID.

Level

Page only.

Details

pat_RecogMatch_Id identifies the page by matching text from any fingerprint Anchor field with the corresponding text on the current page. Fuzzy matching is used. Full-page OCR or ICR must be performed prior to calling this action.

If any Anchor field text in the current page matches the zonal text of any fingerprint, the page is identified by that fingerprint (first match). The Type of the current page is set to the fingerprint page type if a match is found. Full page OCR or ICR must be performed on both the fingerprints and the current image prior to calling this action. Text to be matched is extracted from each fingerprint's Anchor field, which should be defined tightly around the text in the fingerprint. The search area in the current image is the fingerprint-specific field zone in the Document Hierarchy, extended by any associated METRIC variable.

Page identification using pat_RecogMatch_ID (text matching) is mutually exclusive with identification using graphical pattern matching actions (PatternMatch_Identify, etc.). Anchor fields in the Document Hierarchy should be selected carefully so that false positive text matches do not occur.

Example

```
pat_RecogMatch_Id()
```

Parent topic: [PatternMatch actions](#)

pat_RegisterZones

Registers and adjusts the positions of all fields on the current source page, based on the positions of the page's designated Anchor field(s).

Member of namespace

PatternMatch

Syntax

```
bool pat_RegisterZones ()
```

Parameters

None.

Returns

True if the ruleset with this action is bound to a Page object of the Document Hierarchy, and if the action can find all designated Anchor fields. Otherwise, False.

Level

Page only.

Details

`pat_RegisterZones` registers and adjusts the positions of all fields on the current page, based on the previously matched positions of the page's designated Anchor field(s). Anchor fields are determined by the Anchor Field setting in Datacap Studio, for each field. Prior to calling `pat_RegisterZones`, usually in a different task or ruleset, one of the `PatternMatch` actions that performs Anchor matching must be called. Then, when the `pat_RegisterZones` action is called, the expected positions of the Anchor fields on the image (taking into account the Fingerprint classification) are compared with the recognized positions of the fields identified as an Anchor field. The action `ReadZones` must be called prior to `pat_RegisterZones`. If any required Anchors are not matched, an operator may be required to update the Anchor position in a verify or fixup task. All matched or manually adjusted Anchor positions are used for adjustment, Anchors that are not matched are ignored.

- If one Anchor is found, the field positions are all shifted by the same amount.
- If two or more Anchors are found, the field positions are shifted by different amounts, depending on their distance from each Anchor. This process is called Interpolation.

The expected positions of the Anchor fields on the image (taking into account the Fingerprint classification) are compared with the recognized positions of those Anchor fields - or the Anchor positions set manually by a Fixup task's operator.

Example

```
ReadZones ()
pat_RegisterZones ()
PrecognizePageFieldsOCR_S ()
```

Parent topic: [PatternMatch actions](#)

pat_ReleasePageAnchors

An action that can be called at the end of a batch to release information about the identity and location of a page's Anchor field(s).

Member of namespace

PatternMatch

Syntax

```
bool pat_ReleasePageAnchors ()
```

Parameters

None.

Returns

Always True.

Level

Page only.

Details

This action can be optionally called to release the small amount of Anchor memory that was allocated by the action `pat_RegisterZones`. If `pat_ReleasePageAnchors` is not called, the memory will be released at the end of the batch or the next time `pat_RegisterZones` is called.

Example

```
pat_ReleasePageAnchors ()
```

Parent topic: [PatternMatch actions](#)

PatternMatch_Fingerprint

Identifies a page from a specified list of fingerprints.

Member of namespace

PatternMatch

Syntax

```
bool PatternMatch_Fingerprint (StrParam)
```

Parameters

A comma-separated list of one or more Fingerprint IDs.

Returns

False, if the rule that contains this action was not applied to a Page object of the Document Hierarchy; if a parameter is invalid; if a match does not occur; or if one or more of the specified fingerprints do not exist. Otherwise, True.

Level

Page level only.

Details

`PatternMatch_Fingerprint` identifies a page's type and fingerprint by using geometric pattern matching. The locations of unique patterns are configured as Anchor fields for each fingerprint in the Document Hierarchy. One or more Anchor fields can be used to match geometric shapes on a fingerprint to the current image. If one or more Anchor fields on the current page match a fingerprint with equal to or greater than the configured confidence level, the page is identified with that fingerprint. The action does not require all defined anchors to match - the first match is used. The action loads all Anchor field patterns from the specified fingerprints, then searches on the current image for each of the patterns in the associated zones. The search area for each zone is increased by the dimensions that are specified in the page METRIC variable. If METRIC is not specified, the default is 500 pixels horizontal and vertical. When this action finds a match, it sets the matching Fingerprint ID

and Page Type. It also creates page-level fields and update the Anchor fields with Anchor-specific pattern offset values in a field-level *Image_Offset* variable. The offset can be used subsequent to matching a fingerprint. The `pat_RegisterZones` action can be used to align the zones in the fingerprint to the current image, providing more accurately positioned text in each field.

This action requires the current page image to be bi-tonal (black and white). Grayscale or color images cause the action to fail. The fingerprint image must have the same resolution (DPI) as the current page image. The geometric shape that is contained in each Anchor field must be bold and well-defined with clear edges, with crisp, black and white markings that produce a distinct shape. The shape must be thick and compact, not composed of long thin lines. To avoid false positive matches, the shape must not match other shapes or black areas that might exist nearby within the same image.

Example

```
PatternMatch_Fingerprint(1024,1034,1035,1036)
```

This example compares the current page to the four fingerprints that are specified by their IDs.

Parent topic: [PatternMatch actions](#)

PatternMatch_Identify

Identifies a page by using image pattern matching.

Member of namespace

PatternMatch

Syntax

```
bool PatternMatch_Identify ()
```

Parameters

None.

Returns

False, if the rule that contains this action was not applied to a Page object of the Document Hierarchy; if a pattern match is not found; or if fingerprints do not exist. Otherwise, True.

Level

Page level only.

Details

`PatternMatch_Identify` identifies a page's type and fingerprint by using geometric pattern matching. The locations of unique patterns are configured as Anchor fields for each fingerprint in the Document Hierarchy. One or more Anchor fields can be used to match geometric shapes on a fingerprint to the current image. If one or more Anchor fields on the current page match a fingerprint with equal to or greater than the configured confidence level, the page is identified with that fingerprint. The action does not require all defined anchors to match - the first match is used. The action loads all Anchor field patterns from the fingerprint library, then searches on the current image for each of the patterns in the associated zones. The search area for each zone

is increased by the dimensions that are specified in the page METRIC variable. If METRIC is not specified, the default is 500 pixels horizontal and vertical. When this action finds a match, it sets the matching Fingerprint ID and Page Type. It also creates page-level fields and update the Anchor fields with Anchor-specific pattern offset values in a field-level *Image_Offset* variable. The offset can be used subsequent to matching a fingerprint. The *pat_RegisterZones* action can be used to align the zones in the fingerprint to the current image, providing more accurately positioned text in each field.

This action requires the current page image to be bi-tonal (black and white). Grayscale or color images cause the action to fail. The fingerprint image must have the same resolution (DPI) as the current page image. The geometric shape that is contained in each Anchor field must be bold and well-defined with clear edges, with crisp, black and white markings that produce a distinct shape. The shape must be thick and compact, not composed of long thin lines. To avoid false positive matches, the shape must not match other shapes or black areas that might exist nearby within the same image.

Example

```
PatternMatch_Identify()
```

Parent topic: [PatternMatch actions](#)

PatternMatch_PageType

Identifies a page according to its Page Type.

Member of namespace

PatternMatch

Syntax

```
bool PatternMatch_PageType (StrParam)
```

Parameters

One or more Page Types defined in the Document Hierarchy

Returns

False if the rule containing this action was not applied to a Page object of the Document Hierarchy; if the parameter is invalid; if a match does not occur; or if fingerprints do not yet exist. Otherwise, True.

Level

Page level only.

Details

PatternMatch_PageType identifies a page's type and fingerprint using geometric pattern matching. The locations of unique patterns are configured as Anchor Fields for each fingerprint in the Document Hierarchy. One or more Anchor fields can be used to match geometric shapes on a fingerprint to the current image. If one or more Anchor fields on the current page match a fingerprint, at or above the configured confidence level, the page is identified with that fingerprint. The action does not require all defined anchors to match - the first match is used. The action loads all Anchor field patterns from fingerprints with the specified page types, then

searches on the current image for each of the patterns in the associated zones. The search area for each zone is increased by the dimensions specified in the page METRIC variable. If METRIC is not specified, the default is 500 pixels horizontal and vertical. When this action finds a match, it sets the matching Fingerprint ID and Page Type. It will also create page-level fields and update the Anchor fields with Anchor-specific pattern offset values in a field-level *Image_Offset* variable. The offset can be used subsequent to matching a fingerprint. The `pat_RegisterZones` action can be used to align the zones in the fingerprint to the current image, providing more accurately positioned text in each field.

This action requires the current page image to be bitonal (black and white), grayscale or color images will cause the action to fail. The fingerprint image must have the same resolution (DPI) as the current page image. The geometric shape contained in each Anchor field should be bold and well defined with clear edges, with crisp black and white markings, producing a distinct shape. The shape should be thick and compact, not composed of long thin lines. To avoid false positive matches, the shape should not match other shapes or black areas that may exist nearby within the same image.

Example

```
PatternMatch_PageType (HCFA 1500)
```

This action looks for a match among the inventory of fingerprints that have a page type of "HCFA 1500".

Parent topic: [PatternMatch actions](#)

SetMatchConfidence

Sets the confidence threshold for pattern matching.

Member of namespace

PatternMatch

Syntax

```
bool SetMatchConfidence (StrParam)
```

Parameters

The value of the confidence threshold.

The value must be between 0 (lowest confidence) and 9 (highest confidence).

Higher values require fewer differences between the compared areas to return a positive match value.

Returns

False if the parameter is not a number between 0 and 9. Otherwise, True.

Level

All.

Details

Sets the confidence threshold for pattern matching.

Example

```
SetMatchConfidence (9)
```

Parent topic: [PatternMatch actions](#)

Picture actions

Use the Picture actions to do field validations by picture strings. Picture strings define the supported format of a field such as a social security number, phone number, date.

A social security number, for example, is always *<three digits >-<two digits >-<four digits>*. You can define a picture string to represent this format and then use it to make sure that social security number fields contain conforming values.

- [PIC_ApplyPictureString](#)
Validates the current field by using the specified picture string.
- [PIC_FilterFields](#)
Validates the format of the current field, when called from a field, or all fields on the current page, when called from a page. Uses the picture string that is stored in the PictureString variable of the field.
- [PIC_FormatFields](#)
Validates the format of the current field or all fields on the current page and uses another to replace problem characters.
- [PIC_ReplaceBlankField](#)
If the current field is blank, sets the field value to the character that is specified.
- [PIC_SetPictureCharacter](#)
Defines up to 10 custom picture strings (0-9) that you can reference from the PIC_ApplyPictureString action.
- [PIC_ValidateField](#)
Validates the format of the current field by using the picture string that is stored in the PictureString variable of the field.

Parent topic: [Global actions](#)

PIC_ApplyPictureString

Validates the current field by using the specified picture string.

Syntax

```
bool PIC_ApplyPictureString (StrParam)
```

Parameters

The picture string to validate the field.

Returns

False, if called at the wrong level, if the picture string is longer than the field value or if the field fails the picture string validation. Otherwise, True.

Level

Field level.

Details

Validates the current field using a runtime *PictureString* as an argument. See the `PIC_FormatFields` action for picture string details.

Using the provided picture string, this action will test that each of the characters in the current field are allowed. The provided picture string must be the same length or shorter than the data on the field. If the picture string is shorter, then the last character of the picture string will be used to validate all remaining characters in the field.

See the help for action `PIC_FormatFields` for an overview of picture strings. Unlike `PIC_FormatFields` which uses the *PictureString* variable, `PIC_ApplyPictureString` accepts the picture string as a variable only.

Example

```
PIC_SetPictureCharacter("0,01")
PIC_SetPictureCharacter("1,0123")
PIC_SetPictureCharacter("2,-./")
PIC_ApplyPictureString("0N21N2NN")
```

This example creates custom picture strings for 0, 1 and 2. They are then used here to provide tighter control on the allowed input. "0N21N2NN" format matches a typical 6 digit date specification like "01/07/67".

Parent topic: [Picture actions](#)

PIC_FilterFields

Validates the format of the current field, when called from a field, or all fields on the current page, when called from a page. Uses the picture string that is stored in the *PictureString* variable of the field.

Syntax

```
bool PIC_FilterFields ()
```

Parameters

None.

Returns

Always True.

Level

All levels.

Details

Replaces a character and adjusts the confidence based on the *PictureString* defined for the field.

Lowers the Confidence Rating of any character in a field that does not satisfy the Picture String's criteria and replaces the problem character with a low confidence space. It is very similar to the `FormatFields` action but

does not use alternative recognition characters.

This action has two roles. If a character in the field does not match the picture string format defined for that field

1. It replaces any "problem" characters with a space character and marked as low confidence.
2. It lowers the Confidence Rating of any character in a field that does not satisfy the Picture String's criteria.
3. Any alternative recognition characters are removed from the field after execution.

Note: This Action is recursive and will affect all child fields of the calling node. While not direct input to this action, this action works with picture strings that are defined for a field. See the `PIC_FormatFields` action for a list of all available picture string codes and information about the `PictureString` variable.

Example

```
rrSet("XxN,@F.PictureString")
PIC_FilterFields()
```

This example expects the current field to have the first character be either an alphabetic character or a digit, the second character can be an alphabetic character, digit or punctuation character and the remaining characters must only be digits.

Parent topic: [Picture actions](#)

Related reference:

[PIC_FormatFields](#)

[PIC_ValidateField](#)

PIC_FormatFields

Validates the format of the current field or all fields on the current page and uses another to replace problem characters.

Syntax

```
bool PIC_FormatFields ()
```

Parameters

None.

Returns

Always True.

Level

All levels.

Details

Lowers the Confidence Rating of any character in a field that does not satisfy the `PictureString` criteria.

This action adjusts the character confidence of a field, and optionally replaces characters that are based on the picture string set for the field. It is similar to the `FilterFields` action.

This action has two roles, if a character in the field does not match the picture string format that is defined for that field.

1. It replaces any problem characters with an alternative character from a secondary recognition engine, if one exists. If an alternative recognition character does not exist, then the original character is unchanged.
Attention: There must be an equal number of alternative characters as the field length, and the alternative character must also be valid within the field's picture string for substitution to occur. If the alternative recognition character is also not a valid picture string character, then no substitution occurs.
2. It lowers the Confidence Rating of any character in a field that does not satisfy the picture string's criteria.

Alternative recognition characters are removed from the field after execution.

Important: This Action is recursive and affects all child fields of the calling node.

Picture Strings:

This action works with picture strings that are defined for a field. The picture string must be stored in a field variable called *PictureString*. Picture strings improve and filter recognition results, and are used to limit characters that are typed into that field during verify. The PIC_FormatFields and PIC_FilterFields actions can be called to enforce *PictureString* after recognition rules are started. The PIC_ApplyPictureString action is an exception that does not use the *PictureString* variable.

Recognition actions do not pay attention to this property. Individual recognition engines have their own parameters to help guide the recognition. The Web Verify task always enforces *PictureString*. Thick client Verify panels that are constructed by Batch Pilot Autoform also enforces *PictureString* specifications.

PIC_FilterFields replaces non-matching characters with low confidence spaces. PIC_FormatFields lowers the confidence. The DCEdit control enforces them during verify.

The picture values can be set in *PictureString* in two ways.

1. Use the rrunner action rrSet in a rule set. With this action, you can specify the *PictureString* variable and set it to the value that you want.
2. In the Zones tab of Datacap Studio, right-click on the field you want and choose Manage Variables.

While not direct input to this action as a standard parameter, here are the valid picture string characters that can be set in the *PictureString* field variable and are then used by this action.

- A: Alphabetic characters only or a space. Numeric and punctuation characters are not valid.
- a: Alphabetic, space and punctuation characters.
- D: Dates. The dates must be expressed with numeric characters. You can delimit months, dates, and years with hyphens, periods, and forward slashes.
- F: Float numbers, which are fractional numbers. To accommodate fractional values, you can include both numbers and a period (for the decimal separator) in this picture string. The F character allows minus signs to represent negative numbers.
- f: Numeric and punctuation characters.
- L: Lowercase alphabetic and space characters.
- l: Lowercase alphabetic, space, and punctuation characters.
- N: Numeric characters only.
- n: Uppercase alphabetic, numeric, or space characters.
- P: Punctuation and space characters.
- T: Time values. These values are expressed in numbers with a colon. In addition, the characters P, M, and A are allowed to distinguish between morning and afternoon times, and colon characters are allowed to delimit hours, minutes, and seconds.
- U: Uppercase alphabetic and space characters.

- u: Uppercase alphabetic, space, and punctuation characters.
- X: Alphabetic, space and numeric characters.
- x: Alphabetic, space, numeric, and punctuation characters.
- Z: Any character.
- #: Numeric characters and the minus sign.

PIC_SetPictureCharacter can be used to define up to 10 more application-specific picture strings at run time, identified as 0 through 9.

Example

```
rrSet("AN,@F.PictureString")
PIC_FormatFields()
```

This example expects the current field to contain a single alphabetic character followed by an unlimited number of digits. Here the *PictureString* variable is set at run time, but it can instead be configured at design time in the setup DCO in Datacap Studio.

Parent topic: [Picture actions](#)

Related reference:

[PIC_FilterFields](#)

[PIC_ValidateField](#)

[PIC_SetPictureCharacter](#)

PIC_ReplaceBlankField

If the current field is blank, sets the field value to the character that is specified.

Syntax

```
bool PIC_ReplaceBlankField (StrParam)
```

Parameters

A character or string that will be placed into the field if it is blank.

Returns

False if it is called at the wrong level or if the parameter is missing, otherwise True.

Level

Field level.

Details

- If a field is blank, it replaces it with a single character.
- If a field is empty or only contains spaces, it is replaced with the character or string that is passed in as a parameter.
- If the field is replaced with the input parameter, the confidence is changed to a low confidence of 1.

Example

```
PIC_ReplaceBlankField("~")
```

PIC_SetPictureCharacter

Defines up to 10 custom picture strings (0-9) that you can reference from the PIC_ApplyPictureString action.

Syntax

```
bool PIC_SetPictureCharacter (StrParam)
```

Parameters

Two comma-separated parameters

1. The picture string identifier. The value must be between 0 through 9.
2. A string of characters to associate with the picture string identifier (the first parameter).

Returns

False, if the parameter input is invalid. Otherwise, True.

Level

Any level.

Details

Configures application-specific picture strings.

In addition to the predefined character strings, custom picture strings can be configured. The picture string values 0 - 9 can be configured to allow validations that are not covered by the predefined settings.

It is possible to configure your verify panel edit control to restrict keyboard entry that is based on picture strings when you use the *PictureString* field variable. Only predefined picture strings work with the edit control. Any custom picture strings that are created by PIC_SetPictureCharacater action do not cause the edit control to restrict user input.

Examples

This example creates custom picture strings for 0, 1 and 2. They are then used to provide tighter control on the allowed input. "0N21N2NN" format matches a typical 6-digit date specification like "01/07/67".

```
PIC_SetPictureCharacter("0,01")
PIC_SetPictureCharacter("1,0123")
PIC_SetPictureCharacter("2,-./")
PIC_ApplyPictureString("0N21N2NN")
```

This example is the same except that the picture string is set up in the *PictureString* variable in Datacap Studio, so it is not seen here.

```
PIC_SetPictureCharacter("0,01")
PIC_SetPictureCharacter("1,0123")
PIC_SetPictureCharacter("2,-./")
PIC_ValidateField()
```

Related reference:[PIC_FormatFields](#)[PIC_FilterFields](#)[PIC_ApplyPictureString](#)

PIC_ValidateField

Validates the format of the current field by using the picture string that is stored in the `PictureString` variable of the field.

Syntax

```
bool PIC_ValidateField ()
```

Parameters

None.

Returns

False if the field value does not satisfy the Picture String criteria of the field. Otherwise True.

Level

Field level only.

Details

Checks the value of all characters in a field against that field's *PictureString* criteria.

If a character in the field does not match the picture string format defined for that field, it lowers the Confidence Rating of any character in a field that does not satisfy the Picture String's criteria. The criteria is stored in the *PictureString* variable that is bound to the field.

Note: Fields with a status of '-1' (Hidden) are checked but this action will not return false if the value does not match the picture string criteria.

While not direct input parameters to this action, this action works with picture strings that are defined for a field. See the `PIC_FormatFields` action for a list of all available picture string codes and information about the *PictureString* variable.

Example

```
PIC_ValidateField()
```

Parent topic: [Picture actions](#)

Related reference:[PIC_FormatFields](#)[PIC_FilterFields](#)[PIC_SetPictureCharacter](#)

POLR actions

Use the POLR action matches line items from your invoice image to the corresponding purchase order.

The POLR action pre-matches invoice line items with the purchase order before it runs the verification task.

- [CallPOLR](#)
Pre-matches invoice line items with the purchase order before it runs the verification task.

Parent topic: [Global actions](#)

CallPOLR

Pre-matches invoice line items with the purchase order before it runs the verification task.

Syntax

```
bool CallPOLR (StrParam)
```

Parameters

The ADOBDB constant number for the PO number field. When using bind variables, the data type of the PO Number is specified with this action.

Returns

Always True.

Level

Page level.

Details

This action is used to pre-match invoice line items with the PO prior to verify operator verification. The record set for the PO is retrieved using the information in the settings.ini. This calls the record set according to the DSN in the settings.ini. PODSN and POLookup indicate how to obtain the record set. The record set is expected to be the line items for the PO for the current document and is keyed off of the PO number. It then uses the POLR logic to perform the automatic matching.

Note: The TestPODSN and PODSN ini entries support smart parameters to allow for secure connection strings. The settings ini file must contain values for these keys:

- [POLR]
- Qty=
- ItemID=
- Price=
- WriteUnusedPOLInes=
- PriceTolerance=
- SeparatorCharacter=

If the station name has a suffix of "-Test" then this key must exist:

- [Database]
- TestPODSN=
- TestPOLookup=

If the station name does not have a suffix of "-Test" then this key must exist:

- [Database]
- PODSN=
- POLookup=

Example:

```
CallPOLR("200")
```

Parent topic: [POLR actions](#)

Recog_Shared actions

Use the Recog_Shared actions to do various fingerprint and recognition-related functions.

The Recog_Shared actions can recognize things like check box options and write the recognition results to the page data files.

- [AnalyzeImage](#)
Converts the Image file (.tif) that represents the current page to a Fingerprint file (.cco) file for the page.
- [CCONormalization_OFF](#)
Prevents the automatic running of NormalizeCCO procedures after a full-page recognition action was run.
- [CreateTextFile](#)
Creates a Text file (.txt) for the current page; adds the page's recognized values to the file; and places the file in the current batch, in your application's Batches directory.
- [IsBlankPage](#)
Counts the number of words in the Fingerprint file (.cco) file of the current page and returns True if the count is less than or equal to the number you enter as the parameter.
- [RecogContinueOnFailure](#)
Determines if a batch will abort if page or field recognition fails.
- [RecogOMRThreshold](#)
Performs OMR check box recognition by counting black pixels within each OMR box area in a Field with one or more OMR boxes.
- [RegisterPageFields](#)
Returns the field positions for all zoned fields of the current page.
- [RotateTio](#)
Checks if an Image file processed by the ImageFix action that assigns a .tio extension to the file needs to be rotated by 90, 180, or 270 degrees. If so, the action rotates and then saves the Image file with the same .tio extension.
- [SetAdjustFieldToChars](#)
Optional setting for SnapCCOToDCO to adjust the field position to its character positions.
- [SetFingerprintRecogPriority](#)
Sets the option that controls whether a full-page recognition action is to create a Fingerprint file(.cco) - aka a CCO file - for the current page.
- [SetFullPageRecogArea](#)
An optional action that sets the area of the current page that is to be the target of recognition procedures, when full-page recognition action is invoked.
- [SetOutOfProcessRecogTimeout](#)
Sets the number of seconds to wait before it is determined that a recognition action is no longer running properly.
- [SetRecogFailureRetryDelay](#)
Sets the number of seconds to wait before restarting a failed recognition action.

- [SetupAutomaticRetry](#)
Changes the settings that govern the automatic retry mechanism.
- [SnapCCOtoDCO](#)
Transfers the recognition results in the current page's CCO file - its Fingerprint file - to the appropriate Field objects of the Document Hierarchy...its setup DCO.
- [SnapDCOtoCCO](#)
Transfers the recognition results assigned to Field objects of the Document Hierarchy (aka the setup DCO) to the current page's CCO file, also known as its Fingerprint file.
- [SnapFieldtoChars](#)
Adjusts the zone position of the passed dco field to the field's character positions.
- [UseOutOfProcessRecog](#)
Causes recognition to be performed in a process that is separate from the process that is running the recognition actions.

Parent topic: [Global actions](#)

AnalyzeImage

Converts the Image file (.tif) that represents the current page to a Fingerprint file (.cco) file for the page.

Member of namespace

Recog_Shared

Syntax

```
bool AnalyzeImage ()
```

Parameters

None.

Returns

False if the ruleset with this action is not bound to a Page object of the Document Hierarchy. Otherwise, True.

Level

Page level.

Details

This action creates the following items:

CCO fingerprint file	Converts the Image file (.tif) that represents the current page to a CCO fingerprint file for the page. The fingerprint file is a condensed representation of the dark areas on the page. These files can be used with the FindFingerprint and related actions, but they are not compatible with fingerprints that are created by OCR actions. Also, they do not contain text that can be used with locate actions or for click-n-key data entry.
CCOFILE variable	Creates a CCOFILE variable on the current page to indicate the successful creation of the CCO file.

A ruleset with this action should be bound to a Page object that represents an application's source page.

The action is not required if full-page recognition takes place using actions such as `RecognizePageOCR_S` or `RecognizePageICR_C`.

Important: Fingerprint matching accuracy can decline for images with a very large number of small dots. This condition might be due to large dotted or shaded areas on the original document, speckled noise in the scanned image, or images with text characters that are very broken up. If the fingerprint matching is too inaccurate for your purposes, use full-page recognition instead of this action. For more information, see [Changing the fingerprint creation method](#).

Example

```
AnalyzeImage ()
SetProblemValue (0.5)
SetSearchArea (0.5)
FindFingerprint (True)
```

This sequence generates a CCO file for the current page and attempts to match the current page with a fingerprint. For more information about the matching process, see the descriptions of the AutoDoc actions.

Parent topic: [Recog_Shared actions](#)

CCONormalization_OFF

Prevents the automatic running of NormalizeCCO procedures after a full-page recognition action was run.

Member of namespace

Recog_Shared

Syntax

```
bool CCONormalization_OFF ()
```

Parameters

None.

Returns

False if the action does not run at the Page level. Otherwise, True.

Level

Page level.

Details

A full-page recognition action such as `RecognizePageICR_C` automatically calls the `NormalizeCCO` action, which is thorough but time-consuming, after recognition is complete. This action is part of the `cco2cco.rrx` file.

To bypass this procedure, place `CCONormalization_OFF` just before the recognition action.

Example

```
CCONormalization_OFF()  
RecognizePageICR_C()
```

Parent topic: [Recog_Shared actions](#)

CreateTextFile

Creates a Text file (.txt) for the current page; adds the page's recognized values to the file; and places the file in the current batch, in your application's Batches directory.

Member of namespace

Recog_Shared

Syntax

```
bool CreateTextFile ()
```

Parameters

None.

Returns

False if the ruleset with this action is not bound to a Page object of the Document Hierarchy, or if an Image file for the current page is not available. Otherwise, True.

Level

Page only.

Details

This action creates a UTF-8 encoded Text file (.txt) for the current page; adds the page's recognized values to the file; and places the file in the current batch, in your application's Batches directory.

Attention: The Text file generated by this action is handy for debugging purposes, to see what recognition is placing into the page's Fingerprint file (.cco) file. The action should follow a full-page recognition action such as RecognizePageOCR_S, in a rule that is applied to a Page object of the Document Hierarchy.

Example

```
RecognizePageOCR_S()  
CreateTextFile()  
SetProblemValue(0.7)  
SetSearchArea(0.5)  
FindFingerprint(True)
```

After the full-page recognition action (RecognizePageOCR_S), the CreateTextFile() action places the recognized values into a Text file that it has set up for the page, and adds the file to the current batch, in the Batches directory of the application.

The text file that is created has the same filename as the image, but is assigned a .txt filename extension.

Parent topic: [Recog_Shared actions](#)

IsBlankPage

Counts the number of words in the Fingerprint file (.cco) file of the current page and returns True if the count is less than or equal to the number you enter as the parameter.

Member of namespace

Recog_Shared

Syntax

```
bool IsBlankPage (StrParam)
```

Parameters

Long value indicating the maximum number of words in the Fingerprint file (.cco) of a blank source page. "50", for example, tells the action that if a CCO file has 50 words or less, its page is blank. Valid values are 0 to 2,147,483,647.

Returns

False if the action parameter is invalid or if the action is unable to locate the Image file for the current page or its CCO file. Otherwise, True.

Level

Page level.

Details

This action counts the number of words in the CCO file of the current page and returns True if the count is less than or equal to the number you enter as the parameter.

A rule containing this action should apply to a Page object; within the rule, this action should come after one of the actions that creates a fingerprint, such as AnalyzeImage, RecognizePageOCR_S, or RecognizePageICR_C.

Example

```
AnalyzeImage ()  
IsBlankPage (5)  
SetPageType (Separator)
```

This sequence uses AnalyzeImage to create a CCO file, then checks to see if the file contains less than six words. If so, the IsBlankPage(5) action returns True. The final action, a DCO action, establishes the page as a Separator page.

Parent topic: [Recog_Shared actions](#)

RecogContinueOnFailure

Determines if a batch will abort if page or field recognition fails.

Important: The intended use of this legacy action is limited to those action libraries that do not support automatic retry. For all other libraries, the continue-on-failure setting is automatically set to True, which means that batches are not aborted as a result of recognition action failures. For information about automatic retry and the action libraries that support it, see [SetupAutomaticRetry](#).

Member of namespace

Recog_Shared

Syntax

```
bool RecogContinueOnFailure (StrParam)
```

Parameters

String value True or False.

1. True: a recognition failure will not be automatically retried if recognition fails. The batch will continue and the application can use the value assigned to the *RecogStatus* variable to decide how to proceed on success or failure of recognition. For more information on the *RecogStatus* variable, see information about the *RecogContinueOnFailure* action.
2. False: causes the batch to abort if a full-page or field-level recognition action fails. If *UseOutOfProcessRecog* is enabled, the batch will abort only if the second recognition attempt fails.

Returns

Always True.

Level

All.

Details

This action determines if a batch will abort if page or field recognition failed.

Note: If *RecogContinueOnFailure* is not specifically called, the default False value is used. This means that batches will abort if recognition fails.

After a recognition operation is complete, the variable *RecogStatus* is set to indicate the success or failure of recognition. If page-level recognition is being performed, *RecogStatus* values of 0, 1 or 2 are considered successful.

The full list of values includes:

- 0 - Success
- 1 - Recognition was successful but there are no results, the page was empty.
- 2 - Recognition was successful and additional processing such as *RotateImage* was performed.
- 4 - Failure: the recognition engine cannot be instantiated.
- 5 - Failure: the recognition engine timed out (the time specified by the *SetEngineTimeout* action has expired).
- 6 - Failure: could not load image to engine.
- 7 - Failure: could not load image to engine (path not found).
- 8 - Failure: image could not be rotated.
- 10 - Failure: general failure occurred and recognition was not completed.

Example

```
RecogContinueOnFailure(True)  
RecognizePageOCR_S()
```

Parent topic: [Recog_Shared actions](#)

RecogOMRThreshold

Performs OMR check box recognition by counting black pixels within each OMR box area in a Field with one or more OMR boxes.

Member of namespace

Recog_Shared

Syntax

```
bool RecogOMRThreshold (string threshold, string background)
```

Parameters

String: threshold

String: background

Parameters

Floating or integer values that specify the count of black pixels in OMR boxes:

1. Threshold: the percentage of pixels in the zone. The field zone that is not the printed box that must be considered checked. For example, the lightest box that is not just noise, but must be considered a check mark.
2. Background: the percentage of pixels in the zone that might be due to scanner noise or the border of the printed box. This value also controls the range on either side of the Threshold value that is low confidence.

