
- `DNS:fqdn.myserver.com` is the fully qualified domain name of the endpoint the certificate applies to. This matches the endpoints entered in the APICUP installer. See [Deploying the Management subsystem](#)
- `platform-api-example.csr` is the file name for the certificate signing request

Following is an example for how to generate a certificate (`portal-client`) with an EKU `clientAuth` and SAN using `openssl`:

```
openssl x509 -req -days 360 -in portal-client-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out portal-client-cert -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical,CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
```

- Once the certificate has been created, set the certificate by entering the following command:
`apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE] [KEY_FILE] [flags]`

If the certificate is signed by an intermediate CA, the `CA_File` argument must point to a file that concatenates the intermediate CA, followed by the root CA, in that order.

You can find definitions for commands at the following location: [Command reference](#)

If the certificate was generated with an EKU `serverAuth`, it must be assigned to a server certificate. If the certificate was generated with an EKU `clientAuth`, it must be assigned to a client certificate.

- Repeat for additional custom certificates.
- After setting the custom certificates, you can optionally generate the remaining default certificates prior to installation by entering the `apicup certs generate` command. The `generate` command generates any certificates that have not been set, so it will create default certificates for all remaining certificates. It will not overwrite any custom certificates you have set. You can review the certificates prior to installation.
- List all certificates with `apicup certs list SUBSYS`. The results will include the generated default certificates and the custom certificates that you set.

Following is example output from the `apicup certs list` command:

`list` command:

`Common certificates`

7. Install the subsystem with the certificates using `apicup subsys install SUBSYS`. Any missing certificates will be generated. The installation will not proceed if there are any validation issues with the certificates. See [Validation reference](#).
8. Repeat for other subsystems.
9. If necessary, you can replace custom certificates after installation is complete. See [Replacing custom certificates](#).

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Replacing custom certificates

Use the APICUP installer `certs` commands to replace existing certificates.

About this task

Important:

- Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
- To view a list of public, public user-facing, and internal certificates, see [Certificate management: Read This First](#). For details on each certificate, see [Certificate reference](#).

The APICUP installer can be used to update certificates for each subsystem after installation.

Requirements for custom certificates:

- Extended Key Usage (EKU), either `serverAuth` or `clientAuth` depending upon the type of certificate. Certificates of type *Server* must have an Extended Key Usage with `serverAuth` purpose. Certificates of type *Client* must have an Extended Key Usage with `clientAuth` purpose.
- Subject Alternative Name (SAN) for the required hosts
- Any custom common certificates that are being used must be set prior to setting any custom certificates for a subsystem.

See [Certificate Reference](#) to view the list of common certificates and to determine whether an EKU is needed for a certificate and which type of EKU (`serverAuth` or `clientAuth`).

Certificates and identical endpoints:

The Management subsystem has four public endpoints: `api-manager-ui`, `cloud-admin-ui`, `platform-api`, and `consumer-api`. Distinct TLS certificates can be set for each endpoint. However, if any two endpoints are identical, only one TLS certificate will be effective. When 2 or more endpoints are set to the same host, the secrets associated with the endpoints should be the same or contain the same certificate files.

Procedure

1. Generate the custom certificate with the appropriate EKU and SAN. You will need to obtain the private key, public certificate, and CA certificates in non-password-protected PEM format for the custom certificate. Following is an example for how to generate a certificate (`platform-api-example`) with an EKU `serverAuth` and SAN using `openssl`:

```

openssl x509 -req -days 360 -in platform-api-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out
platform-api-cert -sha256
-extfile <(cat /etc/ssl/openssl.cnf <(printf
"
[n[SAN]\nsubjectAltName=DNS: fqdn.myserver.com\nextendedKeyUsage=serverAuth"
))
-extentions SAN

```

where

- `DNS: fqdn.myserver.com` is the fully qualified domain name of the endpoint the certificate applies to. This matches the endpoints entered in the APICUP installer. See [Installing the Management subsystem into a Kubernetes environment](#)
- `platform-api-example.csr` is the file name for the certificate signing request

Following is an example for how to generate a certificate (portal-client) with an EKU clientAuth and SAN using openssl:

```
openssl x509 -req -days 360 -in portal-client-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out portal-client-cert -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical,CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
```

2. Once the certificate has been created, set the certificate by entering the following command:

```
apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE]
```

You can find definitions for commands at the following location: [Command reference](#)

If the certificate is signed by an intermediate CA, the `CA_File` argument must point to a file that concatenates the intermediate CA, followed by the root CA, in that order.

If the certificate was generated with an EKU serverAuth, it must be assigned to a server certificate. If the certificate was generated with an EKU clientAuth, it must be assigned to a client certificate.

3. Install the subsystem with the new certificate using `apicup subsys install SUBSYS`. Any missing certificates will be generated. The installation will not proceed if there are any validation issues with the certificates. See [Validation reference](#).
4. Repeat for other subsystems requiring new certificates.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Setting common certificates

Common certificates are set for one subsystem, but are applied to all subsystems. Use the APICUP installer `certs` commands to set the common certificates.

About this task

Important:

- Customization of public certificates and public user-facing certificates is recommended. Customization of internal certificates is strongly discouraged.
- To view a list of public, public user-facing, and internal certificates, see [Certificate management: Read This First](#). For details on each certificate, see [Certificate reference](#).

The common certificates are identical across subsystems. Subsystems require the common certificates to allow them to register with the management subsystem. When installing any one subsystem, the common certificates will be set for that subsystem and for all the other subsystems. If you are using custom certificates for the common certificates, they must be set prior to setting any custom certificates. See [Certificate reference](#) for a description of the common certificates.

Common certificates cannot be changed between subsystem installs. For example, you cannot set a common certificate for the management subsystem, install the management subsystem, then change a common certificate for the analytics subsystem, then install the analytics subsystem. This scenario will result in a failed installation because the common certificates are not identical.

Procedure

Follow these steps to set custom common certificates. If using default certificates, the common certificates will be set for you. See [Setting default certificates](#).

1. Set up and validate all subsystems. Enter the settings for the subsystem using `apicup subsys set <SUBSYS>` and validate the subsystem settings using `apicup subsys get <SUBSYS> --validate`. The subsystem must pass validation before setting the certificates.
2. Generate a custom certificate with the appropriate EKU and SAN. You will need to obtain the private key, public certificate, and CA certificates in non-password-protected PEM format for the custom certificate. Following is an example for how to generate a certificate (platform-api) with an EKU serverAuth and SAN using openssl:

```
openssl x509 -req -days 360 -in platform-api.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out platform-api-cert -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nsubjectAltName=DNS:ac-msntest.myserver.com,DNS:ac2-msntest.myserver.com\nextendedKeyUsage=serverAuth")) -extensions SAN
```

Following is an example for how to generate a certificate (portal-client) with an EKU clientAuth and SAN using openssl:

```
openssl x509 -req -days 360 -in portal-client.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out portal-client-cert -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical,CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
```

3. Once the certificate has been created and you have a `.pem` file, set the custom common certificates in one of your subsystems. After setting the custom certificates for one subsystem, they will take effect for all subsystems. The command is targeted at a specific subsystem, but the common certificates are copied to all subsystems regardless of which subsystem they are originally set in. Following is an example for setting the `portal-client` certificate:
`apicup certs set mgmt portal-client myCertFile.pem myKeyFile.key myCAFile.crt`
4. Set the remaining certificates for each subsystem, default or custom. See [Setting default certificates](#) and [Setting custom certificates](#).
5. List and validate the certificates for each subsystem. See [Validation reference](#).

6. Install each subsystem using `apicup subsys install SUBSYS`.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Setting the encryption-secret for the management database

Use the APICUP installer `certs` commands to set the encryption-secret for the management database.

About this task

The encryption-secret is a secure random bytes password used for field level encryption in the management database. You can generate 128 random bytes using the following command in openssl:

```
openssl rand -out /path/to/secret/encryption-secret.bin 128
```

Procedure

1. Enter the `apicup certs set SUBSYS CERT_NAME [KEY_FILE]` command and complete the following values:
 - SUBSYS - The subsystem for the `encryption-secret` is the name of your management subsystem, because it is used for field-level encryption for the management database.
 - CERT_NAME - The certificate name is `encryption-secret`.
 - KEY_FILE - Enter the file name for a secure random bytes string that is 128 bytes in length, for example `encryption-secret.bin`.
2. Set the remaining certificates if using custom certificates and install the management subsystem.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Clearing certificates

Certificates can be cleared in order to set new certificates.

About this task

Existing certificates must be cleared in order to set new certificates. When using default certificates, new certificates are created only for those certificates that are not set. Some of the use cases for clearing certificates are: expired certificates and configuration changes. For example, if endpoints are changed, the existing certificates must be cleared and new certificates created.

Procedure

1. Enter the `apicup certs set SUBSYS CERT_NAME --clear` command and complete the following values:
 - SUBSYS - The name of the subsystem
 - CERT_NAME - The name of the certificate that you want to clear.
2. The certificate will be cleared and can be reset, either as a default or custom certificate.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Reference for certificates, commands, and validations

This section contains the reference information for certificates, commands for working with certificates, and validations.

About this task

- [Certificate reference](#)
The Certificate reference provides a description of all the certificates required in API Connect.
- [Command reference](#)
The APICUP installer includes the `certs` commands to set and manage certificates.
- [Validation reference](#)
Certificates are validated using several parameters.

Certificate reference

The Certificate reference provides a description of all the certificates required in API Connect.

Before you begin

APICUP sets default certificates for each subsystem during installation. The default certificates are self-signed so may not provide a level of trust suitable for external communication. Custom certificates can be set and managed following the steps described in [Setting custom certificates](#). The Certificates reference topic lists all certificates that are set by the `apicup certs` commands. The default certificates can be used for the majority of these certificates. The certificates that are marked as *public and user-facing* are recommended to be explicitly set as custom certificates because they are presented to an end user through a browser or Command Line Interface (CLI).

The certificates that are described as *TLS certificate used by ingress* are also considered *public* in the sense that they interact with a client that sits outside of an API Connect cluster.

Certificates that are listed as *auto-generated* cannot be set using the `apicup certs set` command. For example, the common certificate `ingress-ca` is auto-generated and used as an intermediate CA for all default ingress certificates. If you set an ingress certificate as a custom certificate, you will need to configure an intermediate CA if desired.

Important:

When setting custom certificates, additional steps must be taken to provide an Extended Key Usage (EKU) serverAuth and ClientAuth and a Subject Alternative Name (SAN) for the required hosts. These certificates are generated automatically by the `apicup certs` command when using the default certificates.

- For custom certificates of type *server*, an additional extended key usage client authentication (EKU serverAuth) certificate is required.
- For custom certificates of type *client*, an additional extended key usage server authentication (EKU clientAuth) certificate is required.

Procedure

1. **Common certificates** - The following certificates are common to all subsystems in a deployment. Subsystems require the common certificates to allow them to register with the management subsystem. The common certificates are identical across subsystems. When installing any one subsystem, the common certificates will be set for that subsystem and for all the other subsystems. Custom common certificates must be set prior to setting any custom subsystem certificates. Common certificates cannot be changed between subsystem installs. For example, you cannot set a common certificate for the management subsystem, install the management subsystem, then change a common certificate for the analytics subsystem, then install the analytics subsystem. This scenario will result in a failed installation because the common certificates are not identical.

Table 1. Common certificates

Certificate name (value used in <code>apicup certs</code>)	Usage	Requirements	Description
root-ca	CA		CA certificate which forms the root of the certificate chain
ingress-ca	CA	signed by: root-ca	Auto-generated intermediate certificate used to generate certificates for subsystem ingress endpoints if not provided by user. The <code>ingress-ca</code> intermediate certificate cannot be set explicitly, it is always only generated. TLS certificates for the ingresses are not required to use <code>ingress-ca</code> as an intermediate certificate, but if a given ingress TLS certificate remains to be auto-generated then it will be signed by this <code>ingress-ca</code> .
portal-client	Client	Must be signed by the same authority as the one used for the matching ingress TLS certificate <code>portal-admin-ingress</code> . For a two data center deployment, both data centers must have an identical subject name. For example, both data centers subject name could be <code>CN=portal-admin-client</code> , or they could both be <code>CN=ptl-adm-client, O=cert-manager</code> , but they must be identical.	Client certificate used by management subsystem to authenticate with the Portal admin endpoint. Requires EKU clientAuth.
analytics-client-client	Client	Must be signed by the same authority as the one used for the matching ingress TLS certificate <code>analytics-client-ingress</code> . For a two data center deployment, both data centers must have an identical subject name. For example, both data centers subject name could be <code>CN=a7s-client-client</code> , or they could both be <code>CN=a7s-client-client, O=cert-manager</code> , but they must be identical.	Client certificate used by management subsystem to authenticate with analytics client endpoint. Requires EKU clientAuth.
analytics-ingestion-client	Client	Must be signed by the same authority as the one used for the matching ingress TLS certificate <code>analytics-ingestion-ingress</code> . For a two data center deployment, both data centers must have an identical subject name. For example, both data centers subject name could be <code>CN=a7s-ingestion-client</code> , or they could both be <code>CN=a7s-ingestion-client, O=cert-manager</code> , but they must be identical.	Client certificate used by gateway subsystem to authenticate with analytics ingestion endpoint. Requires EKU clientAuth.

2. **Management certificates**

These certificates apply to a single Management subsystem.

The Management subsystem has four public endpoints: *api-manager-ui*, *cloud-admin-ui*, *platform-api*, and *consumer-api*. Distinct TLS certificates can be set for each endpoint. However, if any two endpoints are identical, only one TLS certificate will be effective. When 2 or more endpoints are set to the same host, the secrets associated with the endpoints should be the same or contain the same certificate files.

The encryption-secret certificate is unique in that it is a secure random number. It is used to provide field level encryption in management (Cassandra) database. To set the encryption secret for the management database, use the following command: `apicup certs set SUBSYS CERT_NAME [KEY_FILE]` For example: `apicup certs set mgmt1 encryption-secret /path/to/keyfile`. See [Setting the encryption-secret for the management database](#)

Table 2. Management certificates

Certificate name	Usage	Requirements	Description
encryption-secret	secure random bytes	length: 128 bytes	Encryption secret used to do field level encryption in management (Cassandra) database
platform-api	Server	The host names for which the certificate is valid must include the platform-api endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: <i>store.acme.com</i> , the certificate can be one that is valid for host names matching <i>*.acme.com</i> .	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
consumer-api	Server	The host names for which the certificate is valid must include the consumer-api endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: <i>store.acme.com</i> , the certificate can be one that is valid for host names matching <i>*.acme.com</i> .	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
api-manager-ui	Server	The host names for which the certificate is valid must include the api-manager-ui endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: <i>store.acme.com</i> , the certificate can be one that is valid for host names matching <i>*.acme.com</i> .	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
cloud-admin-ui	Server	The host names for which the certificate is valid must include the cloud-admin-ui endpoint. A wildcard certificate can be used as the first element in a host name, for example, if the endpoint is: <i>store.acme.com</i> , the certificate can be one that is valid for host names matching <i>*.acme.com</i> .	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.
hub-endpoint	Server		Automated Testing Behavior UI and API endpoint
turnstile-endpoint	Server		Automated Testing Behavior UI and API endpoint

3. Portal certificates

These certificates apply to a single portal subsystem.

Table 3. Portal certificates

Certificate name	Usage	Requirements	Description
portal-admin-ingress	Server	host must match admin endpoint	TLS certificate used by ingress. The <code>portal-client</code> common certificate must be set prior to setting the <code>portal-admin-ingress</code> certificate. Requires EKU serverAuth. The <code>portal-admin-ingress</code> TLS certificate does not have any specific requirement on the authority signing it. If the certificate is auto-generated, it is signed by the <code>ingress-ca</code> .
portal-www-ingress	Server	host must match www endpoint	TLS certificate used by ingress. Requires EKU serverAuth. Public and user-facing.

4. Analytics certificates

These certificates apply to a single analytics subsystem.

Table 4. Analytics certificates

Certificate name	Usage	Requirements	Description
analytics-ingestion-ingress	Server	Required hosts: <ul style="list-style-type: none"> ingestion ingress endpoint *.<namespace> *.<namespace>.svc *.<namespace>.svc.cluster.local 	TLS certificate used by ingress. The <code>analytics-ingestion-client</code> common certificate must be set prior to setting the <code>analytics-ingestion-ingress</code> certificate. Requires EKU serverAuth. The <code>analytics-ingestion-ingress</code> TLS certificate does not have any specific requirement on the authority signing it. If the certificate is auto-generated, it is signed by the <code>ingress-ca</code> .

5. OVA/Appliance certificates

These certificates apply only to an appliance in a VMware environment. The `k8s-ca` and `appliance-client` certificates are auto-generated and cannot be set as custom certificates. These are used to set up the Kubernetes cluster in an OVA/Appliance.

Table 5. OVA/Appliance certificates

Certificate name	Usage	Requirements	Description
------------------	-------	--------------	-------------

Certificate name	Usage	Requirements	Description
k8s-ca	CA		Auto-generated CA certificate that forms the root of the certificate chain for the Appliance/Kubernetes cluster components
appliance-client	Client	signed by: k8s-ca	Auto-generated client certificate used to communicate with the Appliance API server. Requires EKU clientAuth.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Command reference

The APICUP installer includes the `certs` commands to set and manage certificates.

About this task

The APICUP installer can be used to set certificates for each subsystem during installation. If certificates are not explicitly set using the `apicup certs set` command, then default certificates are generated by APICUP. We recommend that certificates be set at installation time only (or carried over from an upgrade). The default certificates are self-signed, so they may not be optimal for external communication.

For a description of the certificates that can be set, see [Certificate reference](#). We recommend that all public and user-facing certificates be explicitly set, including `portal-www-ingress` and `api-gateway-ingress`, and the four management endpoints (`platform-api`, `consumer-api`, `api-manager-ui`, and `cloud-admin-ui`). Following is the help reference for the `apicup certs set` command:

```
apicup certs set --help
Set or clear certificates and keys

Usage:
  apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE] [KEY_FILE] [flags]

Flags:
  --clear    Clear out a certificate or key entry
  -h, --help help for set

Global Flags:
  --accept-license  Accept the license for API Connect
  --debug           Enable debug logging
```

Procedure

To set and clear certificates, complete the following steps:

1. Enter the `apicup certs set` command and complete the following values:

Table 1. `apicup certs set`

Command	Values	Result
<code>apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE] [KEY_FILE] [flags]</code>	Parameters are: <ul style="list-style-type: none"> SUBSYS - name of the subsystem to which the certificate applies CERT_NAME - name of the certificate; see Certificate reference for a list of certificates that can be set for each subsystem. CERT_FILE - Path to the certificate file in PEM format. KEY_FILE - Path to the private key file in PEM format. CA_FILE - Path to the Certificate Authority (CA) file. The contents of the file may be the concatenation of an intermediate CA and the root CA (in that order). Note: When setting the <code>root-ca</code> certificate, omit the <code>CA_FILE</code> parameter. 	Applies the certificate when the subsystem is installed.
<code>apicup certs set SUBSYS CERT_NAME [KEY_FILE] [flags]</code>	<code>KEY_FILE</code> - The file containing the encryption-secret for field level encryption in the management database. Applies only to the management subsystem. The certificate name is <code>encryption-secret</code> . The type is secure random bytes with a length of 128 bytes. For example, <code>apicup certs set mgmt1 encryption-secret /path/to/encryption-secret.bin</code> . Note: Do not specify any of the <code>[CERT_FILE KEY_FILE CA_FILE]</code> parameters when setting the encryption-secret.	Applies the <code>encryption-secret</code> when the management subsystem is installed.
<code>flags</code> <ul style="list-style-type: none"> <code>--clear</code> <code>--help</code> 	Flags are: <ul style="list-style-type: none"> <code>--clear</code> - Clears the specified certificate. For example, <code>apicup certs set mgmt1 encryption-secret --clear</code> <code>--help</code> - Displays help for the command. 	The specified certificate will be cleared. When making configuration changes such as changing endpoints, the corresponding certificate must be cleared so that a new certificate can be set.

2. The `apicup certs get` command retrieves a specific certificate for the specified subsystem.

```
apicup certs get --help
Get a certificate

Usage:
  apicup certs get SUBSYS CERT_NAME [flags]

Flags:
  -h, --help help for get
  -o, --output string output to file or - (stdout) (default "-")
```

`-t, --type string` type of object to return: cert, key, ca (default "cert")

Global Flags:

`--accept-license` Accept the license for API Connect
`--debug` Enable debug logging

Table 2. apicup certs get

Command	Values	Result
<code>apicup certs get</code> <code>SUBSYS CERT_NAME</code> <code>[flags]</code>	Parameters are: <ul style="list-style-type: none"> SUBSYS - name of the subsystem to which the certificate applies CERT_NAME - name of the certificate to retrieve; see Certificate reference for a list of certificates 	Returns the specified certificate for the specified subsystem.
<code>flags</code> <ul style="list-style-type: none"> <code>--output string</code> <code>--type string</code> <code>--help</code> 	Flags are: <ul style="list-style-type: none"> <code>--output string</code> - Specify a file for the retrieved values, or specify "-" to send to stdout. Default is "-" to send to stdout. For example, <code>apicup certs get mgmt1 --output myCertsFile</code> <code>--type string</code> - Returns only the specified type. If not specified, the type is cert. For example, <code>apicup certs get mgmt1 --type ca</code> <code>--help</code> - Displays help for the command. 	<ul style="list-style-type: none"> For <code>--output</code>: The specified certificate will be retrieved and sent to stdout or saved to the specified file For <code>--type</code>: Certificates will be retrieved that match the type specified.

3. List all certificates that have been set for a subsystem using the `apicup certs list` command. You can list the certificates at any time to summarize the certificates that have been set.

`apicup certs list -help`

List all configured certificates

Usage:

`apicup certs list SUBSYS [flags]`

Flags:

`-h, --help` help for list

Global Flags:

`--accept-license` Accept the license for API Connect
`--debug` Enable debug logging

Table 3. apicup certs list

Command	Values	Result
<code>apicup certs list SUBSYS</code> <code>[flags]</code>	Parameters are: <ul style="list-style-type: none"> SUBSYS - name of the subsystem for which you want to list certificates 	Returns a list of certificates that are configured for the subsystem.
<code>flags</code> <ul style="list-style-type: none"> <code>--help</code> 	Flags are: <ul style="list-style-type: none"> <code>--help</code> - Displays help for the command. 	Help text is displayed.

Following is example output from the `apicup certs list` command:

Common certificates

Name	Summary	Validation errors
<code>analytics-client-client</code>	CN: analytics-client-client SubjectKeyId: D9:DE:C8:6A:E9:E1:3E:30:48:71:E0:63:E3:09:51:AA AuthorityKeyId: 0B:37:61:5F:81:B3:67:5B:E0:F1:05:A6:6E:08:D5:8E	
<code>analytics-ingestion-client</code>	CN: analytics-ingestion-client SubjectKeyId: 27:60:BF:DF:6C:34:29:FE:8E:83:21:1B:C0:14:B2:9E AuthorityKeyId: 0B:37:61:5F:81:B3:67:5B:E0:F1:05:A6:6E:08:D5:8E	
<code>ingress-ca</code>	CN: ingress-ca SubjectKeyId: 0B:37:61:5F:81:B3:67:5B:E0:F1:05:A6:6E:08:D5:8E AuthorityKeyId: 5E:6D:5C:6E:2C:BE:50:F3:4E:EE:FD:02:76:86:6C:5A	
<code>portal-client</code>	CN: portal-client SubjectKeyId: 08:A8:57:A5:99:BC:79:FA:14:59:A4:98:6D:F7:43:C4 AuthorityKeyId: 0B:37:61:5F:81:B3:67:5B:E0:F1:05:A6:6E:08:D5:8E	
<code>root-ca</code>	CN: root-ca SubjectKeyId: 5E:6D:5C:6E:2C:BE:50:F3:4E:EE:FD:02:76:86:6C:5A AuthorityKeyId:	

Subsystem mgmt certificates

Name	Summary	Validation errors
<code>api-manager-ui</code>	CN: api-manager-ui SubjectKeyId: A3:C1:A1:4F:21:23:21:2F:1F:D7:87:30:E1:1E:33:A3 AuthorityKeyId: 0B:37:61:5F:81:B3:67:5B:E0:F1:05:A6:6E:08:D5:8E	
<code>appliance-client</code>	CN: appliance-client SubjectKeyId: 5C:FB:0F:5D:B8:BF:6F:89:CB:25:DD:54:31:A7:B4:63 AuthorityKeyId: 60:D9:B2:37:0B:17:FB:CD:FC:49:29:32:F6:A6:49:7C	
<code>cloud-admin-ui</code>	CN: cloud-admin-ui SubjectKeyId: E7:E2:D6:35:95:6B:D4:3B:F7:F7:9F:5F:DD:B8:02:E9 AuthorityKeyId: 0B:37:61:5F:81:B3:67:5B:E0:F1:05:A6:6E:08:D5:8E	
<code>consumer-api</code>	CN: consumer-api SubjectKeyId: 2A:80:EB:A6:31:9E:A5:C6:41:D9:1F:69:D1:9E:31:75 AuthorityKeyId: 0B:37:61:5F:81:B3:67:5B:E0:F1:05:A6:6E:08:D5:8E	
<code>encryption-secret</code>	2D:F9:61:0C:45:CB:6E:90:85:E0:0E:D3:DF:CC:B4:47	
<code>k8s-ca</code>	CN: k8s-ca SubjectKeyId: 60:D9:B2:37:0B:17:FB:CD:FC:49:29:32:F6:A6:49:7C AuthorityKeyId:	

```
platform-api      CN: platform-api
                  SubjectKeyId: 6D:E7:60:21:81:7E:F6:40:A4:9A:2F:88:35:D1:18:04
                  AuthorityKeyId: 0B:37:61:5F:81:B3:67:5B:E0:F1:05:A6:6E:08:D5:8E
```

4. The `apicup certs generate` command generates and sets default certificates. The `generate` command only generates and sets a certificate if it is not already set; it only sets the missing default certificates that have not been explicitly set using the `set` command. Execute the `generate` command before running the `apicup subsys install <SUBSYS>` command to confirm the certificates are correct before installing. It allows you to validate all certificates before performing the installation. The `generate` command is used as a tool to assist you when entering a combination of default and custom certificates. If you need to set specific certificates you can set them upfront (using `set`) and then generate the missing ones with default certificates. Or you can generate all certificates upfront and then override specific certificates to set custom certificates. Using `generate` helps to avoid validation errors during the installation procedure. Note that you must configure the subsystems and pass the `--validate` option before generating the default certificates.

```
apicup certs generate -help
Generate all unset certificates
```

```
Usage:
  apicup certs generate SUBSYS [flags]
```

```
Flags:
  -h, --help      help for generate
Global Flags:
  --accept-license  Accept the license for API Connect
  --debug           Enable debug logging
```

Table 4. apicup certs generate

Command	Values	Result
<code>apicup certs generate SUBSYS [flags]</code>	Parameters are: <ul style="list-style-type: none"> SUBSYS - name of the subsystem for which you want to generate certificates 	Generates certificates that have not been set for the subsystem. Generates self-signed certificates.
<code>flags</code> <ul style="list-style-type: none"> <code>--help</code> 	Flags are: <ul style="list-style-type: none"> <code>--help</code> - Displays help for the command. 	Help text is displayed.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details. For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Validation reference

Certificates are validated using several parameters.

The validations described in the following table are applied for all certificates, but are most helpful for custom certificates. For default certificates, the certificate validations will always pass, as the required elements are generated by APICUP. However, with custom certificates, some of the required elements may be missing or incorrect.

Validation	Messages	Error	See also/Action
Verify the certificate is set properly.	<code>certificate <cert> not set</code>	The certificate is not set.	
	<code>unable to load cert <cert></code>	The certificate is set but cannot be read.	
Verify certificate key usage (Extended Key Usage).	<code>unable to verify cert <cert>: missing key usage <n></code>	The certificate is missing the required key usage.	See Certificates Reference to see more information, including the type, for all certificates. See Setting custom certificates for tips on how to generate the EKUs for custom certificates.
Verify the certificate signing CA. If available, the CA file is loaded. Then the certificate is verified against the provided CA file, including enforcement of Extended Key Usage.	<code>unable to parse CA to verify cert <cert></code>	The CA file could not be parsed and loaded.	
	<code>unable to verify cert <cert></code>	The certificate failed verification against the provided CA file.	One possible reason for receiving this error is that the correct EKU is missing. For a custom certificate, see Setting custom certificates for information on generating EKUs.
Verify certificate hosts. The certificate must be valid for the hosts listed for the certificate in the Requirements column in the Certificates Reference.	<code>unable to verify cert <cert>: missing <host></code>	The certificate is not valid for the required host.	See Certificate reference for the required hosts.
Verify that a certificate that is being used as a CA is actually a CA.	<code>unable to verify cert <cert>: certificate is not a CA</code>	The certificate is not a valid CA.	
Verify client certificate match. The <code>portal-client</code> , <code>analytics-client-client</code> , and <code>analytics-ingestion-client</code> certificates are verified against the CA of, respectively, <code>portal-admin-ingress</code> , <code>analytics-client-ingress</code> , and <code>analytics-ingestion-ingress</code> .	<code>a CA certificate must be provided for this certificate</code>	The CA certificate is missing for one of the <code>portal-admin-ingress</code> , <code>analytics-client-ingress</code> , and <code>analytics-ingestion-ingress</code> .	The common certificates <code>portal-client</code> , <code>analytics-client-client</code> , and <code>analytics-ingestion-client</code> must be set prior to setting any custom certificates.

Validation	Messages	Error	See also/Action
	client cert cannot be verified against provided CA certificate	The verification failed.	

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Webhooks deployed and managed by the API Connect Operator

The API Connect Operator deploys and manages various Kubernetes API webhooks in the cluster to assist in management of its custom resources.

The webhooks included admission controllers and conversion webhooks.

Defaulting webhook

- Purpose**
 The defaulting webhook is a type of [Mutating Admission Webhook](#) which runs against Custom Resources (CRs) at **CREATE** or **UPDATE** time to populate default values in the CR's **spec**.
- Creation**
 Currently the defaulting webhook runtime is part of the API Connect Operator runtime, that is it exists within the API Connect Operator pod and container. When the operator boots, it creates **MutatingWebhookConfiguration** resources for each CRD (listed below). This **MutatingWebhookConfiguration** is a cluster-scope resource, but the configuration within will be specific to the namespace and operator instance which created it. If more than one instance of the API Connect Operator is deployed across a cluster (in different namespaces) there will be a set of webhook configurations for each API Connect Operator instance and namespace.

The name for the **MutatingWebhookConfiguration** resource for each CRD will take the following form:

```
<namespace>.<crd-name>.defaulter[.<component>].apiconnect.ibm.com
```

The following CustomResourceDefinitions utilize a defaulting webhook:

```
AnalyticsCluster
ApiconnectCluster
GatewayCluster
ManagementBackup
ManagementCluster
ManagementDBUpgrade
ManagementRestore
PortalCluster
```

- Lifecycle**
 While the defaulting webhook runtime itself lives within the API Connect Operator pod, the **MutatingWebhookConfiguration** is a cluster-scope resource and is stand-alone. When it is created, an **ownerReference** is set on it that references the API Connect Operator's **ClusterRole**. Thus, the lifecycle of the **MutatingWebhookConfiguration** resources will be linked with the **ClusterRole**, which is linked with the installation of the operator itself.

When the operator is uninstalled, the **MutatingWebhookConfiguration** resources for that operator instance are also removed.

- Example**
 The below output shows the defaulting webhook configurations created for an operator deployed in the **apiconnect-operator** namespace. One can be seen for each CRD.

```
$ oc get mutatingwebhookconfiguration
NAME
apiconnect-operator.analyticsclusters.defaulter.analytics.apiconnect.ibm.com    1    4d4h
apiconnect-operator.apiconnectclusters.defaulter.apiconnect.ibm.com            1    4d4h
apiconnect-operator.gatewayclusters.defaulter.gateway.apiconnect.ibm.com      1    4d4h
apiconnect-operator.managementbackups.defaulter.management.apiconnect.ibm.com  1    4d4h
apiconnect-operator.managementclusters.defaulter.management.apiconnect.ibm.com 1    4d4h
apiconnect-operator.managementdbupgrades.defaulter.management.apiconnect.ibm.com 1    4d4h
apiconnect-operator.managementrestores.defaulter.management.apiconnect.ibm.com 1    4d4h
apiconnect-operator.portalclusters.defaulter.portal.apiconnect.ibm.com         1    4d4h
```

Validating webhook

- Purpose**
 The validating webhook is a type of [Validating Admission Webhook](#) which runs against Custom Resources (CRs) at **CREATE** or **UPDATE** time to validate the CR contains a configuration which will yield an operable cluster. The CustomResourceDefinitions use OpenAPI schema validation for basic property checks (such as integer bounds and non-empty strings), but more complex validation of the configuration is done via the webhook.
- Creation**
 Currently the validating webhook runtime is part of the API Connect Operator runtime, i.e. it exists within the API Connect Operator pod and container. When the operator boots, it creates **ValidatingWebhookConfiguration** resources for each CRD (listed below). This **ValidatingWebhookConfiguration** is a cluster-scope resource, but the configuration within will be specific to the namespace and operator instance which created it. If more than one instance of the API Connect Operator is deployed across a cluster (in different namespaces) there will be a set of webhook configurations for each API Connect Operator instance and namespace.

The name for the `ValidatingWebhookConfiguration` resource for each CRD will take the following form:

```
<namespace>.<crd-name>.validator[.<component>].apiconnect.ibm.com
```

The following CustomResourceDefinitions utilize a validating webhook:

```
AnalyticsCluster
ApiconnectCluster
GatewayCluster
ManagementBackup
ManagementCluster
ManagementDBUpgrade
ManagementRestore
PortalCluster
```

- Lifecycle

While the validating webhook runtime itself lives within the API Connect Operator pod, the `ValidatingWebhookConfiguration` is a cluster-scope resource and is stand-alone. When it is created, an `ownerReference` is set on it that references the API Connect Operator's `ClusterRole`. Thus, the lifecycle of the `ValidatingWebhookConfiguration` resources will be linked with the `ClusterRole`, which is linked with the installation of the operator itself.

When the operator is uninstalled, the `ValidatingWebhookConfiguration` resources for that operator instance are also removed.

- Example

The below output shows the validating webhook configurations created for an operator deployed in the `apiconnect-operator` namespace. One can be seen for each CRD.

```
validatingwebhookconfiguration
NAME
apiconnect-operator.analyticsclusters.validator.analytics.apiconnect.ibm.com    1    4d4h
apiconnect-operator.apiconnectclusters.validator.apiconnect.ibm.com            1    4d4h
apiconnect-operator.gatewayclusters.validator.gateway.apiconnect.ibm.com       1    4d4h
apiconnect-operator.managementbackups.validator.management.apiconnect.ibm.com  1    4d4h
apiconnect-operator.managementclusters.validator.management.apiconnect.ibm.com  1    4d4h
apiconnect-operator.managementdbupgrades.validator.management.apiconnect.ibm.com 1    4d4h
apiconnect-operator.managementrestores.validator.management.apiconnect.ibm.com  1    4d4h
apiconnect-operator.portalclusters.validator.portal.apiconnect.ibm.com          1    4d4h
```

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Tips and tricks for using APICUP

The APICUP installer in Install Assist contains built-in time saving functions.

Introduction

This section describes tips and techniques for working with the APICUP installation commands. The APICUP installer creates charts and secrets that are then managed by Helm.

- [APICUP commands for the rotation of secrets on the Developer Portal subsystem](#)
- [Running Tiller with APICUP](#)
- [Entering multiple settings per command](#)
- [Entering multiple values](#)
- [Viewing the settings for a subsystem](#)
- [Validating the settings for a subsystem](#)
- [Output an installation plan](#)
- [Getting help for commands](#)
- [Getting help on a specific command](#)

APICUP commands for the rotation of secrets on the Developer Portal subsystem

To rotate the Developer Portal subsystem secrets, certificates, or both, run the following command:

```
apicup subsys rotate-secrets portal
```

Where:

- `portal` is the name of your Developer Portal subsystem.
- `--certs` (optional) is the list of certificates that you want to rotate. Listing an issuer will rotate all of the certificates that were issued by that issuer, for example, listing `portal-ca` will rotate the `portal-ca`, `portal-client`, and `portal-server` certificates.
- `--encryption-secret` (optional) is the value to set the encryption secret to, if the supplied secret exists in the environment. If not supplied, the rotated secret will be random.
- `--rotate-encryption-secret` (optional) determines whether the encryption secret is rotated. Can be set to `true` or `false`.
- `--wait` (optional) determines whether the command waits for the operation to complete or fail. Can be set to `true` or `false`.
- `--wait-timeout` (optional) is the duration in seconds of the command timeout. Default is 1m0s.

For example, to rotate the encryption secret to a random value run the following command:

```
apicup subsys rotate-secrets portal --rotate-encryption-secret true
```

The following example rotates the encryption secret to a named secret (note that first you must exec into the Developer Portal OVA to create the secret):

```
apicup subsys rotate-secrets portal --rotate-encryption-secret --encryption-secret my-new-secret
```

The following example rotates all of the Developer Portal certificates:

```
apicup subsys rotate-secrets portal --certs portal-ca
```

The following example rotates just the server and client certificates:

```
apicup subsys rotate-secrets portal --certs portal-server,portal-client
```

To list any Developer Portal secret rotations that were created by using the `rotate-secrets` command:

```
apicup subsys list-rotate-secrets portal --timeout 30
```

Where:

- `portal` is the name of your Developer Portal subsystem.
- `--timeout` (optional) is the duration in seconds of the command timeout. Default is 40 seconds.

To delete any Developer Portal secret rotations that were created by using the `rotate-secrets` command:

```
apicup subsys delete-rotate-secret portal --rotate-secret-name secret_name --wait true --wait-timeout 80
```

Where:

- `portal` is the name of your Developer Portal subsystem.
- `--rotate-secret-name` is the name of the Developer Portal secret rotation CR that you want to delete. You can find this name by running the `list-rotate-secrets` command.
- `--wait` (optional) determines whether the command waits for the operation to complete or fail. Can be set to `true` or `false`.
- `--wait-timeout` (optional) is the duration in seconds of the command timeout. Default is 1m0s.

Running Tiller with APICUP

To run Tiller in a namespace:

```
export TILLER_NAMESPACE=apic
```

Entering multiple settings per command

To configure multiple settings per command, enter a space between each setting and enter an equals sign (=) to configure the setting.

In the following examples, be sure to replace [spc] with an actual space.

You can set multiple database parameters on one line:

```
apicup subsys set mgmt cassandra-max-memory-gb=9[spc]cassandra-cluster-size=3[spc]cassandra-volume-size-gb=16[spc]cassandra-backup-protocol=sftp
```

You can set all endpoints on one line:

```
apicup subsys set mgmt platform-api=my.platform.com[spc]api-manager-ui=my.apim.com[spc]cloud-admin-ui=my.cloud.com[spc]consumer-api=my.consumer.com
```

Entering multiple values

Separate multiple values for a key/value pair with commas.

```
apicup subsys set mgmt dns-servers=8.8.8.8,4.4.4.4 search-domains=a.com,b.com
```

Viewing the settings for a subsystem

To view the current values that are set for a subsystem, enter the following command: `apicup subsys get <subsys_name>`. For example: `apicup subsys get mgmt` outputs the current values for the subsystem named `mgmt` and provides a description of each value. is organized into Kubernetes settings and Subsystem settings. Following is an example of the output from the `get` command

Figure 1. Output for the `get` command

```
Endpoints
=====
Name          Value          Description
----          -
api-manager-ui  FQDN of API manager UI endpoint
cloud-admin-ui  FQDN of Cloud admin endpoint
consumer-api    FQDN of consumer API endpoint
platform-api    FQDN of platform API endpoint
```

```
Error: Subsystem validation failure. Run with --validate to see details
```

Validating the settings for a subsystem

The values set for a subsystem can be validated for syntax by entering the `--validate` option for the `get` command: `apicup subsys get <subsys_name> --validate`. For example: `apicup subsys get mgmt --validate` validates the current values for the subsystem named `mgmt`. In the following example of the output for the `--validate` option, the check mark indicates a valid setting. The x indicates an invalid setting with an error message provided.

Figure 2. Output for the `--validate` option

```
Endpoints
=====
Name                               Value
----                               -
api-manager-ui                      X api-manager-ui is not a valid hostname
cloud-admin-ui                      X cloud-admin-ui is not a valid hostname
consumer-api                         X consumer-api is not a valid hostname
platform-api                        X platform-api is not a valid hostname
```

Output an installation plan

Using APICUP, you can generate an installation plan and confirm it is correct prior to running the installation. You can then install the subsystem from the plan.

To output an installation plan, enter the following command:

```
apicup subsys install SUBSYS --out=install-plan
```

where `<install-plan>` is the name of the directory where the installation plan will be stored.

In the example, a directory named `install-plan` is created in the project directory. The `myProject/install-plan` directory contains the configuration parameters for the subsystem.

To install the subsystem from the `install-plan`, enter the following command from the project directory:

```
apicup subsys install SUBSYS --plan-dir=<full-path-to-plan-directory>
```

where `<full-path-to-plan-directory>` is the full qualified path to the plan directory.

Following are general rules for installing from the installation plan:

- Never edit the files in the output directory directly. Instead, if changes are needed, update the parameters using APICUP and generate a new plan.
- Always run APICUP commands from the original project directory created during the initial product installation. The project directory contains the `apiconnect-up.yml` file.
- You can generate the plan in any location, but the `install` command must be run from the project directory. Enter the full path to the plan as the argument to `--plan-dir` to perform an installation.

The plan must be current with the project and the certificates. If the plan is older than the last modification date of the project or certificates, you will receive an error message such as:

```
the project was modified since the plan was generated, regenerate plan or skip this check
with a --skip-health-check flag in the command
```

or

```
the certs were changed since the plan was generated, regenerate plan or skip this check with
a --skip-health-check flag in the command
```

Getting help for commands

You can get help for all commands by entering: `apicup --help`. Following is an example of the output:

Figure 3. Help for Install Assist `apicup` commands

```
APIConnect Install Assist
Usage:
  apicup [command]

Available Commands:
  certs          Subsystem certificates
  completion     Generates bash or zsh completion scripts
  help          Help about any command
  hosts         Commands to configure subsystem hosts
  iface         Commands to configure hosts interfaces
  init          Create a new APIConnect UP project
  registry-upload Retag and upload images to custom registry
  server        Starts the APIConnect cluster operator
  subsys        Subsystem commands
  version       Get the APIConnect UP version

Flags:
  --accept-license  Accept the license for API Connect
  --debug          Enable debug logging
  -h, --help       help for apicup

Use "apicup [command] --help" for more information about a command.
```

Getting help on a specific command

For help on a specific command, enter `--help` after the command. For example, `apicup subsys get mgmt --help` prints out the usage and flags for the `get` command. For example:

Figure 4. Help for get command

```
Get subsystem properties

Usage:
  apicup subsys get SUBSYS [flags]

Flags:
  --endpoints    List endpoints (default true)
  -h, --help     help for get
  --platform     List platform settings (default true)
  --subsystem    List subsystem settings (default true)
  --validate     Validate settings

Global Flags:
  --accept-license  Accept the license for API Connect
  --debug           Enable debug logging
```

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details. For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Installing API Connect

Use these instructions to install or upgrade a deployment of API Connect on VMware.

- [IBM API Connect Version 10 software product compatibility requirements](#)
Ensure that you install the minimum API Connect operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.
- [Requirements for initial deployment on VMware](#)
Review the requirements and considerations for deploying in a VMware environment.
- [What's new for v10 installation](#)
Summary of installation changes for API Connect v10 on VMware.
- [First steps for deploying in a VMware environment](#)
The first steps in deploying in a VMware environment are to obtain the API Connect distribution files and to create a project directory.
- [Signature verification by using PGP](#)
You can verify the integrity of files to ensure that they originated from IBM and are not modified.
- [Deploying the Management subsystem](#)
You can create a virtual server by deploying the relevant IBM API Connect OVA file on a VMware virtual server. Create all of the virtual servers that you want to use in your cloud.
- [Installing the Analytics subsystem](#)
Install the IBM API Connect Analytics subsystem.
- [Deploying the Developer Portal](#)
You create a Developer Portal node by deploying the Developer Portal OVA template. After you deploy the Developer Portal OVA template, you can install the Developer Portal.
- [Deploying DataPower Gateway](#)
API Connect uses IBM DataPower® Gateway to provide the gateway service.
- [Troubleshooting installation and upgrades on VMware](#)
Review the following troubleshooting guidance if you encounter a problem while installing or upgrading API Connect on VMware.
- [Post-deployment steps](#)
When all subsystems are deployed, use the admin account to access the Cloud Manager administrative console and begin configuration. Optionally, take VMware snapshots of the VMs.
- [Configuring API Connect subsystems in a cluster](#)
This topic describes how to configure a cluster of API Connect subsystems (management server, analytics, and Developer Portal) with three VMs for each subsystem, for use with a load balancer, to support a high availability (HA) environment.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details. For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

IBM API Connect Version 10 software product compatibility requirements

Ensure that you install the minimum API Connect operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.

To generate an API Connect requirements report, complete the following steps:

1. Open the [Detailed system requirements for a specific product](#) page on the IBM Software Product Compatibility Reports site.
2. Search for the IBM API Connect product.
3. In the Search results list, select IBM API Connect.
4. From the Version list, select the required version.

5. Use the Filters to refine the contents of the requirements report.
6. Click Submit to generate your requirements report.

Important: When reviewing the report to determine your deployment needs, you should treat the stated CPU and memory requirements as reserved VMware capacity. For example, if the system requirements are 4 CPU and 16GB RAM, then those resources should be available at all times from the underlying hardware and should not be coming from an over-committed pool of resources.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Requirements for initial deployment on VMware

Review the requirements and considerations for deploying in a VMware environment.

- [Deployment requirements on VMware](#)
- [Disk space requirements](#)
- [API Connect configuration on VMware](#)
- [Passwords and certificates](#)
- [Setting and using a hashed default password](#)
- [DataPower Gateway for API Connect on VMware](#)

Deployment requirements on VMware

- Ensure you have supported software requirement versions. See [IBM API Connect Version 10 software product compatibility requirements](#)
- Do not change the hardware version of the OVA during installation. Do not attempt to use an unsupported version, even if VMWare indicates compatibility with other versions. For example, when deploying IBM API Connect, the VMware UI for the APIC OVAs might show information like:

Table 1.

Property	Value
Guest OS	Ubuntu Linux (64-bit)
Compatibility	ESXi 5.5 and later (VM version 10)
VMware Tools	Yes
CPUs	4
Memory	16 GB

Although the **Compatibility** field shows **ESXi 5.5 and later (VM version 10)**, API Connect supports only the versions listed in [IBM API Connect Version 10 software product compatibility requirements](#). Do not change the VM version of the OVA. Ensure that the **Compatibility** field values are not changed, and remain **ESXi 5.5 and later (VM version 10)**.

Attempts to modify the VMware compatibility can typically result in failure to boot the OVA, as per <https://kb.vmware.com/s/article/52683>.

- Ensure that your operating system has one of the supported utilities for creating ISOs. The apicup installer uses **mkisofs** on Linux, and **hdiutil** on macOS. For Windows, you need software that creates ISO files using **mkisofs**, such as CDRTools. Verify that the utility you will use is located in a directory that is referenced by the PATH environment setting for your operating system. When creating the ISO, if you encounter the message **Error: unable to create config ISO for host**, verify that you have sufficient permissions to run the command.
- Important:
Use a single APICUP project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.

The original project directory created with APICUP during the initial product installation (for example, *myProject*) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. Note that the endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored or upgraded system. A good practice is to backup the original project directory to a location from where it can always be retrieved.

Endpoints for the components cannot change between deployments. However, the endpoints for the VMware hosts can be modified for the new deployment.

- For each subsystem, gather the following networking settings, which you will need to supply during configuration:

Table 2.

Required information	Value for your system
IP address of the server	
IP address of the server	
Domain of the server	
IP addresses of the name servers	
IP address of the network gateway (not DataPower® gateway) for the server	
Name of the Ethernet interface	
VLAN	

Some virtualization environments require additional information when you create and configure virtual machines. For example, it might be necessary to assign a specific VLAN ID, Resource Pool, or Datastore. Please refer to information provided by your virtualization environment administrators.

Disk space requirements

- For Version 10, the data disk requirement for the management server is 200 GB. The boot disk requires 100 GB, so a minimum of 300 GB is needed for the management subsystem. You specify the data disk size when you [Deploy the OVF template wizard](#) in the VMware vSphere Web Client.
- The Developer Portal disk requirements vary with usage scenarios. See [Table 1](#).

- Before you install, review all the minimum hardware requirements listed on the Hardware tab in the Software Product on the Compatibility Reports for API Connect. Follow the instructions in [IBM API Connect Version 10 software product compatibility requirements](#).

API Connect configuration on VMware

- API Connect cannot be deployed on NFS.
- The time zone for API Connect pods is set to UTC. In API Connect deployments on VMware, the operating system time zone is also set to UTC. Do not change the time zone for the pods or the operating system.
- Ensure that the time settings match (within a few seconds) between the machine running `apicup` and the VMware `Host` clock. To verify the VMware host clock setting, see <https://kb.vmware.com/s/article/1003736>.

If the clocks are too different, the installation can fail because of invalid certificates due to time discrepancies.

- Deploying multiple similar subsystems in a single namespace is not supported. For example, deploying two management subsystems, `mgmt1`, `mgmt2` in a single namespace where `apiconnect` operator is installed.
- API Connect requires a dedicated IP range for deployment of the Kubernetes pod and Kubernetes service networks. These IP addresses cannot conflict with IP addresses used by other resources in your deployment, such as SMTP servers or user registries. The default values are 172.16.0.0/16 and 172.17.0.0/16, respectively. If a /16 subnet overlaps with existing IPs on the network, a CIDR as small as /22 is acceptable. If the default ranges conflict with other programs, you can modify the API Connect ranges during initial installation. Note that you cannot modify them once an appliance has been deployed. Follow the instructions for your subsystem if you want to modify either of the IP ranges.
- Only static IP addresses that are specified during the `apicup` project configuration before the installation of the OVA's are supported.
- Designated host names must have wildcard aliases or host aliases, which ensures that the different endpoints work together. For example, `*.hostname.mycompany.com`.
- Endpoints cannot contain the underscore character `"_"` or uppercase characters.
- Host names that are used to create endpoints cannot contain the underscore character `"_"` or uppercase letters.
- Kubernetes ingress limits the character set for DNS names to not support the underscore character `"_"`. This means you cannot specify underscores in domain names that are used as endpoints. For example, `my_domain.bar.com` and `my.domain_abc.com` are not supported for `<xxx>.<hostname>.<domainname>`, and will cause an error. For example:

```
Invalid value: "my_domain.bar.com": a DNS-1123 subdomain must consist of lowercase alphanumeric characters, '-' or '.', and must start and end with an alphanumeric character (e.g. 'example.com', regex used for validation is '[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*)'
```
- Note that you cannot change host names or DNS names on a running cluster.
- For Analytics, the installer specifies a default value of 16 GB for `es-max-memory-gb`. The minimum value for this setting is 12 GB.
- Decide the `deployment-profile` to use for the installation.

Table 3. Deployment profiles

deployment-profile	Description
Development	Development deployment-profile deploys a subsystem with the scale of one. Development deployment-profile is recommended for development, testing, and demonstration purposes. Values are specific to each subsystem. The development deployment-profile is not recommended for production environments because it does not provide high availability. <code>apicup subsys set mgmt deployment-profile=n1xc4.m16</code>
Production	Production deployment-profile deploys in high availability deployment-profile for a production environment. Values are specific to each subsystem. For example, for the management subsystem: <code>apicup subsys set mgmt deployment-profile=n3xc4.m16</code>

Use of production deployment-profile is supported only on installations with three or more nodes. Installations with less than three nodes must use a development deployment-profile. If you install in a production deployment-profile with only a single node, some pods can remain in a pending state. To avoid having pods remain pending, either install in development deployment-profile or add additional nodes.

Note that a deployment-profile is set for each subsystem type: Management, Analytics, and Developer Portal.

- For additional considerations for configuring clusters, see [Configuring API Connect subsystems in a cluster](#). Important: For best performance it is recommended that the network latency between any 2 nodes be as low as possible. Do not configure nodes from the same subsystem cluster across multiple data centers with a high latency network. A high latency network is one that experiences more than 30ms latency between nodes.
- Configure a remote server for logging. Follow these instructions: [Configuring remote logging for a VMware deployment](#). Pods are terminated during an upgrade, and the logs will be lost if not stored remotely.

Passwords and certificates

- When creating configuration files for use in generating an ISO image for VMware, ensure that your working directories are secure. The VMware configuration requires an ISO image that contains a plain text password to be used to unlock the VMware data disk. This means that the API Connect project configuration file `apiconnect-up.yml`, and the `/user-data` directory for each host, contain the passwords you specified. This configuration information is used to create the ISO image that you combine with the `..ova` distribution files when deploying (unlocking) the VMware data disk.
- You can use `apicup` to specify an `ssh` keyfile that contains a public certificate for using `ssh` to log in to a virtual machine. Logging in through `ssh` is preferred because it is more secure than password-based login.
- Default certificates are generated for each subsystem by the `apicup subsys install` command. If certificates are not explicitly set using the `apicup certs set` command, then default certificates are automatically generated by `apicup`. The default certificates are self-signed, so they may not provide a level of trust suitable for external communication. See [Working with certificates](#).

Setting and using a hashed default password

During configuration of the Management, Analytics, and Developer Portal subsystems, you create a password to use to log in to the management console for the first time. You must use a password hashing utility to hash the password. You then use `apicup` to assign this hashed password to the subsystem. These configuration steps ensure that the password is not stored in plain text on the data disk.

The syntax of the `apicup` command is:

```
apicup subsys set mgmt default-password='hashed_password'
```

Usage notes:

- The **default-password** is for the **apicadm** user account on the Appliance.
- The password for **apicadm** can be used **only** to log in through the VMware console. You cannot use it to **ssh** into the Appliance as an alternative to using the **ssh-keyfiles**. Interactive login for **ssh** is disabled.
- The **default-password** value configured is only used during initial installation (first boot) of each virtual appliance. Changing the value, then regenerating the ISO, and attaching the new ISO to the virtual appliance does not change the **apicadm** password.
- The **default-password** must be hashed. If it is plain text, you will not be able to log into the Appliance through the VMware console. When you use **apicup** to set or get **default-password**, **apicup** ensures that the hash type of the password is one of the following:
 - MD5
 - SHA1
 - SHA256
 - SHA512
 - BCRYPT
 - MD5-Crypt
- When using **apicup** to set a default password for a subsystem, be aware of syntax differences between operating systems. Windows requires double-quotes. Linux and OSX require single quotes.

Operating system	Command syntax
Linux or OSX	<code>apicup subsys set mgmt default-password='hashed_password'</code>
Windows	<code>apicup subsys set mgmt default-password="hashed_password"</code>

- You can use the **passwd** command (on the appliance) to change the **apicadm** password.
- When using the VMware Remote console to login to the appliance, be aware that the keyboard layout is English. This can cause a problems with hashed passwords, if you created the ISO on a system with a different keyboard layout and you used special characters or symbols. Passwords are hashed when you set the password that you enter to log into your Management appliance for the first time, and when you create hosts.

DataPower Gateway for API Connect on VMware

- Installation and configuration of DataPower Gateway on an appliance (physical or virtual) is completed after you install the API Connect subsystems. For the gateway service in a VMware environment, use the instructions in [Deploying DataPower Gateway](#).
- Ensure that DataPower Gateway firmware version you plan to install is compatible with the API Connect Management server version.
Note: For API Connect Version 10.x, DataPower and API Connect releases may be within one fix pack of each other. For example, API Connect v10.0.1.n runs with DataPower Gateway 10.0.1.n, v10.0.1.n-1, or v10.0.1.n+1.
Important exception: Version 10.0.1.4-eus is not backwards compatible with 10.0.1.3. For example, API Connect 10.0.1.4-eus is not compatible with DataPower Gateway 10.0.1.3. If you deployed API Connect 10.0.1.4-eus, you must deploy either DataPower Gateway 10.0.1.4 or DataPower Gateway 10.0.1.5.

However, before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in [IBM API Connect Version 10 software product compatibility requirements](#) to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software, Integration Middleware, and view the list of compatible DataPower Gateway versions.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

What's new for v10 installation

Summary of installation changes for API Connect v10 on VMware.

- Changes to **apicup** settings:
 - **license-use**. Values changed: **Production** is now **production**. **Nonproduction** is now **nonproduction**.
 - **mode** is deprecated and replaced by **deployment-profile**. Each subsystem (Management, Analytics, Portal) has separate values for development profile and production profiles. For example, for the management subsystem the development profile value is **n1xc4.m16**. The production profile value is **n3xc4.m16**.
 - Deprecated settings:
 - **az-name** - no longer used with the Management subsystem
 - **cross-az-peers** - no longer used with the Management subsystem
 - **cassandra-max-memory-gb** - no longer used with the Management subsystem
 - **es-memory-gb** - no longer used with the Analytics subsystem.
 - All **cassandra-backup-*** settings are no longer used with the Management subsystem. The Cassandra database is deprecated and replaced by Postgres.
 - **cassandra-backup-auth-pass**
 - **cassandra-backup-auth-user**
 - **cassandra-backup-host**
 - **cassandra-backup-path**
 - **cassandra-backup-port**
 - **cassandra-backup-protocol**
 - **cassandra-backup-schedule**
- The minimum size data disk for the Management system increases from 150 GB in v2018 to 200 GB in v10. When combined with the 100 GB requirement for the root disk (unchanged), you need 300 GB for the Management subsystem.
- Upon reboot, any extra disk that was added to the VM is picked up and added to the secure storage (data disk).

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

First steps for deploying in a VMware environment

The first steps in deploying in a VMware environment are to obtain the API Connect distribution files and to create a project directory.

Before you begin

- Review [Requirements for initial deployment on VMware](#).
- See [What's new for v10 installation](#)
- See also [Configuring API Connect subsystems in a cluster](#).

About this task

In these First Steps, you will use Install Assist (**apicup**) to create a project directory that contains the configuration file **apiconnect-up-v10.yml**. When you configure the first subsystem, such as the Management Service, the subsystem configuration settings are placed in the file.

When you want to configure a second subsystem, it is important that you reuse the same project directory. This means that you only need to download Install Assist once, and create a project directory once. The configuration settings for the second subsystem are added to the existing **apiconnect-up-v10.yml**. In this way, the second subsystem, such as Developer Portal, can access the configuration information needed to interact with the first subsystem.

After completing these First Steps, follow the links to instructions for configuring your subsystem. You will specify configuration settings, create an ISO of the subsystem configuration, and then use VMware to deploy the distribution file (.ova file) for the subsystem with your ISO. Note that you create a separate ISO for each subsystem.

Installation and configuration of DataPower® Gateway on an appliance (physical or virtual) is completed after you install the API Connect subsystems. For the gateway service in a VMware environment, use the instructions in [Deploying DataPower Gateway](#).