The action also accepts parameters that are fractional percentages, which are needed to detect marks in large zones.

The parameters must be experimentally adjusted on real-world scanned forms. First, determine the Threshold value that correctly identifies a light mark as checked, and correctly identifies noisy zones as cleared. Second, adjust the value of the Background parameter to achieve an acceptable confidence interval.

Returns

Always True.

Level

Field level.

Details

This action performs OMR check box recognition by counting black pixels within each OMR box area in a Field with one or more OMR boxes.

- **Text Boxes:** The action sets the text value of the field to a string of 0's and 1's (one digit per OMR box). It assigns a Confidence String to the string of digits: 4 for Low Confidence up to 9 for High Confidence.
- **Density String and Confidence Value:** The action also establishes a *DensityString* variable for the Character String, indicating percentage-filled, from ASCII 48 ('0') through 148. For each possible OMR box, is a character. The ASCII value of the character minus 48 is the percentage-filled. If the Density String=0X, the first OMR field was blank, and the second was 40% filled. The ASCII value for X is 88. 88 minus 48 = 40.
- **MultiPunch and Confidence Values:** If the MultiPunch setting is set to 1 and multiple OMRs are filled beyond the threshold, the one that was filled the most is marked and set to Low Confidence.
 - If the percentage-filled is below the second parameter, the OMR box is not selected and the confidence is high.
 - If the percentage-filled is between the two parameters, the OMR box is not selected and the confidence is low.
 - If the percentage-filled is above the first parameter and below double the first parameter minus the second parameter, the OMR box is selected and the confidence is low.
 - If the percentage-filled is above double the first parameter minus the second parameter, the OMR box is selected and the confidence is high.

Note: The `RecogOMRThreshold` action works best on dropout boxes, but with an appropriate background value can work effectively with boxes that are visible in the scanned image.

If you are using small visible boxes on your image, it is best to zone the area by surrounding the entire visible box with room for alignment movement. Then, factor out the black from the box by using the parameters. If you attempt to zone inside the borders of a visible box, you can get a false positive if the page does not align exactly.

The page image must be a 1 bit black and white image. If the image is not 1 bit, the action `C2BW_Convert` in the `ColorToBW` library can be used to convert the image to a black and white 1 bit image.

Examples

For a small to medium size zone, 10% filled might be considered a deliberate mark. Anything below 5% (Background) is not a mark. Anything above 15% ($\text{Threshold} + (\text{Threshold} - \text{Background})$) is a high confidence mark. This works with a non-dropout OMR field where the printed outline of the box takes up less than 5% of the zone area. It also works for dropout forms.

```
RecogOMRThreshold("10", "5")
```

The following example is for a signature line, or a large zone where the percentage-filled is much lower than for a small zone. This example assumes there is low background or noise.

```
RecogOMRThreshold("2", "0")
```

Parent topic: [Recog_Shared actions](#)

RegisterPageFields

Returns the field positions for all zoned fields of the current page.

Member of namespace

Recog_Shared

Syntax

```
RegisterPageFields ()
```

Parameters

None.

Returns

False if a ruleset with this action is not bound to a Page object of the Document Hierarchy; or if the action cannot find the page's Fingerprint file (.cco). Otherwise, True.

Level

Page level.

Details

This action returns the field positions of all zoned fields of the current page. The action is similar to the ReadZones action of the Zones.rrx file.

Note: Use the ReadZones action when possible.

Example

```
RegisterPageFields ()
```

Parent topic: [Recog_Shared actions](#)

RotateTio

Checks if an Image file processed by the ImageFix action that assigns a .tio extension to the file needs to be rotated by 90, 180, or 270 degrees. If so, the action rotates and then saves the Image file with the same .tio extension.

Member of namespace

Recog_Shared

Syntax

```
bool RotateTio (StrParam)
```

Parameters

A String value:

- True to initiate rotation
- False to prevent rotation

Returns

Always True.

Level

Page level.

Details

This action checks if an Image file processed by the ImageFix action that assigns the .tio extension needs to be rotated by 90, 180, or 270 degrees. If rotation is necessary, the action saves the Image file with the same .tio extension.

Example

```
AnalyzeImage ()
RotateTio (True)
RotateImage ()
RecognizePageICR_C ()
```

Parent topic: [Recog_Shared actions](#)

SetAdjustFieldToChars

Optional setting for SnapCCOtoDCO to adjust the field position to its character positions.

Member of namespace

Recog_Shared

Syntax

```
bool SetAdjustFieldToChars (StrParam)
```

Parameters

A String value:

- True to snap character positions
- False to disable snapping

Returns

True.

Level

Page or Field level.

Details

This action has SnapCCOtoDCO adjust the field position (parameter True) to the character positions results after snapping the character values to the field. Off by Default

Example

```
SetAdjustFieldToChars (TRUE)
SnapCCOtoDCO ()
```

Parent topic: [Recog_Shared actions](#)

SetFingerprintRecogPriority

Sets the option that controls whether a full-page recognition action is to create a Fingerprint file(.cco) - aka a CCO file - for the current page.

Member of namespace

Recog_Shared

Syntax

```
bool SetFingerprintRecogPriority (StrParam)
```

Parameters

String value: True or False to control the creation of the CCO.

- True: If a CCO already exists prior to recognition, it is replaced with a brand new one with recognition results.
- False: If SetFingerprintRecogPriority is not called or is set to False and a CCO already exists prior to recognition, the recognition results will be added to that CCO.

Returns

Always True.

Level

All.

Details

This action sets the option that controls whether a full-page recognition action is to create a CCO file for the current page. When the option is On, processing is faster because the call to the AnalyzeImage action is eliminated.

The difference between creating a CCO from scratch with recognition results and adding the recognition results to the existing CCO created by AnalyzeImage is that in the adding case, the recognized characters are put into the CCO in a manner that uses a different fingerprinting technique.

Note: Be sure to place this action before a full-page recognition action.

Example

```
SetFingerprintRecogPriority (True)
```

Parent topic: [Recog_Shared actions](#)

SetFullPageRecogArea

An optional action that sets the area of the current page that is to be the target of recognition procedures, when full-page recognition action is invoked.

Member of namespace

Recog_Shared

Syntax

```
bool SetFullPageRecogArea (StrParam)
```

Parameters

A decimal value indicating the percent of the page to be recognized in response to this action.

For example: "0.1" designates the first 10% of the page, while "1.0" calls for recognition of the entire page.

This action is helpful if you know that a page's values will always be in a particular location on the page, but recognition of the entire page is not necessary.

Returns

False if the ruleset with this action is not bound to a Page object of the Document Hierarchy, or if the action's parameter is not a decimal value. Otherwise, True.

Level

Page level.

Details

This optional action sets the area of the current page that will be the target of recognition procedures when full-page recognition action is called. For example: "0.1" indicates that the first 10% of the page is to be recognized; "1.00" indicates that the entire page is to be recognized.

Example

```
SetFullPageRecogArea (0.5)
```

Parent topic: [Recog_Shared actions](#)

SetOutOfProcessRecogTimeout

Sets the number of seconds to wait before it is determined that a recognition action is no longer running properly.

Important: The intended use of this legacy action is limited to those action libraries that do not support automatic retry. For all other libraries, the timeout setting for out-of-process recognition is automatically configured, which means that this action does not need to be called. For information about automatic retry and the action libraries that support it, see [SetupAutomaticRetry](#).

Member of namespace

Recog_Shared

Syntax

```
bool SetOutOfProcessRecogTimeout (StrParam)
```

Parameters

Numeric value that indicates the number of seconds to wait to determine that a recognition action is stalled or exited.

Returns

Always True.

Level

All.

Details

This action sets the number of seconds to wait before it is assumed that a recognition action is no longer running correctly. When the timeout is reached, the recognition process is removed from memory. The `SetOutOfProcessRecogTimeout` action is effective only when out-of-process recognition is enabled by the use of a `UseOutOfProcessRecog` action.

If a recognition action does not complete within the specified number of seconds indicated by a `SetOutOfProcessRecogTimeout` action or a `SetEngineTimeout` action, it is assumed that the recognition engine encountered a severe error. It is removed from memory and recognition automatically restarts one more time. If the recognition action completes successfully within the specified time on either the first or second attempt, that recognition action is successful. If the recognition action does not complete by the specified time on the second attempt, the recognition action is set to abort, if `RecogContinueOnFailure(False)` was used.

If `SetOutOfProcessRecogTimeout` is not called, the default value of 300 seconds is used. In normal conditions, the default value is sufficient and does not need to be changed. This value needs to be increased only if a single page consistently takes more than 5 minutes to complete, which is not a typical situation. The programmer can choose to shorten this time to reduce the time to detect failures earlier, provided there is time to perform recognition in worst case scenarios. For best results, you can set the timeout to be the same or longer than the value specified in a `SetEngineTimeout` action.

When a `SetOutOfProcessRecogTimeout` action is called, the setting is in effect for the entire batch so that you can set the value once, then call as many recognition actions as you want.

Example

```
SetOutOfProcessRecogTimeout (300)
UseOutOfProcessRecog (True)
RecognizePageOCR_S()
```

Parent topic: [Recog_Shared actions](#)

SetRecogFailureRetryDelay

Sets the number of seconds to wait before restarting a failed recognition action.

Member of namespace

Syntax

```
bool SetRecogFailureRetryDelay (StrParam)
```

Parameters

Numeric value indicating the number of seconds to wait before restarting a failed recognition action, and automatically reactivating recognition one more time.

Returns

Always True.

Level

All.

Details

This action sets the number of seconds to wait after the time specified in either a `SetOutOfProcessRecogTimeout` action or a `SetEngineTimeout` action has expired. Once either timeout has occurred, the recognition engine is removed from memory: the action will then wait the additional time specified by the `SetRecogFailureRetryDelay` action to be sure that the engine has exited before restarting recognition. `SetRecogFailureRetryDelay` only has an effect if out-of-process recognition has been enabled by a `UseOutOfProcessRecog` action.

If a recognition action does not complete within the number of seconds specified by a `SetOutOfProcessRecog` action or a `SetEngineTimeout` action, it is assumed that the recognition engine has encountered a severe error and that recognition will automatically be restarted one more time. If the recognition action completes successfully within the specified time on either the first or second attempt, that recognition action will be successful. If the recognition action does not complete by the specified time on the second attempt, the recognition action will be set to abort if `RecogContinueOnFailure(False)` has been used.

If `SetRecogFailureRetryDelay` is not specifically called, the default value of 10 seconds is used. Under normal conditions, the default value will be sufficient and does not need to be changed. This value needs to be increased only if a log indicates that errors are occurring when attempting to restart a failed recognition action, and the problem can be diagnosed by setting the `RecogStatus` to "4".

When `SetRecogFailureRetryDelay` is called, its setting will be in effect for the entire batch. This allows you to set the value once, and call as many recognition actions as necessary.

Example

```
SetRecogFailureRetryDelay(10)
UseOutOfProcessRecog(True)
RecognizePageOCR_S()
```

Parent topic: [Recog_Shared actions](#)

SetupAutomaticRetry

Changes the settings that govern the automatic retry mechanism.

Important:

- Automatic retry mode is enabled by default. For information about the action libraries that support automatic retry, see the Details section of this action.
- If automatic retry mode is not currently enabled, calling this action enables automatic retry mode. For information about legacy mode, see [SetEngineTimeoutOCR_S](#).

Member of namespace

Recog_Shared

Syntax

```
bool SetupAutomaticRetry (string retryCount, string timeout)
```

Parameters

Smart parameters are supported.

retryCount

The number of times that a failed action is to be retried. If you do not call this action, the default retryCount is 1.

timeout

The number of seconds to wait for an action to complete before the action is retried. (This number is the minimum wait time. Depending on the specific nature of the failure, the operation might not be retried until several seconds after the timeout expires.)

If this action is not called, the default timeout is 180 seconds. This timeout is long enough for most situations, but you might want to change it in some cases. For example, your application might process atypical documents that take longer than normal to complete successfully.

Returns

Always True.

Level

Any level. In a hierarchical way, the retry settings take effect for all DCO objects at the calling level and below the calling level. This level is the level at which you call this action. Here are some examples of the way that the hierarchy works:

Calling level	Objects affected
Batch	All objects in the batch, which includes objects at the document, page, and field levels.
Page	The page object and all fields that are attached to that page.
Batch and page	Both the fields on the page and the page itself use the page level setting while other objects use the batch level setting.

Details

For actions and action libraries that support automatic retry, use this action to change the settings that govern the retry logic. Currently, the OCR/SR action library supports automatic retry.

The intent of automatic retry is to provide transparent recovery for the rare situation in which an operation does not terminate. For example, a peculiar or invalid image might cause the recognition engine to never complete the recognition step. The step can sometimes complete successfully when it is retried.

The logic of the automatic retry mechanism consists of the following elements:

Completion timeout	The mechanism waits for the specified number of seconds for an action to complete.
Timeout expiration	If the action does not complete, the current operation is stopped and retried.
Retry success	If the action is successful after the automatic retry, the action completes and the operation continues as normal.
Retry failure	If the action is not successful, failure is indicated in the usual manner. For details, see the help for the action that failed.

Example:

In the following example, the default value for the timeout is changed right before the attempt to recognize the page.

```
setFingerprinntRecogPriority("TRUE")
SetupAutomaticRetry(1, 240)
RecognizePageOCR_S()
CreateTextFile()
```

Parent topic: [Recog_Shared actions](#)

Related reference:

[OCR_SR actions](#)

SnapCCOtoDCO

Transfers the recognition results in the current page's CCO file - its Fingerprint file - to the appropriate Field objects of the Document Hierarchy...its setup DCO.

Member of namespace

Recog_Shared

Syntax

```
bool SnapCCOtoDCO ()
```

Parameters

None.

Returns

False if a ruleset with this action is not bound to a Page object or Field object of the Document Hierarchy. Otherwise, True.

Level

Page or Field level.

Details

This action transfers the recognition results of the current page's CCO file to the appropriate Field objects of the Document Hierarchy (DCO). Note that the action only transfers values to Field objects. SnapCCOtoDCO will only clear / update field text when all of the following conditions are met:

- Field is not an OMR field, for example var *RecogType*=4).
- Field has positions assigned.
- Field does not have the variable *v_skipsnap* set to 1.
- Field has data mapping to the CCO, at least one character.
- Fixes issue that would affect processing of reserved fields. For example, fields that are used for anchor finding are followed by snapping of data.

Example

```
SnapCCOtoDCO ()
```

Parent topic: [Recog_Shared actions](#)

SnapDCOtoCCO

Transfers the recognition results assigned to Field objects of the Document Hierarchy (aka the setup DCO) to the current page's CCO file, also known as its Fingerprint file.

Member of namespace

Recog_Shared

Syntax

```
bool SnapDCOtoCCO ()
```

Parameters

None.

Returns

False if a rule with this action is not applied to a page. Otherwise, True.

Level

Page level.

Details

This action transfers the recognition results assigned to Field objects of the Document Hierarchy (DCO) to the current page's CCO file.

If zonal recognition is used instead of full-page recognition, the action will populate the current page's CCO file with the results of zonal recognition. Then, when the Verify task runs, a user can use the ClickNKey option to populate fields.

Example

SnapDCOtoCCO ()

Parent topic: [Recog_Shared actions](#)

SnapFieldtoChars

Adjusts the zone position of the passed dco field to the field's character positions.

Member of namespace

Recog_Shared

Syntax

```
bool SnapFieldtoChars (string Smartparam)
```

Parameters

String: Smartparam

Parameters

A Smart Parameter value representing a valid Field location.

Returns

False if a valid DCO field is not returned from the Smart parameter value. Otherwise, True.

Level

Any level.

Details

This action adjusts the field position of the passed DCO to the DCO's character positions. If the field does not have a text value, no adjustment to the field zone is performed.

Example

```
SnapFieldtoChars (@F)
```

Parent topic: [Recog_Shared actions](#)

UseOutOfProcessRecog

Causes recognition to be performed in a process that is separate from the process that is running the recognition actions.

Important: The intended use of this legacy action is limited to those action libraries that do not support automatic retry. For all other libraries, the out-of-process engine is automatically restarted. For information about automatic retry and the action libraries that support it, see [SetupAutomaticRetry](#).

Member of namespace

Syntax

```
bool UseOutOfProcessRecog (strParam)
```

Parameters

True: Recognition actions should run in a separate process.

False: Recognition should run in the same process as the recognition actions.

Returns

Always True.

Level

All.

Details

This action determines in which process recognition will be performed. Using a separate process for recognition provides an additional stability and automatic recovery ability as it will automatically retry a recognition action that runs into trouble, such as recognition that has stalled or unexpectedly terminated. The action must be placed before a full-page or field-level recognition action such as `RecognizePageOCR_S`.

The action is also directly tied to the `SetRecogFailureRetryDelay` action, which determines how long (in seconds) the `UseOutOfProcessRecog` action waits to determine that recognition has stopped responding and must be retried.

If the `UseOutOfProcessRecog` action is not specifically called, its default True setting will be used. If the action is called specifically, the True or False setting will be in effect for the entire batch. This allows you to set the value once, and call as many recognition actions as necessary.

Example

```
UseOutOfProcessRecog (True)
SetRecogFailureRetryDelay (10)
RecognizePageOCR_S ()
```

Parent topic: [Recog_Shared actions](#)

runner actions

Use the runner actions to do miscellaneous utility functions.

The runner actions can check batch integrity, manipulate the values of fields and variables, raise condition flags, and control rule execution.

- [AbortOnError](#)
Determines whether a task that encounters an error stops or continues.
- [CheckAllIntegrity](#)
Checks all documents in the batch to determine whether they meet the document integrity requirements that are specified in the document hierarchy (setup DCO).

- [CheckDocCount](#)
Determines whether the number of documents in the runtime hierarchy matches the expected document count as specified by the scan operator.
- [CheckPageCount](#)
Determines whether the number of pages in the runtime hierarchy matches the expected page count as specified by the scan operator.
- [DebugMode_OFF](#)
Disables enhanced logging.
- [DebugMode_ON](#)
Enables enhanced logging (disabled by default).
- [GoToNextFunction](#)
Returns False, which causes the next function in the ruleset to run.
- [MessageID](#)
Adds a runtime MESSAGE and a MessageID variable to the bound object of the document hierarchy.
- [MessageIDParameter](#)
Adds a runtime Value, Type, and Substitution index for use with a preconfigured MESSAGE and MessageID variable to the bound object of the Document Hierarchy.
- [PilotMessage_Clear](#)
Removes the MESSAGE variable from the current object.
- [PilotMessage_Set](#)
Assigns a message to the MESSAGE variable of the current object.
- [ProcessChildren](#)
Initiates the processing of elements that are represented by the bound object and its children.
- [rr_AbortBatch](#)
Stops processing the current batch and sets its status to Abort.
- [rr_Get](#)
Assigns the value of the specified variable to the Text property of the current object.
- [rr_WriteNode](#)
Creates a separate XML data file for the current object.
- [rrAppend](#)
Appends the value of the source object to the specified field.
- [rrCompare](#)
Compares the values of two variables and returns True if they are the same.
- [rrCompareCase](#)
Runs a comparison of two strings or smart parameters to see whether they are identical.
- [rrCompareCaseLength](#)
Uses the smart parameters that you enter as the parameter to locate and compare the values of two object's variables.
- [rrCompareNot](#)
Compares the values of two variables and returns False if they are the same.
- [rrCompareNotCase](#)
Negates the running of the rrCompareCase action. You can run this action in instances when two of the string or smart parameter values are different.
- [rrCompareNotCaseLength](#)
Negates the running of the rrCompareCaseLength action. You can run this action in instances when two of the values are different.
- [rrCompareNumeric](#)
Uses the Smart Parameters that you enter as the parameter to locate and compare the numeric values of two object's variables.
- [rrContains](#)
Uses the Smart Parameters that you enter as the parameter to locate and compare the values of two objects' variables.

- [rrCopy](#)
Copies the value, confidence levels, and positions from one field to another.
- [rrPrepend](#)
Inserts a value at the beginning of the specified field.
- [rrSet](#)
Assigns a value to a variable or field.
- [SetBatchPriority](#)
Sets the priority of the batch at the completion of the task.
- [SetOperatorID](#)
Sets the ID of the person who is operating Rulerunner.
- [SetReturnValue](#)
Returns True or False depending on the parameter that is specified.
- [SetStationID](#)
Sets the ID of the station where the person is operating Rulerunner.
- [SetTaskStatus](#)
Specifies the task status that is returned to an application as Abort, Canceled, Finished, Hold, or Pending when the current task completes.
- [SkipChildren](#)
Prevents the running of rules on child objects of the current object.
- [Status_Preserve_OFF](#)
Allows rules to change the STATUS value of fields, for example, to assign a problem status.
- [Status_Preserve_ON](#)
Prevents rules from changing the STATUS value of fields.
- [Task_NumberOfSplits](#)
Specifies the number of jobs the batch is sent to when a condition is raised before it returns to the main workflow.
- [Task_RaiseCondition](#)
Specifies the group index and the index of the condition to raise from the list on the Datacap Web Client Workflow tab. 0 is the first condition.

Parent topic: [Global actions](#)

AbortOnError

Determines whether a task that encounters an error stops or continues.

Syntax

```
bool AbortOnError (StrParam)
```

Parameters

True: Abort the batch if an error occurs.

False: Do not abort the batch if an error occurs.

Returns

False if the parameter is not True or False. Otherwise, True.

Level

All.

Details

Determines if tasks that encounter errors are to abort, or continue processing.

Example

```
AbortOnError("Yes")
```

Parent topic: [runner actions](#)

CheckAllIntegrity

Checks all documents in the batch to determine whether they meet the document integrity requirements that are specified in the document hierarchy (setup DCO).

Syntax

```
bool CheckAllIntegrity ()
```

Parameters

None.

Returns

True if the Document Integrity of the current batch meets the requirements as defined in the setup of the Document Hierarchy. Otherwise, False.

Level

Batch level.

Details

Checks that the documents in the batch contain the correct type and number of pages, in line with the Document Integrity requirements of the Document Hierarchy.

Example

```
CreateDocuments ()  
CheckAllIntegrity ()
```

These actions are part of a rule applied to the Batch object of the Document Hierarchy. The first assembles documents from the pages in the batch; the second ensures that the makeup of each document is valid.

Parent topic: [runner actions](#)

CheckDocCount

Determines whether the number of documents in the runtime hierarchy matches the expected document count as specified by the scan operator.

Syntax

```
bool CheckDocCount ()
```

Parameters

None.

Returns

True if the actual count is the same as the expected count. Otherwise, False.

Level

Batch level.

Details

The number of expected documents is usually provided by the operator of a job's Scan task. This very handy action can compare the actual amount to the estimate at any time after a CreateDocuments action has assembled the documents in the batch.

Example

```
CheckDocCount ()
```

Parent topic: [runner actions](#)

CheckPageCount

Determines whether the number of pages in the runtime hierarchy matches the expected page count as specified by the scan operator.

Syntax

```
bool CheckPageCount ()
```

Parameters

None.

Returns

True if the two counts are equal. Otherwise, False.

Level

Batch level.

Details

This action confirms that the number of actual images (pages) in the current task's Page file (.xml) matches the count of expected pages.

Example

```
CheckPageCount ()
```

Parent topic: [runner actions](#)

DebugMode_OFF

Disables enhanced logging.

Syntax

```
bool DebugMode_OFF ()
```

Parameters

None.

Returns

Always True.

Level

All.

Details

This actions turns off the enhanced logging procedures turned on by an earlier DebugMode_On action.

Enhanced logging expands the scope and depth of a processing log's information, and of the logs that a Rulerunner task generates when you are testing a rule and its actions.

This feature also increases a Log file's size significantly, and should only be used when you are testing the impact of an action and rule on the application's workflow.

Example

```
DebugMode_Off ()
```

Parent topic: [runner actions](#)

DebugMode_ON

Enables enhanced logging (disabled by default).

Syntax

```
bool DebugMode_ON ()
```

Parameters

None.

Returns

Always True.

Level

All.

Details

The following example shows enhanced logging during several actions.

Example

```
DebugMode_On ()
ExportOpenConnection (@APPVAR (values/dsn/exportdb:cs))
SetTableName (Invoice)
ExportFieldToColumn (Number, db_Number)
AddRecord ()
DebugMode_Off ()
```

Parent topic: [rrunner actions](#)

GoToNextFunction

Returns False, which causes the next function in the ruleset to run.

Syntax

```
bool GoToNextFunction ()
```

Parameters

None.

Returns

Always False.

Level

All.

Details

Returns a False condition so that the next function in the RuleSet can run.

Example

```
IsFieldMatching ("Skip")
GoToNextFunction ()
```

If the condition in the first action is met, the sequence assigns a False status to the second action and to the rule of which it is a part. As a result, execution continues with the next function in the Rule.

Parent topic: [runner actions](#)

MessageID

Adds a runtime MESSAGE and a MessageID variable to the bound object of the document hierarchy.

Syntax

```
bool MessageID (string Message, string Identifier)
```

Parameters

Two parameters:

1. The message with index substitution indicators to be assigned to the MESSAGE variable. Be sure to surround the message in quotation marks.
2. The ID to be assigned to the message to enable client-side translation.

Returns

Always True.

Level

All

Details

Adds a runtime MESSAGE and a MessageID variable to the bound object of the document hierarchy.

Example

```
MessageID("The field '{0}' has a value of '{1}'.", FieldValueMessage01)
```

Parent topic: [runner actions](#)

Related information:

[Application translation](#)

MessageIDParameter

»Adds a runtime Value, Type, and Substitution index for use with a preconfigured MESSAGE and MessageID variable to the bound object of the Document Hierarchy.«

Syntax

```
bool MessageIDParameter (string Value, string ValueType, int Index)
```

Parameters

Three parameters. Smart parameters are supported.

1. The runtime value that replaces a substitution indicator. Smart parameters are supported.

2. The value's `Type` to enable client-side translation lookup. Permitted `Type` values are `job`, `task`, `shortcut`, `field`, `workflow`, `appname`, `pagetype`, `doctype`, `text`, and `variable`.
3. The index of the substitution.

Returns

Always True.

Level

All

Details

»Adds a runtime Value, Type, and Substitution index for use with a preconfigured MESSAGE and MessageID variable to the bound object of the Document Hierarchy.«

Example

```
MessageID("The field '{0}' has a value of '{1}'.", FieldValueMessage01)
MessageIDParameter("@F.Name", field, 0)
MessageIDParameter("@F", Text, 1
```

Parent topic: [runner actions](#)

Related information:

[Application translation](#)

PilotMessage_Clear

Removes the MESSAGE variable from the current object.

Syntax

```
bool PilotMessage_Clear ()
```

Parameters

None.

Returns

Always True.

Level

All.

Details

Removes the runtime MESSAGE variable from the bound object of the Document Hierarchy.

Example

```
PilotMessage_Clear()
```

Parent topic: [rrunner actions](#)

PilotMessage_Set

Assigns a message to the MESSAGE variable of the current object.

Syntax

```
bool PilotMessage_Set (StrParam)
```

Parameters

The smart parameter message to be assigned to the *MESSAGE* variable. Be sure to surround the message in quotation marks.

Returns

Always True.

Level

All.

Details

Provides a runtime *MESSAGE* variable to the bound object of the Document Hierarchy, and assigns the Action's parameter as the variable value.

Example

```
PilotMessage_Set("Field +@F+ Value is not Valid")
```

Parent topic: [rrunner actions](#)

ProcessChildren

Initiates the processing of elements that are represented by the bound object and its children.

Syntax

```
bool ProcessChildren (StrParam)
```

Parameters

A two-part, comma-separated specification of a Condition and a Command.

The Condition is any valid VBScript expression. The Command is the VB executable that results from the Condition.

Returns

False if the number or sequence of the arguments are invalid. Otherwise, True.

Level

All.

Details

A follow-up action that initiates the processing of elements represented by the bound object, and all its children.

Example

```
ProcessChildren("1,Exit")
```

Parent topic: [rrunner actions](#)

rr_AbortBatch

Stops processing the current batch and sets its status to Abort.

Syntax

```
bool rr_AbortBatch ()
```

Parameters

None.

Returns

Always True.

Level

All.

Details

Stops processing the current batch and sets the status of the batch to Abort.

Example

```
rr_AbortBatch ()
```

Parent topic: [rrunner actions](#)

rr_Get

Assigns the value of the specified variable to the Text property of the current object.

Syntax

```
bool rr_Get (StrParam)
```

Parameters

A smart parameter referencing a value or which is a reference to a value that will be copied to the calling object.

Returns

False the parameter is missing. Otherwise, True.

Level

All.

Details

Uses the parameter's elements to locate the value of a source object's variable, and assign it to the calling object. If the calling object is a field, only the value of the field will be changed.

Example

```
rr_Get("@B.OPERATOR")
```

This example retrieves the value of the Batch object's Operator property and assigns it to the calling object's Text property, if the calling object is a field.

```
rr_Get("@DICT_WORD(..\MONTH)")
```

This example shows how Smart Parameters translates the OMR recognized value of the MONTH field to the text from a predefined dictionary. The text is then assigned to the calling object's *Text* property, if it is a field, or *Text* variable if it is not a field.

Parent topic: [rrunner actions](#)

Related reference:

[rrSet](#)

[rrCompare](#)

rr_WriteNode

Creates a separate XML data file for the current object.

Syntax

```
bool rr_WriteNode ()
```

Parameters

None.

Returns

Always True.

Level

All.

Details

Sets up a separate XML data file element for the calling object during Rulerunner processing.

Example

```
rr_WriteNode()
```

Parent topic: [runner actions](#)

rrAppend

Appends the value of the source object to the specified field.

Syntax

```
bool rrAppend (string varSource, string varTarget)
```

Parameters

Two Smart Parameters:

1. The source value.
2. A reference to the target field.

Both parameters are optional. If a parameter is not specified, it will default to the calling object. If the calling object is a field, it will use the field value.

Returns

False if the action cannot locate the target object or if the source value is empty. Otherwise, True.

Level

All

Details

The action retrieves the value of the source object, and appends it to the target value.

Example

```
rrAppend("@D.DocID", "@F")
```

This action inserts the current calling object's parent DocID variable value and appends it to the calling field's value.

Note: Target can not be a variable. If the source and target are the same, the action has no effect.

Parent topic: [runner actions](#)

Related reference:

[rrPrepend](#)

rrCompare

Compares the values of two variables and returns True if they are the same.

Syntax

```
bool rrCompare (string object1, string object2)
```

Parameters

Two Smart Parameters.

1. A value or a smart parameter, which is a reference to a value.
2. A value or a smart parameter, which is a reference to a value for comparison.

Note: Either reference can specify a variable of the calling object (the bound object of the Document Hierarchy.) Alternatively, both references can identify a variable of an object that is a parent or child of the calling object.

Either parameter is optional. If a parameter is not specified, it will default to the calling object. If the calling object is a field, it will use the field value. For batch, document and page objects, it will use a variable called *Text*, creating the variable if it does not exist.

Returns

False if the compared values do not match. Otherwise, True.

Level

All.

Details

Uses the Smart Parameters that you enter as the parameter to locate and compare the values of two object's variables.

Example

Code	Comment
<pre>rrCompare ("Expected_Pages", "@B.Tot_Pages")</pre>	Solicits a value from the field Expected_Pages of the calling object and compares it to the value of the field @B.Tot_Pages of the Batch object. The action returns False if the values are not the same.
<pre>rrCompare ("Expected Value", "@F\MyFieldToTest")</pre>	Checks the value of the field MyFieldToTest.
<pre>rrCompare ("MyExpectedName", "@TASKNAME")</pre>	Checks the current task name.
<pre>rrCompare ("@EMPTY", "@F\MyFieldToTest")</pre>	Checks whether the field MyFieldToTest contains an empty string.
<pre>rrCompare ("MyExpectedName", "@JOBNAME")</pre>	Checks the current job name.

Parent topic: [rrunner actions](#)

[rrCompareNot](#)

rrCompareCase

Runs a comparison of two strings or smart parameters to see whether they are identical.

Syntax

```
bool rrCompareCase(string object1, string object2, string caseSensitive)
```

Parameters

string object1

string object2

string caseSensitive

Parameters

Three Parameters.

1. A value or a smart parameter, which is a reference to a value.
2. A value or a smart parameter, which is a reference to a value for comparison.
Note: Either reference can specify a variable of the calling object (the bound object of the Document Hierarchy.) Alternatively, both references can identify a variable of an object that is a parent or child of the calling object.

Either parameter is optional. If a parameter is not specified, it defaults to the calling object. If the calling object is a field, it uses the field value. For batch, document and page objects, it uses a variable that is called *Text*, creating the variable if it does not exist.

3. True runs a case-sensitive compare. False runs a case insensitive compare. If not specified, the default is False.

Returns

False If the compared values do not match. Otherwise, True.

Level

All.

Details

Runs a comparison of two strings or smart parameters to see whether they are identical. The comparison can be run as case sensitive or case insensitive.

Example

```
rrCompareCase("Main_Job","JOBID","False")
```

This example compares the string "Main_Job" to the current Job ID. The comparison is case insensitive. If the current Job ID is "MAIN_JOB", the action returns True.

```
rrCompareCase("Main_Job","JOBID","True")
```

This example compares the string "Main_Job" to the current Job ID. The comparison is case-sensitive. If the current Job ID is "MAIN_JOB", the action returns False.

Parent topic: [rrunner actions](#)

Related reference:

[rrCompareNotCase](#)

[rrCompareNot](#)

[rrCompare](#)

rrCompareCaseLength

Uses the smart parameters that you enter as the parameter to locate and compare the values of two object's variables.

Syntax

```
bool rrCompareCaseLength(string object1, string object2,  
string caseSensitive, string length, string fromStart)
```

Parameters

string object1

string object2

string caseSensitive

string length

string fromStart

Parameters

Five Parameters.

1. A value or a smart parameter, which is a reference to a value.
2. A value or a smart parameter, which is a reference to a value for comparison.
3. True runs a case-sensitive compare. False runs a case insensitive compare.
4. An integer for the number of characters to compare. If the length is 0, the entire string is compared.
5. True compares from the start of the string. False compares from the end of the string.

Returns

False If the compared values do not match. Otherwise, True.

Level

All.

Details

Uses the Smart Parameters that you enter as the parameter to locate and compare the values of two object's variables. The comparison can be limited to a specified number of characters from the start or the end of the string. The comparison can be run case-sensitive or case insensitive.

Example

```
rrCompareCaseLength("Main", "@JOBID", "False", 4, "True")
```

This example compares the string "Main" to the current Job ID. Only the first four letters are compared and the compare is case-sensitive. If the current Job ID is "MAIN_JOB", the action returns True.

```
rrCompareCaseLength("Main", "@JOBID", "True", 4, "True")
```

This example compares the string "Main" to the current Job ID. Only the first four letters are compared and the compare is case-sensitive. If the current Job ID is "MAIN_JOB", the action returns False.

```
rrCompareCaseLength("Main Line", "Main Job", "True", 4, "True")
```

This example compares the string "Main Line" to the string "Main Job". The compare is case-sensitive and only the first four letters are compared. The action returns True.

```
rrCompareCaseLength("@P.ScanSrcPath", "GOOD.BMP", "False", 8, "False")
```

This example runs a case insensitive compare of the last 8 characters of the *ScanSrcPath* variable to find the last 8 characters of the string "GOOD.BMP". If the value of *ScanSrcPath* is "c:\test\testvalidate\images\good.bmp", the action returns True.

Parent topic: [runner actions](#)

Related reference:

[rrCompareNotCaseLength](#)

[rrCompareNot](#)

[rrCompare](#)

rrCompareNot

Compares the values of two variables and returns False if they are the same.

Syntax

```
bool rrCompareNot (string object1, string object2)
```

Parameters

Two Smart Parameters.

1. A value or a smart parameter, which is a reference to a value.
2. A value or a smart parameter, which is a reference to a value for comparison.

Note: Either reference can specify a variable of the calling object. Alternatively, both references can identify a variable of an object that is a parent or child of the calling object.

Either parameter is optional. If a parameter is not specified, it will default to the calling object. If the calling object is a field, it will use the field value.

For batch, document and page objects, it will use a variable called *Text*, creating the variable if it does not exist.

Returns

True if the compared values do not match. Otherwise, False.

Level

All.

Details

This action is the negation of `rrCompare`. It can be handy for when an action should be performed only when two values are different.

Example

```
rrCompareNot ("Expected_Pages", "@B.Tot_Pages")
rr_AbortBatch ()
```

This example shows how a value is solicited from the field `Expected_Pages` off of the calling object and the `Batch` object. The two values are then compared: the action returns `True` if the values are not the same. Here, the batch will abort if the expected pages do not match the total pages.

Parent topic: [rrunner actions](#)

rrCompareNotCase

Negates the running of the `rrCompareCase` action. You can run this action in instances when two of the string or smart parameter values are different.

Syntax

```
bool rrCompareNotCase (string object1, string object2, string caseSensitive)
```

Parameters

string object1

string object2

string caseSensitive

Parameters

Three Parameters.

1. A value or a smart parameter, which is a reference to a value.
2. A value or a smart parameter, which is a reference to a value for comparison.
Note: Either reference can specify a variable of the calling object (the bound object of the Document Hierarchy.) Alternatively, both references can identify a variable of an object that is a parent or child of the calling object.

Either parameter is optional. If a parameter is not specified, it defaults to the calling object. If the calling object is a field, it uses the field value. For batch, document and page objects, it uses a variable that is called *Text*, creating the variable if it does not exist.

3. `True` runs a case-sensitive compare. `False` runs a case insensitive compare. If not specified, the default is `False`.

Returns

True if the compared values do not match. Otherwise, False.

Level

All.

Details

This action negates the running of the `rrCompareCase` action. You can run this action in instances when two of the string or smart parameter values are different.

Example

```
rrCompareNotCase("Main_Job", "JOBID", "False")
```

This example compares the string "Main_Job" to the current Job ID. The comparison is case insensitive. If the current Job ID is "MAIN_JOB", the strings match so the action returns False.

```
rrCompareNotCase("Main_Job", "JOBID", "True")
```

This example compares the string "Main_Job" to the current Job ID. The comparison is case-sensitive. If the current Job ID is "MAIN_JOB", the strings do not match so the action returns True.

Parent topic: [runner actions](#)

Related reference:

[rrCompareCase](#)

[rrCompareNot](#)

[rrCompare](#)

rrCompareNotCaseLength

Negates the running of the `rrCompareCaseLength` action. You can run this action in instances when two of the values are different.

Syntax

```
bool rrCompareNotCaseLength(string object1, string object2,  
string caseSensitive, string length, string fromStart)
```

Parameters

string object1

string object2

string caseSensitive

string length

string fromStart

Parameters

Five Parameters.

1. A value or a smart parameter, which is a reference to a value.

2. A value or a smart parameter, which is a reference to a value for comparison.
3. True runs a case-sensitive compare. False runs a case insensitive compare.
4. An integer for the number of characters to compare. If the length is 0, the entire string is compared.
5. True compares from the start of the string. False compares from the end of the string.

Returns

True, if the compared values do not match. Otherwise, False.

Level

All.

Details

Uses the Smart Parameters that you enter as the parameter to locate and compare the values of two object's variables. The comparison can be limited to a specified number of characters from the start or the end of the string. The comparison can be run case-sensitive or case insensitive.

Example

```
rrCompareNotCaseLength("Main", "@JOBID", "False", 4, "True")
```

This example compares the string "Main" to the current Job ID. Only the first four letters are compared and the compare is case-sensitive. If the current Job ID is "MAIN_JOB", the action returns False.

```
rrCompareNotCaseLength("Main", "@JOBID", "True", 4, "True")
```

This example compares the string "Main" to the current Job ID. Only the first four letters are compared and the compare is case-sensitive. If the current Job ID is "MAIN_JOB", the comparison does not match due to case differences so the action returns True.

```
rrCompareNotCaseLength("Main Line", "Main Job", "True", 4, "True")
```

This example compares the string "Main Line" to the string "Main Job". The compare is case-sensitive and only the first four letters are compared. The comparison matches so the action returns False.

```
rrCompareNotCaseLength("@P.ScanSrcPath", "GOOD.BMP", "False", 8, "False")
```

This example runs a case insensitive compare of the last 8 characters of the *ScanSrcPath* variable to find the last 8 characters of the string "GOOD.BMP". If the value of *ScanSrcPath* is "c:\test\testvalidate\images\good.bmp", the comparison matches so the action returns False.

Parent topic: [runner actions](#)

Related reference:

[rrCompareCaseLength](#)

[rrCompareNot](#)

[rrCompare](#)

rrCompareNumeric

Uses the Smart Parameters that you enter as the parameter to locate and compare the numeric values of two object's variables.

Syntax

```
bool rrCompareNumeric( value1, operator, value2)
```

Parameters

Two Smart Parameters and one Operator.

1. A numeric value or a smart parameter, which is a reference to a numeric value.
2. Comparison operator as second parameter. Operator can be "<", ">", or "="
3. A numeric value or a smart parameter, which is a reference to a numeric value, for comparison.

Note: Either reference can specify a variable of the calling object (the bound object of the Document Hierarchy.) Alternatively, both references can identify a variable of an object that is a parent or child of the calling object.

Returns

False, if the parameters to be compared are not numeric, or if operator is not specified, or if the condition is not satisfied. Otherwise, returns True.

Level

All.

Details

Either of the two parameters to be compared is optional. If a parameter is not specified, the action defaults to the calling object. If the calling object is a field, the action uses the field value. For batch, document and page objects, the actions uses the variable *Text*, creating the variable if it does not exist.

Example

```
rrCompareNumeric("@P\Total_Cost", >, "100")
```

Assuming that the rule is configured at page level and getting the "Total_Cost" field value present in that page. If the value in field "Total_Cost" is greater than 100, then the action returns TRUE, else it returns FALSE.

```
rrCompareNumeric("@P.TemplateID", =, "555")
```

This example shows a value from a page variable *@P.TemplateID* to be compared with the value 555, which is the default fingerprint. If the *@P.TemplateID* is equal to 555, then the action returns TRUE, else it returns FALSE. From the result, it can be concluded whether the default fingerprint is being used.

Parent topic: [rrunner actions](#)

rrContains

Uses the Smart Parameters that you enter as the parameter to locate and compare the values of two objects' variables.

Syntax

```
bool rrContains(string object1, string object2, string caseSensitive)
```

Parameters

string object1
string object2
string caseSensitive

Parameters

Two Smart Parameters

1. A value or a smart parameter, which is a reference to a value.
2. A value or a smart parameter, which is a reference to a value, that can contain the value from argument 1.

Note:

Either reference can specify a variable of the calling object (the bound object of the Document Hierarchy). Alternatively, both references can identify a variable of an object that is a parent or child of the calling object.

Either parameter is optional. If a parameter is not specified, it defaults to the calling object. If the calling object is a field, it uses the field value. For batch, document, and page objects, it uses a variable named *Text*, creating the variable if it does not exist.

Returns

True, if the value of argument 1 is found in the value of argument 2. Otherwise, False.

Level

All.

Details

Uses the Smart Parameters that you enter as the parameter to locate and compare the values of two objects' variables.

Example

```
rrContains("Dr", "@P.Name")
```

This example shows how a value *Dr* is used as direct input, and the Page object's *Name* variable is solicited. The two values are then compared. The action returns False if the value *Dr* is not found in the value that is solicited from *@P.Name*.

Parent topic: [runner actions](#)

rrCopy

Copies the value, confidence levels, and positions from one field to another.

Syntax

```
bool rrCopy (string varSource, string varTarget)
```

Parameters

Two Smart Parameters

1. A reference to the source field
2. A reference to the target field

Either parameter is optional. If a parameter is not specified, the calling object must be a field.

Returns

False, if the action cannot retrieve the target or source object. Otherwise, True.

Level

Field level.

Details

The action retrieves the value, confidence, and image references (field positions) of the source field object, and copies them to the target field object. It uses the Smart Parameters that you enter as a parameter to copy the value of a source field object to a target field object. This action is unusual in that it is intended to work only on field objects.

Note: `rrCopy` copies more than just the value of the field. Use `rrSet` if only the field value is to be copied. This action is unusual because it is intended to work only on field objects.

Example

```
rrCopy("@B\OPERATOR", "@P\OPERATOR")
```

This example copies the Operator value of the Batch field to the Operator field of the bound object of the Document Hierarchy.

Parent topic: [runner actions](#)

Related reference:

[rrSet](#)

[rr_Get](#)

rrPrepend

Inserts a value at the beginning of the specified field.

Syntax

```
bool rrPrepend (string varSource, string varTarget)
```

Parameters

Two Smart Parameters:

1. The source value.
2. A reference to the target object.

Either parameter is optional. If a parameter is not specified, it will default to the calling object. If the calling object is a field, it will use the field value.

Returns

False if the calling object and target object are the same, if the action cannot locate the target object's variable, or if the source value argument or object returns an empty string. Otherwise, True.

Level

All, target must be a field object.

Details

The action retrieves the value of the source object, and pre-appends it to the target field value.

Example

```
rrPrepend("@D.DocID", "@F")
```

This action inserts the current calling object's parent DocID variable value and pre-appends it to the calling field's value.

Note: Target can not be a variable.

Parent topic: [rrunner actions](#)

Related reference:

[rrAppend](#)

rrSet

Assigns a value to a variable or field.

Syntax

```
bool rrSet (string varSource, string varTarget)
```

Parameters

Smart parameters are supported.

Both parameters for this action are optional. If you do not specify a parameter, the default item that the parameter references depends on the calling object type as shown in the following table:

Calling object type	Default item referenced
Field	The field that is the calling object
Page, Document, or Batch	The variable Text of the calling object. This variable is created if it does not exist.

varSource

The item whose value is to be copied to the target item.

varTarget

The item that is to receive the copied value.

Returns

False if the action cannot locate the target object. Otherwise, this action returns True.

Level

All.

Details

Use this action to copy the value of a source item to a target item.

To copy a field's value, confidence, and image references (field positions) of the source field object, use `rrCopy`.

Example

In these examples, the target item's value is set to be the same as the source item's value.

Code	Source	Target
<code>rrSet("@P\Date", "@F")</code>	The field Date that is a sibling of the target field.	Current field
<code>rrSet("@P.FieldCount", "@F")</code>	Page variable FieldCount	Current field
<code>rrSet("@F", "@P.Variable")</code>	Current field	Current page variable Variable
<code>rrSet("@F", "@F.Variable")</code>	Current field	Current field variable Variable
<code>rrSet("@P.TemplateID", "@P\F\nfieldName")</code>	Variable TemplateID	The field DCO object FieldName
<code>rrSet("@F.MySourceVar", "@P.\nMyTargetVar")</code>	The calling field MySourceVar variable	The MyTargetVar variable that belongs to the parent page of the calling object
<code>rrSet("@D.Tot_Pages", "@B.To\nt_Pages")</code>	The calling document's Tot_Pages variable. This example assumes that the calling object is a child of a Document object.	The Tot_Pages variable of the Batch object
<code>rrSet("@DICT_VALUE(..\nMONTH)", "")</code>	The OMR recognized value of the MONTH field as translated by the smart parameter to the text from a predefined dictionary	The calling object's Text property if the calling object is a field, or the Text variable if the calling object is not a field

Parent topic: [rrunner actions](#)

Related reference:

[rrCopy](#)

[rr_Get](#)

[rrCompare](#)

SetBatchPriority

Sets the priority of the batch at the completion of the task.

Syntax

```
bool SetBatchPriority (string Priority)
```

Parameters

A single value to update the batch priority at the end of the Task.

Returns

False if the value of the argument is invalid. Otherwise, True.

Level

All.

Details

Values are typically 1-9 with 5 being the median. Batches with priority 1 are processed first, batches with priority 9 are processed last.

Example

```
SetBatchPriority("1")
```

Parent topic: [runner actions](#)

SetOperatorID

Sets the ID of the person who is operating Rulerunner.

Syntax

```
bool SetOperatorID (string OperatorID)
```

Parameters

A Single value representing the new Operator ID value.

Returns

False if setting the value throws an error. Otherwise, True.

Level

All.

Details

Sets the Operator ID at the completion of the Task.

Example

```
SetOperatorID("admin")
```

Parent topic: [runner actions](#)

SetReturnValue

Returns True or False depending on the parameter that is specified.

Syntax

```
bool SetReturnValue (StrParam)
```

Parameters

True: The action will return true.

False: The action will return false.

Returns

True if the action is passed the parameter true. Otherwise, False.

Level

All.

Details

This action will return true or false based on the input parameter.

By passing in true, the action will return true and continue with the actions in the current function. If this is the last action in a function, any following functions within the rule are skipped.

One use for this action is a quick way to disable a rule by adding a new function, that precedes all other functions in the rule, where the new function contains only this action with a parameter of true. This will cause all other functions in the rule to be skipped and the next rule will run.

Using a parameter of false, this action will return false, causing all following actions in the function to be skipped and control carries forward to the next function in the same rule. In this way, the operation is identical to the action `GoToNextFunction`.

Example

```
SetReturnValue("true")
```

Parent topic: [runner actions](#)

Related reference:

[GoToNextFunction](#)

[FailRuleSet \(deprecated\)](#)

[rr_AbortBatch](#)

SetStationID

Sets the ID of the station where the person is operating Rulerunner.

Syntax

```
bool SetStationID (string StationID)
```

Parameters

A Single value representing the new Station ID value.

Returns

False if setting the value throws an error. Otherwise, True.

Level

All.

Details

Sets the Station ID at the completion of the Task.

Example

```
SetStationID("4")
```

Parent topic: [runner actions](#)

SetTaskStatus

Specifies the task status that is returned to an application as Abort, Canceled, Finished, Hold, or Pending when the current task completes.

Syntax

```
bool SetTaskStatus (StrParam)
```

Parameters

Numeric value representing the status that the task is to return to User Application. The statuses include:

- 0 - Abort
- 1 - Cancelled
- 2 - Finished
- 4 - Hold
- 8 - Pending

Returns

False if the parameter is not Numeric. Otherwise, True.

Level

All.

Details

Sets the Task Status value that is to be returned to User Application when the current task finishes processing.

Example

```
SetTaskStatus (4)
```

Parent topic: [runner actions](#)

SkipChildren

Prevents the running of rules on child objects of the current object.

Syntax

```
bool SkipChildren ()
```

Parameters

None.

Returns

Always True.

Level

All.

Details

Prevents rules applied to child objects of the current parent object from being run. The action can optimize the execution of rules by eliminating the need to visit every field on every page.

Example

```
SkipChildren ()
```

Parent topic: [runner actions](#)

Status_Preserve_OFF

Allows rules to change the STATUS value of fields, for example, to assign a problem status.

Syntax

```
bool Status_Preserve_OFF ()
```

Parameters

None.

Returns

Always True.

Level

All.

Details

This action turns the Status Preserve condition of a page and its fields from On to Off.

An object's Off condition allows the actions of a Validate ruleset to assign a problem status to any Field object with an invalid captured value. The Verify task's Data Entry panel will then surround the value with a pink background, alerting the operator to the problem.

Example

```
Status_Preserve_Off()
```

Parent topic: [runner actions](#)

Status_Preserve_ON

Prevents rules from changing the STATUS value of fields.

Syntax

```
bool Status_Preserve_ON ()
```

Parameters

None.

Returns

Always True.

Level

All.

Details

This action changes the Status Preserve condition of a Page object and its Field objects from Off to On.

The On condition prevents a rule and its actions from assigning a "problem" status to a field, even if the field's value fails validation.

Example

```
Status_Preserve_On()
```

Parent topic: [runner actions](#)

Task_NumberOfSplits

Specifies the number of jobs the batch is sent to when a condition is raised before it returns to the main workflow.

Syntax

```
bool Task_NumberOfSplits (nNumOfSplits)
```

Parameters

Integer value of the number of splits. In most cases, you will want to use "1" as the parameter.

Returns

False if the parameter you enter is not Numeric. Otherwise, True.

Level

All.

Details

Specifies how many times sub-batches have been created from the current batch.

Important: The action communicates but does not use the `Number_of_Splits` value you enter as a parameter.

Example

```
Task_NumberOfSplits(1)
Task_RaiseCondition(0,0)
```

In this example, the User Application is alerted to create one sub-batch entry, and to raise the second child job condition for this sub-batch entry.

Parent topic: [rrunner actions](#)

Related reference:

[Task_RaiseCondition](#)

Task_RaiseCondition

Specifies the group index and the index of the condition to raise from the list on the Datacap Web Client Workflow tab. 0 is the first condition.

Syntax

```
bool Task_RaiseCondition (strParam)
```

Parameters

Two comma-separated Integer values:

1. The applicable value of the sub-batch index. 0 is the first sub-batch, 1 is the second, etc. The `Task_NumberOfSplits` action determines how many sub-batches are created.
2. The value that designates the Child Job Condition that should be assigned to the specified sub-batch. 0 is the first Child Job Condition, 1 is the second, etc.

Returns

False if either parameter is not Numeric. Otherwise, True.

Level

All.

Details

Assigns the correct Child Job Condition to the correct sub-batch entry created by the Task_NumberOfSplits action.

Example

```
Task_NumberOfSplits(1)
Task_RaiseCondition(0,0)
```

In this example, the User Application is alerted to create one sub-batch entry, and to raise the second child job condition for this sub-batch entry.

Parent topic: [runner actions](#)

Related reference:

[Task_NumberOfSplits](#)

SharedRecognitionTools actions

Use the actions in this library after you perform OCR. For example, you might perform OCR with actions from the OCR_A or OCR_SR libraries and then use the actions in this library. Actions that can produce the layout XML include OCR_SR.Recognize and OCR_A.Recognize, both of which can process color images and PDF files. To use the Locate actions and perform click 'n' key during verification, use the action CreateCcoFromLayout to create a CCO file for the page after producing the layout XML file.

- [CreateCcoFromLayout](#)
Creates a CCO file after recognition or conversion is performed. The CCO is needed for the locate actions and for click 'n' key during verification.

Parent topic: [Global actions](#)

CreateCcoFromLayout

Creates a CCO file after recognition or conversion is performed. The CCO is needed for the locate actions and for click 'n' key during verification.

Syntax

```
bool CreateCcoFromLayout()
```

Parameters

None.

Returns

Always True.

Level

Page level.

Details

CreateCcoFromLayout requires a previously created layout file (for example: tm000001_layout.xml) where text is grouped into blocks. For more information about layout XML file, see [DocumentAnalytics actions](#).

Example

```
Recognize ()
CreateCcoFromLayout ()
```

Parent topic: [SharedRecognitionTools actions](#)

[Enabling automatic language detection for OCR_S recognition](#)

SignatureValidation actions

Use the Signature Validation actions to detect and validate signatures on a document or zone.

- [CreateNew](#)
Sets a value to determine if new signature records for signatures that do not match are to be added as reference signatures.
- [SetMinimumConfidence](#)
Sets the minimum confidence accepted for matched signatures.
- [SetSignatureReferenceFolderPath](#)
Sets the path to the folder where the signature reference files are stored.
- [ValidateSignature](#)
Performs signature detection and validation. This action should be called after the `CreateNew`, `SetMinimumConfidence`, and `SetSignatureReferenceFolderPath` actions.

Parent topic: [Global actions](#)

CreateNew

Sets a value to determine if new signature records for signatures that do not match are to be added as reference signatures.

Member of namespace

SignatureValidation

Syntax

```
bool CreateNew (string createNewSignatureReference , string
newReferenceSignatureFileName)
```

Parameters

createNewSignatureReference

True or False value indicating whether to add a signature that was not matched to the folder containing all the signature reference files. When set to true, it is expected that a signature that was not matched the first time, will be matched the second time it is processed. Smart parameters are supported.

`newReferenceSignatureFileName`

String value representing the name to use for the new signature file created when `createNewSignatureReference` is set to `True`.

Level

Page and field.

Returns

`True`, always.

Details

Sets a value to determine if new signature records for signatures that do not match are to be added as reference signatures.

For a typical application, it is recommended to have 5 to 10 references for a single signature. A person's signature can vary over time. It can also vary from day to day based on a number of factors such as mood, writing instrument, hand position, incline of the surface, etc. While the engine attempts account for these kind of differences, providing multiple examples of a reference signature helps to improve the accuracy of recognition.

```
SetSignatureReferenceFolderPath("@X.referenceFolderPath", "*" + @X.accountId + "*")
CreateNew("True", "@X.accountId")
SetMinimumConfidence("70")
ValidateSignature(False)
```

This example:

- sets the signature references directory folder path by using the `SetSignatureReferenceFolderPath` action, and compares only against the reference files with names that contain the value of a previously captured `accountId` DCO variable.
- instructs the signature matching algorithm to create a new reference file if the signature is not matched, and to name it using the value of a previously captured `accountId` DCO variable.
- sets the minimum confidence to 70 so that matching signatures with a confidence less than 70 are ignored.
- runs the signature detection/validation.

Parent topic: [SignatureValidation actions](#)

SetMinimumConfidence

Sets the minimum confidence accepted for matched signatures.

Member of namespace

SignatureValidation

Syntax

```
bool SetMinimumConfidence (string confidence)
```

Parameters

confidence

A value indicating the minimum confidence accepted for matched signatures. Valid values are in the range of 0-100. Smart parameters supported.

Level

Page and field.

Returns

True, always.

```
SetSignatureReferenceFolderPath("@X.referenceFolderPath", "*" + @X.accountId + "*")
CreateNew("True", "@X.accountId")
SetMinimumConfidence("70")
ValidateSignature(False)
```

This example:

- sets the signature references directory folder path by using the `SetSignatureReferenceFolderPath` action, and compares only against the reference files with names that contain the value of a previous captured `accountId` DCO variable.
- instructs the signature matching algorithm to create a new reference file if the signature is not matched, and to name it using the value of a previously captured `accountId` DCO variable.
- sets the minimum confidence to 70 so that matching signatures with a confidence less than 70 are ignored.
- runs the signature detection/validation.

Parent topic: [SignatureValidation actions](#)

SetSignatureReferenceFolderPath

Sets the path to the folder where the signature reference files are stored.

Member of namespace

SignatureValidation

Syntax

```
bool SetSignatureReferenceFolderPath (string referenceFileFolderPath , string
referenceFileFilter)
```

Parameters

referenceFileFolderPath

The path to the signature references directory. Smart parameters supported.

referenceFileFilter

Sets the filter to use when selecting reference files from the signatures reference directory. This is a DOS filter which supports the * and ? wild cards to determine which files from within the reference directory should be used to validate the signature. Smart parameters are supported.

Level

Page and field.

Returns

True, always.

Details

Sets the path to the folder where the signature reference files are stored. The directory can contain reference files for multiple signatures. Only the reference files that match the `referenceFileFilter` file mask will be used to match the target signature. For example, a filter of `*JohnSmith*` would match all reference files in the directory that have "JohnSmith" in the file name.

```
SetSignatureReferenceFolderPath("@X.referenceFolderPath", "*" + @X.accountId + *")
CreateNew("True", "@X.accountId")
SetMinimumConfidence("70")
ValidateSignature(False)
```

This example:

- sets the signature references directory folder path by using the `SetSignatureReferenceFolderPath` action, and compares only against the reference files with names that contain the value of a previously captured `accountId` DCO variable.
- instructs the signature matching algorithm to create a new reference file if the signature is not matched, and to name it using the value of a previously captured `accountId` DCO variable.
- sets the minimum confidence to 70 so that matching signatures with a confidence less than 70 are ignored.
- runs the signature detection/validation.

Parent topic: [SignatureValidation actions](#)

ValidateSignature

Performs signature detection and validation. This action should be called after the `CreateNew`, `SetMinimumConfidence`, and `SetSignatureReferenceFolderPath` actions.

Member of namespace

SignatureValidation

Syntax

```
bool ValidateSignature (bool createFields)
```

Parameter

`createFields`

True or False value indicating whether to add a new field to the current object for each signature that is detected in the document. Runs the signature detection and validation.

Details

Performs signature detection and validation. This action should be called after the `CreateNew`, `SetMinimumConfidence`, and `SetSignatureReferenceFolderPath` actions.

Note:

This action is supported at the page level only for images identified as US checks. If the page is not a US check, then the signature must be in a zoned field that contains only the signature. To determine if an image is a check, use the actions in the appropriate [check processing](#) library. It is possible that signature stamps might be validated by this action, however signature stamps are not supported.

After the action runs, variables are created at the calling DCO level when the following conditions are met:

1. A signature is detected and matched. When this condition occurs, the following variables are created:
 - *SignatureFound* is set to "1".
 - *SignatureConf* is set to an integer value representing the confidence of the match.
 - *SignatureReference* is set to a string value representing the name of the best matching signature reference.
 - *SignatureIndex* is set to an integer value representing the index of the best matching signature reference file.
 - *SignatureValidated* is set to "1".
2. A signature is detected, but not matched. When this condition occurs, the following variable is created:
 - *Signature_NotVerifiedX*, where X is the index of the signature that was detected but not validated.

Level

Page and field.

Returns

True, always.

```
SetSignatureReferenceFolderPath("@X.referenceFolderPath", "*" + @X.accountId + "*")
CreateNew("True", "@X.accountId")
SetMinimumConfidence("70")
ValidateSignature(False)
```

This example:

- sets the signature references directory folder path by using the `SetSignatureReferenceFolderPath` action, and compares only against the reference files with names that contain the value of a previous captured *accountId* variable.
- instructs the signature matching algorithm to create a new reference file if the signature is not matched, and to name it using the value of a previously captured *accountId* variable.
- sets the minimum confidence to 70 so that matching signatures with a confidence less than 70 are ignored.
- runs the signature detection/validation.

Parent topic: [SignatureValidation actions](#)

SPEXport actions

Use the SPEXport actions to upload documents to a Microsoft SharePoint library.

The SPEXport actions integrate Datacap applications with the SharePoint library. You run these actions to access the SharePoint server, set up document attributes and folders on the server, and upload documents to the server for storage.

- [SP_CreateFolder](#)
Creates the folder in the SharePoint where you import your documents.

- [SP_Login](#)
Creates the connection to SharePoint library by using the user ID, password, optional SharePoint domain.
- [SP_SetContentType](#)
Sets the type of content in the SharePoint library for the uploaded documents, such as an Invoice.
- [SP_SetFileType](#)
Sets the format in which to upload the document to the SharePoint library, for example TIF or PDF.
- [SP_SetProperty](#)
Sets the column property in SharePoint for the documents you want to upload.
- [SP_SetUploadMode](#)
Identifies the files to upload into the SharePoint library.
- [SP_SetUrl](#)
Sets the URL address of the SharePoint library.
- [SP_Upload](#)
Uploads the image file and any indexes that are specified for the batch, document, or page into SharePoint.
- [SP_UploadDir](#)
Uploads the file into the specified folder.

Parent topic: [Global actions](#)

SP_CreateFolder

Creates the folder in the SharePoint where you import your documents.

Syntax

```
bool SP_CreateFolder (StrParam)
```

Parameters

The URL that specifies the folder to create in SharePoint. Smart parameters are supported. Refer to the Smart Parameter documentation for more information.

Returns

True if the folder was created successfully or if it already exists. Otherwise, False.

Level

All.

Details

Creates the SharePoint folder specified in the parameter string.

Note: The SP_SetUrl action optionally can define directories and subdirectories to be created during the upload.

Example

```
SP_CreateFolder ("http://blue/Docs/Documents/Test")
```

Parent topic: [SPExport actions](#)

SP_Login

Creates the connection to SharePoint library by using the user ID, password, optional SharePoint domain.

Syntax

```
bool SP_Login(StrParam)
```

Parameters

A string containing 3 comma separated input parameters.

1. SharePoint userID.
2. Password.
3. An optional SharePoint domain. If not included, do not include the preceding comma.

Smart Parameters are supported. Use smart parameters to prevent clear text passwords in your application by obtaining the password from the application service.

Returns

True if the login succeeded. Otherwise, False.

Note: If the login parameters are invalid, a failure may not occur until you call SP_Upload.

Level

All.

Details

Login to SharePoint with credentials other than the logged-in Windows User.

Example

```
SP_SetUrl("http://blue/Docs/Documents/+#BatchID/+#ID")
SP_Login("userID,password,domain")
SP_SetContentType("Invoice")
SP_SetFileType("jpg")
SP_SetProperty("Date,@Value")
SP_Upload()
```

Alternatively, you can use smart parameters to obtain information from the application service to prevent clear text passwords. Here is an example where the password is stored in a custom value called SPPassword in the application service:

```
SP_Login("userID,@APPVAR(values/adv/SPPassword),domain")
```

Parent topic: [SPExport actions](#)

SP_SetContentType

Sets the type of content in the SharePoint library for the uploaded documents, such as an Invoice.