Note:

- For upgrades, do not use the procedures on this page. See [Upgrading API Connect](#).
- Some **apicup** commands have changed from previous versions of API Connect. See [What's new for v10 installation](#).
- When maintaining API Connect, do not use **kubect1 exec** commands to access API Connect pods unless advised by IBM. Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

Procedure

1. Obtain the API Connect files.

The following files are used for initial deployment on VMware:

IBM® API Connect <version> Management for VMware
Management subsystem files

IBM® API Connect <version> Developer Portal for VMware
Developer Portal subsystem files

IBM® API Connect <version> Analytics for VMware
Analytics subsystem files

IBM® API Connect <version> Install Assist for <operating_system_type>
The apicup installation utility. Required for all installations on VMware.

IBM® API Connect <version> Toolkit for <operating_system_type>

Toolkit command line utility. Packaged standalone, or with API Designer or Loopback:

- IBM® API Connect <version> Toolkit for <operating_system_type>
- IBM® API Connect <version> Toolkit with Loopback for <operating_system_type>
- IBM® API Connect <version> Toolkit Designer with Loopback for <operating_system_type>

Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See [Installing the toolkit](#).

IBM® API Connect <version> Local Test Environment

Optional test environment. See [Testing an API with the Local Test Environment](#)

IBM® API Connect <version> Security Signature Bundle File

Checksum files that you can use to verify the integrity of your downloads.

2. Select one of the following actions:

- If you are configuring your first subsystem, go to step [3](#).
- If you have already configured a subsystem, go to step [5](#).

3. Install the installation utility.

- a. Locate the apicup installation utility file for your operating system.
- b. Rename the file for your OS type to **apicup**. Note that the instructions in this documentation refer to **apicup**.
- c. OSX and Linux® only: Make the apicup file an executable file by entering the following command:

```
chmod +x apicup
```

d. Set your path to the location of your apicup file.

- For the OSX and Linux operating systems:

```
export PATH=$PATH:/Users/your_path/
```

- For the Windows operating system:

```
set PATH=c:\your_path;%PATH%
```

4. Create a project called *myProject* and optionally copy the `apicup` executable into the project directory:
 - a. Create a project:

```
apicup init myProject
```

- b. Read and accept the license agreement.
 - c. Optionally, copy the `apicup` executable into the *myProject* directory or folder created by the `apicup init` command.

Important:

Use a single APICUP project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.

The original project directory created with APICUP during the initial product installation (for example, *myProject*) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. Note that the endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored or upgraded system. A good practice is to backup the original project directory to a location from where it can always be retrieved.

Endpoints for the components cannot change between deployments. However, the endpoints for the VMware hosts can be modified for the new deployment.

The `apiconnect-up-v10.yml` file is created in that directory.

Important: The `apiconnect-up-v10.yml` file must be in a secure and permanent location. The file contains password information and other information that is exposed in text format. Ensure that the project directory is secure.

5. Continue with the configuration steps for your subsystem:

- [Deploying the Management subsystem](#)
- [Deploying the Analytics subsystem](#)
- [Deploying the Developer Portal](#)

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Signature verification by using PGP

You can verify the integrity of files to ensure that they originated from IBM and are not modified.

About this task

You can use code signatures to verify that a downloaded file was created by IBM and that no bits in the file were changed. The signature files that are used are `*.asc`. The key/cert file is `APICHURSLEY.pub.gpg`.

Procedure

1. Import the public key.

```
$ gpg --import APICHURSLEY.pub.gpg
gpg: key D43AB29897005BF2: public key "APICHURSLEY" imported
gpg: Total number processed: 1
gpg:          imported: 1

$ gpg --list-key --fingerprint APICHURSLEY
pub   rsa2048 2020-02-17 [SCEA]
     1467 C004 A754 4718 7C6B 19DF D43A B298 9700 5BF2
uid           [ unknown ] APICHURSLEY
```

When the key is imported, it does not need to be imported again. It is not signed, but you should make a note of the fingerprint so you can compare to make sure that the key is IBM's:

```
1467 C004 A754 4718 7C6B 19DF D43A B298 9700 5BF2
```

2. Verify the files.

```
$ $ gpg --verify helper_files.zip.asc
gpg: assuming signed data in 'helper_files.zip'
gpg: Signature made Mon 28 Sep 17:35:17 2020 PDT
gpg:          using RSA key D43AB29897005BF2
gpg: Good signature from "APICHURSLEY" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: 1467 C004 A754 4718 7C6B 19DF D43A B298 9700 5BF2
```

The verification shows that the key matches the signature and that shows the fingerprint of the key, which should match the import:

```
1467 C004 A754 4718 7C6B 19DF D43A B298 9700 5BF2
```

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Deploying the Management subsystem

You can create a virtual server by deploying the relevant IBM® API Connect OVA file on a VMWare virtual server. Create all of the virtual servers that you want to use in your cloud.

Before you begin

Before you deploy:

- Review the [Deployment requirements on VMware](#).
- Review the [API Connect configuration on VMware](#).
- Review [What's new for v10 installation](#)
- For information on deploying a cluster, see [Configuring API Connect subsystems in a cluster](#)
- If you are upgrading from a previous version, see [Upgrading API Connect](#).

About this task

You must deploy the API Connect OVA template to create each Management virtual server that you want in your cloud.

Attention: The following settings apply to features that are currently not supported, and should not be modified:

- Subsystem settings: test-and-monitor-enabled
- Certificate settings: hub, turnstile

Procedure

Complete each of the following tasks in order:

1. [Configuring the management subsystem](#)
2. [Deploying the management subsystem OVA file](#)
3. [Verify installation of the management subsystem](#)

What to do next

If you want to deploy an API Connect Analytics OVA file, continue with [Deploying the Analytics subsystem](#).

If you want to deploy an API Connect Developer Portal OVA file, continue with [Deploying the Developer Portal](#).

Identify the DataPower® appliances to be used as gateway servers in the API Connect cloud and obtain the IP addresses.

- [Configuring the management subsystem](#)
Specify configuration properties for your management subsystem, and create an ISO.
- [Deploying the management subsystem OVA file](#)
After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.
- [Verify installation of the management subsystem](#)
Verify that deployment of the management subsystem OVA file succeeded.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Configuring the management subsystem

Specify configuration properties for your management subsystem, and create an ISO.

Before you begin

Review [Deploying the Management subsystem](#)

About this task

Use the `apicup` installation utility to specify configuration settings for your management subsystem.

Procedure

1. Ensure that you obtained the distribution file and have a project directory, as described in [First steps for deploying in a VMware environment](#).
2. Change to the project directory.

```
cd myProject
```

3. Create a management subsystem.

```
apicup subsys create mgmt management
```

Where:

- *mgmt* is the name of your management server that you are creating. You can assign it any name, as long as the identifier consists of lowercase alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character.
- *management* indicates that you are creating a management microservice.

The API Connect Helm charts are deployed into the default namespace. You do not need to specify a namespace.

Tip: At any time, you can view the current management subsystem values in the apiconnect-up.yml by running the `apicup subsys get mgmt` command:

```
apicup subsys get mgmt
```

If you have not yet configured the subsystem, the command might return errors. Also, if you have not updated the value, a default value is listed, if there is one that is available.

After configuration is complete, you can view output similar to the following sample:

Appliance settings

```
=====
```

Name	Value
Description	-----

additional-cloud-init-file	
(Optional) Path to additional cloud-init yml file	
data-device	sdb
VM disk device (usually `sdb` for SCSI or `vdb` for VirtIO)	
default-password	
\$6\$rounds=4096\$vtcqpAVK\$dzqrOeYP33WTVTug38Q4Rld5l8TmdQgezzTnkX/PFwkzTiZ2S0CqNRr1S4b08tOc4p.OEg4BtzBe/r8RAk.gW/	
(Optional) Console login password for `apicadm` user, password must be pre-hashed	
dns-servers	[8.8.8.8]
List of DNS servers	
extra-values-file	
(Optional) Path to additional configuration yml file	
k8s-pod-network	172.16.0.0/16
(Optional) CIDR for pods within the appliance	
k8s-service-network	172.17.0.0/16
(Optional) CIDR for services within the appliance	
public-iface	eth0
Device for API/UI traffic (Eg: eth0)	
search-domain	[subnet1.example.com]
List for DNS search domains	
ssh-keyfiles	[/home/vsphere/.ssh/id_rsa.pub]
List of SSH public keys files	
traffic-iface	eth0
Device for cluster traffic (Eg: eth0)	

Subsystem settings

```

FQDN of Test and Monitor hub endpoint, only required if Test and Monitor is enabled	
management-replication	
FQDN of Management replication endpoint, only required if HA is enabled	
platform-api	platform-api.testsrv0231.subnet1.example.com
FQDN of platform API endpoint	
turnstile	
FQDN of Test and Monitor turnstile endpoint, only required if Test and Monitor is enabled	

4. For production environments, specify `deployment-profile=n3xc4.m16`.

```
apicup subsys set mgmt deployment-profile=n3xc4.m16
```

The `deployment-profile=n3xc4.m16` parameter indicates that you are deploying in high availability (HA) mode for a production environment. The `deployment-profile=n1xc4.m16` indicates a system for use in development and testing. For more information, see [Requirements for initial deployment on VMware](#).

5. Specify the license version you purchased.

```
apicup subsys set mgmt
license-use=<license_type>
```

The `license_type` must be either `production` or `nonproduction`. If not specified, the default value is `nonproduction`.

6. Optional: Configure backups of the subsystem. Note that once you set up scheduled backups, you can also run backups on-demand. Follow the instructions in [Configure your Management subsystem backup](#).

Important: It is highly recommend that you configure backups and also take additional steps to ensure that your configuration and data can be restored in the event of a disaster event. See [Disaster recovery of the management subsystem on VMware](#).

7. Optional: Configure your logging.

Logging can be configured at a later time, but you must enable it before installation to capture the log events from the installation.

- Complete the procedure at [Configuring remote logging for a VMware deployment](#).
- Enter the following command to create the log file:

```
apicup subsys set mgmt additional-cloud-init-file=config_file.yml
```

8. Enter the following commands to update the `apiconnect-up.yml` with the information for your environment:

- Set your search domain. Multiple search domains should be separated by commas.

```
apicup subsys set mgmt search-domain=your_search_domain
```

Where `your_search_domain` is the domain of your servers, entered in all lowercase. Setting this value ensures that your searches also append these values, which are based on your company's DNS resolution, at the end of the search value. A sample search domain is `mycompany.example.com`.

Ensure that the value for `your_search_domain` is resolved in the system's `/etc/resolv.conf` file to avoid "502" errors when accessing the Cloud Manager web site. For example:

```
# Generated by resolvconf
search your_search_domain ibm.com other.domain.com
```

- Set your domain name servers (DNS).

Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

```
apicup subsys set mgmt dns-servers=ip_address_of_dns_server[,ip_address_of_another_dns_server_if_necessary]
```

- Use `apicup` to set your endpoints.

You can use wildcard aliases or host aliases with your endpoints.

Optionally, you can specify all endpoints with one `apicup` command.

Note: You cannot specify the underscore character "_" in domain names that are used in endpoints. See [API Connect configuration on VMware](#).

Table 1. Management subsystem endpoints

Setting	Endpoint host description
<code>platform-api</code>	Platform API endpoint. The host where your platform API calls are routed. <code>apicup subsys set mgmt platform-api=platform-api.hostname.domain</code>
<code>consumer-api</code>	Consumer API endpoint. The host where your consumer API calls are routed. <code>apicup subsys set mgmt consumer-api=consumer-api.hostname.domain</code>
<code>cloud-admin-ui</code>	Cloud admin user interface API endpoint. The host where your cloud administrator user-interface API calls are routed. <code>apicup subsys set mgmt cloud-admin-ui=cloud-admin-ui.hostname.domain</code>
<code>api-manager-ui</code>	API Manager user interface endpoint. The host where your API Manager API calls are routed. <code>apicup subsys set mgmt api-manager-ui=api-manager-ui.hostname.domain</code>
<code>hub</code>	The core microservice components for the Automated API behavior testing capability. <code>apicup subsys set mgmt hub hub.hostname.domain</code>
<code>turnstile</code>	Allows for communication between the Test pods and the API Management subsystem. <code>apicup subsys set mgmt turnstile turnstile.hostname.domain</code>

9. Set a Public key.

```
apicup subsys set mgmt ssh-keyfiles=path_to_public_ssh_keyfile
```

Setting this key enables you to use `ssh` with this key to log in to the virtual machine to check the status of the installation. You will perform this check in later in [Deploying the management subsystem OVA file](#).

10. Set the password that you enter to log into your Management appliance for the first time.

- Important:** Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).
- If you do not have a password hashing utility, install one.

Operating system	Command
Ubuntu, Debian, OSX	If the <code>mkpasswd</code> command utility is not available, download and install it. (You can also use a different password hashing utility.) On OSX, use the command: <code>gem install mkpasswd</code> .
Windows, Red Hat	If necessary, a password hashing utility for the Windows operating system, like OpenSSL

c. Create a hashed password

Operating system	Command
Ubuntu, Debian, OSX	<code>mkpasswd --method=sha-512 --rounds=4096 password</code>
Windows, Red Hat	For example, using OpenSSL: <code>openssl passwd -1 password</code> . Note that you might need to add your password hashing utility to your path; for example, on Windows: <code>set PATH=c:\cygwin64\bin;%PATH%</code>

d. Set the hashed password for your subsystem:

```
apicup subsys set mgmt default-password='hashed_password'
```

11. Optional: If the default IP ranges for the API Connect Kubernetes pod and the service networks conflict with IP addresses that must be used by other processes in your deployment, modify the API Connect values.

You can change the IP ranges of the Kubernetes pod and the service networks from the default values of 172.16.0.0/16 and 172.17.0.0/16, respectively. In the case that a /16 subnet overlaps with existing IPs on the network, a Classless Inter-Domain Routing (CIDR) as small as /22 is acceptable. You can modify these ranges during initial installation and configuration only. You cannot modify them once an appliance has been deployed. See [API Connect configuration on VMware](#).

a. Update the IP range for the Kubernetes pod

```
apicup subsys set mgmt k8s-pod-network='new_pod_range'
```

Where `new_pod_range` is the new value for the range.

b. Update the IP range for Service networks.

```
apicup subsys set mgmt k8s-service-network='new_service_range'
```

Where `new_service_range` is the new value for the range.

12. Add your hosts.

```
apicup hosts create mgmt hostname.domainname hd_password
```

Where the following are true:

- `hostname.domainname` is the fully qualified name of the server where you are hosting your Management service, including the domain information.
- `hd_password` is the password that the Linux Unified Key Setup uses to encrypt the storage for your Management service. This password is hashed when it is stored on the server or in the ISO. Note that the password is base64 encoded when stored in `apiconnect-up.yml`.

Repeat this command for each host that you want to add.

Note: Host names cannot be changed on a cluster after the initial installation.

13. Create your interfaces.

```
apicup iface create mgmt hostname.domainname physical_network_id host_ip_address/subnet_mask network_gateway_ip_address
```

Where `physical_network_id` is the network interface ID of your physical server. The value is most often `eth0`. The value can also be `ethx`, where `x` is a number identifier.

The format is similar to the following example: `apicup iface create mgmt myHostname.domain eth0 192.0.2.10/255.255.255.0 192.0.2.1`.

Note: The `network_gateway_ip_address` is the network gateway (not a DataPower Gateway). If you are creating multiple network interfaces, each one must be on a different subnet with a different gateway.

14. Optional: Use `apicup` to view the configured hosts:

```
apicup hosts list mgmt
testsrv0231.subnet1.example.com
  Device  IP/Mask  Gateway
  eth0    1.2.152.231/255.255.254.0  1.2.152.1
```

Note: This command might return the following messages, which you can ignore:

```
* host is missing traffic interface
* host is missing public interface
```

Note: If you are configuring two data center deployment, continue with the installation instructions in [Installing a two data center deployment](#).

15. Optional: Verify that the configuration settings are valid.

```
apicup subsys get mgmt --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting. See the following sample output.

```

16. Create your ISO file.

```
apicup subsys install mgmt --out mgmtplan-out
```

The `--out` parameter and value are required.

In this example, the ISO file is created in the `myProject/mgmtplan-out` directory.

If the system cannot find the path to your software that creates ISO files, create a path setting to that software by running a command similar to the following command:

Operating system	Command
Ubuntu, Debian, OSX	<code>export PATH=\$PATH:/Users/your_path/</code>
Windows, Red Hat	<code>set PATH="c:\Program Files (x86)\cdrtools";%PATH%</code>

17. Deploy the subsystem ISO. Continue with [Deploying the management subsystem OVA file](#).

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Deploying the management subsystem OVA file

After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.

Before you begin

You must have completed the configuration of the project file entries for the management subsystem, for one of the following scenarios:

- During initial installation, [Configuring the management subsystem](#).
- When upgrading from 2018, [Upgrading v2018 subsystems to v10](#)
- When upgrading from 10 to 10.0.1.2-ifix1-eus, [Upgrading subsystems from 10 to 10.0.1.2-eus on VMware](#)

About this task

Procedure

1. Log into the VMWare vSphere Web Client.
2. Using the VSphere Navigator, navigate to the directory where you are deploying the OVA file.
3. Right-click the directory and select Deploy OVF Template.
4. Complete the Deploy OVF Template wizard.
 - a. Select the apiconnect-management.ova template by navigating to the location where you downloaded the file from Passport Advantage®.
 - b. Enter a name and location for your file.
 - c. Select a resource for your template.
 - d. Review the details for your template.
 - e. Select the size of your configuration.
 - f. Select the storage settings.

Important: Select at least 200 GB for the data disk size. Note that the boot disk needs 100 GB, so you need a total of 300 GB for the API Connect management subsystem.
 - g. Select the networks.
 - h. Customize the Template, if necessary.
 - i. Review the details to ensure that they are correct.
 - j. Select Finish to deploy the virtual machine.

Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See [Requirements for initial deployment on VMware](#).

The template creation appears in your Recent Tasks list.

5. Select the Storage tab in the Navigator.
6. Navigate to your datastore.
7. Upload your ISO file.
 - a. Select the Navigate to the datastore file browser icon in the icon menu.
 - b. Select the Upload a file to the Datastore icon in the icon menu.
 - c. Navigate to the ISO file that you created in your project.

It is the myProject/mgmtplan-out
 - d. Upload the ISO file to the datastore.
8. Leave the datastore by selecting the VMs and Templates icon in the Navigator.
9. Locate and select your virtual machine.
10. Select the Configure tab in the main window.
11. Select Edit....
 - a. On the Virtual Hardware tab, select CD/DVD Drive 1.
 - b. For the Client Device, select Datastore ISO File.
 - c. Find and select your datastore in the Datastores category.
 - d. Find and select your ISO file in the Contents category.
 - e. Select OK to commit your selection and exit the Select File window.
 - f. Ensure that the Connect At Power On check box is selected.

Tip:

 - Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
 - Note that VMware related issues with ISO mounting at boot may occur if Connect At Power On
 - g. Select OK to commit your selection and close the window.
12. Start the virtual machine by selecting the play button on the icon bar.

The installation might take several minutes to complete, depending on the availability of the system and the download speed.
13. Verify the API Connect installation. Continue with [Verify installation of the management subsystem](#)

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Verify installation of the management subsystem

Verify that deployment of the management subsystem OVA file succeeded.

Before you begin

You must have completed [Deploying the management subsystem OVA file](#).

About this task

After you configure an ISO and deploy it with the management subsystem ova, as described in [Deploying the management subsystem OVA file](#), verify that the subsystem installed correctly and is functional.

Procedure

1. Log in to the virtual machine by using an SSH tool to check the status of the installation:
 - a. Enter the following command to connect to *mgmt* using SSH:

```
ssh ip_address -l apicadm
```

- You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.
- b. Select Yes to continue connecting.
Your host names are automatically added to your list of hosts.
 - c. Run the **apic status** command to verify that the installation completed and the system is running correctly.
Note that after installation completes, it can take several minutes for all servers to start. If you see the error message **Subsystems not running**, wait a few minutes, try the command again, and review the output in the **Status** column.

The command output for a correctly running Management system is similar to the following lines:

```
apicadm@testsys0181:~$ sudo apic status

INFO[0001] Log level: info

d. If you configured backups, create the management backup secret:

```
$ kubectl create secret generic mgmt-backup-secret --from-literal=key='<YOUR ACCESS KEY>' --from-literal=keysecret='<YOUR ACCESS KEY SECRET>'
```

For more information, see [Configure your Management subsystem backup](#).

2. Ensure that you have saved all the necessary artifacts to enable you to restore the management subsystem in case of a disaster event. See [Preparing the management subsystem for disaster recovery on VMware \(10.0.1.0-eus\)](#)
3. Verify you can access the API Connect Cloud Manager. Enter the URL in your browser. The syntax is `https://<hostname.domain>/admin`. For example:

```
https://cloud-admin-ui.testsrv0231.subnet1.example.com/admin
```

The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. See [Accessing the Cloud Manager user interface](#).

4. If you configured an S3 backup during installation, verify that the configuration succeeded. See [Verify configuration for s3 backup](#).

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Installing the Analytics subsystem

Install the IBM® API Connect Analytics subsystem.

Before you begin

Review the section on [Planning your Analytics deployment](#) to ensure that you understand the choices for configuring the topology, disk space, and other elements of the Analytics subsystem. It is important to follow these steps in sequence, finishing with *Deploying the Analytics subsystem*.

- [Creating the analytics-extra-values file](#)
Create the installation extra-values file for IBM API Connect Analytics so that you can deploy the Analytics subsystem with additional configuration settings on VMware.
- [Configuring your topology](#)
Update the `analytics-extra-values.yaml` file to configure the topology of your IBM API Connect Analytics deployment.
- [Modifying your analytics data](#)
Update the `analytics-extra-values.yaml` file to customize data in your IBM API Connect Analytics deployment.
- [Defining your internal storage space](#)
If you don't want to use the shared storage that's configured by default for VMware, update the `analytics-extra-values.yaml` file for your IBM API Connect Analytics deployment.
- [Deploying the Analytics subsystem](#)
You can add analytics data collection by deploying the IBM API Connect Analytics OVA file on a VMware virtual server.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Creating the analytics-extra-values file

Create the installation extra-values file for IBM® API Connect Analytics so that you can deploy the Analytics subsystem with additional configuration settings on VMware.

Before you begin

You only need to create the `analytics-extra-values` file if you plan to add configuration options while installing the Analytics subsystem. For information on the available configuration options, see [Planning your Analytics deployment](#).

About this task

To apply configuration options to the Analytics subsystem during installation, create an extra-values file where you can specify your settings. You can name the file anything you want but you must save it as a `.yaml` file. The examples in the installation documentation call the file `analytics-extra-values.yaml`. Use the `analytics-extra-values.yaml` file to apply configuration settings when you install, upgrade, and update the configuration of your Analytics subsystem.

Procedure

1. Create a file called `analytics-extra-values` and open it for editing.
2. For the first line in the file, add:

```
spec:
```

All of your configuration options must follow this line, and must be indented with 2 spaces (or more for nested values).

3. Save the file.

What to do next

Add configuration options to the `analytics-extra-values` as explained in the following topics.

- [Reference: Fields in the analytics-extra-values](#)

Use the table of Analytics-specific fields to configure the `analytics-extra-values` for installing your IBM API Connect Analytics subsystem.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Reference: Fields in the `analytics-extra-values`

Use the table of Analytics-specific fields to configure the `analytics-extra-values` for installing your IBM® API Connect Analytics subsystem.

Table 1 lists the Analytics-specific fields that you can set in the `analytics-extra-values` file and describes each field. In Table 1, fields are shown using dot notation to indicate nested sections. For example, the field specified in Table 1 as `storage.data.volumeClaimTemplate.volumeSize` should be formatted in the `analytics-extra-values` file as follows:

```
storage:
  data:
    volumeClaimTemplate:
      volumeSize:
```

Table 1. Fields that you can set in the `analytics-extra-values` file

Field	Type	Required	Default value	Description	Comments
<code>client.enabled</code>	boolean	no	<code>true</code>	Whether to deploy this microservice	This microservice serves the Analytics UI and REST API. Only disable it if you do not need the Analytics views in API Connect.
<code>client.endpoint</code>	object	if <code>client.enabled == true</code>	-	FQDN and TLS Secrets for client endpoint	Identifies the endpoint that enables the Cloud Manager, API Manager, and Developer Portal to communicate with the Analytics subsystem.
<code>client.clientSubjectDN</code>	string	if <code>client.enabled == true</code>	-	Subject DN (distinguished name) for authenticating with client endpoint (RFC 2253)	
<code>client.style</code>	<code>carbon, bx</code>	no	<code>carbon</code>	UI style for Analytics views	Setting to <code>bx</code> reverts the Analytics UI styles to the v2018 styles. Not recommended.
<code>client.rateLimitEnabled</code>	boolean	no	<code>false</code>	Enabled saved object creation rate limiting	Saved objects refer to dashboards, visualizations, and searches in the UI. This setting enforces a limit on how many can be created per provider organization.
<code>client.rateLimitLimit</code>	integer > 0	no	1000	Max limit of saved objects when enabled	See <code>client.rateLimitEnabled</code> .
<code>client.basePath</code>	string	no	<code>/analytics</code>	Base path of the Analytics web server	Modifying this without modifying unexposed settings in the analytics-proxy causes errors. Not recommended.
<code>client.clientAuthEnabled</code>	boolean	no	<code>true</code>	Whether to enable client auth	Changing this to false causes security issues with the Analytics service. Not recommended.

Field	Type	Required	Default value	Description	Comments
cronjobs.enabled	boolean	no	true	Whether to deploy this microservice	This microservice manages indexes and data retention in storage. Only disable it if internal storage is also disabled.
cronjobs.retentionSchedule	string	no	30 1 * * *	Cron schedule for retention cronjob	This cronjob cleans up all indices older than the configured data retention age. If you need to run this more or less often based on your data retention settings, configure it here.
cronjobs.rolloverSchedule	string	no	15,45 * * *	Cron schedule for rollover cronjob	This cronjob attempts to rollover the storage index. If you need to run this more or less often based on your index rollover settings, configure it here.
ingestion.enabled	boolean	no	true	Whether to deploy this microservice	This microservice routes analytics data to internal or external storage. There is no supported topology of Analytics that disables this microservice.
ingestion.endpoint	object	if ingestion.enabled == true	-	FQDN and TLS Secrets for client endpoint	Identifies the endpoint that enables the Gateway to push your analytics data. Must be different from the client.endpoint
ingestion.clientSubjectDN	string	if ingestion.enabled == true	-	Subject DN (distinguished name) for authenticating with ingestion endpoint (RFC 2253)	
ingestion.geoIPEnabled	boolean	no	false	Whether to decorate API event data with geoip data	This populates the client_geoip and gateway_geoip fields using the IPs in client_ip and gateway_ip, respectively.
ingestion.filter	string	no	"	Filter to modify all API event data	See Modifying your analytics data for more information.
ingestion.pipelineWorkers	4 <= integer <= 128	no	24	Number of pipeline workers	More workers means more CPU and memory requirements, but gives you the benefit of additional threads to pull data off the ingestion http interface and process it for storage. This has diminishing returns as the size increases, and should usually be multiple of the number of cores on your hardware. Adjust with caution.
ingestion.pipelineBatchSize	10 <= integer <= 10000	no	250	Batch size of a pipeline worker	Pulling more or less data off the http interface per worker can have benefits. Ideally this would limit impedance on match batches sent from the gateway, but that is not a proven result. Recommended values are 125, 250, and 500. Increasing the value requires more memory. Adjust with caution.
ingestion.pipelineBatchDelay	10 <= integer <= 5000	no	50	Batch delay of a pipeline worker	How long to wait for the batch size to fill before leaving the http interface to process for storage. Having threads wait too long causes idle threads in your system; however, setting this value too low decreases performance. Adjust with caution.
ingestion.pipelineUnsafeShutdown	boolean	no	false	Whether to allow unsafe shutdown of the pipeline	Typically, the pipeline attempts to empty all workers' batches before shutting down, to prevent data loss. You might need to enable this setting if the pipeline is badly configured and refuses to respond to kill requests (extremely uncommon). Adjust with caution.
ingestion.configReloadAutomatic	boolean	no	true	Whether to automatically reload the pipeline on configuration changes	Typically, when the underlying files for the pipeline are modified, the pipeline process automatically reloads and picks up the changes. However, in Kubernetes environments where the pipeline is mapped to configmaps, this is unreliable. Ingestion microservice restarts are usually required.
ingestion.clientAuthEnabled	boolean	no	true	Whether to enable client auth	Setting this to false does not improve performance and makes Analytics extremely insecure. Not recommended at this time.
mq.enabled	boolean	no	false	Whether to deploy these microservices	See Adding a message queue for more information.
mq.kafka.volumeClaimTemplate.storageClassName	string	no	default	Storage class name	Name of the storage class configured to use for creating the microservice persistent volume.
mq.kafka.volumeClaimTemplate.volumeSize	string	no	5Gi	Volume size	Size of the volume used for kafka. See MQ storage: estimate disk space needs for more information.
mq.zk.volumeClaimTemplate.storageClassName	string	no	default	Storage class name	Name of the storage class configured to use for creating the microservice persistent volume.
mq.zk.volumeClaimTemplate.volumeSize	string	no	5Gi	Volume size	Size of the volume used for zk. See MQ storage: estimate disk space needs for more information.
storage.enabled	boolean	no	true	Whether to deploy this microservice	this microservice is used for storing and aggregating your data. only disable if you are only offloading and do not need internal storage
storage.type	unique,shared	no	unique	Type of storage deployment	See Declaring your storage type for more information.
storage.coord.clientAuthEnabled	boolean	no	true	Whether to enable client auth	Setting this to false does not improve performance and makes Analytics extremely insecure. Not recommended.

Field	Type	Required	Default value	Description	Comments
storage.data.volumeClaimTemplate.storageClassName	string	no	default	Storage class name	Name of the storage class configured to use for creating the microservice persistent volume
storage.data.volumeClaimTemplate.volumeSize	string	no	50Gi	Volume size	Size of the volume used for data storage. See Estimating internal storage space for more information.
storage.data.clientAuthEnabled	boolean	no	true	Whether to enabled client auth	Setting this to false does not improve performance and makes Analytics extremely insecure. Not recommended.
storage.master.volumeClaimTemplate.storageClassName	string	no	default	Storage class name	Name of the storage class configured to use for creating the microservice persistent volume.
storage.master.volumeClaimTemplate.volumeSize	string	no	5Gi	Volume size	Size of the volume used for data storage. See Estimating internal storage space for more information.
storage.master.clientAuthEnabled	boolean	no	true	Whether to enabled client auth	Setting this to false does not improve performance and makes Analytics extremely insecure. Not recommended.
storage.shared.volumeClaimTemplate.storageClassName	string	no	default	Storage class name	Name of the storage class configured to use for creating the microservice persistent volume
storage.shared.volumeClaimTemplate.volumeSize	string	no	50Gi	Volume size	Size of the volume used for data storage. See Estimating internal storage space for more information.
storage.shared.clientAuthEnabled	boolean	no	true	Whether to enabled client auth	Setting this to false does not improve performance and makes Analytics extremely insecure. Not recommended.
external.offload.enabled	boolean	no	false	Whether to enable this integration	See Offloading data to a third-party system for more information.
external.offload.filter	string	no	" "	Filter configuration for external offload	See Offloading data to a third-party system for more information.
external.offload.output	string	no	" "	Output configuration for external offload	See Offloading data to a third-party system for more information.
external.offload.secretName	string	no	" "	Name of secret for mounting files to use in external offload configuration	See Offloading data to a third-party system for more information.
databaseBackup.host	string	no	" "	The URL to your S3 storage.	See Configuring backup settings for Analytics
databaseBackup.path	string	no	" "	The path to your S3 storage at the URL specified by <code>databaseBackup.host</code>	See Configuring backup settings for Analytics
databaseBackup.schedule	string	no		Specifies the frequency of automatic backups, using any valid <code>cron</code> string.	See Configuring backup settings for Analytics
databaseBackup.credentials	string	no	" "	The name of the secret used for authenticating with your S3 storage	See Configuring backup settings for Analytics
databaseBackup.enableCompression	boolean	no	true		See Configuring backup settings for Analytics
databaseBackup.chunkSize	string	no	1Gi		See Configuring backup settings for Analytics
databaseBackup.enableServerSideEncryption	boolean	no			See Configuring backup settings for Analytics

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Configuring your topology

Update the `analytics-extra-values.yaml` file to configure the topology of your IBM® API Connect Analytics deployment.

About this task

Based on the decisions you made while [defining your topology](#), configure your the deployment options by completing the steps in the following topics to add a message queue, configure data offloading, and reduce storage complexity.

- [Adding a message queue](#)
Update the `analytics-extra-values.yaml` file to enable a message queue and increase reliability in the analytics data pipeline in your IBM API Connect Analytics deployment.
- [Offloading data to a third-party system](#)
Update the `analytics-extra-values.yaml` file to configure data offloading from your IBM API Connect Analytics deployment to a third-party system.
- [Declaring your storage type](#)
Update the `analytics-extra-values.yaml` file to assign a storage type in your IBM API Connect Analytics deployment.
- [Disabling internal storage](#)
Update the `analytics-extra-values.yaml` file to offload all data and disable local storage in your IBM API Connect Analytics deployment.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Adding a message queue

Update the `analytics-extra-values.yaml` file to enable a message queue and increase reliability in the analytics data pipeline in your IBM® API Connect Analytics deployment.

Before you begin

This task is only needed if you do not want to enable the message queue using the default values:

- `storageClassName` set to `local-storage`
- `volumeSize` set to `5Gi`

If you want to use the default values, skip this task.

About this task

For information about using a message queue in your Analytics deployment, see [Planning to add a message queue](#).

Procedure

1. Open the `analytics-extra-values.yaml` file for editing.
2. Add the `mq` section to the file as shown in the following example:

```
mq:
  enabled: true
  kafka:
    volumeClaimTemplate:
      storageClassName: $STORAGE_CLASS
  zk:
    volumeClaimTemplate:
      storageClassName: $STORAGE_CLASS
```

where `$STORAGE_CLASS` is the Kubernetes storage class to be used for persistent volume claims (for more information, see [Planning the Analytics profile and storage](#)).

3. Save the file.
4. Optional: If you want to increase the message size limit for the message queue, see [Overriding size limits for message queue on VMware](#).

What to do next

If you do not want to add any more configuration options, skip to the topic on [Defining your internal storage space](#), which is the last step before running the installation.

Otherwise, continue adding configuration options to the file as explained in the following topics.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Offloading data to a third-party system

Update the `analytics-extra-values.yaml` file to configure data offloading from your IBM® API Connect Analytics deployment to a third-party system.

About this task

For information about offloading data from your Analytics deployment, see [Planning to offload data to a third-party system](#).

Procedure

1. Open the `analytics-extra-values.yaml` file for editing.
Remember: All additions to the file must appear after the `spec:` statement.
2. Add the following section to the file:

```
spec:
  external:
    offload:
      enabled: true
      output: |
        $EXTERNAL_OFFLOAD_OUTPUT
```

where `$EXTERNAL_OFFLOAD_OUTPUT` is the plugin output for the target third-party system.

For example, the following example enables offloading to HTTP:

```
spec:
  external:
    offload:
      enabled: true
      output: |
        http {
          url => "example.com"
          http_method => "post"
          codec => "json"
          content_type => "application/json"
          id => "offload_http"
        }
```

For examples of output plugins, see [Sample output plugins for offloading data](#).

3. Optional: Modify the output plugin to include certificates for connecting to a secure endpoint.
Important: Certificates can only be applied after the Analytics subsystem is deployed. If you want to configure an output plugin that references a certificate, you must install the Analytics subsystem first, then create a secret and apply it to the Analytics deployment, configure the output plugin, and re-install Analytics. For instructions on the correct procedure for applying a certificate to the Analytics deployment, see [Providing a custom certificate for Analytics offload](#).
If your third-party endpoint requires a particular certificate, you can configure the certificate and then reference it in the offload plugin. Include the `secretName` as well as the `cacert`, `client_cert`, and `client_key` settings.

For example, the following output plugin enables offloading to HTTP and provides information on the certificate that is needed for authenticating with the endpoint:

```
spec:
  external:
    offload:
      secretName: offload-certificates
      enabled: true
      output: |
        http {
          url => "https://example.com:443"
          http_method => "post"
          codec => "json"
          content_type => "application/json"
          id => "offload_http"
          cacert => "/etc/velox/external_certs/offload/cacert.pem"
          client_cert => "/etc/velox/external_certs/offload/client.pem"
          client_key => "/etc/velox/external_certs/offload/client.key"
        }
```

The secret and its defined files are mounted to the `/etc/velox/external_certs/offload` directory.

4. Optional: Add a `filter` after the output plugin to modify data prior to offloading it.
The following example filter removes the `query_string` field:

```
spec:
  external:
    offload:
      enabled: true
      output: |
        http {
          url => "example.com"
          http_method => "post"
          codec => "json"
          content_type => "application/json"
          id => "offload_http"
        }
      filter: |
        ruby {
          remove_field => ["query_string"]
        }
```

For information about modifying offloaded data, see [Planning to modify your analytics data](#).

5. Save the file.

What to do next

If you do not want to add any more configuration options, skip to the topic on [Defining your internal storage space](#), which is the last step before running the installation.

Otherwise, continue adding configuration options to the file as explained in the following topics.

Attention: The third-party endpoint must be available at all times to prevent the loss of analytics data.

- [Sample output plugins for offloading data](#)

Review sample output plugins to see how to code your own plugins for offloading data from IBM API Connect Analytics.

- [Providing a custom certificate for Analytics offload](#)

Prepare a private or self-signed certificate for use when offloading data, and then re-install IBM API Connect Analytics deployment on VMware to apply the certificate.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Sample output plugins for offloading data

Review sample output plugins to see how to code your own plugins for offloading data from IBM® API Connect Analytics.

Configure output plugins that direct analytics data to your third-party systems. An output plugin specifies where analytics data is offloaded, plus any information required to access that system, such as certificate information. The output plugin for displaying analytics data in the Analytics user interface is configured by default.

Referencing a certificate in an output plugin

If your third-party system requires a private or self-signed certificate, you can include a reference to the certificate in your output plugin. See the second HTTP output plugin for an example showing how to reference the certificate.

Important: Analytics must be deployed before you attempt to use the certificate. If you want to configure an output plugin that references a certificate, you must install the Analytics subsystem first, then create a secret and apply it to the Analytics deployment, configure the output plugin, and re-install Analytics. For instructions on the correct procedure for applying a certificate to the Analytics deployment, see [Providing a custom certificate for Analytics offload](#).

HTTP

To configure data offload to an HTTP server, you must provide the server URL. You can optionally add standardized or custom HTTP headers to define additional operating parameters.

The following example configures an HTTP output plugin.

```
http {
  url => "example.com"
  http_method => "post"
  codec => "json"
  content_type => "application/json"
  id => "offload_http"
}
```

The following example configures an HTTP output plugin that references a custom certificate for accessing the third-party endpoint.

```
http {
  url => "https://example.com:443"
  http_method => "post"
  codec => "json"
  content_type => "application/json"
  id => "offload_http"
  cacert => "/etc/velox/external_certs/offload/cacert.pem"
  client_cert => "/etc/velox/external_certs/offload/client.pem"
  client_key => "/etc/velox/external_certs/offload/client.key"
}
```

For more information on offloading to HTTP, refer to the Logstash documentation on configuring the [HTTP output plugin](#).

Elasticsearch V6, V7

To configure data offload to an Elasticsearch cluster, you must provide one or more server URLs, define how indices should be created by specifying a dynamically configured name, specify the number of primary shards for storing the indexed documents, and specify a number of replica shards for redundancy. You can optionally specify server authentication credentials.

The naming syntax that you specify for your indices determines how many indices are created and how they are characterized. For example, you can define indices that are created based on a date pattern (for example, daily or weekly), or indices that are created to store data by provider organization or by API name.

The following example configures an Elasticsearch output plugin.

```

elasticsearch {
  hosts => "https://example.com:443"
  index => "apiconnect"
  ssl => true
  cacert => "/etc/pki/tls/cert.pem"
}

```

For more information on offloading to Elasticsearch, refer to the Elasticsearch documentation on the [Elasticsearch output plugin](#).

Apache Kafka V1.0.0

To configure data offload to a Kafka cluster, you must provide host and port connection details for one or more servers, and the name of the Kafka topic to which you want to publish the offloaded data. For logging and monitoring purposes within Kafka, you can optionally specify a string identifier by which API Connect can be uniquely identified.

The following example configures a Kafka output plugin.

```

kafka {
  topic_id => "test"
  bootstrap_servers => "example.com:9093"
  codec => "json"
  id => "kafka_offload"
  ssl_truststore_location => "/usr/lib/jvm/jre/lib/security/cacerts"
  ssl_truststore_password => "changeit"
  ssl_truststore_type => "JKS"
  security_protocol => SSL
}

```

For more information on offloading to Apache Kafka, refer to the Logstash documentation on the [Kafka output plugin](#). Note that the Logstash plugin is based on kafka-client version 2.3.1 and not v2.1.0 as specified in the Logstash documentation.

Syslog

To configure data offload to Syslog, you must provide host and port connection details for the server.

Restriction: Syslog does not support the use of chained client certificates for TLS profiles.

The following example configures a Syslog output plugin.

```

syslog {
  host => "example.com"
  port => 601
  protocol => "ssl-tcp"
  id => "offload_syslog"
  appname => "apiconnect"
  msgid => "%{org_id}"
  facility => "log audit"
  severity => "informational"
  codec => "json"
  ssl_cacert => "/etc/pki/tls/cert.pem"
}

```

Attention: Due to a third-party issue with Logstash, most of the facility values are not set correctly on the offload server. As a temporary workaround, set the facility to "user-level" to ensure that the corresponding value is correctly sent to the offload server. When Logstash corrects this problem, you must update the offload configuration to change the value to a more appropriate setting.

For more information on offloading to Syslog, refer to the Logstash documentation on the [Syslog output plugin](#).

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Providing a custom certificate for Analytics offload

Prepare a private or self-signed certificate for use when offloading data, and then re-install IBM® API Connect Analytics deployment on VMware to apply the certificate.

Before you begin

Install the Analytics subsystem on VMware as explained in [Deploying the Analytics subsystem](#). Analytics must be deployed before you attempt to use the certificate.

When you re-install Analytics after applying the certificate, you can upload the analytics-extra-values.yaml file to include additional configuration options.

Procedure

1. Use SSH to log into the virtual machine on a server that has kubectl access to the Kubernetes cluster where API Connect Analytics is deployed.
 - a. Run the following command to connect as the API Connect administrator.

```
ssh ip_address -l apicadm
```

- b. When prompted, select Yes to continue connecting.
2. Encode the certificate file in base64.

You can use either JKS files or text-based files such as PEM files:

- If you use a JKS file for certificate, you must encode the file now, before proceeding to the next step.
- If you use a text-based file such as PEM, then you can choose between encoding the file now or skipping this step and adding the keys to the secret in the next step.

There are several ways to encode the file. If `cat` and `base64` are available, then you can run the following command to encode the file:

```
cat keystore.jks | base64
```

Copy the output so that you can paste it into the secret in the next step.

3. Create a Kubernetes secret to contain the certificate.

a. Create a YAML file to contain the secret; for example, you can call the file `analytics_certs.yaml`.

The secret's name that you specify in the file does not have to match the file name. In this example, the secret's name is `offload-certificates`. Do not use the underscore character (`_`) in the secret name.

Add as many keys as you want, using any field names that you want. For each key, a file based on the corresponding field name is created in the container at `/etc/velox/external_certs/offload`. For example, if you paste a certificate in the `cacert` field as shown in the following example, then a file named `cacert.pem` is stored in the `/etc/velox/external_certs/offload` location.

```
apiVersion: v1
kind: Secret
metadata:
  # Change value of name to be whatever you wish secret to be called
  name: offload-certificates
  # Only base64 encoded data should be placed in data section; JKS keys would go here
data:
  keystore.jks: "output_of_base64_encoded_jks"
stringData:
  cacert: |-
    -----BEGIN CERTIFICATE-----
    MIIDIDCCAomgAwIBAgIEND70zzANBgkqhkiG9w0BAQUFAQBOMQswCQYDVQGEwJVUzEQMA4GA1UE
    CHMRXFl1aWZheDEtMCsGA1UECzMkRXFl1aWZheCBTZWN1cmUgQ2Vydg1maWNhdGUGQXV0aG9yaXR5
    MB4XDTEk4MDgyMjE2NDE1MV0XDTE4MDgyMjE2NDE1MVowTjE1MAkGA1UEBhMCVVMxEDA0BgNVBAsT

    Af8wGgYJKoZIhV9Z9B0EABA0wCxsFVjMuMGMDAgbAMA0GCsGqGSIB3DQEBBQUAA4GBAFjOKer89961
    zqK5F7WF0bnj4JXMTJENAKaSbn+2km0eUJXRmm/kEd5jhW6Y7qj/WsjTVbJmcVfchwChRPSqnI0kB
    BIZCe/zuf6IWURvNz9NA2zsmWLIodz2uFHdh1voqZiegDfqc1zqcPGUIWVEX/r87yl0qaKHee95
    70+sB3c4
    -----END CERTIFICATE-----
```

b. Paste the certificate into the file.

The method for adding the certificate to the secret depends on whether you encoded the file in the previous step:

- Base64-encoded file: In the `data` section of the secret, type a name for the field (you can choose the name). Paste the encoded output from the previous step (enclosed in `" "`) as the value.
- Plain text file: In the `stringData` section of the secret, type a name for the key or certificate (you can choose the name), and paste the value.

c. Save the file.

4. Apply Kubernetes secret it to the cluster where the Analytics subsystem is deployed.

Run the following command to update the cluster:

```
kubectl apply -f file_name_of_secret.yaml -n namespace
```

where:

- `file_name_of_secret.yaml` is the secret's file name.
- `namespace` is the name of the namespace where Analytics is deployed.

5. Edit the Analytics CR and add a reference to the secret in the `offload` section; for example:

```
offload:
  enabled: true
  output: |
    kafka {
      ...
    }
  secretName: offload-certificates
```

6. If you want to reference the certificate in an [offload plugin](#), configure the plugin now.

Step 3 of that procedure shows how you can include the certificate information in the plugin.

7. Install the Analytics subsystem again as explained in [Deploying the Analytics subsystem](#), making sure to upload the `analytics-extra-values.yaml` file that contains your offload configuration.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Declaring your storage type

Update the `analytics-extra-values.yaml` file to assign a storage type in your IBM® API Connect Analytics deployment.

About this task

By default, Analytics uses shared storage on VMware. Edit the `analytics-extra-values.yaml` file and add a `storage` section with the specific setting as explained in the following instructions.

Procedure

1. Open the `analytics-extra-values.yaml` file for editing.
2. Add a `storage` section as shown in the following example:

```
storage:
  type: shared
  shared:
    volumeClaimTemplate:
      storageClassName: $STORAGE_CLASS
```

where `$STORAGE_CLASS` is the Kubernetes storage class to be used for persistent volume claims (for more information, see [Planning the Analytics profile and storage](#)).

3. Save the file.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Disabling internal storage

Update the `analytics-extra-values.yaml` file to offload all data and disable local storage in your IBM® API Connect Analytics deployment.

About this task

For information about disabling internal storage in your Analytics deployment, see [Planning to disable internal storage](#).

Procedure

1. Required: Configure data offloading as explained in [Offloading data to a third-party system](#).
Before you disable internal storage, ensure that data is offloading properly to your third-party system. Then complete the remaining steps to disable internal storage of analytics data.

2. Open the `analytics-extra-values.yaml` file for editing.
3. Add the `client` section as shown in the following example:

```
client:
  enabled: false
```

4. Add the `cronjobs` section as shown in the following example:
You can append the new section to the end of the file. Be sure to follow the spacing that is already in use in the file.

```
cronjobs:
  enabled: false
```

5. Add the `storage` section as shown in the following example:

```
storage:
  enabled: false
```

6. Save the file.

What to do next

If you do not want to add any more configuration options, skip to the topic on [Defining your internal storage space](#), which is the last step before running the installation.

Otherwise, continue adding configuration options to the file as explained in the following topics.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Modifying your analytics data

Update the `analytics-extra-values.yaml` file to customize data in your IBM® API Connect Analytics deployment.

Before you begin

Review the use of filters for modifying analytics data, and make sure that you understand the restrictions. For information about customizing data, see [Planning to modify your analytics data](#).

About this task

Customizing the analytics data is optional. You can enable the inclusion of geoIP information, and define filters that add, modify, or remove other fields.

Upgrade note: In V2018, multiple configuration files were used for defining filters that were applied at different points in the ingestion pipeline. In V10, you define filters in the `analytics-extra-values.yaml` file.

Procedure

1. Open the `analytics-extra-values.yaml` file for editing.
Remember: All additions to the file must appear after the `spec:` statement.
2. Enable the inclusion of geoIP fields in your analytics data by adding the following lines:

```
spec:
  ingestion:
    geoIPEnabled: true
```

By default the `client_geoip` and `gateway_geoip` fields are not included in the analytics data. These are calculated from the `client_ip` and `gateway_ip` fields, respectively. Setting `geoIPEnabled` to `true` enables this feature.

3. Add a `filter` definition.
You can add filters for `ingestion` and for `offloading`. Add the appropriate section name for the filter. If the section already exists in the file, add your filter into the existing section. For information about where to add filters for local data and offloaded data, see [Which pipeline is affected by the filter?](#)

For example filters, see [Sample filters for modifying analytics data](#).

For example, you can add a filter into the `ingestion` section defined in the previous step. The following example filter removes the `query_string` field:

```
spec:
  ingestion:
    ...
    geoIPEnabled: true
    filter: |
      mutate {
        remove_field => ["query_string"]
      }
```

4. Save the file.

What to do next

Proceed to the topic on [Defining your internal storage space](#), which is the last step before running the installation.

- [Sample filters for modifying analytics data](#)
Review sample filters to see how to code your own filters for refining IBM API Connect Analytics data by adding fields, removing fields, or modifying field contents.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Sample filters for modifying analytics data

Review sample filters to see how to code your own filters for refining IBM® API Connect Analytics data by adding fields, removing fields, or modifying field contents.

You can use these sample filters in the `ingestion.filter` and the `external.offload.filter` configurations.

Adding a new field

You can add custom data to API event data by adding a field to the logging document. For example, if you want to search or visualize data that is stored in request and response headers, you can add fields to a filter to include that information.

To avoid naming conflicts with future or current analytics fields, include a prefix that ensures your new field name is unique. For example, instead of naming the field `employee_num` you might name it `x_mycompany_employee_num`.

The following example copies the contents of the `x-Employee-Num` field from the request header and adds it to the `x_mycompany_employee_num` field in the event data. Adding the field to the event data enables you to use the information in visualizations.

```
if [request_http_headers] {
  ruby {
    code => "event.get(['request_http_headers']).collect {|i| event.set(['x_mycompany_employee_num'], i['X-Employee-Num']) if
i.has_key?('X-Employee-Num')}"
  }
}
```

Modifying an existing field

Sometimes you don't want to remove a field entirely from your data, you just want to redact sensitive information such as IDs to prevent them from being exposed in visualizations. You can modify the contents of a field and replace information with a symbols or a message.

Remember: The following fields should not be modified if the data is being written to internal analytics storage: `org_id`, `catalog_id`, `space_id`, `developer_org_id`, `datetime`, and `@timestamp`.

The following example replaces sensitive information in the `X-Employee-Name` and `X-Employee-ID` request headers with the string: `*****sanitized*****`.

```
if [request_http_headers] {
  ruby {
    code => "headers=['X-Employee-Name','X-Employee-ID']; newHeaders = event.get(['request_http_headers']).collect {|i|
headers.each {|header| i[header] = '*****sanitized*****' if i.has_key?(header)}; i}; event.set(['request_http_headers'],
newHeaders)"
  }
}
```

Removing an existing field

Use the mutate `remove_field` operation to delete a field from the Analytics data. To remove multiple fields, delimit the field names with commas.

The following example removes multiple fields (`request_http_headers`, `response_http_headers`, `request_body`, `response_body`, and `query_string`) from the Analytics data:

```
mutate {
  remove_field => ["request_http_headers", "response_http_headers", "request_body", "response_body", "query_string"]
}
```

Filter and output plugin for splunk

When you create a filter for use with splunk, you must also create an output plugin for it.

Filter:

```
if "apicapievent" in [tags] {
  ruby {
    code => "event.set(['@metadata][newevent]', event.to_json)"
  }
}
```

Output plugin:

```
http {
  url => "http://your-domain/services/collector/event"
  http_method => "post"
  codec => "json"
  content_type => "application/json"
  id => "offload_http"
  format => "message"
  message => '{"event": "%{[@metadata][newevent]}", "index": "applications-int-ms", "sourcetype": "json:apimlogs"}'
  headers => ["Authorization", "Splunk XXXX"]
}
```

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Defining your internal storage space

If you don't want to use the shared storage that's configured by default for VMware, update the `analytics-extra-values.yaml` file for your IBM® API Connect Analytics deployment.

Before you begin

This task only applies to deployments that use internal storage or have a message queue enabled. If you disabled internal storage but did not enable the message queue, then skip this task.

Review [Estimating internal storage space](#) to make sure you know how much disk space to allocate for internal storage. If you disabled internal storage, skip this task.

About this task

For information about offloading data from your Analytics deployment, see [Planning to offload data to a third-party system](#).

The steps that you complete to define your internal storage allocations depend on the deployment options that you configured.

Data & Master storage

Complete the following steps only if you did retain the default shared storage configuration (described in [Declaring your storage type](#)).

1. Open the `analytics-extra-values.yaml` file for editing.
Remember: All additions to the file must appear after the `spec:` statement.

2. In the file, add the `storage.data` section as shown in the following example:

```
spec:
  storage:
    data:
      volumeClaimTemplate:
        storageClassName: ...
        volumeSize: $DATA_VOLUME_SIZE
```

Replace `$DATA_VOLUME_SIZE` with the value that you calculated for `Storage per node` in [Data storage: calculate how much data you want to store](#).

3. Next, add the `storage.master` section and add the `volumeSize` field as shown in the following example:

```
spec:
  storage:
    master:
      volumeClaimTemplate:
        storageClassName: ...
        volumeSize: $VOLUME_SIZE
```

Replace `$VOLUME_SIZE` with the value that you calculated in [Master storage: estimate disk space needs](#).

4. Save the file.

5. Skip to the section for MQ storage.

Shared storage

If you are using shared storage (the default setting), complete the following steps to allocate disk space for the share storage.

1. Open the `analytics-extra-values.yaml` file for editing.
Remember: All additions to the file must appear after the `spec:` statement.
2. In the file, add the `storage.shared` section as shown in the following example:

```
spec:
  storage:
    shared:
      volumeClaimTemplate:
        storageClassName: ...
        volumeSize: $STORAGE_PER_NODE
```

Replace `$STORAGE_PER_NODE` with the value that you calculated for `Storage per node` in [Data storage: calculate how much data you want to store](#).

3. Save the file.

4. Continue to the section for MQ storage.

MQ storage

Complete this procedure only if you added a message queue to your Analytics topology by setting `mq.enabled: true` as explained in [Adding a message queue](#).

1. In the file, add the `mq:` section.
2. Add the `mq.zk` section as shown in the following example:

```
spec:
  mq:
    zk:
      volumeClaimTemplate:
        storageClassName: ...
        volumeSize: $VOLUME_SIZE
```

Replace `$VOLUME_SIZE` with the value that you calculated for `mq-zk` in [MQ storage: estimate disk space needs](#).

3. Add the `mq.kafka` section as shown in the following example:

```
spec:
  mq:
    kafka:
      volumeClaimTemplate:
        storageClassName: ...
        volumeSize: $VOLUME_SIZE
```

Replace `$VOLUME_SIZE` with the value that you calculated for `mq-kafka` in [MQ storage: estimate disk space needs](#).

4. Save and close the file.

What to do next

Your Analytics configuration is complete. Proceed to [Deploying the Analytics subsystem](#).

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Deploying the Analytics subsystem

You can add analytics data collection by deploying the IBM® API Connect Analytics OVA file on a VMware virtual server.

Before you begin

Before you deploy:

- Review the [Deployment requirements on VMware](#).
- Review the [API Connect configuration on VMware](#).
- Review [What's new for v10 installation](#)
- For information on deploying a cluster, see [Configuring API Connect subsystems in a cluster](#)
- If you are upgrading from a previous version, see [Upgrading API Connect](#).

About this task

You must deploy the API Connect OVA template to create each Analytics virtual server that you want in your cloud.

Procedure

Complete the following steps in order:

1. Specify configuration settings for the Analytics subsystem and create an ISO. See [Configuring the Analytics subsystem](#)
2. Deploy the subsystem OVA into an appliance VM. See [Deploying the Analytics subsystem OVA file](#).
3. Verify the deployment. See [Verifying deployment of the Analytics subsystem](#)

Results

An analytics installation starts the following Kubernetes pods:

- Full installation in **Prod** deployment-profile:
Table 1. Kubernetes pods in a full Analytics installation

Number	Pod
2	client
2	ingestion
2	mtls
1	operator
equal to the number of nodes	analytics-storage-basic

Note that for all pod types except analytics-storage-basic, there is only one of each pod when installed with **dev** deployment-profile. For analytics-storage-basic, the number of pods always matches the number of nodes in the subsystem, regardless of installation mode.

- Message queue deployment in **Prod** mode: All of the pods shown in Table [Table 1](#), plus:
Table 2. Additional pods used for Message Queue deployments

Number	Pod
equal to the number of nodes	mq-kafka
equal to the number of nodes	mq-zookeeper

Note that the number of pods for mq-kafka and mq-zookeeper always match the number of nodes in the subsystem, regardless of installation mode.

- Ingestion-only installation in **Prod** deployment-profile:
Table 3. Kubernetes pods in an ingestion-only Analytics installation

Number	Pods
2	ingestion
2	mtls

Note that in **Dev** deployment-profile there is only one of each pod.

What to do next

Identify the DataPower® appliances to be used as gateway servers in the API Connect cloud and obtain the IP addresses.

Define your API Connect configuration by using the API Connect cloud console. For more information, see [Defining the cloud](#).

- [Configuring the Analytics subsystem](#)
Specify configuration properties for your Analytics subsystem, and create an ISO.
- [Deploying the Analytics subsystem OVA file](#)
After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.
- [Verifying deployment of the Analytics subsystem](#)
Verify that deployment of the Analytics OVA file succeeded.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Configuring the Analytics subsystem

Specify configuration properties for your Analytics subsystem, and create an ISO.

Before you begin

Review the requirements. See [Deploying the Analytics subsystem](#).

About this task

Use the `apicup` installation utility to specify configuration settings for your Analytics subsystem.

Procedure

1. Ensure that you obtained the distribution file and have a project directory, as described in [First steps for deploying in a VMware environment](#).
2. Change to the project directory.

```
cd myProject
```

3. Create an analytics subsystem.

```
apicup subsys create analyt analytics
```

Where:

- `analyt` is the name of the analytics server that you are creating. You can assign it any name, as long as the identifier consists of lowercase alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character.
- `analytics` indicates that you want it to create an Analytics microservice.

The `apiconnect-up.yml` file that is in that directory is updated to add the analytics-related entries.