Syntax

```
bool SP_SetContentType (StrParam)
```

Parameters

A valid SharePoint content type in the selected Library. No error is raised if it is not a valid content type. Smart Parameters are supported.

Returns

True if the content type was successfully set or if the content type is not a valid content type. False if there is failure returned from SharePoint.

Level

All.

Details

This action sets the SharePoint Content Type for each document that is subsequently uploaded. Content Type is a SharePoint concept that defines a subset of columns (fields) within a library of documents, to be displayed and edited for a specific purpose.

Example

```
SP_SetContentType ("Invoice")
```

Parent topic: [SPExport actions](#)

SP_SetFileType

Sets the format in which to upload the document to the SharePoint library, for example TIF or PDF.

Syntax

```
bool SP_SetFileType (StrParam)
```

Parameters

A string indicating the type or filename extension of the images to be uploaded for each document or batch. When uploading the Batch or Document this extension is appended to the BatchID or DocumentID to select the image. The IMAGEFILE property takes precedence for Page uploads. See the description of SP_Upload for details. Valid parameters include: tif, tiff, jpg, jpeg, jpe, gif or pdf. The parameter may optionally include a period (for example .tif and .jpeg are also valid).

Smart parameters are supported.

Returns

False if the parameter is not a three-character extension, jpeg, or tiff, with or without a leading period. Otherwise True.

Note: If a three-character extension is supplied that is invalid for SharePoint images, the upload may fail.

Level:

All.

Details

Note: SP_SetUploadMode takes precedence over SP_SetFileType, if SP_SetUploadMode is called prior to SP_Upload this parameter has no effect. If neither SP_SetFileType nor SP_SetUploadMode are called, tif is used as the default file type.

Example

```
SP_SetFileType("jpg")
```

Parent topic: [SPExport actions](#)

Related reference:

[SP_Upload](#)

SP_SetProperty

Sets the column property in SharePoint for the documents you want to upload.

Syntax

```
bool SP_SetProperty(StrParam)
```

Parameters

Two comma separated values:

1. Column name is the name or ID of the target column in SharePoint.
2. Data value is the value to be uploaded to that column. Refer to the documentation for more information about the column types.

Smart Parameters are supported.

Returns

True if the parameters are not blank. The index information is uploaded to SharePoint when a document is subsequently uploaded. Otherwise, False.

Level

All.

Details

Sets an index value (column in SharePoint) for the documents to follow. Can be called multiple times to set multiple index values.

Notes®:

- Any spaces in column names must be replaced with “_0x02c_”.
- The real column name may be different from what is displayed in SharePoint. To determine the real Column name select the column settings and check the browser address.
- For example for the property called Description you may see "...3F2%7D Field=Comments" at the end. This means that the real name of the Column to be used in the SP_SetProperty action is "Comments".

Example

```
SP_SetProperty("Date,@Value")
SP_Upload()
```

Moves the value of the current field to the SharePoint column named Date.

Parent topic: [SPExport actions](#)

SP_SetUploadMode

Identifies the files to upload into the SharePoint library.

Syntax

```
bool SP_SetUploadMode (StrParam)
```

Parameters

A string or Smart Parameter identifying the page level variable where file name stored. If this action is not called the value defaults to blank and regular upload logic applied. For example `SP_SetUploadMode("ParentImage")` will cause uploading file with the name stored in *ParentImage* variable on the page level.

Returns

Always True.

Level

Batch, Document or Page level.

Details

Use this action to identify the files that will be uploaded to SharePoint.

Example

```
SP_SetUploadMode (ParentImage)
SP_Upload()
```

Parent topic: [SPExport actions](#)

SP_SetUrl

Sets the URL address of the SharePoint library.

Syntax

```
bool SP_SetUrl (StrParam)
```

Parameters

The full URL to the SharePoint repository. Smart parameters are supported. Refer to the Smart Parameter documentation for more information.

Returns

True if the action succeeded. Otherwise, False.

Level

All.

Details

Sets target URL of location to which image files are uploaded.

Note: /Docs/Documents/ is the default Document Library within SharePoint site.

Example:

```
SP_SetUrl("http://blue/Docs/Documents/>{@BatchID}/{@ID}")
```

With this example, directories with names defined by />{@BatchID}/{@ID} are created automatically during upload.

Parent topic: [SPExport actions](#)

SP_Upload

Uploads the image file and any indexes that are specified for the batch, document, or page into SharePoint.

Syntax

```
bool SP_Upload()
```

Parameters

None.

Returns

True if all documents and indexes were successfully uploaded. Otherwise, False.

Level

All.

Details

Uploads the image file and any indexes specified for the current page, document, or batch to SharePoint. Uses TiffMerge file naming scheme to find document level or batch level image file: DocID.TIF or BatchID.TIF by default. Pages associated with other image file types (e.g. TM000001.pdf, TM000001.jpg, etc) can be uploaded.

Note: After uploading, the variable *Upload_Folder* in the page/doc/batch will be set to the SharePoint URL where the document(s) were uploaded.

Note: If some documents in a batch are successfully uploaded and some fail, and the batch is rerun through the SharePoint Upload task, only documents that failed to upload will be re-uploaded.

Note: If any document is re-uploaded, SharePoint will replace the existing document with the newer one, or save the old version and replace it with the new version, depending on SharePoint Versioning settings.

Example

```
SP_Upload()
```

Parent topic: [SPExport actions](#)

SP_UploadDir

Uploads the file into the specified folder.

Syntax

```
bool SP_UploadDir(StrParam)
```

Parameters

Two comma separated parameters:

1. The Windows folder containing only document files to upload.
2. A Boolean. True means delete file after upload, false means move file to the Uploaded folder in current directory.

Smart parameters are supported.

Returns

True if the upload succeeds for all files in the directory. Otherwise, False.

Level

Batch or Document level.

Details

Uploads all files in specified folder.

Example

```
SP_UploadDir("C:\ParentDir\Invoice\Images\Input\", false)
```

Parent topic: [SPExport actions](#)

Split actions

Use the Split action to split a batch into smaller batches so each can be processed separately.

The Split action splits batches based on the value of the specified document-level variable.

- [SplitBatch](#)
Splits a batch into smaller batches that are based on the value of the specified document-level variable.

Parent topic: [Global actions](#)

SplitBatch

Splits a batch into smaller batches that are based on the value of the specified document-level variable.

Syntax

```
bool SplitBatch (StrParam)
```

Parameters

A smart parameter pointing to a Document or Page variable that determines if the Document or Page is to be split to a Child Batch.

Important: The action evaluates all documents and pages (including unbound* pages) in the batch.

The values of the smart parameter variable found during the document and page evaluation are grouped into buckets:

1. Pages/documents that contain the variable and the variable values are identical go into the same bucket.
2. If there are multiple buckets, all pages/documents that share the same value will split to the same child batch.
3. There can be only one child batch for each unique bucket value.

Child batches have the same name as the parent batch, but include an additional two character alpha-decimal suffix such as .01, .02, .0A, ..., up to .ZZ. This hexadecimal numbering for child batches is required by Datacap Server. Datacap Server creates the batch and queue entries for the child batches after the task is finished, when the split condition is processed. There is a maximum of 1295 child batches.

Example: @D.Inbox. If there is an Inbox variable in each document, this will split documents by the value of the Inbox variable.

Important: Any document or unbound* page that does not have this Inbox variable value, will remain in the parent batch.

*An unbound page is any page not inside a document.

Returns

False if an error occurs like a file could not be created, etc., and the batch will be set to abort. Otherwise True.

If the specified variable is not found in any documents or unbound pages, meaning there is nothing to split, the action is still considered to be successful and will return true.

Each child batch split off will generate a condition, which should be configured for Split in the workflow.

Any page or document with a blank value for the splitting value will remain in the original "parent" batch.

Level

Batch level only.

Details

This action will process all of the documents and unbound pages that are in the batch and attempt to split the identified documents and pages into child batches. The action will look in the documents or unbound pages for the variable specified in the `a` parameter, group the objects that have a matching value, and split each group into a unique child batch. Only documents and unbound pages will be processed. Pages that are already placed within in a document structure will not be processed individually, the pages will be as part of their document, not as a separate page.

Additional considerations:

There is only one job routing condition raised by this action: it is the first one in the task's list of conditions.

The task's Task Setup/Task Settings screen must be configured as Job Router, and a single condition defined (by convention, call it Split).

1. Any and all child batches will be routed via this single condition.
2. If the application wants to treat the individual buckets differently, then the first step in the workflow after splitting can check the same smart parameter value and branch or re-route the child batch using that value.
3. All the structure and variables, etc. that were in the parent batch docs/pages are retained in the child batches.
4. In addition, new variables *ParentBatch* and *ParentBatchDir* are added.
5. The action can only be used once per Parent Batch.
6. The maximum number of child batches is 1295.
7. The page count and document count in child batches is not accurate after splitting. It is updated and will be accurate once the next task completes.

Example

```
SplitBatch (@D.Inbox)
```

Parent topic: [Split actions](#)

Statistics actions

These statistics actions are used by the Profile Statistics and Export Statistics rulesets to save information about field recognition accuracy and page classification accuracy.

- [AddToDBTotals](#)
Updates the application summary statistics in the reportTotal table in the Engine database with the cumulative batch size total in KB (*rt_SizeKB*) and the cumulative total number of checks processed (*rt_Feature1Count*).
- [CompareFieldsText](#)
Calculates the page type classification and field recognition accuracy statistics and updates database report tables. Call this action after data verification to calculate accuracy based on changes to the data during verification.
- [IsBatchAborted](#)
Checks if the batch has already been aborted and stops running the ruleset if so.
- [SaveFieldsText](#)
Saves recognized page types and field values after recognition for accuracy calculations.

Parent topic: [Global actions](#)

AddToDBTotals

Updates the application summary statistics in the reportTotal table in the Engine database with the cumulative batch size total in KB (*rt_SizeKB*) and the cumulative total number of checks processed (*rt_Feature1Count*).

Syntax

```
bool AddToDBTotals (strParam)
```

Parameters

None

Returns

Always True

Level

Batch level only

Details

When this action runs, it also sets the *TotalStatsUpdated* batch variable to avoid double-counting.

Example

```
AddToDBTotals ()
```

Parent topic: [Statistics actions](#)

CompareFieldsText

Calculates the page type classification and field recognition accuracy statistics and updates database report tables. Call this action after data verification to calculate accuracy based on changes to the data during verification.

Syntax

```
bool CompareFieldsText (strParam)
```

Parameters

None

Returns

Always True

Level

Batch level only

Details

CompareFieldsText requires that you have previously run the SaveFieldsText action between the recognition (Profiler) and verification tasks. You can prevent inclusion of a page or field in accuracy statistics by setting the *ClassifiedPageType* or *RecognizedText* variables to an empty string before calling CompareFieldsText. The action will populate the following batch variables:

PageClassifiedErrors

The number of page classification errors (errors that result in a change to the page type after auto-classification).

PageClassifiedCount

The number of pages classified in the batch.

FieldRecognitionCount

The number of fields recognized.

FieldRecognitionErrors

The number of fields that were incorrectly recognized (fields that were changed after recognition).

Example

```
CompareFieldsText ()
```

Parent topic: [Statistics actions](#)

IsBatchAborted

Checks if the batch has already been aborted and stops running the ruleset if so.

Syntax

```
bool IsBatchAborted ()
```

Parameters

None

Returns

True if the batch is set to abort, otherwise False.

Level

Any

Example

```
IsBatchAborted ()
```

Parent topic: [Statistics actions](#)

SaveFieldsText

Saves recognized page types and field values after recognition for accuracy calculations.

Syntax

```
bool SaveFieldsText (strParam)
```

Parameters

None

Returns

Always True

Level

Batch level only

Details

Call this action after page classification and recognition and before verification to save the original recognized data for statistics calculations. The action will populate the following page and field variables:

ClassifiedPageType

Set for each page to the current page type

RecognizedText

Set for each non-empty field to the current value of the field.

Example

```
SaveFieldsText ()
```

Parent topic: [Statistics actions](#)

TifMerge actions

Use the TifMerge actions to combine individual TIFF images into a multi-page TIFF file. This action is typically run at the end of the workflow so that you can upload or release the batch images as a single file.

The TifMerge actions determine the path to the Batch directory, creates the multi-page file, and lets you specify the compression to use in the final image.

- [TifMerge_CheckStatus](#)
Filters merged pages and documents that are based on their DCO status.
- [TifMerge_ExportToBatchDir](#)
Indicates that the path for the multi-Image file is to the current Batch directory.
- [TifMerge_MergeImages](#)
Merges the images associated with the object of the Document Hierarchy to which the action's ruleset applies into a single, multi-Image file.
- [TifMerge_MyImage](#)
Adds each single image to the multi-Image file.
- [TifMerge_PreserveCompression](#)
Determines the output compression type for merged images.
- [TifMerge_SetFileName](#)
Sets the name of the multi-Image file (.tif) to be created by TifMerge.

- [TifMerge_SetFilePath](#)
Sets the path for the multi-Image file.

Parent topic: [Global actions](#)

TifMerge_CheckStatus

Filters merged pages and documents that are based on their DCO status.

Syntax

```
bool TifMerge_CheckStatus (string AcceptablePageStatuses, string  
DisregardPageStatuses, string AcceptableDocStatuses, string DisregardDocStatuses)
```

Parameters

AcceptablePageStatuses
Type: string

DisregardPageStatuses
Type: string

AcceptableDocStatuses
Type: string

DisregardDocStatuses
Type: string

Parameters

1. AcceptablePageStatuses: a comma-separated list of the Page status values that are merged.
2. DisregardPageStatuses: a comma-separated list of the Page status values that are not merged.
3. AcceptableDocStatuses: a comma-separated list of the Document status values that are merged.
4. DisregardDocStatuses: a comma-separated list of the Document status values that are not merged.

Returns

Always True

Level

Any

Details

This action configures the acceptable statuses for documents and pages when you call the `TifMerge_MergeImages` action. If this action is not called, the status values of documents and pages is not checked.

In the following example, only the pages with an acceptable status of '0' or '49' are merged. The disregard page status of '75' is redundant because of its exclusion from the acceptable status values. By contrast, the disregard document status of '128' prevents all of the child pages of the document from being merged.

Example

```
TifMerge_CheckStatus("0,49","75","","128")
TifMerge_MergeImages("All")
```

Parent topic: [TifMerge actions](#)

TifMerge_ExportToBatchDir

Indicates that the path for the multi-Image file is to the current Batch directory.

Syntax

```
()
```

Parameters

None.

Returns

False if the path does not exist or is not accessible. Otherwise, True.

Level

Batch or Document usually, but Page or Field is permissible.

Details

When saving a multi-image file, this action is used to configure the current batch directory as the destination for the output file. This action must be called before the action to merge the images.

Example

```
TifMerge_ExportToBatchDir()
TifMerge_MergeImages("All")
```

Parent topic: [TifMerge actions](#)

TifMerge_MergeImages

Merges the images associated with the object of the Document Hierarchy to which the action's ruleset applies into a single, multi-Image file.

Syntax

```
bool TifMerge_MergeImages (sPageType)
```

Parameters

String value indicating either:

1. All if the multi-Image file is to contain images of all pages without regard to Page Type.
2. The Page Type(s) of the images to be included (comma-separated list, if the parameter includes more than one Page Type.)

Smart parameters are supported.

Returns

False if the action cannot create the multi-Image file. Otherwise, True.

Level

Batch or Document.

Details

This action merges the images associated with the object to which the action's rule applies into a single, multi-Image file.

At the Batch level, the action merges all Image files in the batch into one multi-Image file – or those Image files representing pages of the Page Type you specify as a parameter. At the Document level, the action assembles a new multi-Image file for each document in the batch. If you specify a Page Type, the multi-Image file for each document will include only images of pages of that type.

Actions `TifMerge_SetFileName` and `TifMerge_SetFilePath` must be called before `TifMerge_MergeImages`.

Example

```
TifMerge_SetFileName("@BATCHID+@DATE(dd.mm.yyyy)")
TifMerge_SetFilePath("C:\ParentDir\Invoice\batches\MultiImage")
TifMerge_MergeImages("All")
```

```
TifMerge_SetFileName("Doc_+@ID+@DATE(dd.mm.yyyy)")
TifMerge_SetFilePath("C:\ParentDir\Invoice\MultiImage")
TifMerge_MergeImages("Invoice,Attachment")
```

The first example merges all images into a multi-Image file that uses the Batch ID and the processing Date for its name.

The second example applies to a Document object of the Document Hierarchy. It assembles a multi-Image file for each document in the batch; the images in a file are limited to Invoice and Attachment pages.

Parent topic: [TifMerge actions](#)

TifMerge_MyImage

Adds each single image to the multi-Image file.

Syntax

```
bool TifMerge_MyImage ()
```

Parameters

None.

Returns

False if the action's ruleset is not applied to a Page object or if the corresponding image file for the current page cannot be found. Otherwise, True.

Level

Page level.

Details

Adds the current page image to the multi-Image TIF file. Actions that proceed the TifMerge_MyImage action allow you to specify under which conditions an image is to be added to the multi-Image file.

A rule with this action can only be applied to a Page object. The output image file name and destination path must have been previously set using TifMerge_SetFileName and TifMerge_SetFilePath.

Example

```
ChkDDCOStatus ("0")  
TifMerge_MyImage ()
```

In this example, the ChkDDCOStatus action checks that the status of the current page is "0". If so, the image for the current page will be added to the multi-Image file.

If the current status of this page is not "0", the rule will fail and the TifMerge_MyImage action will not be run; therefore, the current image will not be added to the multi-Image file.

This ChkDDCOStatus action is used as an example. You can use many other actions to be sure the current image meets your merging criteria.

Parent topic: [TifMerge actions](#)

Related reference:

[TifMerge_SetFileName](#)

[TifMerge_SetFilePath](#)

TifMerge_PreserveCompression

Determines the output compression type for merged images.

Syntax

```
bool TifMerge_PreserveCompression (string PreserveCompression)
```

Parameters

string PreserveCompression

Parameters

True: Preserves the original compression type of the source image.

False: Uses G4 compression for black and white images. JPEG is used for color images.

Returns

Always True.

Level

Any.

Details

This action will configure the output format for TifMerge_MergeImages. If this action is not called, then the default value of False is used, so the original image compression is not preserved.

Example

```
TifMerge_PreserveCompression("TRUE")
TifMerge_MergeImages("All")
```

Parent topic: [TifMerge actions](#)

TifMerge_SetFileName

Sets the name of the multi-Image file (.tif) to be created by TifMerge.

Syntax

```
bool TifMerge_SetFileName (StrParam)
```

Parameters

String value of the file name to be assigned to the multi-page file. Smart parameters are supported.

Returns

Always True.

Level

All.

Details

This action sets the name of the multi-Image file (.tif) to be created by the TifMerge actions. The file name can be text, or a combination of text and the value of a variable you enter as a parameter. The action automatically adds the “.tif” extension to the file.

Example

The following example assumes that the rules with these actions are applied to a Document object. The names combine text values such as “Doc_” with values assigned to variables by using smart parameters.

```
TifMerge_SetFileName("Doc_+@ID+@DATE(dd.mm.yyyy)")
TifMerge_SetFilePath("c:\ParentDir\Invoice\MultiImage")
TifMerge_MergeImages("All")
```

This example combines "MultiTif_" with the ID of the Document Hierarchy object to which the ruleset is applied. Usually, a rule that contains this action applies to a Batch object or Document object, but can apply to a Page or Field object.

```
TifMerge_SetFileName ("MultiTif_+@ID")
```

Parent topic: [TifMerge actions](#)

Related reference:

[TifMerge_SetFilePath](#)

TifMerge_SetFilePath

Sets the path for the multi-Image file.

Syntax

```
bool TifMerge_SetFilePath (strParam)
```

Parameters

String value for the output path of the multi-Image TIF file. Smart parameters are supported.

Returns

False if the specified drive does not exist or the path cannot be created. Otherwise, True.

Level

All.

Details

Sets the path for where the multi-Image file will be created. If the folder designated in the parameter does not exist, the action will create the folder in which the TIF file will be placed.

Usually, a rule containing this action applies to a Batch object or Document object of the Document Hierarchy, but can apply to a Page or Field object.

Example

```
TifMerge_SetFileName ("Doc_+@ID+@DATE (dd.mm.yyyy) ")  
TifMerge_SetFilePath ("c:\ParentDir\Invoice\MultiImage")  
TifMerge_MergeImages ("All")
```

TM524 actions

The TM524 actions are for compatibility with older versions of Datacap and are no longer used

Parent topic: [Global actions](#)

Validations actions

Use the Validations actions to check and modify the content and format of the current field value.

Other actions in the Validations library do arithmetic calculations, assign values, copy values, and check variables.

The Validations actions are described in the following table.

- [AddLeadingZeros](#)
Inserts zeros at the beginning of a value so the character count equals the number that is specified.
- [AddPaddingToEnd](#)
Pads the captured value of the current Field object with spaces from after the last character in the string out to the number of specified characters.
- [AddPaddingToStart](#)
Pads the captured value of the current Field object with spaces from the start of the string up to the first character until the specified length is reached.
- [AddTrailingZeros](#)
Adds zeros to the end of captured value of the current Field until the length of the value reaches the maximum *n* you enter as the parameter.
- [AllowOnlyChars](#)
Removes all of the characters that are not specified as supported.
- [AppendFromField](#)
Appends the captured value of the specified Field object to the captured value of the current Field object.
- [AppendToField](#)
Appends the captured value of the current Field object to the captured value of the Field object that is specified by the parameter.
- [AssignFieldDefault](#)
Assigns a default value to the current field.
- [CalculateDateDifference](#)
Calculate the differences between two dates and stores the calculation in a user defined variable.
- [CalculateFields](#)
Evaluates a specified expression as either True or False.
- [CheckSubFields](#)
Determines whether the values of the specified child fields meet the specified criteria and deletes the parent field if they do not.
- [CompareFields](#)
Compares the values of two fields by using the specified matching criteria that supports fuzzy matching.
- [ConvertFieldToCurrency](#)
Converts the value of the current field to a currency value.
- [ConvertToLowerCase](#)
Converts any upper case characters in the captured value of a Field object to lower case characters.
- [ConvertToUpperCase](#)
Converts the lower case characters in the captured value of a Field object to upper case characters.
- [CopyField](#)
Copies the value of the current field to a specified field.
- [CopyFieldToField](#)
Copies the value of the current field to a specified field.
- [DateStampField](#)
Updates the current Field object with today's date.
- [DeleteAllAlpha](#)
Deletes all of the alphabetic characters from the captured value of the current Field object.
- [DeleteAllMiscChars](#)
Deletes all of the UNICODE Symbol Category characters from the captured value of the current Field object.
- [DeleteAllNumeric](#)
Deletes all of the numeric characters from the captured value of the current Field object.

- [DeleteAllPunct](#)
Deletes all of the punctuation from the value of the current field.
- [DeleteAllSysChars](#)
Deletes all of the characters with ASCII values 0 through 31 from the captured value of the current Field object.
- [DeleteChildType](#)
Deletes all of the child objects of the type that you designate as a parameter from the Document Hierarchy.
- [DeleteLCSpaces](#)
Deletes all of the low confidence spaces from the value of the current field.
- [DeleteParentObj](#)
Deletes the parent of the Document Hierarchy object to which a rule that contains this action is bound.
- [DeleteSelectedChars](#)
Deletes a specified character sequence from the value of the current field. This action is a more flexible version of the FilterFieldSelectedChars action.
- [EmptyFieldValue](#)
Clears the text value in the field represented by the Field object of the Document Hierarchy that is specified by the parameter.
- [FieldContainsValue](#)
Determines whether the current field value contains some or all of the specified text but no additional text.
- [FilterFieldSelectedChars](#)
Deletes the specified characters from the value of the current field.
- [FormatNumberToLocale](#)
Evaluates the current field value for known number patterns and if a known pattern is detected, updates the decimal and digit separators characters to match that of the current locale.
- [GetJobID](#)
Assigns the current job ID to the Text property of the current object.
- [HasChildOfType](#)
Determines whether the current object has a child of the specified type.
- [InsertChars](#)
Inserts one or more characters into the value of the current field.
- [InsertDecimalPoint](#)
Inserts a decimal point into the value of the current field at the specified position.
- [IsFieldCurrency](#)
Determines if the captured value of the Field meets the currency format of the current locale.
- [IsFieldDate](#)
Checks that the value of the field has an acceptable Date format. This action uses the current locale setting to determine valid patterns.
- [IsFieldDateEqualOrAfter](#)
Checks that the Date value in the current field represented by the bound Field object of the Document Hierarchy is greater than or equal to the Date value in the field that is specified as the parameter.
- [IsFieldDateEqualOrBefore](#)
Checks that the date in the current field represented by the bound Field object of the Document Hierarchy is less than or equal to the Date value in the field that is specified as the parameter.
- [IsFieldDateUpToToday](#)
Checks that the Date value of the current Field object is today's date or earlier.
- [IsFieldDateWithinRange](#)
Checks that the value assigned to the Text property of the bound object is a valid Date. If yes, this action then confirms that the Date is within the range specified by the parameters.
- [IsFieldDateWithinXDays](#)
Checks that the captured Date value of the current Field object is within *n* days of the number entered as a parameter.

- [IsFieldDateWithReformat](#)
Confirms that the data of a field is a valid date and then formats the Date value according to the format entered as the parameter.
- [IsFieldEmpty](#)
Checks that the Field object designated as a parameter does not have a captured value.
- [IsFieldFilled](#)
Determines whether the Field object designated as a parameter contains a captured value or is empty.
- [IsFieldGreaterOrEqual](#)
Determines if the captured value of the current Field object is greater than or equal to the value entered as a parameter.
- [IsFieldHidden](#)
Checks that the calling field is Hidden, which means the field has a variable *STATUS* that is equal to -1.
- [IsFieldLengthMax](#)
Checks that the character length of the current Field object's captured value is equal to or less than the value set as a parameter.
- [IsFieldLengthMin](#)
Checks the character length of the current Field object's captured value to see if its length is equal to or longer than a number *n*.
- [IsFieldLessOrEqual](#)
Determines if the captured value of the current Field object is less than or equal to the value entered as a parameter.
- [IsFieldMatching](#)
Determines if the value entered as the parameter is identical to the captured value of the current Field object.
- [IsFieldPercentAlpha](#)
Determines if the characters in the captured value of current Field object are *n%* alphabetic.
- [IsFieldPercentNonNumeric](#)
Determines if any of the characters in the captured value of the current Field object are *n%* not numeric characters.
- [IsFieldPercentNumeric](#)
Determines if the characters in the captured value of the current Field object are *n%* numeric characters.
- [IsMatchingJobID](#)
Checks that the Job ID of the current User Application job matches the Job ID value of the parameter.
- [IsMaxOMRChecked](#)
Indicates the maximum number of check boxes that can contain a value, such as a check.
- [IsMinOMRChecked](#)
Indicates the minimum number of check boxes that can contain a value, such as a check.
- [IsPatternInField](#)
Checks that the value of the current field contains the specified VBScript regular expression.
- [IsSupportedImageFile](#)
Checks that the image file attached to the current page is in a supported image format.
- [IsThisFieldEmpty](#)
Checks that the value of the current field is empty.
- [IsThisFieldFilled](#)
Checks that the current field has a captured value.
- [IsVariableEmpty](#)
Checks that the variable specified by the parameter does not contain a value.
- [IsVariableFilled](#)
Checks that the variable specified by the parameter contains a value.
- [ParseMultilineAddress](#)
Splits the value of the current field at each comma and saves the substrings to the specified fields. Typically used for address fields.

- [ParseName](#)
Splits the three word value of the current field and saves the substrings to the specified fields. Typically used for name fields, such as first name, middle name/initial, last name.
- [ReplaceChars](#)
Replaces a character or string of characters in the captured value of the current Field object with a String that you enter as one of the parameters.
- [ReplaceValueAtPosition](#)
Replaces the value at the specified position within the current field with a replacement string, or deletes the value.
- [ResetField](#)
Deletes the value of the current field and sets the Position attribute of the field to 0,0,0,0.
- [SetIsOverrideable](#)
Specifies if the user can or cannot override a validation that fails for the current object.
- [SplitFieldValuePreserveEnd](#)
Splits the captured value of a Field object at the first instance of the character specified as a parameter.
- [SplitFieldValuePreserveStart](#)
Splits the captured value of a Field object at the first instance of the character specified as a parameter.
- [SumFields](#)
Adds the values of all child fields of the specified type and assigns the result to the current field. You can also use this action to sum the values of the specified variable for all child objects.
- [TimeStampField](#)
Updates the current Field object with the current time.
- [TrimSpaces](#)
Deletes extra spaces at the beginning and end of the captured value of the current Field object.
- [TruncateFromEnd](#)
Deletes characters from the end of the captured value of the current Field object until the length of the value equals the length indicated by the parameter.
- [TruncateFromStart](#)
Deletes characters from the start of the captured value of the current Field object until the length of the value equals the length specified by the parameter.

Parent topic: [Global actions](#)

AddLeadingZeros

Inserts zeros at the beginning of a value so the character count equals the number that is specified.

Syntax

```
bool AddLeadingZeros (strParam)
```

Parameters

A number n which is the maximum length of the value. Smart parameters are supported.

Returns

False if the parameter you enter is not numeric. Otherwise, True.

Level

Field level.

Details

Adds zeros ("0") to the beginning of the captured value of the current Field object until the total length of the value reaches the maximum *n* you specify as the parameter.

Example

```
AddLeadingZeros("10")
2240.00 becomes 0002240.00
```

Parent topic: [Validations actions](#)

Related reference:

[AddTrailingZeros](#)

[IsFieldLengthMax](#)

[AddPaddingToLeft \(deprecated\)](#)

AddPaddingToEnd

Pads the captured value of the current Field object with spaces from after the last character in the string out to the number of specified characters.

Syntax

```
bool AddPaddingToEnd (strParam)
```

Parameters

A number *n* indicating the maximum permissible length of the value. If the action finds that a value's length is less than this number, it will insert spaces until the maximum length is reached. Smart parameters are supported.

Returns

Always True.

Level

Field level.

Details

Example

```
AddPaddingToEnd("10") uses spaces to expand a value with less than 10 characters. For example:
456.11 becomes 456.11_ _ _ _
```

Parent topic: [Validations actions](#)

Related reference:

[AddPaddingToStart](#)

AddPaddingToStart

Pads the captured value of the current Field object with spaces from the start of the string up to the first character until the specified length is reached.

Syntax

```
bool AddPaddingToStart (strParam)
```

Parameters

A number n indicating the maximum permissible length of the value. If the action finds that a value's length is less than this number, it inserts spaces until the maximum length is reached. Smart parameters are supported.

Returns

Always True.

Level

Field level.

Details

Example

```
AddPaddingToStart("12") uses spaces to expand a value with less than 12 characters.
```

```
For example: RSJ-112 becomes _ _ _ _ _RSJ-112
```

Parent topic: [Validations actions](#)

Related reference:

[AddPaddingToEnd](#)

AddTrailingZeros

Adds zeros to the end of captured value of the current Field until the length of the value reaches the maximum n you enter as the parameter.

Syntax

```
bool AddTrailingZeros (strParam)
```

Parameters

A number n which is the maximum length of the value. Smart parameters are supported.

Returns

False if the parameter you enter is not numeric; otherwise, True.

Level

Field level.

Details

Example

```
AddTrailingZeros("10")  
2240.00 becomes 2240.00000
```

Parent topic: [Validations actions](#)

Related reference:

[AddLeadingZeros](#)

AllowOnlyChars

Removes all of the characters that are not specified as supported.

Syntax

```
bool AllowOnlyChars (StrParam)
```

Parameters

A Regular Expression that specifies permitted characters in the current word.

Returns

Always True.

Level

Field level.

Details

This action employs a Regular Expression as its parameter to identify and remove all of the characters that are not in the parameter from the value of the Field.

An empty argument removes all characters.

Example

```
AllowOnlyChars("ABCDEFG.")  
HELLO DOLLY. becomes ED.
```

Parent topic: [Validations actions](#)

AppendFromField

Appends the captured value of the specified Field object to the captured value of the current Field object.

Syntax

```
bool AppendFromField (strParam)
```

Parameters

The name of the Field object whose text value is to be appended to the value of the current field.

Returns

False if the parameter is not the name of a Field object. Otherwise, True.

Level

Page or Field Level.

Details

You can also apply the action at the Page level. A Text page-level variable with the appended value is added to the Data file of the page.