Tip: At any time, you can view the current analytics subsystem values in the `apiconnect-up.yml` by running the `apicup get` command:

```
apicup subsys get analyt
```

If you have not updated the value, a default value is listed, if there is one that is available.

Sample output from `apicup subsys get`, after configuration is completed:

```
apicup subsys get analyt
```

```
Appliance settings
```

```
=====
```

Name	Value	Description
----	-----	-----
<code>additional-cloud-init-file</code>	<code>yml_file</code>	(Optional) Path to additional cloud-init
<code>data-device</code>	<code>sdb</code>	VM disk device (usually <code>`sdb`</code> for SCSI or <code>`vdb`</code> for VirtIO)
<code>default-password</code>	<code>\$6\$rounds=4096\$iMCJ9cfhFJ8X\$pbmAl9ClWzcYzHZFoQ6n7OnYcf/owQZIIiCpAtWazs/FUn/uE8uLD.9jwHE0AX4upFSqx/jf0ZmDbHPZ9bUlCY1</code>	(Optional) Console login password for
<code>`apicadm` user</code>		
<code>dns-servers</code>	<code>[1.2.136.11]</code>	List of DNS servers
<code>k8s-pod-network</code>	<code>172.16.0.0/16</code>	(Optional) CIDR for pods within the
<code>appliance</code>		
<code>k8s-service-network</code>	<code>172.17.0.0/16</code>	(Optional) CIDR for services within the
<code>appliance</code>		
<code>deployment-profile</code>	<code>n3xc4.m16</code>	
<code>public-iface</code>	<code>eth0</code>	Device for API/UI traffic (Eg: eth0)
<code>search-domain</code>	<code>[subnet1.example.com]</code>	List for DNS search domains
<code>ssh-keyfiles</code>	<code>[/home/vsphere/.ssh/id_rsa.pub]</code>	List of SSH public keys files
<code>traffic-iface</code>	<code>eth0</code>	Device for cluster traffic (Eg: eth0)
<code>license-use</code>	<code>production</code>	

```
Endpoints
```

```
=====
```

Name	Value	Description
----	-----	-----
<code>analytics-client</code>	<code>a7s-client.testsrv0233.subnet1.example.com</code>	FQDN of Analytics client/UI endpoint
<code>analytics-ingestion</code>	<code>a7s-in.testsrv0233.subnet1.example.com</code>	FQDN of Analytics ingestion endpoint

4. Specify your `deployment-profile`.

```
apicup subsys set analyt deployment-profile=profile_type
```

Use one of the following values for the `profile_type`, based on the decision you made while [Planning the Analytics profile and storage](#):

- For development use: `n1xc2.m16`
- For production use: `n3xc4.m16`: production profile

For example, to deploy using the a production profile, run the following command:

```
apicup subsys set analyt deployment-profile=n3xc4.m16
```

5. Specify the license use that you purchased.

```
apicup subsys set analyt license-use=license_type
```

The `license_type` must be either `production` or `nonproduction`. If not specified, the default value is `nonproduction`.

6. Optional: Configure backups of the subsystem. Follow the instructions in [Backing up and restoring the Analytics database on VMware](#).

Important: It is highly recommend that you configure backups and also take additional steps to ensure that your configuration and data can be restored in the event of a disaster event. See [Preparing the Analytics subsystem for disaster recovery on VMware](#).

7. Optional: Enable the message queue microservice with the default values.

If you did not previously enable message queue with custom settings, you can enable it now with the following default values:

- `storageClassName` set to `local-storage`
- `volumeSize` set to `5Gi`

a. List the settings of your Analytics subsystem by running the following command:

```
apicup subsys get Analytics_subsystem_name
```

Confirm that the `enable-message-queue` field is set to `false` (the message queue is not enabled by default).

b. Enable the message queue by running the following command to set `enable-message-queue` to `true`:

```
apicup subsys set Analytics_subsystem_name enable-message-queue=true
```

8. Optional: Configure your logging.

Logging can be configured at a later time, but you must enable it before installation to capture the log events from the installation.

a. Complete the procedure at [Configuring remote logging for a VMware deployment](#).

b. Enter the following command to create the log file:

```
apicup subsys set analyt additional-cloud-init-file=config_file.yml
```

9. Enter the following commands to update the `apiconnect-up.yml` with the information for your environment:

a. Use `apicup` to set your endpoints.

The endpoints must be unique host names that both point to the IP address of the OVA (single node deployment), or to the IP of a load balancer configured in front of the OVA nodes.

Setting	Endpoint host description
analytics-client	Your <code>unique_hostname</code> identifies the endpoint that enables the Cloud Manager, API Manager, and Developer Portal to communicate with the Analytics subsystem. <code>apicup subsys set analyt analytics-client=unique_hostname.domain</code> If you plan to disable internal storage for Analytics data, omit this setting.
analytics-ingestion	Your <code>unique_hostname</code> identifies the endpoint that enables the Gateway to push your analytics data. The values for the <code>analytics-ingestion</code> and <code>analytics-client</code> must be different. <code>apicup subsys set analyt analytics-ingestion=unique_hostname.domain</code>

b. Set your search domain. Multiple search domains should be separated by commas.

```
apicup subsys set analyt search-domain=your_search_domain
```

Where `your_search_domain` is the domain of your servers, entered in all lowercase. Setting this value ensures that your searches also append these values, which are based on your company's DNS resolution, at the end of the search value. A sample search domain is `mycompany.example.com`.

Ensure that the value for `your_search_domain` is resolved in the system's `/etc/resolv.conf` file to avoid "502" errors when accessing the Cloud Manager web site. For example:

```
# Generated by resolvconf
search your_search_domain ibm.com other.domain.com
```

c. Set your domain name servers (DNS).

Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

```
apicup subsys set analyt dns-servers=ip_address_of_dns_server
```

DNS entries may not be changed on a cluster after the initial installation.

10. Set a Public key.

```
apicup subsys set analyt ssh-keyfiles=path_to_public_ssh_keyfile
```

Setting this key enables you to use `ssh` with this key to log in to the virtual machine to check the status of the installation. You will perform this check later in [Verifying deployment of the Analytics subsystem](#).

11. You can set the password that you enter to log into your Analytics server for the first time.

a. Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).

b. If you do not have a password hashing utility, install one.

Operating system	Command
Ubuntu, Debian, OSX	If the <code>mkpasswd</code> command utility is not available, download and install it. (You can also use a different password hashing utility.) On OSX, use the command: <code>gem install mkpasswd</code> .
Windows, Red Hat	If necessary, a password hashing utility for the Windows operating system, like OpenSSL

c. Create a hashed password

Operating system	Command
Ubuntu, Debian, OSX	<code>mkpasswd --method=sha-512 --rounds=4096 password</code>
Windows, Red Hat	For example, using OpenSSL: <code>openssl passwd -1 password</code> . Note that you might need to add your password hashing utility to your path; for example, on Windows: <code>set PATH=c:\cygwin64\bin;%PATH%</code>

d. Set the hashed password for your subsystem:

```
apicup subsys set analyt default-password='hashed_password'
```

Notes:

- The password is hashed. If it is in plain text, you cannot log into the VMWare console.
- Note that the password can only be used to login through the VMWare console. You cannot use it to SSH into the Appliance as an alternative to using the `ssh-keyfiles`.
- On Linux or OSX, use single quotes around `hashed_password`. For Windows, use double quotes.
- If you are using a non-English keyboard, understand the limitations with using the remote VMWare console. See [Requirements for initial deployment on VMWare](#).

12. Optional: If the default IP ranges for the API Connect Kubernetes pod and the service networks conflict with IP addresses that must be used by other processes in your deployment, modify the API Connect values.

You can change the IP ranges of the Kubernetes pod and the service networks from the default values of 172.16.0.0/16 and 172.17.0.0/16, respectively. In the case that a /16 subnet overlaps with existing IPs on the network, a Classless Inter-Domain Routing (CIDR) as small as /22 is acceptable. You can modify these ranges during initial installation and configuration only. You cannot modify them once an appliance has been deployed. See [API Connect configuration on VMWare](#).

a. Update the IP range for the Kubernetes pod

```
apicup subsys set analyt k8s-pod-network='new_pod_range'
```

Where `new_pod_range` is the new value for the range.

b. Update the IP range for Service networks.

```
apicup subsys set analyt k8s-service-network='new_service_range'
```

Where `new_service_range` is the new value for the range.

13. Add your hosts.

```
apicup hosts create analyt hostname.domainname hd_password
```

Where the following are true:

- `hostname.domainname` is the fully qualified name of the server where you are hosting your Analytics service, including the domain information.
- `hd_password` is the password of the Linux Unified Key Setup uses to encrypt the storage for your Analytics service. This password is hashed when it is stored on the server or in the ISO. Note that the password is base64 encoded when stored in `apiconnect-up.yml`.

Repeat this command for each host that you want to add.

Note: Host names and DNS entries may not be changed on a cluster after the initial installation.

14. Create your interfaces.

```
apicup iface create analyt hostname.domainname physical_network_id host_ip_address/subnet_mask gateway_ip_address
```

Where `physical_network_id` is the network interface ID of your physical server. The value is most often `eth0`. The value can also be `ethx`, where `x` is a number identifier.

The format is similar to this example: `apicup iface create analyt myHostname.domain eth0 192.0.2.1/255.255.1.1 192.0.2.1`

15. Optional: Use `apicup` to view the configured hosts:

```
apicup hosts list analyt
testsrv0233.subnet1.example.com
  Device  IP/Mask  Gateway
  eth0    1.2.152.233/255.255.254.0  1.2.152.1
```

16. Verify that the configuration settings are valid.

```
apicup subsys get analyt --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting. See the following sample output.

```
apicup subsys get analyt --validate
```

Appliance settings

=====

analytics-ingestion	a7s-in.testsrv0233.subnet1.example.com	✓

17. If you configured additional deployment options in an extra-values file, run the following command to make the file available during installation:

```
apicup subsys set analyt extra-values-file path/analytics-extra-values.yaml
```

where `extra-values.yaml` is the name of the file containing your deployment settings.

18. Create your ISO file.

```
apicup subsys install analyt --out analytplan-out
```

The `--out` parameter and value are required. In this example, the ISO file is created in the `myProject/analytplan-out/node-config` directory.

If the system cannot find the path to your software that creates ISO files, create a path setting to that software by running a command similar to the following command:

Operating system	Command
Ubuntu, Debian, OSX	<code>export PATH=\$PATH:/Users/your_path/</code>
Windows, Red Hat	<code>set PATH="c:\Program Files (x86)\cdrtools";%PATH%</code>

19. Next, use the ISO to deploy the OVA file. Continue with [Deploying the Analytics subsystem OVA file](#).

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Deploying the Analytics subsystem OVA file

After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.

Before you begin

You must have completed the configuration of the project file entries for the Analytics subsystem, for one of the following scenarios:

- During initial installation, [Configuring the Analytics subsystem](#).
- When upgrading from 2018, [Upgrading v2018 subsystems to v10](#)
- When upgrading from 10 to 10.0.1.2-ifix1-eus, [Upgrading subsystems from 10 to 10.0.1.2-eus on VMware](#)

Procedure

1. Log into the VMWare vSphere Web Client.
2. Using the VSphere Navigator, navigate to the directory where you are deploying the OVA file.
3. Right-click the directory and select Deploy OVF Template.
4. Complete the Deploy OVF Template wizard.
 - a. Select the apiconnect-analytics.ova template by navigating to the location where you downloaded the file from [Passport Advantage](#).
 - b. Enter a name and location for your file.
 - c. Select a resource for your template.
 - d. Review the details for your template.
 - e. Select the size of your configuration.
 - f. Select the storage settings.
 - g. Select the networks.
 - h. Customize the Template, if necessary.
 - i. Review the details to ensure that they are correct.
 - j. Select Finish to deploy the virtual machine.

Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See [Requirements for initial deployment on VMware](#).

The template creation appears in your Recent Tasks list.

5. Select the Storage tab in the Navigator.
6. Navigate to your datastore.
7. Upload your ISO file.
 - a. Select the Navigate to the datastore file browser icon in the icon menu.
 - b. Select the Upload a file to the Datastore icon in the icon menu.
 - c. Navigate to the ISO file that you created in your project.
It is the `myProject/analytplan-out/node-config`
 - d. Upload the ISO file to the datastore.
8. Leave the datastore by selecting the VMs and Templates icon in the Navigator.
9. Locate and select your virtual machine.
10. Select the Configure tab in the main window.
11. Select Edit....

- a. On the Virtual Hardware tab, select CD/DVD Drive 1.
 - b. For the Client Device, select Datastore ISO File.
 - c. Find and select your datastore in the Datastores category.
 - d. Find and select your ISO file in the Contents category.
 - e. Select OK to commit your selection and exit the Select File window.
 - f. Ensure that the Connect At Power On check box is selected.
- Tip:
- Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
 - Note that VMware related issues with ISO mounting at boot may occur if Connect At Power On
- g. Select OK to commit your selection and close the window.

12. Start the virtual machine by selecting the play button on the icon bar.

The installation might take several minutes to complete, depending on the availability of the system and the download speed.

13. Next, verify the deployment. Continue with [Verifying deployment of the Analytics subsystem](#).

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Verifying deployment of the Analytics subsystem

Verify that deployment of the Analytics OVA file succeeded.

Before you begin

You must have completed [Deploying the Analytics subsystem OVA file](#).

About this task

After you configure an ISO and deploy it with the Analytics subsystem OVA, as described in [Deploying the Analytics subsystem OVA file](#), verify that the subsystem installed correctly and is functional.

Procedure

1. Log in to the virtual machine by using an SSH tool to check the status of the installation:

- a. Enter the following command to connect to *apicadm* using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.

- b. Select Yes to continue connecting.

Your host names are automatically added to your list of hosts.

- c. Run the **apic status** command to verify that the installation completed and the system is running correctly.

The command output for a correctly running Analytics system is similar to the following lines:

```
#sudo apic status
INFO[0000] Log level: info

Cluster members:
- testsrv0233.subnet1.example.com (1.2.152.233)
  Type: BOOTSTRAP MASTER
  Install stage: DONE
  Upgrade stage: UPGRADE_DONE
  Docker status:
    Systemd unit: running
  Kubernetes status:
    Systemd unit: running
    Kubelet version: testsrv0233 (4.4.0-138-generic) [Kubelet v1.10.6, Proxy v1.10.6]
  Etcd status: pod etcd-testsrv0233 in namespace kube-system has status Running
  Addons: calico, dns, helm, kube-proxy, metrics-server, nginx-ingress,
Etcd cluster state:
- etcd member name: testsrv0233.subnet1.example.com, member id: 12836860275847862867, cluster id:
14018872452420182423,
  leader id: 12836860275847862867, revision: 365042, version: 3.1.17
```

- For a list of the Kubernetes pods started by the deployment, see the Results section in [Deploying the Analytics subsystem](#).
- If you have now installed all subsystems, continue to [Post-deployment steps](#).

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Deploying the Developer Portal

You create a Developer Portal node by deploying the Developer Portal OVA template. After you deploy the Developer Portal OVA template, you can install the Developer Portal.

Before you begin

Before you deploy:

- Review the [Deployment requirements on VMware](#).
- Review the [API Connect configuration on VMware](#).
- Review [What's new for v10 installation](#)
- For information on deploying a cluster, see [Configuring API Connect subsystems in a cluster](#)
- If you are upgrading from a previous version, see [Upgrading API Connect](#).

Note:

Ensure that your kernel or Kubernetes node has the value of its `inotify` watches set high enough so that the Developer Portal can monitor and maintain the files for each Developer Portal site. If set too low, the Developer Portal containers might fail to start or go into a `non-ready` state when this limit is reached. If you have many Developer Portal sites, or if your sites contain a lot of content, for example, many custom modules and themes, then a larger number of `inotify` watches are required. You can start with a value of 65,000, but for large deployments, this value might need to go up as high as 1,000,000. The Developer Portal containers take `inotify` watches only when they need them. The full number is not reserved or held, so it is acceptable to set this value high.

About this task

You must deploy the Developer Portal OVA template to create each Developer Portal node that you want in your cloud. Each node has a separate CLI password account that is required to log in through a Secure Shell (SSH) to complete specific administrative actions for only that node.

Important deployment information for Developer Portal:

- You must deploy the Developer Portal OVA template by using a version of the VMware vSphere Client that supports the SHA-512 Cryptographic Hash Algorithm.
- The Developer Portal node is initially configured with a default password of `7iron-hide`, with the user name of `admin`. For security reasons, change the default password by completing one of the following actions:
 - During deployment, if the feature is available in your VMware instance, enter a new password. If you specify a password during deployment, the password for the Developer Portal command line interface (CLI) is modified. Use the new password when you log into the CLI. You cannot modify the admin user name for the CLI.
 - After deployment, log in to the CLI for each virtual appliance and run the command to change the default password for that specific node. The CLI command is `passwd`.

Note that this console uses a US keyboard configuration, in which the `@` symbol can be in a different place to other keyboard configurations. If you are not using a US keyboard, ensure that you typed the password correctly.

- Only static IP addresses that are specified during the `apicup` project configuration before the installation of the OVAs are supported.

- To enable effective high availability for your Portal service, you need a latency that is less than 50ms between all OVAs to avoid the risk of performance degradation. Servers with uniform specifications are required, as any write actions occur at the speed of the slowest OVA, as the write actions are synchronous across the cluster of OVAs. It is recommended that there are three servers in each cluster of OVAs for the high availability configuration. The three servers can be situated in the same data center, or across three data centers to ensure the best availability. However, you can configure high availability with two data centers.

Procedure

Complete the following steps in order:

Note: The following steps apply to VMware only. Depending on the VMware version that you are using, some of the steps might vary. For example, you might not be able to change the user name and password during deployment.

1. Specify configuration settings for the Developer Portal subsystem and create an ISO. See [Configuring the Developer Portal subsystem](#)
2. Deploy the subsystem OVA into an appliance VM. See [Deploying the Developer Portal subsystem OVA file](#).
3. Verify the deployment. See [Verifying deployment of the Developer Portal subsystem](#)
4. Optional: Define multiple Developer Portal endpoints. See [Defining multiple portal endpoints for a VMware environment](#)

What to do next

If you want to deploy an API Connect Analytics OVA file, continue with [Deploying the Analytics subsystem](#).

If you did not specify a new password during deployment in VMware, then after deployment, log in to the command-line interface (CLI) for each appliance and run the command `passwd` to change the password.

- [Configuring the Developer Portal subsystem](#)
Specify configuration properties for your Developer Portal subsystem, and create an ISO.
- [Deploying the Developer Portal subsystem OVA file](#)
After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.
- [Verifying deployment of the Developer Portal subsystem](#)
Verify that deployment of the Developer Portal OVA file succeeded.
- [Configuring two NICs on the Developer Portal](#)
Configure the Developer Portal to use two network interface cards.
- [Specifying a range of allowable client IP addresses for Developer Portal](#)
Specify the range of client IP addresses to be allowed in a deployment of the Developer Portal
- [Defining multiple portal endpoints for a VMware environment](#)
Multiple public facing endpoints (portal-www) can be defined for the Developer Portal.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Configuring the Developer Portal subsystem

Specify configuration properties for your Developer Portal subsystem, and create an ISO.

Before you begin

Review the requirements and important deployment information for Developer Portal. See [Deploying the Developer Portal](#).

About this task

Use the `apicup` installation utility to specify configuration settings for your Developer Portal subsystem.

Procedure

1. Ensure that you obtained the distribution file and have a project directory, as described in [First steps for deploying in a VMware environment](#).
2. Change to the project directory.

```
cd myProject
```

3. Create a portal subsystem.

```
apicup subsys create port portal
```

Where:

- `port` is the name of the Developer Portal server that you are creating. You can assign it any name, as long as the identifier consists of lowercase alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character.
- `portal` indicates that you want it to create a Developer Portal microservice.

Note: Unless you are installing a two data center deployment, leave `multi-site-ha-enabled` as false, and ignore `multi-site-ha-mode`, `replication-peer-fqdn`, `site-name`, and the `portal-replication` endpoint, as these options are all related to that feature. For more information, see [Installing a two data center deployment](#).

The `apiconnect-up.yml` file that is in that directory is updated to add the portal-related entries.

Tip: At any time, you can view the current developer portal subsystem values in the `apiconnect-up.yml` by running the `apicup get` command:

apicup subsys get port

If you have not yet configured the subsystem, the command might return errors. Also, if you have not updated the value, a default value is listed, if there is one that is available.

After configuration is complete, you can view output similar to the following sample:

Appliance settings

=====

Name	Value
------	-------

Description	Value
-------------	-------

additional-cloud-init-file

(Optional) Path to additional cloud-init yml file

data-device sdb

VM disk device (usually `sdb` for SCSI or `vdb` for VirtIO)

default-password

\$6\$r0unds=4096\$vtcqpAVK\$dzqrOeYP33WTVtug38Q4Rld5l8TmdQgezzTnkX/PFwkzTiZ2S0CqNRr1S4b08tOc4p.OEg4BtzBe/r8RAk.gW/

(Optional) Console login password for `apicadm` user, password must be pre-hashed

dns-servers [192.168.1.201]

List of DNS servers

extra-values-file

(Optional) Path to additional configuration yml file

k8s-pod-network 172.16.0.0/16

(Optional) CIDR for pods within the appliance

k8s-service-network 172.17.0.0/16

(Optional) CIDR for services within the appliance

public-iface eth0

Device for API/UI traffic (Eg: eth0)

search-domain [subnet1.example.com]

List for DNS search domains

ssh-keyfiles [/home/vsphere/.ssh/id_rsa.pub]

List of SSH public keys files

traffic-iface eth0

Device for cluster traffic (Eg: eth0)

Subsystem settings

=====

Name	Value
------	-------

Description	Value
-------------	-------

deployment-profile n1xc2.m8

Deployment profile (n1xc2.m16/n3xc4.m16) for analytics, (n1xc4.m16/n3xc4.m16) for management, (n1xc2.m8/n3xc4.m8) for portal

license-use nonproduction

License use (production/nonproduction)

multi-site-ha-enabled false

Multi site HA enabled

multi-site-ha-mode active

Multi site HA mode (active/passive)

replication-peer-fqdn

Replication peer fully qualified name (replication endpoint of active mode site)

site-name

Site name, used in k8s resource names

Endpoints

=====

Name	Value
------	-------

Description	Value
-------------	-------

portal-admin portal-api.example.com

FQDN of Portal admin endpoint

portal-replication

FQDN of Portal replication endpoint, only required if HA is enabled

portal-www portal-www.example.com

FQDN of Portal web endpoint

4. For production environments, specify `deployment-profile`.

```
apicup subsys set port deployment-profile=n3xc4.m8
```

The `deployment-profile` parameter indicates that you are deploying in high availability (HA) mode for a production environment. To specify a development profile, for use in development and testing, specify `deployment-profile=n1xc2.m8`. For more information, see [Requirements for initial deployment on VMware](#).

5. Specify the license version you purchased.

```
apicup subsys set port  
license-use=<license_type>
```

The `license_type` must be either `production` or `nonproduction`. If not specified, the default value is `nonproduction`.

6. Optional: Configure scheduled backups of the subsystem. This step is optional but is recommended.

Refer to the instructions in [Backing up and restoring the Developer Portal in a VMware environment](#).

7. Optional: Configure your logging.

Logging can be configured at a later time, but you must enable it before installation to capture the log events from the installation.

- a. Complete the procedure at [Configuring remote logging for a VMware deployment](#).
- b. Enter the following command to create the log file:

```
apicup subsys set port additional-cloud-init-file=config_file.yml
```

8. Enter the following commands to update the apiconnect-up.yml with the information for your environment:

a. Use **apicup** to set your endpoints.

You can use wildcard aliases or host aliases with your endpoints.

Optionally, you can specify all endpoints with one **apicup** command.

Note: You cannot specify the underscore character "_" in domain names that are used in endpoints. See [API Connect configuration on VMware](#).

The endpoints must be unique hostnames which both point to the IP address of the OVA (single node deployment), or to the IP of a load balancer configured in front of the OVA nodes. See examples in the sample output in step 3.

Setting	Endpoint host description
portal-admin	This is the <i>unique_hostname</i> for communication between your Cloud Manager and API Manager, and your Developer Portal. The values for the portal-admin and portal-www must be different. <code>apicup subsys set port portal-admin=<i>unique_hostname</i>.<i>domain</i></code>
portal-www	This is the <i>unique_hostname</i> for the Developer Portal Internet site that is created for the Developer Portal. Multiple portal-www endpoints may be configured, as described here: Defining multiple portal endpoints for a VMware environment . <code>apicup subsys set port portal-www=<i>unique_hostname</i>.<i>domain</i></code>

b. Set your search domain. Multiple search domains should be separated by commas.

```
apicup subsys set port search-domain=your_search_domain
```

Where *your_search_domain* is the domain of your servers, entered in all lowercase. Setting this value ensures that your searches also append these values, which are based on your company's DNS resolution, at the end of the search value. A sample search domain is *mycompany.example.com*.

Ensure that the value for *your_search_domain* is resolved in the system's /etc/resolv.conf file to avoid "502" errors when accessing the Cloud Manager web site. For example:

```
# Generated by resolvconf
search your_search_domain ibm.com other.domain.com
```

c. Set your domain name servers (DNS).

Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

```
apicup subsys set port dns-servers=ip_address_of_dns_server[,ip_address_of_another_dns_server_if_necessary]
```

DNS entries may not be changed on a cluster after the initial installation.

9. Set a Public key.

```
apicup subsys set port ssh-keyfiles=path_to_public_ssh_keyfile
```

Setting this key enables you to use **ssh** with this key to log in to the virtual machine to check the status of the installation. You will perform this check in [Verifying deployment of the Developer Portal subsystem](#).

10. You can set a hashed password that you enter to log in to your Developer Portal server for the first time.

a. **Important:** Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).

b. If you do not have a password hashing utility, install one.

Operating system	Command
Ubuntu, Debian, OSX	If the mkpasswd command utility is not available, download and install it. (You can also use a different password hashing utility.) On OSX, use the command: <code>gem install mkpasswd</code> .
Windows, Red Hat	If necessary, a password hashing utility for the Windows operating system, like OpenSSL

c. Create a hashed password

Operating system	Command
Ubuntu, Debian, OSX	<code>mkpasswd --method=sha-512 --rounds=4096 <i>password</i></code>
Windows, Red Hat	For example, using OpenSSL: <code>openssl passwd -1 <i>password</i></code> . Note that you might need to add your password hashing utility to your path; for example, on Windows: <code>set PATH=c:\cygwin64\bin;%PATH%</code>

d. Set the hashed password for your subsystem:

```
apicup subsys set port default-password="hashed_password"
```

Notes:

- The password is hashed. If it is in plain text, you cannot log into the VMWare console.
- Note that the password can only be used to login through the VMWare console. You cannot use it to SSH into the Appliance as an alternative to using the **ssh-keyfiles**.
- On Linux or OSX, use single quotes around *hashed_password*. For Windows, use double quotes.
- If you are using a non-English keyboard, understand the limitations with using the remote VMWare console. See [Requirements for initial deployment on VMware](#).

11. Optional: If the default IP ranges for the API Connect Kubernetes pod and the service networks conflict with IP addresses that must be used by other processes in your deployment, modify the API Connect values.

You can change the IP ranges of the Kubernetes pod and the service networks from the default values of 172.16.0.0/16 and 172.17.0.0/16, respectively. In the case that a /16 subnet overlaps with existing IPs on the network, a Classless Inter-Domain Routing (CIDR) as small as /22 is acceptable. You can modify these ranges during initial installation and configuration only. You cannot modify them once an appliance has been deployed. See [API Connect configuration on VMware](#).

a. Update the IP range for the Kubernetes pod

```
apicup subsys set port k8s-pod-network='new_pod_range'
```

Where `new_pod_range` is the new value for the range.

b. Update the IP range for Service networks.

```
apicup subsys set port k8s-service-network='new_service_range'
```

Where `new_service_range` is the new value for the range.

12. Add your hosts.

```
apicup hosts create port hostname.domainname hd_password
```

Where the following are true:

- `hostname.domainname` is the fully qualified name of the server where you are hosting your Developer Portal, including the domain information.
- `hd_password` is the password of the Linux Unified Key Setup uses to encrypt the storage for your Developer Portal. This password is hashed when it is stored on the server or in the ISO. Note that the password is base64 encoded when stored in `apiconnect-up.yml`. Repeat this command for each host that you want to add.

Note: Host names and DNS entries may not be changed on a cluster after the initial installation.

13. Create your interfaces.

```
apicup iface create port hostname.domainname physical_network_id host_ip_address/subnet_mask gateway_ip_address
```

Where `physical_network_id` is the network interface ID of your physical server. The value is most often `eth0`. The value can also be `ethx`, where `x` is a number identifier.

The format is similar to this example: `apicup iface create port myHostname.domain eth0 192.0.2.1/255.255.1.1 192.0.2.1`

Note: You can optionally configure a second network interface (NIC) card for use with Developer Portal. In this scenario, one NIC is used for internal traffic between the Portal and APIM, and the second is used as a public interface. If you are creating multiple network interfaces, each one must be on a different subnet with a different gateway. For information on configuring two NICs for Developer Portal, see [Configuring two NICs on the Developer Portal](#).

14. Optional: You can specify a range of allowable client IP addresses.

You can optionally restrict which IP addresses can access any of the ingresses by creating an allowlist annotation, which then will only allow the specified IP addresses to access the ingress and will deny all other source IP addresses. See [Specifying a range of allowable client IP addresses for Developer Portal](#).

Note: One usage of this restriction is the scenario where you split traffic between your private and public networks in 2 NIC configuration.

15. Optional: Use `apicup` to view the configured hosts:

```
apicup hosts list port
apimdev0232.hursley.ibm.com
Device IP/Mask Gateway
eth0 1.2.152.232/255.255.254.0 1.2.152.1
```

Note: If you are configuring a two data center deployment, continue with the installation instructions in [Installing a two data center deployment](#).

16. Leave `multi-site-ha-enabled` set to `false`.

17. Optional: Verify that the configuration settings are valid.

```
apicup subsys get port --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting. See the following sample output.

```

18. Create your ISO file.

```
apicup subsys install port --out portplan-out
```

The `--out` parameter and value are required. In this example, the ISO file is created in the `myProject/portplan-out` directory.

If the system cannot find the path to your software that creates ISO files, create a path setting to that software by running a command similar to the following command:

Operating system	Command
Ubuntu, Debian, OSX	<code>export PATH=\$PATH:/Users/your_path/</code>
Windows, Red Hat	<code>set PATH="c:\Program Files (x86)\cdrtools";%PATH%</code>

19. Next, use the ISO to deploy the subsystem OVA. Continue with [Deploying the Developer Portal subsystem OVA file](#).

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details. For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Deploying the Developer Portal subsystem OVA file

After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.

Before you begin

You must have completed the configuration of the project file entries for the Developer Portal subsystem, for one of the following scenarios:

- During initial installation, [Configuring the Developer Portal subsystem](#).
- When upgrading from 2018, [Upgrading v2018 subsystems to v10](#)
- When upgrading from 10 to 10.0.1.2-ifix1-eus, [Upgrading subsystems from 10 to 10.0.1.2-eus on VMware](#)

Procedure

1. Log into the VMWare vSphere Web Client.
2. Using the VSphere Navigator, navigate to the directory where you are deploying the OVA file.
3. Right-click the directory and select Deploy OVF Template.
4. Complete the Deploy OVF Template wizard.
 - a. Select the Portal subsystem .OVA file template by navigating to the location where you downloaded the file in [First steps for deploying in a VMware environment](#).
 - b. Enter a name and location for your file.
 - c. Select a resource for your template.
 - d. Review the details for your template.
 - e. Select the size of your configuration.
 - f. Select the storage settings.

Note that the number of Central Processing Units, RAM, and size of disk that you need for the Developer Portal varies depending on the number of sites that are hosted and the number of concurrent users you expect your site to have:

Table 1. Developer Portal hardware requirements

Number of sites	Number of concurrent users	Number of CPUs	Amount of RAM (GB)	Data Disk Size (GB)++
1	1	2**	4	50
20	5	4	16	70
100	20	8	32	100
100	100	16	64	500

Important:

- ++The data disk size is extra to the main disk of the OVA. The main disk of the OVA is sized at 100GB, and should not be changed. Therefore, the total disk size of the OVA is 100GB plus the data disk size. The default data disk size is 200GB. If you want to select a different value, then you need to do this by using the OVF Tool, or the VMware GUI, before you power on the VM. Note that certain versions of the VMware GUI may not allow you to resize the data disk, and in this case you should use the OVF Tool.
- **The requirement of 2 CPUs is suitable only for proof-of-concept work, and non-high availability deployments. For example, this configuration is suitable for the demo mode of the apicup installation, which is set by using the command `apicup subsys set port deployment-profile=n1xc2.m8`.
- It's not recommended to have more than 100 sites per Developer Portal service. Note that it's not necessary to have a Portal site for every Catalog, for example Catalogs that are only for API Developers don't need a Portal site, as the APIs can be tested by using credentials from the API Manager. If more than 100 sites are required, you should configure additional Developer Portal services; see [Registering a Portal service](#).

- Select the networks.
- Customize the Template, if necessary.
- Review the details to ensure that they are correct.
- Select Finish to deploy the virtual machine.

Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See [Requirements for initial deployment on VMware](#).

The template creation appears in your Recent Tasks list.

- Select the Storage tab in the Navigator.
- Navigate to your datastore.
- Upload your ISO file.
 - Select the Navigate to the datastore file browser icon in the icon menu.
 - Select the Upload a file to the Datastore icon in the icon menu.
 - Navigate to the ISO file that you created in your project.
It is the `myProject/portplan-out`
 - Upload the ISO file to the datastore.
- Leave the datastore by selecting the VMs and Templates icon in the Navigator.
- Locate and select your virtual machine.
- Select the Configure tab in the main window.
- Select Edit....
 - On the Virtual Hardware tab, select CD/DVD Drive 1.
 - For the Client Device, select Datastore ISO File.
 - Find and select your datastore in the Datastores category.
 - Find and select your ISO file in the Contents category.
 - Select OK to commit your selection and exit the Select File window.
 - Ensure that the Connect At Power On check box is selected.

Tip:

 - Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
 - Note that VMware related issues with ISO mounting at boot may occur if Connect At Power On
 - Select OK to commit your selection and close the window.
- Start the virtual machine by selecting the play button on the icon bar.
The installation might take several minutes to complete, depending on the availability of the system and the download speed.
- Continue with [Verifying deployment of the Developer Portal subsystem](#).

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Verifying deployment of the Developer Portal subsystem

Verify that deployment of the Developer Portal OVA file succeeded.

Before you begin

You must have completed [Deploying the Developer Portal subsystem OVA file](#).

About this task

After you configure an ISO and deploy it with the Developer Portal subsystem OVA, as described in [Deploying the Developer Portal subsystem OVA file](#), verify that the subsystem installed correctly and is functional.

Procedure

- Log in to the virtual machine by using an SSH tool to check the status of the installation:
 - Enter the following command to connect to `port` using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of `apicadm`, which is the API Connect ID that has administrator privileges.

- Select Yes to continue connecting.
Your host names are automatically added to your list of hosts.
- Run the `apic status` command to verify that the installation completed and the system is running correctly.
The command output for a correctly running Developer Portal system is similar to the following lines:

```
$ sudo apic status
INFO[0000] Log level: info
```

```

Cluster members:
- testsrv1251.subnet1.example.com (1.2.3.4)

Running			

- Optional: Define multiple Developer Portal endpoints. See [Defining multiple portal endpoints for a VMware environment](#).
- If you have now installed all subsystems, continue to [Post-deployment steps](#).

Note:

When you create or register a Developer Portal service, the Portal subsystem checks that the Portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the `portal-www` pod, admin container logs, if the endpoint cannot be reached:

```

An error occurred contacting the provided portal web endpoint: example.com
The provided Portal web endpoint example.com returned HTTP status code 504

```

In this instance, you can disable the Portal web endpoint check so that the Developer Portal service can be created successfully. To disable the endpoint check, complete the following update:

On VMware

In your `apicup` project, create a file called `ptl-extra-values.yaml` (or edit the file if one already exists), and add the following section:

```

spec:
  template:
    - containers:
      - env:
        - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
          value: "true"
        name: admin
        name: www

```

Run the following commands:

```

apicup subsys set <ptl_subsys> extra-values-file <path-to-ptl-extra-values-yaml-file>
apicup subsys install <ptl_subsys>

```

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details. For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Configuring two NICs on the Developer Portal

Configure the Developer Portal to use two network interface cards.

About this task

When deploying the Developer Portal, you can optionally separate network traffic such that the portal has network interface in your private network, where the communications to the APIM manager take places, and another network interface in your public network, where the end users can access the Portal web sites.

You can do this by using the iface on eth0 for your traffic and defining an extra iface definition (eth1) for your public interface. Do this as part of the initial configuration of the Developer Portal. Note the following requirements:

- iface eth0 and eth1 must have different subnets. This means that you cannot test the configuration by using two IP addresses on the same subnet, due to the routing table produced by the OVA at bootstrap.
- The hostname of the machine must be reachable via eth0 and you must use eth0 as the traffic (private interface) and eth1 as the public interface.

Procedure

1. Verify that you have created a first interface, by following the instructions in [Step 13 of Configuring the Developer Portal subsystem](#).
2. Use `apicup` to add an extra iface definition as follows for your public interface:

```
apicup iface create test-stack-portal test0094.test.example.com eth1 1.2.3.232/255.255.254.0 1.2.3.1
```

3. Set the hostname of your portal-www ingress to the hostname that is associated with the IP address given on `eth1`.

```
apicup subsys set my-portal portal-www portal.myhost0232.company.com
```

4. When configuring the second NIC during initial installation, return to [Step 14 of Configuring the Developer Portal subsystem](#). Follow the remaining steps in the configuration instructions, and then create the Portal OVA and deploy it as usual.

Notes:

- If you are creating multiple network interfaces, each one must be on a different subnet with a different gateway.
- Before powering on the Portal, use the VMware GUI to add a second network card to the VM, with the correct settings for your public network.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Specifying a range of allowable client IP addresses for Developer Portal

Specify the range of client IP addresses to be allowed in a deployment of the Developer Portal

About this task

Use an extra-values-file, which serves as a portal CR override, to provide an allowable addresses annotation.

Procedure

In your `apicup` project, create a file called `pt1-extra-values.yaml` with the necessary content. For example:

```
spec:
  portalUIEndpoint:
    annotations:
      ingress.kubernetes.io/whitelist-source-range: 1.2.88.0/24
```

In this example, `1.2.88.0/24` is the acceptable range of client IP addresses.

Note: Depending on your network configuration for the forwarding of client IP addresses, you might need to run several test iterations to work out which client IP addresses to include in the list.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Defining multiple portal endpoints for a VMware environment

Multiple public facing endpoints (portal-www) can be defined for the Developer Portal.

About this task

You can override the single endpoint definition for portal-WWW, and the associated portal-www-ingress TLS certificate, to support multiple portal-www endpoints.

Procedure

1. Create an `ingress-issuer`, ssh into one appliance node, change to root by using `sudo -i`, then create a file `ingress-issuer.yaml` with the content:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: ingress-ca
spec:
  secretName: ingress-ca
  commonName: "ingress-ca"
  usages:
  - digital signature
  - key encipherment
  - cert sign
  isCA: true
  issuerRef:
    name: selfsigning-issuer
    kind: Issuer
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: ingress-issuer
spec:
  ca:
    secretName: ingress-ca
```

Run `kubectl apply -f ingress-issuer.yaml`.

Note: Instead of creating an `ingress-issuer`, you can replace that step, and not use `cert-manager`, by creating `portal-web-host1`, `portal-web-host2`, and `portal-web-host3`, so that they contain certificates for the respective endpoints. In this case, the `ptl-extra-values.yaml` would not contain reference to `cert-manager`:

```
spec:
  portalUIEndpoint:
    hosts:
    - name: ptl.host1.example.com
      secretName: portal-web-host1
    - name: ptl.host2.example.com
      secretName: portal-web-host2
    - name: ptl.host3.example.com
      secretName: portal-web-host3
```

To create the certificates for each `portal-www` endpoint, complete the following steps:

- a. If you are using self-signed certificates, create the TLS secrets for each `portal-www` endpoint by generating the certificates. The following example shows how to generate certificates for each `portal-www` endpoint by using OpenSSL:

```
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host1-tls.key -out ptl.host1-tls.crt -subj
"/CN=ptl.host1.example.com"
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host2-tls.key -out ptl.host2-tls.crt -subj
"/CN=ptl.host2.example.com"
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host3-tls.key -out ptl.host3-tls.crt -subj
"/CN=ptl.host3.example.com"
```

- b. Store the SSL certificates in a secret. Firstly, copy the certificates to the Portal virtual machine, for example:

```
scp ptl.host1-tls.key ptl.host1-tls.crt ptl.host2-tls.key ptl.host2-tls.crt ptl.host3-tls.key ptl.host3-tls.crt
apicadm@portal-vm-address
```

Then, access the virtual machine by using SSH, and store the SSL certificates in a secret, for example:

```
create secret tls portal-web-host1 --key ptl.host1-tls.key --cert ptl.host1-tls.crt
sudo kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls portal-web-host2 --key ptl.host2-tls.key --
cert ptl.host2-tls.crt
sudo kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls portal-web-host3 --key ptl.host3-tls.key --
cert ptl.host3-tls.crt
```

2. In your `apicup` project, create a file called `ptl-extra-values.yaml` with the content:

```
spec:
  portalUIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ptl.host1.example.com
      secretName: portal-web-host1
    - name: ptl.host2.example.com
      secretName: portal-web-host2
    - name: ptl.host3.example.com
      secretName: portal-web-host3
```

Run the commands:

```
apicup subsys set <ptl_subsys> extra-values-file <path-to-ptl-extra-values-yaml-file>
apicup subsys install <ptl_subsys>
```

3. You should see the change on your appliance:

```

root@ptl:~# kubectl get ingress
NAME                                HOSTS                                ADDRESS                                PORTS                                AGE
ptl-portal-director                 api.ptl.example.com                80, 443                               25m
ptl-portal-web                       ptl.host1.example.com,ptl.host2.example.com,ptl.host3.example.com 80, 443                               25m

```

Results

You have defined multiple Developer Portal endpoints for a VMware environment.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Deploying DataPower Gateway

API Connect uses IBM® DataPower® Gateway to provide the gateway service.

The instructions in this section describe how to deploy IBM DataPower Gateway from files obtained from [Passport Advantage®](#), and apply to the following API Connect scenarios:

- API Connect deployments for the VMware environment
- API Connect deployments for Kubernetes, with a DataPower Gateway in a *non-Kubernetes* environment.

For these scenarios, continue with [Installing DataPower Gateway](#).

Note: Do not use these instructions if you are deploying API Connect deployments for Kubernetes, with DataPower Gateway in a *Kubernetes* environment. In this case, you can use DataPower Gateway files that are packaged with API Connect, on the API Connect section of Fix Central, and configured by using the API Connect Install Assist (`apicup`) commands. Follow the instructions in [Obtaining product files](#).

- [Installing DataPower Gateway](#)
Install and configure IBM DataPower Gateway in a non-Kubernetes environment for use with API Connect.
- [Configuring DataPower Gateway for API Connect](#)
You can configure the IBM DataPower Gateway to prepare for a registration with the API Connect Management server.
- [Sample configuration for multiple peering objects on gateway services external to Kubernetes](#)
Sample for reconfiguring the API Connect domain configuration for your gateway services to include multiple peering objects.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Installing DataPower Gateway

Install and configure IBM® DataPower® Gateway in a non-Kubernetes environment for use with API Connect.

Before you begin

Do not use these instructions for either of the following deployment scenarios:

- Both API Connect and DataPower Gateway in a Kubernetes environment.
In this scenario, use the instructions in [Obtaining product files](#).
- An existing DataPower Gateway in a non-Kubernetes environment, and you want to install a newer Fix Pack.
In this scenario, complete an *upgrade* rather than a new installation. See [Upgrading DataPower Gateway Service](#).

To review the installation and configuration scenarios, see [Deploying DataPower Gateway](#).

Procedure

1. Ensure that DataPower Gateway firmware version you plan to install is compatible with the API Connect Management server version.
Note: For API Connect Version 10.x, DataPower and API Connect releases may be within one fix pack of each other. For example, API Connect v10.0.1.n runs with DataPower Gateway 10.0.1.n, v10.0.1.n-1, or v10.0.1.n+1.
Important exception: Version 10.0.1.4-eus is not backwards compatible with 10.0.1.3. For example, API Connect 10.0.1.4-eus is not compatible with DataPower Gateway 10.0.1.3. If you deployed API Connect 10.0.1.4-eus, you must deploy either DataPower Gateway 10.0.1.4 or DataPower Gateway 10.0.1.5.

However, before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in [IBM API Connect Version 10 software product compatibility requirements](#) to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software, Integration Middleware, and view the list of compatible DataPower Gateway versions.

2. Obtain your DataPower files from IBM [Passport Advantage®](#).
Note that the DataPower files from [Passport Advantage](#) have entitled services for API Connect users.
See also [Download the firmware image from Passport Advantage](#).

3. Follow the DataPower Gateway installation information: <https://www.ibm.com/docs/en/datapower-gateway>.
Note: Set the timezone to UTC on all DataPower installations for use with API Connect.
4. Continue with [Configuring DataPower Gateway for API Connect](#).

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Configuring DataPower Gateway for API Connect

You can configure the IBM® DataPower® Gateway to prepare for a registration with the API Connect Management server.

About this task

API Connect and DataPower supports two different types of gateway configurations. The DataPower Gateway (v5 compatible) provides the same support as the gateway support that was available with API Connect version 5.x. The DataPower API Gateway is an enhanced gateway that is performance-focused. See [API Connect gateway types](#) for more information about the differences between the gateway types.

Continue with the instructions for the type of Gateway Service you are configuring:

- [Configuring DataPower API Gateway](#)
Configure the DataPower API Gateway to prepare for registration with the API Connect Management server.
- [Configuring DataPower Gateway \(v5 compatible\)](#)
You can configure the DataPower Gateway (v5 compatible) to prepare for a registration with the API Connect Management server.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Configuring DataPower API Gateway

Configure the DataPower® API Gateway to prepare for registration with the API Connect Management server.

Before you begin

- These instructions are for DataPower API Gateway deployments in a non-Kubernetes environment. Do not use these instructions if you installed API Connect on Kubernetes, with your DataPower API Gateway Service also in the Kubernetes environment. To review deployment scenarios, see [Deploying DataPower Gateway](#).
- Ensure you have installed a version of DataPower API Gateway that is compatible with the version of the API Connect Management server. See [Installing DataPower Gateway](#).
- A shared certificate and private key is used for securing the communication between the API Connect Management server and the gateway. See *Generating keys and certificates* in the appropriate version of the [DataPower documentation](#) for instructions on how to create them with the DataPower tools.
- Ensure that the time zone for the DataPower API Gateway is set to UTC.

About this task

- These instructions provide the basic steps for configuring a gateway service with a single gateway server. The lowest-level configuration objects are created first, then used in other configuration objects.
- Adding gateways to configure a peering environment is similar to creating the first gateway, and is recommended for resiliency in a production environment. A minimum of three gateway servers in a gateway service is recommended for high availability. See *Gateway peering* in the [DataPower documentation](#) for more information about configuring additional gateways for peering. See *Providing the gateway service to API Connect* in the [DataPower documentation](#) for more details about the DataPower settings and procedures.

Procedure

To configure a DataPower API Gateway to communicate with API Connect, complete the following steps:

Note: Use these instructions only for DataPower API Gateway . If you are configuring DataPower Gateway (v5 compatible) see [Configuring DataPower Gateway \(v5 compatible\)](#).

1. Open the DataPower WebGUI interface.
Most of the configuration procedure is done in the DataPower WebGUI interface, not in the Blueprint Console.
2. Optional: Enable the XML management interface in the default domain.
The XML management interface is optional for DataPower API Gateway. If enabled, this interface allows you to send status and configuration requests to the DataPower appliance through a standard SOAP interface, using SOAP messages.
 - a. Search for XML management interface in the navigation search bar, and select it.
 - b. Set the Administrative state to enabled.
 - c. You can specify a different port number if you do not want to use the default of **5550**.
 - d. Select Apply to make the changes
 - e. Save changes to the default domain by selecting Save Configuration.

3. Optional: Enable the REST management interface in the default domain.
The REST management interface is required if you want to enable to the Trace feature in the assembly Test tab in the API Manager.
 - a. Search for REST management interface in the navigation search bar, and select it.
 - b. Set the Administrative state to enabled.
 - c. You can specify a different port number if you do not want to use the default of **5554**.
 - d. Select Apply to make the changes
 - e. Save changes to the default domain by selecting Save Configuration.
4. Create an application domain.
This domain receives your traffic. The name of the DataPower domain where you configure the API Connect Gateway Service must be the same on each DataPower Gateway.
 - a. Search for Application domain in the navigation search bar, and select it.
 - b. Select Add to create the application domain.
 - c. Enter a unique name for your domain.
 - d. Ensure that enabled is selected for the Administrative state.
 - e. Ensure that the default domain is listed in the Visible application domain list.
 - f. Select Apply.
 - g. Change to your new application domain by selecting Domain in the menu bar, and selecting the domain that you created.
 - h. Select Save changes and switch domains.
All of the remaining steps on the DataPower gateway must be done in the application domain that you created.
 - i. Save changes to the domain by selecting Save Configuration.
5. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.
See *Managing the NTP service* in the [DataPower documentation](#).
6. Ensure that you have set a unique **System Identifier** for each v10 DataPower gateway. See *Initializing the DataPower Gateway* in the [DataPower documentation](#).
7. Create a self-signed certificate and private key to be used to protect the traffic between the management server and the API gateway service process. You can generate a certificate and private key using DataPower or by using other tools, such as **OpenSSL**. See *Generating keys and certificates* in the appropriate version of the [DataPower documentation](#) for instructions on how to create a crypto key with the DataPower tools.
8. Upload your private crypto key file to the domain.
 - a. Search for Crypto key in the navigation search bar, and select it.
 - b. Select Add to create a key object.
 - c. Create a unique name for the key object in the Name field.
 - d. Select Upload....
 - e. Browse for the key file (which must be a .pem or .p12 file) and select it.
 - f. If you want to rename it, enter a new name for the file.
 - g. Select Upload to move it to the server in the cert:// folder.
 - h. Select Apply to save the changes.
9. Upload your crypto certificate file to the domain.
Note: If your certificate is signed by an Intermediate CA, you must include the entire chain in a single key file (either .pem or .p12) for uploading.
 - a. Search for Crypto certificate in the navigation search bar, and select it.
 - b. Select Add to create a certificate object.
 - c. Create a unique name for the certificate object in the Name field.
 - d. Select Upload....
 - e. Browse for the key file (which must be a .pem or .p12 file) and select it.
 - f. If you want to rename it, enter a new name for the file.
 - g. Select Upload to move it to the server in the cert:// folder.
 - h. Select Apply to save the changes.
10. Associate the Crypto key with the Crypto certificate by setting the Identification credential.
 - a. Search for Crypto Identification Credentials in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a name for your credential.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. In the Crypto Key field, select the name of the key object that you created from the drop-down menu.
 - f. In the Certificate object field, select the name of the certificate object that you created from the drop-down menu.
 - g. Select Apply to commit your changes.
11. Create your TLS Client profile.
 - a. Search for TLS Client profile in the navigation search bar, and select it.
 - b. Select Add to create a client profile.
 - c. Create a unique name for the profile in the Name field.
 - d. Select your Identification credential from the drop-down list.
 - e. Ensure that the value of Validate server certificate is set to off.
 - f. Ensure that the value of Use SNI is set to on.
 - g. Select Apply to save the changes.
12. Create your TLS Server profile.
 - a. Search for TLS Server Profile in the navigation search bar, and select it.
 - b. Select Add to create a server profile.
 - c. Create a unique name for the profile in the Name field.
 - d. Select your Identification credential from the drop-down list.
 - e. Ensure that the value of Request client authentication is set to off.
Disabling the request for client authentication for the TLS client profile and the validation of server certificates for the TLS server profile disables security for the ease of configuring the gateway. To enable the secure communication using mutual TLS between IBM API Connect and Gateway, see [Binding a TLS server profile to a gateway service](#).
 - f. Select Apply to save the changes.
13. Define a configuration sequence.
The configuration sequence specifies how DataPower implements the APIs that are defined in API Connect.
 - a. Search for Configuration sequence in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a name for your configuration sequence.

The name **apic-config** is not allowed because it is already used internally.

- d. Ensure that the Administrative state has a value of enabled.
 - e. Ensure that the value in the Location profiles field is set to local:///
- This is the default value, so you might not need to change it.
- f. Select the Access profile.

For instructions on creating access profiles, see *Configuring the access profile for a configuration sequence* in the appropriate version of the [DataPower documentation](#).

- g. Change the value of the Configuration execution interval field to 3000.
- The other fields can retain their default settings.
- h. Select Apply to commit your changes.

14. Configure your gateway peering object for the API Connect Gateway Service.

This step is required when you set up a peer group of gateways, even if there is only a single gateway server in the gateway service.

- a. Search for Gateway peering in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a unique name for your gateway peering object.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. Select a local address for the communications among the members of the peer group.
 - f. Select a local port for the communication.
- You can use the default value of 16380.
- g. Select a monitor port for the communication.
- You can use the default value of 26380.
- h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
 - i. Clear the Enable TLS check box. TLS is not needed for a single peer.
 - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
 - k. Select Apply to commit your changes.

15. Configure your gateway peering object for rate limit information.

- a. Search for Gateway peering in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a unique name for your gateway peering object.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. Select a local address for the communications among the members of the peer group.
 - f. Select a local port for the communication.
- Use a unique port, different than the ports used for communication by other gateway peering objects.
- g. Select a monitor port for the communication.
- Use a unique port, different than the ports used for monitoring by other gateway peering objects.
- h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
 - i. Clear the Enable TLS check box. TLS is not needed for a single peer.
 - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
 - k. Select Apply to commit your changes.

16. Optional: If you are using the ratelimit module described in the [DataPower documentation](#), configure your gateway peering object for GatewayScript rate limiting information.

- a. Search for Gateway peering in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a unique name for your gateway peering object.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. Select a local address for the communications among the members of the peer group.
 - f. Select a local port for the communication.
- Use a unique port, different than the ports used for communication by other gateway peering objects.
- g. Select a monitor port for the communication.
- Use a unique port, different than the ports used for monitoring by other gateway peering objects.
- h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
 - i. Clear the Enable TLS check box. TLS is not needed for a single peer.
 - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
 - k. Select Apply to commit your changes.

17. Configure your gateway peering object for subscription information.

- a. Search for Gateway peering in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a unique name for your gateway peering object.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. Select a local address for the communications among the members of the peer group.
 - f. Select a local port for the communication.
- Use a unique port, different than the ports used for communication by other gateway peering objects.
- g. Select a monitor port for the communication.
- Use a unique port, different than the ports used for monitoring by other gateway peering objects.
- h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
 - i. Clear the Enable TLS check box. TLS is not needed for a single peer.
 - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
 - k. Select Apply to commit your changes.

18. Configure the gateway peering object for the API probe.

In order for API Connect to receive trace data in the Test tab's debugger, the DataPower API Gateway must be configured to support the API probe.

- a. Search for Gateway peering in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a unique name for your gateway peering object.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. Select a local address for the communications among the members of the peer group.
 - f. Select a local port for the communication.
- Use a unique port, different than the ports used for communication by other gateway peering objects.

- g. Select a monitor port for the communication.
Use a unique port, different than the ports used for monitoring by other gateway peering objects.
- h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
 - i. Clear the Enable TLS check box. TLS is not needed for a single peer.
 - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
 - k. Select Apply to commit your changes.
19. Configure the gateway peering manager.
 - a. Search for Gateway Peering Manager in the navigation search bar, and select it.
 - b. Set the Administrative state to enabled.
 - c. In the pull-down menu next to API Connect Gateway Service, select the gateway peering object configured in Step 14 for the API Connect Gateway Service.
 - d. In the pull-down menu next to Rate Limit, select the gateway peering object configured in Step 15 for rate limit information.
 - e. In the pull-down menu next to Subscription, select the gateway peering object configured in Step 17 for subscription.
 - f. In the pull-down menu next to API Probe, select the gateway peering object that you configured in Step 18 for the API probe.
 - g. If you are using the ratelimit module described in the [DataPower documentation](#), then for Gateway rate limiting, select the gateway peering object that you configured in Step 16 for rate limit information.
 - h. Select Apply to commit your changes.
20. Configure the API probe settings object.
 - a. Search for API probe settings in the navigation search bar, and select it.
 - b. Set the Administrative state to enabled.
 - c. Set the maximum number of records to 1000.
 - d. Set the expiration to 60 minutes.
 - e. In the pull-down menu next to Gateway Peering, select the gateway peering object that you configured in Step 18 for the API probe.
 - f. Select Apply to commit your changes.
21. Set the API Connect Gateway service to define the communication interface with the API Connect Management server and for API transactions.
 - a. Search for API Connect Gateway service in the navigation search bar, and select it.
 - b. Ensure that the Administrative state is set to enabled.
 - c. In the Local address field, enter the IP address of the DataPower gateway to which you want the traffic from the API Connect Management server to be sent.
 - d. Specify a value for Local port. You can use the default value of 3000, or specify a different port value.
Note: The Local port specifies the port through which API Connect connects to manage the API Connect Gateway Service. Use this port when you configure a Gateway Service on API Connect. Beyond this port, the gateway service uses two additional consecutive ports after the defined local port to bind to a loopback address. Therefore, you must ensure that there are no conflicts on all three consecutive ports that start from the defined local port.
 - e. In the TLS client field drop-down list, select the name of the TLS client profile that you created.
 - f. In the TLS server field drop-down list, select the name of the TLS server profile that you created.
 - g. In the API gateway address field, enter the IP address for the DataPower gateway to which you want the API traffic sent.
 - h. Use the default port value of 9443 for the API gateway port.
If the port is not being used by another service, you can also change it to port 443 if you want API transactions to be sent to the default port for HTTPS.
 - i. For DataPower API Gateway, set the Gateway Peering to **(none)**.
When no gateway peering object is configured for the DataPower API Gateway, the peering configuration defined in the Gateway Peering Manager configuration is used.
 - j. Select whether you want the DataPower Gateway (v5 compatible) or the DataPower API Gateway.
When the option is selected, it enables the registration of a DataPower Gateway (v5 compatible) gateway. Clear it to enable a DataPower API Gateway.
22. Register the gateway service in the API Connect Cloud Manager console:
 - a. Open the API Connect Cloud Manager console.
 - b. Navigate to Configure Topology.
 - c. Select Register Service.
 - d. Select DataPower API Gateway for the DataPower API Gateway.
 - e. Add a title, name, and summary for the gateway connection.
 - f. Optional: Configure the OAuth Shared Secret.
This setting allows OAuth tokens to be shared across multiple gateway services.
 - g. Enter one of the following values in the API Invocation Endpoint field:
 - IP address of the load balancer for the API transactions
 - IP address or host name of one of the gateways
 For example: `https://192.0.2.0:9443/`
 - h. Enter the one of the following values in the Management Endpoint field:
 - IP address of the load balancer for the management server traffic set to port 3000
 - IP address or hostname of one of the gateways
 For example: `https://192.0.2.0:3000/`
23. Select the default TLS Client Profile
24. Optional: Configure Server Name Indication (SNI) profiles.
SNI profiles allow different TLS certificates to be used for API transaction requests from different host names.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Configuring DataPower Gateway (v5 compatible)

You can configure the DataPower® Gateway (v5 compatible) to prepare for a registration with the API Connect Management server.

Before you begin

- These instructions are for DataPower API Gateway deployments in a non-Kubernetes environment. Do not use these instructions if you installed API Connect on Kubernetes, with your DataPower API Gateway Service also in the Kubernetes environment. To review deployment scenarios, see [Deploying DataPower Gateway](#).
- Ensure you have installed a version of DataPower API Gateway that is compatible with the version of the API Connect Management server. See [Installing DataPower Gateway](#).

- A shared certificate and private key is used for securing the communication between the API Connect Management server and the gateway. See *Generating keys and certificates* in the appropriate version of the [DataPower documentation](#) for instructions on how to create them with the DataPower tools.
- Ensure that the time zone for the DataPower API Gateway is set to UTC.

About this task

- These instructions provide the basic steps for configuring a gateway service with a single gateway server. The lowest-level configuration objects are created first, then used in other configuration objects.
- Adding gateways to configure a peering environment is similar to creating the first gateway, and is recommended for resiliency in a production environment. A minimum of three gateway servers in a gateway service is recommended for high availability. See *Gateway peering* in the [DataPower documentation](#) for more information about configuring additional gateways for peering. See *Providing the gateway service to API Connect* in the [DataPower documentation](#) for more details about the DataPower settings and procedures.

Procedure

To configure a DataPower gateway to communicate with API Connect, complete the following steps:

Note: Use these instructions only for DataPower Gateway (v5 compatible). If you are configuring DataPower API Gateway, see [Configuring DataPower API Gateway](#).

1. Open the DataPower WebGUI interface.
Most of the configuration procedure is done in the DataPower WebGUI interface, not in the Blueprint Console.
2. Enable the XML management interface in the **default** domain, if required. The XML management interface is required for DataPower Gateway (v5 compatible). The XML management interface is optional for DataPower API Gateway.
 - a. Search for **XML management interface** in the navigation search bar, and select it.
 - b. Set the Administrative state to enabled.
 - c. You can specify a different port number if you do not want to use the default of **5550**.
 - d. Select Apply to make the changes
 - e. Save changes to the default domain by selecting Save Configuration.
3. Create an application domain.
This domain receives your traffic. The name of the DataPower domain where you configure the API Connect Gateway Service must be the same on each DataPower Gateway.
 - a. Search for Application domain in the navigation search bar, and select it.
 - b. Select Add to create the application domain.
 - c. Enter a unique name for your domain.
 - d. Ensure that enabled is selected for the Administrative state.
 - e. Ensure that the default domain is listed in the Visible application domain list.
 - f. Select Apply.
 - g. Change to your new application domain by selecting Domain in the menu bar, and selecting the domain that you created.
 - h. Select Save changes and switch domains.
All of the remaining steps on the DataPower gateway must be done in the application domain that you created.
 - i. Save changes to the domain by selecting Save Configuration.
4. For the DataPower Gateway (v5 compatible) only: Enable statistics in the domain you created for **API Connect**.
 - a. Search for and select Statistics settings in the navigation search.
 - b. Select enabled for the Administrative state.
 - c. Select Apply.
5. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.
See [Managing the NTP service](#).
6. Ensure that you have set a unique **System Identifier** for each v10 DataPower gateway. See [Initializing the DataPower Gateway](#).
7. Create a self-signed certificate and private key to be used to protect the traffic between the management server and the API gateway service process. You can generate a certificate and private key using DataPower or by using other tools, such as **OpenSSL**. See *Generating keys and certificates* in the appropriate version of the [DataPower documentation](#) for instructions on how to create a crypto key with the DataPower tools.
8. Upload your private crypto key file to the domain.
 - a. Search for Crypto key in the navigation search bar, and select it.
 - b. Select Add to create a key object.
 - c. Create a unique name for the key object in the Name field.
 - d. Select Upload...
 - e. Browse for the key file (which must be a .pem or .p12 file) and select it.
 - f. If you want to rename it, enter a new name for the file.
 - g. Select Upload to move it to the server in the cert:// folder.
 - h. Select Apply to save the changes.
9. Upload your crypto certificate file to the domain.
Note: If your certificate is signed by an Intermediate CA, you must include the entire chain in a single key file (either .pem or .p12) for uploading.
 - a. Search for Crypto certificate in the navigation search bar, and select it.
 - b. Select Add to create a certificate object.
 - c. Create a unique name for the certificate object in the Name field.
 - d. Select Upload...
 - e. Browse for the key file (which must be a .pem or .p12 file) and select it.
 - f. If you want to rename it, enter a new name for the file.
 - g. Select Upload to move it to the server in the cert:// folder.
 - h. Select Apply to save the changes.
10. Associate the Crypto key with the Crypto certificate by setting the Identification credential.
 - a. Search for Crypto Identification Credentials in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a name for your credential.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. In the Crypto Key field, select the name of the key object that you created from the drop-down menu.
 - f. In the Certificate object field, select the name of the certificate object that you created from the drop-down menu.
 - g. Select Apply to commit your changes.

11. Create your TLS Client profile.
 - a. Search for TLS Client profile in the navigation search bar, and select it.
 - b. Select Add to create a client profile.
 - c. Create a unique name for the profile in the Name field.
 - d. Select your Identification credential from the drop-down list.
 - e. Ensure that the value of Validate server certificate is set to off.
 - f. Ensure that the value of Use SNI is set to on.
 - g. Select Apply to save the changes.
12. Create your TLS Server profile.
 - a. Search for TLS Server Profile in the navigation search bar, and select it.
 - b. Select Add to create a server profile.
 - c. Create a unique name for the profile in the Name field.
 - d. Select your Identification credential from the drop-down list.
 - e. Ensure that the value of Request client authentication is set to off.

Disabling the request for client authentication for the TLS client profile and the validation of server certificates for the TLS server profile disables security for the ease of configuring the gateway. To enable the secure communication using mutual TLS between IBM API Connect and Gateway, see [Binding a TLS server profile to a gateway service](#).
 - f. Select Apply to save the changes.
13. Configure your gateway peering object for the API Connect Gateway Service.

This step is required when you set up a peer group of gateways, even if there is only a single gateway server in the gateway service.

 - a. Search for Gateway peering in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a unique name for your gateway peering object.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. Select a local address for the communications among the members of the peer group.
 - f. Select a local port for the communication.

You can use the default value of 16380.
 - g. Select a monitor port for the communication.

You can use the default value of 26380.
 - h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
 - i. Clear the Enable TLS check box. TLS is not needed for a single peer.
 - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
 - k. Select Apply to commit your changes.
14. Set the API Connect Gateway service to define the communication interface with the API Connect Management server and for API transactions.
 - a. Search for API Connect Gateway service in the navigation search bar, and select it.
 - b. Ensure that the Administrative state is set to enabled.
 - c. In the Local address field, enter the IP address of the DataPower gateway to which you want the traffic from the API Connect Management server to be sent.
 - d. Use the default port value of 3000 for the Local port.
 - e. In the TLS client field drop-down list, select the name of the TLS client profile that you created.
 - f. In the TLS server field drop-down list, select the name of the TLS server profile that you created.
 - g. In the API gateway address field, enter the IP address for the DataPower gateway to which you want the API traffic sent.
 - h. Use the default port value of 9443 for the API gateway port.

If the port is not being used by another service, you can also change it to port 443 if you want API transactions to be sent to the default port for HTTPS.
 - i. For DataPower Gateway (v5 compatible), select the gateway peering object that you created in Step [13](#).
 - j. Select whether you want the DataPower Gateway (v5 compatible) or the DataPower API Gateway.

When the option is selected, it enables the registration of a DataPower Gateway (v5 compatible) gateway.
15. Register the gateway service in the API Connect Cloud Manager console:
 - a. Open the API Connect Cloud Manager console.
 - b. Navigate to Configure Topology.
 - c. Select Register Service.
 - d. Select DataPower Gateway (v5 compatible) for the gateway that was available in version 5.
 - e. Add a title, name, and summary for the gateway connection.
 - f. Optional: Configure the OAuth Shared Secret.

This setting allows OAuth tokens to be shared across multiple gateway services.
 - g. Enter one of the following values in the API Invocation Endpoint field:
 - IP address of the load balancer for the API transactions
 - IP address or host name of one of the gateways

For example: `https://192.0.2.0:9443/`
 - h. Enter the one of the following values in the Management Endpoint field:
 - IP address of the load balancer for the management server traffic set to port 3000
 - IP address or hostname of one of the gateways

For example: `https://192.0.2.0:3000/`
16. Select the default TLS Client Profile
17. Optional: Configure Server Name Indication (SNI) profiles.

SNI profiles allow different TLS certificates to be used for API transaction requests from different host names.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
 For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Sample configuration for multiple peering objects on gateway services external to Kubernetes

Sample for reconfiguring the API Connect domain configuration for your gateway services to include multiple peering objects.

- This reference shows how to configure API Connect domain configuration with gateway-peering configuration. To review domain configuration settings, see [Configuring DataPower Gateway for API Connect](#).
- This sample applies only to gateway services that are deployed external to Kubernetes, on either a physical or virtual appliance. This sample does not apply to gateway services that are deployed on Kubernetes.

The following examples show sample configuration for 3 different gateways, listed here with sample IP addresses of 1.1.1.1, 2.2.2.2, and 3.3.3.3. Note the following:

- The priority should be set differently on each of the three gateways. Set the lowest priority for the gateway that will run as primary.
- **persistence** should be set to **memory** for all configured peering objects.
- Optionally, add SSL configuration.

Configuration on gateway 1 (1.1.1.1)

```

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Troubleshooting installation and upgrades on VMware

Review the following troubleshooting guidance if you encounter a problem while installing or upgrading API Connect on VMware.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

- [Skipping health check when re-running upgrade](#)

The cloud-final.service fails during upgrade

Sometimes during upgrade, there is an issue with the `cloud-final.service` and a node, and the appliance-manager enters a bad state.

To determine whether your upgrade encountered this problem, complete the following steps:

1. Check the output of `apic health-check` command for a result similar to the following example:

```
# apic health-check
INFO[0000] Log level: info
FATA[0000] Unable to cluster status: rpc error: code = Unavailable desc = connection error: desc = "transport: Error while dialing dial tcp 9.20.153.38:9178: connect: connection refuse"
```

2. Check the response to the `journalctl -u appliance-manager | grep cloud-final` command and see if it looks like the following example:

```
# journalctl -u appliance-manager | grep cloud-final
Nov 21 19:41:58 apimdev1040 apic[2569]: Job for cloud-final.service failed because the control process exited with error code.
Nov 21 19:41:58 apimdev1040 apic[2569]: See "systemctl status cloud-final.service" and "journalctl -xe" for details.
```

If you determined that this was the problem, you can correct it by running each of the following commands on every node:

1. `systemctl restart cloud-final.service`
2. `apic lock`
3. `apic unlock`

Some containers in the kube-system namespace show a status of ErrImageNeverPull

When upgrading, some of the containers in the `kube-system` namespace might show a status of `ErrImageNeverPull`. This happens due to Docker not successfully loading all images from the upgrade .tgz file. To resolve this issue and enable the upgrade to proceed, complete the following steps:

1. Run the following command to determine which node is missing the control plane files:

```
kubectl -n kube-system get pods -owide
```

This command returns the names of the nodes containing pods with the `ErrImageNeverPull` status, which indicates missing control plane files.

2. On the node that is missing the control plane files, run the following command to determine which versions of the control plane are missing:

```
cat /var/lib/apiconnect/appliance-control-plane-current
```

- For each missing control plane, run the following command on the same node to add it, replacing `<version>` with the version of the control plane:

```
docker load < /usr/local/lib/appliance-control-plane/<version>/kubernetes.tgz
```

Pod stuck in Pending status during upgrade

When upgrading, the scheduler might deploy a subset of the same microservice pods on the same node. This can prevent other pods with `requiredDuringSchedulingIgnoredDuringExecution` affinity rules from being deployed due to a lack of resources on a subset of nodes. To allow the pending containers to be deployed successfully, identify any pods of the same type that are scheduled on the same node and delete one of them. This will free up space and cause the deleted pod to get rescheduled. To identify pods that are eligible to be deleted, and then delete the pods, complete the following steps:

- Run the following command and check for any pods of the same type that are on the same node:

```
kubectl get po -o=custom-columns='name:.metadata.name, node:.spec.nodeName, antiAffinity:.spec.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution' | grep -v '<none>' | awk '{print $1" "$2}'
```

In the following example snippet, one of the two `apim` pods on the node `test0186` should be deleted:

```
stv3-management-analytics-proxy-56848c8c69-phpdh test0186
stv3-management-analytics-proxy-56848c8c69-sc45f test0187
stv3-management-analytics-proxy-56848c8c69-scf6g test0188
stv3-management-apim-5574796948-6lnwj test0186
stv3-management-apim-5574796948-h9dgx test0186
stv3-management-apim-5574796948-tsb4g test0188
```

- Run the following command to delete a pod:

```
kubectl delete po <pod_name>
```

Database replica pods stuck in Unknown or Pending state

In certain scenarios, a postgres replica pod may not recover to a healthy state when a restore completes, a node outage occurs, or after a fresh install or upgrade. In these cases, a postgres pod remains in a `Unknown` or a `Pending` state after a number of minutes. The pod fail to get into a `Running` state.

This situation occurs when the replicas do not initialize properly. You can use the `patronictl reinit` command to reinitialize the replica. Note that this command syncs the replica's volume data from the current Primary pod.

Use the following steps to get the pod back into a working state:

- SSH into the VM as root.
- Exec onto the failing pod:

```
kubectl exec -it <postgres_replica_pod_name> -n <namespace> -- bash
```

- List the cluster members:

```
patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+-----+-----+
| Member | Host | Role | State | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+
| fxpk-management-01191b80-postgres-586f899fdf-6s25b | 172.16.172.244 | | start failed | | unknown |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51 | Leader | running | 3 | |
| fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m | 172.16.53.68 | | running | 3 | 0 |
+-----+-----+-----+-----+-----+-----+
```

In the example shown above `fxpk-management-01191b80-postgres-586f899fdf-6s25b` is not in running state.

Note the `clusterName` and `replicaName` which are not up:

- `clusterName` - `fxpk-management-01191b80-postgres`
- `replicaName` - `fxpk-management-01191b80-postgres-586f899fdf-6s25b`

- Run:

```
patronictl reinit <clusterName> <replicaName-which-is-not-running>
```

Example:

```
patronictl reinit fxpk-management-01191b80-postgres fxpk-management-01191b80-postgres-586f899fdf-6s25b
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+-----+-----+
| Member | Host | Role | State | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+
| fxpk-management-01191b80-postgres-586f899fdf-6s25b | 172.16.172.244 | | start failed | | unknown |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51 | Leader | running | 3 | |
| fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m | 172.16.53.68 | | running | 3 | 0 |
+-----+-----+-----+-----+-----+-----+
Are you sure you want to reinitialize members fxpk-management-01191b80-postgres-586f899fdf-6s25b? [y/N]: y
Success: reinitialize for member fxpk-management-01191b80-postgres-586f899fdf-6s25b
```

- Run `patronictl list` again.

You may also observe that the replica is on a different Timeline (TL) and possibly have a Lag in MB. It may take a few minutes for the pod to switch onto the same TL as the others and the Lag should slowly go to 0.

For example:

```
bash-4.2$ patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+-----+-----+
| Member | Host | Role | State | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+
```

fxpk-management-01191b80-postgres-586f899fdf-6s25b	172.16.172.244		running	1	23360
fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s	172.16.148.51	Leader	running	3	
fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m	172.16.53.68		running	3	0

6. The pod that previously was in an **Unknown** or **Pending** state or (0/1) **Running** state is now in (1/1) **Running** state.

Additional postgres replica created during installation or upgrade

If you see an installation or upgrade procedure stall with more than 2 postgres replica deployment in a n3 profile, delete the pending replica deployment by completing the following steps:

1. SSH into the VM as root.

2. Get the name of the pending postgres deployments:

```
kubectl get deploy -n <namespace> | grep postgres
```

3. Delete the pending postgres replica deployment:

```
kubectl delete deploy <replica_deployment_name> -n <namespace>
```

etcd pod stuck in Terminating state

During an upgrade, you might see a health-check reporting the upgrade is stuck in **ETCD** stage and that an **etcd** pod is stuck in the **Terminating** state.

Verify the issue by completing the following steps:

1. SSH into the VM as root.

2. Run the following command and verify that the upgrade stage is **ETCD**:

```
apic status
```

3. Run the following command to determine whether an **etcd** pod is stuck in the **Terminating** state:

```
kubectl get pods -n namespace | grep etcd
```

Resolve the issue by completing the following steps:

1. Run the following command to retrieve the names of the **etcd** pods:

```
kubectl get pods -n namespace -o wide | grep etcd
```

2. On the pod that is stuck, SSH into the VM as root.

3. Run the following command to restart the pod:

```
systemctl restart kubelet
```

Management subsystem upgrade imagePullBackOff issue

When upgrading the management subsystem, for example from v10.0.1.6 to v10.0.1.11, the postgres pods might run into an **imagePullBackOff** issue, where the postgres pods are looking for the v10.0.1.6 images that exist in the Docker registry, but the images haven't been loaded into the **Containerd** registry. To work around this issue, complete the following steps to manually move each image from the Docker registry to the **Containerd** registry:

1. Save the following Docker images, **ibm-apiconnect-management-k8s-init**, **crunchy-pgbackrest-repo**, **crunchy-pgbackrest**, **crunchy-pgbouncer**, and **crunchy-postgres-ha**, into a .tar file and keep in a secure location. For example, from v10.0.1.6:

```
docker save 127.0.0.1:8675/10.0.1.6/crunchy-pgbouncer > crunchy-pgbouncer.tar
```

2. Import each saved image into the **Containerd** registry. For example:

```
ctr --namespace k8s.io image import crunchy-pgbouncer.tar --digests=true
```

3. Re-tag the **import-*<datestamp>*@sha256:nnn** images to their appropriate ifix2 tags and digests. For example:

```
ctr --namespace k8s.io image tag <source> <target>
```

Portal db pods restart mysqld if the database state transfer takes more than 5 minutes

In IBM® API Connect Version 10.0.1.5-eus, if the portal database state transfer takes longer than 5 minutes from one **db** pod to another, then the **db** pod sending the data incorrectly thinks that the database process is stuck in a bad state, and will restart the database process. This situation would typically happen if you have more than 10 or 12 sites, a slow network between the **db** pods, such as in a distant multi-site high availability setup, or both.

In such cases, the following entry would be seen in one of the ready **db** containers inside a **db** pod:

```
dbstatus: ERROR: stuck in Donor mode for 5m31s!, restarting the database
```

To prevent this situation from happening, add the following environment variable to your portal deployment.

1. Create an extra values file to contain the environment variable, as follows:

```
spec:
  template:
    - containers:
      - env:
        - name: DONOR_STALE_SECS
          value: "7200"
```

```
name: db
name: db
```

2. Save the file as `dbstate.yaml`, and run the following command:

```
apicup subsys set <portal_subsystem_name> extra-values-file dbstate.yaml
```

3. Then, update the portal VMware with the updated setting by running the following command:

```
apicup subsys install <portal_subsystem_name>
```

4. To ensure that you get the new configuration and the database can startup correctly, you must delete all of the `db` pods by running the following command:

```
kubectl delete pod <portal-mydc-db-0> <portal-mydc-db-1> <portal-mydc-db-2>
```

To run this command you must log in to the virtual machine portal subsystem by using an SSH tool.

Issues when installing Drupal 8 based custom modules or sub-themes into the Drupal 9 based Developer Portal

From IBM API Connect 10.0.1.4-eus, the Developer Portal is based on the Drupal 9 content management system. If you want to install Drupal 8 custom modules or sub-themes into the Drupal 9 based Developer Portal, you must ensure that they are compatible with Drupal 9, including any custom code that they contain, and not using any deprecated APIs, for example. There are tools available for checking your custom code, such as [Drupal check](#) on GitHub, which checks Drupal code for deprecations.

For example, any Developer Portal sites that contain modules or sub-themes that don't contain a Drupal 9 version declaration will fail to upgrade, and errors like the following output will be seen in the `admin` logs:

```
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: Checking theme: emeraldgreen

[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: /tmp/restore_site.355ec8 is NOT
Drupal 9 compatible
...
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: Checking module: custom_mod_1
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '' found for custom_mod_1
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: Checking module: custom_mod_2
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '8.x' found for custom_mod_2
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Found modules incompatible with
Drupal 9: emeraldgreen rubyred
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: sitel.com is NOT Drupal 9
compatible
```

To fix version compatibility errors, all custom modules and sub-themes should declare a `core_version_requirement` key in their `*.info.yml` file that indicates Drupal 9 compatibility. For example:

```
name: Example module
type: module
description: Purely an example
core: 8.x
core_version_requirement: '^8 || ^9'
package: Example module

# Information added by Drupal.org packaging script on 2020-05-31
version: '8.x-1.3'
project: 'example_module'
datestamp: 1590905415
```

This example specifies that the module is compatible with all versions of Drupal 8 and 9. For more information, see [Let Drupal know about your module with an .info.yml file](#) on the drupal.org website.

If you have a backup of a site that you need to restore, and are getting the version compatibility error, but the module or theme `*.info.yml` file cannot be changed easily, then you have two options. Either:

- Add an environment variable into the portal CR for the `www` pod of the `admin` container stating `SKIP_D9_COMPAT_CHECK: "true"`. However, if you choose this method, you must be positive that all of the custom modules and themes for your sites are Drupal 9 compatible, as otherwise the sites may end up inaccessible after the upgrade or restore.
 1. On VMware, create an extra values file to contain the environment variable, as follows:

```
spec:
  template:
    - containers:
      - env:
        - name: SKIP_D9_COMPAT_CHECK
          value: "true"
        name: admin
      name: www
```

2. Save the file as `d9compat.yaml`, and run the following command:

```
apicup subsys set <portal_subsystem_name> extra-values-file d9compat.yaml
```

3. Then, update the portal VMware with the updated setting by running the following command:

```
apicup subsys install <portal_subsystem_name>
```

Or:

- Extract the site backup, edit the relevant files inside it, and then tar the backup file again. Note that this procedure will overwrite the original backup file, so ensure that you keep a separate copy of the original file before you start the extraction. For example:
 1. `mkdir /tmp/backup`
 2. `cd /tmp/backup`
 3. `tar xzf path_to_backup.tar.gz`
 4. Edit the custom module and theme files to make them Drupal 9 compatible, and add the correct `core_version_requirement` setting.
 5. `rm -f path_to_backup.tar.gz`
 6. `tar cfz path_to_backup.tar.gz`
 7. `cd /`
 8. `rm -rf /tmp/backup`

Postgres pods fail to start after upgrade

When upgrading the management subsystem as part of [Upgrading to 10.0.1.8-eus on VMware](#), you might encounter an error message when checking the subsystem health upon completion of the upgrade. For example:

```
apic health-check
INFO[0000] Log level: info
FATA[0006] Cluster not in good health:
ManagementCluster (current ha mode: active) is not ready | State: 15/16 Phase: Pending
```

To troubleshoot when a message like this occurs:

1. Check the state of postgres pods:

```
kubectl get pods | grep postgres
```

For example:

```
root@apimdev1146:~# kubectl get pods | grep postgres
fxpk-management-fd8b0b1f-postgres-577594c7f-k54pk          0/1      Init:CrashLoopBackOff   17      22h
fxpk-management-fd8b0b1f-postgres-backrest-shared-repo-7fctp88w  1/1      Running                 2       22h
fxpk-management-fd8b0b1f-postgres-elbx-698f445649-rlc2g      0/1      Init:CrashLoopBackOff   16      22h
fxpk-management-fd8b0b1f-postgres-pgbouncer-64f57b7cc7-52bk8  1/1      Running                 2       22h
fxpk-management-fd8b0b1f-postgres-pgbouncer-64f57b7cc7-jjjvb  1/1      Running                 1       22h
fxpk-management-fd8b0b1f-postgres-pgbouncer-64f57b7cc7-qp4zh  1/1      Running                 2       22h
fxpk-management-fd8b0b1f-postgres-stanza-create-6pt6c        0/1      Completed              0       22h
fxpk-management-fd8b0b1f-postgres-ubba-79ccdd5cc6-kj4zx      0/1      Init:CrashLoopBackOff   17      22h
postgres-operator-85fb96db4b-gk8k8                          4/4      Running                 8       22h
```

2. If any pods show `Init:CrashLoopBackOff` status, restart the pods. To force a restart, delete the pods:

```
kubectl delete pod <name_of_postgres_pod>
```

For example:

```
kubectl delete pod fxpk-management-fd8b0b1f-postgres-577594c7f-k54pk
kubectl delete pod fxpk-management-fd8b0b1f-postgres-elbx-698f445649-rlc2g
kubectl delete pod fxpk-management-fd8b0b1f-postgres-ubba-79ccdd5cc6-kj4zx
```

When pods are deleted, the deployment automatically restarts them.

3. Re-run the health check. For example:

```
apicup subsys health-check <subsys_name>
```

4. When health check is successful, return to [Upgrading from v10.0.1.2 to v10.0.1.2 with the latest iFix on VMware](#).

Upgrading a 3 node profile to IBM API Connect 10.0.1.4-ifix1-eus might result in some portal-db/www pods being stuck in the Pending state

IBM API Connect 10.0.1.4-ifix1-eus introduces the pod anti-affinity required rule, meaning that in a 3 node profile deployment, all 3 db and www pods can run only if there are at least 3 running worker nodes. This rule can cause some upgrades to version from 10.0.1.4-eus or earlier to become stuck in the **Pending** state, in which case some extra steps are needed during the upgrade to workaround the issue. See the following example for detailed information about the issue, and how to continue with the upgrade.

If you are upgrading from 10.0.1.4-ifix1-eus or later, to 10.0.1.5-eus or later, this problem does **not** occur. The problem can occur only when upgrading from 10.0.1.4-eus or earlier.

Important: You must have a backup of your current deployment before starting the upgrade.

To run the commands that are needed to workaround this issue, you must log in to the virtual machine portal subsystem by using an SSH tool.

1. Run the following command to log in as `apicadm`, which is the API Connect ID that has administrator privileges:

```
ssh portal_ip_address -l apicadm
```

Where `portal_ip_address` is the IP address of the portal subsystem.

2. Then get a root shell by running the following command:

```
sudo -i
```

In the following example, the VMware stack has 3 VMs (worker nodes):

```
$ kubectl get nodes
NAME          STATUS    ROLES    AGE   VERSION
apimdev0103   Ready    worker   42m   v1.20.0
```

```
apimdev0129 Ready worker 45m v1.20.0
apimdev1066 Ready worker 39m v1.20.0
```

The pods have been scheduled across only 2 of the 3 worker nodes due to a transient problem with `apimdev1066`, as shown in the following pod list. Pods without persistent storage, such as `nginx-X`, can be rescheduled to `apimdev1066` as soon as they are restarted, but any pods with persistent local storage, such as `db-X` and `www-X`, have to be rescheduled onto the same worker node as that is where their files live.

```
$ kubectl get po -o wide
```

NAME	READY	STATUS	RESTARTS	AGE	IP	NODE	NOMINATED	NODE

The upgrade to version 10.0.1.4-ifix1 is started and the following pod list is observed:

```
$ kubectl get po -o wide
```

NAME	READY	STATUS	RESTARTS	AGE	IP	NODE	NOMINATED	NODE
READINESS GATES								
ejs-portal-nginx-84f57ffd8c-hbf66	1/1	Running	0	10m	888.16.109.208	apimdev0103	<none>	<none>
ejs-portal-nginx-84f57ffd8c-mvq96	1/1	Running	0	10m	888.16.142.215	apimdev0129	<none>	<none>
ejs-portal-nginx-84f57ffd8c-vpmtl	1/1	Running	0	10m	888.16.142.214	apimdev0129	<none>	<none>
ejs-portal-sitel-db-0	2/2	Running	0	10m	888.16.109.209	apimdev0103	<none>	<none>

ejs-portal-sitel-www-0	2/2	Running	0	9m51s	888.16.109.210	apimdev0103	<none>	<none>
ejs-portal-sitel-www-1	2/2	Running	0	12m	888.16.142.213	apimdev0129	<none>	<none>
ejs-portal-sitel-www-2	0/2	Pending	0	111s	<none>	<none>	<none>	<none>
ibm-apiconnect-75b47f9f87-p25dd	1/1	Running	0	10m	888.16.109.207	apimdev0103	<none>	<none>

The pod list shows that `db-2` has restarted, and has been rescheduled to `apimdev0129` as there were no other db pods running on that node. However, `db-1` and `www-2` are both stuck in `Pending` state, as there is already a pod of the same type running on the worker node that is hosting the local storage that they are bound to. If you run a `describe` command of either pod you will see the following output:

```
Events:
```

Type	Reason	Age	From	Message
Warning	FailedScheduling	10s (x4 over 2m59s)	default-scheduler	0/3 nodes are available: 1 node(s) didn't match pod affinity/anti-affinity, 1 node(s) didn't match pod anti-affinity rules, 2 node(s) had volume node affinity conflict.

To resolve this situation you need to delete the PVCs for each pod, and then delete the pod itself, so that Kubernetes will regenerate the PVCs and schedule the pod on the worker node that does not have the anti-affinity conflict.

Therefore, for the `db-1` pod the following commands must be run:

```
$ kubectl get pvc | grep ej-s-portal-sitel-db-1
```

db-ejs-portal-sitel-db-1	Bound	local-pv-fa445e30	250Gi	RWO	local-storage	15m
dblogs-ejs-portal-sitel-db-1	Bound	local-pv-d57910e7	250Gi	RWO	local-storage	15m

```
$ kubectl delete pvc db-ejs-portal-sitel-db-1 dblogs-ejs-portal-sitel-db-1
persistentvolumeclaim "db-ejs-portal-sitel-db-1" deleted
persistentvolumeclaim "dblogs-ejs-portal-sitel-db-1" deleted
```

```
$ kubectl delete po ej-s-portal-sitel-db-1
pod "ej-s-portal-sitel-db-1" deleted
```

For the `www-2` pod the following commands must be run:

```
$ kubectl get pvc | grep ej-s-portal-sitel-www-2
```

admin-ejs-portal-sitel-www-2	Bound	local-pv-48799536	245Gi	RWO	local-storage	51m
backup-ejs-portal-sitel-www-2	Bound	local-pv-a93f5607	245Gi	RWO	local-storage	51m
web-ejs-portal-sitel-www-2	Bound	local-pv-facd4489	245Gi	RWO	local-storage	51m

```
$ kubectl delete pvc admin-ejs-portal-sitel-www-2 backup-ejs-portal-sitel-www-2 web-ejs-portal-sitel-www-2
persistentvolumeclaim "admin-ejs-portal-sitel-www-2" deleted
persistentvolumeclaim "backup-ejs-portal-sitel-www-2" deleted
persistentvolumeclaim "web-ejs-portal-sitel-www-2" deleted
```

```
$ kubectl delete po ej-s-portal-sitel-www-2
pod "ej-s-portal-sitel-www-2" deleted
```

If the PVC has `persistentVolumeReclaimPolicy: Delete` set on it, as is the case for the OVA deployments, then no cleanup is necessary as the old data will have been deleted on the worker node that is no longer running the `db-1` and `www-2` pods.

Kubernetes can now reschedule the pods. All pods with persistent storage are now spread across the available worker nodes, and the pods whose PVCs were deleted will get a full copy of the data from the existing running pods. The following pod list is now observed in our example:

```
$ kubectl get po -o wide
```

NAME	READY	STATUS	RESTARTS	AGE	IP	NODE	NOMINATED	NODE

Skipping health check when re-running upgrade

The `apicup subsys install` command automatically runs `apicup health-check` prior to attempting the upgrade. An error is displayed if a problem is found that will prevent successful upgrade.

In some scenarios, if you encounter an upgrade failure, an attempt to rerun `apicup subsys install` is blocked by errors found by `apicup health-check`. Even when you have fixed the error (such as reconfiguration of an incorrect upgrade CR), the failed upgrade can continue to cause the health check to fail.

You can work around the problem by adding the `--skip-health-check` flag to suppress the health check:

```
apicup subsys install <subsystem_name> --skip-health-check
```

In this case, use of `--skip-health-check` allows the upgrade to rerun successfully.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details. For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Post-deployment steps

When all subsystems are deployed, use the admin account to access the Cloud Manager administrative console and begin configuration. Optionally, take VMware snapshots of the VMs.

About this task

When you have deployed all required API Connect components, and all subsystems are running, complete the following:

Procedure

1. If you have not previously accessed the Cloud Manager, verify you can access the API Connect Cloud Manager. Enter the URL in your browser. The syntax is `https://<hostname.domain>/admin`. For example:

```
https://cloud-admin-ui.testsrv0231.subnet1.example.com/admin
```

The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. See [Accessing the Cloud Manager user interface](#).

2. Define your API Connect configuration by using the API Connect Cloud Manager. See [Cloud Manager configuration checklist](#).
3. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVA's and restoring from normal backups. Important: VM snapshots are not an alternative to the standard API Connect backups. You should have completed an API Connect backup of each subsystem when verifying initial deployment, as advised in:
 - [Verify installation of the management subsystem](#)
 - [Verifying deployment of the Developer Portal subsystem](#)
 - [Verifying deployment of the Analytics subsystem](#)

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details. For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Configuring API Connect subsystems in a cluster

This topic describes how to configure a cluster of API Connect subsystems (management server, analytics, and Developer Portal) with three VMs for each subsystem, for use with a load balancer, to support a high availability (HA) environment.

Before you begin

To create a cluster of hosts for each API Connect subsystem, use `apicup` to create a subsystem with all the required parameters, and to add as many hosts as needed to the configuration file. The configuration file is a `.yaml` file in the project directory.

For each host of a subsystem added in the `.yaml` file, a separate ISO file is created for the cluster member VM. Note that the ISO files for each VM must stay attached during the whole lifetime of the VM.

In an API Connect cluster in a VMware environment, the first three nodes are master nodes. Additional nodes are worker nodes.

Note: To add a new host to an existing cluster, you can create the host, regenerate the ISO and attach it to the new virtual machine, and it will automatically join the cluster.

To use these instructions, you should first review:

- [Requirements for initial deployment on VMware](#)
- [Load balancer configuration in a VMware deployment](#)
- [Deployment overview for endpoints and certificates](#)
- [Firewall requirements on VMware](#)
- [Firewall enabled ports for clustered OVA deployments](#)
- Important: For best performance it is recommended that the network latency between any 2 nodes be as low as possible. Do not configure nodes from the same subsystem cluster across multiple data centers with a high latency network. A high latency network is one that experiences more than 30ms latency between nodes.

About this task

This page presents a concise step-by-step flow, with sample commands, for the configuration of each subsystem. As you step through the flow, you might want to refer back to the detailed configuration steps for each subsystem. The detailed instructions provide additional considerations for each step, and include optional configuration tasks for backups, logging, message queues (analytics), and password hashing. Each of the subsystem pages describe how to use the VMware console to deploy the ISOs that you create here.

Detailed configuration steps:

- [Deploying the Management subsystem](#)
- [Deploying the Analytics subsystem](#)
- [Deploying the Developer Portal](#)

The example commands uses the following values for DNS server, internet gateway, host names and IP addresses:

Component	Host names and IP addresses
DNS Name Server	IP: 192.168.1.1
Internet gateway	IP: 192.168.1.2
Manager on VM1	Hostname: manager1.sample.example.com IP: 192.168.1.101
Manager on VM2	Hostname: manager2.sample.example.com IP: 192.168.1.102
Manager on VM3	Hostname: manager3.sample.example.com IP: 192.168.1.103
Analytics on VM4	Hostname: analytics1.sample.example.com IP: 192.168.1.104
Analytics on VM5	Hostname: analytics2.sample.example.com IP: 192.168.1.105
Analytics on VM6	Hostname: analytics3.sample.example.com IP: 192.168.1.106
Developer Portal on VM7	Hostname: portal1.sample.example.com IP: 192.168.1.107
Developer Portal on VM8	Hostname: portal2.sample.example.com IP: 192.168.1.108
Developer Portal on VM9	Hostname: portal3.sample.example.com IP: 192.168.1.109

Procedure

1. Create the Management subsystems

a. Create the Management subsystem.

```
apicup subsys create mgmt management
```

b. Set deployment-profile to n3xc4.m16.

```
apicup subsys set mgmt deployment-profile=n3xc4.m16
```

If you omit this step, the deployment-profile defaults to n1xc4.16, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

c. Specify the license version you purchased.

```
apicup subsys set mgmt  
license-use=<license_type>
```

The *license_type* must be either **production** or **nonproduction**. If not specified, the default value is **nonproduction**.

d. Set management endpoints

Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following values point to a sample load balancer URL.

Component	Command
Management REST API URL	apicup subsys set mgmt platform-api platform-api.sample.example.com
Consumer (Portal) REST API URL	apicup subsys set mgmt consumer-api consumer-api.sample.example.com
Cloud Manager UI	apicup subsys set mgmt cloud-admin-ui cloud-admin-ui.sample.example.com
API Manager UI	apicup subsys set mgmt api-manager-ui api-manager-ui.sample.example.com

e. Set the search domain for the VM.

```
apicup subsys set mgmt search-domain sample.example.com
```

f. Set the DNS Name Server for the VM to look up endpoints.

```
apicup subsys set mgmt dns-servers 192.168.1.1
```

g. Set a Public Keyfile.

This is the public key of the user account that you want to use to **ssh** from, to the appliance.

```
apicup subsys set mgmt ssh-keyfiles "id_rsa.pub"
```

h. Create the hosts for the subsystem.

You must specify a password to use to encrypt the disks that the appliance uses. Replace the example password in the previous example with a strong password that meets your security requirements.

```
apicup hosts create mgmt manager1.sample.example.com password123
apicup hosts create mgmt manager2.sample.example.com password123
apicup hosts create mgmt manager3.sample.example.com password123
```

i. Set the network interface. Note that the last parameter is the Internet Gateway.

```
apicup iface create mgmt manager1.sample.example.com eth0 192.168.1.101/255.255.255.0 192.168.1.2
apicup iface create mgmt manager2.sample.example.com eth0 192.168.1.102/255.255.255.0 192.168.1.2
apicup iface create mgmt manager3.sample.example.com eth0 192.168.1.103/255.255.255.0 192.168.1.2
```

j. Set the network traffic interfaces.

```
apicup subsys set mgmt traffic-iface eth0
apicup subsys set mgmt public-iface eth0
```

k. Verify the host configuration.

```
apicup hosts list mgmt
```

Note: This command might return the following messages, which you can ignore:

```
* host is missing traffic interface
* host is missing public interface
```

l. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use **apicup** to set the hashed password for your subsystem:

```
apicup subsys set mgmt default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
```

Important: Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).

m. Validate the installation.

```
apicup subsys get mgmt --validate
```

n. Create an ISO file in a plan folder. For example, **mgmtplan-out**.

```
apicup subsys install mgmt --out mgmtplan-out
```

If you have multiple nodes listed for the hosts, when you run the **--out** command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

o. To deploy the ISOs on VMware, see step [overview_installing_mgmtvm_apimgmt.html#overview_installing_mgmtvm_mgmt_ova_iso](#) in [Deploying the Management subsystem](#).

2. Create the analytics subsystems

a. Create the subsystem:

```
apicup subsys create analyt analytics
```

b. Set deployment-profile to **n3xc4.m16**.

```
apicup subsys set analyt deployment-profile=n3xc4.m16
```

If you omit this step, the deployment-profile defaults to **n1xc2.16**, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

c. Specify the license version you purchased.

```
apicup subsys set analyt
license-use=<license_type>
```

The *license_type* must be either **production** or **nonproduction**. If not specified, the default value is **nonproduction**.

d. Set analytics endpoints

Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following values point to a sample load balancer URL.

Component	Command
analytics-ingestion	<code>apicup subsys set analyt analytics-ingestion=analytics-ingestion.sample.example.com</code>
analytics-client	<code>apicup subsys set analyt analytics-client=analytics-client.sample.example.com</code>

e. Set the search domain for the VM.

```
apicup subsys set analyt search-domain sample.example.com
```

f. Set the DNS Name server for the VM to look up endpoints.

```
apicup subsys set analyt dns-servers 192.168.1.1
```

g. Set a Public Keyfile.

This is the public key of the user account that you want to use to **ssh** from, to the appliance

```
apicup subsys set analyt ssh-keyfiles "id_rsa.pub"
```

- h. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use **apicup** to set the hashed password for your subsystem:

```
apicup subsys set analyt default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
```

Important: Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).

- i. Create the hosts for the subsystem. You must specify a password to use to encrypt the disks that the appliance uses. Replace the example password in the following password with a strong password that meets your security requirements.

```
apicup hosts create analyt analytics1.sample.example.com password123
apicup hosts create analyt analytics2.sample.example.com password123
apicup hosts create analyt analytics3.sample.example.com password123
```

- j. Set the network interface.

Note that the last parameter is the Internet Gateway.

```
apicup iface create analyt analytics1.sample.example.com eth0 192.168.1.104/255.255.255.0 192.168.1.2
apicup iface create analyt analytics2.sample.example.com eth0 192.168.1.105/255.255.255.0 192.168.1.2
apicup iface create analyt analytics3.sample.example.com eth0 192.168.1.106/255.255.255.0 192.168.1.2
```

- k. Check the host configuration for problems.

```
apicup hosts list analyt
```

- l. Validate the installation.

```
apicup subsys get analyt --validate
```

- m. Create an ISO file in a plan folder. For example, **analytplan-out**.

```
apicup subsys install analyt --out analytplan-out
```

If you have multiple nodes listed for the hosts, when you run the **--out** command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

- n. To deploy the ISOs, see [Deploying the Analytics subsystem](#)

3. Create the portal subsystems

- a. Create the portal.

```
apicup subsys create port portal
```

- b. For production environments, set deployment-profile to **n3xc4.m8**.

```
apicup subsys set port deployment-profile=n3xc4.m8
```

If you omit this step, the deployment-profile defaults to **n1xc4.m8**, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

- c. Specify the license version you purchased.

```
apicup subsys set port
license-use=<license_type>
```

The *license_type* must be either **production** or **nonproduction**. If not specified, the default value is **nonproduction**.

- d. Set the portal endpoints.

Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following values point to a sample load balancer URL.

Component	Command
portal-admin	<code>apicup subsys set port portal-admin=portal-admin.sample.example.com</code>
portal-www	<code>apicup subsys set port portal-www=portal-www.sample.example.com</code>

- e. Set the search domain for the VM.

```
apicup subsys set port search-domain sample.example.com
```

- f. Set the DNS Name server for the VM to look up endpoints.

```
apicup subsys set port dns-servers 192.168.1.1
```

- g. Set a Public Keyfile.

This is the public key of the user account that you want to use to **ssh** from, to the appliance

```
apicup subsys set port ssh-keyfiles "id_rsa.pub"
```

- h. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use **apicup** to set the hashed password for your subsystem:

```
apicup subsys set port default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
```

Important: Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).

- i. Create the hosts for the subsystem. You must specify a password to use to encrypt the disks that the appliance uses.

```
apicup hosts create port portal1.sample.example.com password123
apicup hosts create port portal2.sample.example.com password123
apicup hosts create port portal3.sample.example.com password123
```

Replace the example password in the previous example with a strong password that meets your security requirements.

- j. Set the network interface.

Note that the last parameter is the Internet Gateway.

```

apicup iface create port portal1.sample.example.com eth0 192.168.1.107/255.255.255.0 192.168.1.2
apicup iface create port portal2.sample.example.com eth0 192.168.1.108/255.255.255.0 192.168.1.2
apicup iface create port portal3.sample.example.com eth0 192.168.1.109/255.255.255.0 192.168.1.2

```

k. Check the host configuration for problems.

```
apicup hosts list port
```

l. Validate the installation.

```
apicup subsys get port --validate
```

m. Create an ISO file in a plan folder. For example, `portplan-out`.

```
apicup subsys install port --out portplan-out
```

If you have multiple nodes listed for the hosts, when you run the `--out` command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

n. To deploy the ISOs on VMware, see step [tapim_portal_ova_install.html#tapim_portal_ova_install_ova_iso](#) in [Deploying the Developer Portal](#)

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Upgrading API Connect

Upgrade API Connect on VMware to a newer version.

After reviewing the overview, use the procedures in this section to upgrade API Connect on VMware.

Note: For information about how to maintain a two data center deployment, including upgrade considerations, see [Maintaining a two data center deployment](#).

- [Upgrade considerations on VMware](#)
Before upgrading API Connect on VMware, ensure that your deployment meets all the upgrade requirements.
- [Upgrading to the latest version of 10.0.1.x-eus on VMware](#)
Upgrade API Connect to the latest version of 10.0.1.x-eus on VMware.
- [Upgrading DataPower Gateway Service](#)
Use these instructions when upgrading DataPower Gateway Service in a non-Kubernetes environment, during upgrade of API Connect.
- [Enabling Analytics after upgrading](#)
After the upgrade successfully completes, enable the Analytics message queue and restart Analytics data collection.
- [Troubleshooting installation and upgrades on VMware](#)
Review the following troubleshooting guidance if you encounter a problem while installing or upgrading API Connect on VMware.
- [Upgrading from older versions on VMware](#)
If you are upgrading API Connect from an older version, see the instructions in this section.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Upgrade considerations on VMware

Before upgrading API Connect on VMware, ensure that your deployment meets all the upgrade requirements.

Contents:

- [Supported upgrade paths](#)
- [Requirements](#)
- [Disable Analytics data collection before upgrading](#)
- [Disable the Analytics message queue feature before upgrading](#)
- [Validating an API definition file with the API Dev Tools Swagger Parser](#)
- [x-ibm-gateway-cors-allow-credentials-when-no-cors-policy API property is deprecated](#)

Tip: After upgrade, clear your browser cache, and open a new browser window. This action avoids stale cache issues in your browser, that can result in unexpected behavior in the Cloud Manager and API Manager UIs.

Supported upgrade paths

Restriction: A direct upgrade from any version of 10.0.1.x to API Connect 10.0.6.0 or later is not supported. You must upgrade to 10.0.5.x as an interim step before upgrading to 10.0.6.0.

Upgrade from:	How to upgrade to 10.0.1.15-eus:
<ul style="list-style-type: none"> • 10.0.1.12-eus Versions 10.0.1.13-eus and 10.0.1.14-eus were skipped 	Direct upgrade; see Upgrading to the latest version of 10.0.1.x-eus on VMware

<ul style="list-style-type: none"> 10.0.1.11-eus Version 10.0.1.10-eus was skipped 10.0.1.9-eus 	
<ul style="list-style-type: none"> 10.0.1.8-eus 	Two upgrades required; see: <ol style="list-style-type: none"> Upgrading to 10.0.1.9-eus on VMware Upgrading to the latest version of 10.0.1.x-eus on VMware
<ul style="list-style-type: none"> 10.0.1.7-eus 10.0.1.6-eus plus iFixes 10.0.1.5-eus plus iFixes 10.0.1.4-eus plus iFixes 10.0.1.2-eus plus iFixes 	Direct upgrade; see Upgrading to the latest version of 10.0.1.x-eus on VMware
<ul style="list-style-type: none"> 10.0.1.1-eus 	Upgrading to the latest version of 10.0.1.x requires a disaster-recovery process; see Upgrading from 10.0.1.1-eus to the latest 10.0.1.x-eus on VMware
<ul style="list-style-type: none"> 10.0.1.0-eus 10.0.0.0-ifix2 10.0.0.0 	Not supported
<ul style="list-style-type: none"> 2018 FP24 and later 	See Upgrading from 2018 to the latest 10.0.1.x-eus on VMware

Requirements

- The instructions for upgrading apply to the *latest* Fix Pack plus iFix version (if any). Ensure that you are upgrading to the latest Fix Pack version. For information on the latest Fix Pack, see [What's New in the latest release](#).
- Before starting the upgrade, verify that API Connection deployment is fully operational. See [Checking cluster health on VMware](#). This step is optional because a health check will be run automatically as part of the `apicup subsys install` command. Note that you might still want to run the health check when preparing for the upgrade, to ensure the health of the backup image you must create prior to running `apicup subsys install`.
- When upgrading API Connect, complete a manual backup of the management database and Portal subsystem just prior to starting the upgrade. Note that this backup is in addition to any scheduled backups that you have configured. The manual backup ensures that any data changes that occurred after the most recent scheduled backup are captured. For details on creating a backup, see [Backing up the Management subsystem in a VMware environment](#) and [Backing up and restoring the Developer Portal in a VMware environment](#).
- Ensure that port 9178 is open between the Analytics, Management, and Portal subsystems and the system running `apicup`. An i/o timeout error can occur if the firewall rejects traffic to the appliance. Make sure port 9178 is open and try again. Example error message:

```
apicup subsys install test-analytics upgrade_analytics_its_v10.0.1.0.tgz
INFO[0000] Preparing update
INFO[0010] Sending update packet to cluster (connected to testsrv0192.subnet1.example.com)
Error: failed to install the subsystem: unable to open file send stream:
  rpc error: code = Unavailable desc = all SubConns are in TransientFailure,
  latest connection error: connection error:
  desc = "transport: Error while dialing dial tcp 1.2.3.4:9178: i/o timeout"
```

- If not already set up, send your deployment logs to a remote server. The upgrade process terminates pods, and the logs will be lost if not stored remotely. To send your deployment logs to a remote server, see [Configuring remote logging for a VMware deployment](#).
- Download the Install Assist (APICUP) installer from the same URL where you download your Fix Pack version. You must use the latest Install Assist package with the latest product version.
- The original project directory created with the APICUP installer during the initial product installation (for example, *myProject*) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. A good practice is to back up the original project directory to a location from which it can always be retrieved.
- If the upgrade is initiated from the original project directory, the certificates are automatically copied into the upgraded version. The original project directory contains the `apiconnect-up-v10.yml` file. An upgrade using the same project directory as the one used for installation will transfer the `encryption-secret` and all other certificates for the project to the upgraded version.
- All external traffic to the management server must be blocked during the upgrade of the management subsystem. This restriction applies to traffic from all sources via the user interfaces (Cloud Manager, API Manager), CLI, and REST API. The Cloud Manager and API Manager UIs cannot be used during the upgrade of the management subsystem. The Developer Portal also cannot be used to create, update, or delete any applications, subscriptions, memberships, or consumer organizations during the time.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order: (1) Management, (2) Portal (3) Analytics (4) Gateway. Management must be upgraded first. Gateway must be upgraded after Management because upgrading the Management service before the Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
- When maintaining API Connect, do not use `kubectl exec` commands to access API Connect pods unless advised by IBM. Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

Disable Analytics data collection before upgrading

Temporarily [stop the Analytics data collection](#) to avoid losing event data during the upgrade. After the upgrade is complete, you can [start Analytics data collection](#) again.

Disable the Analytics message queue feature before upgrading

If you enabled the analytics message queue feature, you must disable it before upgrading. You can re-enable the message queue feature after the profile change is complete.

To disable the message queue:

1. Edit the `analytics-extra-value.yaml` file.
2. Locate the `mq` subsection and change the `enabled` setting to `false`.

```
mq:
  enabled: false
```

3. Apply the change:

```
apicup subsys install <subsystem_name>
```

Validating an API definition file with the API Dev Tools Swagger Parser

From IBM® API Connect Version 10.0.1.4-ifix1-eus, SwaggerDoc (OpenAPI 2.0) and OpenAPI 3.0 documents that form API definition files are now validated at stage or publish time by the API Dev Tools Swagger Parser. Before upgrading, you should ensure that your existing API definition files are parsable and considered valid by the Swagger Parser tool. Note that any API definitions that are already staged or published are not impacted, but would undergo Swagger Parser validation again should they be re-staged or re-published in the future.

You can use either of the following techniques to ensure that existing API definition files are parsable and considered valid by the Swagger Parser:

- Download and install the `swagger-parser-cli` tool (see <https://www.npmjs.com/package/swagger-cli>). This tool includes a `validate` command that can validate local API definition files against the SwaggerDoc (OpenAPI 2.0) and OpenAPI 3.0 schemas, in both JSON and YAML formats.
- Use the browser-based Swagger Parser Validator available at <https://apitools.dev/swagger-parser/online/>; this accepts a URL to existing files available online, or can accept text copied and pasted into the tool, in both JSON and YAML formats. It can likewise validate against the SwaggerDoc (OpenAPI 2.0) and OpenAPI 3.0 schemas.

Note: Staging or publishing an API in API Connect results in additional syntactic validation of IBM extensions to SwaggerDoc (OpenAPI 2.0) and OpenAPI 3.0, as well as semantic validation to make sure that policies and other resources that the API refers to are valid within the context of the staging or publishing operation. Any errors associated with this additional validation will not be caught by the local or online Swagger Parser tool, nor will they be caught by the `apic validate` toolkit CLI command.

The Swagger Parser tool will report an invalid OpenAPI document. For example, if a document is missing a mandatory section such as `info` or `paths`, the following error is reported:

```
[object Object] is not a valid Swagger API definition
```

If a required property is missing from a given section, a specific error is reported. For example, if the `info` section is missing the required `version` property, the following error is reported:

```
Swagger schema validation failed.
Missing required property: version at #/info
JSON_OBJECT_VALIDATION_FAILED
```

Additionally, if the document contains any local references (that is, values of `$ref` properties) that do not resolve to an existing reference within the document (known as de-referencing), this is also be flagged as an error. For example, if a document contains the following as a reference:

```
schema:
  $ref: '#/definitions/Pet'
```

then the definition of `Pet` (that is, `#/definitions/Pet`) **must** exist in the same document, at the given path (`definitions` section in this example), similar to the following:

```
definitions:
  Pet:
    type: object
    required:
      - name
    properties:
      id:
        type: integer
        format: int64
```

If the local reference is not found within the document, the following de-referencing error is reported:

```
Token "Pet" does not exist.
```

x-ibm-gateway-cors-allow-credentials-when-no-cors-policy API property is deprecated

In v2018, when cross-origin resource sharing (CORS) is enabled for an API, every response to a CORS request contains the header:

```
Access-Control-Allow-Credentials: true
```

Inclusion of Access-Control-Allow-Credentials (ACAC) does not provide optimal security, so starting with v2018.4.1.17, an API property can be set to prevent this header from being returned:

```
Name: x-ibm-gateway-cors-allow-credentials-when-no-cors-policy
Collection: *
Value (string): off
```

The `Collection` setting refers to a specific Catalog to which a property value applies. The `"*"` value means the value applies to all catalogs. You can either specify `*` or a Catalog (collection) name.

The property can also be set by using the DataPower CLI:

```
api-definition myAPI
property x-ibm-gateway-cors-allow-credentials-when-no-cors-policy * off
```

`exit`

Important: The value of this property must be exactly the string `off` (case-sensitive) in order to remove the header.

It is only possible to turn off this header, or leave it on, for an entire API. In order to have more control, such as returning the header for some origins and not others, you must upgrade to version 10 and use the CORS policy feature. For more info, see:

- [Enabling CORS support for an API](#)
- OpenAPI 3.0 editor: [Setting API properties](#)
- OpenAPI 2.0 editor: [Setting API properties](#)

In API Connect v10.0.1.4-ifix1-eus or later, the `x-ibm-gateway-cors-allow-credentials-when-no-cors-policy` property works, but only for API definitions which do NOT contain a cors-policy. You cannot define both this property and a CORS Policy on the same API definition.

This property is deprecated in version 10: a warning will be written to the log for every CORS request received by an API whose definition contains this property.

For version 10, the recommended way to ensure the ACAC header does not appear in CORS responses is to add a CORS policy to the API definition. In version 10, any API definition which has a cors-policy defined will NOT return the ACAC header by default. Note that it is possible in the CORS policy rules to explicitly return the ACAC header for some or all origins.

If you move your configuration from 2018 to 10.0.1.4-ifix1-eus or later, and have this custom property defined in your API definitions, you will not see any change in behavior, other than new warnings in the log. This property will remove the ACAC header for any API definition where it appears.

If, when you move your configuration from 2018 to version 10, you want to have the ACAC header present in the CORS responses, you can leave the API definitions as-is (without the new property defined) and the ACAC header will be returned, as long as a cors-policy is not added to the API definition. Note also that even with a CORS policy defined for an API, the ACAC header can be returned if desired by explicitly allowing it in the rules of the CORS policy.

Note that the `x-ibm-gateway-cors-allow-credentials-when-no-cors-policy` property in an API definition:

- Will cause a commit-time error in version 10 if a cors-policy is also present in the same API definition
- Will NOT work in version 10 or version 2018 to turn ON the ACAC header; it can ONLY be used to turn OFF the header. Explanation:
 - In 2018, ACAC is on by default
 - In 10, without cors-policy, ACAC is on by default
 - In 10, with cors-policy, ACAC can be turned on for specific origins via rules in cors-policy

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Upgrading to the latest version of 10.0.1.x-eus on VMware

Upgrade API Connect to the latest version of 10.0.1.x-eus on VMware.

Before you begin

- Review the supported upgrade paths and upgrade requirements in [Upgrade considerations on VMware](#). Your deployment must be at 10.0.1.7-eus or later before you can upgrade to the newest version of API Connect 10.0.1.x-eus.
- Enable keep-alive in your SSH configuration to avoid problems during the upgrade. For information, consult the documentation for your version of SSH.

Attention: Upgrading directly to the latest release from releases earlier than 10.0.1.6-ifix1-eus might run into problems. For best results, first upgrade to 10.0.1.6-ifix1-eus and make a full set of backups before proceeding to upgrade to the latest release.

About this task

- The upgrade order for subsystems is important. Upgrade the subsystems in the following order: (1) Management, (2) Portal, (3) Analytics, (4) Gateway. Management must be upgraded first. Upgrading the Management service before the Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
- When you run the install, the program sends the compressed tar file, which contains the upgrade images, to all cluster members. The compressed tar file is about 2 GB, and transfer can take some time. When the install command exits, the compressed tar file has arrived at each member. The upgrade process is now underway, and might continue for some time depending on factors such as the size of your deployment, your network speed, etc.
- The `apicup subsys install` command automatically runs `apicup health-check` prior to attempting the upgrade. An error is displayed if a problem is found that will prevent successful upgrade. When troubleshooting a problem with an upgrade, you can optionally suppress the health check. See [Skipping health check when re-running upgrade](#).
- For each subsystem, you will be instructed to manually run `apicup health-check` after the upgrade, to ensure that the upgrade was successful.
 - Be sure to allow a few minutes for the subsystem upgrade to complete before running the health check. Note that the time required for upgrade to complete varies depending on the size of your deployment.
 - The health check command returns silently if no errors are found.
 - For more info, see [Checking cluster health on VMware](#).
- The Gateway subsystem remains available during the upgrade of the Management, Portal, and Analytics subsystems.

Procedure

Attention: If you encounter an issue while performing the upgrade, see [Troubleshooting installation and upgrades on VMware](#).