Example

```
AppendFromField("Number")
```

Parent topic: [Validations actions](#)

AppendToField

Appends the captured value of the current Field object to the captured value of the Field object that is specified by the parameter.

Syntax

```
bool AppendToField (strParam)
```

Parameters

The name of the Field object to which the value is to be appended.

Returns

False if the parameter is not the name of a Field object. Otherwise, True.

Level

Field level.

Details

Example

```
AppendToField("FirstName")
```

If the current Field object is MiddleInitial, a rule with this action appends the value of the Middle Initial field to the FirstName Field object.

Parent topic: [Validations actions](#)

AssignFieldDefault

Assigns a default value to the current field.

Syntax

```
bool AssignFieldDefault (StrParam)
```

Parameters

The String value you're assigning to the field.

Returns

False if not called on the correct level. Otherwise, True.

Level

Field level.

Details

Example

```
AssignFieldDefault("Bill Paid")  
or  
AssignFieldDefault("PastDue!")
```

Parent topic: [Validations actions](#)

CalculateDateDifference

Calculate the differences between two dates and stores the calculation in a user defined variable.

Syntax

```
bool CalculateDateDifference (string startDate, string endDate, string  
targetVariable, string dateProperty)
```

Parameters

- startDate : The starting date
- endDate : The ending date
- targetVariable : The variable to hold the calculated result value
- dateProperty : The value to calculate, 0 = days, 1 = months, 2 = quarters, 3 = years.

Smart parameters are supported.

Returns

False if the format of either date is invalid. Otherwise, True.

Level

Any level.

Details

Calculates the number of days, months, quarters or years between two dates. Only whole numbers are returned. Any fractional parts of the value are dropped. Quarters are calculated simply by dividing the number of months by 3. The order of the dates does not matter.

This action only supports Gregorian short dates as input and the date format must match the default format of the current locale.

Example

```
CalculateDateDifference("4/20/2012", "5/19/2012", "@P.Months", 1)
```

This example creates the page variable *Months* with a value of 0.

```
CalculateDateDifference("4/20/2012", "5/20/2012", "@P.Months", 1)
```

This example creates the page variable *Months* with a value of 1.

```
CalculateDateDifference("4/20/2012", "4/19/2013", "@P.Years", 3)
```

This example creates the page variable *Years* with a value of 0.

```
CalculateDateDifference("4/20/2012", "4/20/2013", "@P.Years", 3)
```

This example creates the page variable *Years* with a value of 1.

```
CalculateDateDifference(@P\MyDate1, @P\MyDate2, "@P.Days", 0)
```

This example creates the page variable *Days* with the number of days between the dates specified by the values in field MyDate1 and field MyDate2.

```
CalculateDateDifference(@P.MyDate1, @P.MyDate2, "@P.Days", 0)
```

This example creates the page variable *Days* with the number of days between the dates specified by page variables MyDate1 and MyDate2.

Parent topic: [Validations actions](#)

CalculateFields

Evaluates a specified expression as either True or False.

Syntax

```
bool CalculateFields (string Equation, string DecimalDigits, string PreserveStatus)
```

Parameters

Equation

The expression to evaluate. An expression consists of two or more subexpressions as defined by comparison operators (such as “=” or “>”). For example, if an expression has one comparison operator, it has two subexpressions: one subexpression to the left of the comparison operator and one subexpression to the right of the comparison operator. If an expression has two comparison operators, it has three subexpressions. And so on.

Each subexpression consists of one or more terms that are separated by arithmetic operators (+, -, *, /, ^). A term can be a numeric constant or the name of a field object. The fields that a subexpression references are called *dependent fields*. Surround any dependent field names with single quotation marks (').

Any dependent field with a value of null is treated as if the field had a value of zero.

Restriction: A locale mismatch can prevent this action from properly evaluating the expression. A mismatch occurs if the value of a dependent field is not formatted for that field's locale. For information about setting the locale, see [Setting locale values](#).

DecimalDigits

Optional. The number of decimal places to use for comparing the numerical results of subexpressions.

PreserveStatus

Optional. There are two possible values that determine whether the validation status of dependent fields is updated:

"True"	The validation status of dependent fields is not updated.
"False"	<p>The validation status of dependent fields is updated in the following manner:</p> <ul style="list-style-type: none">• If the expression evaluates to False, the validation status of dependent fields is updated to a failed status value. For information about validation failures, see Show validation failures to an operator.• If the expression evaluates to True, the validation status of dependent fields is updated to a done status value. <p>Important: The validation status of dependent fields could be updated by other rules and actions. When you configure your application, sequence your validation logic to work in tandem with this action.</p>

The default value is "False".

Returns

True if the expression can be evaluated and the expression evaluates to True. Otherwise, the action returns False.

For example, the expression cannot be evaluated if a field's value is not numeric.

Level

Field level.

Details

Example

Code	Comment
<code>CalculateFields("'SubTotal' + 'Shipping' + 'Tax' = 'Total'")</code>	
<code>CalculateFields("('SubTotal' + 'Shipping' + 'Tax') - '0.05' = 'Total'")</code>	

Code	Comment
<pre>CalculateFields("('Wages' + 'Interest' + 'Unemployment')>=('Gross'-.05')") CalculateFields("('Wages' + 'Interest' + 'Unemployment')<=('Gross'+.05')")</pre>	Call this action twice to validate that the result is within a range.

Parent topic: [Validations actions](#)

CheckSubFields

Determines whether the values of the specified child fields meet the specified criteria and deletes the parent field if they do not.

Syntax

```
bool CheckSubFields (StrParam)
```

Parameters

An expression that specifies which LINEITEM child fields are to be checked for the presence or absence of captured values. Within the expression, the name of each child Field object must be surrounded with single quotation marks ('). You can also use parentheses () in your expression. Action is placed on the parent of the LINEITEM field.

Returns

Always True.

Level

Field level.

Details

Validates an instance of a parent Field object by confirming the presence (or absence) of captured values for one or more of its child fields. (In the Invoices application, as an example, child fields of the LINEITEM parent include: ItemID, ItemDesc, Quantity, Price and LineTotal.)

Invalid parent Field objects are deleted if they do not meet this criteria.

This action usually runs in its own RuleSet (for example, in a Filter RuleSet) and would be applied to the DETAILS Field object (parent object to the LINEITEM field) in the Invoices example.

Example 1

```
Example 1: The captured values for a LINEITEM field are:
ItemID = 12345
ItemDesc =
Price = 12.00
LineTotal =
```

```
The action's parameter contains this expression:
CheckSubFields("('ItemID' OR 'ItemDesc') AND ('Price' OR 'LineTotal')")
```

In this example the action returns True and the current LINEITEM object is Valid.

Example 2

The captured values for the LINEITEM field are:
ItemID = 12345
ItemDesc = Thank you for your order
Price =
LineTotal =

The action's parameter contains this expression:
CheckSubFields("('ItemID' OR 'ItemDesc') AND ('Price' OR 'LineTotal')")

In this example the action's equation returns is False and the current LINEITEM object is Invalid. The field and the values of its child fields are deleted from the Data file.

Example 3

The captured values for the LINEITEM field are:
ItemID = 12345
LineTotal = gonetolunch

The action's parameter contains this expression:
CheckSubFields("('ItemID') AND ('LineTotal')")

In this example, the action returns True and validates the LINEITEM field, despite the presence of a nonsense entry in the LineTotal child field.

Parent topic: [Validations actions](#)

CompareFields

Compares the values of two fields by using the specified matching criteria that supports fuzzy matching.

Syntax

```
bool CompareFields (StrParam)
```

Parameters

Five comma-separated values:

1. String value of the source field's name. This is the field with a value to be compared.
2. String value of the target field's name. This is the field with a value to be compared to.
3. String value: Y or Yes; N or No. Alternatively, a Numeric value: 0 = No or 1=Yes. Yes (or Y or 1) allows the action to carry out a fuzzy rather precise comparison of the fields' values.
4. Numeric value of the percentage of required precision. Numbers less than 100 permit increasing fuzziness.
5. String value: Y or Yes; N or No. Alternatively, a Numeric value: 0 = No or 1=Yes. Yes (or Y or 1) directs the action to compare values in the fields word-by-word.

Returns

False if the designations of Field objects in the first two parameters are not valid, or if the Data Types of the values in the first two fields do not match. Otherwise, True.

Level

All.

Details

Locates values in two fields specified by the first two parameters. If values are present in both fields, the action compares the values according to the matching criteria of the last three parameters.

Example

```
CompareFields("Invoice_Date, Due_Date, Yes, 100, Yes")
```

Parent topic: [Validations actions](#)

ConvertFieldToCurrency

Converts the value of the current field to a currency value.

Syntax

```
bool ConvertFieldToCurrency ()
```

Parameters

None.

Returns

True if the text value is numeric and greater than one character. Otherwise, False.

Level

All levels, but generally applied at the Field level.

Details

Formats the text value of a field as a currency value. The following steps are performed on the field:

1. Removes existing currency symbols.
2. Replaces negative value characters such as parenthesis, 'NEG', 'CR' and trailing hyphen with a leading hyphen.
3. If a decimal exists, its position is not changed.
4. If a decimal does not exist and the field contains 2 or more characters, a decimal is inserted before the last two characters in the field.
5. If a decimal does not exist and the field contains less than 2 characters, no decimal is inserted.

Example

```
ConvertFieldToCurrency()  
A value of 1 remains 1  
A value of 12 becomes .12  
A value of 105 becomes 1.05  
A value of 104.009 remains 104.009
```

Parent topic: [Validations actions](#)

ConvertToLowerCase

Converts any upper case characters in the captured value of a Field object to lower case characters.

Syntax

```
bool ConvertToLowerCase ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Example

```
ConvertToLowerCase ()
```

To ensure that the characters in all Product ID's are lower case, a Validate rule that applies to a Document Hierarchy's Item Field object would include this action.

Parent topic: [Validations actions](#)

Related reference:
[ConvertToUpperCase](#)

ConvertToUpperCase

Converts the lower case characters in the captured value of a Field object to upper case characters.

Syntax

```
bool ConvertToUpperCase ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Example

```
ConvertToUpperCase ()
```

A Validate rule with this action, if applied to a State Field object which accepts only abbreviations, would be sure the captured values contain Upper Case letters (AZ, AL, etc.)

Parent topic: [Validations actions](#)

Related reference:

[ConvertToLowerCase](#)

CopyField

Copies the value of the current field to a specified field.

Syntax

```
bool CopyField (strParam)
```

Parameters

The name of the target Field object.

Returns

False if the parameter does not match the name of a Field object. Otherwise, True.

Level

Field level.

Details

Assigns the captured value of the current Field object to a sibling Field object you specify as the parameter.

Example

```
CopyField("Date")
```

This action places the captured value of the current field into the Date field.

Parent topic: [Validations actions](#)

CopyFieldToField

Copies the value of the current field to a specified field.

Syntax

```
bool CopyFieldToField (strParam)
```

Parameters

The name of the target Field object of the Document Hierarchy.

Returns

False, if the parameter does not match the name of a Field object. Otherwise, True.

Level

Field level.

Details

Copies the captured value of the current Field object to the Field object designated as the parameter of the action.

Example

```
If the current field's value is "1/1/05"
```

```
CopyFieldToField("Date")
```

```
assigns "1/1/05" (without the quotation marks) to the Document Hierarchy's Date field.
```

Parent topic: [Validations actions](#)

Related reference:

[CopyField](#)

DateStampField

Updates the current Field object with today's date.

Syntax

```
bool DateStampField (StrParam)
```

Parameters

A Date format such as mm/dd/yy or dd/mm/yy. (* defaults to mm/dd/yyyy)

Smart parameters are supported.

Returns

Always True.

Level

Field level.

Details

Example

```
DateStampField("*") produces  
01/20/2005
```

```
DateStampField("dd/mm/yy") produces  
20/01/05
```

Parent topic: [Validations actions](#)

DeleteAllAlpha

Deletes all of the alphabetic characters from the captured value of the current Field object.

Syntax

```
bool DeleteAllAlpha ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Example

```
DeleteAllAlpha ()  
JAN2003 becomes 2003
```

Parent topic: [Validations actions](#)

Related reference:

[DeleteSelectedChars](#)
[DeleteAllMiscChars](#)
[DeleteAllNumeric](#)
[DeleteAllPunct](#)

DeleteAllMiscChars

Deletes all of the UNICODE Symbol Category characters from the captured value of the current Field object.

Syntax

```
bool DeleteAllMiscChars ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Example

```
DeleteAllMiscChars ()  
  
'100c = $1' becomes '100 1'
```

Parent topic: [Validations actions](#)

Related reference:

[DeleteSelectedChars](#)

[DeleteAllAlpha](#)

[DeleteAllNumeric](#)

DeleteAllNumeric

Deletes all of the numeric characters from the captured value of the current Field object.

Syntax

```
bool DeleteAllNumeric ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Example

```
DeleteAllNumeric ()  
  
JAN2003 becomes JAN
```

Parent topic: [Validations actions](#)

Related reference:

[DeleteSelectedChars](#)
[DeleteAllAlpha](#)
[DeleteAllMiscChars](#)
[DeleteAllPunct](#)

DeleteAllPunct

Deletes all of the punctuation from the value of the current field.

Syntax

```
bool DeleteAllPunct ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Removes all characters with ASCII values 33-47,58-64,91-96, and 123-191 from the captured value of the current Field object.

Example

```
DatePUNCT ()
```

Parent topic: [Validations actions](#)

Related reference:

[DeleteSelectedChars](#)

[DeleteAllAlpha](#)

[DeleteAllMiscChars](#)

[DeleteAllNumeric](#)

DeleteAllSysChars

Deletes all of the characters with ASCII values 0 through 31 from the captured value of the current Field object.

Syntax

```
bool DeleteAllSysChars ()
```

Parameters

None.

Returns

Always True.

Level

Field only.

Details

Example

```
DeleteAllSysChars()  
A field containing Hello Dolly becomesHelloDolly.
```

Parent topic: [Validations actions](#)

DeleteChildType

Deletes all of the child objects of the type that you designate as a parameter from the Document Hierarchy.

Syntax

```
bool DeleteChildType (StrParam)
```

Parameters

String value of the child object Type.

Field, for example, eliminates all Field objects. In the Invoices application, LineItem removes the child fields of the Details parent Field object.

Returns

False if the child objects do not exist. Otherwise, True.

Level

All except Batch.

Details

Example

```
DeleteChildType ("Field")
```

Parent topic: [Validations actions](#)

DeleteLCSpaces

Deletes all of the low confidence spaces from the value of the current field.

Syntax

```
bool DeleteICSpaces ()
```

Parameters

None.

Returns

False if the action is unable to isolate the spaces in a field's value. Otherwise, True.

Level

All levels, but generally at the Field level.

Details

Uses the *ReqConf Setup dco* variable as threshold for low confidence values; defaults to 9.

Example

```
DeleteICSpaces ()
```

Parent topic: [Validations actions](#)

DeleteParentObj

Deletes the parent of the Document Hierarchy object to which a rule that contains this action is bound.

Syntax

```
bool DeleteParentObj ()
```

Parameters

None.

Returns

False if a parent or grandparent object cannot be found, or if the deletion of the parent object fails. Otherwise, True.

Level

Document, Page, and Field.

Details

Example

```
DeleteParentObj ()
```

DeleteSelectedChars

Deletes a specified character sequence from the value of the current field. This action is a more flexible version of the FilterFieldSelectedChars action.

Syntax

```
bool DeleteSelectedChars (strParam)
```

Parameters

strParam

A comma-delimited string that consists of the following parts:

Deletion string	The string that is to be deleted from the current field value. This string can consist of one character. Smart parameters are supported. To specify a comma as part of the deletion string, use the smart parameter @CHR as shown in the example.
Segment position	The position within the current field value that is the beginning of the string segment in which deletion is to occur. The default segment position is 1.
Instance maximum	The maximum number of deletion string instances that are to be deleted. To delete all instances, specify an asterisk ("*"). The default instance maximum is 1.

Returns

Always True.

Level

Field level.

Details

Example

```
DeleteSelectedChars("-", , "*")  
"223-56-7669" becomes "223567669"
```

```
DeleteSelectedChars("-", 5, "*")  
"223-86-7669" becomes "223-867669"
```

```
DeleteSelectedChars("@CHR(44), , 2")  
"Hello, Roger, Tom, and Jan" becomes "Hello Roger Tom, and Jan"
```

```
DeleteSelectedChars("er+@CHR(44), , *")  
"Hello, Roger, Tom, and Jan" becomes "Hello, Rog Tom, and Jan"
```

Related reference:[DeleteAllAlpha](#)[DeleteAllMiscChars](#)[DeleteAllNumeric](#)[DeleteAllPunct](#)

EmptyFieldValue

Clears the text value in the field represented by the Field object of the Document Hierarchy that is specified by the parameter.

Syntax

```
bool EmptyFieldValue (strParam)
```

Parameters

The name of the Field object that is to be emptied.

Returns

False if the field specified by the parameter does not exist. Otherwise, True.

Level

Page or Field level.

Details

Parent topic: [Validations actions](#)

FieldContainsValue

Determines whether the current field value contains some or all of the specified text but no additional text.

Syntax

```
bool FieldContainsValue (StrParam)
```

Parameters

Text that the action is looking for in the current field. Smart parameters are supported.

Returns

False if the *CurrentObj.Text* variable of the object does not contain the parameter value. Otherwise, True.

Level

All, but generally at the Field level.

Details

This action determines if a field represented by the bound object of the Document Hierarchy contains some or all of the parameter's text value, without additional unspecified text.

Example

```
FieldContainsValue("NEW")
Parameter: "NEW" = TRUE
Parameter: "NEW Action" = TRUE
Parameter: "Project" = FALSE
Parameter: "NEW Project" = TRUE
Parameter: "Development" = FALSE
```

Parent topic: [Validations actions](#)

FilterFieldSelectedChars

Deletes the specified characters from the value of the current field.

Syntax

```
bool FilterFieldSelectedChars (StrParam)
```

Parameters

A String containing the character or characters to be removed.

Every instance of the characters are removed from the captured value.

Returns

Always True.

Level

Field level.

Details

Removes all instances of the characters that you enter as parameters from the captured value of the current Field object.

Example

```
FilterFieldSelectedChars(0)
11002900 becomes 1129
```

Parent topic: [Validations actions](#)

Related reference:

[DeleteSelectedChars](#)

FormatNumberToLocale

Evaluates the current field value for known number patterns and if a known pattern is detected, updates the decimal and digit separators characters to match that of the current locale.

Syntax

```
bool FormatNumberToLocale ()
```

Returns

True, if no errors are encountered. Otherwise, False.

Level

Field level.

Details

This action evaluates the current field value for known number patterns, If a known pattern is detected, the action updates the decimal and digit separators characters (if present) to match the current locale. For use when processing fields with number types formatted incorrectly for the current locale, such as US versus European locales. Known patterns are industry standard digits with or without 3-digit group separators, and 1-2 digits following a decimal separator.

Distinct Analyzed groups:

1. Numerals with decimal point
 - Group Separators using comma, apostrophe, or space characters.
 - Decimal Separator using decimal character.
2. Numerals with decimal comma
 - Group Separator using decimal, apostrophe, or space characters.
 - Decimal Separator using comma character.
3. Numerals with Arabic/Persian characters
 - Group Separator using Arabic/Persian character.
 - Decimal Separator using Arabic/Persian character.

Note: Numerals with lakhs layout and decimal mark (pattern of `n, nn, nn, nnn.dd`) are not supported.

Example

a) Given a US number 1,234.56 to be formatted to UK.
`FormatNumberToLocale()`
New format will be 1.234,56

b) Given a US number 1234.5 to be formatted to UK.
`FormatNumberToLocale()`
New format will be 1234,5

c) Given a US number 1,234.567 to be formatted to UK.
`FormatNumberToLocale()`
Format will remain 1,234.567 since 3 digits following the decimal are not supported.

d) Given a US number 12345678.90 to be formatted to UK.
`FormatNumberToLocale()`
New format will be 12345678.90

e) Given a UK number 1.234.567,89 to be formatted to US.
`FormatNumberToLocale()`

New format will be 1,234,567.89

f) Given a UK number 0,5 to be formatted to US.
FormatNumberToLocale()
New format will be 0.5

Parent topic: [Validations actions](#)

GetJobID

Assigns the current job ID to the Text property of the current object.

Syntax

```
bool GetJobID ()
```

Parameters

None.

Returns

False if the action cannot find a JobID value. Otherwise, True.

Level

All.

Details

Assigns the Job ID of the current User Application job (the Pilot.JobID property of the job) to the *CurrentObj.Text* variable of the bound object of the Document Hierarchy.

Example

```
GetJobID ()
```

Parent topic: [Validations actions](#)

HasChildOfType

Determines whether the current object has a child of the specified type.

Syntax

```
bool HasChildOfType (StrParam)
```

Parameters

The name of a level of the Document Hierarchy (Batch, Document, Page, Field) or of a runtime variable.

Returns

False if the bound object does not include a child or children specified by the parameter, or a variable identified by the parameter. Otherwise, True.

Level

All.

Details

Determines if the bound object of the Document Hierarchy has a child or children of the type specified by the parameter. The action can also determine if a runtime variable specified as a parameter has been assigned to the bound object.

Example

```
HasChildOfType ("Page")
```

This example determines if the bound object is the parent of one or more pages.

```
HasChildOfType ("IGNORE")
```

In this example, the action determines if IGNORE is a runtime variable of the bound object.

Parent topic: [Validations actions](#)

InsertChars

Inserts one or more characters into the value of the current field.

Syntax

```
bool InsertChars (strParam)
```

Parameters

1. The characters or character string to be inserted; defaults to a space.
2. A number n indicating the target position within the captured value; defaults to the end of the value.
3. The number of insertions; defaults to 1.

Returns

Always True.

Level

Field level.

Details

Inserts a character or string of characters into the captured value, one or more times.

Example

```
InsertChars ("=$,1,1")  
345.67 becomes =$345.67
```

```
InsertChars ("=$,1,2")
345.67 becomes  =$=$345.67
```

Parent topic: [Validations actions](#)

InsertDecimalPoint

Inserts a decimal point into the value of the current field at the specified position.

Syntax

```
bool InsertDecimalPoint (strParam)
```

Parameters

A number *n* indicating the character position at which to place the decimal. Smart parameters are supported.

Returns

Always True.

Level

Field level.

Details

Places a decimal character in the captured value, at the character position specified as a parameter. The parameter indicates the position of the decimal point, moving from right to left.

Example

```
InsertDecimalPoint ("2")
324556 becomes 3245.56
```

```
InsertDecimalPoint ("2")
355 becomes 3.55
```

Parent topic: [Validations actions](#)

IsFieldCurrency

Determines if the captured value of the Field meets the currency format of the current locale.

Syntax

```
bool IsFieldCurrency ()
```

Parameters

None.

Returns

True if the current locale's format criteria are met. Otherwise, False.

Level

Field level.

Details

This determination includes the number of decimal places, decimal and digit separator characters and any present currency indicators.

Example

```
IsFieldCurrency()  
$1,200 returns False  
$1,200.00 returns True
```

Parent topic: [Validations actions](#)

IsFieldDate

Checks that the value of the field has an acceptable Date format. This action uses the current locale setting to determine valid patterns.

Syntax

```
bool IsFieldDate ()
```

Parameters

None.

Returns

True if the specifications of the action are met. Otherwise, False.

Level

Field level.

Details

This action accepts any valid date from January 1st year 1 through December 31st 9999.

Example

```
IsFieldDate()  
  
In locale en-US (United States):  
April 6, 1944 returns True  
04/06/44 returns True  
30.6.44 returns False  
Feb 31,2003 returns False
```

Parent topic: [Validations actions](#)

IsFieldDateEqualOrAfter

Checks that the Date value in the current field represented by the bound Field object of the Document Hierarchy is greater than or equal to the Date value in the field that is specified as the parameter.

Syntax

```
bool IsFieldDateEqualOrAfter (StrParam)
```

Parameters

The name of the Field object of the Document Hierarchy to be compared with the Date value of the current field.

Returns

False if the date condition is not met, if the action is not applied at the Field level, or either field does not contain a valid date. Otherwise, True.

Level

Field level.

Details

Example

```
IsFieldDateEqualOrAfter ("24aDtFr1")
```

Parent topic: [Validations actions](#)

Related reference:

[IsFieldDateEqualOrBefore](#)

IsFieldDateEqualOrBefore

Checks that the date in the current field represented by the bound Field object of the Document Hierarchy is less than or equal to the Date value in the field that is specified as the parameter.

Syntax

```
bool IsFieldDateEqualOrAfter (StrParam)
```

Parameters

The name of the Field object of the Document Hierarchy to be compared with Date value of the current field.

Returns

False if the date condition is not met, if the action is not applied at the Field level, or if either field does not contain a valid date value. Otherwise, True.

Level

Field Level.

Details

Example

```
IsFieldDateEqualOrBefore ("24aDtFr1")
```

Parent topic: [Validations actions](#)

Related reference:

[IsFieldDateEqualOrAfter](#)

IsFieldDateUpToToday

Checks that the Date value of the current Field object is today's date or earlier.

Syntax

```
bool IsFieldDateUpToToday ()
```

Parameters

None.

Returns

False if the value of the field is not a valid date or if the date is after Today. Otherwise, True.

Level

Field level.

Details

Example

```
IsFieldDate ()  
IsFieldDateUpToToday ()
```

This sequence confirms that a value is a date and that it is the same as, or earlier than, today's date.

Parent topic: [Validations actions](#)

Related reference:

[IsFieldDate](#)

[DateStampField](#)

IsFieldDateWithinRange

Checks that the value assigned to the Text property of the bound object is a valid Date. If yes, this action then confirms that the Date is within the range specified by the parameters.

Syntax

```
bool IsFieldDateWithinRange (StrParam)
```

Parameters

Comma-separated Dates that define the range:

1. Start Date
2. End Date

TODAY can represent the current Date. Smart parameters are supported.

Returns

False if the value assigned to the Text property of the current object is not a valid date; if either parameters is invalid; or the Date value of the Text property is not within the range that is specified by the parameters. Otherwise, True.

Level

All, but generally at the Field Level.

Details

Example

```
IsFieldDateWithinRange ("1/1/2006, 1/31/2006")  
IsFieldDateWithinRange ("1/1/2006, TODAY")
```

Parent topic: [Validations actions](#)

IsFieldDateWithinXDays

Checks that the captured Date value of the current Field object is within *n* days of the number entered as a parameter.

Syntax

```
bool IsFieldDateWithinXDays (StrParam)
```

Parameters

A number *n* that specifies how many days make up the review period. Smart parameters are supported.

Returns

False if the value of the field is not a valid date or if the date is older than the number of days in the parameter. Otherwise, True.

Level

Field level.

Details

Example

```
IsFieldDate()  
IsFieldDateWithinXDays("30")
```

This sequence checks that a value is a date within 30 days of today's date.

Parent topic: [Validations actions](#)

Related reference:

[IsFieldDate](#)

[IsFieldDateUpToToday](#)

IsFieldDateWithReformat

Confirms that the data of a field is a valid date and then formats the Date value according to the format entered as the parameter.

Syntax

```
bool IsFieldDateWithReformat (StrParam)
```

Parameters

The Date format you want to use.

- mm/dd/yyyy
- mm/dd/yy
- dd/mm/yy
- mm.dd.yy, etc.

Defaults to system short date format if no format or single * is used. Smart parameters are supported.

Returns

False if the parameter is invalid, or the current field value is not a valid date given the specified format. Otherwise True.

Level

Field level.

Details

Example

```
IsFieldDateWithReformat("*")  
June 3, 2002 becomes 06/03/2002  
  
IsFieldDateWithReformat("mm.dd.yy")  
June 3, 2002 becomes 06.03.02
```

Parent topic: [Validations actions](#)

IsFieldEmpty

Checks that the Field object designated as a parameter does not have a captured value.

Syntax

```
bool IsFieldEmpty (strParam)
```

Parameters

The name of the Field object.

Returns

False if the name of the Field object does not exist or if the field contains a captured value. Otherwise, True.

Level

All.

Details

Example

```
IsFieldEmpty("Shipping")  
AssignFieldDefault("NoShipping")
```

In this example, if the captured value of the Shipping Field object is \$921.11, this action return a False condition and terminates the rule.

If the Shipping Field object does not have a value (True), the AssignFieldDefault action enters the NoShipping parameter as the captured value of the Field object.

Parent topic: [Validations actions](#)

Related reference:

[AssignFieldDefault](#)

[IsFieldFilled](#)

IsFieldFilled

Determines whether the Field object designated as a parameter contains a captured value or is empty.

Syntax

```
bool IsFieldFilled (strParam)
```

Parameters

The name of the Field object.

Returns

False if the name of the Field object does not exist or if the field does not contain a captured value. Otherwise, True.

Level

All.

Details

Example

```
IsFieldFilled("PaymentDue")
```

If the action returns True because the field does contain a value, the rule invokes its next action.

If the action returns False, the rule closes and the task applies the next rule, which might include a CopyFieldToField action.

Parent topic: [Validations actions](#)

Related reference:

[AssignFieldDefault](#)

[IsFieldEmpty](#)

IsFieldGreaterOrEqual

Determines if the captured value of the current Field object is greater than or equal to the value entered as a parameter.

Syntax

```
bool IsFieldGreaterOrEqual (strParam)
```

Parameters

The Numeric or Currency value which is the basis for comparison. Smart parameters are supported.

Returns

False if the parameter or the captured value of the Field object is not Numeric. Or if the result does not meet the action's requirements. Otherwise, True.

Level

Field level.

Details

If the value of the field is not Numeric or currency, the action returns a False condition.

Example

```
IsFieldGreaterOrEqual("624")  
Returns True if the Field object's value is 625.00  
Returns False if the value is 623.99.  
Returns True if the value is 624.00.
```

Parent topic: [Validations actions](#)

Related reference:

IsFieldHidden

Checks that the calling field is Hidden, which means the field has a variable *STATUS* that is equal to -1.

Syntax

```
bool IsFieldHidden ()
```

Parameters

None.

Returns

True if the *STATUS* variable of the Field object = -1. Otherwise False.

Level

Field level.

Details

This action returns True if the calling field is Hidden, the corresponding Field object of the Document Hierarchy has a variable *STATUS* that is equal to -1.

Example

```
IsFieldHidden ()
```

Parent topic: [Validations actions](#)

IsFieldLengthMax

Checks that the character length of the current Field object's captured value is equal to or less than the value set as a parameter.

Syntax

```
bool IsFieldLengthMax (StrParam)
```

Parameters

A number *n* designating the maximum length of the value. Smart parameters are supported.

Returns

False if the parameter that you enter is not numeric, or if the number of characters exceeds the value of the parameter. Otherwise, True.

Level

Field level.

Details

Example

```
IsFieldLengthMax("6")  
EU2240 returns True  
EU002240 returns False
```

Parent topic: [Validations actions](#)

Related reference:

[IsFieldLengthMin](#)

IsFieldLengthMin

Checks the character length of the current Field object's captured value to see if its length is equal to or longer than a number *n*.

Syntax

```
bool IsFieldLengthMin (StrParam)
```

Parameters

A number *n* designating the minimum length of the value. Smart parameters are supported.

Returns

False if the parameter that you enter is not numeric, or if the number of characters is less than the parameter's value. Otherwise, True.

Level

Field level.

Details

Example

```
IsFieldLengthMin("6")  
EU2240 returns True  
EU22 returns False
```

Parent topic: [Validations actions](#)

Related reference:

[IsFieldLengthMax](#)

IsFieldLessOrEqual

Determines if the captured value of the current Field object is less than or equal to the value entered as a parameter.

Syntax

```
bool IsFieldLessOrEqual (strParam)
```

Parameters

The Numeric or Currency value you want to compare against. Smart parameters are supported.

Returns

False if the parameter or captured value of the Field object is not Numeric. Or if the result does not meet the action's requirements. Otherwise, True.

Level

Field level.

Details

If the value of the field is not Numeric or Currency, the action returns a False condition.

Example

```
IsFieldLessOrEqual("625")  
Returns True if the Field object's value is 624.99  
Returns False if the value is 625.01  
Returns True if the value is 625.00
```

Parent topic: [Validations actions](#)

Related reference:

[IsFieldGreaterOrEqual](#)

IsFieldMatching

Determines if the value entered as the parameter is identical to the captured value of the current Field object.

Syntax

```
bool IsFieldMatching (strParam)
```

Parameters

The value to be checked against the value of the Field object.