1. Upgrading from 10.0.1.8-eus or earlier, or from 10.0.4.0-ifix3 or earlier: Run the following command to retain the source version images for the upgrade:
 - Target version 10.0.1.9-eus:

```
cp -R /var/lib/apiconnect-subsystem/registry/* /var/lib/apiconnect/side-registry/
```

- Target version 10.0.1.11 or later:

```
cp -R /var/lib/apiconnect-subsystem/registry/* /usr/local/lib/appliance-side-registry
```

2. Ensure that your deployment meets the upgrade requirements. See [Upgrade considerations on VMware](#).

3. Back up the Postgres images on one of the Management Server VMs following the steps below for your current version of API Connect:

- 10.0.1.8 or earlier:

```
SSH to one of the Management Server VMs:  
ssh <ip_address_of_management_vm> -l apicadm  
Sudo to root:  
sudo -i
```

Run the following commands:

```
postgres_operator=$(kubectl get pod -l app.kubernetes.io/name=postgres-operator -o name)  
  
docker pull `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_PGO_RMDATA")].value}'`  
docker pull `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_PGO_BACKREST_REPO")].value}'`  
docker pull `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_CRUNCHY_PGBOUNCER")].value}'`  
docker pull `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_CRUNCHY_POSTGRES_HA")].value}'`  
docker save `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_PGO_RMDATA")].value}'` -o rmdata.tar  
docker save `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_PGO_BACKREST_REPO")].value}'` -o backrestrepo.tar  
docker save `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_CRUNCHY_PGBOUNCER")].value}'` -o pgbouncer.tar  
docker save `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_CRUNCHY_POSTGRES_HA")].value}'` -o postgres-ha.tar  
  
postgres_pod=$(kubectl get pod -l role=master -o name)  
docker save `kubectl get $postgres_pod -o jsonpath='{.spec.initContainers[].image}'` -o k8s-init.tar
```

- 10.0.1.9 or later:

```
SSH to one of the Management Server VMs:  
ssh <ip_address_of_management_vm> -l apicadm  
Sudo to root:  
sudo -i
```

Get the name of the node hosting the postgres-backrest:

```
k get pods -o wide | grep postgres-backrest
```

SSH into the node hosting the postgres-backrest.

Run the following commands:

```
postgres_operator=$(kubectl get pod -l app.kubernetes.io/name=postgres-operator -o name)  
  
ctr --namespace k8s.io images pull --plain-http=true `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_PGO_RMDATA")].value}'`  
ctr --namespace k8s.io images export rmdata.tar `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_PGO_RMDATA")].value}'`  
ctr --namespace k8s.io images export backrestrepo.tar `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_PGO_BACKREST_REPO")].value}'`  
ctr --namespace k8s.io images export pgbouncer.tar `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_CRUNCHY_PGBOUNCER")].value}'`  
ctr --namespace k8s.io images export postgres-ha.tar `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_CRUNCHY_POSTGRES_HA")].value}'`  
  
postgres_pod=$(kubectl get pod -l role=master -o name)  
ctr --namespace k8s.io images export k8s-init.tar `kubectl get $postgres_pod -o jsonpath='{.spec.initContainers[].image}'`
```

Note: After performing the upgrade, if you see that the Postgres pods are in the `imagePullBackOff` state, correct the issue by following steps 2 and 3 in [Management subsystem upgrade imagePullBackOff issue](#) to import each of the images you saved in this step.

4. Remove obsolete files to ensure a clean upgrade.

Attention: If you do not remove the obsolete files, the upgrade might fail.

a. SSH into the node:

- Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```

- When prompted, select Yes to continue connecting.

- When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

b. Check the `/etc/apt/sources.list.d` directory for files of the format: `repo-<subsystem>-<version>-<appliance version>.list`

c. Delete all files with names that match the format in substep b.

Run the following command for each file to delete it:

```
rm <file_path>
```

5. Prepare for upgrading the management subsystem.

a. Verify that the `pgcluster` is healthy:

- SSH into the appliance as `root`.

- ii. Get the name of the `pgcluster`:

```
kubectl get pgcluster -n <APIC_namespace>
```

The response displays the name of the postgres cluster running in the specified namespace.

- iii. Check the status of the `pgcluster`:

```
kubectl get pgcluster <pgcluster_name> -n <APIC_namespace> -o yaml | grep status -A 2 | tail -n3
```

The response for a healthy `pgcluster` looks like the following example, where the state is `Initialized`:

```
status:
  message: Cluster has been initialized
  state: pgcluster Initialized
```

Important: If the `pgcluster` returns any other state, it is not healthy and an upgrade will fail.

- If there are any ongoing backup or restore jobs, wait until they complete and then check the status again. Do not proceed with the upgrade until the status is `Initialized`.
- If all of the background jobs complete but the `pgcluster` remains unhealthy, contact IBM Support for assistance.

- b. Verify sufficient free disk space.

For each appliance node that you are planning to upgrade:

- i. SSH into the appliance, and switch to user `root`.

- ii. Check disk space in `/data/secure`:

```
df -h /data/secure
```

Make sure the disk usage shown is below 70%. If it is not, add disk capacity. See [Adding disk space to a VMware appliance](#).

- iii. Check free disk space in `/`:

```
df -h /
```

Make sure usage is below 70%. If it is not, consider deleting or offloading older `/var/log/syslog*` files.

6. Complete the prerequisites:

- a. Verify the API Connect deployment is healthy and fully operational. See [Checking cluster health on VMware](#)
- b. Remove any stale upgrade files:

```
apic clean-upgrade-files
```

- c. Complete a manual backup of the API Connect subsystems. See [Backing up and restoring \(10.0.1.1-eus or later\)](#).

Note:

- Do not start an upgrade if a backup is scheduled to run within a few hours.
- Do not perform maintenance tasks such as rotating key-certificates, restoring from a backup, or starting a new backup, at any time while the upgrade process is running.

7. Run the pre-upgrade health check:

- a. Run the health check on the Management subsystem:

- i. SSH into the server:

1. Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```

2. When prompted, select Yes to continue connecting.

3. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

- ii. Verify that the `apicops` utility is installed by running the following command to check the current version of the utility:

```
apicops --version
```

If the response indicates that `apicops` is not available, install it now. See [The API Connect operations tool: apicops](#) in the API Connect documentation.

- iii. Run the version-check script and verify that there are no errors:

```
apicops version:pre-upgrade
```

- iv. Run the appliance health check and verify that there are no errors:

```
apicops appliance-checks:appliance-pre-upgrade
```

- b. Run the health check on the Portal subsystem:

- i. SSH into the server.

- ii. Verify that the `apicops` utility is installed by running the following command to check the current version of the utility:

```
apicops --version
```

If the response indicates that `apicops` is not available, install it now. See [The API Connect operations tool: apicops](#) in the API Connect documentation.

- iii. Run the following command to check the system status, and verify that there are no errors:

```
apicops upgrade:check-subsystem-status
```

- iv. Run the appliance health check and verify that there are no errors:

```
apicops appliance-checks:appliance-pre-upgrade
```

Important: If you need to restart the deployment, wait until all Portal sites complete the upgrade. Run the following commands to check the status of the sites:

- i. Get the portal service ID and endpoint:

```
apic portal-services:get -o admin -s <management_server_endpoint> \
--availability-zone <availability-zone-default> <portal-service-name> \
--output - --format json
```

- ii. List the sites:

```
apic --mode portaladmin sites:list -s <management_server_endpoint> \
--portal_service_name <portal-service-name> \
--format json
```

Any sites currently upgrading display the **UPGRADING** status; any site that completed its upgrade displays the **INSTALLED** status and the new platform version. Verify that all sites display the **INSTALLED** status before proceeding.

For more information on the `sites` command, see [apic sites:list](#) and [Using the sites commands](#).

- iii. After all sites are in **INSTALLED** state and have the new platform listed, run:

```
apic --mode portaladmin platforms:list -s <management_server_endpoint> \
--portal_service_id <portal_service_id_from_above_command> \
--portal_service_endpoint <portal_service_endpoint_from_above_command> \
--format json
```

Verify that the new version of the platform is the only platform listed.

For more information on the `platforms` command, see [apic platforms:list](#) and [Using the platforms commands](#).

- c. Run the health check on the Analytics subsystem:

- i. SSH into the server.
- ii. Verify that the `apicops` utility is installed by running the following command to check the current version of the utility:

```
apicops --version
```

If the response indicates that `apicops` is not available, install it now. See [The API Connect operations tool: apicops](#) in the API Connect documentation.

- iii. Run the following command to check the system status, and verify that there are no errors:

```
apicops upgrade:check-subsystem-status
```

- iv. Run the appliance health check and verify that there are no errors:

```
apicops appliance-checks:appliance-pre-upgrade
```

8. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details.

Important:

- This action requires a brief outage while all of the VMs in the subsystem cluster are shut down.
- Do not take snapshots of running VMs, as they might not restore successfully.
- VM snapshots are not an alternative to the standard backups that are described in the previous steps, and which must be taken in order to use the API Connect restore feature.

9. If you are upgrading from 10.0.1.9-eus and there is a Helm instance of the fluent-bit service running, uninstall the service by running the following command:

```
helm uninstall fluent-bit
```

In newer versions of API Connect, fluent-bit is installed as part of the upgrade process.

By default, the fluent-bit service is configured to forward container logs to `/var/log/syslog` on the local machine. If you want like to update the output destination to a remote Syslog server, see [Configuring remote logging for a VMware deployment](#).

10. Download the API Connect files:

You can access the latest files from [IBM Fix Central](#) by searching for the API Connect product and your installed version.

The following files are used during upgrade on VMware, from 10.0.1.2-eus or later to the latest version of 10.0.1.x-eus:

- IBM® API Connect <version> Management Upgrade File for VMware Management subsystem files
- IBM® API Connect <version> Developer Portal Upgrade File for VMware Developer Portal subsystem files
- IBM® API Connect <version> Analytics Upgrade File for VMware Analytics subsystem files
- IBM® API Connect <version> Install Assist for <operating_system_type> The apicup installation utility. Required for all installations on VMware.

The following files are not used during upgrade, but can be installed as new installations used to replace prior versions:

- IBM® API Connect <version> Toolkit for <operating_system_type> Toolkit command line utility. Packaged standalone, or with API Designer or Loopback:
 - IBM® API Connect <version> Toolkit for <operating_system_type>
 - IBM® API Connect <version> Toolkit with Loopback for <operating_system_type>
 - IBM® API Connect <version> Toolkit Designer with Loopback for <operating_system_type>
- Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See [Installing the toolkit](#).

IBM® API Connect <version> Local Test Environment

Optional test environment. See [Testing an API with the Local Test Environment](#)

IBM® API Connect <version> Security Signature Bundle File

Checksum files that you can use to verify the integrity of your downloads.

11. Download Control Plane files from the same Fix Pack page.

Control Plane files provide support for specific Kubernetes versions (VMware is hosted on Kubernetes). When upgrading API Connect, you must install all of the Control Plane files that are required for the new version to ensure that all current Kubernetes versions are supported.

You will install the Control Plane files with each subsystem as part of the upgrade process.

Table 1. Control Plane files needed for upgrading

Version to upgrade from	Control Plane files required for upgrading to 10.0.1.15-eus
<ul style="list-style-type: none">10.0.1.12-eus Versions 10.0.1.13-eus and 10.0.1.14-eus were skipped	No control-plane file needed
<ul style="list-style-type: none">10.0.1.11-eus10.0.1.9-eus Version 10.0.1.10-eus was skipped	Download: <ul style="list-style-type: none">appliance-control-plane-1.25.x.tgz

For information on the Control Planes required for older versions of API Connect, see [Control Plane files for earlier releases](#).

12. Verify that the subsystem upgrade files are not corrupted.

a. Run the following command separately for the Management, the Developer Portal, and the Analytics upgrade files:

- Mac or Linux:

```
sha256sum <upgrade-file-name>
```

Example:

```
sha256sum upgrade_management_10.0.1.11
```

- Windows:

```
C:\> certUtil -hashfile C:\<upgrade-file-name> SHA256
```

Example:

```
C:\> certUtil -hashfile C:\upgrade_management_10.0.1.11 SHA256
```

b. Compare the result with the checksum values to verify that the files are not corrupted.

If the checksum does not match the value for the corresponding version and subsystem, then the upgrade file is corrupted. Delete it and download a new copy of the upgrade file. The following list shows the checksum values for the current release. If you are upgrading to an older release, see [Checksum values for earlier releases](#).

Checksum values for 10.0.1.12-eus:

```
10.0.1.15 analytics : a369d5eafd391ea80bd7437dcbdf8f2578c207394555ded31d187c807db2a234
10.0.1.15 management : 3ea52cea61f8e6fc9cff1b004d897404c6805b46d8194d4f7ae2d661dcd91d6e
10.0.1.15 portal : c1a5c8c8defb74e0de7574dbbd0fd5cf1d48b90bfe7d461262b8c587e797fed8
```

13. Upgrade the management subsystem.

a. Install the newer management subsystem files, control plane files, and installer files.

Be sure to use the Install Assist **apicup** installer that matches the API Connect version you are upgrading to.

Note: If you replaced the pgbouncer image as described in Step [#upgrading_vmware_v10012_latest_v10_pgbouncer](#) you do not need to run the **apicup subsys install** again. Skip this step, and proceed to the next step to verify that all pods have started.

Use the following install command:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file>
```

If you downloaded multiple control plane files, include all of them in the command. The sequence of file names in the command does not matter.

Tip: If the upgrade gets stuck, run the following command to reboot the appliance:

```
sudo systemctl restart appliance-manager
```

b. Verify that all pods have started.

Follow the procedure in [Postgres pods fail to start after upgrade](#).

c. Verify that the upgrade was successful by running a health check with the following command:

```
apicup subsys health-check <subsystem_name>
```

d. If the health check indicates that a reboot is needed, run the following command:

```
systemctl reboot
```

e. Use the latest version of **apicops** to validate the certificates.

For information on the **apicops** tool, see [The API Connect operations tool: apicops](#).

i. Run the following command:

```
apicops upgrade:stale-certs -n <namespace>
```

ii. Delete any stale certificates that are managed by cert-manager.

If a certificate failed the validation and it is managed by cert-manager, you can delete the stale certificate secret, and let cert-manager regenerate it. Run the following command:

```
kubectl delete secret <stale-secret> -n <namespace>
```

iii. Restart the corresponding pod so that it can pick up the new secret.

To determine which pod to restart, see the following topics:

- [List of external certificates](#)

- [List of internal certificates](#)

14. Upgrade the Portal subsystem.

- a. Run the following command:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file>
```

If you downloaded multiple control plane files, include all of them in the command. The sequence of file names in the command does not matter.

- b. Verify that the upgrade was successful by running a health check with the following command:

```
apicup subsys health-check <subsystem_name>
```

Important: If the health check indicates that a reboot is required, first complete the upgrade for all Portal sites and verify that all sites were upgraded before running the reboot command as instructed at this end of this step.

- c. Verify that Portal sites were upgraded:

- i. Log in as an admin user:

```
apic login -s <server_name> --realm admin/default-idp-1 --username admin --password <password>
```

- ii. Get the portal service ID and endpoint:

```
apic portal-services:get -o admin -s <management_server_endpoint> \
  --availability-zone availability-zone-default <portal-service-name> \
  --output - --format json
```

- iii. List the sites:

```
apic --mode portaladmin sites:list -s <management_server_endpoint> \
  --portal_service_name <portal-service-name> \
  --format json
```

Any sites currently upgrading display the **UPGRADING** status; any site that completed its upgrade displays the **INSTALLED** status and the new platform version. Verify that all sites display the **INSTALLED** status before proceeding.

For more information on the `sites` command, see [apic sites:list](#) and [Using the sites commands](#).

- iv. After all sites are in **INSTALLED** state and have the new platform listed, run:

```
apic --mode portaladmin platforms:list -s <server_name> --portal_service_name <portal_service_name>
```

Verify that the new version of the platform is the only platform listed.

For more information on the `platforms` command, see [apic platforms:list](#) and [Using the platforms commands](#).

- d. If all Portal sites are upgraded and the health check indicates that a reboot is needed, then run the following command:

```
systemctl reboot
```

15. Upgrade the Analytics subsystem

- a. `apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file>`

If you downloaded multiple control plane files, include all of them in the command. The sequence of file names in the command does not matter.

- b. Verify that the upgrade was successful by running a health check with the following command:

```
apicup subsys health-check <subsystem_name>
```

- c. If the health check indicates that a reboot is needed, run the following commands:

- i. `apic lock`

- ii. `systemctl reboot`

16. Complete a manual backup of the upgraded API Connect subsystems. See [Backing up and restoring \(10.0.1.1-eus or later\)](#).

17. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVAs and restoring from normal backups.

Important: VM snapshots are not an alternative to the standard backups that are described in the previous step, and which must be taken in order to use the API Connect restore feature.

- [Control Plane files for earlier releases](#)

If you are upgrading to an earlier version than 10.0.1.15-eus, refer to the following tables to determine which Control Plane files are required.

- [Checksum values for earlier releases](#)

If you are upgrading to an earlier version than 10.0.1.15-eus, use the corresponding checksum values to verify your downloaded upgrade files.

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Control Plane files for earlier releases

If you are upgrading to an earlier version than 10.0.1.15-eus, refer to the following tables to determine which Control Plane files are required.

Attention: Upgrading directly to the latest release from releases earlier than 10.0.1.6-ifix1-eus might run into problems. For best results, first upgrade to 10.0.1.6-ifix1eus and make a full set of backups before proceeding to upgrade to the latest release.

Control planes for upgrading to 10.0.1.15-eus

Installs with `appliance-control-plane-1.26.x.tgz`

Table 1. Control Plane files needed for earlier releases

API Connect version	Control Plane files needed

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Upgrading DataPower Gateway Service

Use these instructions when upgrading DataPower Gateway Service in a non-Kubernetes environment, during upgrade of API Connect.

Before you begin

Ensure you have completed the upgrade of the API Connect subsystems (Management service, Developer Portal, Analytics) before upgrading DataPower Gateway. Upgrading the Management service before the DataPower Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.

To review API Connect upgrade on VMware, see [Upgrading from 2018 to the latest 10.0.1.x-eus on VMware](#) or [Upgrading from 10.0.1.1-eus to the latest 10.0.1.x-eus on VMware](#) or [Upgrading to 10.0.1.8-eus on VMware](#).

Note: For API Connect Version 10.x, DataPower and API Connect releases can be within one fix pack of each other. For example, API Connect 10.0.1.n runs with DataPower Gateway 10.0.1.n, 10.0.1.n-1, or 10.0.1.n+1.

Important exception: Version 10.0.1.4-eus is not backwards compatible with 10.0.1.3. For example, API Connect 10.0.1.4-eus is not compatible with DataPower Gateway 10.0.1.3. If you deployed API Connect 10.0.1.4-eus, you must deploy either DataPower Gateway 10.0.1.4 or DataPower Gateway 10.0.1.5.

However, before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in [IBM API Connect Version 10 software product compatibility requirements](#) to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software, Integration Middleware, and view the list of compatible DataPower Gateway versions.

About this task

- The DataPower Gateway Service in a non-Kubernetes environment can be on either a physical appliance or in a virtual DataPower deployment.
- The upgrade of DataPower Gateway Service in a non-Kubernetes environment, for use in API Connect deployments in a VMware environment, does not use the API Connect Install Assist program (**apicup**). Use DataPower Gateway instructions in the following steps.

Note: To upgrade the DataPower Gateway Service in a Kubernetes environment, do not use the following procedure. Instead, see [Upgrading to 10.0.1.8-eus on Kubernetes](#) or [Upgrading 2018 to the latest 10.0.1.x-eus on native Kubernetes](#).

Procedure

1. Ensure that the DataPower Gateway firmware version you plan to install is compatible with the API Connect management server version.
2. When upgrading a high-availability cluster, ensure that you meet the requirements:
 - Gateways must be updated one at a time.
 - Before starting the upgrade, a single gateway must be running as primary for all gateway-peering definitions.
 - When upgrading multiple gateways, the primary gateway must be upgraded last.

To determine which gateway is running as primary, use either the `show gateway-peering-status` command in the DataPower CLI, or use the Gateway Peering Status display in the WebGUI in the API Connect application domain. To move the primary to the DataPower on which you're currently working, you can issue the `gateway-peering-switch-primary <peering-object-name>` command.

3. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.

See [Managing the NTP service](#).

4. Ensure that you have set a unique `System Identifier` for each version 10 DataPower gateway. See [Initializing the DataPower Gateway](#).

5. Follow the upgrade instructions on the DataPower Gateway documentation. See [Installation operations](#).

Note:

- If upgrading a cluster (high-availability) deployment, ensure that you have identified which gateway is running a primary in gateway-peering definitions, and that you upgrade that gateway last.
- For troubleshooting help with DataPower operator v1.2.0 deployments, see [IBM DataPower Operator documentation](#).

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Enabling Analytics after upgrading

After the upgrade successfully completes, enable the Analytics message queue and restart Analytics data collection.

Procedure

1. If you disabled the Analytics message queue before upgrading, enable it now by completing the following steps:

- a. Edit the `analytics-extra-value.yaml` file.
- b. Locate the `mq` section and change the `enabled` setting to `true`.
- c. Apply the change by running the following command:

```
apicup subsys install <subsystem_name>
```

2. [Start Analytics data collection](#).

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

Troubleshooting installation and upgrades on VMware

Review the following troubleshooting guidance if you encounter a problem while installing or upgrading API Connect on VMware.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

- [Postgres pods fail to start after upgrade](#)
- [Upgrading a 3 node profile to IBM API Connect 10.0.1.4-ifix1-eus might result in some portal-db/www pods being stuck in the Pending state](#)
- [Skipping health check when re-running upgrade](#)

The `cloud-final.service` fails during upgrade

Sometimes during upgrade, there is an issue with the `cloud-final.service` and a node, and the appliance-manager enters a bad state.

To determine whether your upgrade encountered this problem, complete the following steps:

1. Check the output of `apic health-check` command for a result similar to the following example:

```
# apic health-check
INFO[0000] Log level: info
FATA[0000] Unable to cluster status: rpc error: code = Unavailable desc = connection error: desc = "transport: Error while dialing dial tcp 9.20.153.38:9178: connect: connection refuse"
```

2. Check the response to the `journalctl -u appliance-manager | grep cloud-final` command and see if it looks like the following example:

```
# journalctl -u appliance-manager | grep cloud-final
Nov 21 19:41:58 apimdev1040 apic[2569]: Job for cloud-final.service failed because the control process exited with error
code.
Nov 21 19:41:58 apimdev1040 apic[2569]: See "systemctl status cloud-final.service" and "journalctl -xe" for details.
```

If you determined that this was the problem, you can correct it by running each of the following commands on every node:

1. `systemctl restart cloud-final.service`
2. `apic lock`
3. `apic unlock`

Some containers in the `kube-system` namespace show a status of `ErrImageNeverPull`

When upgrading, some of the containers in the `kube-system` namespace might show a status of `ErrImageNeverPull`. This happens due to Docker not successfully loading all images from the upgrade `.tgz` file. To resolve this issue and enable the upgrade to proceed, complete the following steps:

1. Run the following command to determine which node is missing the control plane files:

```
kubectl -n kube-system get pods -owide
```

This command returns the names of the nodes containing pods with the `ErrImageNeverPull` status, which indicates missing control plane files.

2. On the node that is missing the control plane files, run the following command to determine which versions of the control plane are missing:

```
cat /var/lib/apiconnect/appliance-control-plane-current
```

3. For each missing control plane, run the following command on the same node to add it, replacing `<version>` with the version of the control plane:

```
docker load < /usr/local/lib/appliance-control-plane/<version>/kubernetes.tgz
```

Pod stuck in `Pending` status during upgrade

When upgrading, the scheduler might deploy a subset of the same microservice pods on the same node. This can prevent other pods with `requiredDuringSchedulingIgnoredDuringExecution` affinity rules from being deployed due to a lack of resources on a subset of nodes. To allow the pending containers to be deployed successfully, identify any pods of the same type that are scheduled on the same node and delete one of them. This will free up space and cause the deleted pod to get rescheduled. To identify pods that are eligible to be deleted, and then delete the pods, complete the following steps:

1. Run the following command and check for any pods of the same type that are on the same node:

```
kubectl get po -o=custom-columns='name:.metadata.name, node:.spec.nodeName,
antiaffinity:.spec.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution' | grep -v '<none>' | awk
'{print $1" "$2}'
```

In the following example snippet, one of the two `apim` pods on the node `test0186` should be deleted:

```
stv3-management-analytics-proxy-56848c8c69-phpdh test0186
stv3-management-analytics-proxy-56848c8c69-sc45f test0187
stv3-management-analytics-proxy-56848c8c69-scf6g test0188
stv3-management-apim-5574796948-6lnwj test0186
stv3-management-apim-5574796948-h9dgx test0186
stv3-management-apim-5574796948-tsb4g test0188
```

2. Run the following command to delete a pod:

```
kubectl delete po <pod_name>
```

Database replica pods stuck in `Unknown` or `Pending` state

In certain scenarios, a postgres replica pod may not recover to a healthy state when a restore completes, a node outage occurs, or after a fresh install or upgrade. In these cases, a postgres pod remains in a `Unknown` or a `Pending` state after a number of minutes. The pod fail to get into a `Running` state.

This situation occurs when the replicas do not initialize properly. You can use the `patronictl reinit` command to reinitialize the replica. Note that this command syncs the replica's volume data from the current Primary pod.

Use the following steps to get the pod back into a working state:

1. SSH into the VM as root.
2. Exec onto the failing pod:

```
kubectl exec -it <postgres_replica_pod_name> -n <namespace> -- bash
```

3. List the cluster members:

```
patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+
| Member | Host | Role | State | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+
| fxpk-management-01191b80-postgres-586f899fdf-6s25b | 172.16.172.244 | | start failed | | unknown |
| fxpk-management-01191b80-postgres-rkw-795665698f-4rh4s | 172.16.148.51 | Leader | running | 3 | |
| fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m | 172.16.53.68 | | running | 3 | 0 |
+-----+-----+-----+-----+-----+-----+
```

In the example shown above `fxpk-management-01191b80-postgres-586f899fdf-6s25b` is not in running state.

Note the `clusterName` and `replicaName` which are not up:

- `clusterName` - `fxpk-management-01191b80-postgres`
- `replicaName` - `fxpk-management-01191b80-postgres-586f899fdf-6s25b`

4. Run:

```
patronictl reinit <clusterName> <replicaName-which-is-not-running>
```

Example:

```
patronictl reinit fxpk-management-01191b80-postgres fxpk-management-01191b80-postgres-586f899fdf-6s25b
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+-----+
| Member | Host | Role | State | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+
| fxpk-management-01191b80-postgres-586f899fdf-6s25b | 172.16.172.244 | | start failed | | unknown |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51 | Leader | running | 3 | |
| fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m | 172.16.53.68 | | running | 3 | 0 |
+-----+-----+-----+-----+-----+-----+
Are you sure you want to reinitialize members fxpk-management-01191b80-postgres-586f899fdf-6s25b? [y/N]: y
Success: reinitialize for member fxpk-management-01191b80-postgres-586f899fdf-6s25b
```

5. Run `patronictl list` again.

You may also observe that the replica is on a different Timeline (TL) and possibly have a Lag in MB. It may take a few minutes for the pod to switch onto the same TL as the others and the Lag should slowly go to 0.

For example:

```
bash-4.2$ patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+-----+
| Member | Host | Role | State | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+
| fxpk-management-01191b80-postgres-586f899fdf-6s25b | 172.16.172.244 | | running | 1 | 23360 |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51 | Leader | running | 3 | |
| fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m | 172.16.53.68 | | running | 3 | 0 |
+-----+-----+-----+-----+-----+-----+
```

6. The pod that previously was in an `Unknown` or `Pending` state or `(0/1) Running` state is now in `(1/1) Running` state.

Additional postgres replica created during installation or upgrade

If you see an installation or upgrade procedure stall with more than 2 postgres replica deployment in a n3 profile, delete the pending replica deployment by completing the following steps:

1. SSH into the VM as root.
2. Get the name of the pending postgres deployments:

```
kubectl get deploy -n <namespace> | grep postgres
```

3. Delete the pending postgres replica deployment:

```
kubectl delete deploy <replica_deployment_name> -n <namespace>
```

etcd pod stuck in Terminating state

During an upgrade, you might see a health-check reporting the upgrade is stuck in `ETCD` stage and that an `etcd` pod is stuck in the `Terminating` state.

Verify the issue by completing the following steps:

1. SSH into the VM as root.
 2. Run the following command and verify that the upgrade stage is `ETCD`:
- ```
apic status
```
3. Run the following command to determine whether an `etcd` pod is stuck in the `Terminating` state:

```
kubectl get pods -n namespace | grep etcd
```

Resolve the issue by completing the following steps:

1. Run the following command to retrieve the names of the `etcd` pods:

```
kubectl get pods -n namespace -o wide | grep etcd
```

2. On the pod that is stuck, SSH into the VM as root.
3. Run the following command to restart the pod:

```
systemctl restart kubelet
```

## Management subsystem upgrade imagePullBackOff issue

When upgrading the management subsystem, for example from v10.0.1.6 to v10.0.1.11, the postgres pods might run into an `imagePullBackOff` issue, where the postgres pods are looking for the v10.0.1.6 images that exist in the Docker registry, but the images haven't been loaded into the `Containerd` registry. To work around this issue, complete the following steps to manually move each image from the Docker registry to the `Containerd` registry:

1. Save the following Docker images, `ibm-apiconnect-management-k8s-init`, `crunchy-pgbackrest-repo`, `crunchy-pgbackrest`, `crunchy-pgbouncer`, and `crunchy-postgres-ha`, into a .tar file and keep in a secure location. For example, from v10.0.1.6:

```
docker save 127.0.0.1:8675/10.0.1.6/crunchy-pgbouncer > crunchy-pgbouncer.tar
```

2. Import each saved image into the `Containerd` registry. For example:

```
ctr --namespace k8s.io image import crunchy-pgbouncer.tar --digests=true
```

3. Re-tag the `import-<timestamp>@sha256:nnn` images to their appropriate `ifix2` tags and digests. For example:

```
ctr --namespace k8s.io image tag <source> <target>
```

## Portal `db` pods restart `mysqld` if the database state transfer takes more than 5 minutes

In IBM® API Connect Version 10.0.1.5-eus, if the portal database state transfer takes longer than 5 minutes from one `db` pod to another, then the `db` pod sending the data incorrectly thinks that the database process is stuck in a bad state, and will restart the database process. This situation would typically happen if you have more than 10 or 12 sites, a slow network between the `db` pods, such as in a distant multi-site high availability setup, or both.

In such cases, the following entry would be seen in one of the ready `db` containers inside a `db` pod:

```
dbstatus: ERROR: stuck in Donor mode for 5m31s!, restarting the database
```

To prevent this situation from happening, add the following environment variable to your portal deployment.

1. Create an extra values file to contain the environment variable, as follows:

```
spec:
 template:
 - containers:
 - env:
 - name: DONOR_STALE_SECS
 value: "7200"
 name: db
 name: db
```

2. Save the file as `dbstate.yaml`, and run the following command:

```
apicup subsys set <portal_subsystem_name> extra-values-file dbstate.yaml
```

3. Then, update the portal VMware with the updated setting by running the following command:

```
apicup subsys install <portal_subsystem_name>
```

4. To ensure that you get the new configuration and the database can startup correctly, you must delete all of the `db` pods by running the following command:

```
kubect1 delete pod <portal-mydc-db-0> <portal-mydc-db-1> <portal-mydc-db-2>
```

To run this command you must log in to the virtual machine portal subsystem by using an SSH tool.

## Issues when installing Drupal 8 based custom modules or sub-themes into the Drupal 9 based Developer Portal

From IBM API Connect 10.0.1.4-eus, the Developer Portal is based on the Drupal 9 content management system. If you want to install Drupal 8 custom modules or sub-themes into the Drupal 9 based Developer Portal, you must ensure that they are compatible with Drupal 9, including any custom code that they contain, and not using any deprecated APIs, for example. There are tools available for checking your custom code, such as [drupal check](#) on GitHub, which checks Drupal code for deprecations.

For example, any Developer Portal sites that contain modules or sub-themes that don't contain a Drupal 9 version declaration will fail to upgrade, and errors like the following output will be seen in the `admin` logs:

```
[queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: Checking theme: emeraldgreen
[queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: Incompatible
core_version requirement '' found for emeraldgreen

core_version requirement '8.x' found for rubyred
[queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: Found themes incompatible with
Drupal 9: emeraldgreen rubyred
[queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: /tmp/restore_site.355ec8 is NOT
Drupal 9 compatible
...
[queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: Checking module: custom_mod_1
[queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Incompatible
core_version requirement '' found for custom_mod_1
[queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: Checking module: custom_mod_2
[queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Incompatible
core_version requirement '8.x' found for custom_mod_2
[queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Found modules incompatible with
Drupal 9: emeraldgreen rubyred
[queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: site1.com is NOT Drupal 9
compatible
```

To fix version compatibility errors, all custom modules and sub-themes should declare a `core_version_requirement` key in their `*.info.yml` file that indicates Drupal 9 compatibility. For example:

```
name: Example module
type: module
description: Purely an example
core: 8.x
core_version_requirement: '^8 || ^9'
package: Example module

Information added by Drupal.org packaging script on 2020-05-31
version: '8.x-1.3'
project: 'example_module'
datestamp: 1590905415
```

This example specifies that the module is compatible with all versions of Drupal 8 and 9. For more information, see [Let Drupal know about your module with an .info.yml file](#) on the drupal.org website.

If you have a backup of a site that you need to restore, and are getting the version compatibility error, but the module or theme \*.info.yml file cannot be changed easily, then you have two options. Either:

- Add an environment variable into the portal CR for the `www` pod of the `admin` container stating `SKIP_D9_COMPAT_CHECK: "true"`. However, if you choose this method, you must be positive that all of the custom modules and themes for your sites are Drupal 9 compatible, as otherwise the sites may end up inaccessible after the upgrade or restore.
  1. On VMware, create an extra values file to contain the environment variable, as follows:

```
spec:
 template:
 - containers:
 - env:
 - name: SKIP_D9_COMPAT_CHECK
 value: "true"
 name: admin
 name: www
```

2. Save the file as `d9compat.yaml`, and run the following command:

```
apicup subsys set <portal_subsystem_name> extra-values-file d9compat.yaml
```

3. Then, update the portal VMware with the updated setting by running the following command:

```
apicup subsys install <portal_subsystem_name>
```

Or:

- Extract the site backup, edit the relevant files inside it, and then tar the backup file again. Note that this procedure will overwrite the original backup file, so ensure that you keep a separate copy of the original file before you start the extraction. For example:
  1. `mkdir /tmp/backup`
  2. `cd /tmp/backup`
  3. `tar xzf path_to_backup.tar.gz`
  4. Edit the custom module and theme files to make them Drupal 9 compatible, and add the correct `core_version_requirement` setting.
  5. `rm -f path_to_backup.tar.gz`
  6. `tar cfz path_to_backup.tar.gz`
  7. `cd /`
  8. `rm -rf /tmp/backup`

## Postgres pods fail to start after upgrade

When upgrading the management subsystem as part of [Upgrading to 10.0.1.8-eus on VMware](#), you might encounter an error message when checking the subsystem health upon completion of the upgrade. For example:

```
apic health-check
INFO[0000] Log level: info
FATA[0006] Cluster not in good health:
ManagementCluster (current ha mode: active) is not ready | State: 15/16 Phase: Pending
```

To troubleshoot when a message like this occurs:

1. Check the state of postgres pods:

```
kubectl get pods | grep postgres
```

For example:

```
root@apimdev1146:~# kubectl get pods | grep postgres
fxpk-management-fd8b0b1f-postgres-577594c7f-k54pk 0/1 Init:CrashLoopBackOff 17 22h
fxpk-management-fd8b0b1f-postgres-backrest-shared-repo-7fctp88w 1/1 Running 2 22h
fxpk-management-fd8b0b1f-postgres-elbx-698f445649-rlc2g 0/1 Init:CrashLoopBackOff 16 22h
fxpk-management-fd8b0b1f-postgres-pgbouncer-64f57b7cc7-52bk8 1/1 Running 2 22h
fxpk-management-fd8b0b1f-postgres-pgbouncer-64f57b7cc7-jjjvb 1/1 Running 1 22h
fxpk-management-fd8b0b1f-postgres-pgbouncer-64f57b7cc7-qp4zh 1/1 Running 2 22h
fxpk-management-fd8b0b1f-postgres-stanza-create-6pt6c 0/1 Completed 0 22h
fxpk-management-fd8b0b1f-postgres-ubba-79ccdd5cc6-kj4zx 0/1 Init:CrashLoopBackOff 17 22h
postgres-operator-85fb96db4b-gk8k8 4/4 Running 8 22h
```

2. If any pods show `Init:CrashLoopBackOff` status, restart the pods. To force a restart, delete the pods:

```
kubectl delete pod <name_of_postgres_pod>
```

For example:

```
kubectl delete pod fxpk-management-fd8b0b1f-postgres-577594c7f-k54pk
kubectl delete pod fxpk-management-fd8b0b1f-postgres-elbx-698f445649-rlc2g
kubectl delete pod fxpk-management-fd8b0b1f-postgres-ubba-79ccdd5cc6-kj4zx
```

When pods are deleted, the deployment automatically restarts them.

3. Re-run the health check. For example:

```
apicup subsys health-check <subsys_name>
```

4. When health check is successful, return to [Upgrading from v10.0.1.2 to v10.0.1.2 with the latest iFix on VMware](#).

## Upgrading a 3 node profile to IBM API Connect 10.0.1.4-ifix1-eus might result in some portal-db/www pods being stuck in the Pending state

IBM API Connect 10.0.1.4-ifix1-eus introduces the pod anti-affinity required rule, meaning that in a 3 node profile deployment, all 3 db and www pods can run only if there are at least 3 running worker nodes. This rule can cause some upgrades to version from 10.0.1.4-eus or earlier to become stuck in the **Pending** state, in which case some extra steps are needed during the upgrade to workaround the issue. See the following example for detailed information about the issue, and how to continue with the upgrade.

If you are upgrading from 10.0.1.4-ifix1-eus or later, to 10.0.1.5-eus or later, this problem does **not** occur. The problem can occur only when upgrading from 10.0.1.4-eus or earlier.

Important: You must have a backup of your current deployment before starting the upgrade.

To run the commands that are needed to workaround this issue, you must log in to the virtual machine portal subsystem by using an SSH tool.

1. Run the following command to log in as `apicadm`, which is the API Connect ID that has administrator privileges:

```
ssh portal_ip_address -l apicadm
```

Where `portal_ip_address` is the IP address of the portal subsystem.

2. Then get a root shell by running the following command:

```
sudo -i
```

In the following example, the VMware stack has 3 VMs (worker nodes):

```
$ kubectl get nodes
NAME STATUS ROLES AGE VERSION
apimdev0103 Ready worker 42m v1.20.0
apimdev0129 Ready worker 45m v1.20.0
apimdev1066 Ready worker 39m v1.20.0
```

The pods have been scheduled across only 2 of the 3 worker nodes due to a transient problem with `apimdev1066`, as shown in the following pod list. Pods without persistent storage, such as `nginx-X`, can be rescheduled to `apimdev1066` as soon as they are restarted, but any pods with persistent local storage, such as `db-X` and `www-X`, have to be rescheduled onto the same worker node as that is where their files live.

```
$ kubectl get po -o wide
NAME READY STATUS RESTARTS AGE IP NODE NOMINATED NODE
READINESS GATES
ejs-portal-nginx-84f57ffd8c-hbf66 1/1 Running 0 5m12s 888.16.109.208 apimdev0103 <none> <none>

```

The upgrade to version 10.0.1.4-ifix1 is started and the following pod list is observed:

```
$ kubectl get po -o wide
NAME READY STATUS RESTARTS AGE IP NODE NOMINATED NODE
READINESS GATES
ejs-portal-nginx-84f57ffd8c-hbf66 1/1 Running 0 10m 888.16.109.208 apimdev0103 <none> <none>
ejs-portal-nginx-84f57ffd8c-mvq96 1/1 Running 0 10m 888.16.142.215 apimdev0129 <none> <none>
ejs-portal-nginx-84f57ffd8c-vpmtl 1/1 Running 0 10m 888.16.142.214 apimdev0129 <none> <none>
ejs-portal-sitel-db-0 2/2 Running 0 10m 888.16.109.209 apimdev0103 <none> <none>
ejs-portal-sitel-db-1 0/2 Pending 0 91s <none> <none> <none>
ejs-portal-sitel-db-2 2/2 Running 0 2m41s 888.16.142.218 apimdev0129 <none> <none>
ejs-portal-sitel-www-0 2/2 Running 0 9m51s 888.16.109.210 apimdev0103 <none> <none>
ejs-portal-sitel-www-1 2/2 Running 0 12m 888.16.142.213 apimdev0129 <none> <none>
ejs-portal-sitel-www-2 0/2 Pending 0 111s <none> <none> <none>
ibm-apiconnect-75b47f9f87-p25dd 1/1 Running 0 10m 888.16.109.207 apimdev0103 <none> <none>
```

The pod list shows that `db-2` has restarted, and has been rescheduled to `apimdev0129` as there were no other db pods running on that node. However, `db-1` and `www-2` are both stuck in **Pending** state, as there is already a pod of the same type running on the worker node that is hosting the local storage that they are bound to. If you run a `describe` command of either pod you will see the following output:

```
Events:
 Type Reason Age From Message
 ---- -
Warning FailedScheduling 10s (x4 over 2m59s) default-scheduler 0/3 nodes are available: 1 node(s) didn't match pod affinity/anti-affinity, 1 node(s) didn't match pod anti-affinity rules, 2 node(s) had volume node affinity conflict.
```

To resolve this situation you need to delete the PVCs for each pod, and then delete the pod itself, so that Kubernetes will regenerate the PVCs and schedule the pod on the worker node that does not have the anti-affinity conflict.

Therefore, for the `db-1` pod the following commands must be run:

```
$ kubectl get pvc | grep ejs-portal-sitel-db-1
db-ejs-portal-sitel-db-1 Bound local-pv-fa445e30 250Gi RWO local-storage 15m
dblogs-ejs-portal-sitel-db-1 Bound local-pv-d57910e7 250Gi RWO local-storage 15m
```

```
$ kubectl delete pvc db-ejs-portal-sitel-db-1 dblogs-ejs-portal-sitel-db-1
persistentvolumeclaim "db-ejs-portal-sitel-db-1" deleted
persistentvolumeclaim "dblogs-ejs-portal-sitel-db-1" deleted
```

```
$ kubectl delete po ejs-portal-sitel-db-1
pod "ejs-portal-sitel-db-1" deleted
```

For the `www-2` pod the following commands must be run:

```
$ kubectl get pvc | grep ejs-portal-sitel-www-2
admin-ejs-portal-sitel-www-2 Bound local-pv-48799536 245Gi RWO local-storage 51m
backup-ejs-portal-sitel-www-2 Bound local-pv-a93f5607 245Gi RWO local-storage 51m
web-ejs-portal-sitel-www-2 Bound local-pv-facd4489 245Gi RWO local-storage 51m
```

```
$ kubectl delete pvc admin-ejs-portal-sitel-www-2 backup-ejs-portal-sitel-www-2 web-ejs-portal-sitel-www-2
persistentvolumeclaim "admin-ejs-portal-sitel-www-2" deleted
persistentvolumeclaim "backup-ejs-portal-sitel-www-2" deleted
persistentvolumeclaim "web-ejs-portal-sitel-www-2" deleted
```

```
$ kubectl delete po ejs-portal-sitel-www-2
pod "ejs-portal-sitel-www-2" deleted
```

If the PVC has `persistentVolumeReclaimPolicy: Delete` set on it, as is the case for the OVA deployments, then no cleanup is necessary as the old data will have been deleted on the worker node that is no longer running the `db-1` and `www-2` pods.

Kubernetes can now reschedule the pods. All pods with persistent storage are now spread across the available worker nodes, and the pods whose PVCs were deleted will get a full copy of the data from the existing running pods. The following pod list is now observed in our example:

```
$ kubectl get po -o wide
NAME READY STATUS RESTARTS AGE IP NODE NOMINATED NODE
READINESS GATES
ejs-portal-nginx-84f57ffd8c-f85wm 1/1 Running 0 30s 888.16.29.136 apimdev1066 <none> <none>
ejs-portal-nginx-84f57ffd8c-k5klb 1/1 Running 0 103s 888.16.142.220 apimdev0129 <none> <none>
ejs-portal-nginx-84f57ffd8c-lqhqs 1/1 Running 0 1m53s 888.16.109.212 apimdev0103 <none> <none>
ejs-portal-sitel-db-0 2/2 Running 0 6m43s 888.16.109.211 apimdev0103 <none> <none>
ejs-portal-sitel-db-1 2/2 Running 0 8m20s 888.16.29.134 apimdev1066 <none> <none>
ejs-portal-sitel-db-2 2/2 Running 0 14m 888.16.142.218 apimdev0129 <none> <none>
ejs-portal-sitel-www-0 2/2 Running 0 93s 888.16.109.213 apimdev0103 <none> <none>
ejs-portal-sitel-www-1 2/2 Running 0 3m55s 888.16.142.219 apimdev0129 <none> <none>
ejs-portal-sitel-www-2 2/2 Running 0 7m27s 888.16.29.135 apimdev1066 <none> <none>
ibm-apiconnect-75b47f9f87-p25dd 1/1 Running 0 22m 888.16.109.207 apimdev0103 <none> <none>
```

## Skipping health check when re-running upgrade

The `apicup subsys install` command automatically runs `apicup health-check` prior to attempting the upgrade. An error is displayed if a problem is found that will prevent successful upgrade.

In some scenarios, if you encounter an upgrade failure, an attempt to rerun `apicup subsys install` is blocked by errors found by `apicup health-check`. Even when you have fixed the error (such as reconfiguration of an incorrect upgrade CR), the failed upgrade can continue to cause the health check to fail.

You can work around the problem by adding the `--skip-health-check` flag to suppress the health check:

```
apicup subsys install <subsystem_name> --skip-health-check
```

In this case, use of `--skip-health-check` allows the upgrade to rerun successfully.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Upgrading from older versions on VMware

If you are upgrading API Connect from an older version, see the instructions in this section.

- [Upgrading to 10.0.1.9-eus on VMware](#)  
Upgrade API Connect to the version of 10.0.1.9-eus on VMware.
- [Upgrading from 10.0.1.1-eus to the latest 10.0.1.x-eus on VMware](#)  
You can upgrade API Connect on VMware from 10.0.1.1-eus to the latest version of 10.0.1.x-eus.
- [Upgrading from 2018 to the latest 10.0.1.x-eus on VMware](#)  
You can upgrade API Connect on VMware from 2018 to the latest 10.0.1.x-eus version on VMware.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Upgrading to 10.0.1.9-eus on VMware

Upgrade API Connect to the version of 10.0.1.9-eus on VMware.

## About this task

- The upgrade order for subsystems is important. Upgrade the subsystems in the following order: (1) Management, (2) Portal, (3) Analytics, (4) Gateway. Management must be upgraded first. Upgrading the Management service before the Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
- When you run the install, the program sends the compressed tar file, which contains the upgrade images, to all cluster members. The compressed tar file is about 2 GB, and transfer can take some time. When the install command exits, the compressed tar file has arrived at each member. The upgrade process is now underway, and might continue for some time depending on factors such as the size of your deployment, your network speed, etc.
- The `apicup subsys install` command automatically runs `apicup health-check` prior to attempting the upgrade. An error is displayed if a problem is found that will prevent successful upgrade. When troubleshooting a problem with an upgrade, you can optionally suppress the health check. See [Skipping health check when re-running upgrade](#).
- For each subsystem, you will be instructed to manually run `apicup health-check` after the upgrade, to ensure that the upgrade was successful.
  - Be sure to allow a few minutes for the subsystem upgrade to complete before running the health check. Note that the time required for upgrade to complete varies depending on the size of your deployment.
  - The health check command returns silently if no errors are found.
  - For more info, see [Checking cluster health on VMware](#).
- The Gateway subsystem remains available during the upgrade of the Management, Portal, and Analytics subsystems.

Note: Upon successful completion of each subsystem upgrade, restart as required:

1. For each subsystem, the upgrade process automatically runs `apicup health-check` upon completion of the upgrade. When `apicup health-check` gives a message that reboot is required for a server, SSH onto that server and check the subsystem custom resource status:

```
kubectl get <name_of_cr>
```

For example:

```
kubectl get managementCluster
```

If both the deployment is **READY** (displays matching values x/x) and the **RECONCILED VERSION** shows the version you are upgrading to, then reboot that server.

2. During the upgrade, repeat this action for each subsystem when the message from `apicup subsys health-check` that says reboot is required for a server. However, if the health check command states that a reboot is required for the Portal subsystem, you must ensure that all of the Portal sites have been installed first before performing the reboot. See the instructions in Step [#upgrading\\_vmware\\_v10012\\_latest\\_v10\\_step\\_portal](#) for details.

## Procedure

Attention: If you encounter an issue while performing the upgrade, see [Troubleshooting installation and upgrades on VMware](#).

1. Ensure that your deployment meets the upgrade requirements. See [Upgrade considerations on VMware](#).
2. Prepare for upgrading the management subsystem.
  - a. Verify that the `pgcluster` is healthy:
    - i. SSH into the appliance as `root`.
    - ii. Get the name of the `pgcluster`:

```
kubectl get pgcluster -n <APIC_namespace>
```

The response displays the name of the postgres cluster running in the specified namespace.

- iii. Check the status of the `pgcluster`:

```
kubectl get pgcluster <pgcluster_name> -n <APIC_namespace> -o yaml | grep status -A 2 | tail -n3
```

The response for a healthy `pgcluster` looks like the following example, where the state is **Initialized**:

```
status:
 message: Cluster has been initialized
 state: pgcluster Initialized
```

Important: If the `pgcluster` returns any other state, it is not healthy and an upgrade will fail.

- If there are any ongoing backup or restore jobs, wait until they complete and then check the status again. Do not proceed with the upgrade until the status is **Initialized**.
- If all of the background jobs complete but the `pgcluster` remains unhealthy, contact IBM Support for assistance.

- b. Verify sufficient free disk space.

For each appliance node that you are planning to upgrade:

- i. SSH into the appliance, and switch to user `root`.
- ii. Check disk space in `/data/secure`:

```
df -h /data/secure
```

Make sure the disk usage shown is below 70%. If it is not, add disk capacity. See [Adding disk space to a VMware appliance](#).

- iii. Check free disk space in `/`:

```
df -h /
```

Make sure usage is below 70%. If it is not, consider deleting or offloading older `/var/log/syslog*` files.

3. Complete the prerequisites:

- a. Verify the API Connect deployment is healthy and fully operational. See [Checking cluster health on VMware](#)
- b. Remove any stale upgrade files:

```
apic clean-upgrade-files
```

- c. Complete a manual backup of the API Connect subsystems. See [Backing up and restoring \(10.0.1.1-eus or later\)](#).

Note:

- Do not start an upgrade if a backup is scheduled to run within a few hours.
  - Do not perform maintenance tasks such as rotating key-certificates, restoring from a backup, or starting a new backup, at any time while the upgrade process is running
4. Run the pre-upgrade health check:
    - a. Run the health check on the Management subsystem:
      - i. SSH into the server:
        1. Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:
 

```
ssh ip_address -l apicadm
```
        2. When prompted, select Yes to continue connecting.
        3. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:
 

```
sudo -i
```
      - ii. Verify that the `apicops` utility is installed by running the following command to check the current version of the utility:
 

```
apicops --version
```

If the response indicates that `apicops` is not available, install it now. See [The API Connect operations tool: apicops](#) in the API Connect documentation.
      - iii. Run the version-check script and verify that there are no errors:
 

```
apicops version:pre-upgrade
```
      - iv. Run the appliance health check and verify that there are no errors:
 

```
apicops appliance-checks:appliance-pre-upgrade
```
    - b. Run the health check on the Portal subsystem:
      - i. SSH into the server.
      - ii. Verify that the `apicops` utility is installed by running the following command to check the current version of the utility:
 

```
apicops --version
```

If the response indicates that `apicops` is not available, install it now. See [The API Connect operations tool: apicops](#) in the API Connect documentation.
      - iii. Run the following command to check the system status, and verify that there are no errors:
 

```
apicops upgrade:check-subsystem-status
```
      - iv. Run the appliance health check and verify that there are no errors:
 

```
apicops appliance-checks:appliance-pre-upgrade
```
    - c. Run the health check on the Analytics subsystem:
      - i. SSH into the server.
      - ii. Verify that the `apicops` utility is installed by running the following command to check the current version of the utility:
 

```
apicops --version
```

If the response indicates that `apicops` is not available, install it now. See [The API Connect operations tool: apicops](#) in the API Connect documentation.
      - iii. Run the following command to check the system status, and verify that there are no errors:
 

```
apicops upgrade:check-subsystem-status
```
      - iv. Run the appliance health check and verify that there are no errors:
 

```
apicops appliance-checks:appliance-pre-upgrade
```
5. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details.
 

Important:

  - This action requires a brief outage while all of the VMs in the subsystem cluster are shut down.
  - Do not take snapshots of running VMs, as they might not restore successfully.
  - VM snapshots are not an alternative to the standard backups that are described in the previous steps, and which must be taken in order to use the API Connect restore feature.
6. Download the API Connect files:
 

You can access the latest files from [IBM Fix Central](#) by searching for the API Connect product and your installed version.

The following files are used during upgrade on VMware, from 10.0.1.2-eus or later to the latest version of 10.0.1.x-eus:

  - IBM® API Connect `<version>` Management Upgrade File for VMware Management subsystem files
  - IBM® API Connect `<version>` Developer Portal Upgrade File for VMware Developer Portal subsystem files
  - IBM® API Connect `<version>` Analytics Upgrade File for VMware Analytics subsystem files
  - IBM® API Connect `<version>` Install Assist for `<operating_system_type>` The `apicup` installation utility. Required for all installations on VMware.

The following files are not used during upgrade, but can be installed as new installations used to replace prior versions:

  - IBM® API Connect `<version>` Toolkit for `<operating_system_type>` Toolkit command line utility. Packaged standalone, or with API Designer or Loopback:
    - IBM® API Connect `<version>` Toolkit for `<operating_system_type>`

- IBM® API Connect <version> Toolkit with Loopback for <operating\_system\_type>
  - IBM® API Connect <version> Toolkit Designer with Loopback for <operating\_system\_type>
- Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See [Installing the toolkit](#).

IBM® API Connect <version> Local Test Environment  
 Optional test environment. See [Testing an API with the Local Test Environment](#)  
 IBM® API Connect <version> Security Signature Bundle File  
 Checksum files that you can use to verify the integrity of your downloads.

- Download Control Plane files from the same Fix Pack page.  
 Control Plane files provide support for specific Kubernetes versions (VMware is hosted on Kubernetes). When upgrading API Connect, you must install all of the Control Plane files that are required for the new version to ensure that all current Kubernetes versions are supported.

You will install the Control Plane files with each subsystem as part of the upgrade process.

Table 1. Control Plane files needed for upgrading to 10.0.1.9-eus

| API Connect version                                                                                                                                                                                                                                | Control Plane files needed                                                                                                                                               |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>• 10.0.1.8-eus</li> <li>• 10.0.1.7-eus</li> </ul>                                                                                                                                                           | No Control Plane file needed.                                                                                                                                            |
| <ul style="list-style-type: none"> <li>• 10.0.4.0 and iFixes</li> </ul>                                                                                                                                                                            | Download: <ul style="list-style-type: none"> <li>• <code>appliance-control-plane-1.23.x.tgz</code></li> </ul>                                                            |
| <ul style="list-style-type: none"> <li>• 10.0.3.0 and iFixes</li> <li>• 10.0.2.0 and iFixes</li> <li>• 10.0.1.6-eus and iFixes</li> <li>• 10.0.1.5-eus and iFixes</li> <li>• 10.0.1.4-eus and iFixes</li> <li>• 10.0.1.2-eus and iFixes</li> </ul> | Download: <ul style="list-style-type: none"> <li>• <code>appliance-control-plane-1.23.x.tgz</code></li> <li>• <code>appliance-control-plane-1.22.x.tgz</code></li> </ul> |

For information on the Control Planes required for older versions of API Connect, see [Control Plane files for earlier releases](#).

- Verify that the subsystem upgrade files are not corrupted.
  - Run the following command separately for the Management, the Developer Portal, and the Analytics upgrade files:

- Mac or Linux:

```
sha256sum <upgrade-file-name>
```

Example:

```
sha256sum upgrade_management_10.0.1.9
```

- Windows:

```
C:\> certUtil -hashfile C:\<upgrade-file-name> SHA256
```

Example:

```
C:\> certUtil -hashfile C:\upgrade_management_10.0.1.9 SHA256
```

- Compare the result with the checksum values to verify that the files are not corrupted.

If the checksum does not match the value for the corresponding version and subsystem, then the upgrade file is corrupted. Delete it and download a new copy of the upgrade file. The following list shows the checksum values for the current release. If you are upgrading to an older release, see [Checksum values for earlier releases](#).

Checksum values for 10.0.1.9-eus:

```
10.0.1.9 analytics : fd4b3cab78dc251d2deb3a33294021d126646dedba6a27cb4fa4ea0013ad632
10.0.1.9 management : d2cf7dd2cab0feb1b74491ea8c56061fd388eab77eb498a17011e71ba5e770bc
10.0.1.9 portal : 929a6a1ae54a2b1ae498790708936fd71505edae2958fc0987c55852eadd65fe
```

- If necessary, replace the pgbouncer image before upgrading the management subsystem. Follow the instruction that applies to your deployment scenario:

Upgrading from 10.0.1.2-ifix1-eus, 10.0.1.2-ifix2-eus, or later

Do not replace pgbouncer. Go to step [10](#).

Upgrading from 10.0.1.2-eus (without any ifixes) and the 10.0.1.2-eus installation completed without errors

Replace pgbouncer. Go to step [10.a](#).

Upgrading from 10.0.1.2-eus (without any ifixes) and the 10.0.1.2 installation encountered an error

- If the error was **server DNS lookup failed**, replace pgbouncer. Go to step [10.a](#).
- If any other error was encountered, do not replace pgbouncer. Please contact IBM Support for assistance.