Returns

True if the requirement of the action is met. Otherwise, False.

Level

Field level.

Details

Example

If the Field object's value is 525.00:

```
IsFieldMatching("525.00") returns True  
IsFieldMatching("525") returns False
```

Parent topic: [Validations actions](#)

Related reference:

[IsFieldPercentAlpha](#)

[IsFieldPercentNumeric](#)

IsFieldPercentAlpha

Determines if the characters in the captured value of current Field object are *n%* alphabetic.

Syntax

```
bool IsFieldPercentAlpha (StrParam)
```

Parameters

A number (0-100) indicating the percentage necessary to return a True condition. The value must be numeric, without the percent sign. Smart parameters are supported.

Returns

True if the requirements of the parameter are met. Otherwise False, including if the Field is empty.

Level

Field level.

Details

Example

```
IsFieldPercentAlpha("50") #RPR-1421 returns False  
IsFieldPercentAlpha("30") #RPR1421 returns True
```

Parent topic: [Validations actions](#)

Related reference:

[IsFieldPercentNumeric](#)

[IsFieldMatching](#)

IsFieldPercentNonNumeric

Determines if any of the characters in the captured value of the current Field object are *n%* not numeric characters.

Syntax

```
bool IsFieldPercentNonNumeric (StrParam)
```

Parameters

A number (0-100) indicating the percentage that results in a True condition. The default percentage is 100. The value must be numeric, without the percent sign. Smart parameters are supported.

Returns

False if the parameter is non-numeric, if the field is empty, or if the value of the field exceeds the parameter's percentage of numeric characters. Otherwise, True.

Level

Field level.

Details

This determination includes and is not limited to valid decimal and numeric separator characters.

Example

```
Given the current value is "1,234.56US"  
(Percentage of non-numeric characters is 40%)  
IsFieldPercentNonNumeric("0") returns True  
IsFieldPercentNonNumeric("30") returns True  
IsFieldPercentNonNumeric("40") returns True  
IsFieldPercentNonNumeric("70") returns False  
IsFieldPercentNonNumeric("100") returns False
```

Parent topic: [Validations actions](#)

Related reference:

[IsFieldPercentAlpha](#)

[IsFieldMatching](#)

IsFieldPercentNumeric

Determines if the characters in the captured value of the current Field object are *n*% numeric characters.

Syntax

```
bool IsFieldPercentNumeric (StrParam)
```

Parameters

A number (0-100) indicating the percentage that results in a True condition. The default percentage is 100. The value must be numeric, without the percent sign. Smart parameters are supported.

Returns

False if the parameter is non-numeric, if the field is empty, or if the value of the field exceeds the parameter's percentage of numeric characters. Otherwise, True.

Level

Field level.

Details

This determination does not include, and is not limited to, valid decimal and numeric separator characters.

Example

```
Given the current value is "1,234.56US"  
(Percentage of numeric characters is 60%)  
IsFieldPercentNumeric("0") returns True  
IsFieldPercentNumeric("50") returns True  
IsFieldPercentNumeric("60") returns True  
IsFieldPercentNumeric("70") returns False  
IsFieldPercentNumeric("100") returns False
```

Parent topic: [Validations actions](#)

Related reference:

[IsFieldPercentAlpha](#)

[IsFieldMatching](#)

IsMatchingJobID

Checks that the Job ID of the current User Application job matches the Job ID value of the parameter.

Syntax

```
bool IsMatchingJobID (StrParam)
```

Parameters

String value of the Job ID to be compared to the current Job ID.

Returns

True if the current Job ID matches the value of the parameter. Otherwise, False.

Level

All.

Details

Example

```
IsMatchingJobID("Main")
```

Parent topic: [Validations actions](#)

IsMaxOMRChecked

Indicates the maximum number of check boxes that can contain a value, such as a check.

Syntax

```
bool IsMaxOMRChecked (StrParam)
```

Parameters

An Integer value specifying this maximum. Smart parameters are supported.

Returns

False if the parameter you enter is not numeric, or the field is not an OMR field.

True if the number of OMR boxes checked is less than or equal to the parameter value that you entered.

Level

Field level.

Details

Example

```
IsMaxOMRChecked("1")
```

Parent topic: [Validations actions](#)

Related reference:

[IsMinOMRChecked](#)

IsMinOMRChecked

Indicates the minimum number of check boxes that can contain a value, such as a check.

Syntax

```
bool IsMinOMRChecked (StrParam)
```

Parameters

An Integer value specifying this minimum. Smart parameters are supported.

Returns

False if the parameter you enter is not numeric, or the field is not an OMR field.

True if the number of OMR boxes checked is greater than or equal to the parameter value that you entered.

Level

Field level.

Details

Example

```
IsMinOMRChecked("1")
```

Parent topic: [Validations actions](#)

Related reference:

IsPatternInField

Checks that the value of the current field contains the specified VBScript regular expression.

Syntax

```
bool IsPatternInField (StrParam)
```

Parameters

String value of the Regular Expression. The expression can include any Regular Expression characters. Smart parameters are supported.

Returns

True, if the pattern is found within the field. Otherwise, False.

Level

All, but generally at the Field level.

Details

Uses VBScript Regular Expression Pattern entered as parameter to search for a matching pattern in the Text value of the current object.

Attention: If you are using an input boundary, ^, it must be followed by a space and then the remainder of the search string.

Example

```
IsPatternInField("[\^\b\s\n\r]*Inv[oO][iItl1]ce[\b\s]*")  
IsPatternInField("@STRING([\^\b\s\n\r]*Inv[oO][iItl1]ce[\b\s]*")
```

This example searches for the word “Invoice” in the current field. To allow for recognition errors, the search allows for common recognition substitutions in “o” and “i” by matching “Invoice”, “InvOice”, “InvOice”, “Inv01ce”, “Involce”, and so on. The search also ignores any text that is placed before or after the word. Encapsulating the parameter with @STRING is recommended when the value is not a Smart Parameter.

Parent topic: [Validations actions](#)

IsSupportedImageFile

Checks that the image file attached to the current page is in a supported image format.

Syntax

```
bool IsSupportedImageFile (StrParamInput)
```

Parameters

A Boolean that determines the type of test to perform.

True: Tests the validity of the image by checking the file extension and attempting to load the image.

False: Only a file extension check is performed to determine if it is a supported file.

Returns

True if parameter is valid, the action is called at the page level and the page's *IMAGEFILE* variable (set at scan time by the scan tasks) points to a file whose format is supported (can be displayed) by the Image view control. Otherwise False.

Level

Page level.

Details

This action tests a file to determine if the file format is supported. The extension is checked to determine if it denotes a supported image type. If True is passed as a parameter, it also attempts to load the file into the Image view control.

Using False as a parameter improves the speed of this action. A parameter of True slows down the processing, especially if the images are very large, but it adds an extra confirmation that the file is not corrupted and confirm that any subformat of the file type, such as compression type, is also supported.

Example

```
IsSupportedImageFile ()
```

Parent topic: [Validations actions](#)

IsThisFieldEmpty

Checks that the value of the current field is empty.

Syntax

```
bool IsThisFieldEmpty ()
```

Parameters

None.

Returns

False if not applied to the Field level, or if the current field has a text value. Otherwise, True.

Level

Field level.

Details

Confirms if the current field has no captured value.

Example

```
IsThisFieldEmpty()
```

Parent topic: [Validations actions](#)

Related reference:

[IsThisFieldFilled](#)

[IsFieldEmpty](#)

IsThisFieldFilled

Checks that the current field has a captured value.

Syntax

```
bool IsThisFieldFilled ()
```

Parameters

None.

Returns

False if not applied to the Field level, or if the current field has no text value. Otherwise, True.

Level

Field level.

Details

Confirms if the current field has a captured value.

Example

```
IsThisFieldFilled()
```

Parent topic: [Validations actions](#)

Related reference:

[IsThisFieldEmpty](#)

[IsFieldFilled](#)

IsVariableEmpty

Checks that the variable specified by the parameter does not contain a value.

Syntax

```
bool IsVariableEmpty (strParam)
```

Parameters

Name of the variable of the current object to be checked.

Returns

False if the parameter is invalid, or if the variable contains a value. Otherwise, True.

Level

All.

Details

This action only checks variables of the current object.

Example

```
IsVariableEmpty("TemplateID")
```

Parent topic: [Validations actions](#)

Related reference:

[IsVariableFilled](#)

IsVariableFilled

Checks that the variable specified by the parameter contains a value.

Syntax

```
bool IsVariableFilled (strParam)
```

Parameters

Name of the variable of the current object to be checked.

Returns

False if the parameter is invalid, or if the variable does not contain a value. Otherwise, True.

Level

All.

Details

This action only checks variables of the current object.

Example

```
IsVariableFilled("TemplateID")
```

Parent topic: [Validations actions](#)

Related reference:

[IsVariableEmpty](#)

ParseMultilineAddress

Splits the value of the current field at each comma and saves the substrings to the specified fields. Typically used for address fields.

Syntax

```
bool ParseMultilineAddress (strParam)
```

Parameters

Comma-separated Smart Parameter String values of the names of fields that hold the parsed data, in the following order:

Name, AddressLine1, AddressLine2, City, State, Zip code or postal code, Phone

Returns

False, if the parameters are invalid or parsing cannot take place. Otherwise, True.

Level

Field level.

Details

Parses a multiline US address Field object's captured value.

Comma-separated String values of the names of fields that hold the parsed data, in the following order: Name, AddressLine1, AddressLine2, City, State, Zip code or postal code, and Phone. The example assumes that fields are sibling fields of the calling object. For other relationships, review smart parameter syntax.

Expected Pattern:

- Phone Number (optional)
- Name
- Address Line One
- Address Line Two (optional)
- City, State, Zip code or postal code
- Phone Number (optional)

Note: Parsing logic assumes that State and Zip or postal code are on the same address line. Only one Phone number per address field is supported. The expected pattern shows the two optional positions for this value.

Example

```
ParseMultilineAddress ("VendorName,VenAddress1,VenAddress2,VenCity,VenState,VenZip,VenPhone")
```

Parent topic: [Validations actions](#)

ParseName

Splits the three word value of the current field and saves the substrings to the specified fields. Typically used for name fields, such as first name, middle name/initial, last name.

Syntax

```
bool ParseName (StrParam)
```

Parameters

Three comma separated parameters:

1. The name of the Last Name Field object.
2. The name of the First Name Field object.
3. The name of the Middle Name or Middle Initial Field object.

Returns

False if not placed at the Field level; if the current field contains no data; or if the parameters are invalid. Otherwise, True.

Level

Field level.

Details

Parses the captured values of a name Field object. Applied to a Name field, the action parses the Last, First, and Middle names into the fields specified by the parameter.

Example

```
ParseName ("LastName, FirstName, MidName")
```

Bound to a Name Field object which includes values for all three names, the action place the Last name into the LastName field, the First name into the FirstName field, and the Middle name (or middle initial) into the MiddleName field.

Parent topic: [Validations actions](#)

Related reference:

[ParseMultilineAddress](#)

ReplaceChars

Replaces a character or string of characters in the captured value of the current Field object with a String that you enter as one of the parameters.

Syntax

```
bool ReplaceChars (StrParam)
```

Parameters

1. The character or string of characters to be replaced; defaults to a space. Smart Parameter Enabled.
2. The characters of the replacement String. Smart Parameter Enabled.

3. The number of times replacement is to occur. The default is 1 and * replaces all instances.

Returns

Always True.

Level

Field level.

Details

Example

```
ReplaceChars(".", "/", "*")  
01.02.2005 becomes 01/02/2005
```

Parent topic: [Validations actions](#)

ReplaceValueAtPosition

Replaces the value at the specified position within the current field with a replacement string, or deletes the value.

Syntax

```
bool ReplaceValueAtPosition (StrParam)
```

Parameters

Two-part comma-separated value:

1. The position that contains the value to be replaced.
2. The replacement string; this parameter defaults to "" indicating a deletion.

Returns

True if the character replacement is successful. Otherwise, False.

Level

Field level.

Details

Example

```
ReplaceValueAtPosition("3, /")
```

Parent topic: [Validations actions](#)

ResetField

Deletes the value of the current field and sets the Position attribute of the field to 0,0,0,0.

Syntax

```
bool ResetField ()
```

Parameters

None.

Returns

False if not called on the field level. Otherwise, True.

Level

Field level.

Details

The action does not clear any Alt-Text values that are associated with the bound Field object. That is the responsibility of a ClearAltText action.

Example

```
ResetField()
```

This action typically belongs to a follow-up Validate rule that deals with a False response to an action such as IsDate() in the previous rule. If the value of the field is not a date (in this example), the ResetField action removes the value that is there.

This action example also sets the Position attribute of the field to 0,0,0,0.

Parent topic: [Validations actions](#)

SetIsOverrideable

Specifies if the user can or cannot override a validation that fails for the current object.

Syntax

```
bool SetIsOverrideable (StrParam)
```

Parameters

None.

Returns

Always True.

Level

All.

Details

Important: This status might prevent an operator from overriding validations on a field and then continuing to subsequent pages.

Example

```
SetIsOverrideable("False")  
IsFieldPercentNumeric("100")
```

In this sequence, if the captured value of the field is not 100% Numeric, an operator cannot override a Validation rule's subsequent rejection of the value.

Parent topic: [Validations actions](#)

SplitFieldValuePreserveEnd

Splits the captured value of a Field object at the first instance of the character specified as a parameter.

Syntax

```
bool SplitFieldValuePreserveEnd (strParam)
```

Parameters

String value of the separating character. Smart parameters are supported.

Returns

True if the separator character is found. Otherwise False.

Level

Field level.

Details

The action deletes all characters prior to the separating character, as well as the separation character. All text after the separating character remains.

Example

```
SplitFieldValuePreserveEnd("=")
```

If the value of the object is InvNumber=A1234, this action truncates it to A1234.

Parent topic: [Validations actions](#)

Related reference:

[SplitFieldValuePreserveStart](#)

SplitFieldValuePreserveStart

Splits the captured value of a Field object at the first instance of the character specified as a parameter.

Syntax

```
bool SplitFieldValuePreserveStart (strParam)
```

Parameters

String value of the separating character. Smart parameters are supported.

Returns

True if the separator character is found. Otherwise False.

Level

SplitFieldValuePreserveEndField level.

Details

The action deletes all characters to the end of the string starting from the separating character, as well as the separation character. All text prior to the separating character remains.

Example

```
SplitFieldValuePreserveStart("c")
```

If the value of the object is Description, this action truncates it to Des.

Parent topic: [Validations actions](#)

Related reference:

[SplitFieldValuePreserveEnd](#)

SumFields

Adds the values of all child fields of the specified type and assigns the result to the current field. You can also use this action to sum the values of the specified variable for all child objects.

Syntax

```
bool SumFields (StrParam)
```

Parameters

String value of a Field object's Type property or the name of a variable.

Returns

Always True.

Level

All.

Details

Sums captured values of any child Field if a child object's Type property is identical to the Type you specify as a parameter. Alternatively, the actions sums values assigned to a variable of the child Field objects. In this case, the variable is the same as the variable entered as a parameter.

Remember: This action must be applied to the parent object.

Example

```
SumFields("Detail")
```

```
SumFields("LineTotal")
```

The first action in the example sums the captured values of Detail Field objects that are children of the current Field object.

The second action in the example sums values assigned to the *LineTotal* variable of child Field objects.

In both cases, the result is a Long number.

Parent topic: [Validations actions](#)

TimeStampField

Updates the current Field object with the current time.

Syntax

```
bool TimeStampField (StrParam)
```

Parameters

A time format, for example, HH:MM:SS, or HH:MM.

* defaults to HH:MM:SS. Smart parameters are supported.

Returns

Always True.

Level

Field level.

Details

Example

```
TimeStampField("*") produces  
09:20:02
```

```
TimeStampField("HH:MM") produces  
09:20
```

Parent topic: [Validations actions](#)

Related reference:

TrimSpaces

Deletes extra spaces at the beginning and end of the captured value of the current Field object.

Syntax

```
bool TrimSpaces ()
```

Parameters

None.

Returns

Always RightTruncate.

Level

Field level.

Details

Example

```
TrimSpaces ()  
456.11_ _ _ _ becomes 456.11
```

Parent topic: [Validations actions](#)

Related reference:

[RightTruncate \(deprecated\)](#)

TruncateFromEnd

Deletes characters from the end of the captured value of the current Field object until the length of the value equals the length indicated by the parameter.

Syntax

```
bool TruncateFromEnd (StrParam)
```

Parameters

A Number n that is the maximum length of the value. Smart parameters are supported.

Returns

False if the parameter is not Numeric. Otherwise, True.

Level

Field level.

Details

This action deletes characters from the end of the captured value of the current Field object until the length of the value equals the length indicated by the parameter.

Example

```
TruncateFromEnd("6")  
EU0002240 becomes EU0002
```

Parent topic: [Validations actions](#)

Related reference:

[TruncateFromStart](#)

[IsFieldLengthMax](#)

TruncateFromStart

Deletes characters from the start of the captured value of the current Field object until the length of the value equals the length specified by the parameter.

Syntax

```
bool TruncateFromStart (StrParam)
```

Parameters

A number n that is the maximum length of the value. Smart parameters are supported.

Returns

Always True.

Level

Field level.

Details

This action deletes characters from the start of the captured value of the current Field object until the length of the value equals the length specified by the parameter.

Example

```
TruncateFromStart("6") reduces the following value:  
3,344.01 becomes 344.01
```

Parent topic: [Validations actions](#)

Related reference:

[TruncateFromEnd](#)

Vote actions

Use the Vote action when you do multi-pass data entry to check whether the first and second passes match.

The Vote action returns True if the data entered for by the first operator matches the data that is entered by the second operator.

- [VoteFld](#)
Checks to see whether the data entered by the first Data Entry operator matches the data that is entered by the second Data Entry operator.

Parent topic: [Global actions](#)

VoteFld

Checks to see whether the data entered by the first Data Entry operator matches the data that is entered by the second Data Entry operator.

Syntax

```
bool VoteFld ()
```

Parameters

None.

Returns

False, if the values do not match. Otherwise, True.

Level

Field level.

Details

Checks to see whether the data entered by the first Data Entry operator matches the data entered by the second Data Entry operator.

Failed (mismatched) values set the confidence for the entire string to '1', which flags the field as Low Confidence. Positive matches set the entire strings confidence to '9' (High Confidence).

This action needs to run after the second Data Entry task is complete.

This action is used for workflows by using third pass data entry.

Example

```
VoteFld()
```

Parent topic: [Vote actions](#)

Vscan actions

Use the Vscan actions to create a batch by using existing image files.

Important: If any concurrently running threads might be using the same source directory, your Vscan-related tasks cannot be run in a multi-threaded configuration. Instead, use single-threaded tasks only. For information about configuring threads in Rulerunner, see [Rulerunner thread configuration](#). For information about the source directory, see [SetSourceDirectory](#).

The Vscan actions determine which documents are included in the batch and how to handle these documents as part of the scan task.

- [AddDocument](#)
Adds a document node to the runtime hierarchy. All scanned pages become children of the document node.
- [CopyFile](#)
When used before the Scan action, this action tells the Scan action to also copy the files to the specified location.
- [DeleteImageFile](#)
When used before the Scan action, this action tells the Scan action to delete the source files from the images folder.
- [MoveImageFileToDirectory](#)
When used before the Scan action, this action tells the Scan action to move the files from the images folder to the specified location.
- [Scan](#)
Copies image files from the location that is specified by the SetSourceDirectory action to the batch folder and creates the runtime hierarchy.
- [SearchInSubdirectory](#)
When used before the Scan action, this action tells the Scan action to look in subdirectories of the images folder.
- [SetAlternateImageNames](#)
Sets the file naming scheme of the Scan action.
- [SetFastMode](#)
Increases speed by preventing the Scan action from opening the files it is scanning. This action is provided only for compatibility with older applications, it is no longer used.
- [SetImageType](#)
Specifies the extensions of image file types to use, defaults to .tif.
- [SetMaxImageFiles](#)
Limits the number of files the Scan action copies.
- [SetMultiPageTiff](#)
When used before the Scan action, this action tells the Scan action to split multipage TIFF files into single page TIFF files.
- [SetSortOrder](#)
Specifies the order in which image files are imported.
- [SetSourceDirectory](#)
Specifies the path to the images folder. This action must precede the Scan action.

Parent topic: [Global actions](#)

AddDocument

Adds a document node to the runtime hierarchy. All scanned pages become children of the document node.

Syntax

```
bool AddDocument ()
```

Parameters

None.

Returns

False if this action is invoked or called at the wrong level or if the setup DCO does not contain any document structure. In this case, the action will not add a document. Otherwise, True.

Level

Batch level.

Details

Places all scanned pages into a single, batch-wide document. This action must be called before the Scan action.

The action also adds ED (Expected Documents), AD (Actual Documents), EP (Expected Pages) and AP (Actual Pages) properties to the Page file (.xml) of a task.

This action allows a VScan task to create a batch that has all the same characteristics of a batch that is created using a standard scan task. It is not required to call this action. Use this action if your application relies on a document structure on import.

This action must precede the Scan action. If AddDocument is used and the Scan action is never subsequently called, the action will not be performed.

Example

```
AddDocument ()
SetSortOrder ("Name,ASC")
SetMaxImageFiles ("100")
Scan ()
```

Parent topic: [Vscan actions](#)

CopyFile

When used before the Scan action, this action tells the Scan action to also copy the files to the specified location.

Syntax

```
bool CopyFile (StrParamSP)
```

Parameters

1. The String value of the name of the target file system folder.
2. Optional. The file extension you wish to use for each file. If you provide an extension, it must not be preceded by a period. The action defaults to .tif if this parameter is blank.

Smart parameters are supported.

Returns

Always True. If the target directory does not exist or if the files cannot be created, the files are not copied but the action still returns True.

Level

Any level but usually the batch level.

Details

A housekeeping action that copies the current source image file to a location that you specify and specifies the copied file's extension.

The source image file will remain in the input directory while a copy is placed into the specified directory. This action is typically used when it is desired to place images into a specific location for archiving. A copy of the image will still be placed into the batch directory as well.

If the target directory already contains a file of the same name, it will give a unique name to the new file.

This action must precede the Scan action. The CopyFile sets an indicator for the Scan action to copy the file. If CopyFile is used and the Scan action is never subsequently called, the copy will not be performed. The destination directory must already exist or a message will be logged and no files will be copied.

Example

```
CopyFile("C:\ParentDirectory\Application\Images\copies,tif")
Scan()
```

This example copies the source image file to the copies folder and then adds it to the batch. It does not delete the image from the source folder.

```
CopyFile("@APPPATH(vscancopydir),tif")
Scan()
```

This variant example copies the source image file to the copies folder that was specified in the application service.

Parent topic: [Vscan actions](#)

Related reference:

[Scan](#)

DeleteImageFile

When used before the Scan action, this action tells the Scan action to delete the source files from the images folder.

Syntax

```
bool DeleteImageFile ()
```

Parameters

None.

Returns

Always True.

Level

Any level but usually the batch level.

Details

A housekeeping action that deletes the current source image file. A Scan action must follow this action, which will perform the delete during the vscan process. If Scan is never called, the files are not deleted.

Example

```
DeleteImageFile ()  
Scan ()
```

This sequence deletes the image files from their current location after they were added to the current batch folder.

Parent topic: [Vscan actions](#)

MoveImageFileToDirectory

When used before the Scan action, this action tells the Scan action to move the files from the images folder to the specified location.

Syntax

```
bool MoveImageFileToDirectory (SmartParam)
```

Parameters

The full path to the target location of the Image file. Smart parameters are supported.

Returns

False if the parameter is not a valid directory, or if permission to access/write to the directory is denied. Otherwise, True.

If the file cannot be written to the destination directory, the batch status will be set to abort.

Level

Any level but usually the batch level.

Details

A housekeeping action that moves the current Image file to a location you specify. The source image file will be removed from the input directory and moved to the specified directory. This action is typically used when it is desired to place images into a specific location for archiving. A copy of the image will still be placed into the batch directory.

If the target directory already contains a file of the same name, it will give a unique name to the new file.

This action must precede the Scan action. If MoveImageFileToDirectory is used and the Scan action is never subsequently called, the file move will not be performed. If the move to the new directory fails, the batch will be set to abort.

Example

```
MoveImageFiletoDirectory("C:\ParentDirectory\Application\backup")
SetMaxImageFiles("100")
Scan()
```

This sequence copies the source image files to the current batch, then moves the Image files to the specified directory.

```
MoveImageFiletoDirectory("@APPPATH(vscanmovedir)")
Scan()
```

This variant example uses a smart parameter to obtain the directory path from the application service.

Parent topic: [Vscan actions](#)

Scan

Copies image files from the location that is specified by the SetSourceDirectory action to the batch folder and creates the runtime hierarchy.

Syntax

```
bool Scan ()
```

Parameters

None.

Returns

False if a SetSourceDirectory action does not precede this action. False is also be returned if fast mode is enabled and SetMultiPageTiff was called. Otherwise, True.

Level

Batch level.

Details

Scans a set of waiting Image files, according to the parameters set by earlier actions.

This is usually the last action in a vScan rule.

Example

```
SetImageType(".tif")
SetSourceDirectory("@APPPATH(vscanimagedir)")
SetMaxImageFiles("100")
Scan()
```

These are the elements of a sample vScan Rule. The Scan action will load the specified number of images (if available) from the specified folder into the current batch folder.

Parent topic: [Vscan actions](#)

SearchInSubdirectory

When used before the Scan action, this action tells the Scan action to look in subdirectories of the images folder.

Syntax

```
bool SearchInSubdirectory ()
```

Parameters

None.

Returns

Always True.

Level

Any level but usually the batch level.

Details

Looks for source files in sub-directories of the directory you designated with a SetSourceDirectory action. For this action to take effect, it must be called before the Scan action.

Example

```
SetSourceDirectory ("@APPPATH (vscanimagedir) ")  
SearchInSubdirectory ()
```

In this example, if the scan directory obtained from the application service includes sub-directories, this action directs the Scan action to process the contents of the sub-directories.

Parent topic: [Vscan actions](#)

Related reference:

[SetSourceDirectory](#)

SetAlternateImageNames

Sets the file naming scheme of the Scan action.

Syntax

```
()
```

Parameters

0: Sets the naming scheme of the input files to the format used by eDocument Conversion actions.

Any other input value uses the traditional naming scheme of TM000001, TM000002, etc.

Returns

Always True.

Level

Any level but usually the batch level.

Details

If you are using the Convert action library, it is recommended that you enable this batch file naming scheme.

If this action is not called prior to the Scan action, then the Scan uses the traditional naming scheme of TM000001, TM000002, etc.

Example

```
SetAlternateImageNames ("0")  
Scan ()
```

Parent topic: [Vscan actions](#)

Related reference:

[Scan](#)

SetFastMode

Increases speed by preventing the Scan action from opening the files it is scanning. This action is provided only for compatibility with older applications, it is no longer used.

Syntax

```
bool SetFastMode ()
```

Parameters

None.

Returns

Always True.

Level

Any level but usually the batch level.

Details

This action prevents the testing that the TIF files are valid and avoid conversion of TIF files to G4 compression for processing. Calling this action will allow TIF files that are not compatible with Datacap to be placed into a batch.

This action is provided as backwards compatibility to older applications where this action was required to properly enable fast mode for PDF files.

SetImageType will automatically enable fast mode, if it is called with a extension other than TIF or JPG. For this action to take effect, it must be called before the Scan action.

Example

```
SetImageType (.pdf)
SetFastMode ()
Scan ()
```

Parent topic: [Vscan actions](#)

SetImageType

Specifies the extensions of image file types to use, defaults to .tif.

Syntax

```
bool SetImageType (StrParam)
```

Parameters

String value of the file's identifying extension. If you are listing multiple types, separate each one with a comma.

It is not necessary to include a period before each extension. The parameters are not case-sensitive.

Returns

True, if the parameter is one of the values that is specified above. Otherwise, False.

Level

Any level but usually the batch level.

Details

Uses the value of a file extension to specify the type of files the task scans.

This is an optional vScan action. The task scans .tif files by default. For this action to take effect, it must be called before the Scan action.

This action automatically enables Fast Mode scanning, if the input parameter is not a single extension of type .tiff, .tif, .jpeg, or.jpg.

Example

```
SetImageType (.tif)
Scan ()
```

This sequence scans only TIF files and does not enable Fast Mode.

```
SetImageType ("tiff")
Scan ()
```

This sequence scans only TIFF files and does not enable Fast Mode.

```
SetImageType ("bmp, jpg, jpeg, msg, tif, tiff, pdf, zip, doc, docx, xls, xlsx, eml, gif")  
Scan()
```

This sequence scans all file types listed and enables Fast Mode.

Parent topic: [Vscan actions](#)

SetMaxImageFiles

Limits the number of files the Scan action copies.

Syntax

```
bool SetMaxImageFiles (StrParam)
```

Parameters

An optional string value specifying the maximum number of files.

If you do not enter a value, the task will scan all images in the target folder (up to 32767 files) and this action returns True.

Returns

False if the parameter is not Numeric. Otherwise, True.

Level

Any level but usually the batch level.

Details

Limits the number of Image files the vScan task will add to a single batch. This action must be placed before the Scan action for the setting to take effect during Scan.

Example

```
SetMaxImageFiles ("50")  
Scan()
```

Sets the maximum number of files to add to a batch at fifty.

Remember: A vScan task is a Batch Creation task: it sets up a new batch each time it scans Image files.

Parent topic: [Vscan actions](#)

SetMultiPageTiff

When used before the Scan action, this action tells the Scan action to split multipage TIFF files into single page TIFF files.

Syntax

```
bool SetMultiPageTiff ()
```

Parameters

None.

Returns

Always True.

Level

Any level but usually the batch level.

Details

Permits the use of multipage source image files. For this action to take effect, it must be called before the Scan action.

This action cannot be used if fast mode is enabled. It also requires that SetImageType be called with only one extension of TIF, TIFF, JPG or JPEG. If this action is used when fast mode is enabled, the Scan action returns False.

Example

```
SetImageType(".tif")
SetMultiPageTiff()
Scan()
```

If the Scan action in this sequence encounters a multipage .tif file, then it reads each one into the current batch as a separate image, thereby bursting the multipage file into individual images.

Parent topic: [Vscan actions](#)

SetSortOrder

Specifies the order in which image files are imported.

Syntax

```
bool SetSortOrder (strParam)
```

Parameters

Two comma-separated String values:

Parameter 1. Designation of the images' sorting field can be specified with text or numerically:

- 1 or Name : The input file name.
- 2 or Type : The file type.
- 3 or DateCreated : The File creation date.
- 4 or DateLastAccessed : The last file access date.
- 5 or DateLastModified : The last file modification date.
- 6 or Size : The file size.

Parameter 2. Optional: ASC or 1 (Ascending), DESC or 2 (Descending). If you do not include this parameter, the action defaults to ASC (1).

Returns

False if the parameters are not valid. Otherwise, True.

Level

Any level but usually the batch level.

Details

Sets the order in which Image files will be imported to the batch. The input files can be sorted by their file name, file type, date created, date accessed, date modified or file size. Using the optional second parameter, you can control if the values are sorted in ascending or descending order.

For this action to take effect, it must be called before the Scan action.

Example

```
SetSortOrder ("Name, ASC")
Scan ()
```

Parent topic: [Vscan actions](#)

SetSourceDirectory

Specifies the path to the images folder. This action must precede the Scan action.

Syntax

```
bool SetSourceDirectory (SmartParam)
```

Parameters

String value of the directory's name and path. Instead, you can use a Smart Parameter, such as @APPPATH, to establish the name and path of the Source Directory.

Returns

False, if the parameter is blank or the directory does not exist. Otherwise, True.

If the source directory does not exist, the batch status is set to abort.

Level

Any level but usually the batch level.

Details

This action indicates the name and path of the directory that contains the Image files to be scanned.

This is a required action. A task that employs a vScan rule cannot process images unless it has this key locator. This action must be called before the scan action.

Example

In the following example, the full path to the images directory is coded directly into the application rules.

```
SetSourceDirectory("c:\ParentDirectory\Application\Images")
```

In the following example, @APPPATH obtains the vscan directory from the application service. This makes the application more flexible because the same application that is installed in two different environments, such as test and production, can use two different input directories. The subdirectory Input is appended to the path.

```
SetSourceDirectory("@APPPATH(vscanimagedir)+\+Input")
```

Parent topic: [Vscan actions](#)

Web Services actions

This library of actions facilitates communication with external web services. You can use these actions to retrieve formatted responses or image files. The actions can handle both XML and JSON formatted responses, with XML as the default choice. You will need to know the web service's endpoint, any applicable parameters, and the response type before using these actions.