- Use `apicup` with the `--skip-health-check` option to deploy the subsystem files, control plane files, and installer files:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file> --skip-health-check
```

If you downloaded multiple control plane files, include all of them in the command. The sequence of file names in the command does not matter.

- `ssh` into the Management subsystem VM.

- Obtain the pgbouncer image from the registry for the latest version 10 images; for example:

```
127.0.0.1:8675/10.0.1.7-eus/ibm-apiconnect-management-crunchy-
pgbouncer@sha256:4a5caaf4e5cd405ccb3de7d39b8e343b0c4ebca7cae694ccbfb80924d98752
```

- Get the pgbouncer deployment name:

```
kubectl get deploy -n <namespace> | grep pgbouncer
```

- Replace the container image section with the new pgbouncer image:

```
kubectl edit deploy <pgbouncer-deployment-name> -n <namespace>
```

- f. Restart the pgbouncer pod.
- g. Next, verify that the version of the new pgbouncer is correct. Get the pgbouncer pod name:

```
kubectl get pods -n <namespace> | grep 'pgbouncer'
```

- h. Exec into the pgbouncer pod:

```
kubectl exec -it <pgbouncer-pod> -n <namespace> -- bash
```

- i. Execute `pgbouncer --version` and make sure it matches:

```
bash-4.4$ pgbouncer --version
PgBouncer 1.15.0
libevent 2.1.8-stable
adns: evdns2
tls: OpenSSL 1.1.1g FIPS 21 Apr 2020
systemd: yes
```

- j. Get the logs for newly started pgbouncer microservice, and verify there are no errors for DNS lookup:

```
kubectl logs <pgbouncer-pod-name> -n <namespace> | grep 'server DNS lookup failed'
```

The message `server DNS lookup failed` should not be included in the logs.

- k. Verify that the system is stable:

```
apicup subsys health-check <subsystem_name>
```

The health check should return with exit code 0.

- l. Choose one of the following:

- If the 10.0.1.2-eus installation did not encounter any errors, the workaround is complete. Go to step [10](#).
- If the 10.0.1.2-eus installation encountered the `server DNS lookup failed` error, you must also delete several microservices:
  - i. `apim`: Get the pod name and delete the microservice:

```
kubectl get pods -n <namespace> | grep 'apim'
kubectl delete pod <apim-pod> -n <namespace>
```

- ii. `lur`: Get the pod name and delete the microservice:

```
kubectl get pods -n <namespace> | grep 'lur'
kubectl delete pod <lur-pod> -n <namespace>
```

- iii. `task manager`: Get the pod name and delete the microservice:

```
kubectl get pods -n <namespace> | grep 'task'
kubectl delete pod <task-manager-pod> -n <namespace>
```

## 10. Upgrade the management subsystem.

- a. Install the newer management subsystem files, control plane files, and installer files.  
Be sure to use the Install Assist `apicup` installer that matches the API Connect version you are upgrading to.

Note: If you replaced the pgbouncer image as described in step [9](#) you do not need to run the `apicup subsys install` again. Skip this step, and go directly to step [10.b](#).

Use the following install command:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file>
```

If you downloaded multiple control plane files, include all of them in the command. The sequence of file names in the command does not matter.

Tip: If the upgrade gets stuck, run the following command to reboot the appliance:

```
sudo systemctl restart appliance-manager
```

- b. Verify that all pods have started.  
Follow the procedure in [Postgres pods fail to start after upgrade](#).
- c. Verify that the upgrade was successful by running the following command:

```
apicup subsys health-check <subsys_name>
```

- d. Restart the subsystem when the health check command displays a message instructing you to do so.  
See the [reboot steps](#) in the Note at the beginning of this page.
- e. Use `apicops` v10 version 0.10.57+ to validate the certificates.  
For information on the `apicops` tool, see [The API Connect operations tool: apicops](#).

- i. Run the following command:

```
apicops upgrade:stale-certs -n <namespace>
```

- ii. Delete any stale certificates that are managed by cert-manager.

If a certificate failed the validation and it is managed by cert-manager, you can delete the stale certificate secret, and let cert-manager regenerate it.  
Run the following command:

```
kubectl delete secret <stale-secret> -n <namespace>
```

- iii. Restart the corresponding so that it can pick up the new secret.

To determine which pod to restart, see the following topics:

- [List of external certificates](#)
- [List of internal certificates](#)

## 11. Upgrade the Portal subsystem.

a. `apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file>`

If you downloaded multiple control plane files, include all of them in the command. The sequence of file names in the command does not matter.

b. Verify that the upgrade was successful.

```
apicup subsys health-check <subsys_name>
```

Important: If the health check command states that a reboot is required, you must ensure that all Portal sites have been upgraded first before performing the reboot. To check that the Portal sites have upgraded, inspect the `platform` and `state` values for each site. The sites should all be in `INSTALLED` state, and have `platform` equal to the new platform that you can identify with `platforms:list`. Note that there will be two platforms present in the list while the site upgrades are happening. There should be only one `platform` after they have completed. Use the commands in step [12.c](#) to list the sites, and then reboot.

c. Ensure that the Portal sites were upgraded:

i. Obtain the portal service id and endpoint:

```
apic portal-services:get -o admin -s <management_server_endpoint> \
--availability-zone availability-zone-default <portal-service-name> \
--output - --format json
```

ii. List the sites:

```
apic --mode portaladmin sites:list -s <management_server_endpoint> \
--portal_service_id <portal_service_id_from_above_command> \
--portal_service_endpoint <portal_service_endpoint_from_above_command> \
--format json
```

Any sites currently upgrading will be listed as `UPGRADING`. Once all sites have finished upgrading they should have the `INSTALLED` status and the new platform version listed.

See also: [apic sites:list](#) and [Using the sites commands](#).

iii. After all sites are in `INSTALLED` state and have the new platform listed, run:

```
apic --mode portaladmin platforms:list -s <management_server_endpoint> \
--portal_service_id <portal_service_id_from_above_command> \
--portal_service_endpoint <portal_service_endpoint_from_above_command> \
--format json
```

The new version of the platform should be the only platform listed.

See also: [apic platforms:list](#) and [Using the platforms commands](#).

d. If the health check command states that a restart is required, and you have verified that all portal sites are installed, reboot the subsystem. See the [reboot steps](#) in the Note at the beginning of this page.

## 12. Upgrade the Analytics subsystem

a. `apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file>`

If you downloaded multiple control plane files, include all of them in the command. The sequence of file names in the command does not matter.

b. Verify that the upgrade was successful.

```
apicup subsys health-check <subsys_name>
```

c. Restart the subsystem when the health check command displays a message instructing you to do so. See the [reboot steps](#) in the Note at the beginning of this page.

13. Complete a manual backup of the API Connect subsystems. See [Backing up and restoring \(10.0.1.1-eus or later\)](#).

14. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVAs and restoring from normal backups.

Important: VM snapshots are not an alternative to the standard backups that are described in the previous step, and which must be taken in order to use the API Connect restore feature.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Upgrading from 10.0.1.1-eus to the latest 10.0.1.x-eus on VMware

You can upgrade API Connect on VMware from 10.0.1.1-eus to the latest version of 10.0.1.x-eus.

To upgrade from 10.0.1.1-eus, you must deploy a fresh cluster and restore existing data into it. The process is similar to a disaster recovery. There is no option for a traditional in-place upgrade.

For the management subsystem you must run custom scripts to extract configuration.

For the Developer Portal and the Analytics subsystem, you will install the latest distribution files, and then restore from version 10 backups.

Note that you will install the latest release using the same Fix Central distribution files as are used for a brand new API Connect installation.

## Automatic shortening of subsystem names with greater than 63 characters (10.0.1.1-eus upgrade only)

Version 10.0.1.2-eus (and later) imposes a length restriction of 63 characters for subsystem names. Prior releases of version 10 did not impose the restriction. If your 10.0.1.1-eus subsystem names are greater than 63 characters in length, you must shorten them prior to upgrading. If you do not shorten them, the upgrade will programmatically shorten them for you. You will then want to check `apiconnect-up-v10.yaml` to determine the new shortened name. The new value is found in `spec.subsystems[n].metadata.name`. For example, for a management subsystem, see the `name: abcde-management` entry below:

```
apiVersion: v1
kind: apic.ibm.com/APIConnectCluster
metadata:
 creationTimestamp: "2021-03-04T13:52:50Z"
 name: abcde
spec:
 secret-name: abcde-my-secret
 subsystems:
 - apiVersion: v1
 kind: apic.ibm.com/ManagementSubsystem
 metadata:
 creationTimestamp: "2021-03-04T13:52:50Z"
 name: abcde-management
 spec:
 ApplianceProperties:
 data-device: sdb
```

- [Prepare 10.0.1.1-eus for upgrade to the latest 10.0.1.x-eus](#)  
Prepare your 10.0.1.1-eus deployment for upgrade to the latest 10.0.1.x-eus release by completing preparation steps for subsystem recovery, and taking current backups.
- [Upgrading subsystems from 10.0.1.1-eus to the latest 10.0.1.x-eus on VMware](#)  
Install the latest API Connect 10.0.1.x-eus and recover the data from your original 10.0.1.1-eus deployment.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Prepare 10.0.1.1-eus for upgrade to the latest 10.0.1.x-eus

Prepare your 10.0.1.1-eus deployment for upgrade to the latest 10.0.1.x-eus release by completing preparation steps for subsystem recovery, and taking current backups.

### About this task

To prepare the management subsystem, obtain and run an upgrade script to capture important information, such as credentials and secrets. This information will be used later during the restore. Next, complete a backup of the subsystem. For the Developer Portal subsystem and the Analytics subsystem, complete a backup.

### Procedure

1. Make sure the API Connect cluster is healthy. For each subsystem (Management, Developer Portal, and Analytics) run the following command:

```
apicup subsys health-check <subsystem_name>
```

If the cluster is healthy, the health-check command returns silently with a 0 return code.

2. Remove any stale upgrade files:

```
apic clean-upgrade-files
```

3. Take a backup of the project directory. Use SFTP or S3 as the backup protocol.

4. Prepare your management subsystem.

- a. Download **IBM API Connect <version> script and assets required for v10 <latest\_v10\_version> side-by-side upgrades** from the Fix Central distribution page. You can find the link to the latest Fix Pack on [What's new in the latest release](#).
- b. Uncompress this file to access `dr-preparation.py.zip`. Uncompress the zip, which contains a Python script that you will use to capture important information. For example:

```
$ unzip dr-preparation.py.zip
```

- c. Copy (`scp`) the Python script to the management system, ssh into the appliance, and run it as `root`:

```
sudo -i
python3 dr-preparation.py
```

The script creates the output file `apicup-commands.txt` with commands that you will use later to create the secrets necessary to recover the management subsystem.

Example output when the script runs without error:

```
apicup certs set management atm-credential --encoded-string '<encoded_string>'
apicup certs set management consumer-toolkit-credential --encoded-string '<encoded_string>'
apicup certs set management designer-credential --encoded-string '<encoded_string>'
apicup certs set management toolkit-credential --encoded-string '<encoded_string>'
apicup certs set management juhu-credential --encoded-string '<encoded_string>'
apicup certs set management consumer-ui-credential --encoded-string '<encoded_string>'
```

```

apicup certs set management ui-credential --encoded-string '<encoded_string>'
apicup certs set management encryption-secret --encoded-string '<encoded_string>'
apicup subsys set management site-name='<site_name>'

```

Note: If any of the secrets are missing, the script will display an error message. You must resolve the errors before continuing, or you cannot successfully recover from a disaster event.

- d. Save the `apicup-commands.txt` to your local machine for later reference.
- e. Backup your version 10 management subsystem. See [Backing up the management subsystem](#).
5. Backup your version 10 Developer Portal subsystem. See [Backing up the Developer Portal subsystem](#).
6. Backup your version 10 Analytics subsystems. See [Running a backup of the Analytics database](#).
7. Continue with [Upgrading subsystems from 10.0.1.1-eus to the latest 10.0.1.x-eus on VMware](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Upgrading subsystems from 10.0.1.1-eus to the latest 10.0.1.x-eus on VMware

Install the latest API Connect 10.0.1.x-eus and recover the data from your original 10.0.1.1-eus deployment.

### Procedure

1. Obtain the API Connect files:
  - a. Go to the [What's New in the latest version](#) information page.
  - b. Locate the Note: *You can access the latest files from <URL link>*. Select the *<URL link>* to go directly to the Announce page on Fix Central, where you can download files for the latest version of API Connect.

Note: When upgrading on VMware from 10.0.1.1-eus to the latest 10.0.1.x-eus version, you will use the same Fix Central files as are used for a **new** API Connect installation. Do not use the **upgrade** files.  
The following files are used for upgrade of 10.0.1.1-eus on VMware:

IBM® API Connect *<version>* Management for VMware  
Management subsystem files

IBM® API Connect *<version>* Developer Portal for VMware  
Developer Portal subsystem files

IBM® API Connect *<version>* Analytics for VMware  
Analytics subsystem files

IBM® API Connect *<version>* Install Assist for *<operating\_system\_type>*  
The apicup installation utility. Required for all installations on VMware.

IBM® API Connect *<version>* script and assets required for version 10-to-*<latest\_v10\_version>* side-by-side upgrades  
The package contains a script to run on 10.0.1.1-eus prior to upgrade and two scripts to run after upgrade.

IBM® API Connect *<version>* Toolkit for *<operating\_system\_type>*

Toolkit command line utility. Packaged standalone, or with API Designer or Loopback:

- IBM® API Connect *<version>* Toolkit for *<operating\_system\_type>*
- IBM® API Connect *<version>* Toolkit with Loopback for *<operating\_system\_type>*
- IBM® API Connect *<version>* Toolkit Designer with Loopback for *<operating\_system\_type>*

Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See [Installing the toolkit](#).

IBM® API Connect *<version>* Local Test Environment

Optional test environment. See [Testing an API with the Local Test Environment](#)

IBM® API Connect *<version>* Security Signature Bundle File

Checksum files that you can use to verify the integrity of your downloads.

2. Install the installation utility.
  - a. Locate the Install Assist (apicup) installation utility file for your operating system.
  - b. Rename the file for your OS type to `apicup`. Note that the instructions in this documentation refer to `apicup`.
  - c. Make `apicup` available on your operating system:

| Operating system    | Configuration                                                                                                                                                                           |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ubuntu, Debian, OSX | i. Make the apicup file an executable file: <code>chmod +x apicup</code><br>ii. Set your path to the location of your apicup file:<br><code>export PATH=\$PATH:/Users/your_path/</code> |
| Windows, RedHat:    | Set your path to the location of your apicup file:<br><code>set PATH=c:\your_path;%PATH%</code>                                                                                         |

3. Use the following links to upgrade the subsystems, in the specified order:
  - a. [Upgrading management subsystem from 10.0.1.1-eus to the latest 10.0.1.x-eus](#)
  - b. [Upgrading Developer Portal subsystem from 10.0.1.1-eus to the latest 10.0.1.x-eus](#)
  - c. [Upgrading Analytics subsystem from 10.0.1.1-eus to the latest 10.0.1.x-eus](#)
4. Upgrade your DataPower Gateway. See [Upgrading DataPower Gateway Service](#).
5. Optionally, install new versions of other API Connect packages:  
For each of the following distribution packages there is no upgrade process. You replace the existing tools or binaries with the new versions for the latest version of version 10.

IBM® API Connect *<version>* Toolkit for *<operating\_system\_type>*

Toolkit command line utility. Packaged standalone, or with API Designer or Loopback:

- IBM® API Connect *<version>* Toolkit for *<operating\_system\_type>*
- IBM® API Connect *<version>* Toolkit with Loopback for *<operating\_system\_type>*

- IBM® API Connect <version> Toolkit Designer with Loopback for <operating\_system\_type>  
Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See [Installing the toolkit](#).

IBM® API Connect <version> Local Test Environment

Optional test environment. See [Testing an API with the Local Test Environment](#)

IBM® API Connect <version> Security Signature Bundle File

Checksum files that you can use to verify the integrity of your downloads.

6. After confirming the latest 10.0.1.x-eus deployment is fully restored and running as expected, you can delete the VMs of the previous deployment.  
If the latest 10.0.1.x-eus deployment has not restored as expected, or you need to revert to your previous installation for any reason, shutdown the new VMs and power-on those of your original deployment. You must also restore the project directory. Use the VM images, and saved project directory, that you created in [Prepare 10.0.1.1-eus for upgrade to the latest 10.0.1.x-eus](#).
7. Optional: If the latest 10.0.1.x-eus deployment is fully restored, take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVAs and restoring from normal backups.  
Important: VM snapshots are not an alternative to the standard API Connect backups, which are required to use the API Connect restore feature.
  - [Upgrading management subsystem from 10.0.1.1-eus to the latest 10.0.1.x-eus](#)  
Upgrade the management subsystem from 10.0.1.1-eus to the latest 10.0.1.x-eus version by completing configuration, deployment, and restoration steps.
  - [Upgrading Developer Portal subsystem from 10.0.1.1-eus to the latest 10.0.1.x-eus](#)  
Upgrade the Developer Portal subsystem from 10.0.1.1-eus to the latest 10.0.1.x-eus version by completing configuration, deployment, and restoration steps.
  - [Upgrading Analytics subsystem from 10.0.1.1-eus to the latest 10.0.1.x-eus](#)  
Upgrade the Analytics subsystem by installing the latest 10.0.1.x-eus version with the 10.0.1.1-eus configuration and restoring the subsystem from backups.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Upgrading management subsystem from 10.0.1.1-eus to the latest 10.0.1.x-eus

Upgrade the management subsystem from 10.0.1.1-eus to the latest 10.0.1.x-eus version by completing configuration, deployment, and restoration steps.

### Before you begin

You should have completed the necessary steps in [Prepare 10.0.1.1-eus for upgrade to the latest 10.0.1.x-eus](#) and [Upgrading subsystems from 10.0.1.1-eus to the latest 10.0.1.x-eus on VMware](#).

### About this task

The upgrade process uses the same project directory as you used on version of 10.0.1.1. The configuration file is called `apiconnect-up-v10.yml`.

Run `apicup` commands you saved in `apicup-commands.txt`. The commands in the file create the necessary secrets. Next, deploy the latest 10.0.1.x-eus management subsystem, and restore the management data from a backup.

Note: If your subsystem name on 10.0.1.1 was greater than 63 characters, and you did not manually shorten it prior to upgrading, the upgrade shortened it automatically. To view the new subsystem name:

```
apicup subsys list
```

For more info, see [Automatic shortening of subsystem names with greater than 63 characters \(10.0.1.1-eus upgrade only\)](#).

### Procedure

1. Ensure that you obtained the distribution file **IBM® API Connect <version> Management for VMware** and installed the `apicup` installation utility.
2. Run the commands in `apicup-commands.txt`. Use the `apicup` binary from the latest version of version 10.
3. The configuration in your project directory should now be complete. Optionally, you can review the contents of `apiconnect-up-v10.yml`. Since you are using the same project directory as used previously, the configuration properties for the subsystem should already have values set.

Important:

- The hostnames of the Endpoints cannot be changed, and must remain the same in the Management subsystem used for installation now as they were for the original installation.
- The Management subsystem name must remain the same in the upgraded installation as the original.

4. Before deploying the latest version 10 version OVA, shutdown your existing version 10 VMs but do not delete them.

Note: You may need to rename the old VM after shutting it down to not conflict with the latest v10 replacement you will deploy.

5. Create your ISO file

```
apicup subsys install mgmt --out mgmtplan-out
```

The `--out` parameter and value are required.

In this example, the ISO file is created in the `myProject/mgmtplan-out` directory.

6. Deploy the file into the VM. See [Deploying the management subsystem OVA file](#).
7. Verify the deployment. See [Verify installation of the management subsystem](#).
8. Restore the Management subsystem from backup. See [Restoring the management subsystem](#).
9. Confirm the restore has completed successfully:

```
apicup subsys health-check <management_subsystem_name>
```

When no problems are detected, the health-check commands returns silently with a 0 return code.

10. Next, upgrade the Developer Portal subsystem. See [Upgrading Developer Portal subsystem from 10.0.1.1-eus to the latest 10.0.1.x-eus](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Upgrading Developer Portal subsystem from 10.0.1.1-eus to the latest 10.0.1.x-eus

Upgrade the Developer Portal subsystem from 10.0.1.1-eus to the latest 10.0.1.x-eus version by completing configuration, deployment, and restoration steps.

---

### About this task

The upgrade process uses the same project directory as you used on version 10.0.1.1-eus. The configuration file is called `apiconnect-up-v10.yml`.

Deploy the Developer Portal subsystem for the latest 10.0.1.x-eus, and restore the Developer Portal data from a backup.

Note: If your subsystem name on 10.0.1.1 was greater than 63 characters, and you did not manually shorten it prior to upgrading, the upgrade shortened it automatically. To view the new subsystem name:

```
apicup subsys list
```

For more info, see [Automatic shortening of subsystem names with greater than 63 characters \(10.0.1.1-eus upgrade only\)](#).

---

### Procedure

1. Obtain **IBM® API Connect <version> Developer Portal for VMware** from Fix Central, as described in [Upgrading subsystems from 10.0.1.1-eus to the latest 10.0.1.x-eus on VMware](#).
2. The configuration in your project directory should be complete. Optionally, you can review the contents of `apiconnect-up-v10.yml`. Since you are using the same project directory as used previously, the configuration properties for the subsystem should already have values set.
3. Before deploying the latest 10.0.1.x-eus OVA, shutdown your existing v10 VMs but do not delete them.  
Note: You may need to rename the old VM after shutting it down to not conflict with the latest v10 replacement you will deploy.

4. Create your ISO file.

```
apicup subsys install port --out portplan-out
```

The `--out` parameter and value are required. In this example, the ISO file is created in the `myProject/portplan-out` directory.

5. Deploy the file into the VM. See [Deploying the Developer Portal subsystem OVA file](#).
6. Verify the deployment: See [Verifying deployment of the Developer Portal subsystem](#).
7. Restore Portal using the backup taken on version 10. See [Restoring the Developer Portal subsystem](#).
8. Confirm the restore has completed successfully:

```
apicup subsys health-check <portal_subsystem_name>
```

When no problems are detected, the health-check commands returns silently with a 0 return code.

Important: If the health check command states that a reboot is required, you must ensure that all Portal sites have been upgraded first before performing the reboot. To check that the Portal sites have upgraded, inspect the `platform` and `state` values for each site. The sites should all be in **INSTALLED** state, and have `platform` equal to the new platform that you can identify with `platforms:list`. Note that there will be two platforms present in the list while the site upgrades are happening. There should be only one `platform` after they have completed. To check that the Portal sites were upgraded:

- a. Obtain the portal service id and endpoint:

```
apic portal-services:get -o admin -s <management_server_endpoint> \
--availability-zone availability-zone-default <portal-service-name> \
--output - --format json
```

- b. List the sites:

```
apic --mode portaladmin sites:list -s <management_server_endpoint> \
--portal_service_id <portal_service_id_from_above_command> \
--portal_service_endpoint <portal_service_endpoint_from_above_command> \
--format json
```

Any sites currently upgrading will be listed as **UPGRADING**. Once all sites have finished upgrading they should have the **INSTALLED** status and the new platform version listed.

See also: [apic sites:list](#) and [Using the sites commands](#).

- c. After all sites are in **INSTALLED** state and have the new platform listed, run:

```
apic --mode portaladmin platforms:list -s <management_server_endpoint> \
--portal_service_id <portal_service_id_from_above_command> \
--portal_service_endpoint <portal_service_endpoint_from_above_command> \
--format json
```

The new version of the platform should be the only platform listed.

See also: [apic platforms:list](#) and [Using the platforms commands](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Upgrading Analytics subsystem from 10.0.1.1-eus to the latest 10.0.1.x-eus

Upgrade the Analytics subsystem by installing the latest 10.0.1.x-eus version with the 10.0.1.1-eus configuration and restoring the subsystem from backups.

### About this task

---

You will verify your configuration, create an ISO, deploy the .ova distribution file for the latest 10.0.1.x-eus into the VM, and restore your Analytics data from backup.

The upgrade process uses the same project directory as you used on version 10.0.1.1. The configuration file is called `apiconnect-up-v10.yml`.

Note: If your subsystem name on 10.0.1.1 was greater than 63 characters, and you did not manually shorten it prior to upgrading, the upgrade shortened it automatically. To view the new subsystem name:

```
apicup subsys list
```

For more info, see [Automatic shortening of subsystem names with greater than 63 characters \(10.0.1.1-eus upgrade only\)](#).

### Procedure

---

1. Obtain **IBM® API Connect <version> Analytics for VMware** from Fix Central, as described in [Upgrading subsystems from 10.0.1.1-eus to the latest 10.0.1.x-eus on VMware](#).
2. The configuration in your project directory should be complete. Optionally, you can review the contents of `apiconnect-up-v10.yml`. Since you are using the same project directory as used previously, the configuration properties for the subsystem should already have values set.
3. Create your ISO file.

```
apicup subsys install analyt --out analytplan-out
```

The `--out` parameter and value are required. In this example, the ISO file is created in the `myProject/analytplan-out/node-config` directory.

4. Before deploying the newer OVA, shutdown your existing version 10 VMs but do not delete them.  
Note: You may need to rename the old VM after shutting it down to not conflict with the latest v10 version replacement you will deploy.
5. Deploy the file into the VM. See [Deploying the Analytics subsystem OVA file](#).
6. Restart the `ingress-controller` pods in the Analytics subsystem by running the following command:

```
for pod in $(kubectl get pods -n <namespace> | grep ingress | awk '{print $1}'); do kubectl delete pod ${pod} -n <namespace>; done
```

where `<namespace>` is the namespace where you installed the Analytics subsystem.

If you neglect to restart the `ingress-controller` pods, no data will display in the Analytics UI.

7. Verify the deployment: See [Verifying deployment of the Analytics subsystem](#).
8. Restore **Analytics** from a backup. See [Restoring the Analytics database](#).
9. Confirm the restore has completed successfully:  
Note: You might see the following error in the operator log. The error is harmless and can be ignored:

```
"error": "Elastic search sync-flush returned status code 409 : a replica shard failed to sync-flush"
```

```
apicup subsys health-check <analytics_subsystem_name>
```

When no problems are detected, the health-check commands returns silently with a 0 return code.

10. Return to [Upgrading subsystems from 10.0.1.1-eus to the latest 10.0.1.x-eus on VMware](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Upgrading from 2018 to the latest 10.0.1.x-eus on VMware

You can upgrade API Connect on VMware from 2018 to the latest 10.0.1.x-eus version on VMware

Important: Review the following Support page to determine whether your Version 2018 deployment can be directly upgraded to the latest release of Version 10.0.1.x: [API Connect: v2018 to v10 upgrade paths](#).

Complete the API Connect upgrade from 2018 to 10.0.1.x-eus by performing the following tasks:

- [Upgrade from v2018: overview and considerations](#)  
Review the upgrade overview, requirements, and limitations before upgrading your API Connect 2018 deployment to 10.0.1.x-eus on VMware.
- [Preparing the 2018 deployment for upgrade](#)  
Prepare your 2018 deployment for upgrade to the latest 10.0.1.x-eus on VMware.

- [Upgrading Version 2018 subsystems to Version 10.0.1.x-eus](#)

Install the new 10.0.1.x-eus system and configure each subsystem with configuration information from 2018.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Upgrade from v2018: overview and considerations

Review the upgrade overview, requirements, and limitations before upgrading your API Connect 2018 deployment to 10.0.1.x-eus on VMware.

Attention: Review the IBM Support page [API Connect: v2018 to v10 upgrade paths](#) to determine whether your Version 2018 deployment can be directly upgraded to the latest release of API Connect.

- [Overview of upgrade procedure](#)
- [Planning a 10.0.1.x-eus deployment](#)
- [Required backups of 2018 subsystems](#)
- [Required disk space for extraction of 2018 management subsystem data](#)
- [Automatic shortening of subsystem names with greater than 63 characters](#)
- [Upgrade Limitations](#)
- [Getting started with the upgrade procedure](#)

---

## Overview of upgrade procedure

Note: Version 2018 FP24 cannot be upgraded to version 10.0.1.9 on VMware.

The upgrade from v2018 to the latest version of 10.0.1.x-eus is a fresh install of the 10.0.1.x-eus subsystems, followed by restoration of saved 2018 data and configuration.

For the management subsystem, you will use custom scripts to extract management database configuration from 2018, and then load it onto a fresh install of 10.0.1.x-eus. The scripts complete the necessary conversion of the Management database information from Cassandra format to Postgres format. The scripts are provided as part of the latest API Connect 10 distribution files on Fix Central.

For the Developer Portal and the Analytics subsystem, you will do a fresh install of the subsystem and then restore data from the 2018 backups.

When all subsystem upgrades are complete, you can upgrade DataPower Gateway.

Gateways can continue to run during this process so API traffic is not impacted.

Summary of the upgrade task flow:

1. On the 2018 deployment:
  - a. Backup each 2018 subsystem.
  - b. For the management subsystem, use the provided script to extract the 2018 database.
  - c. Power off the 2018 cluster.
2. On a new 10.0.1.x-eus installation:
  - a. Create a new 10.0.1.x-eus cluster using the 2018 project directory, the 10.0.1.x-eus installation utility ([apicup](#)) and the 10.0.1.x-eus distribution images (.ova).
  - b. Install the management subsystem. Start the 10.0.1.x-eus system using the newly created ISO.
  - c. Use a provided script to load the extracted v2018 database info into the new 10.0.1.x-eus database.
  - d. Install the Developer Portal subsystem and run a restore to load the 2018 backup data.
  - e. Install the Analytics subsystem and run a restore to load the 2018 backup data.
  - f. Upgrade the DataPower Gateway.

---

## Planning a 10.0.1.x-eus deployment

Before you move from 2018 to 10.0.1.x-eus, plan your 10.0.1.x-eus deployment by reviewing requirements and features:

- [IBM API Connect Version 10 software product compatibility requirements](#)
- [Requirements for initial deployment on VMware](#)
- [Planning your deployment](#)
- [What's New in the latest release](#) and [What's new for v10 installation](#).
- [Version 10 known limitations](#)

---

## Required backups of 2018 subsystems

Subsystems on 2018 must be backed up in the following order:

1. Management subsystem
2. Developer Portal subsystem
3. Analytics subsystem

Ensure that your archives are valid.

Note: You cannot use a VMware snapshot to skip the preparation steps for the upgrade. VMware snapshots do not provide the necessary API Connect data and backups in a form that can be applied to a new API Connect 10.0.1.x-eus deployment in a VM.

## Required disk space for extraction of 2018 management subsystem data

The upgrade from 2018 to 10.0.1.x-eus includes extraction of management database data. Prior to running the extract job, ensure that your virtual machine has sufficient disk space to hold a file containing this data.

The amount of disk space required scales with the amount of data on your system. As a minimum, ensure you have 3 times the size of the backup file for your 2018 Cassandra database.

To locate the backup file for your 2018 Cassandra database, see Step 3 in [Restoring the management database in a Kubernetes environment](#).

## Automatic shortening of subsystem names with greater than 63 characters

Version 10 imposes a length restriction of 63 characters for subsystem names. Version 2018 did not impose the restriction. If your v2018 subsystem names are greater than 63 characters in length, you must shorten them prior to upgrading. If you do not shorten them, the upgrade will programmatically shorten them for you. You will then want to check `apiconnect-up-v10.yaml` to determine the new shortened name.

The new value is found in `spec.subsystems[n].metadata.name`. For example, for a management subsystem, see the `name: abcde-management` entry below:

```
apiVersion: v1
kind: apic.ibm.com/APICoordinateCluster
metadata:
 creationTimestamp: "2021-03-04T13:52:50Z"
 name: abcde
spec:
 secret-name: abcde-my-secret
 subsystems:
 - apiVersion: v1
 kind: apic.ibm.com/ManagementSubsystem
 metadata:
 creationTimestamp: "2021-03-04T13:52:50Z"
 name: abcde-management
 spec:
 ApplianceProperties:
 data-device: sdb
```

## Upgrade Limitations

The upgrade is designed to bring your 2018 configuration and data onto a new 10.0.1.x-eus deployment. Note the following limitations:

- The location of the 10.0.1.x-eus backups for the management subsystem must be different from the location of the 2018 backups of the management subsystem. Note that for 10.0.1.x-eus, the management database changes from Cassandra to Postgres, so a new backup configuration is required.
- The upgrade does not capture customizations to your 2018 configuration that you made with an extra-values file. If you created an extra-values file on 2018, you must modify it for the 10.0.1.x-eus deployment, as follows:
  - For the management subsystem, the upgrade process uses a temporary extra-values file to configure upgrade settings, and then removes the temporary file upon successful completion of the upgrade. You can then recreate your extra-values file. See also [Upgrading Management subsystem from 2018 to 10.0.1.x-eus](#)
  - For the Developer Portal subsystem and the Analytics subsystem, if you have an extra-values file on Version 2018, you must convert the file format for Version 10, prior to deploying the Version 10 subsystem. See the instructions in [Upgrading Developer Portal from 2018 to 10.0.1.x](#) and [Upgrading Analytics from 2018 to 10.0.1.x-eus](#)
- Analytics data may be lost during the time between the shutdown of the 2018 deployment and the start of the new 10.0.1.x-eus deployment. Optionally, you can stop the collection of 2018 Analytics data and write to disk any data that is currently in the pipeline. When data collection is stopped, the Analytics subsystem stops acknowledging requests from the gateway, and relies on the buffer there to avoid losing data. See the procedure in [Stopping Analytics data collection](#).

## x-ibm-gateway-cors-allow-credentials-when-no-cors-policy API property is deprecated

In 2018, when cross-origin resource sharing (CORS) is enabled for an API, every response to a CORS request contains the header:

```
Access-Control-Allow-Credentials: true
```

Inclusion of Access-Control-Allow-Credentials (ACAC) does not provide optimal security, so starting with 2018.4.1.17, an API property can be set to prevent this header from being returned:

```
Name: x-ibm-gateway-cors-allow-credentials-when-no-cors-policy
Collection: *
Value (string): off
```

The `Collection` setting refers to a specific Catalog to which a property value applies. The "\*" value means the value applies to all catalogs. You can either specify \* or a Catalog (collection) name.

The property can also be set by using the DataPower CLI:

```
api-definition myAPI
property x-ibm-gateway-cors-allow-credentials-when-no-cors-policy * off
exit
```

Important: The value of this property must be exactly the string `off` (case-sensitive) in order to remove the header.

It is only possible to turn off this header, or leave it on, for an entire API. In order to have more control, such as returning the header for some origins and not others, you must upgrade to v10 and use the CORS policy feature. For more info, see:

- [Enabling CORS support for an API](#)
- OpenAPI 3.0 editor: [Setting API properties](#)
- OpenAPI 2.0 editor: [Setting API properties](#)

In API Connect 10.0.1.4-ifix1-eus or later, the `x-ibm-gateway-cors-allow-credentials-when-no-cors-policy` property works, but only for API definitions which do NOT contain a cors-policy. You cannot define both this property and a CORS Policy on the same API definition.

**This property is deprecated in v10:** a warning will be written to the log for every CORS request received by an API whose definition contains this property.

For version 10, the recommended way to ensure the ACAC header does not appear in CORS responses is to add a CORS policy to the API definition. In version 10, any API definition which has a cors-policy defined will NOT return the ACAC header by default. Note that it is possible in the CORS policy rules to explicitly return the ACAC header for some or all origins.

If you move your configuration from 2018 to 10.0.1.4-ifix1-eus or later, and have this custom property defined in your API definitions, you will not see any change in behavior, other than new warnings in the log. This property will remove the ACAC header for any API definition where it appears.

If, when you move your configuration from 2018 to 10, you want to have the ACAC header present in the CORS responses, you can leave the API definitions as-is (without the new property defined) and the ACAC header will be returned, as long as a cors-policy is not added to the API definition. Note also that even with a CORS policy defined for an API, the ACAC header can be returned if desired by explicitly allowing it in the rules of the CORS policy.

Note that the `x-ibm-gateway-cors-allow-credentials-when-no-cors-policy` property in an API definition:

- Will cause a commit-time error in version 10 if a cors-policy is also present in the same API definition
- Will NOT work in 10 or 2018 to turn ON the ACAC header; it can ONLY be used to turn OFF the header. Explanation:
  - In 2018, ACAC is on by default
  - In 10 without cors-policy, ACAC is on by default
  - In 10 with cors-policy, ACAC can be turned on for specific origins via rules in cors-policy

## Getting started with the upgrade procedure

---

The first task in the upgrade procedure is to prepare your 2018 deployment for upgrade. To get started, go to [Preparing the 2018 deployment for upgrade](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Preparing the 2018 deployment for upgrade

---

Prepare your 2018 deployment for upgrade to the latest 10.0.1.x-eus on VMware.

### Before you begin

---

Before you move from 2018 to 10.0.1.x-eus, ensure that you have reviewed [Upgrade from v2018: overview and considerations](#).

Attention: Review the IBM Support page [API Connect: v2018 to v10 upgrade paths](#) to determine whether your Version 2018 deployment can be directly upgraded to the latest release of API Connect.

### About this task

---

On your v2018 deployment, gather the API Connect information that is needed to restore the 2018 configuration onto a new 10.0.1.x-eus deployment.

### Procedure

---

1. Ensure that the management subsystem is on a 2018 version that is supported for upgrading to the target version, as listed in [Upgrade from v2018: overview and considerations](#).

To view the version, ssh to the VM and run `sudo -i`. Use `apic version`. For example:

```
apic version
INFO[0000] Log level: info
.
.
.
Packages:
.
.
.
- subsystem-management:<version_number>
```

2. Make sure the API Connect cluster is healthy. For each subsystem (Management, Developer Portal, and Analytics) run the following command:

```
apic health-check
```

If the cluster is healthy, the health-check command returns silently with a 0 return code.

3. Remove any stale upgrade files:

```
apic clean-upgrade-files
```

4. Complete a full backup for the API Connect v2018 Management, Portal, and Analytics subsystems. See [Backing up and restoring](#).

Tip: Ensure your backup archives are valid. For example:

```
$ tar -tzf <FILENAME>.tar.gz >/dev/null
```

On success, the command returns to the command line prompt with no output. If there is a problem with the file, an error similar to the following would be reported:

```
tar: 0511-169 A directory checksum error on media; -559038737 not equal to 67008.
```

5. On the v2018 management subsystem deployment, use the `apicops` utility to ensure the v2018 management database is consistent: Note that `apicops` is distinct from `apicup`.

Important: Upgrade will fail if the `apicops` command is not successfully completed within 2 hours of starting the management upgrade. If the management upgrade must be run more than once, you must run the command in fix mode each time within 2 hours of starting the management upgrade.

- a. Obtain the latest v2018 release of `apicops` from <https://github.com/ibm-apiconnect/apicops#latest-v2018-release>.
- b. Download the `apicops` binary to one of the Management cluster servers, and make it executable:

```
chmod +x apicops
```

See also `apicops` set up requirements: <https://github.com/ibm-apiconnect/apicops#requirements>

- c. Run `apicops` as root:

```
sudo -i
apicops preupgrade -m fix --upgrade_to v10 -l <outputLogFileName>
```

- The `-m` option runs the utility in fix mode. Running the utility in fix mode resolves most problems. If the utility identifies a problem it cannot resolve, contact IBM Support.
- Set the `-l` option to send output to a log file.

- d. Confirm from the logs that all issues are fixed.

6. Make sure cluster is healthy before proceeding:

```
apic health-check
```

If the cluster is healthy, the health-check command returns silently with a 0 return code.

7. Obtain the needed upgrade script and supporting files.

- a. Go to the [What's New in the latest version](#) information page.
- b. Locate the Note: *You can access the latest files from <URL link>*. Select the *<URL link>* to go directly to the Announce page on Fix Central, where you can download files for the latest version of API Connect.
- c. Download **IBM® API Connect <version> scripts and assets required for v2018 > <v10.0.1.x\_version> side-by-side upgrades** from API Connect Fix Central.
- d. Decompress the tar file and copy (`scp`) the `dr-upgrade` directory to the v2018 management system. The directory contains `dr-upgrade-extract.py`, which you will use to extract v2018 configuration.

8. Ensure that traffic to the management endpoints is stopped before running the python script. For example, a load balancer might need to mark the backends as down so that no incoming traffic is accepted.

9. Extract the v2018 data that is needed for upgrade. Change directory to the `dr-upgrade` directory and run the python extract script as `root`:

```
sudo -i
python3 dr-upgrade-extract.py
```

Tip: You can optionally run the script in the background:

```
nohup python3 dr-upgrade-extract.py &> extract.log &
tail -f extract.log
```

- The script creates `2018-extracted-data.zip`. Example output:

```
.
.
.
Extract job is in Running state.
Extract job is complete
Time elapsed: 0:06:17.397687
Zipped 2018 extracted data and logs under '2018-extracted-data.zip'
```

The amount of time required for the extraction is a function of the amount of data in the v2018 database.

The file `2018-extracted-data.zip` contains your application data in an unencrypted format. This data should be kept secure. The data is required to successfully upgrade to 10.0.1.x-eus.

- If the extract script encounters an error:
  - Run the cleanup script:

```
python3 dr-upgrade-cleanup.py
```

- Resolve the errors.
- Re-run the extract script:

```
python3 dr-upgrade-extract.py
```

10. Save the following files to a location where you can access them later, while installing the 10.0.1.x-eus system:

- `2018-extracted-data.zip`
- The `apicup` project directory. You must use this project directory on your 10.0.1.x-eus system.

11. Power off the virtual machine with the 2018 system.

12. Continue with [Upgrading Version 2018 subsystems to Version 10.0.1.x-eus](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

# Upgrading Version 2018 subsystems to Version 10.0.1.x-eus

Install the new 10.0.1.x-eus system and configure each subsystem with configuration information from 2018.

## Before you begin

You must have completed [Preparing the 2018 deployment for upgrade](#).

## About this task

To upgrade the Management subsystem from 2018 to the latest 10.0.1.x-eus version, you will do a fresh install of 10.0.1.x-eus, and then run a script to load management data from 2018. For the Developer Portal subsystem and the Analytics subsystem, you will do a fresh install of each subsystem and then restore data from the 2018 backups.

When all subsystem upgrades are complete, you can upgrade DataPower Gateway. Optionally, you can then install the API Connect toolkit and lightweight test environment.

## Procedure

1. Obtain the API Connect files:
  - a. Go to the [What's New in the latest version](#) information page.
  - b. Locate the Note: *You can access the latest files from <URL link>*. Select the <URL link> to go directly to the Announce page on Fix Central, where you can download files for the latest version of API Connect.Note: When upgrading from 2018 to the latest 10.0.1.x-eus version, you will use the same Fix Central files as are used for a **new** API Connect installation. Do not use the separate product distribution files for **upgrade** of each subsystem on VMware.  
The following files are used for upgrade from 2018 on VMware:

- IBM® API Connect <version> Management for VMware  
Management subsystem files
- IBM® API Connect <version> Developer Portal for VMware  
Developer Portal subsystem files
- IBM® API Connect <version> Analytics for VMware  
Analytics subsystem files
- IBM® API Connect <version> Install Assist for <operating\_system\_type>  
The apicup installation utility. Required for all installations on VMware.

2. Install the installation utility.
  - a. Locate the apicup installation utility file for your operating system.
  - b. Rename the file for your OS type to **apicup**. Note that the instructions in this documentation refer to **apicup**.
  - c. Make **apicup** accessible on your operating system:

| Operating system | Configuration                                                                                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OSX and Linux®   | <ol style="list-style-type: none"><li>i. Make the apicup file an executable file: <code>chmod +x apicup</code></li><li>ii. Set your path to the location of your apicup file:<br/><pre>export PATH=\$PATH:/Users/your_path/</pre></li></ol> |
| Windows:         | Set your path to the location of your apicup file:<br><pre>set PATH=c:\your_path;%PATH%</pre>                                                                                                                                               |

3. Use the following links to upgrade the subsystems, in the specified order:
  - a. [Upgrading Management subsystem from 2018 to 10.0.1.x-eus](#)
  - b. [Upgrading Developer Portal from 2018 to 10.0.1.x](#)
  - c. [Upgrading Analytics from 2018 to 10.0.1.x-eus](#)
4. Upgrade the DataPower Gateway. See [Upgrading DataPower Gateway Service](#).  
DataPower Gateways requires a firmware upgrade from 2018 to 10 after the upgrade of the other API Connect subsystems is complete.
5. Optionally, install new versions of other API Connect packages:  
For each of the following distribution packages there is no upgrade process. You replace the existing tools or binaries with the new versions for the latest version of 10.0.1.x-eus.

- IBM® API Connect <version> Toolkit for <operating\_system\_type>  
Toolkit command line utility. Packaged standalone, or with API Designer or Loopback:
  - IBM® API Connect <version> Toolkit for <operating\_system\_type>
  - IBM® API Connect <version> Toolkit with Loopback for <operating\_system\_type>
  - IBM® API Connect <version> Toolkit Designer with Loopback for <operating\_system\_type>Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See [Installing the toolkit](#).

- IBM® API Connect <version> Local Test Environment  
Optional test environment. See [Testing an API with the Local Test Environment](#)

- IBM® API Connect <version> Security Signature Bundle File  
Checksum files that you can use to verify the integrity of your downloads.

6. When you complete the installation and configuration, best practice is to immediately take backups of the new 10.0.1.x-eus deployment. See:
  - [Backing up the management subsystem](#)
  - [Backing up the Developer Portal subsystem](#)

- [Running a backup of the Analytics database](#)
- [Upgrading Management subsystem from 2018 to 10.0.1.x-eus](#)  
Upgrade the management subsystem to 10.0.1.x-eus by installing the latest 10.0.1.x-eus management subsystem and loading the management database information from 2018.
- [Upgrading Developer Portal from 2018 to 10.0.1.x](#)  
Upgrade the Developer Portal by installing the latest 10.0.1.x with the 2018 configuration and restoring the subsystem from backups.
- [Upgrading Analytics from 2018 to 10.0.1.x-eus](#)  
Upgrade the Analytics subsystem by installing the latest 10.0.1.x-eus with the 2018 configuration and restoring the subsystem from backups.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Upgrading Management subsystem from 2018 to 10.0.1.x-eus

Upgrade the management subsystem to 10.0.1.x-eus by installing the latest 10.0.1.x-eus management subsystem and loading the management database information from 2018.

### Before you begin

You should have previously completed the following steps in [Upgrading Version 2018 subsystems to Version 10.0.1.x-eus](#):

- Download **IBM® API Connect <version> scripts and assets required for v2018 > <Latest\_v10\_version> side-by-side upgrades** and **IBM® API Connect <version> Management for VMware** from Fix Central.
- Install **apicup** installation utility.

### About this task

Install the latest 10.0.1.x-eus management subsystem, load the 2018 management database information, and run a cleanup script after the load completes.

### Procedure

1. Use the 10.0.1.x-eus version of **apicup** to map your 2018 configuration settings from **apiconnect-up.yml** to the 10.0.1.x-eus configuration file **apiconnect-up-v10.yml**:

```
apicup subsys get <subsystem_name>
```

Note: If your subsystem name on 2018 was greater than 63 characters, and you did not manually shorten it prior to upgrading, the upgrade shortened it automatically. To view the new subsystem name:

```
apicup subsys list
```

For more information, see [Automatic shortening of subsystem names with greater than 63 characters](#)

- a. Review the output from the command. Note the following:
    - Some settings will be automatically converted from their 2018 values.
    - Existing extra-values files that were used on 2018 will need review as they cannot be used as is. If necessary, you can add an extra-values for 10.0.1.x-eus in [Step 9](#).
  - b. Use **apicup** provide a completely new backup location for the management subsystem in 10.0.1.x-eus. See [Reconfiguring backup settings for the management subsystem \(10.0.1.1-eus or greater\)](#).  
Important:
    - For the management subsystem, you cannot use the same backup locations as were used for 2018.
      - For s3 backups you must specify a different s3 bucket for the version 10 deployment, to avoid having version 2018 backups mixed with version 10 backups for the management server.
      - For SFTP backups, create a different folder for version 10 backups, or move the 2018 backups to another location.
    - For 10.0.1.x-eus, there is a new (additional) setting **database-backup-s3provider**. This settings is used with S3 backups. This value must be set before install, if S3 backups are being used. The management subsystem may not come online without this parameter being set.
2. Set a temporary configuration to support loading the v2018 data:
    - a. Place the following text in to a new yaml file, with a name of your choosing:

```
spec:
 template:
 - name: apim
 enabled: false
 - name: apim-schema
 enabled: false
 - name: apim-data
 enabled: false
 - name: taskmanager
 enabled: false
 - name: lur
 enabled: false
 - name: lur-schema
 enabled: false
 - name: lur-data
 enabled: false
 - name: analytics-proxy
 enabled: false
```

```

- name: portal-proxy
 enabled: false
- name: billing
 enabled: false
- name: juhu
 enabled: false
- name: websocket-proxy
 enabled: false
- name: ui
 enabled: false

```

b. Set the new yaml file as an extra-values configuration file:

```
apicup subsys set <management_subsystem_name> extra-values-file=<path-to-extra-values-file>/<your_extra_values_file>.yaml
```

3. Create your ISO file

```
apicup subsys install mgmt --out mgmtplan-out
```

The `--out` parameter and value are required.

In this example, the ISO file is created in the `myProject/mgmtplan-out` directory.

4. Deploy the ISO and **IBM® API Connect <version> Management for VMware** ova file. Go to [Deploying the management subsystem OVA file](#).

Note: Wait for the cluster to form - this can take some time.

5. Verify the installation:

```
apicup subsys health-check <management_subsystem_name>
```

Note: This is not a standard install. Some services are disabled during this process, so there will be some pods missing. As a result, you cannot use the Cloud Manager UI to verify the management subsystem until the data from v2018 is loaded.

6. Copy (`scp`) the entire `dr-upgrade.tgz` to the 10.0.1.x-eus management system VM. Uncompress the file (`tar -xzf`). Verify that the directory contains these files:

- `dr-upgrade-load.py`  
A script to load the v2018 data.
- `dr-upgrade-cleanup.py`  
A script to cleanup after load of the v2018 data
- `2018-extracted-data.zip`  
The data from your v2018 deployment

The directory contains other template files that are used by the scripts.

7. Now load 2018 data into 10.0.1.x-eus database.

a. ssh into the appliance as `root`.

b. Change directory to the `dr-upgrade` directory

The `dr-upgrade-load.py` script requires `2018-extracted-data.zip` to be in the same directory

c. Run the python script `dr-upgrade-load.py`:

```
sudo -i
python3 dr-upgrade-load.py
```

Tip: You can optionally run the script in the background:

```
nohup python3 dr-upgrade-load.py &> load.log &
tail -f load.log
```

- The length of time needed for the load script to complete scales with the size of the data in your system. The upgrade-load job creates a Kubernetes pod named `apiconnect-v10-upgrade-load-xxxxxx`. You can follow the Kubernetes logs if you want to track the progress of the script.
- The python script outputs the location (`volume_path`) of the data/logs directories to backup.
- Once `dr-upgrade-load.py` returns successfully the load is complete.

Note: If `dr-upgrade-load.py` encounters an error:

- ssh into the appliance as `root`, and gather the upgrade logs. Check pod logs and PV logs (`volume_path`). To create a zip file with the contents of directories with the logs:

```
zip -r upgrade-pvc.zip {{volume_path}}
```

- Contact IBM Support for guidance on how to resolve the errors.
- After the errors are resolved, run the clean up script:

```
python3 dr-upgrade-cleanup.py --load-error
```

Be sure to include the required parameter `--load-error`. Note that the health-check will fail until the load script is run again in the next step.

- Re-run `dr-upgrade-load.py`

```
python3 dr-upgrade-load.py --rerun
```

Be sure to include the required parameter `--rerun`.

8. Wait for the completion of the job and then return to your local machine (used for configuration) and use `apicup` to unset the extra-values file To unset:

```
apicup subsys set <management_subsystem_name> extra-values-file=
```

9. Set an extra-values file if needed for your customizations:

```
apicup subsys set <management_subsystem_name> extra-values-file=<your_extra_values_file>
```

For example, see [Setting rate limits for public APIs on the management service](#).

10. Install the subsystem:

```
apicup subsys install <management_subsystem_name>
```

11. Verify all management resources have come up

```
apicup subsys health-check <management_subsystem_name>
```

If the subsystem is healthy, the health-check command returns silently with a 0 return code.

If an error is encountered, see [Upgrade Limitations](#).

Your load of v2018 data is now complete.

12. When the dr-upgrade-load job has succeeded, backup the PVC data and logs from the dr-upgrade-load job:

- ssh into the appliance as root.
- Find the path to the volume:

```
kubectl get pv | grep 'pv-claim-apiconnect-v10-upgrade' | awk '{print $1}' | xargs kubectl get pv -o jsonpath='{.spec.local.path}'
```

c. Zip up the directory:

```
zip -r upgrade-pvc.zip {{volume_path}}
```

d. Run the cleanup script:

```
python3 dr-upgrade-cleanup.py
```

This script cleans up the following:

- Load job `apiconnect-v10-upgrade-load`
- Load PVC `pv-claim-apiconnect-v10-upgrade`
- `2018-extracted-data.zip`
- Unpacked `2018-extracted-data.zip` from the PV

13. Next, upgrade the other subsystems. Return to [Upgrading Version 2018 subsystems to Version 10.0.1.x-eus](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Upgrading Developer Portal from 2018 to 10.0.1.x

Upgrade the Developer Portal by installing the latest 10.0.1.x with the 2018 configuration and restoring the subsystem from backups.

### About this task

You will verify your configuration, create an ISO, deploy the 10.0.1.x OVA file into the VM, and restore your Developer Portal data from backup.

You do not have to specify configuration settings because the Portal configuration is defined in the 2018 project directory, which you will continue to use for 10.0.1.x. However, you must review the backups settings.

### Procedure

- Obtain **IBM® API Connect <version> Developer Portal for VMware** from Fix Central, as described in [Upgrading v2018 subsystems to v10](#).
- Use the version 10 release of `apicup` to map your 2018 configuration settings from `apiconnect-up.yml` to the 10.0.1.x configuration file `apiconnect-up-v10.yml`:

```
apicup subsys get <subsystem_name>
```

- Review the output from the command, and ensure backup settings from 2018 have been set or migrated to the configuration for version 10. See [Configuring backup settings for the Developer Portal subsystem](#).
- If your 2018 deployment included an extra-values-file, you must first convert the format of the file for 10.0.1.x. For example, if you had an extra-values-file to support multiple Portal endpoints, review the new format in the version 10 documentation. See [Defining multiple portal endpoints for a VMware environment](#).

Note: If your subsystem name on 2018 was greater than 63 characters, and you did not manually shorten it prior to upgrading, the upgrade shortened it automatically. To view the new subsystem name:

```
apicup subsys list
```

For more information, see [Automatic shortening of subsystem names with greater than 63 characters](#)

3. Create your ISO file.

```
apicup subsys install port --out portplan-out
```

The `--out` parameter and value are required. In this example, the ISO file is created in the `myProject/portplan-out` directory.

- Deploy the file into the VM. See [Deploying the Developer Portal subsystem OVA file](#).
- Verify the deployment: See [Verifying deployment of the Developer Portal subsystem](#).

6. Restore Portal using the backup taken on 2018. See [Restoring the Developer Portal subsystem](#).
7. Confirm the restore has completed successfully:

```
apicup subsys health-check <portal_subsystem_name>
```

When no problems are detected, the health-check commands returns silently with a 0 return code.

Important: If the health check command states that a reboot is required, you must ensure that all Portal sites have been upgraded first before performing the reboot. To check that the Portal sites have upgraded, inspect the `platform` and `state` values for each site. The sites should all be in `INSTALLED` state, and have `platform` equal to the new platform that you can identify with `platforms:list`. Note that there will be two platforms present in the list while the site upgrades are happening. There should be only one `platform` after they have completed. To check that the Portal sites were upgraded:

- a. Obtain the portal service id and endpoint:

```
apic portal-services:get -o admin -s <management_server_endpoint> \
 --availability-zone availability-zone-default <portal-service-name> \
 --output - --format json
```

- b. List the sites:

```
apic --mode portaladmin sites:list -s <management_server_endpoint> \
 --portal_service_id <portal_service_id_from_above_command> \
 --portal_service_endpoint <portal_service_endpoint_from_above_command> \
 --format json
```

Any sites currently upgrading will be listed as `UPGRADING`. Once all sites have finished upgrading they should have the `INSTALLED` status and the new platform version listed.

See also: [apic sites:list](#) and [Using the sites commands](#).

- c. After all sites are in `INSTALLED` state and have the new platform listed, run:

```
apic --mode portaladmin platforms:list -s <management_server_endpoint> \
 --portal_service_id <portal_service_id_from_above_command> \
 --portal_service_endpoint <portal_service_endpoint_from_above_command> \
 --format json
```

The new version of the platform should be the only platform listed.

See also: [apic platforms:list](#) and [Using the platforms commands](#).

If an error is encountered, see [Upgrade Limitations](#).

8. Return to [Upgrading Version 2018 subsystems to Version 10.0.1.x-eus](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Upgrading Analytics from 2018 to 10.0.1.x-eus

Upgrade the Analytics subsystem by installing the latest 10.0.1.x-eus with the 2018 configuration and restoring the subsystem from backups.

### About this task

You will verify your configuration, create an ISO, deploy the 10.0.1.x-eus OVA file into the VM, and restore your Analytics data from backup.

### Procedure

1. Obtain **IBM® API Connect <version> Analytics for VMware** from Fix Central, as described in [Upgrading v2018 subsystems to v10](#).
2. Use the 10.0.1.x-eus version of `apicup` to map your 2018 configuration settings from `apiconnect-up.yml` to the 10.0.1.x-eus configuration file `apiconnect-up-v10.yml`:

```
apicup subsys get <subsystem_name>
```

Note: If your subsystem name on 2018 was greater than 63 characters, and you did not manually shorten it prior to upgrading, the upgrade shortened it automatically. To view the new subsystem name:

```
apicup subsys list
```

For more information, see [Automatic shortening of subsystem names with greater than 63 characters](#)

Complete the following steps:

- a. Review the output from the command.
- b. Specify backup settings for 10.0.1.x-eus. You cannot use the settings from 2018. See [Configuring backup settings for Analytics](#).
- c. If your 2018 deployment included an extra-values-file, you must first convert the format of the file for 10.0.1.x-eus. To review creation of extra-values files for 10.0.1.x-eus, see [Creating the analytics-extra-values file](#).
3. Create your ISO file.

```
apicup subsys install analyt --out analytplan-out
```

The `--out` parameter and value are required. In this example, the ISO file is created in the `myProject/analytplan-out/node-config` directory.

4. Deploy the file into the VM. See [Deploying the Analytics subsystem OVA file](#)
5. Verify the deployment. See [Verifying deployment of the Analytics subsystem](#)
6. Restore **Analytics** using the backup taken on v2018. See [Restoring the Analytics database](#).

Note: The **backup name** used in the v2018 backup is what will be passed to `--id` and `--override` must be set to `true`. For example:

```
apicup subsys restore [SUBSYS_NAME] --id [BACKUP_NAME] --override="true"
```

7. Confirm the restore has completed successfully:

```
apicup subsys health-check <analytics_subsystem_name>
```

When no problems are detected, the health-check commands returns silently with a 0 return code.

If an error is encountered, see [Upgrade Limitations](#).

8. Return to [Upgrading Version 2018 subsystems to Version 10.0.1.x-eus](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Maintaining API Connect

You can use utilities to complete maintenance tasks such as backup, restore, and certificate management in a VMware environment.

Note: When maintaining API Connect, do not use `kubectl exec` commands to access API Connect pods unless advised by IBM.

Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

- [Advanced configuration](#)  
You can optionally install and configure advanced features.
- [Backing up and restoring](#)  
You can backup and restore API Connect on VMware
- [Disaster recovery](#)  
Prepare for disaster events and recover API Connect on VMware if a disaster event occurs.
- [Disabling the Analytics subsystem on VMware](#)  
Disable the Analytics subsystem by shutting down the VM that hosts it.
- [Maintaining a two data center deployment](#)  
How to maintain a two data center disaster recovery (DR) deployment on VMware, including information about normal operation, failure handling, and recovery.
- [Monitoring and health checks](#)  
Monitor your deployment and complete health checks on subsystems.
- [Logging](#)  
Configure logging for your deployment on VMware.
- [Troubleshooting](#)  
Troubleshoot your deployment on VMware.
- [Troubleshooting Analytics on VMware](#)  
If your API Connect Analytics subsystem encounters problems, review the following topics for help resolving the issue.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Advanced configuration

You can optionally install and configure advanced features.

See:

- [Advanced installation on VMware](#)  
Optionally install additional software.
- [Advanced configuration on VMware](#)  
Perform configuration tasks on your API Connect deployment on VMware.
- [Advanced configuration for management subsystem](#)  
Specify advanced configuration for the management subsystem.
- [Advanced configuration for the gateway subsystem on VMware](#)  
Specify advanced configuration for the gateway subsystem on VMware.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Advanced installation on VMware

Optionally install additional software.

See:

- [Modifying configuration settings after installation](#)  
You can use `apicup` to change configuration of a subsystem after the initial installation.
- [Installing a two data center deployment](#)  
Additional installation instructions explaining how to deploy a two data center disaster recovery deployment on VMware.
- [Installing the IBM License Metric Tool on VMware](#)  
The IBM License Metric Tool (ILMT) helps you determine whether your IBM® API Connect deployment is compliant with licensing requirements.
- [Installing the toolkit](#)
- [Installing the Automated API behavior testing application](#)  
Install the Automated API behavior testing application in your IBM API Connect deployment on VMware.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Modifying configuration settings after installation

You can use `apicup` to change configuration of a subsystem after the initial installation.

The Install Assist utility (`apicup`) is used to configure and complete initial installation of all subsystems in VMware deployments. After initial installation, you can use the same `apicup` commands to reconfigure some of the settings from your existing deployment without having to completely reinstall the subsystem.

For example, if you did not configure optional features such as backup/restore or logging during initial installation, you can configure them later.

Note: VMware deployments include subsystem settings that cannot be reconfigured without a complete deployment. For example, for the Management Service these settings include hosts, endpoints, interfaces (`public-iface`, `traffic-iface`), IP ranges of the Kubernetes pod and the service networks (`k8s-pod-network`, `k8s-service-network`). Before reconfiguring, review the installation instructions for your subsystem to determine which settings are optional during initial installation and thus able to be updated later.

For both initial installation and reconfiguration, you specify configuration values by using `apicup subsys set` commands, and then activate them with `apicup subsys install`.

```
apicup subsys set <subsystem_name> <parameter_name>=<parameter_value>
```

```
apicup subsys install <subsystem_name>
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Installing a two data center deployment

Additional installation instructions explaining how to deploy a two data center disaster recovery deployment on VMware.

---

### Before you begin

Ensure that you understand the concepts of a two data center disaster recovery deployment in API Connect. For more information, see [A two data center deployment strategy on VMware](#).

Review the information in [Requirements for initial deployment on VMware](#) and, if appropriate, [What's new for version 10 installation](#).

Familiarize yourself with the instructions in [First steps for deploying in a VMware environment](#). You will need to complete these instructions in conjunction with the additional steps in this topic that are specific to installing a two data center disaster recovery deployment.

---

### About this task

Installing API Connect as a two data center disaster recovery (DR) deployment is very similar to a single installation, as the deployment in each data center is effectively an instance of the same API Connect deployment. The following endpoints must be the same on both data centers:

Management subsystem endpoints

- `platform-api`
- `consumer-api`
- `cloud-admin-ui`
- `api-manager-ui`

Portal subsystem endpoints

- `portal-admin`
- `portal-www`

For more information about how to set the endpoints, see [Configuring the management subsystem](#) and [Configuring the Developer Portal subsystem](#). The main difference is that the deployments for both the API Manager and the Developer Portal subsystems must include `multi-site-ha` settings. These settings are added to the deployment by using `apicup` commands, as shown in the installation instruction sections later in this topic.

A two data center DR deployment is created by deploying two API Manager subsystems, and two Developer Portal subsystems, in the same APICUP project. By default, two data center DR is not enabled.

The `multi-site-ha` settings are described in the following table.

Table 1. The `multi-site-ha` settings

| Setting                             | Description                                                                                                                                                                                                                                                                                 |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>multi-site-ha-enabled</code>  | Indicates whether two data center DR deployment is enabled. Set to <code>true</code> to enable two data center DR. Set to <code>false</code> to disable two data center DR. The default value is <code>false</code> .                                                                       |
| <code>multi-site-ha-mode</code>     | The state of the data center in the context of the two data center deployment. Valid values are: <ul style="list-style-type: none"> <li>• <code>active</code> - indicates the primary data center</li> <li>• <code>passive</code> - indicates the standby data center</li> </ul>            |
| <code>management-replication</code> | Required only for the Management subsystem. The external ingress name for the Management subsystem in the current data center in the two data center deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center. |
| <code>portal-replication</code>     | Required only for the Portal subsystem. The external ingress name for the Portal subsystem in the current data center in the two data center deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.         |
| <code>replication-peer-fqdn</code>  | The ingress hostname for the other data center in the two data center deployment. This information is required so that the two data centers can communicate with each other.                                                                                                                |

The `siteName` property is a unique descriptive name for the Portal subsystem, and the Management subsystem, in each data center, for example `dallas` on data center 1, and `raleigh` on data center 2. You must set different a `siteName` on the active data center, to the one set on the passive data center. This name is used in the hostnames, and so can contain only `a-z` and `0-9` characters. Note that you can set a `siteName` in the `ManagementCluster` or `PortalCluster` CR only when the subsystems are first deployed, and you cannot change the name after deployment. If you don't set a `siteName` at first deployment, an automated `siteName` is created for you. For example, if you are converting an existing single Management cluster to a two data center Management cluster by adding the multi-site HA values, you will not be able to configure a `siteName` for the existing Management cluster.

To install a two data center disaster recovery deployment, you must follow the instructions in [Deploying the Management subsystem](#) and [Deploying the Developer Portal](#) to configure the OVA templates, as well as setting the multi-site HA values that are detailed here, before then installing the subsystems. Some examples of complete subsystem value settings are shown in the [Example](#) section.

Important:

- You must use a single APICUP project for all subsystems. Multiple projects will result in multiple certificate chains that will not match.
- The original project directory created with APICUP during the initial product installation (for example, `myProject`) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory, because it contains pertinent information about the cluster. Note that the endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored or upgraded system. Best practice is to back up the original project directory to a location from where it can always be retrieved.
- Ideally you should use one project directory across both data centers as a single source of truth for your two data center deployment. However, if network access is limited, you can copy the original project directory across to the second data center, but you must ensure that the copied project directory does not diverge from the original, or critical functionality will be impacted.
- Endpoints for the components cannot change between deployments. However, the endpoints for the VMware hosts can be modified for the new deployment.
- Note that the subsystem name of the management and portal services must consist of lowercase alphanumeric characters or '-', with no spaces, start with an alphabetic character, and end with an alphanumeric character.

See the following instructions for information about how to configure a two data center DR deployment:

- [Installing to an active data center](#)
- [Installing to a passive data center](#)
- [Converting a single data center deployment to two data centers](#)
- [Validating your two data center deployment](#)

## Procedure

### • Installing to an active data center

The following example shows how to configure the multi-site HA settings for deploying to an active data center (DC). In this instance we are deploying to a local data center called `dallas` (DC1), that has a remote data center called `raleigh` (DC2).

1. Complete the steps in [Configuring the management subsystem](#) up to and including Step 14 to create a Management subsystem in Dallas (DC1).
2. Configure the multi-site HA values to set Dallas to be active for the API Manager service on DC1.

Run the following commands:

```
apicup subsys set mgmt_dallas multi-site-ha-enabled=true
apicup subsys set mgmt_dallas multi-site-ha-mode=active
apicup certs set mgmt_dallas management-replication-ingress --clear
apicup subsys set mgmt_dallas management-replication=mgrreplicationdallas.cluster1.example.com
apicup subsys set mgmt_dallas replication-peer-fqdn=mgrreplicationraleigh.cluster2.example.com
apicup subsys set mgmt_dallas site-name=dallas
```

where

- `mgmt_dallas` is the name of the management service that you are configuring.
- `mgrreplicationdallas.cluster1.example.com` is the ingress hostname for the current data center in the two data center deployment.

- `mgrreplicationraleigh.cluster2.example.com` is the ingress hostname for the other data center in the two data center deployment.
  - `dallas` is the name of the site in the current data center. This name must be different to the site name in DC2.
3. Complete the remainder of the Steps in [Configuring the management subsystem](#) from Step 15, to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
  4. Complete the steps in [Configuring the Developer Portal subsystem](#) up to and including Step 15 to create a Portal subsystem in Dallas (DC1).
  5. Configure the multi-site HA values to set Dallas to be active for the Developer Portal service on DC1.

Run the following commands:

```
apicup subsys set port_dallas multi-site-ha-enabled=true
apicup subsys set port_dallas multi-site-ha-mode=active
apicup certs set port_dallas portal-replication-ingress --clear
apicup subsys set port_dallas portal-replication=ptlreplicationdallas.cluster1.example.com
apicup subsys set port_dallas replication-peer-fqdn=ptlreplicationraleigh.cluster2.example.com
apicup subsys set port_dallas site-name=dallas
```

where

- `port_dallas` is the name of the Portal service that you are configuring.
  - `ptlreplicationdallas.cluster1.example.com` is the ingress hostname for the current data center in the two data center deployment.
  - `ptlreplicationraleigh.cluster2.example.com` is the ingress hostname for the other data center in the two data center deployment.
  - `dallas` is the name of the site in the current data center. This name must be different to the site name in DC2.
6. Complete the remainder of the Steps in [Configuring the Developer Portal subsystem](#) from Step 17, to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
  7. Log in to the virtual machine subsystems on DC1 by using an SSH tool, and check the status of the installation by running the `apic status` command.
  8. Set your dynamic router to direct all traffic to DC1.

This includes setting the four endpoints for the API Manager cluster, and the two endpoints for the Developer Portal cluster.

#### • Installing to a passive data center

The following example shows how to set the multi-site HA values for the remote data center called `raleigh` (DC2), which is being installed as the passive, standby location.

Important: Remember to use the same APICUP project directory as for the active data center. If you cannot use the same project directory, you must ensure that the copied project directory hasn't diverged from the original, or critical functionality will be impacted.

1. Complete the steps in [Configuring the management subsystem](#) up to and including Step 14 to create a Management subsystem in Raleigh (DC2).
2. Configure the multi-site HA values to set Raleigh to be passive for the API Manager service on DC2.

Run the following commands:

```
apicup subsys set mgmt_raleigh multi-site-ha-enabled=true
apicup subsys set mgmt_raleigh multi-site-ha-mode=passive
apicup certs set mgmt_raleigh management-replication-ingress --clear
apicup subsys set mgmt_raleigh management-replication=mgrreplicationraleigh.cluster2.example.com
apicup subsys set mgmt_raleigh replication-peer-fqdn=mgrreplicationdallas.cluster1.example.com
apicup subsys set mgmt_raleigh site-name=raleigh
```

where

- `mgmt_raleigh` is the name of the management service that you are configuring.
  - `mgrreplicationraleigh.cluster2.example.com` is the ingress hostname for the current data center in the two data center deployment.
  - `mgrreplicationdallas.cluster1.example.com` is the ingress hostname for the other data center in the two data center deployment.
  - `raleigh` is the name of the site in the current data center.
3. Set the encryption key manually for Raleigh (DC2) by copying it from Dallas (DC1).

Run the following commands:

```
apicup certs get mgmt_dallas encryption-secret -t key > mgmt-encryption-secret
apicup certs set mgmt_raleigh encryption-secret mgmt-encryption-secret
```

4. Check that the management encryption key is set the same on both DC1 and DC2.

Run the following commands, and verify that the outputs match:

```
apicup certs get mgmt_dallas encryption-secret -t key
apicup certs get mgmt_raleigh encryption-secret -t key
```

5. Complete the remainder of the Steps in [Configuring the management subsystem](#) from Step 15, to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
6. Complete the steps in [Configuring the Developer Portal subsystem](#) up to and including Step 15 to create a Portal subsystem in Raleigh (DC2).
7. Configure the multi-site HA values to set Raleigh to be passive for the Developer Portal service on DC2.

Run the following commands:

```
apicup subsys set port_raleigh multi-site-ha-enabled=true
apicup subsys set port_raleigh multi-site-ha-mode=passive
apicup certs set port_raleigh portal-replication-ingress --clear
apicup subsys set port_raleigh portal-replication=ptlreplicationraleigh.cluster2.example.com
apicup subsys set port_raleigh replication-peer-fqdn=ptlreplicationdallas.cluster1.example.com
apicup subsys set port_raleigh site-name=raleigh
```

where

- `port_raleigh` is the name of the Portal service that you are configuring.
- `ptlreplicationraleigh.cluster2.example.com` is the ingress hostname for the current data center in the two data center deployment.
- `ptlreplicationdallas.cluster1.example.com` is the ingress hostname for the other data center in the two data center deployment.
- `raleigh` is the name of the site in the current data center.

8. Copy the encryption key for the Portal service on DC1 over to the Portal service on DC2.

Run the following command to get the encryption key for the Portal service on DC1, and put it into a file that is called `port-encryption-secret`:

```
apicup certs get port_dallas encryption-secret -t key > port-encryption-secret
```

Run the following command to use the `port-encryption-secret` file to set the same encryption key on DC2:

```
apicup certs set port_raleigh encryption-secret port-encryption-secret
```

Where `port_dallas` is the name of the Portal service on DC1, and `port_raleigh` is the name of the Portal service on DC2.

To check that the encryption key is set the same on both DC1 and DC2, you can run the following commands and verify that the outputs match:

```
apicup certs get port_dallas encryption-secret -t key
```

```
apicup certs get port_raleigh encryption-secret -t key
```

9. Complete the remainder of the Steps in [Configuring the Developer Portal subsystem](#) from Step 17, to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.

10. Log in to the virtual machine subsystems on DC2 by using an SSH tool, and check the status of the installation by running the `apic status` command.

#### • Converting a single data center deployment to two data centers

When converting a single data center deployment into a two data center deployment, it is best practice to use the existing data center as the active one, and add a new passive data center elsewhere. This practice ensures that the data is retained.

Remember:

- Both data centers must have the same `portal-admin` and `portal-www` endpoints.
- You cannot configure a `site-name` for the existing Management or Portal cluster, because the `site-name` property can be configured only at first deployment.
- The API Manager and Developer Portal ingress endpoint values cannot be changed after the system has been deployed. When you convert a single data center deployment into a two data center deployment, the ingress endpoint values from the single data center deployment will now be the new global ingress endpoints for the new two center deployment. They can then be routed to either DC1 or DC2.

The following example shows how to update the multi-site HA values for making the existing data center called `dallas` (DC1) active, and for setting the new remote data center called `raleigh` (DC2) as passive.

1. Configure the multi-site HA values to set Dallas to be active for the API Manager service on DC1.

Run the following commands:

```
apicup subsys set mgmt_dallas multi-site-ha-enabled=true
```

```
apicup subsys set mgmt_dallas multi-site-ha-mode=active
```

```
apicup certs set mgmt_dallas management-replication-ingress --clear
```

```
apicup subsys set mgmt_dallas management-replication=mgrreplicationdallas.cluster1.example.com
```

```
apicup subsys set mgmt_dallas replication-peer-fqdn=mgrreplicationraleigh.cluster2.example.com
```

where

- `mgmt_dallas` is the name of the management service that you are configuring.
- `mgrreplicationdallas.cluster1.example.com` is the ingress hostname for the current data center in the two data center deployment.
- `mgrreplicationraleigh.cluster2.example.com` is the ingress hostname for the other data center in the two data center deployment.

Note: As the API Manager service already exists, you cannot set the `site-name` property.

2. Configure the multi-site HA values to set Dallas to be active for the Developer Portal service on DC1.

Run the following commands:

```
apicup subsys set port_dallas multi-site-ha-enabled=true
```

```
apicup subsys set port_dallas multi-site-ha-mode=active
```

```
apicup certs set port_dallas portal-replication-ingress --clear
```

```
apicup subsys set port_dallas portal-replication=ptlreplicationdallas.cluster1.example.com
```

```
apicup subsys set port_dallas replication-peer-fqdn=ptlreplicationraleigh.cluster2.example.com
```

where

- `port_dallas` is the name of the Portal service that you are configuring.
- `ptlreplicationdallas.cluster1.example.com` is the ingress hostname for the current data center in the two data center deployment.
- `ptlreplicationraleigh.cluster2.example.com` is the ingress hostname for the other data center in the two data center deployment.

Note: As the Developer Portal service already exists, you cannot set the `site-name` property.

3. Run `apicup` to update the settings in each subsystem, for example:

```
apicup subsys install mgmt_service_name
```

or

```
apicup subsys install ptl_service_name --skip-health-check
```

where `service_name` is the name of the management or portal service that you want to update, for example `mgmt_dallas`.

4. Log in to the virtual machine subsystems on DC1 by using an SSH tool, and check the status of the installation by running the `apic status` command.

5. Add the new DC, Raleigh (DC2) by completing the steps in [Configuring the management subsystem](#) up to and including Step 14 to create a Management subsystem in Raleigh (DC2).

Note:

- Remember to use the same APICUP project directory as for the active data center.
- Remember to set the same `portal-admin` and `portal-www` endpoints as for DC1.

6. Configure the multi-site HA values to set Raleigh to be passive for the API Manager service on DC2.

Run the following commands:

```
apicup subsys set mgmt_raleigh multi-site-ha-enabled=true
apicup subsys set mgmt_raleigh multi-site-ha-mode=passive
apicup certs set mgmt_raleigh management-replication-ingress --clear
apicup subsys set mgmt_raleigh management-replication=mgrreplicationraleigh.cluster2.example.com
apicup subsys set mgmt_raleigh replication-peer-fqdn=mgrreplicationdallas.cluster1.example.com
apicup subsys set mgmt_raleigh site-name=raleigh
```

where

- `mgmt_raleigh` is the name of the management service that you are configuring.
- `mgrreplicationraleigh.cluster2.example.com` is the ingress hostname for the current data center in the two data center deployment.
- `mgrreplicationdallas.cluster1.example.com` is the ingress hostname for the other data center in the two data center deployment.
- `raleigh` is the name of the site in the current data center.

Note: As this is a new deployment of the API Manager service, you can set the `site-name` property.

7. Set the encryption key manually for Raleigh (DC2) by copying it from Dallas (DC1).

Run the following commands:

```
apicup certs get mgmt_dallas encryption-secret -t key > mgmt-encryption-secret
apicup certs set mgmt_raleigh encryption-secret mgmt-encryption-secret
```

8. Check that the management encryption key is set the same on both DC1 and DC2.

Run the following commands, and verify that the outputs match:

```
apicup certs get mgmt_dallas encryption-secret -t key
apicup certs get mgmt_raleigh encryption-secret -t key
```

9. Complete the remainder of the Steps in [Configuring the management subsystem](#) from Step 15, to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
10. Complete the steps in [Configuring the Developer Portal subsystem](#) up to and including Step 15 to create a Portal subsystem in Raleigh (DC2).
11. Configure the multi-site HA values to set Raleigh to be passive for the Developer Portal service on DC2.

Run the following commands:

```
apicup subsys set port_raleigh multi-site-ha-enabled=true
apicup subsys set port_raleigh multi-site-ha-mode=passive
apicup certs set port_raleigh portal-replication-ingress --clear
apicup subsys set port_raleigh portal-replication=ptlreplicationraleigh.cluster2.example.com
apicup subsys set port_raleigh replication-peer-fqdn=ptlreplicationdallas.cluster1.example.com
apicup subsys set port_raleigh site-name=raleigh
```

where

- `port_raleigh` is the name of the Portal service that you are configuring.
- `ptlreplicationraleigh.cluster2.example.com` is the ingress hostname for the current data center in the two data center deployment.
- `ptlreplicationdallas.cluster1.example.com` is the ingress hostname for the other data center in the two data center deployment.
- `raleigh` is the name of the site in the current data center.

12. Run the following command to generate the default Portal certificates on the passive site:

```
apicup certs generate port_raleigh
```

13. Copy the encryption key for the Portal service on DC1 over to the Portal service on DC2.

Run the following command to get the encryption key for the Portal service on DC1, and put it into a file that is called `port-encryption-secret`:

```
apicup certs get port_dallas encryption-secret -t key > port-encryption-secret
```

Run the following command to use the `port-encryption-secret` file to set the same encryption key on DC2:

```
apicup certs set port_raleigh encryption-secret port-encryption-secret
```

Where `port_dallas` is the name of the Portal service on DC1, and `port_raleigh` is the name of the Portal service on DC2.

To check that the encryption key is set the same on both DC1 and DC2, you can run the following commands and verify that the outputs match:

```
apicup certs get port_dallas encryption-secret -t key
apicup certs get port_raleigh encryption-secret -t key
```

14. Complete the remainder of the Steps in [Configuring the Developer Portal subsystem](#) from Step 17, to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.

15. Log in to the virtual machine subsystems on DC2 by using an SSH tool, and check the status of the installation by running the `apic status` command.

16. Set your dynamic router to direct all traffic to DC1.

This includes setting the four endpoints for the API Manager cluster, and the two endpoints for the Developer Portal cluster.

#### • Validating your two data center deployment

To validate that your two data center deployment is working, execute a test failover, and confirm that all of the expected data is present and correct on the newly active site. See [Failure handling of a two data center deployment](#) for details.

## Example

Example of the management subsystem values that you can view by running the `apicup subsys get mgmt_name` command. For example:

```
apicup subsys get mgmt_dallas
```

#### Appliance settings

```

Meaning of the **haMode** for the active data center:

- **active** - this is the active data center, or the only data center, and all pods are ready and accepting traffic.
- **progressing to active** - this is the active data center, or the only data center, and there are no pods ready yet.
- **progressing to active (ready for traffic)** - this is the active data center, or the only data center, and there is at least one pod of each type, www, db, and nginx, ready, so the data center is accepting traffic.

Example of the status section of a **PortalCluster** CR file for a passive data center that you can view by running the `kubectl describe port_name` command:

## Installing the IBM License Metric Tool on VMware

The IBM License Metric Tool (ILMT) helps you determine whether your IBM® API Connect deployment is compliant with licensing requirements.

### About this task

---

ILMT provides useful features for managing virtualized environments and measuring license utilization. ILMT discovers the software that is installed in your infrastructure, helps you to analyze the consumption data, and allows you to generate audit reports. Each report provides you with different information about your infrastructure, for example the computer groups, software installations, and the content of your software catalog.

By default, every ILMT audit report presents data from the previous 90 days. You can customize the type and amount of information displayed in a report by using filters, and save your personal settings for future use. You can also export the reports to .csv or .pdf format, and schedule report emails so that specified recipients are notified when important events occur.

For more information about ILMT, see the [IBM License Metric Tool](#) documentation.

Note: The following instructions describe the ILMT installation for API Connect deployments in a VMware environment, and apply to the Management, Developer Portal, and Analytics OVAs.

### Procedure

---

To download the BigFix Agent for the Ubuntu operating system, complete the following steps:

1. Navigate to <http://support.bigfix.com/bes/release/> and then follow the link to the latest release; for example: <http://support.bigfix.com/bes/release/9.5/patch11/>.
2. In the Agent section of the table, click the Download link corresponding to the following release:

- Operating System: Ubuntu
- Version: 16
- Architecture: x86\_64

In this example, the direct download link is: <http://software.bigfix.com/download/bes/95/BESAgent-9.5.11.191-ubuntu10.amd64.deb>

Upload the BigFix Agent package to each OVA server, as follows:

3. Upload the BigFix Agent .deb package to each running OVA server. Following is an example of the command for uploading the file that was downloaded in Step 2:

```
scp BESAgent-9.5.11.191-ubuntu10.amd64.deb apicadm@<OVA_Hostname>:~
```

The generic command is:

```
scp <BigFix_Agent_Package_File_Path> apicadm@<OVA_Hostname>:~
```

The BigFix Agent .deb package will be uploaded to `/home/apicadm`.

Install the BigFix client on each OVA server, as follows:

4. Log in, with a secure shell connection, to the server as the `apicadm` user.
5. Become root by entering `sudo -s`.
6. Follow [IBM Bigfix installation instructions Ubuntu](#) to install the .deb package.

### What to do next

---

Ensure that TCP/IP port 52311 is open on your firewall.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

### About this task

---

The toolkit is provided as executable files, so no actual installation is necessary, you just need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + LoopBack + Designer: provides a command line environment for working with IBM API Connect, including LoopBack® support, and the API Designer application.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + LoopBack + Designer option, an executable file for launching the API Designer application.

You can download the toolkit from one of the following locations:

- From IBM Fix Central.

- From the Cloud Manager or API Manager user interface.

## Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.
  - To download the toolkit from IBM Fix Central, complete the following steps:
    - Open the [IBM Fix Central site](#) in your browser.
    - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
    - Select your Installed Version and click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
    - In the Text field, enter `toolkit`, then click Continue.
    - Select the toolkit file that you want to download.
    - Click Continue, then follow the instructions to complete the download operation.
  - To download the toolkit from Cloud Manager or API Manager user interface, complete the following steps:
    - Open the Cloud Manager or API Manager user interface.
    - On the welcome page, click the Download Toolkit tile. The two toolkit options are listed.
    - Click your platform alongside either the CLI option or the CLI + LoopBack + Designer option as required, then save the associated compressed file to your local file system.
    - To download the API Designer credentials (Client ID and Client Secret), click Download alongside API Designer Credentials, then save the `designer_credentials.json` file to your local file system. A command is provided for installing the credentials, as described in detail in step [6](#).
    - To download the toolkit credentials (Client ID and Client Secret), click Download alongside Credential, then save the `credentials.json` file to your local file system. A command is provided for installing the credentials, as described in detail in step [5](#).
    - Close the Install API Connect Toolkit window.
2. Extract the contents of the toolkit compressed file to a folder of your choice.
 

The contents of the file depend on the your chosen toolkit option and platform, as follows:

  - The `apic-slim` or `apic-slim.exe` file is the CLI for IBM API Connect.
  - The `apic` or `apic.exe` file is the CLI for IBM API Connect including LoopBack support.
 

Tip: If you are using the CLI option, then if you rename the `apic-slim` file to `apic`, or the `apic-slim.exe` file to `apic.exe`, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + LoopBack + Designer option.
  - The `api_designer-platform` file is the API Designer user interface application for the specified platform.
3. Optional: Delete the `$HOME/.apiconnect/node_cli` directory.
 

You need to do this only if you replaced a version of `apic` or `apic.exe` and are using the `apic lb4` command. You need to delete the directory `get apic` to unpack the new loopback.

On Windows, `$HOME` is defined by environment `USERPROFILE`.

4. Run the CLI.
  - For the Mac OSX or Linux® platforms, complete the following steps:
    - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
    - Make the CLI file an executable file by entering the following command:
 

```
chmod +x download_name
```

Where `download_name` is the name of the toolkit file that you downloaded, either `apic` or `apic-slim`.
    - Run CLI commands as follows:
 

```
./apic command_name_and_parameters
```

or

```
./apic-slim command_name_and_parameters
```

For details of the CLI commands, see [apic](#).
  - For the Windows platform, complete the following steps:
    - Open a command prompt and navigate to the folder where you extracted the contents of the toolkit compressed file.
    - Run CLI commands as follows:
 

```
apic command_name_and_parameters
```

or

```
apic-slim command_name_and_parameters
```

For details of the CLI commands, see [apic](#).

Tip: Add the folder location of your CLI file to your `PATH` variable so that you can run CLI commands from anywhere in your file system.

5. Install the toolkit credentials.

If you do not install the toolkit credentials that are provided for download, as detailed previously in the [toolkit credentials download instructions](#), API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the credentials into your local toolkit, run the following command:

```
apic client-creds:set toolkit_credentials_file_path/credentials.json
```

where `credentials_file_path` is the location to which you downloaded the toolkit credentials JSON file. After you have run this command, your toolkit uses these new credentials to authenticate with the management server.

Note: At any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.

To revert to the default toolkit credentials for all login operations from the toolkit CLI, use the following command:

```
apic client-creds:clear
```

For increased security, an administrator can remove the default credentials from the management server by completing the following steps:

- a. Log in to the management server as an administrator; see [Logging in to a management server](#).

b. Delete the default credentials by running the following commands:

```
apic registrations:delete toolkit --server mgmt_endpoint_url
apic registrations:delete consumer-toolkit --server mgmt_endpoint_url
```

6. Install the API Designer credentials.

If you do not install the API Designer credentials that are provided for download, as detailed previously in the [API Designer credentials download instructions](#), API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the custom credentials into your local API Designer, set the `APIC_DESIGNER_CREDENTIALS` environment variable to the credentials download location, using the mechanism appropriate for your operating system.

After you have set the `APIC_DESIGNER_CREDENTIALS` environment variable, your API Designer uses the new credentials to authenticate with the management server.

- Windows:

If you are using Windows, create an environment variable using one of the following methods:

- Create a permanent environment variable so that you can start API Designer from any location on your computer:
  - Open the Environment Variables page: Click Start, Settings, System and in the "Related Settings" section of the page, click Advanced System Settings.
  - On the Advanced tab of the System Properties dialog box, click Environment Variables.
  - In the "User variables" section, click New and create an environment variable with the following settings:
    - Variable: `APIC_DESIGNER_CREDENTIALS`
    - Value: `<designer_credentials_file_path>\designer_credentials.json` where `<designer_credentials_file_path>` is the location where you stored the `designer_credentials.json` file.
  - Click OK to save the new environment variable, and then exit the dialog box.
- If you don't have the required permissions to create a permanent environment variable, you can create a temporary one that will only be used while you are running the API Designer application. The following steps must be performed every time you start API Designer:
  - Open the Windows command prompt.
  - Run the following command to set the temporary environment variable:

```
set APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>\designer_credentials.json
```

where `<designer_credentials_file_path>` is the location where you stored the `designer_credentials.json` file.

Note: Leave the command prompt open for the next step. You must set the temporary variable and start the API Designer within the same Windows command session.

- Now run the following command to start API Designer:

```
C:\>"Program Files\API Designer\API Designer.exe"
```

By default, API Designer is installed in the C:\Program Files\API Designer folder as shown in the example. If you installed it into a different location, use your own location in the command. Note that the path and file name are enclosed in quotation marks because they contain spaces.

- Mac:

If you are using Mac OS X, create an environment variable using one of the following methods:

- Run the following command to set the global environment variable:

```
launchctl setenv APIC_DESIGNER_CREDENTIALS <designer_credentials_file_path>/designer_credentials.json
```

where `<designer_credentials_file_path>` is the location where you stored the API Designer credentials JSON file.

- Pass in the environment variable while starting API Designer from the command line. With this method, you must run the following command every time you start API Designer:

```
APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>/designer_credentials.json open <designer_application_file_path>/API Designer.app
```

where:

- `<designer_credentials_file_path>` is the location to which you downloaded the API Designer credentials JSON file.
- `<designer_application_file_path>` is the location to which you downloaded and uncompressed the API Designer application.

7. Start the API Designer application from the location to where you stored the extracted file.

Note:

- To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
  - In Windows File Explorer, navigate to the `USER_HOME\AppData\Local\Programs\api-designer` folder.
  - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
- To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

## Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see [Developing your APIs and applications](#).

For information on using the toolkit CLI, see [Using the developer toolkit command-line tool](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Installing the Automated API behavior testing application

Install the Automated API behavior testing application in your IBM® API Connect deployment on VMware.

### About this task

---

Use the following steps to install the Automated API behavior testing application as part of your initial deployment, or to add it in later.

### Procedure

---

1. Run the following `apicup` commands to install or update your deployment with the the Automated API behavior testing application:

```
apicup subsys set mgmt test-and-monitor-enabled true
apicup certs set mgmt hub --clear
apicup certs set mgmt turnstile --clear
apicup subsys set mgmt hub hub-endpoint
apicup subsys set mgmt turnstile turnstile-endpoint
apicup subsys install mgmt
```

where:

- `mgmt` is the name of your Management server (which you are either installing or updating).
- `hub-endpoint` is an endpoint on the ingress subdomain for the API Connect stack; for example: `hub.testsrv0231.subnet1.example.com`.
- `turnstile-endpoint` is an endpoint on the ingress subdomain for the API Connect stack; for example: `turnstile.testsrv0231.subnet1.example.com`.

Attention: The hub and turnstile endpoints should be distinct and must not overlap with any of the 4 management endpoints.

2. Verify that the application deployed properly by completing the following steps:
  - a. Log in to API Manager.
  - b. On the Home page, click the Test APIs tile.
  - c. Verify that the Automated API behavior testing opens.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Advanced configuration on VMware

Perform configuration tasks on your API Connect deployment on VMware.

See:

- [Adding disk space to a VMware appliance](#)  
Increase disk space on the VMware appliance.
- [Adding a static route on a virtual machine](#)  
You can add a static route to the routing table when deploying API Connect on a VMware virtual machine.
- [Appliance boot mode configuration](#)  
Configure the boot mode for the appliance VMs.
- [Running commands at boot with iso-ignored boot mode](#)  
When `iso-ignored` boot mode is configured, complete the following steps on each appliance that should run commands at boot.
- [Changing deployment profiles on VMware](#)  
You can change an API Connect installation to use different deployment profiles.
- [Configuring SSHD to limit access to your deployment](#)  
How to configure SSHD in order to limit host access to your VMware deployment.
- [Managing an appliance data disk](#)  
You can use `apic` commands to manage appliance data disks in your VMware deployment.
- [Replica override for microservices on VMware](#)  
Modify the replica count for microservices by using template overrides for Custom Resources.
- [Changing the DNS server configuration on appliances](#)  
Complete this task only if you must change the DNS addresses after the initial boot of the VM.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Adding disk space to a VMware appliance

Increase disk space on the VMware appliance.

### About this task

---

For multi-node deployment of the appliance, only one VM at a time should have its disk space augmented. The subsystem should be in good health before proceeding to the next node. Health of the subsystem can be checked with `apicup subsys health-check <subsystem-name>`.

#### Restriction:

The increased disk capacity of a VMware appliance won't be reflected in the storage size of the PVCs that are hosted on the appliance, as those PVCs are immutable. This restriction doesn't impact the Portal and Analytics subsystems, as the PVC storage size isn't used to enforce any disk usage limit, so the subsystems can use all of the additional disk space. However, for the Management subsystem the PVC storage size is used in the database storage utilization computation, and that might trigger disk usage warnings.

The most common reason for the Management subsystem database to run out of disk space, is due to Write Ahead Log (WAL) file accumulation in relation to an incorrectly configured backup, or an unavailable backup server. If this type of condition arises, adding disk space might help with the health of the appliance control plane, but it won't increase the disk space that's available to the database, so you must resolve the WAL file accumulation condition. If the disk space that's available to the Management database must be increased, you should carry out a disaster recovery operation of the Management subsystem, using a larger data disk size for the new installation, so that adding disk space after the install won't be needed.

## Procedure

1. Shutdown the virtual machine, either by issuing a shutdown command as root from the VM, or by using the VMware console or command line interface. For example, use the VMware console user interface and click the red rectangle.
2. Use either the VMware console or command line interface to add a new device to the VM, of type Hard Disk and of the desired size to be added to the appliance. For example, on the VMware console:
  - a. Click Edit settings.
  - b. Click Add new device. From the drop-down menu, select Hard Disk.
  - c. Enter size in GB and click OK.
3. Use either the VMware console or the command line interface to power on the VM. As the VM starts it should detect the newly added disk and use it to augment the available capacity for the `/data/secure` mount point.
4. Optionally you may verify that a new disk `sdc` was added (or `sdd` if you already added one disk, and so on). Log in to the server and observe the new disk. For example:

```
root@apimdev1139:~# lsblk
NAME MAJ:MIN RM SIZE RO TYPE MOUNTPOINT
sda 8:0 0 100G 0 disk
├─sda1 8:1 0 99.9G 0 part /
├─sda14 8:14 0 4M 0 part
├─sda15 8:15 0 106M 0 part /boot/efi
sdb 8:16 0 250G 0 disk
├─apiconnect-data 252:0 0 260G 0 lvm
├─apicSecureDisk 252:1 0 260G 0 crypt /data/secure
sdc 8:32 0 10G 0 disk
├─apiconnect-data 252:0 0 260G 0 lvm
├─apicSecureDisk 252:1 0 260G 0 crypt /data/secure
sr0 11:0 1 44K 0 rom
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Adding a static route on a virtual machine

You can add a static route to the routing table when deploying API Connect on a VMware virtual machine.

### About this task

Add commands to your additional `cloud-init` file. You can do this for the Management, Analytics, and Portal subsystems.

## Procedure

1. Specify an additional cloud-init file:

```
apicup subsys set <subsys> additional-cloud-init-file <path-to-cloud-init-file>
```

2. Add lines to your cloud-init file.

Syntax:

```
bootcmd:
- ip route add <destination>/<mask> via <gateway> dev eth<n>
```

Example:

```
bootcmd:
- ip route add 172.27.218.0/24 via 172.27.218.1 dev eth1
- ip route add 172.26.203.0/24 via 172.27.218.1 dev eth1
```

Note: If you configure the appliance to boot in `iso-ignored` mode, as documented in [Appliance boot mode configuration](#), the `bootcmd` lines will be ignored or ineffective.

3. Regenerate the ISO file.

```
apicup subsys install <subsys> --out <plan-directory>
```

4. Restart the ISO, and ensure that the node(s) have this updated ISO attached at startup.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Appliance boot mode configuration

Configure the boot mode for the appliance VMs.

By default every appliance node requires the presence of an ISO file attached at boot.

**Version 10.0.1.5-eus or later:** You can configure individual VMs so that they can be booted and rebooted without an ISO being attached. Each appliance VM (node) is configured individually.

You can:

- [Check the current boot mode of an appliance](#)
- [Configure an appliance for iso-ignored boot mode](#)
- [Configure an appliance for iso-required boot mode](#)
- [Revert back to iso-required boot mode by booting the appliance in rescue mode](#)

---

## Check the current boot mode of an appliance

The default boot mode for all appliances is `iso-required`. To check the current boot mode:

1. Connect to the target appliance via SSH then switch to the root user:

```
ssh apicadm@{ova appliance hostname}
sudo -i
```

2. Use `apic boot-mode` to check the current boot mode of the appliance. For example:

```
root@ip-192-168-122-241:~# apic boot-mode
INFO[0000] Log level: info
INFO[0000] current boot mode is: iso-required
```

---

## Configure an appliance for iso-ignored boot mode

An appliance can be configured to use the `iso-ignored` boot mode instead of the default `iso-required`. Prerequisite: The appliance must have first booted with its configuration ISO attached and in `iso-required` boot mode (default) before the boot mode can be changed to `iso-ignored`.

You can configure an appliance to use the `iso-ignored` boot mode instead of the default `iso-required`.

**Prerequisite:** The appliance must have first booted with its configuration ISO attached and in `iso-required` boot mode (default), before you can change the boot mode to `iso-ignored`.

Note: If you added a static route to the routing table, as documented in [Adding a static route on a virtual machine](#), and if you are relying on a `bootcmd` from the ISO, then using the `iso-ignored` boot mode causes the `bootcmd` section being ignored or ineffective.

1. Connect to the target appliance via SSH then switch to the root user:

```
ssh apicadm@{ova appliance hostname}
sudo -i
```

2. Edit the file `/etc/default/grub.d/50-cloudimg-settings.cfg` to ensure that the `GRUB_TIMEOUT` and `GRUB_RECORDFAIL_TIMEOUT` are set to the value 5. Then run the command `update-grub`. For example:

```
root@ip-192-168-122-241:~# update-grub
Sourcing file `/etc/default/grub'
Sourcing file `/etc/default/grub.d/50-cloudimg-settings.cfg'
Sourcing file `/etc/default/grub.d/init-select.cfg'
Generating grub configuration file ...
Found linux image: /boot/vmlinuz-5.4.0-84-generic
Found initrd image: /boot/initrd.img-5.4.0-84-generic
done
```

3. Set the appliance boot mode to `iso-ignored` with the command `apic boot-mode iso-ignored`. For example:

```
root@ip-192-168-122-241:~# apic boot-mode iso-ignored
INFO[0000] Log level: info
INFO[0000] current boot mode is: iso-ignored
```

4. Shutdown the VM, and remove the CD/DVD device from the VM configuration through VSphere. For any subsequent boot of the appliance while it remains in `iso-ignored` boot mode, any ISO file attached will be ignored, and the boot will proceed as normal, whether an ISO file is attached or not.

Warning: If the appliance was booted in `iso-ignored` boot mode, it is possible to change its boot mode to `iso-required`. However, as stated in the prerequisites, it is not possible to immediately switch back to `iso-ignored`, and the next boot of the appliance must happen with the configuration ISO attached and boot mode `iso-required`.

## Configure an appliance for `iso-required` boot mode

The mode `iso-required` is the default boot mode for all appliances. If the appliance boot mode was changed to `iso-ignored` you can revert back to `iso-required` boot mode.

Note: If the appliance was booted in `iso-ignored` boot mode, it is possible to change its boot mode to `iso-required`. However, you cannot immediately switch back to `iso-ignored`, and the next boot of the appliance must happen with the configuration ISO attached and boot mode `iso-required`. After the appliance is booted with ISO attached in `iso-required` boot mode, the boot mode can then be switched to `iso-ignored` if needed.

1. Connect to the target appliance via SSH then switch to the root user:

```
ssh apicadm@{ova appliance hostname}
sudo -i
```

2. Set the appliance boot mode to `iso-required` with the command `apic boot-mode iso-required`. For example:

```
root@ip-192-168-122-241:~# apic boot-mode iso-required
INFO[0000] Log level: info
INFO[0000] current boot mode is: iso-required
```

Important: For any subsequent boot of the appliance while it remains in `iso-required` boot mode, the configuration ISO file must be connected at boot and for every boot.

## Revert back to `iso-required` boot mode by booting the appliance in rescue mode

When an appliance is configured with the `iso-ignored` boot mode, the boot sequence ignores any attached ISO. This means that it is not possible to influence the appliance configuration during its boot. In case the appliance is not booting properly and the boot mode needs to be reverted back to `iso-required`, proceed as follows:

1. Access to the VMware console for the Appliance, and after causing it to reboot, bring up a console to the appliance. You can give focus to the window by clicking the mouse into it. Press the `Esc` key to access the Linux grub boot menu. For example:

```
GNU GRUB version 2.04
```

```
*Ubuntu
Advanced options for Ubuntu
```

2. Press `e` and navigate using arrow keys to the line starting with `linux` to append `systemd.unit=rescue.target`

```
GNU GRUB version 2.04
.
.
.
insmod part_gpt
insmod ext2
if [x${feature_platform_search_hint} = xy]; then
 search --no-floppy --fs-uuid --set=root e46dalb8-55ao-4df9-842e-\
8d80c3a22ffc
else
 search --no-floppy --fs-uuid --set=root e46dalb8-55ao-4df9-842e-8\
d80c3a22ffc
fi
linux /boot/vmlinuz-5.4.0-84-generic root=LABEL=cloudimg-roo\
tfs ro console=tty1 console=ttyS0 net.ifnames=0 biosdevname=0 systemd.unit\
=rescue.target
initrd /boot/initrd.img-5.4.0-84-generic
```

3. Press `Ctrl+x` to boot.
4. Press `Enter` to enter maintenance mode. Run the commands:

```
rm -f /etc/cloud/cloud-init.disabled
```

and

```
echo -n "iso-required" > /usr/local/lib/appliance-config/boot-mode
```

```

root@ip-192-168-122-241:~#
```

5. Reboot the appliance with correct configuration ISO attached.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Running commands at boot with `iso-ignored` boot mode

When `iso-ignored` boot mode is configured, complete the following steps on each appliance that should run commands at boot.

### About this task

---

If you configured the appliance to boot in `iso-ignored` mode as documented in [Appliance boot mode configuration](#), the `bootcmd` lines will be ignored. For each appliance node that should run commands at boot, complete the following steps.

### Procedure

---

1. SSH into the appliance as root.
2. Create the `/usr/local/bin/appliance-boot-commands.sh` script to be executed at boot; for example:

```
cat << EOF > /usr/local/bin/appliance-boot-commands.sh
#!/bin/bash

ip route add 172.27.218.0/24 via 192.168.122.1 dev eth0
ip route add 172.26.203.0/24 via 192.168.122.1 dev eth0
EOF
```

This step takes the same example, and essentially achieves the same result, as the procedure in [Adding a static route on a virtual machine](#).

3. Make the script executable by running the following command:

```
chmod +x /usr/local/bin/appliance-boot-commands.sh
```

4. Create the following systemd service file `/lib/systemd/system/appliance-boot-commands.service`:

```
cat << EOF > /lib/systemd/system/appliance-boot-commands.service
[Unit]
After=network-online.target

[Service]
Type=oneshot
ExecStart=/usr/local/bin/appliance-boot-commands.sh
RemainAfterExit=false
StandardOutput=journal

[Install]
WantedBy=multi-user.target
EOF
```

5. Enable the systemd service by running the following command:

```
systemctl enable appliance-boot-commands
```

Upon subsequent boots, the `/usr/local/bin/appliance-boot-command.sh` script will be executed.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Changing deployment profiles on VMware

You can change an API Connect installation to use different deployment profiles.

### About this task

---

After you complete initial installation of the API Connect subsystems, you can change to another of the deployment profiles that are supported for the subsystem.

Important considerations:

- If you are changing from a development profile to a production profile, ensure that you have production profile hardware (3 nodes).
- While it is possible to use a development profile installation in a production deployment, it is not recommended.
  - For the management subsystem and the portal subsystem, the development profiles do not provide the failover resiliency nor the downtime guarantee that is needed to maintain high availability (HA) production deployments.
  - For the analytics subsystem, the development deployment option was designed to have a small impact on your hardware and as such it will not scale, and it will not perform as well as the production profile.
- Based on the resources configured for each microservice in the profile, there might be downtime during the profile change.

- If you enabled the analytics message queue feature, you must disable it before changing to another deployment profile. You can re-enable the message queue feature after the profile change is complete.

To disable the message queue:

1. Edit the analytics-extra-value.yaml file.
2. Locate the `mq` subsection and change the `enabled` setting to `false`.

```
mq:
 enabled: false
```

3. Apply the change:

```
apicup subsys install <subsystem_name>
```

To re-enable the message queue:

1. Edit the analytics-extra-value.yaml file.
2. Locate the `mq` subsection and change the `enabled` setting to `true`.
3. Apply the change:

```
apicup subsys install <subsystem_name>
```

Supported profiles:

Management subsystem

- Development profile

```
profile: n1xc4.m16
```

Describes a hardware profile of 1 node, 4 cores, and 16 GB memory. Deploys a subsystem with the scale of one; a single node, non-HA subsystem. Recommended for development and testing.

- Production profile

```
profile: n3xc4.m16
```

Describes a hardware profile of 3 nodes, 4 cores, and 16 GB memory. Deploys in HA mode for a production environment. Not supported for fewer than three nodes.

Portal subsystem

- Development profiles deploy a subsystem with the scale of one; a single node, non-HA subsystem. Development profiles are recommended for development or testing.
- Production profiles deploys in HA mode for a production environment. Not supported for fewer than three nodes.

- Development profile

```
profile: n1xc8.m16
```

Describes a hardware profile of 1 node, 8 cores, and 16 GB memory

- Development profile (reduced CPU)

```
profile: n1xc4.m16
```

Describes a hardware profile of 1 node, 4 cores, and 16 GB memory. For use when the deployment environment has limited CPU resources.

- Development profile (reduced CPU and Memory)

```
profile: n1xc2.m8
```

Describes a hardware profile of 1 node, 2 cores, and 8 GB memory. For use when the deployment environment has limited CPU and Memory resources.

- Production profile

```
profile: n3xc8.m16
```

Describes a hardware profile of 3 nodes, 8 cores, and 16 GB memory.

- Production profile (reduced CPU and Memory)

```
profile: n3xc4.m8
```

Describes a hardware profile of 3 nodes, 4 cores, and 8 GB memory. For use when the deployment environment has limited CPU and Memory resources.

Analytics subsystem

- Development profile

```
n1xc2.m16
```

Describes a hardware profile of 1 node, 2 cores, and 16 GB memory. Deploys a single-node, non-HA, non-scalable Analytics solution. The development profile is only recommend for development and test environments.

- Production profile

```
n3xc4.m16
```

Describes a hardware profile of 3 nodes, 4 cores, and 16 GB memory. Deploys a three-node, HA, scalable Analytics solution. The production profile requires at least 3 nodes to work properly, and is the recommended option for production environments.

## Procedure

- **Switching from a development profile to a production profile**

1. Management subsystem:

- a. **Workaround for deployments that upgraded to Version 10.0.1.5-eus from a previous version of API Connect**

If you upgraded to 10.0.1.5-eus, you must first patch role secret to add permissions. Otherwise, proceed directly to Step [1.b](#).

- i. Log in to the appliance as root:

```
sudo su
```

- ii. Patch the role secret to add permissions:

```
kubectl -n <namespace> patch secret pgorole-pgoadmin --type=json' -p='[{"op" : "replace" , "path" :
"/data/permissions" , "value" : "Kg=="}]'
```

- iii. Add 2 more nodes by setting up hosts and ifaces using the `apicup` installer. See [Configuring the management subsystem](#)

- iv. Generate ISOs for the new nodes. See [Deploying the management subsystem OVA file](#)

- v. Configure the project to the desired production profile:

```
apicup subsys set <subsystem_name> deployment-profile=<prod-profile>
```

- vi. Use the new profile

```
apicup subsys install <subsystem_name>
```

2. Portal subsystem:

- a. Add 2 more nodes by setting up hosts and ifaces using the `apicup` installer. See [Configuring the Developer Portal subsystem](#)

- b. Generate ISOs for the new nodes. See [Deploying the Developer Portal subsystem OVA file](#)

- c. Configure the project to the desired production profile:

```
apicup subsys set <subsystem_name> deployment-profile=<prod-profile>
```

- d. Use the new profile

```
apicup subsys install <subsystem_name>
```

3. Analytics subsystem:

- a. To avoid data loss for analytics, it is recommended that data collection be stopped while the profile switch is in progress. See [Stopping Analytics data collection](#).

- b. Add 2 more nodes by setting up hosts and ifaces using the `apicup` installer. See [Configuring the Analytics subsystem](#)

- c. Generate ISOs for the new nodes. See [Deploying the Analytics subsystem OVA file](#)

- d. Configure the project to the desired production profile:

```
apicup subsys set <subsystem_name> deployment-profile=<prod-profile>
```

- e. Use the new profile

```
apicup subsys install <subsystem_name>
```

- f. Restart analytics data collection as explained in the topic, [Restarting Analytics pods and data collection](#).

- **Switching from production profile to development profile**

1. Analytics only: To avoid data loss for analytics, it is recommended that data collection be stopped while the profile switch is in progress. See [Stopping Analytics data collection](#).

2. **Workaround for deployments that upgraded to Version 10.0.1.5-eus from a previous version of API Connect**

For the management subsystem, if you upgraded to 10.0.1.5-eus, you must first patch role secret to add permissions. Otherwise, move straight to Step [3](#).

- a. Log in to the appliance as root:

```
sudo su
```

- b. Patch role secret to add permissions:

```
kubectl -n <namespace> patch secret pgorole-pgoadmin --type=json' -p='[{"op" : "replace" , "path" :
"/data/permissions" , "value" : "Kg=="}]'
```

3. For each subsystem:

- a. Configure the project to the desired production profile:

```
apicup subsys set <subsystem_name> deployment-profile=<dev-profile>
```

- b. Use the new profile

```
apicup subsys install <subsystem_name>
```

4. Analytics only: Restart analytics data collection as explained in the topic, [Restarting Analytics pods and data collection](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Configuring SSHD to limit access to your deployment

How to configure SSHD in order to limit host access to your VMware deployment.

## About this task

---

The following example shows how to configure SSHD in order to limit VMware access to a certain set of IP addresses.

Attention:

- SSHD configuration settings are not included in the IBM® API Connect backups. However, the settings are kept when you upgrade to a new fix pack.
- If you change the SSHD cipher level, and encounter issues with the new configuration, you must revert your cipher changes and retest. If after the retest you still have issues, then contact IBM Support.

## Procedure

---

1. Log in to the target virtual machine by using an SSH tool, and switch to the root user. For example, to log in to the Management subsystem, run the following commands:

```
ssh ip_address -l apicadm
sudo -i
```

2. Move to the following folder:

```
/etc/ssh/sshd_config.d
```

3. Create a new configuration file with the extension `.conf` that contains the IP address of the host that you want to allow to access your deployment. For example, to create the file run the following command:

```
vi filename.conf
```

Then, edit the file by using the following format, which in this example is allowing users from IP address `123.135.1.2`:

```
AllowUsers *@123.135.1.2
```

Additional hosts can be added by separating the IP address patterns with a space. For example:

```
AllowUsers *@123.135.1.2 *@135.168.1.2
```

4. Restart the SSHD service by running the following command:

```
systemctl restart sshd.service
```

## Results

---

Access to your VMware is now limited to a certain set of IP addresses.

## What to do next

---

If you want to remove a cipher from your SSHD configuration, you can edit the `/etc/ssh/sshd_config` file. For example, if your security department decides that you must stop using the 128 bit UMAC cipher, you can remove it from your supported ciphers list by editing the `/etc/ssh/sshd_config` file and changing the following line from:

```
MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,umac-128-etm@openssh.com,hmac-sha2-512,hmac-sha2-256,umac-128@openssh.com
```

to:

```
MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,hmac-sha2-512,hmac-sha2-256
```

Then restart the SSHD service by running the following command:

```
systemctl restart sshd.service
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Managing an appliance data disk

You can use `apic` commands to manage appliance data disks in your VMware deployment.

The API Connect deployment on VMware uses 2 partitions. The first contains the base operating system, while the second is encrypted so that any customer data that is stored on disk uses the encrypted volume. Encryption is done with Linux Unified Key Setup (LUKS) disk encryption.

During installation of each API Connect subsystem, you specify a password `HD-PASSWD` when configuring the host:

```
apicup hosts create <SUBSYS> <HOSTNAME> <HD-PASSWD>
```

If you want to force a restart of processes, without requiring a full restart of the virtual machine, you can use the command `apic lock` to stop the Kubernetes node on the virtual machine and lock the secured storage. When you are ready to restart processes, you can use `apic unlock` to restart the Kubernetes node. The command `apic unlock` uses the password to unlock the partition so that files can be read from it and written to it. The unlock command also starts the `apic` daemon, also known as the `appliance-manager` service.

You can check that status of this service with:

```
sudo systemctl status appliance-manager
```

One `appliance-manager` daemon runs on each node, where it manages the Kubernetes cluster, processes update and upgrade requests, and gathers logs.

| apic command         | Description                                               |
|----------------------|-----------------------------------------------------------|
| <code>lock</code>    | Shut down appliance services and lock the secured storage |
| <code>logs</code>    | Retrieve logs from all nodes in the cluster               |
| <code>status</code>  | Report on cluster status                                  |
| <code>unlock</code>  | Unlock the secure storage and start the appliance         |
| <code>version</code> | Get the API Connect appliance base version                |

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Replica override for microservices on VMware

Modify the replica count for microservices by using template overrides for Custom Resources.

When API Connect is deployed, the deployment profile you select drives the number of replicas to be used for most deployment. For development profiles, typically specified by `n1x...`, the replica count is 1. For production profiles, typically specified by `n3x...`, replica count is 3.

You can override the replica count for individual deployments by using template overrides.

- Template overrides are a piece of yaml that should be added to the Kubernetes custom resource. The examples provided in this topic show only that the `template:` element should be under the main `spec:` element of a CR. The rest of the CR is not shown.
- When applying overrides for Appliance deployments (virtual machines), the yaml sample provided as example must be added in an extra-values-file for the subsystem. To view an example of documenting a template override for an Appliance, see [Setting rate limits for public APIs on the management service](#)

---

## Management subsystem

For a Management CR in Kubernetes or OpenShift, the following override specifies 5 replicas for the `apim` deployment:

```
spec:
 template:
 - name: apim
 replicaCount: 5
```

You can also configure replicate count through a similar template override for:

- `juhu`
- `ldap`
- `lur`

---

## Analytics subsystem

The Analytics microservices that can be scaled using template override are:

- `client`
- `ingestion`
- `mq-kafka`
- `mq-zk`
- `mtls-gw`
- `storage-coord`
- `storage-data`
- `storage-master`

Note that this microservice cannot be scaled below 2 replicas when using a 3 node (production) deployment profile. Also, when using this `unique` storage type, you must have at least 1 replica available for the 3 storage roles (coord, data and master).

- `storage-shared`

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Changing the DNS server configuration on appliances

Complete this task only if you must change the DNS addresses after the initial boot of the VM.

---

### Before you begin

Verify that you have VMware console access to the VM, as well as the correct password. If you cannot `ssh` into the appliance, you can use the VMware console interactive login instead (use the `apicadm` login and the password configured as `default-password` in the `apicup` project).

## About this task

---

This task is only valid for making changes to DNS resolution. The IP address of the VM cannot be changed at any time after the initial boot.

## Procedure

---

1. Edit the `/etc/netplan/50-cloud-init.yaml` file and update the list of nameserver addresses.

Attention: Typically, you do not edit this file manually. You should only make direct changes to the `/etc/netplan/50-cloud-init.yaml` file when you need to update the nameserver addresses.

The following example shows what the list of nameserver addresses looks like in the file:

```
network:
 ethernets:
 eth0:
 addresses:
 - 192.168.122.242/24
 nameservers:
 addresses:
 - 1.1.1.1
 - 1.0.0.1
 - 8.8.8.8
 search:
 - nip.io
 routes:
 - metric: 10
 to: 0.0.0.0/0
 via: 192.168.122.1
 version: 2
```

2. Run the following command to apply the changes:

```
sudo netplan apply
```

3. Run the following command to verify the changes:

```
cat /run/systemd/resolve/resolv.conf
```

4. Attach an updated ISO to the VM to ensure all artifacts are up-to-date in case a disaster recovery is needed.
  - a. Update the `apicup` project configuration with the correct DNS values.
  - b. Generate a new ISO based on the updated project.
  - c. Attach the new ISO to the VM.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Advanced configuration for management subsystem

---

Specify advanced configuration for the management subsystem.

Note: VMware deployments include subsystem settings that cannot be reconfigured without a complete deployment. For example, for the Management Service these settings include hosts, endpoints, interfaces (`public-iface`, `traffic-iface`), IP ranges of the Kubernetes pod and the service networks (`k8s-pod-network`, `k8s-service-network`). Before reconfiguring, review the installation instructions for your subsystem to determine which settings are optional during initial installation and thus able to be updated later.

See:

- [Setting rate limits for public APIs on the management service](#)  
Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.
- [Configuring maximum size of client requests to the Management subsystem on VMware](#)  
You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.
- [Configuring monetization on VMware](#)  
You can optionally configure monetization in API Connect on a VMware virtual machine by enabling the billing microservice.
- [Configuring use of an external NTP server](#)  
You can optionally configure an external NTP server for use by API Connect when deploying on a VMware virtual machine.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Setting rate limits for public APIs on the management service

Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.