The Web Services library includes actions to set the url, execute connection requests, download and upload files, and set header and parameter values.

- [WsClearHeaders](#)
Clear all the previously set web service headers.
- [WsClearParameters](#)
Clear all of the previously set web service parameters. Call this action if you need to send a new set of parameters for your next call to any web service.
- [WsClearResultItems](#)
Clear all key-value pairs associating the result keys and previously set target DCO variables. Call this action if you need to send a new set of result items for your next call to any web service.
- [WsEncodeParameter](#)
Set a parameter to a specific encoding as required by the web service endpoint.
- [WsGetFile](#)
Downloads a file from a web service using the provided file name.
- [WsGetValues](#)
The WsGetValues action returns one or more values from a web service.
- [WsSetCredentials](#)
Associates credentials that you send with web service calls for authentication.
- [WsSetHeader](#)
Specify any header information about the response content.
- [WsSetNamespace](#)
Specify the namespace associated with the web service response.
- [WsSetParameter](#)
Set the parameters required by the web service endpoint.
- [WsSetResultItem](#)
This action will associate the keys(xpath or tags) to the values from the response to the DCO objects to which you want to assign them. If the source already exists its corresponding target will be replaced with the new target value.

- [WsSetTimeout](#)
The timeout value specified with this action will be used for all subsequent requests to web services.
- [WsUploadData](#)
Upload data to a Webservice endpoint using a POST request.
- [WsUploadFile](#)
Uploads a file to a web service.

Parent topic: [Global actions](#)

WsClearHeaders

Clear all the previously set web service headers.

Syntax

```
bool WsClearHeaders ()
```

Parameters

None.

Returns:

True, if the action succeeds. Otherwise, **False**.

Level

All levels.

Details

Call this action if you need to send a new set of headers for your next call to any web service.

Example

```
WsClearHeaders ()
```

Parent topic: [Web Services actions](#)

WsClearParameters

Clear all of the previously set web service parameters. Call this action if you need to send a new set of parameters for your next call to any web service.

Syntax

```
bool WsClearParameters ()
```

Parameters

None.

Returns:

True, if the action succeeds. Otherwise, **False**.

Level

All levels.

Example

```
WsSetParameter("FromCurrency", "USD", false)
WsSetParameter("ToCurrency", @APPVAR(values/gen/ToCurrency), false)
WsSetResultItem("double", "@B.ConversionRate")
WsGetvalues(@APPVAR(values/gen/CurrencyConvertor), "", "", "", "", "")
WsClearParameters()
WsClearResultItems()
WsSetParameter("address", "10 Downing Street, London", false)
WsSetParameter("sensor", "false", false)
WsSetResultItem("GeocodeResponse/result/geometry/location/lat",
"@B.Latitude")
WsSetResultItem("GeocodeResponse/result/geometry/location/lng",
"@B.Longitude")
WsGetvalues("http://maps.googleapis.com/maps/api/geocode/xml?", "", "", "",
"", "")
```

Parent topic: [Web Services actions](#)

WsClearResultItems

Clear all key-value pairs associating the result keys and previously set target DCO variables. Call this action if you need to send a new set of result items for your next call to any web service.

Syntax

```
bool WsClearResultItems ()
```

Parameters

None.

Returns:

True, if the action succeeds. Otherwise, **False**.

Level

All levels.

Example

```
WsSetParameter("FromCurrency", "USD", false)
WsSetParameter("ToCurrency", "GBP", false)
WsSetResultItem("double", "@B.ConversionRate")
```

```
WsGetvalues("http://www.websvcicex.net/CurrencyConvertor.asmx/ConversionRate?", "",
"", "", "", "")
    WsClearParameters()
    WsClearResultItems()
    WsSetParameter("address", "10 Downing Street, London", false)
    WsSetParameter("sensor", "false", false)
    WsSetResultItem("GeocodeResponse/result/geometry/location/lat",
"@B.Latitude")
    WsSetResultItem("GeocodeResponse/result/geometry/location/lng",
"@B.Longitude")
    WsGetvalues("http://maps.googleapis.com/maps/api/geocode/xml?", "", "", "",
"", "")
```

Parent topic: [Web Services actions](#)

WsEncodeParameter

Set a parameter to a specific encoding as required by the web service endpoint.

Syntax

```
bool WsEncodeParameter (string name, string encoding)
```

Parameters

name

The name of the parameter to be encoded.

encoding

The type of encoding to apply. URI or DATA types are supported.

Returns:

Always **True**.

Level

All levels.

Details

Call this action if you need to encode a parameter value for a call to any web service.

Example

```
WsSetParameter("CountryName", "United States", false)

WsSetParameter("CityName", "Newark", false)

WsEncodeParameter("CountryName", "data")

WsGetvalues("http://www.websvcicex.net/globalweather.asmx/GetWeather?", "",
"", "", "@B.htmltext", "")
```

Parent topic: [Web Services actions](#)

WsGetFile

Downloads a file from a web service using the provided file name.

Syntax

```
bool WsGetFile (string url, string filename, int timeout)
```

Parameters

url

Required: the URL of the web service. Smart parameters are supported.

filename

Required: the name to use for the downloaded file. Smart parameters are supported.

timeout

Optional: the timeout value in milliseconds before abandoning the request.

Returns:

True, if the action succeeds. Otherwise, **False**.

Level

All levels.

Details

Smart parameters are supported for all parameters. The timeout value specified for this operation will override any timeout value set elsewhere. The default timeout value is 60000 milliseconds, or one minute.

Example

```
WsGetfile("http://maps.googleapis.com/maps/api/staticmap?center=Costa  
Mesa,CA&zoom=14&size=400x400&sensor=false", "C:\Test\CMmap.png", 120000)
```

Parent topic: [Web Services actions](#)

WsGetValues

The WsGetValues action returns one or more values from a web service.

Syntax

```
bool WsGetValues (string url, string nsprefix, string nsuri, string source, string  
target, string format, string savefile)
```

Parameters

url

Required: the URL of the web service.

nsprefix

Optional: the prefix of the Namespace if you are using tags to obtain results.

nsuri

Optional: the Namespace URI. If a namespace has already been set, you do not need to set the URI.

source

Optional: the xpath or tag to obtain the value. The xpath/tag and target are set separately.

target

Optional: the target DCO. You can set the xpath/tag and target separately, and if no path is set then the entire result set is saved to the target.

format

Optional: the return format type. The default is XML.

savefile

Optional: save the response results to this file for reference.

Returns:

True, if the action succeeds. Otherwise, **False**.

Level

All levels.

Details

The value for the URL should include the end point. This is the only required value if the parameters and target values are set before calling the action.

Smart parameters are supported.

Example

Example 1 uses xpath with a namespace to obtain information from the web service:

```
WsGetvalues("http://api.worldbank.org/countries?format=xml", "wb",  
"http://www.worldbank.org", "//wb:countries/wb:country[5]/wb:name", "@B.Country",  
"", "C:\myfolder\myfile.xml")
```

Example 2 uses tag value to obtain the information:

```
WsGetvalues("http://www.webservices.net/CurrencyConvertor.asmx/ConversionRate?  
FromCurrency=USD&ToCurrency=GBP", "", "", "double", "@B.ConversionRate", "", "")
```

Example 3 shows the syntax for JSON:

```
WsSetParameter("symbols", "USD", true)  
    WsSetParameter("symbols", "GBP", true)  
    WsGetvalues("http://api.fixer.io/latest?", "", "", "", "", "JSON",  
"@PILOT(BATCHDIR)+/rates+.json")
```

Parent topic: [Web Services actions](#)

WsSetCredentials

Associates credentials that you send with web service calls for authentication.

Syntax

```
bool WsSetCredentials (string username, string password)
```

Parameters

username

The credential user name. Smart parameters are supported.

password

The credential password. Smart parameters are supported.

Returns:

True, if the action succeeds. Otherwise, **False**.

Level

All levels.

Details

Use this action with the [WsUploadData](#) or [WsUploadFile](#) actions.

Example

```
WsSetCredentials ("abcdef", "xyz123")
```

Parent topic: [Web Services actions](#)

WsSetHeader

Specify any header information about the response content.

Syntax

```
bool WsSetHeader (string name, string value, bool add)
```

Parameters

name

The name of the header. Smart parameters are supported.

value

The value for the specified header. Smart parameters are supported.

add

If the specified header already exists, then set this parameter to TRUE for the new value to be added to the existing value. If you set this parameter to FALSE, then the existing value will be replaced by the new value.

Returns:

True, if the action succeeds. Otherwise, **False**.

Level

All levels.

Example

```
WsSetHeader("Content-Type", "text/xml", true)
```

Parent topic: [Web Services actions](#)

WsSetNamespace

Specify the namespace associated with the web service response.

Syntax

```
bool WsSetNamespace (string prefix, string uri)
```

Parameters

prefix

The prefix for the namespace. Smart parameters are supported.

uri

The URI of the namespace. Smart parameters are supported.

Returns:

True, if the action succeeds. Otherwise, **False**.

Level

All levels.

Example

```
WsSetNamespace ("wb", "http://www.worldbank.org")  
WsGetvalues ("http://api.worldbank.org/countries?format=xml", "wb", "",  
"/wb:countries/wb:country[5]/wb:name", "@B.Country", "")
```

Parent topic: [Web Services actions](#)

WsSetParameter

Set the parameters required by the web service endpoint.

Syntax

```
bool WsSetParameter (string name, string value, bool add)
```

Parameters

name

The name of the parameter. Smart parameters are supported.

value

The value for the parameter. Smart parameters are supported.

add

If the specified parameter already exists, then set this parameter to **TRUE** for the new value to be added to the existing value. If you set the parameter to **FALSE**, then the existing value will be replaced by the new value.

Returns:

True, if the action succeeds. Otherwise, **False**.

Level

All levels.

Example

```
WsSetParameter("FromCurrency", "USD", false)
WsSetParameter("ToCurrency", "GBP", false)

WsGetvalues("http://www.websvc.net/CurrencyConvertor.asmx/ConversionRate", "",
"", "double", "@B.GBPConversionRate", "")
    WsSetParameter("ToCurrency", "EUR", false)

WsGetvalues("http://www.websvc.net/CurrencyConvertor.asmx/ConversionRate", "",
"", "double", "@B.EURConversionRate", "")
```

Parent topic: [Web Services actions](#)

WsSetResultItem

This action will associate the keys(xpath or tags) to the values from the response to the DCO objects to which you want to assign them. If the source already exists its corresponding target will be replaced with the new target value.

Syntax

```
bool WsSetResultItem (string source, string target)
```

Parameters

source

The xpath or tags to find the value in the result. Smart parameters are supported.

target

Destination item to assign the value.

Returns:

True, if the action succeeds. Otherwise, **False**.

Level

All levels.

Details

This action must be set before calling the response. Use this action if you want to get more than a single value from the response.

Example 1

```
WsSetParameter("FromCurrency", "USD", false)
    WsSetParameter("ToCurrency", "GBP", false)
    WsSetResultItem("double", "@B.ConversionRate")

WsGetvalues("http://www.webservices.net/CurrencyConvertor.asmx/ConversionRate?", "",
"", "", "", "")
```

Example 2

```
WsSetResultItem("@STRING(rates.USD)", "@B.EUR2USD")
    WsSetResultItem("@STRING(rates.GBP)", "@B.EUR2GBP")
    WsGetvalues("http://api.fixer.io/latest?", "", "", "", "", "JSON", "")
```

Parent topic: [Web Services actions](#)

WsSetTimeout

The timeout value specified with this action will be used for all subsequent requests to web services.

Syntax

```
bool WsSetTimeout (int timeout)
```

Parameters

timeout
Timeout value in milliseconds.

Returns:

True, if the action succeeds. Otherwise, **False**.

Level

All levels.

Details

If no timeout value is specified, the default value of 60000 (60 seconds) is used.

Example

```
WsSetTimeout(120000)
```

Parent topic: [Web Services actions](#)

WsUploadData

Upload data to a Webservice endpoint using a POST request.

Syntax

```
bool WsUploadData (string url, string uploadData, string sessionkeys, string format, string responsefile)
```

Parameters

url

Required: the URL of the web service.

uploadData

Required: the data to upload.

sessionkeys

Optional: comma-separated list of session key names.

format

Optional: return format type. The default is xml.

responsefile

Optional: save the response results to this file for later use.

Returns:

True, if the action succeeds. Otherwise, **False**.

Level

All levels.

Details

Smart parameters are supported for all parameters.

Example

The example shows how to use wTM endpoints to log on and create a batch:

```
WsSetHeader("@STRING(Content-Type)", "@STRING(application/xml)", false)
WsUploadData("http://localhost:8010/ServicewTM.svc/Session/Logon",
  "Demo901adminladmin", "", "xml", "C:\myfolder\logon.xml")
WsUploadData("http://localhost:8010/ServicewTM.svc/Queue/CreateBatch",
  "Demo901Demo_SingleTIFFs", "Set-Cookie", "", "C:\myfolder\createbatch.xml")
```

Parent topic: [Web Services actions](#)

WsUploadFile

Uploads a file to a web service.

Syntax

```
bool WsUploadFile (string url, string filename, string method, int timeout)
```

Parameters

url

Required: the URI of the resource to receive the file. Smart parameters are supported.

filename

Required: the file to send to the resource. Smart parameters are supported.

method

Optional: the file upload method. By default, 'POST' is used for http and 'STOR' for ftp.

timeout

Optional: the timeout value in milliseconds before abandoning the request. Smart parameters are supported.

Returns:

True, if the action succeeds. Otherwise, **False**.

Level

All levels.

Details

The timeout value specified for this operation will override any timeout value set elsewhere. The default timeout value is 60000 milliseconds, or one minute. If no method is specified, the default is "POST" for http and "STOR" for ftp.

Example

```
WsUploadFile("http://server/service", "C:\Test\myfile.jpg", "", "120000")
```

Parent topic: [Web Services actions](#)

Zones actions

Use the Zones actions to work with the zones that define the position of each field on the page.

You can read zone information from a fingerprint (CCO) file, update the zone position information in the runtime hierarchy, and locate the recognition text for a specific zone. You can also assign values to fields in the runtime hierarchy, locate repeating data blocks, and more.

- [AdjustZonesToImageOffset](#)
Offsets fields on the current image in response to zone criteria in the CCO file of the source page - after the image has been offset.
- [AnchorPage](#)
Finds the Anchor field on a source page, and uses the Anchor field's coordinates to locate and offset the page's other zoned fields.
- [CalculateLocalOffset](#)
Calculates the X and/or Y offset amount for the calling field.
- [CreateBlockCCO](#)
Creates a temporary in memory CCO object, containing only the words and lines in the calling fields zone position - using the source page's CCO file.
- [FindBlocks_WhiteSpace](#)
Uses a vertical white space (pixels) to find blocks of data within the current source page. Returns each block's position assigned to a series of repeating fields based on the first child field of the calling object.

- [FindDataBlocks](#)
Uses Start and End key words to find blocks of data within the current source page.
- [FindRegExBlocks](#)
Uses a Regular Expression to find blocks of data within the current source page. Returns the position of each block that is assigned to a series of repeating fields based on the first child field of the calling object.
- [FindZoneLineItems](#)
Uses settings for zones to assemble a portion of the current page, limited to Line Item Detail.
- [GetZoneText](#)
Retrieves the text in a zoned object of the current page.
- [InheritParentPosition](#)
Provides the bound child object of the Document Hierarchy with the zone parameters of a parent object identified by the parameter.
- [LoadBlockCCO](#)
Loads the CCOBlock set up by a previous CreateBlockCCO action. That action assigns the block's location to the CCOBlock variable of the current Page object.
- [LoadZones](#)
Same as the ReadZones action, except that it loads position information for the specified fingerprint ID.
- [MCCOPositionAdjust](#)
Combines extra pages of a multi-page document into the CCO file for the first page.
- [MergeZones](#)
Merges the zone from calling field with zone of DCO fields passed as smart parameters.
- [PadZone](#)
Pads the zone by the value passed. Number of CSV passed values varies padding value by vector.
- [PopulateZNField](#)
Puts the recognition data from the CCO file that lies in the zone boundaries of the field into the current field in the page data file.
- [PopulateZNLineItemField](#)
Populates the page data file with the recognized value in the zone for the current line item child field. Assign this action to each line item child field in the document hierarchy.
- [ReadZones](#)
Loads the position information for the current object and its children from the document hierarchy (setup DCO). Adjusts the position of each object by using any Image_Offset value.
- [RegisterPage](#)
Locates specially marked fields and adjusts their vertical zone positions to compensate for any drift.
- [ScanDetails](#)
Searches a line item grid object for line items. You assign this action to the grid region in the document hierarchy.
- [ScanDetailsByLines](#)
Searches a line item grid object for line items, where each line item consists of the specified number of rows.
- [ScanDetailsByVSpace](#)
Searches a line item grid object for line items, where each line item is defined as the specified height in pixels.
- [ScanLineItem](#)
Searches a line item object for fields. You assign this action to each line item in the document hierarchy.
- [SetEOL](#)
Sets the End of Line character that will be used to separate data from a zone that contains multiple lines of text.
- [SetEOL_CRLF](#)
Sets the End Of Line character that are used to separate data from a zone with multiple lines of text.
- [ZoneBOTTOM_ImageBottom](#)
Uses the lower boundary of the current image to specify the bottom boundary of the zone position of the

- current field in the page data file.
- [ZoneBOTTOM_LowerBound](#)
Uses the lower boundary of the current word that is located by using the actions in the Locate library to specify the bottom boundary of the zone position of the current field in the page data file.
 - [ZoneBOTTOM_UpperBound](#)
Uses the upper boundary of the current word that is located by using the actions in the Locate library to specify the bottom boundary of the zone position of the current field in the page data file.
 - [ZoneImage_SaveAs](#)
Saves the current Objects Zone area of an image as a separate Image file.
 - [ZoneLEFT_ImageLeft](#)
Uses the left boundary of the current image to specify the left boundary of the zone position of the current field in the page data file.
 - [ZoneLEFT_LeftBound](#)
Uses the left boundary of the current image to specify the left boundary of the zone position of the current field in the page data file.
 - [ZoneLEFT_RightBound](#)
Uses the right boundary of the current image to specify the left boundary of the zone position of the current field in the page data file.
 - [ZoneRIGHT_ImageRight](#)
Uses the right boundary of the current image to specify the right boundary of the zone position of the current field in the page data file.
 - [ZoneRIGHT_LeftBound](#)
Uses the left boundary of the current word* to specify the right boundary of the zone position of the current field in the page data file.
 - [ZoneRIGHT_RightBound](#)
Uses the right boundary of the current word* to specify the right boundary of the zone position of the current field in the page data file.
 - [ZoneTOP_ImageTop](#)
Uses the top boundary of the current image to specify the top boundary of the zone position of the current field in the page data file.
 - [ZoneTOP_LowerBound](#)
Uses the lower boundary of the current word that is located by using the actions in the Locate library to specify the top boundary of zone position of the current field in the page data file.
 - [ZoneTOP_UpperBound](#)
Uses the upper boundary of the current word that is located by using the actions in the Locate library to specify the top boundary of the zone position of the current field in the page data file.

Parent topic: [Global actions](#)

AdjustZonesToImageOffset

Offsets fields on the current image in response to zone criteria in the CCO file of the source page - after the image has been offset.

Syntax

```
bool AdjustZonesToImageOffset ()
```

Parameters

None.

Returns

False if the action cannot locate the CCO file of the current page or an image offset value does not exist for the current page. Otherwise, True.

Level

Page level.

Details

Offsets fields on the current image in response to zone criteria in the CCO file of the source page - after the image has been offset.

Example

```
AdjustZonesToImageOffset ()
```

Parent topic: [Zones actions](#)

AnchorPage

Finds the Anchor field on a source page, and uses the Anchor field's coordinates to locate and offset the page's other zoned fields.

Syntax

```
bool AnchorPage ()
```

Parameters

None.

Returns

False if the action cannot find the Anchor field on the page. Otherwise, True.

Level

Page level.

Details

Finds the Anchor field on a source page, and uses the coordinates of the Anchor field to locate and offset the other zoned fields on the page.

Example

```
AnchorPage ()
```

Parent topic: [Zones actions](#)

CalculateLocalOffset

Calculates the X and/or Y offset amount for the calling field.

Syntax

```
bool CalculateLocalOffset (StrParam)
```

Parameters

X and/or Y

The action uses these parameters to calculate a new parent page Image_Offset value by comparing the fingerprint zone for the calling field against the current field zone.

Returns

Always True.

Level

Field only.

Details

Calculates the X and/or Y offset amount for the calling field.

Example

```
CalculateLocalOffset ("XY")
```

Parent topic: [Zones actions](#)

CreateBlockCCO

Creates a temporary in memory CCO object, containing only the words and lines in the calling fields zone position - using the source page's CCO file.

Syntax

```
bool CreateBlockCCO ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Useful when searching for images where the data is located asymmetrically across the page. Using this action focuses the CCO to only look at the words and lines within the defining zone in all future searches for this page.

This does not affect the run time CCO. Reloading the page reloads the CCO bound to the page, releasing this temporary CCO.

Example

```
CreateBlockCCO()
```

Parent topic: [Zones actions](#)

FindBlocks_WhiteSpace

Uses a vertical white space (pixels) to find blocks of data within the current source page. Returns each block's position assigned to a series of repeating fields based on the first child field of the calling object.

Syntax

```
bool FindBlocks_WhiteSpace (Strparam)
```

Parameters

A single parameter indicating the number of pixel between lines.

Returns

False if the action cannot divide or create any child field/zones. Otherwise, True.

Level

Field having 1 child field.

Details

Creates a child field with the position of each zone divided out of the CCO of the calling page.

Example

```
FindBlocks_WhiteSpace ("27")
```

Parent topic: [Zones actions](#)

FindDataBlocks

Uses Start and End key words to find blocks of data within the current source page.

Syntax

```
bool FindDataBlocks (Strparam)
```

Parameters

Key word Start Value, and its End Value.

Returns

True if the action can locate the Data block indicated by the parameter. Otherwise, False.

Level

Page level.

Details

Uses Start and End key words to find blocks of data within the current source page. Returns each block's position assigned to a series of repeating fields based on the first child field of the calling object. If the Fingerprint file (.cco) of the page has a Line position be sure to use action GoFirstLine() to set the Line position to the first word on the first line in the current zone.

Example

```
GoFirstLine ()  
FindDataBlocks ("FROM, THRU")
```

Parent topic: [Zones actions](#)

FindRegExBlocks

Uses a Regular Expression to find blocks of data within the current source page. Returns the position of each block that is assigned to a series of repeating fields based on the first child field of the calling object.

Syntax

```
bool FindRegExBlocks (Strparam)
```

Parameters

Regular Expression that contains the data block's Start Value, and its End Value. Parameter is a two part comma separated value of the Values to look for in the current CCO.

1. StartValue
2. EndValue

Start and End values can be adjusted up or down by xLines using the 3rd (adj top) and 4th (adj bottom) CSV positions.

Returns

True if the action can locate the Data block indicated by the parameter. Otherwise, False.

Level

Page level.

Details

Uses a Regular Expression to find blocks of data within the current source page.

Attention: Locate.rra is required for this action.

Example

```
FindRegExBlocks ("/bFROM/b, /bTHRU/b")
```

Parent topic: [Zones actions](#)

FindZoneLineItems

Uses settings for zones to assemble a portion of the current page, limited to Line Item Detail.

Syntax

```
bool FindZoneLineItems (string createSubfields, string createTempCCO, string subfieldFillType, string offsetPercent, string intersectionRatio)
```

Parameters

1. True or False
 - o True if the action is to create Line-item fields and their sub-fields.
 - o False if the action is to create Line-item fields only.
2. True or False (OPTIONAL: defaults to True)
 - o True if the action is to analyze both the calling zone and the word and line relationships based only on the zone contents that are found in the search.
 - o False if the action is to use the existing word and line relationships (CCO for image).
3. 1 or 2 (OPTIONAL: Fill Sub fields option - defaults to 1)
 - o 1 - fill by CCO word; if the CCO words overlap by a certain intersection value then fill sub field with its value. Also has sub setting of a colon followed by a group words value. For example, 1:1.5 treats words 1.5 character spaces apart or closer as one word.
 - o 2 - fill by CCO character; if the CCO characters overlap by a certain intersection value then fill sub field with the character value.
4. 0 to 100 (OPTIONAL: Percent offset adjustment - defaults to 0) - moderates the flexibility for the left offset based on the overall length of the line. Use larger values for shorter line items.
5. .01 to .99 (OPTIONAL: Intersection Ratio - defaults to .25) - changes the intersection ratio of Words and Lines used to determine creation and value of Lineitems and their subfields.

Returns

False if there is no zone or position information for the Line Item block and its subfields, or if the parent block does not contain Line Item children. Otherwise, True.

Level

Field having 1 child field.

Details

Uses settings for a previously-established zone covering a block of Line Item Detail, and zones for individual Line Items, to assemble a portion of the current page, limited to Line Item Detail.

Example

```
FindLineItems ("True", "", "", "", "")
```

This action retrieves zonal information from the fingerprint about a block of Line Item Detail, individual rows, and their fields and subfields. The action applies this data to the full-length current page. It creates a file with an extension of cco (fingerprint format file) containing just Line Item Detail for use during batch processing. This file can be discarded after batch processing has finished.

Parent topic: [Zones actions](#)

GetZoneText

Retrieves the text in a zoned object of the current page.

Syntax

```
bool GetZoneText ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Retrieves the text in a zoned object of the current page.

Example

```
GetZoneText ()
```

This action assumes that you have established zone parameters for this Field object of the Document Hierarchy.

Parent topic: [Zones actions](#)

InheritParentPosition

Provides the bound child object of the Document Hierarchy with the zone parameters of a parent object identified by the parameter.

Syntax

```
bool InheritParentPosition (StrParam)
```

Parameters

Case sensitive string value of the name of the parent object. Details, for example, is the name of a parent Field object in the Invoice application. If the bound object is LINEITEM, the action provides the zone parameters of

the parent to this child object.

Returns

False if the action cannot locate the parent field. Otherwise, True.

Level

Field level.

Details

Provides the bound child object (a subfield of another field) of the Document Hierarchy with the zone parameters of a parent object identified by the parameter.

Example

```
InheritParentPosition("Details")
```

Parent topic: [Zones actions](#)

LoadBlockCCO

Loads the CCOBlock set up by a previous CreateBlockCCO action. That action assigns the block's location to the CCOBlock variable of the current Page object.

Syntax

```
bool LoadBlockCCO ()
```

Parameters

None.

Returns

False if the block cannot be found. Otherwise, True.

Level

Page level.

Details

Loads the CCOBlock set up by a previous CreateBlockCCO action. That action assigns the block's location to the current Page object's CCOBlock variable.

Example

```
CreateBlockCCO ()  
LoadBlock ()
```

Parent topic: [Zones actions](#)

LoadZones

Same as the ReadZones action, except that it loads position information for the specified fingerprint ID.

Syntax

```
bool LoadZones (StrParam)
```

Parameters

Fingerprint ID.

Returns

Always True.

Level

Page or Field level.

Details

Loads position information for each node in the calling object and children. Pre-adjusts these values based on offset information stored in an *Image_Offset* variable at any node level.

Position information is based on the setup DCO position for the fingerprint ID passed as a parameter. The offset value is applied to all child objects of a node where an *Image_Offset* variable is found; unless overwritten by a child node also having an *Image_Offset* value to apply.

Parent topic: [Zones actions](#)

MCCOPositionAdjust

Combines extra pages of a multi-page document into the CCO file for the first page.

Syntax

```
bool MCCOPositionAdjust ()
```

Parameters

None.

Returns

False if the current document does not consist of more than one source page, or if a page to be merged did not have an associated CCO file created. Otherwise, True.

Level

Page level.

Details

MCCOPositionAdjust is an important action for applications using merged multiple page documents. It normalizes position coordinates populated to the DCO when the data is generated from a document using a merged CCO. The coordinates are adjusted relative to the page and also sets the DCO ImageFile property to the name of the TIFF that the data was found on.

Attention: All files to be merged must have an associated CCO file.

This action is used in conjunction with action MergeCCO_ByType from the Autodoc library in a prior ruleset.

Example

```
MCCOPositionAdjust()
```

Parent topic: [Zones actions](#)

MergeZones

Merges the zone from calling field with zone of DCO fields passed as smart parameters.

Syntax

```
bool MergeZones (string SmartParameters)
```

Parameters

A CSV of smart parameter strings indicating the DCO fields to merge zones with.

Returns

False if the calling field does not have a valid position value. Otherwise, True.

Level

Field level.

Details

Merges calling field's position with each passed dco position.

Example

```
MergeZones("@P\5PAddTel,@P\5PAddZip,@P\2PatName")
```

Parent topic: [Zones actions](#)

PadZone

Pads the zone by the value passed. Number of CSV passed values varies padding value by vector.

Syntax

```
bool PadZone (string SmartParameters)
```

Parameters

A CSV of smart parameter strings that indicate the pixels value by which to pad the calling field.

Returns

False, if the calling field does not have a valid position that is not a zero.

False, if there are zero or more than four CSV parameters.

False, if the Smart Parameter value returns as a non-numeric.

Otherwise, True.

Level

Field level.

Details

Pads calling field's position with each value passed. Number of passed values varies padding vector as follows:

1. Pads Left, Top, Right, and Bottom by this value (that is, expand if positive)
2. Pads as X,Y (X: pad to Left and Right, Y: pad to Top and Bottom)
3. Pads as Left, Top, Right, and Bottom. (missing values are treated as zero).
4. Pads as Left, Top, Right, and Bottom.

Example

```
PadZone("15") Pads 15 pixels to the Left, Right, Top and Bottom position.  
PadZone("5,10") Pads 5 pixels to the Left and Right position, and 10 to the Top  
and Bottom position.  
PadZone("-5,0,12,25") Pads -5 pixels to the Left, 0 to the Right, 12 to the Top  
and 25 to the Bottom position.
```

Parent topic: [Zones actions](#)

PopulateZNField

Puts the recognition data from the CCO file that lies in the zone boundaries of the field into the current field in the page data file.

Syntax

```
bool PopulateZNField ()
```

Parameters

None.

Returns

True if a value is found. Otherwise, False.

Level

Field level.

Details

This action populates the field value with the full-page recognition results (in the CCO) that fall within the boundaries of the field zone.

This action should be used with fields such as the Total or Number field in the Invoice application.

Example

```
PopulateZNField()
```

Parent topic: [Zones actions](#)

PopulateZNLineItemField

Populates the page data file with the recognized value in the zone for the current line item child field. Assign this action to each line item child field in the document hierarchy.

Syntax

```
bool PopulateZNLineItemField ()
```

Parameters

None.

Returns

True if a value is found or if the calling field has no position information. Otherwise, False.

Level

Field level.

Details

Populates the fingerprint's Data file with the recognized value contained inside the zone of a child Field object of a LINEITEM parent field. This action should only be used with subfields of the LINEITEM field (ItemID, ItemDesc, Quantity, Price) in the Invoices application.

Example

```
PopulateZNLineItemField()
```

Parent topic: [Zones actions](#)

ReadZones

Loads the position information for the current object and its children from the document hierarchy (setup DCO). Adjusts the position of each object by using any *Image_Offset* value.

Syntax

```
bool ReadZones ()
```

Parameters

None.

Returns

Always True.

Level

Page or Field level.

Details

Loads position information for each node in the calling object and its children. Pre-adjusts these values based on offset information stored in an *Image_Offset* variable at any node level.

Position information is based on the setup DCO position for the fingerprint ID of the parent page. The offset value is applied to all child objects of a node where an *Image_Offset* variable is found; unless overwritten by a child node also having an *Image_Offset* value to apply.

Parent topic: [Zones actions](#)

RegisterPage

Locates specially marked fields and adjusts their vertical zone positions to compensate for any drift.

Syntax

```
bool RegisterPage ()
```

Parameters

None.

Returns

Always True.

Level

Page level.

Details

RegisterPage adjusts the y positions of special fields to coordinate zone positions with the current word location of the fingerprint. Searches the calling page object for run time field names beginning with the word 'Anchor' (case sensitive). Of these fields a search is performed for variables named Word followed by the calling fingerprint ID (example: 'Word555'). The value of the variable retrieved is search for in the current pages CCO, and if found the field's zone position is 'y' axis adjusted for any word 'drift' for the given field value.

Example

```
RegisterPage ()
```

Parent topic: [Zones actions](#)

ScanDetails

Searches a line item grid object for line items. You assign this action to the grid region in the document hierarchy.

Syntax

```
bool ScanDetails ()
```

Parameters

None.

Returns

True if the bound Field object contains lines of data. Otherwise, False.

Level

Field level.

Details

Searches the DETAILS Field object's zone for instances of a LINEITEM Field object. Captures the data in the rows of a Line Item table, row by row.

This action captures all potential LINEITEM rows within the parent DETAILS field, even rows that may not fit your criteria for content.

Attention: You must run additional rulesets to delete ineligible Line Items. In the APT application, these are the Clean and Filter rulesets.

Example

```
ScanDetails ()
```

Parent topic: [Zones actions](#)

ScanDetailsByLines

Searches a line item grid object for line items, where each line item consists of the specified number of rows.

Syntax

```
bool ScanDetailsByLines (sParam)
```

Parameters

Number of lines in each lineitem.

Returns

True if the bound Field object contains lines of data. Otherwise, False.

Level

Field level.

Details

Searches the DETAILS Field object's zone for instances of a LINEITEM Field object. Captures the data based on the number of lines (parameter) in a Line Item table, row by row.

This action captures all potential LINEITEM rows (consisting of 2 lines each) in the parent DETAILS field, even rows that may not fit your criteria for content.

Attention: You must run additional rulesets to delete ineligible Line Items. In the Invoices application, these are the Clean and Filter rulesets.

Example

```
ScanDetailsByLines ("2")
```

Parent topic: [Zones actions](#)

ScanDetailsByVSpace

Searches a line item grid object for line items, where each line item is defined as the specified height in pixels.

Syntax

```
bool ScanDetailsByVSpace (sParam)
```

Parameters

Number of vertical pixels in each lineitem.

Returns

True if the bound Field object contains lines of data. Otherwise, False.

Level

Field level.

Details

Searches the DETAILS Field object's zone for instances of a LINEITEM Field object. Captures the data based on the number of vertical pixels (parameter) in a Line Item table, row by row.

Example

```
ScanDetailsByLines ("45")
```

This action capture all potential LINEITEM rows (consisting of 45 pixels lines each) in the parent DETAILS field, even rows that might not fit your criteria for content.

Attention: You must run additional rulesets to delete ineligible Line Items. In the Invoices application, these are the Clean and Filter rulesets.

Parent topic: [Zones actions](#)

ScanLineItem

Searches a line item object for fields. You assign this action to each line item in the document hierarchy.

Syntax

```
bool ScanLineItem ()
```

Parameters

None.

Returns

False if not called from a Field. Otherwise, True.

Level

Field level.

Details

This action captures each subfield within the parent LINEITEM row.

Example

```
ScanLineItem ()
```

Parent topic: [Zones actions](#)

SetEOL

Sets the End of Line character that will be used to separate data from a zone that contains multiple lines of text.

Syntax

```
bool SetEOL (bParam)
```

Parameters

The End of Line separator character.

Returns

Always True.

Level

All.

Details

If this action is not used, the default character is a space.

Example

```
SetEOL ("|")
```

This example sets the End of Line character to the '|' (pipe) character. A capture zone with two lines of text contains the captured value separated by this new character.

Parent topic: [Zones actions](#)

SetEOL_CRLF

Sets the End Of Line character that are used to separate data from a zone with multiple lines of text.

Syntax

```
bool SetEOL_CRLF ()
```

Parameters

None.

Returns

Always True.

Level

All.

Details

Sets the End Of Line character that is used to separate data from a zone with multiple lines of text to the carriage return and Line Feed characters: ASCII values 13 and 10.

Example

```
SetEOL_Crlf()
```

This example sets the End of Line character to the Carriage Return and Line Feed characters. A capture zone with two lines of text contains the captured value separated by these characters.

Parent topic: [Zones actions](#)

ZoneBOTTOM_ImageBottom

Uses the lower boundary of the current image to specify the bottom boundary of the zone position of the current field in the page data file.

Syntax

```
bool ZoneBOTTOM_ImageBottom ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Uses the bottom boundary of the current field's IMAGE to define the bottom edge of the field's ZONE. Attention: An image of a field is often larger than a zone of a field, and almost always larger than the field's word.

Example

```
ZoneBOTTOM_ImageBottom()
```

Parent topic: [Zones actions](#)

ZoneBOTTOM_LowerBound

Uses the lower boundary of the current word that is located by using the actions in the Locate library to specify the bottom boundary of the zone position of the current field in the page data file.

Syntax

```
bool ZoneBOTTOM_LowerBound ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Uses the lower boundary of the current field's ZONE to specify the bottom of the field's WORD. This can result in a taller or shorter word, depending on the location of the zone's boundary.

Example

```
ZoneBOTTOM_LowerBound()
```

If you find that an unacceptably high percentage of values for a particular field are entered a line too high, consider the use of this action in a follow-up Locate rule to search for the misplaced value.

Parent topic: [Zones actions](#)

ZoneBOTTOM_UpperBound

Uses the upper boundary of the current word that is located by using the actions in the Locate library to specify the bottom boundary of the zone position of the current field in the page data file.

Syntax

```
bool ZoneBOTTOM_UpperBound ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Uses the lower boundary of the current field's ZONE to specify the top of the field's WORD. This can result in a taller or shorter word, depending on the location of the zone's lower boundary.

Example

```
ZoneBOTTOM_UpperBound()
```

This action is helpful when experience shows that a certain number of values in this field extend beyond the word's upper limit. A follow-up Locate rule with this action can find those values.

Parent topic: [Zones actions](#)

ZoneImage_SaveAs

Saves the current Objects Zone area of an image as a separate Image file.

Syntax

```
bool ZoneImage_SaveAs (StrFileName)
```

Parameters

A string that defines the file name.

You can use these options to format the file name:

- **+@BATCHID** : Adds the BatchID to the Zone Image File Name
- **+@ID** : Adds the Object ID to the Zone Image File Name
- **+@STATUS** : Adds the Object Status to the Zone Image File Name
- **+@TYPE** : Adds the Object Type to Zone Image File Name
- **+@DATE+mm/dd/yyyy** : Adds a Date Stamp to the Zone Image File Name, the required trailing date format argument shows as the default, also '+' can be used
- **+@TIME+HH:MM:SS** : Adds a Time Stamp Value to the Zone Image File Name, the required trailing time format argument shows as the default, also '+' can be used
- **+@VALUE** : Adds Object Text to Zone Image File Name
- **+#name** : Appends the value of a child name to the Image File Name

Attention: **+#name** appends the value of child name to the image name.

Returns

False if an image cannot be saved. Otherwise, True.

Level

Page or Field level.

Details

Saves the current Objects Zone area of an image as a separate Image file. The Zone Image file is always placed in the Batches directory; saving to the current page creates a multi-page TIFF file with the additional image as its zone.

Example

```
ZoneImage_SaveAs ("SAMMY+@TYPE+@DATE+JJJ")
```

As part of a rule bound to the Details Field object of the Document Hierarchy, the action produces this Image File Name: ...\\SAMMYDETAILS243.tif.

Parent topic: [Zones actions](#)

ZoneLEFT_ImageLeft

Uses the left boundary of the current image to specify the left boundary of the zone position of the current field in the page data file.

Syntax

```
bool ZoneLEFT_ImageLeft ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Uses the left boundary of the current field's image to define the left edge of the field's zone. This can extend or contract the width of the zone, depending on the placement of the left side of the image.

Attention: A field's image is often larger than a field's zone, and almost always larger than the field's word.

Example

```
ZoneLEFT_ImageLeft ()
```

Parent topic: [Zones actions](#)

ZoneLEFT_LeftBound

Uses the left boundary of the current image to specify the left boundary of the zone position of the current field in the page data file.

Syntax

```
bool ZoneLEFT_LeftBound ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Uses the left boundary of the current field's word to define the left edge of the field's zone. This extends the width of the zone to accommodate the current word.

Example

```
ZoneLEFT_LeftBound()
```

If the field's recognized values reach beyond the zone's limits, you can use this action to expand the zone appropriately.

Parent topic: [Zones actions](#)

ZoneLEFT_RightBound

Uses the right boundary of the current image to specify the left boundary of the zone position of the current field in the page data file.

Syntax

```
bool ZoneLEFT_RightBound ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Uses the right boundary of the current field's word to designate the left edge of the field's zone. This extends the width of the zone to accommodate the current word.

Example

```
ZoneLEFT_RightBound()
```

Attention: The image of a field is often larger than the field's zone, and almost always larger than the field's word.

Parent topic: [Zones actions](#)

ZoneRIGHT_ImageRight

Uses the right boundary of the current image to specify the right boundary of the zone position of the current field in the page data file.

Syntax

```
bool ZoneRIGHT_ImageRight ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Uses the right boundary of the current field's image to define the right edge of the field's zone. This can extend or contract the width of the zone, depending on the placement of the right side of image.

Attention: A field's image is often larger than a field's zone, and almost always larger than the field's word.

Example

```
ZoneRight_ImageRight()
```

Parent topic: [Zones actions](#)

ZoneRIGHT_LeftBound

Uses the left boundary of the current word* to specify the right boundary of the zone position of the current field in the page data file.

Syntax

```
bool ZoneRIGHT_LeftBound ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Uses the left boundary of the current field's word to designate the right edge of the field's zone. This action also excludes the word from the zone.

Example

ZoneRight_LeftBound()

This action can clean the zone by eliminating the word it contains.

Parent topic: [Zones actions](#)

ZoneRIGHT_RightBound

Uses the right boundary of the current word* to specify the right boundary of the zone position of the current field in the page data file.

Syntax

```
bool ZoneRIGHT_RightBound ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Uses the right boundary of the current field's word to designate the right edge of the field's zone.

This is a convenient action if a percentage of the field's entered values extend beyond the right edge of the zone.

Example

```
ZoneRIGHT_RightBound()
```

Parent topic: [Zones actions](#)

ZoneTOP_ImageTop

Uses the top boundary of the current image to specify the top boundary of the zone position of the current field in the page data file.

Syntax

```
bool ZoneTOP_ImageTop ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

Uses the upper boundary of the current field's image to designate the top edge of the field's zone. This can extend or contract the width of the zone, depending on the placement of the left side of the image.

Example

```
ZoneTOP_ImageTop ()
```

Parent topic: [Zones actions](#)

ZoneTOP_LowerBound

Uses the lower boundary of the current word that is located by using the actions in the Locate library to specify the top boundary of zone position of the current field in the page data file.

Syntax

```
bool ZoneTOP_LowerBound ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

This action uses the upper boundary of the current field's zone to indicate the bottom of the field's word. This action can expand or contract the height of the zone, depending on the placement of the word's lower boundary within the current page.

Example

```
ZoneTOP_LowerBound ()
```

If you find that a high percentage of values for a particular field are entered a line too high, you can use this action in a follow-up Locate rule to search for the misplaced value.

Parent topic: [Zones actions](#)

ZoneTOP_UpperBound

Uses the upper boundary of the current word that is located by using the actions in the Locate library to specify the top boundary of the zone position of the current field in the page data file.

Syntax

```
bool ZoneTOP_UpperBound ()
```

Parameters

None.

Returns

Always True.

Level

Field level.

Details

This action is helpful when you know that a certain number of values in this field will be shorter than the zone's height. A follow-up Locate rule with this action will find those values.

Example

```
ZoneTOP_UpperBound ()
```

Parent topic: [Zones actions](#)

Application specific actions

The Datacap applications use actions that are specific to them.

- [Medical Claims actions](#)
The following are actions specific to the Medical Claims application.
- [Datacap Accounts Payable actions](#)
Use the Datacap Accounts Payable actions when you work with batches of invoices on APT.

Parent topic: [Action library summaries](#)

Medical Claims actions

The following are actions specific to the Medical Claims application.

- [4010Common](#)
- [4010Institutional](#)
- [4010Professional](#)
- [5010Common](#)
- [5010Institutional](#)

- [5010Professional](#)
- [MC_Identify](#)
Use the MC_Identify actions to identify claim forms in a batch.
- [MC_Validation](#)

Parent topic: [Application specific actions](#)

4010Common

The set of *4010Common* actions are common to both Institutional and Professional medical claim forms.

Action	Description
Load4010 Settings	Load settings from the .ini file that is passed as a parameter. You can change default values and customize how the 4010 form is built. Smart parameter enabled.
Merge4010	Zips the 4010 file path, file name, and file extension settings into one file. Smart parameter enabled.

Parent topic: [Medical Claims actions](#)

4010Institutional

This action is specific to the Institutional 4010 form.

Action	Description
Institutional_4010	Used to build a single 4010 file for each Institutional claim. Use the action on a page or a document. The action allows you to create a single export page file for each document.

Parent topic: [Medical Claims actions](#)

4010Professional

This action is specific to the Professional 4010 form.

Action	Description
Professional_4010	Used to build a single 4010 file for each Professional claim. Use the action on a page or a document. The action allows you to create a single export page file for each document.

Parent topic: [Medical Claims actions](#)

5010Common

The set of *5010Common* actions are common to both Institutional and Professional medical claim forms.

Action	Description
Load5010 Settings	Load settings from the .ini file that is passed as a parameter. You can change default values and customize how the 5010 form is built. Smart parameter enabled.
Merge5010	Zips the 5010 file path, file name, and file extension settings into one file. Smart parameter enabled.

Parent topic: [Medical Claims actions](#)

5010Institutional

This action is specific to the Institutional 5010 form.

Action	Description
Institutional_5010	Used to build a single 5010 file for each Institutional claim. Use the action on a page or a document. The action allows you to create a single export page file for each document.

Parent topic: [Medical Claims actions](#)

5010Professional

This action is specific to the Professional 5010 form.

Action	Description
Professional_5010	Used to build a single 5010 file for each Professional claim. Use the action on a page or a document. The action allows you to create a single export page file for each document.

Parent topic: [Medical Claims actions](#)

MC_Validation

The actions in the *MC_Validation* library are used specifically with Professional and Institutional claim forms. The actions allow for the manipulation of batches, batch hierarchies, and data.

Action	Description
AddCenturyTo2DigitYear	Converts two-digit Year values to four-digit Year values.
AddToDetailErrorMessage	Adds the value to the existing value for the page variable ErrorMessage.
AddToErrorMessage	Adds the value to the existing value for the page variable ErrorMessage.
CalculateHCFALineCharges	Calculates charges for HCFA service lines.
CalculateResult	Determines if the calculation provided by the parameter is True or False.
CalculateUB	UB04 action that determines if the amounts in the 47ttchg fields sum correctly.
CalculateUBLineCharges	Calculates charges for UB service lines.
CheckDocID	Checks document IDs and updates them to the proper format.
ClearErrorMessage	Clears the value of the page variable ErrorMessage.
CommonParseAddresses	Parses addresses in certain fields in HCFA and UB04 forms into appropriate subfields.
CommonValAddresses	Validates address values.
ConvertHyphen	Removes spaces, commas and hyphens from the current field.
FilterPID	Filters qualifier from attending physician field for UB04 claims.
FormatFieldLengths	Truncates length and sets the last character to a low confidence recognition of the field.
InheritSnippets	Assigns the snippet position information of the current Field object to the Field objects specified in the parameter.

Action	Description
MC_ReadZones	Adjusts autofield based OMR field zone positions on the calling page.
Parse31aPhSig	Parses field 31aPhSig of the HCFA application.
Parse58ainsnm	Parses field 58ainsnm of the UB04 application.
Parse58binsnm	Parses field 58binsnm of the UB04 application.
Parse58cinsnm	Parses field 58cinsnm of the UB04 application.
Parse82name	Parses field 82name of the UB04 application.
Parse83aname	Parses field 83aname of the UB04 application.
Parse83bname	Parses field 83bname of the UB04 application.
ParseLastFirstIniNames	Parses the name information in the first line of an address superfield.
ParseNDC	An action that detects and parses NDC data elements from the calling field value.
ParseUB_Eighties	Special action to parse fields 82 (Attending Physician ID) and 83 (Other Physician ID) of the UB92 application.
PopulateFromField	Copies the value from the field specified by the parameter into the current field.
SetConf	Sets confidence string for a field.
SetOriginalTIF	Replaces current working TIF file.
StripTrailingAlpha	Removes all alpha characters from the captured value, except any in the first character position.
TransformLI	Remaps the Line Item Table fields into a hierarchical structure.
UpdateCredentialList	
ValidateNPI	Validates the NPI value by evaluating the 10 digits in the value uses a modified LUHN checkdigit algorithm.
ValidateStateMil	Checks to see if the value in the field represented by the bound Field object is a valid two-character State abbreviation.
ValProcedureCode	Validates the Procedure Code fields of a HCFA-1500 form.
ValRequiredGroup	Checks that all fields in a designated group are filled with data.

Parent topic: [Medical Claims actions](#)

Datacap Accounts Payable actions

Use the Datacap Accounts Payable actions when you work with batches of invoices on APT.

Datacap Accounts Payable actions are divided into the following categories:

Category	Description
Localization	Detects the localization and decimal separator settings of a workstation and changes the rules execution and data for the documents that you are processing if needed.
Custom	Customizes the fields in the invoice image to accommodate locale requirements and other things.

Category	Description
Concatenate line values	Merges line item values into page variable and page field values into document variables.
Documents	Creates and manages the documents in the batch.
FlexID	Starts the FlexID panel to manually identify the pages in the document batch.
Intellocate learning	Determines the new zones in the invoice image and adds these zones to the DCO.
Page ID	Separates and processes the page objects in the documents.
PreVerify setup	Sets the label variable that is used by Datacap Web Client and Datacap Desktop to display the label on each field.
Redaction	Redacts selected information in your invoice image for security purposes.

Embedded help is provided in Datacap Studio for all of the Datacap Accounts Payable actions. To access the embedded help, select an action in the Actions Library tab and click information. For detailed information, including information about parameters, refer to the embedded help.

- [APT_Localization](#)
Use the APT_Localization actions to work with currency values when you process documents generated from a locale that is different from the locale of your workstation.
- [APTCustom](#)
Use the APTCustom actions to customize your APT applications.

Parent topic: [Application specific actions](#)

APT_Localization

Use the APT_Localization actions to work with currency values when you process documents generated from a locale that is different from the locale of your workstation.

The APT_Localization actions are described in the following table.

Action	Description
--------	-------------

Action	Description
CheckAndFixLocalDecimal	Checks and fixes issues when the decimal in a currency value is not recognized and is replaced with a comma or a space. Also converts the decimal separator to use the local setting.
ConvertToLocalDecimal	Reads the computer settings and sets the decimal place.
IsFieldLocalCurrency	Queries the local decimal separator and checks to see whether the field contains a local currency value.
IsLocalDecimalSeparator	Checks to see whether the decimal separator on the workstation matches the locale of the document that you are processing.
IsOriginalEuroFormat	Checks the document level Euro Format and USCanUK Format variables for the currency values in the recognized data. Votes on the decimal format that is used in the document.
IsWorkstationLocale	Checks to see which decimal separator is used on the workstation.

Parent topic: [Datacap Accounts Payable actions](#)

APTCustom

Use the APTCustom actions to customize your APT applications.

The APTCustom actions are described in the following table.

Action	Description
AddAllTaxesToTaxField	Takes every tax detail line value and adds it to a field called Tax.
AddToDate	Specifies a time to add to the date value stored in a field.
CalculateInvoiceTotalLocalized	Calculates the total value of the localized invoice.
CalculateLineItemLocalized	Calculates the value of the localized line item.
ClearCurrentField	Erases the data from the current field.
ConvertEuroDateToUS	Converts the Date values from a European format to a US format.
ConvertUSDateToEuro	Converts the Date values from a US format to a European format.
FindTaxValue	Locates the taxes on an invoice.
IsDate_FormatEuro	Checks to see whether the Date value is in a valid European format.
IsInvoiceFromUS	Checks to see whether the invoice is from a company in the United States.
MakeFieldHighConfidence	Sets all of the character confidence field values to high confidence.
PopulateTaxType	Populates the Tax Details section with Tax Type information.

Parent topic: [Datacap Accounts Payable actions](#)

ConcatLineValues

Use the ConcatLineValues actions to merge line items and page fields in your APT applications.

The ConcatLineValues are described in the following table.

Action	Description
MergeLineItemFieldToPageField	Merges the line item values on the invoice image into a page variable
MergePageFieldToDocVar	Merges the page field values on the invoice images into a document variable

Parent topic: [Datacap Accounts Payable actions](#)

Documents

Use the Documents actions to create and manage documents on your APT applications.

The Documents actions are described in the following table.

Action	Description
CombinePreviousDoc	Copies the pages of the previous named document into the front of this document.
CountPagesToDocVar	Counts the number of page objects in a document and writes the result in a document variable.
IsFirstDocInBatch	Checks to see whether this object is the first document in the batch.
RemoveDocumentStructure	Levels the document/page hierarchy from the batch. For example, if the batch consists of multiple documents that each contain a set of pages, the document level is removed. All of the pages become a flat structure.

Parent topic: [Datacap Accounts Payable actions](#)

FlexID

Use the FlexID action to run the panel for the FlexID task.

The FlexID action is described in the following table.

Action	Description
RunFlexIDPanel	Runs the panel for the FlexID task in APT.

Parent topic: [Datacap Accounts Payable actions](#)

Intellocate_Learning

Use the Intellocate_Learning actions to allow APT to determine the new zones in your invoice image and add these zones to the DCO.

The Intellocate_Learning actions are described in the following table.

Action	Description
Learn_Zones	Learns about a new zone and adds the zone to the DCO.

Action	Description
Learn_ZonesFPX	Learns about a new zone and adds the zone to the DCO. Learn_ZonesFPX is FPXML compatible and it learns only the first line item in the zone. To write the zone to FPXML, this action must be followed by a WriteZonesFPX action.

Parent topic: [Datacap Accounts Payable actions](#)

PageID

Use the PageID actions to work with pages in your APT documents.

The PageID actions are described in the following table.

Action	Description
PageIDByBCSep	Separates the pages in the batch by using bar code separator sheets.
PageIDBySeqTypes	Applies a sequence of comma-separated page types, in order, to the pages of type Other in a batch, and repeats the sequence indefinitely.
PageIDByVariableChange	Processes all of the pages with a page type that is set according to the input parameters. For example, when pages are PageID, a variable for the page can be watched so when that variable changes, a new page type is created.

Parent topic: [Datacap Accounts Payable actions](#)

PreVerifySetup

Use the PreVerifySetup action to set the label variable before you run the Verification task on the batch of documents.

The PreVerifySetup action is described in the following table.

Action	Description
SetLabels	Reads the .ini file and sets up label variable that is used by Datacap Web Client and Datacap Desktop to display the label on each field.

Parent topic: [Datacap Accounts Payable actions](#)

Redaction

Use the Redaction actions to redact selected information in your APT invoice images for security purposes.

The Redaction actions are described in the following table.

Action	Description
EraseRect	Redacts the area of the invoice image that you specify in pixels. For example, you can configure this action as EraseRect(x1, y1, y2, bBlack) to redact the area in the image that corresponds to the specified coordinates.

Action	Description
GetAll Barcodes	Gets as many as 10 bar codes from the invoice image.
RedactByRegex	Checks for a specified regular expression and redacts all occurrences of that regular expression.
RedactField	Redacts an area of the invoice image by using the current coordinates of the field.

Adding keyboard shortcuts to an application

You can create keyboard shortcuts for navigating and selecting user-interface controls within a specific task in an application. To add a new shortcut to an application, you must edit the corresponding task's configuration XML file.

About this task

Any existing keyboard shortcuts, which are defined by the default Datacap installation, take precedence over new keyboard shortcuts. When you add shortcuts, ensure that they do not conflict with existing shortcuts.

Procedure

To add a keyboard shortcut for a task in an application:

1. Open the task's configuration XML file.
Tip: The task's configuration XML file is located at *default installation location\application name\dco_application name\task name.set.xml*. For example, the location of the configuration file for the Fixup task in the TravelDocs application is C:\Datacap\TravelDocs\dco_TravelDocs\fixup.set.xml.
 2. Determine the user-interface control for which you want to add a keyboard shortcut. For example, to add a shortcut to a control that is named Page Status, search for `label="Page Status"` in the XML file.
 3. On the same line where you located the `label`, add this code: `hotkey=`.
 4. Enter a value for `hotkey=`. For example, if you enter `hotkey=A`, then Ctrl-A is the keyboard shortcut for selecting Page Status.
 5. Save the XML file.
- [Keyboard shortcuts for the ASPX web pages](#)
You can use the Datacap Web Client keyboard shortcuts to view images on the aVerify, ImgEnter, Restruct, and VeriFine web pages.
 - [Keyboard shortcuts for the Datacap Desktop Scan task](#)
You can use keyboard shortcuts to navigate and select user-interface controls in Datacap Desktop.
 - [Keyboard shortcuts for the Datacap Desktop Fixup task](#)
You can use keyboard shortcuts to navigate and select user-interface controls in Datacap Desktop.
 - [Keyboard shortcuts for the Datacap Desktop Verify task](#)
You can use keyboard shortcuts to navigate and select user-interface controls in Datacap Desktop.

Keyboard shortcuts for the ASPX web pages

You can use the Datacap Web Client keyboard shortcuts to view images on the aVerify, ImgEnter, Restruct, and VeriFine web pages.

Table 1. Keyboard shortcuts for the aVerify.aspx page

To Do This	Do This
Go to the next image in a multipage document	Shift+Alt, then press >
Go to the previous image in a multipage document	Shift+Alt, then press <
Zoom in image (image expands)	Shift+Alt, then press +
Zoom out image (image shrinks)	Shift+Alt, then press -
Zoom image by quarter	Shift+Alt, then press Q
Scroll image	Shift+Alt, then press Up Arrow, Down Arrow, Left Arrow, or Right Arrow

Table 2. Keyboard shortcuts for the ImgEnter.aspx page

To Do This	Do This
Next LC and Problem field	Alt+I
Go to next field in DCO order by using the Tab key	Press Tab, then press Enter
Go to previous field in DCO order by using the Tab key	Shift+Tab, then press Enter
Change the orientation of the edit box to be displayed either above or below a snippet	Shift+Up Arrow or Shift+ Down Arrow
Shift all field zones (offset fields)	Ctrl+Shift+Arrows
Move field rectangle to change the field position variable	Alt+Shift+Arrows
Resize current field zone	Alt+Arrows
Select all in the field	Ctrl+A
Clear all in the field	Ctrl+X
Navigate to the start of the field value and to the end of the field value	PageUp, PageDn

Table 3. Keyboard shortcuts for the Restruct.aspx page

To Do This	Do This
Select next node in tree structure	Press Down Arrow
Select previous node in tree structure	Press Up Arrow
Move page down or up in tree structure	Shift+Down Arrow or Shift+Up Arrow
Collapse node to hide child in tree structure	Ctrl+Left Arrow
Expand node to show child in tree structure	Ctrl+Right Arrow
Split document in tree structure	Shift+Right Arrow

Table 4. Keyboard shortcuts for the VeriFine.aspx page

To Do This	Do This
Next LC	Alt + L
Load the next or previous image in a multipage document	Shift+Alt, then press Page Up or Page Down
Select next node in the tree structure	Press Down Arrow
Select previous node in the tree structure	Press Up Arrow
Move page down or up in the tree structure	Shift+Down Arrow or Shift+Up Arrow
Collapse node to hide child in the tree structure	Ctrl+Left Arrow
Expand node to show child in the tree structure	Ctrl+Right Arrow
Split document in the tree structure	Shift+Right Arrow

Parent topic: [Adding keyboard shortcuts to an application](#)

Keyboard shortcuts for the Datacap Desktop Scan task

You can use keyboard shortcuts to navigate and select user-interface controls in Datacap Desktop.

Depending on how the corresponding Datacap Desktop task is configured, some of the keyboard shortcuts might not be applicable in your environment.

Table 1. General keyboard shortcuts for the Datacap Desktop Scan task

Keyboard shortcut	Function
Alt + E	Open Edit menu
Alt + N	Open Navigate menu
Alt + I	Open View menu
Alt + M	Open Image menu
Alt + H	Open Help menu
F6	Submit, Done, or Finish
F7	Full image view
F8	Fit image to width
Ctrl + Q	Place batch on Hold
Alt + Q	Quarter Zoom displays sections of the image.
Ctrl + Alt + I	Toggle the Image View
Ctrl + Alt + S	Toggle the Batch View
Alt + I, then press S, then press Enter	Displays the Start Batch Panel.

Table 2. Scan Settings keyboard shortcuts

Keyboard shortcut	Function
-------------------	----------

Keyboard shortcut	Function
Alt + S	Open Scan Settings menu
Alt + Shift + B	Save as batch settings
Alt + Shift + U	Save as user settings
Alt + Shift + S	Save as station settings
Alt + Shift + C	Save as custom settings
Ctrl + Shift + C	Load custom settings
Ctrl + Shift + B	Load batch settings
Ctrl + Shift + U	Load user settings
Ctrl + Shift + S	Load station settings

Parent topic: [Adding keyboard shortcuts to an application](#)

Keyboard shortcuts for the Datacap Desktop Fixup task

You can use keyboard shortcuts to navigate and select user-interface controls in Datacap Desktop.

Depending on how the corresponding Datacap Desktop task is configured, some of the keyboard shortcuts might not be applicable in your environment.

Table 1. Datacap Desktop Fixup keyboard shortcuts

Keyboard shortcut	Function
F6	Finish batch
F5	Refresh
Delete	Remove image
Insert	Insert scanned images
Ctrl + Z	Cancel batch
Ctrl + B	Focus on Batch Tree
Ctrl + C	Stop Scanning
Ctrl + D	Delete (Remove)
Ctrl + F	Rotate image 180°
Ctrl + L	Rotate Left (90° counterclockwise)
Ctrl + O	Open
Ctrl + P	Replace (rescan)
Ctrl + R	Rotate Right (90° clockwise)
Ctrl + S	Focus on Scan Panel
Ctrl + T	Toggle thumbnail view
Ctrl + U	Navigate backwards through images. (Manual image selection mode only. For more information, see Configuring the image selection mode for the Datacap Desktop Fixup task).

Keyboard shortcut	Function
Ctrl + Y	Navigate forwards through images. (Manual image selection mode only. For more information, see Configuring the image selection mode for the Datacap Desktop Fixup task).
Ctrl + F8	Display the page type
Ctrl + F9	Mark the page for review
Ctrl + Up Arrow	Move up
Ctrl + Down Arrow	Move down

Keyboard shortcuts for the Datacap Desktop Verify task

You can use keyboard shortcuts to navigate and select user-interface controls in Datacap Desktop.

Depending on how the corresponding Datacap Desktop task is configured, some of the keyboard shortcuts might not be applicable in your environment.

Table 1. Keyboard shortcuts for Datacap Desktop

Keyboard shortcut	Menu	Command
Ctrl + P	Navigate	Go to Previous Problem Page
Ctrl + N	Navigate	Go to Next Problem Page
Ctrl + Shift + P	Navigate	Go to Previous Page
Ctrl + Shift + N	Navigate	Go to Next Page
Alt + L	Navigate	Go to Next Low Confidence (LC) Field
Alt + V	Navigate	Validate
F6	Navigate	Submit
Ctrl + Q	Navigate	Place batch on Hold
F11	Edit	Clear All Fields
Ctrl + Shift + A	Edit	Automatic login
Ctrl + Alt + I	View	Toggle the Image View
Ctrl + Alt + S	View	Toggle the Batch View
Alt + Shift + P	View	Display Previous Image in document
Alt + Shift + N	View	Display Next Image in document
Alt + Shift + NumPad8	Snippet	Move up
Alt + Shift + NumPad2	Snippet	Move down
Alt + Shift + NumPad4	Snippet	Move left
Alt + Shift + NumPad6	Snippet	Move right
Alt + Shift + I	Snippet	Zoom in
Alt + Shift + O	Snippet	Zoom out

Keyboard shortcut	Menu	Command
Alt + Shift + R	Snippet	Restore
F4	Image	Draw Fields
Alt + Q	Image	Zoom Quarter displays sections of the image.
F8	Image	Fit to width
F7	Image	Full image view
Alt + W	Image	Draw CCO Words
Alt + R	Image	Draw CCO Lines
Alt + Shift + 9	Image	Rotate 90°
Alt + Shift + F	Image	Rotate 180°
Alt + Shift + 7	Image	Rotate 270°