## Before you begin

Note: This article refers to third-party software that IBM does not control. As such, the software may change and this information may become outdated. These instructions assume you have the kubectl command-line tool installed. For more information, see <https://kubernetes.io>.

## About this task

Rate limits can be set for public APIs on the management service. Rate limits on APIs help provide protection from DDoS (distributed denial of service) attacks. Without a rate limit, API calls from public APIs are unlimited.

The rate limit configuration requires that the header contains the actual client IP address. Any load balancer or proxy (for example, HAProxy) that is installed in front of the management service must be configured to pass the actual client IP address.

This procedure must be performed on a running API Connect deployment.

Rate limits are calculated as requests per seconds per client.

Note: If the rate limit has been reached on the management subsystem, the client will get an HTTP error: **429 Too Many Requests**.

## Procedure

- Set a rate limit:

1. Create, or edit if one already exists, a management subsystem extra-values file in the `apicup` management project directory, and enter the following configuration details:

```
spec:
 template:
 - name: juhu
 containers:
 - name: juhu
 env:
 - name: RATE_LIMIT_PER_CLIENT
 value: "10"
 - name: LIMIT_REQUEST_OPTION
 value: "burst=10 nodelay"
```

In this example, the first option sets the rate to 10 requests per second (10r/s). The second option allows 10 requests boosted without delay within < 1 second. You can customize as needed.

The `rateLimitPerClient` property sets `rate`, and `limitRequestOption` sets `[burst=number] [nodelay | delay=number]` in the following nginx configuration:

```
limit_req_zone key zone=name:size rate=rate;
limit_req zone=name [burst=number] [nodelay | delay=number];
```

Note that `zone` has been pre-defined and can't be configured. For more details, see the nginx doc [http://nginx.org/en/docs/http/nginx\\_http\\_limit\\_req\\_module.html](http://nginx.org/en/docs/http/nginx_http_limit_req_module.html).

2. Save the extra-values file with a filename of your choice, but it must have a `.yaml` or `.yml` extension.
3. Use `apicup` to update the VMware `extra-values-file` attribute to point to the new or updated management subsystem extra-values file:

```
apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
```

Where:

- `<mgmt_subsystem_name>` is the name of the management subsystem that you are configuring.
- `<extra_values_file_path_and_name>` is the fully qualified path and name of your extra-values file.

For example:

```
apicup subsys set ds10-management extra-values-file /workspace/v10012/my_extra_values.yaml
```

4. Verify that the configuration settings are valid in the `apiconnect-up-v10.yaml` by running the following command:

```
apicup subsys get <mgmt_subsystem_name> --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.

5. Run `apicup` to update the settings in the deployed Management subsystem.

```
apicup subsys install <management-subsystem>
```

6. Enter the following command to connect to the management subsystem using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of `apicadm`, which is the API Connect ID that has administrator privileges.

7. Select Yes to continue connecting, and once connected:

```
sudo -i
```

8. Validate that the juhu pod has restarted by listing the pods:

```
kubectl get pods | grep juhu
```

9. Check the AGE column to ensure a new juhu pod has started.
10. If the older juhu pod is still running, delete it with the following command:

```
kubectl delete pods <old-juhu-pod>
```

- Disable a rate limit:
  1. Remove the values from the extra-values-file.
  2. Run `apicup` to update the settings in the deployed Management subsystem.

```
apicup subsys install <management-subsystem>
```

3. Enter the following command to connect to the management subsystem using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of `apicadm`, which is the API Connect ID that has administrator privileges.

4. Select Yes to continue connecting, and once connected:

```
sudo -i
```

5. Validate that the juhu pod has restarted by listing the pods:

```
kubectl get pods | grep juhu
```

6. Check the AGE column to ensure a new juhu pod has started.
7. If the older juhu pod is still running, delete it with the following command:

```
kubectl delete pods <old-juhu-pod>
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Configuring maximum size of client requests to the Management subsystem on VMware

You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.

### About this task

The default maximum size is 8 megabytes. You can increase this value.

Increasing the setting can be useful if you get errors when using the CLI to import a large API. Example error:

```
HTTP/1.1 413 Request Entity Too Large
```

Note:

- These instructions apply only to VMware installations. For Kubernetes installations, see [Configuring maximum size of client requests to the Management subsystem](#).
- These instructions use an extra-values file. This file can be used to define CR overrides. Note that extra-values files for a CR can contain more than one override. If you already use an extra-values file, you can add the new override to it.
- All of the commands must be run in the `apicup` management project directory.

### Procedure

1. Create, or edit if one already exists, a management subsystem extra-values file in the `apicup` management project directory, and enter the following configuration details:

```
spec:
 template:
 - name: juhu
 containers:
 - name: juhu
 env:
 - name: CLIENT_MAX_BODY_SIZE
 value: "12m"
```

2. Save the extra-values file with a filename of your choice, but it must have a `.yaml` or `.yml` extension.
3. Use `apicup` to update the VMware `extra-values-file` attribute to point to the new or updated management subsystem extra-values file:

```
apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
```

Where:

- `<mgmt_subsystem_name>` is the name of the management subsystem that you are configuring.
- `<extra_values_file_path_and_name>` is the fully qualified path and name of your extra-values file.

For example:

```
apicup subsys set ds10-management extra-values-file /workspace/v10011/my_extra_values.yaml
```

4. Verify that the configuration settings are valid in the `apiconnect-up.yaml` by running the following command:

```
apicup subsys get <mgmt_subsystem_name> --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.

5. Update the management VMware with the updated setting.

```
apicup subsys install <mgmt_subsystem_name>
```

6. Monitor the health-check output until the management subsystem is healthy by running the following command:

```
apicup subsys health-check <mgmt_subsystem_name>
```

If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of 1. The following output is an example of unhealthy output while the install is running:

```
Error: Cluster not in good health:
ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
```

When all of the health criteria are successfully met, the command displays no output, and exits with a status of 0.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Configuring monetization on VMware

You can optionally configure monetization in API Connect on a VMware virtual machine by enabling the billing microservice.

### Before you begin

Important: If the optional billing microservice is enabled, you must increase the memory for the API Manager for VMware component by 0.5 GB.

### About this task

API Connect includes a subscription billing microservice that allows API providers to define pricing plans in their API Products, and monetize their API offerings. If a Product contains a pricing plan, API Consumers must enter their payment information into the Developer Portal before they can subscribe to that plan. API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.

Note:

- These instructions apply only to VMware installations. For Kubernetes installations, see [Configuring monetization on Kubernetes](#).
- To use Stripe as your credit card processing vendor, you must have port 443 open to HTTPS communication between the Stripe API and your Developer Portal management and the Management cluster servers. See [Firewall requirements on Kubernetes](#) and [Firewall requirements on VMware](#) for more information about this requirement.
- Provider organizations cannot add any billing integrations until the billing microservice is enabled.
- After provider organizations have added billing integrations, the billing microservice must not be disabled.
- All of the commands must be run in the `apicup` management project directory.

To enable or disable the billing microservice, you must configure a management subsystem extra-values file. See the following instructions:

- [Enabling the billing microservice](#)
- [Disabling the billing microservice](#)

## Procedure

- **Enabling the billing microservice**

1. Create, or edit if one already exists, a management subsystem extra-values file in the `apicup` management project directory, and enter the following configuration details:

```
spec:
 billing:
 enabled: true
```

2. Save the extra-values file with a filename of your choice, but it must have a .yaml or .yml extension.
3. Update the VMware `extra-values-file` attribute to point to the new or updated management subsystem extra-values file. Run the following `apicup` command to insert the location of the extra-values file:

```
apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
```

Where:

- `<mgmt_subsystem_name>` is the name of the management subsystem that you are configuring.
- `<extra_values_file_path_and_name>` is the fully qualified path and name of your extra-values file.

For example:

```
apicup subsys set ds10-management extra-values-file /workspace/v10011/monetization.yaml
```

4. Verify that the configuration settings are valid in the `apiconnect-up.yaml` by running the following command:

```
apicup subsys get <mgmt_subsystem_name> --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.

5. Update the management VMware with the updated billing value.

Install the new setting for the billing microservice by running the following command:

```
apicup subsys install <mgmt_subsystem_name> --debug
```

Including the `--debug` option enables the debug output for the command.

6. Monitor the health-check output until the management subsystem is healthy by running the following command:

```
apicup subsys health-check <mgmt_subsystem_name>
```

If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

```
Error: Cluster not in good health:
ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
```

When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.

The billing microservice is now enabled, and provider organization owners can create billing integration resources for API providers in the API Manager UI. For more information, see [Monetizing your Products](#).

- **Disabling the billing microservice**

Important: After provider organizations have added billing integrations, the billing microservice must not be disabled.

1. Edit the management subsystem extra-values file in the `apicup` management project directory, and change the `enabled` configuration option to `false`:

```
spec:
 billing:
 enabled: false
```

2. Save the changed extra-values file.

3. Verify that the configuration settings are valid in the `apiconnect-up.yaml` by running the following command:

```
apicup subsys get <mgmt_subsystem_name> --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.

4. Update the management VMware with the altered billing value.

Install the updated setting for the billing microservice by running the following command:

```
apicup subsys install <mgmt_subsystem_name> --debug
```

Including the `--debug` option enables the debug output for the command.

5. Monitor the health-check output until the management subsystem is healthy by running the following command:

```
apicup subsys health-check <mgmt_subsystem_name>
```

If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

```
Error: Cluster not in good health:
ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
```

When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.

The billing microservice is now disabled.

---

## Configuring use of an external NTP server

You can optionally configure an external NTP server for use by API Connect when deploying on a VMware virtual machine.

### About this task

Secure communication between API Connect subsystems relies on the system time being in sync on all hosts. For example, time stamps are checked to ensure that certificates are valid. When API Connect is deployed behind a firewall that blocks access to the internet, the API Connect subsystems cannot by default access a Network Time Protocol (NTP) server.

You can use an additional cloud-init file to manually specify an NTP server for use by the subsystems. Complete the following steps.

## Procedure

---

1. Create the cloud-init file extra values file, and enter the configuration details that you want to overwrite. For example:

```
ntp:
 enabled: true
 ntp_client: systemd-timesyncd
 servers:
 - time.google.com
```

2. Use `apicup` to specify the cloud-init file.

Syntax:

```
apicup subsys set <subsys> additional-cloud-init-file <path-to-cloud-init-file>
```

Example:

```
apicup subsys set mgmt additional-cloud-init-file myCloudInitFile.yaml
```

3. Install the subsystem. Note that the output directory must be empty:

```
apicup subsys install mgmt --out mgmtplan-out
```

4. Deploy the VMware image (.ova) with the ISO file that is generated.

To review the deployment steps, see [Deploying the Management subsystem](#).

5. Verify that the correct NTP server is being used:

```
journalctl -u systemd-timesyncd
```

Example output for the NTP server that was set in Step 1:

```
Nov 05 21:09:24 h-apicdev-4 systemd[1]: Starting Network Time Synchronization...
Nov 05 21:09:24 h-apicdev-4 systemd[1]: Started Network Time Synchronization.
Nov 05 21:09:24 h-apicdev-4 systemd-timesyncd[1697]: Synchronized to time server 216.239.35.8:123 (time.google.com).
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Advanced configuration for the gateway subsystem on VMware

Specify advanced configuration for the gateway subsystem on VMware.

See:

- [Dynamically re-registering and reconfiguring a Gateway service in a VMware deployment](#)

In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Dynamically re-registering and reconfiguring a Gateway service in a VMware deployment

In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.

If a Gateway service is not configured properly for resiliency and is restarted, the gateways in the Gateway service will lose the configuration from the Management server. Configuration data from the Management server is maintained on the gateway service according to the gateway peering configuration on the gateways.

## Preventing the loss of configuration data

---

For high availability in production environments, use a minimum of three gateways in the Gateway service. In non-production environments, if a single gateway is used, then availability can be improved by ensuring the persistence setting on the gateway peering configuration is set to `local://` or `RAID`; these settings apply to virtual and physical appliances only.

## Forcing re-population of the configuration data

---

To repopulate the configuration data, complete the steps in the following section to trigger an outage-less DRR.

## Triggering an outage-less DRR

To force a Dynamic Reregistration and Reconfiguration across a peer group from within the gateway service without requiring a restart, complete the following steps using the CLI. This process flushes the primary peering object configured for the apic-gw-service. This task can only be performed with CLI, and requires the default admin ID for running the `diag` command.

1. Use `ssh` to connect to gateway service.

2. Switch to the API Connect application:

```
switch <APIC_APP_DOMAIN>
```

3. Show the current gateway-peering-status:

```
show gateway-peering-status
```

4. If the server to which the ssh connection was made is not primary for the apic-gw-service gateway-peering object, force this server to become primary:

```
config; gateway-peering-switch-primary <gateway-peering-name-for-apic-gw-service>;
```

5. Flush the apic-gw-service gateway-peering object:

```
diag; gateway-peering-flush <gateway-peering-name-for-apic-gw-service>; exit
```

6. Disable and then re-enable the apic-gw-service object for every member of the gateway service:

```
config; apic-gw-service; admin-state disabled; exit
apic-gw-service; admin-state enabled; exit; exit
```

7. Confirm that the apic-gw-service was flushed and is now waiting for gateway service registration:

Look in the debug log target for the apic-gw-service, located in `logtemp:///` and check for a message similar to the following example:

```
20200618T232339.332Z [0x88e000d7][apic-gw-service][notice]
apic-gw-service(default): tid(2653): Waiting for gateway service registration.
```

The DRR will be triggered by the next arrival of a webhook event. The Management server sends a heartbeat to the gateway at five-minute intervals, prompting the gateway to check whether it has lost its configuration and if so, trigger a DRR. In addition, if the Management server has previously marked a Catalog or cloud as being unavailable for a particular gateway service, a successful heartbeat triggers synchronization for that Catalog or cloud on that gateway service.

8. (Optional) Force a BAU webhook event to be sent from API Manager to trigger the DRR:

If you do not want to wait for the Management server to send a heartbeat, you can trigger the DRR manually by completing the following steps:

- Open the API Manager.
- Open the Catalog.
- Click Settings, Edit.
- Update the Summary field with some text so that it is modified.
- Click Save.

When the event is received, the DRR is initiated.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Backing up and restoring

You can backup and restore API Connect on VMware

Backups are for recovery of the API Connect subsystems in the same environment that the backups were taken, or in a different environment that has the same network configuration, API Connect form factor and deployment topology. You cannot use backups to move an API Connect installation to a different environment that has different endpoints.

See the instructions for your version of API Connect.

Note: For information about how to maintain a two data center deployment, including backup and restore considerations, see [Maintaining a two data center deployment](#).

- [Backing up and restoring \(10.0.1.1-eus or later\)](#)  
You can backup and restore API Connect on VMware. Use these instructions for v10.0.1.1-eus or later.
- [Backing up and restoring \(10.0.0.0 or 10.0.1.0-eus\)](#)  
You can backup and restore API Connect subsystems. Use these instructions for 10.0.0.0 or 10.0.1.0-eus.
- [Troubleshooting management subsystem backups on VMware](#)  
You can troubleshoot failures of the management subsystem backups.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Backing up and restoring (10.0.1.1-eus or later)

You can backup and restore API Connect on VMware. Use these instructions for v10.0.1.1-eus or later.

- You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.
- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.
- When restoring, the Gateway and all deployed subsystems (Management, Analytics, and Developer Portal) must be at the same version level.
- API Connect does not support restoring API Connect configuration from a VMware snapshot. Snapshots are not the same as API Connect backups. A snapshot is a change log of the original virtual disk, and is not portable. Therefore, do not rely on it as your API Connect backup process. The virtual machine runs on the most current snapshot, not the original vmdk disk files.
- **[Backing up and restoring the management subsystem](#)**  
You can back up and restore your Management subsystem in your VMware environment.
- **[Backing up and restoring the Developer Portal](#)**  
You can backup and restore a Developer Portal in a VMware environment.
- **[Backing up and restoring the Analytics database on VMware](#)**  
The IBM® API Connect Analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required; for example, IBM Cloud Object Storage.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Backing up and restoring the management subsystem

You can back up and restore your Management subsystem in your VMware environment.

### About this task

---

Note: These instructions apply to API Connect 10.0.1.1 or later. For API Connect 10.0.1.0-eus or earlier, see [Backing up and restoring the management subsystem on VMware](#).

- You use the `apicup` utility to configure backup settings for the management subsystem.
- Database backups can be used to restore the database for disaster recovery.
- Backups can be scheduled or generated manually (on-demand). You can then list what backups are available and then use one to restore your Management subsystem if required.
- SFTP support:
  - In 10.0.1.0-eus, Local Backups can be stored remotely on an sftp server, and retrieved later from the sftp server for restore operations. For steps on uploading local-backup files to an sftp server, and for downloading local-backup files from a sftp server for the purposes of a restore, see [Using an sftp server for backup files on VMware](#).
  - In 10.0.1.1-eus, SFTP backup/restore procedure is now automatically handled by apiconnect operator and SFTP documentation in the below sections are applicable to 10.0.1.1-eus and greater versions
  - If you upgrade API Connect from 10.0.1.0-eus to 10.0.1.1-eus, and configure SFTP for 10.0.1.1-eus, API Connect resyncs upstream sftp backups and creates relevant CRs of type record.
- Postgres replica pods depend on a successful completed backup. If backup configuration is not correct, replica pods won't come up.
- Restoring a backup restores the registration credentials (client\_ID, client\_secret) that were in use at the time that the selected backup was created. For information on the registration credentials, see [Changing the registration client id and client secret for applications](#).

Note: You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.

Types of backups supported:

- Cloud-based S3 storage
  - IBM Cloud Object Storage
  - AWS S3
  - **10.0.1.2-eus or later:** Any custom S3, such as minIO
- SFTP  
In 10.0.1.1-eus, SFTP backup/restore procedure is now automatically handled by apiconnect operator.
- Local Backups
- **[Configuring backup settings during initial installation of the management subsystem \(10.0.1.1-eus or greater\)](#)**  
You can use the `apicup` utility to configure backup settings during initial installation of the management subsystem
- **[Verify configuration for s3 backup](#)**  
Verify that the configuration for s3 backups succeeded.
- **[Reconfiguring backup settings for the management subsystem \(10.0.1.1-eus or greater\)](#)**  
You can use the `apicup` utility to add or reconfigure backup settings for the management subsystem, after completion of initial installation.
- **[Backing up the management subsystem](#)**  
Use `apicup` to create a manual backup of the management subsystem
- **[Restoring the management subsystem](#)**  
Use `apicup` to list backups and restore a selected backup of the management subsystem

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

# Configuring backup settings during initial installation of the management subsystem (10.0.1.1-eus or greater)

You can use the `apicup` utility to configure backup settings during initial installation of the management subsystem

## Before you begin

Review [Backing up and restoring the management subsystem](#).

Note: You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.

## About this task

- During an initial installation, use these steps to configure the backup settings prior to creating the initial management ISO.
- You can configure scheduled backups, or generate manual (on-demand) backups.
- In 10.0.1.1-eus and greater, a new parameter called `database-backup-protocol` is required.
- Changing backup settings results in database downtime, unless `database-backup-protocol=sftp`.
- Backup to S3 providers of type `custom` is supported in 10.0.1.2-eus or greater. For `custom` S3, provide values for `database-backup-certs` and `database-backup-s3-uri-style`.
- In Version 10.0.1.4-ifix1-eus or later, OpenSSH key authentication for SFTP is supported.

Important: For S3 backups of the management subsystem, do not use retention features provided by Cloud-based S3 storage providers. Use of such features can result in periodic deletion of archived backups, which can cause backup corruptions which can cause database restores to fail.

## Procedure

1. Use `apicup` to specify backup settings:

- For most settings, use `apicup subsys:`

```
apicup subsys set <subsystem_name> <setting>=<value>
```

- When configuring ssh-key authentication for SFTP, use `apicup certs`

```
apicup certs set <subsystem_name> database-backup-auth-ssh-key <ssh-key-file-path>
```

Table 1. Configuration settings for backup of management subsystem

| Parameter                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>database-backup-protocol</code>     | The type of the backup. Supported types: <ul style="list-style-type: none"><li>• <code>objstore</code><br/><pre>apicup subsys set mgmt database-backup-protocol=objstore</pre></li><li>• <code>sftp</code><br/><pre>apicup subsys set mgmt database-backup-protocol=sftp</pre><p>The default value is <code>sftp</code>.</p></li><li>• <code>local</code> - Local storage backups<br/><pre>apicup subsys set mgmt database-backup-protocol=local</pre></li></ul> Note: <ul style="list-style-type: none"><li>• The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: <code>x509: certificate signed by unknown authority</code>.</li></ul> |
| <code>database-backup-auth-pass</code>    | The password for the server specified in <code>database-backup-host</code> . If using object store, this would be the S3 Secret Access Key parameter. The password will be stored in Base64 encoded format. For example:<br><pre>apicup subsys set mgmt database-backup-auth-pass '&lt;password&gt;'</pre> Note that you cannot use the <code>'='</code> sign to assign the password to <code>database-backup-auth-pass</code> .                                                                                                                                                                                                                                                                                                                                                                         |
| <code>database-backup-auth-ssh-key</code> | <b>Version 10.0.1.4-ifix1-eus or later:</b> Optional. OpenSSH private key for DB backups using SFTP only. Changing this value will restart the DB. Important: <ul style="list-style-type: none"><li>• Use <code>apicup certs</code> to set this value. Do not use <code>apicup subsys</code>.</li><li>• Only OpenSSH keys are supported.<sup>1</sup></li></ul> <pre>apicup certs set mgmt database-backup-auth-ssh-key &lt;ssh private key filepath&gt;</pre>                                                                                                                                                                                                                                                                                                                                            |
| <code>database-backup-auth-user</code>    | The username for the server specified in <code>database-backup-host</code> . If using object store, this would be the S3 Secret Key ID.<br><pre>apicup subsys set mgmt database-backup-auth-user &lt;user name&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Parameter                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Parameter                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>database-backup-certs</code>               | <p><b>10.0.1.2-eus or later:</b><br/>Custom certificate. Used only when <code>s3Provider</code> is set to <code>custom</code>. Most of the custom S3 providers are created based on custom CA certificate.</p> <p>This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be <code>ca.crt</code> and value should be base64 encoded value of CA certificate.</p> <p>The API Connect management subsystem validates the custom S3 certificate against the customer-provided CA certificate.</p> <p>Sample bash script to create the Kubernetes secret:</p> <pre>cat &gt;customs3ca.yaml &lt;&lt;EOF apiVersion: v1 data:   ca.crt: \$(base64 &lt;path-to-ca-certificate&gt;   tr -d '\n' ) kind: Secret metadata:   name: custom-server-ca type: generic EOF  kubectl apply -f customs3ca.yaml -n &lt;namespace&gt;</pre> <p>For example:</p> <pre>apicup subsys set mgmt database-backup-certs=my-custom-s3-ca-cert</pre> |
| <code>database-backup-s3-uri-style</code>        | <p><b>10.0.1.2-eus or later:</b><br/>Valid values: <code>host</code> and <code>path</code>. Default value: <code>host</code></p> <p>Only allowed if <code>s3Provider</code> is set to <code>custom</code>.</p> <p>Some custom S3 providers require URI style to be set to <code>path</code>. For example, minIO supports both <code>host</code> and <code>path</code> style setup. You can create a minIO S3 server to only accept <code>path</code> style client communications.</p> <p><b>Important:</b> Contact your custom S3 administrator before configuring this field. If not properly configured, upstream custom S3 can reject connections from the client, such as API Connect management subsystem.</p> <pre>apicup subsys set mgmt database-backup-s3-uri-style='&lt;host path&gt;'</pre>                                                                                                                                                                                           |
| <code>database-backup-repo-retention-full</code> | <p><b>10.0.1.4-ifix1-eus or later:</b> The number of full S3 or local backups to retain. Not supported for sftp.</p> <p>When the next full backup successfully completes, and the specified number of retained backups is reached, the oldest full backup is deleted. All incremental backups and archives associated with the oldest full backup also expire. Incremental backups are not counted for this setting.</p> <p>Applies to both manual backups and scheduled backups.</p> <p>Minimum value: 1</p> <p>Maximum value: 9999999</p> <p>Default: none (S3 backups), 14 (local backups).</p> <p>Important: <b>v10.0.1.5 and earlier:</b> There is a known limitation that prevents the use of <code>apicup</code> to set the backup repo retention values when using local backups. See <a href="#">Workaround for scheduling and retaining local backups on management subsystem on VMware</a>.</p>                                                                                       |

2. Verify that your settings are valid:

- To view all subsystem settings except `database-backup-auth-ssh-key`:

```
apicup subsys get <subsystem_name> --validate
```

- To view `database-backup-auth-ssh-key`:

```
apicup certs get <subsystem_name> database-backup-auth-ssh-key --type key
```

3. Return to the instructions for installing the management subsystem: [Deploying the Management subsystem](#).

Note that the configuration settings for backups will be installed when you run `apicup subsys install <subsystem_name>` after all configuration settings are complete.

4. **S3 backups only:** After you complete the deployment of the Management subsystem in the previous step, continue to [Verify configuration for s3 backup](#).

<sup>1</sup> PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see <https://www.puttygen.com/>.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Verify configuration for s3 backup

Verify that the configuration for s3 backups succeeded.

### About this task

When you configure Management subsystem backups, the operator runs a `stanza-create` job. This job creates the stanza (Postgres cluster configuration) on the upstream S3 server, which is used for backup and archive procedures. The job also brings up the necessary pod.

## Procedure

1. SSH into the management appliance.
2. Check the status of the `stanza-create` job:

```
kubectl get jobs -n <namespace> | grep stanza
```

- On success:

- The `stanza-create` job status is 1/1:

```
kubectl get jobs | grep stanza
m1-b722e361-postgres-stanza-create 1/1 5s 127m
```

- The `stanza-create` job shows `status: "True"` and `type: Complete`:

```
kubectl get job m1-b722e361-postgres-stanza-create -o yaml
```

```
status:
 completionTime: "2021-04-13T18:38:50Z"
 conditions:
 - lastProbeTime: "2021-04-13T18:38:50Z"
 lastTransitionTime: "2021-04-13T18:38:50Z"
 status: "True"
 type: Complete
 startTime: "2021-04-13T18:38:45Z"
 succeeded: 1
```

- The `stanza-create` pod is in `Completed` state:

```
kubectl get pods | grep stanza
m1-b722e361-postgres-stanza-create-q4fvp 0/1 Completed 0 127m
```

- Exec into the pod:

```
kubectl exec -it <backrest-shared-repo-pod> -- bash
```

- The `pgbackrest` command returns the S3 contents in valid JSON:

```
pgbackrest info --output json --repol-type s3
```

```
"backup": {"held": false}, "message": "ok"}] [pgbackrest@m1-b722e361-postgres-backrest-shared-repo-69cdfdfdd5-rs882 /
```

- On failure, see [Troubleshooting stanza-create job for S3 backup configuration](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Reconfiguring backup settings for the management subsystem (10.0.1.1-eus or greater)

You can use the `apicup` utility to add or reconfigure backup settings for the management subsystem, after completion of initial installation.

### About this task

Warning: If you use the S3 backup protocol, changes to the backup settings result in a short period of database downtime.

- After initial installation, use these steps to add or reconfigure the backup settings.
- When you add or reconfigure backups after completion of the initial installation, the steps are the same as configuring during the initial installation, with the addition of using `apicup` to install (activate) the new settings immediately after adjusting the settings. During initial configuration, you typically wait to use `apicup` to activate settings until all other subsystem settings (unrelated to backup) are complete.
- You can add or reconfigure scheduled backups, or generate manual (on-demand) backups.

Note: You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.

## Procedure

1. Use `apicup` to specify backup settings:

```
apicup subsys set <subsystem_name> <setting>=<value>
```

Table 1. Configuration settings for backup of management subsystem

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| database-backup-protocol     | <p>The type of the backup. Supported types:</p> <ul style="list-style-type: none"> <li>• <code>objstore</code></li> </ul> <pre>apicup subsys set mgmt database-backup-protocol=objstore</pre> <ul style="list-style-type: none"> <li>• <code>sftp</code></li> </ul> <pre>apicup subsys set mgmt database-backup-protocol=sftp</pre> <p>The default value is <code>sftp</code>.</p> <p>Note: <b>Workaround for reconfiguring from S3 to SFTP on 10.0.1.2-eus, including ifixes</b><br/>When switching from S3 to SFTP, the <code>s3provider</code> field remains in the CR after switching the protocol, which can prevent the cluster from coming up. To workaround this issue, complete the following steps:</p> <ul style="list-style-type: none"> <li>• ssh into a Management VM and log in as <code>root</code>.</li> <li>• Edit the CR file: <pre>kubectl edit mgmt -oyaml</pre> </li> <li>• Remove the <code>s3provider</code> field under <code>spec.databaseBackup</code></li> <li>• Ensure that <code>restartDB</code> is set to <code>true</code> <pre>restartDB:   accept: true</pre> </li> </ul> <ul style="list-style-type: none"> <li>• <code>local</code> - Local storage backups</li> </ul> <pre>apicup subsys set mgmt database-backup-protocol=local</pre> <p>Note:</p> <ul style="list-style-type: none"> <li>• The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: <code>x509: certificate signed by unknown authority</code>.</li> </ul> |
| database-backup-auth-pass    | <p>The password for the server specified in <code>database-backup-host</code>. If using object store, this would be the S3 Secret Access Key parameter. The password will be stored in Base64 encoded format.<br/>For example:</p> <pre>apicup subsys set mgmt database-backup-auth-pass '&lt;password&gt;'</pre> <p>Note that you cannot use the <code>'='</code> sign to assign the password to <code>database-backup-auth-pass</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| database-backup-auth-ssh-key | <p><b>Version 10.0.1.4-ifix1-eus or later:</b> Optional. OpenSSH private key for DB backups using SFTP only. Changing this value will restart the DB.<br/>Important:</p> <ul style="list-style-type: none"> <li>• Use <code>apicup certs</code> to set this value. Do not use <code>apicup subsys</code>.</li> <li>• Only OpenSSH keys are supported.<sup>1</sup></li> </ul> <pre>apicup certs set mgmt database-backup-auth-ssh-key &lt;ssh private key filepath&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| database-backup-auth-user    | <p>The username for the server specified in <code>database-backup-host</code>. If using object store, this would be the S3 Secret Key ID.</p> <pre>apicup subsys set mgmt database-backup-auth-user &lt;user name&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <code>database-backup-schedule</code>     | <p>Cron like schedule for performing automatic backups. The format for the schedule is:</p> <ul style="list-style-type: none"> <li>* * * * *</li> <li>-----</li> <li>     </li> <li>      +----- day of week (0 - 6) (Sunday=0)</li> <li>   +----- month (1 - 12)</li> <li>    +----- day of month (1 - 31)</li> <li>  +----- hour (0 - 23)</li> <li>+----- min (0 - 59)</li> </ul> <p>The backup schedule defaults to <code>0 0 * * *</code>. This means a backup is run every day at midnight and minute zero.</p> <p>The timezone for backups is UTC.</p> <p>When you configure a host, if you do not specify a value for <code>database-backup-schedule</code>, the default backup schedule is automatically set. Note that the default backup schedule is not set, and scheduled backups not enabled, until host configuration is completed.</p> <pre>apicup subsys set mgmt database-backup-schedule="0 0 * * *"</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>backup-certs</code>                 | <p><b>Version 10.0.1.2-eus or later</b></p> <p><b>Optional.</b> Backup certificates to use for TLS communication between API Connect and the backup server. Supported for custom s3 backups only. Use this setting when you have set <code>database-backup-s3provider=custom</code></p> <p>For example:</p> <pre>apicup subsys set mgmt backup-certs=&lt;certificate_name&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>database-backup-s3-uri-style</code> | <p><b>Version 10.0.1.2-eus or later</b></p> <p><b>Optional:</b> Specifies whether the URI is in the form of <code>host</code> or <code>path</code>. Used only with custom s3providers. Use this setting when you have set <code>database-backup-s3provider=custom</code>.</p> <pre>apicup subsys set mgmt database-backup-s3-uri-style='&lt;host path&gt;'</pre> <p>Supported values:</p> <ul style="list-style-type: none"> <li><code>host</code></li> <li><code>path</code></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Note: To view all subsystem settings for the management subsystem:

```
apicup subsys get <subsystem_name> --validate
```

2. Apply the settings:

```
apicup subsys install <subsystem_name>
```

Note: The `apicup subsys install` command automatically runs `apicup health-check` prior to installing the new configuration. An error is displayed if a problem is found that will prevent successful reconfiguration.

In some scenarios, after you fix the problem, the health check might continue to fail. In this case, you can use the `--skip-health-check` flag to suppress the automatic health check:

```
apicup subsys install <subsystem_name> --skip-health-check
```

3. Ensure that the changes were applied successfully:

```
apicup subsys health-check <subsystem_name>
```

<sup>1</sup> PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see <https://www.puttygen.com/>.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Backing up the management subsystem

Use `apicup` to create a manual backup of the management subsystem

### Before you begin

You must have configured backups for the subsystem. See [Configuring backup settings during initial installation of the management subsystem \(10.0.1.1-eus or greater\)](#)

### About this task

Use this task to create an on-demand, or manual, backup of the management system.

To set up scheduled backups, see the `schedule` option in [Configuring backup settings during initial installation of the management subsystem \(10.0.1.1-eus or greater\)](#).

### Procedure

1. Ensure that there are no Management subsystem backups in Running state before creating a new Management backup.
2. Ensure your system is healthy:

```
apicup subsys health-check [subsystem_name]
```

When successful, the command returns silently with an exit code of 0.

3. Make sure that the management cluster status is Running and the READY condition displays the same value before and after the "/>. SSH into the appliance and run `kubect1`:

```
kubect1 get mgmt
NAME READY STATUS VERSION RECONCILED VERSION AGE
mgmt 16/16 Running 10.0.1-eus 10.0.1.1-eus-0-eus 19h
```

Note: Be sure **READY** status is 16/16. If you have just configured or reconfigured the backup settings, there is a period of time when the postgres pods are taken offline and brought back up with the new configuration. During this time, the `kubect1 get mgmt` command will show 11/11 instead of 16/16. If you start a backup before the Management cluster is on 16/16, the backup attempt might stall indefinitely.

4. Create a backup:

```
apicup subsys backup [subsystem_name] [flags]
```

Decide which of the two types of manual backups you want to do:

- **full**: backs up the entire Management subsystem database.

```
apicup subsys backup management --type full
```

- **incr**: backs up any data that has not been backed up since the last **full** or **incr** backup.

```
apicup subsys backup management --type incr
```

To view additional flags, use

```
-h:
```

```
./apicup subsys backup management -h
Backup management subsystem
Usage:
 backup SUBSYS [flags]Flags:
 --debug Enable debug logging
 -h, --help help for backup
 --type string Type of backup to take ['incr' (backup data starting from last backup), 'full' (complete backup)] (default "full")
 --wait Wait for the operation to complete or fail.
 --wait-timeout duration Command timeout in seconds. (default 40s)
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Restoring the management subsystem

Use `apicup` to list backups and restore a selected backup of the management subsystem

### Before you begin

- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.
- When restoring, the Gateway and all deployed subsystems (Management, Analytics, and Developer Portal) must be at the same version level.
- Restoring the Management Service requires database downtime and is a destructive process that deletes current data and copies backup data. During the restoration process, external traffic must be stopped.
- In a Disaster Recovery scenario, do not log in to the administration UI or attempt to configure or change any settings prior to restoring the backup. Restore the backup immediately after installing the subsystem.
- To restore the management database, you must use the original project directory that was created with `apicup` during the initial product installation. You cannot restore the database without the initial project directory because it contains pertinent information about the cluster. The endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored system. Successful restoration depends on use of a *single apicup* project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.
- Endpoints for the components cannot change between deployments. However, the endpoints for the VMware hosts can be modified for the new deployment.
- Map the DNS entries from the source cluster to the corresponding IP addresses on the target cluster. Record the DNS entries for each endpoint before starting the restore.
- When restoring the management database, the endpoints (on the new cluster which is the target for the restoration) have to be the same as those on the old cluster (the source of the backup).

## About this task

Restoring a backup restores the registration credentials (`client_ID`, `client_secret`) that were in use at the time that the selected backup was created. For information on the registration credentials, see [Changing the registration client\\_id and client\\_secret for applications](#).

Note: There is a known issue where sometimes a restore from the Management subsystem's SFTP backup succeeds but the data is not restored. If this happens, run the restore again.

## Procedure

1. To list the available backups:

```
apicup subsys list-backups [subsystem_name] [flags]
```

Example:

```
apicup subsys list-backups mgmt
NAME STATUS ID CLUSTER TYPE CR TYPE AGE
management-3aa3bebf Ready 20200929-152150F management full record 10h
management-3c4ca8df Ready 20200929-115520F management full record 20h
management-5tbxj Ready 20200929-224349F management full create 17h
management-f10af337 Ready 20200925-133703F management full record 5d2h
management-jtlcd Ready 20200929-224349F management full create 25h
management-zxjtz Ready 20200929-224349F management full create 28h
```

Optional flags:

```
./apicup subsys list-backups -h
List backups of the subsystem
Usage:
 apicup subsys list-backups SUBSYS [flags]
Flags:
 -h, --help help for list-backups
 --timeout duration Command timeout in seconds. (default 40s)
Global Flags:
 --accept-license Accept the license for API Connect
 --debug Enable debug logging
```

Attention: You can restore the Management subsystem from any backup where the STATUS is Ready; however, you should avoid restoring to the initial system backup. During installation, the Management database is used for an initial system backup before certain database schema jobs are complete. Restoring to this backup will result in an unstable system.

2. To restore a selected backup:

```
apicup subsys restore [subsystem_name] --name <backup_name> [flags]
```

Example, where `management-zxjtz` is the value of `<backup_name>`, chosen from the backup NAMES listed by `apicup subsys list-backups` in Step 1:

```
apicup subsys restore mgmt --name management-zxjtz
```

Optional flags:

```
apicup subsys restore management -h
Restore management subsystem
Usage:
 restore SUBSYS_NAME [flags]
Flags:
 --debug Enable debug logging
 -h, --help help for restore
 --name string Name of the backup to restore
 --wait Wait for the operation to complete or fail.
 --wait-timeout duration Command timeout in seconds. (default 40s)
```

3. You can list your restores and their statuses.

```
apicup subsys list-restores [subsystem_name] [flags]
```

To view the optional flags, use `-h`:

```
apicup subsys list-restores -h
List restores of the subsystem
```

**Usage:**

```
apicup subsys list-restores SUBSYS [flags]
```

**Flags:**

```
-h, --help help for list-restores
--timeout duration Command timeout in seconds. (default 40s)
```

**Global Flags:**

```
--accept-license Accept the license for API Connect
--debug Enable debug logging
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Backing up and restoring the Developer Portal

You can backup and restore a Developer Portal in a VMware environment.

### About this task

---

Note: These instructions apply to API Connect 10.0.1.1-eus or later. For API Connect 10.0.1.0-eus or earlier, see [Backing up and restoring the Developer Portal in a VMware environment](#).

It is strongly recommended that you configure the backup parameters for your portal service during installation. If you did not do so when you installed API Connect in your runtime environment, you must configure the backups for the Developer Portal before performing an upgrade. These backups can then be used to restore the Developer Portal if required. When your Developer Portal subsystem is running, you can also make on-demand backups by using the command line.

Note:

- You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.
- When restoring, the Gateway and all deployed subsystems (Management, Analytics, and Developer Portal) must be at the same version level.

The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

- To complete a backup and restore of your Portal Subsystem, you must use `apicup` to configure the backup settings.
- Backups can be scheduled or generated manually (on-demand).
- You can then list the available backups are available and select one to restore your Portal Subsystem when necessary.
- Supported backup types:
  - Cloud-based S3 storage
    - IBM Cloud Object Storage
    - AWS S3
  - SFTP
- [Configuring backup settings for the Developer Portal subsystem](#)  
You can use the `apicup` utility to configure backup settings for the Developer Portal subsystem
- [Backing up the Developer Portal subsystem](#)  
After you have configured backup settings, you can use `apicup` to create a manual backup of the Developer Portal.
- [Restoring the Developer Portal subsystem](#)  
You can use `apicup` to restore the Developer Portal subsystem.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Configuring backup settings for the Developer Portal subsystem

You can use the `apicup` utility to configure backup settings for the Developer Portal subsystem

### Before you begin

---

Review [Backing up and restoring the Developer Portal](#).

## About this task

Note: These instructions apply to API Connect 10.0.1.1-eus or later.

- During an initial installation, use these steps to configure the backup settings prior to creating the initial management ISO.
- You can configure scheduled backups, or generate manual (on-demand) backups.
- In 10.0.1.1-eus and greater, a new optional parameter `site-priority-list` enables prioritization of sites to restore.
- **Version 10.0.1.4-ifix1-eus or later:** OpenSSH key authentication for SFTP is supported.

The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

Tip: If you are using remote backups, and there are a large number of rows in your `portalbackup` list that have a `CR TYPE` of `record`, there might be a slow down in system performance, including during Developer Portal upgrades. Although there is no upper limit to how many portal backups you can have, it is recommended that you prune your remote backups so that the number of rows does not become excessively large. One `portalbackup` row of type `record`, corresponds to one backup file on the configured remote backup server. For more information, see [Overview of the Developer Portal backup resources](#).

## Procedure

1. Open your API Connect installation project directory.
2. Run the following commands to set the location and timing of your backups:

```
apicup subsys set <subsystem_name> <setting>=<value>

apicup subsys set ptl site-backup-host=mybackuphost.com
apicup subsys set ptl site-backup-port=22
apicup subsys set ptl site-backup-auth-user=mybackupauthusername
apicup subsys set ptl site-backup-auth-pass=mybackupauthpassword

apicup subsys set ptl site-backup-path=/site-backups
apicup subsys set ptl site-backup-protocol=sftp
apicup subsys set ptl site-backup-certs=<custom-s3-server-CA-cert>
apicup subsys set ptl site-backup-s3-uri-style=<host-or-path>
apicup subsys set ptl site-backup-schedule="0 2 * * *"
apicup subsys set ptl site-priority-list=portal.a1.example.com/test-1/spacecatalog,portal.a1.example.com/test-4/cat3,portal.a1.example.com/test-3/cat1
```

Use `apicup certs` instead of `apicup subsys` to configure ssh-key authentication for SFTP:

```
apicup certs set ptl site-backup-auth-ssh-key <ssh-key-file-path>
```

The backup parameters are detailed in the following table.

Table 1. Portal backup parameters

| Parameter                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>site-backup-host</code>         | The fully qualified domain name of the backup server, in lowercase only. <ul style="list-style-type: none"><li>• For <code>objstore</code> type backup, specify S3 endpoint with the corresponding S3 region in the format <code>&lt;S3endpoint&gt;/&lt;S3region&gt;</code><br/><pre>apicup subsys set ptl site-backup-host=s3.eu-gb.cloud-object-storage.appdomain.cloud</pre></li><li>• For <code>sftp</code> type, the SFTP server hostname<br/><pre>apicup subsys set ptl site-backup-host=my.sftp.backup.domain.example.com</pre></li></ul> |
| <code>site-backup-port</code>         | The port for the protocol to connect to the <code>site-backup-host</code> . Defaults to 22 if not explicitly set. The backup port is not required for object storage.<br><pre>apicup subsys set ptl site-backup-port=22</pre>                                                                                                                                                                                                                                                                                                                    |
| <code>site-backup-auth-user</code>    | The user name for the server specified in <code>site-backup-host</code> . If using object storage, the user name is the S3 Secret Key ID.<br><pre>apicup subsys set ptl site-backup-auth-user=&lt;user_name&gt;</pre>                                                                                                                                                                                                                                                                                                                            |
| <code>site-backup-auth-pass</code>    | The password for the server specified in <code>site-backup-host</code> . If using object storage, the password is the S3 Secret Access Key parameter. The password is stored in Base64 encoded format, and must not be edited directly in the <code>apiconnect-up.yml</code> file.<br><pre>apicup subsys set ptl site-backup-auth-pass=password</pre>                                                                                                                                                                                            |
| <code>site-backup-auth-ssh-key</code> | <b>Version 10.0.1.4-ifix1-eus or later:</b> OpenSSH key for database backups using SFTP.<br>Important: <ul style="list-style-type: none"><li>• Use <code>apicup certs</code> to set this value. Do not use <code>apicup subsys</code>.</li><li>• Only OpenSSH keys are supported.<sup>1</sup></li></ul> <pre>apicup certs set ptl site-backup-auth-ssh-key=&lt;ssh-key-file-path&gt;</pre>                                                                                                                                                       |

| Parameter                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>site-backup-path</code>         | <p>The location of where the backups are stored:</p> <ul style="list-style-type: none"> <li>S3 - the name of your S3 bucket to store backup data, optionally followed by a <code>/</code> and then any subdirectories inside the bucket. Valid examples: <ul style="list-style-type: none"> <li><code>bucket</code></li> <li><code>bucket/path</code></li> <li><code>bucket/lots/of/paths</code></li> </ul> </li> </ul> <p>Example:</p> <pre>apicup subsys set ptl site-backup-path=apic-backup</pre> <ul style="list-style-type: none"> <li>SFTP - the full absolute path of the folder on the SFTP server, beginning with <code>/</code>. <pre>apicup subsys set ptl site-backup-path=~/folder</pre> </li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>site-backup-protocol</code>     | <p>The protocol that is used to communicate with your remote backup endpoint. Specify one of the following values:</p> <ul style="list-style-type: none"> <li><code>sftp</code> - for secure file transfer protocol</li> <li><code>local</code> - for local storage</li> <li><code>objstore</code> - for S3 compatible object storage</li> </ul> <p>Starting in 10.0.1.4-ifix1-eus, the default protocol is <code>local</code> (earlier releases used <code>sftp</code> as the default). For example:</p> <pre>apicup subsys set ptl site-backup-protocol=local</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>site-backup-certs</code>        | <p>The name of a custom certificate that contains your upstream custom S3 CA certificate. Supported beginning with 10.0.1.2-eus. This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be <code>ca.crt</code> and the value is the base64-encoded value of the CA certificate.</p> <p>If the server certificate that is presented by your S3/object-store endpoint is signed by a well known CA and includes any intermediate certificates in the chain, then you do not need to provide the CA certificate using this feature because the Portal subsystem already trusts the server certificate. You can test this by configuring the Portal backup to your S3/object-store server without providing the CA certificate.</p> <p>If you do need to provide the CA certificate then you must provide the entire chain in the <code>ca.crt</code> member of the secret, as follows:</p> <pre>intermediate-certificate-1 intermediate-certificate-2 . . . intermediate-certificate-n root-certificate</pre> <p>Where the first certificate in the <code>ca.crt</code> member (intermediate-certificate-1) is the issuer of the S3/object-store server certificate, and each subsequent certificate in the <code>ca.crt</code> member is the issuer of the preceding certificate. The root certificate in the <code>ca.crt</code> member must be self-signed.</p> <p>If there are no intermediate certificates involved, then the <code>ca.crt</code> member contains only the root certificate.</p> <p>The following sample bash script creates a Kubernetes secret:</p> <pre>cat &gt;customs3ca.yaml &lt;&lt;EOF apiVersion: v1 data:   ca.crt: \$(base64 &lt;path-to-ca-certificate&gt;   tr -d '\n' ) kind: Secret metadata:   name: custom-server-ca type: generic EOF</pre> <pre>kubectl apply -f customs3ca.yaml -n &lt;namespace&gt;</pre> |
| <code>site-backup-s3-uri-style</code> | <p>Optional. Indicates whether URIs to your S3 backup should use specify a host or a path value. When not specified, defaults to <code>host</code>. Supported beginning with 10.0.1.2-eus. Valid values: <code>host</code> and <code>path</code>.</p> <p>Some custom S3 providers require URI style to be set to <code>path</code>. For example, MinIO supports both <code>host</code> and <code>path</code> style setup. You can create a MinIO S3 server to only accept <code>path</code> style client communications.</p> <p><b>Important:</b> Contact your custom S3 administrator before configuring this field. If not properly configured, an upstream custom S3 can reject connections from the client, such as the API Connect Management subsystem.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>site-backup-schedule</code>     | <p>The schedule for how often automatic Portal backups are run. The format for the schedule is any valid cron string, as follows:</p> <pre>* * * * * - - - - -                   +----- day of week (0 - 6) (Sunday=0)       +----- month (1 - 12)     +----- day of month (1 - 31)   +----- hour (0 - 23) +----- min (0 - 59)</pre> <p>For example: <code>30 22 * * 1</code> performs backups at 10:30 pm on Mondays. The default backup schedule is <code>0 2 * * *</code> (runs every day at 2 am).</p> <p>The timezone for backups is UTC.</p> <pre>apicup subsys set ptl site-backup-schedule="0 2 * * *"</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| site-priority-list | Optional list of prioritized sites to restore. Default: empty.<br><br><pre>apicup subsys set &lt;portal-subsystem-name&gt; site-priority-list &lt;comma-separated-list-of-sites&gt;</pre> <p>For example:</p> <pre>apicup subsys set ptl site-priority-list portal.a1.example.com/e2etest-1/spacecatalog,portal.a1.example.com/e2etest-4/cat3,portal.a1.example.com/e2etest-3/cat1</pre> |

3. At any time you can view the current Portal subsystem values:

- For most values:

```
apicup subsys get ptl
```

where `ptl` is the name that you assigned to your Portal service. The output from this command lists all of the subsystem settings, including backup, and indicates whether there are any errors. You must fix any errors before continuing.

- Version 10.0.1.4-ifix1-eus or later:** For ssh-key authentication for SFTP:

```
apicup certs get ptl site-backup-auth-ssh-key
```

4. Activate the backup settings by running the following command:

```
apicup subsys install ptl
```

where `ptl` is the name that you assigned to your Portal service.

Note: The `apicup subsys install` command automatically runs `apicup health-check` prior to installing the new configuration. An error is displayed if a problem is found that will prevent successful reconfiguration.

In some scenarios, after you fix the problem, the health check might continue to fail. In this case, you can use the `--skip-health-check` flag to suppress the automatic health check:

```
apicup subsys install <subsystem_name> --skip-health-check
```

5. Validate the installation with the new backup parameters by running the following command:

```
apicup subsys get ptl --validate
```

where `ptl` is the name that you assigned to your Portal service. The output from this command lists all of the subsystem settings, including backup, and indicates whether the values are valid or invalid. You must correct any invalid values before continuing.

6. Ensure that the changes were applied successfully:

```
apicup subsys health-check <subsystem_name>
```

- [Overview of the Developer Portal backup resources](#)

How to manage your Developer Portal remote backup resources.

<sup>1</sup> PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see <https://www.puttygen.com/>.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Overview of the Developer Portal backup resources

How to manage your Developer Portal remote backup resources.

Note: This information is relevant only if you're taking remote Developer Portal backups.

The Developer Portal uses two types of portal backup resources. When you run the command `kubect1 get portalbackup`, you see a list of backups, for example:

| NAME                | ID              | TASK ID      | STATUS | TYPE   | CR TYPE | CLUSTER | AGE   | COMMENT |
|---------------------|-----------------|--------------|--------|--------|---------|---------|-------|---------|
| my-backup-f91ms     | n/a             | 20b47fe090f5 | Ready  | system | create  | portal  | 78m   |         |
| portal-record-222cg | 20220108.010033 |              | Ready  | system | record  | portal  | 94m   |         |
| portal-record-22xdc | 20220702.010339 |              | Ready  | site   | record  | portal  | 9m49s |         |
| portal-record-245j7 | 20221002.010340 |              | Ready  | site   | record  | portal  | 5m    |         |
| portal-record-246hm | 20221218.010103 |              | Ready  | site   | record  | portal  | 32m   |         |
| portal-record-24h44 | 20220509.010037 |              | Ready  | site   | record  | portal  | 68m   |         |
| portal-record-24wb4 | 20221003.010029 |              | Ready  | site   | record  | portal  | 60m   |         |
| portal-record-264mh | 20221119.010453 |              | Ready  | system | record  | portal  | 78m   |         |

There are two types of resources listed, and these are denoted by the `CR TYPE` column; `create` or `record` types.

- create:** This resource is a representation of a `portalbackup` task that was created manually. See [Backing up and restoring the Developer Portal in a Kubernetes environment](#), [Backing up Developer Portal on OpenShift and Cloud Pak for Integration](#), or [Backing up the Developer Portal subsystem](#) on VMware, for information about how to create a manual portal backup.
- record:** This resource is generated by the operator, and it's a representation of a backup file that's stored on the remote backup server. A record listing can be modified only to add a comment to it. You can describe each record to understand which file it is referring to by running the following command:

```
kubect1 describe portalbackup portal-record-name
```

For example:

```
kubect1 describe portalbackup portal-record-zmmfw
```

```
:
```

```
Name: portal-record-zmmfw
Namespace: apic
Labels: createdBy
.
Full Backup Name: my-portal-s3-hostname@my-porg@catal-20220604.010302.tar.gz
```

Record rows are generated and updated on a schedule, according to the backups that exist on your remote backup server. If you have 10 backup files stored on your remote server, then there will be 10 record rows; one row for each file.

The Developer Portal doesn't have a retention policy for remote backups. Therefore, it's your responsibility to ensure that you're keeping the number of backups that are stored remotely under control. An excessive number of portal backups results in delays administrating and upgrading the Developer Portal. This is due to the operator needing to maintain the excessive number of record rows that correspond to each remote portal backup.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Backing up the Developer Portal subsystem

After you have configured backup settings, you can use `apicup` to create a manual backup of the Developer Portal.

---

### About this task

Note: These instructions apply to API Connect 10.0.1.1-eus or later.

You can make on-demand backups of your Developer Portal system, sites, and complete service, by running the following `apicup` commands in your API Connect installation project directory.

Tip: If you are using remote backups, and there are a large number of rows in your `portalbackup` list that have a `CR TYPE` of `record`, there might be a slow down in system performance, including during Developer Portal upgrades. Although there is no upper limit to how many portal backups you can have, it is recommended that you prune your remote backups so that the number of rows does not become excessively large. One `portalbackup` row of type `record`, corresponds to one backup file on the configured remote backup server. For more information, see [Overview of the Developer Portal backup resources](#).

---

### Procedure

1. Ensure your system is healthy:

```
apicup subsys health-check [subsystem_name]
```

When successful, the command returns silently with an exit code of 0.

2. Create a backup:

```
apicup subsys backup [subsystem_name] [flags]
```

- To backup the Portal system configuration (and not the sites), run the following command:

```
apicup subsys backup ptl --type system
```

- To backup a specific Portal site or all sites, run the following command:

```
apicup subsys backup ptl --type site --site-name arg
```

where `arg` is a specific site UUID or URL, or to backup all sites use the argument `installed`.

- To backup the entire Portal service (the system and all installed sites), run the following command:

```
apicup subsys backup ptl
```

Where `ptl` is the name that you assigned to your Portal service.

Note: To restore a Developer Portal service, you need backups of both the Portal system and the installed sites.

To view additional flags, use `-h`:

```
apicup subsys backup portal -h
Backup portal subsystem
```

```
Usage:
 backup SUBSYS [flags]
```

```
Flags:
 --comment string Comment to add to the backup CR before creation
 --debug Enable debug logging
 -h, --help help for backup
 --site-name string Site to restore to the remote server if TYPE=site. Accepts site uuid/url or 'installed' to
backup all installed sites.
 --type string Type of backup to take ['system' (backup Portal System), 'site' (backup Portal Site),
'all' (complete backup)] (default "all")
 --wait Wait for the operation to complete or fail.
 --wait-timeout duration Command timeout in seconds. (default 40s)
```

3. To view the available backups and their status:

```
apicup subsys list-backups [subsystem_name] [flags]
```

Optional flags:

```
./apicup subsys list-backups -h
List backups of the subsystem
Usage:
 apicup subsys list-backups SUBSYS [flags]
Flags:
 -h, --help help for list-backups
 --timeout duration Command timeout in seconds. (default 40s)
Global Flags:
 --accept-license Accept the license for API Connect
 --debug Enable debug logging
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Restoring the Developer Portal subsystem

You can use **apicup** to restore the Developer Portal subsystem.

### About this task

Note: These instructions apply to API Connect 10.0.1.1-eus or later.

You can restore your Developer Portal service by using the backups that exist on your remote server, by running the following **apicup** commands in your API Connect installation project directory. Note that before you can run these commands, you must have configured your remote backup server details, and have valid backups of both the Portal system and the installed sites. See [Configuring backup settings for the Developer Portal subsystem](#) and [Backing up the Developer Portal subsystem](#).

Note:

- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.
- Restoration requires a functioning Developer Portal. In a disaster recovery scenario, you might need to reinstall the Developer Portal subsystem before you can restore the backed-up data. To reinstall, refer to [Deploying the Developer Portal](#).

### Procedure

1. To view the available backups and their status:

```
apicup subsys list-backups [subsystem_name] [flags]
```

Optional flags:

```
./apicup subsys list-backups -h
List backups of the subsystem
Usage:
 apicup subsys list-backups SUBSYS [flags]
Flags:
 -h, --help help for list-backups
 --timeout duration Command timeout in seconds. (default 40s)
Global Flags:
 --accept-license Accept the license for API Connect
 --debug Enable debug logging
```

2. Review which restore actions will be performed.

To see what restore actions are performed when the **apicup subsys restore ptl** command is run, you can use the following command:

```
apicup subsys restore ptl --dry-run --timestamp [now|YYYYMMDD.HHMMSS]
```

where **--timestamp** can be **now**, so the latest backup file that is available is used. Or you can specify a timestamp in the format of **YYYYMMDD.HHMMSS** to retrieve the nearest backup file to a specified time, searching backwards from the timestamp given.

Note:

- From IBM® API Connect Version 10.0.1.4-ifix1-eus, the timestamp format changed to **YYYYMMDD.HHMMSS**. For Version 10.0.1.2-eus and earlier, the timestamp format is **YYYY-MM-DD HH:MM:SS**.
- With the **--dry-run** option, the utility runs through the restore steps without executing them. You can use this option to see if the restore from the selected backup will succeed.

The **--dry-run** option starts with the following output message:

```
Starting restore...please check later for completion status of restore
PortalRestore is Running
```

To view the results of the dry-run, you can either look in the portal restore CR for a message of completion (or failure) or you can get a high-level status by entering:

```
apicup subsys list-restores <subsys_name>
```

Status values can be: **Ready**, **Completed**, **Failed** or **Running**.

3. Run the following command, and attach any flags as appropriate.

```
apicup subsys restore [SUBSYS_NAME] [flags]
```

- To restore your Portal service, run the following command:

```
apicup subsys restore ptl --timestamp [now|YYYYMMDD.HHMMSS]
```

where `--timestamp` can be `now`, so the latest backup file that is available is used. Or you can specify a timestamp in the format of `YYYYMMDD.HHMMSS` to retrieve the nearest backup file to a specified time, searching backwards from the timestamp given. This command executes the portal restore process, which downloads the system backup and all of the site backups from the remote server, and installs them within the Portal stack. This process will then restore the system configuration from the found backup, and restore all of the sites. Note that if a backed up site is already installed on the current stack, then the site is reinstalled by using the backup (the site is overwritten by the backup). If there are multiple sites to restore, then these sites are queued for restoring. You can track the restoration process within the Portal `www admin` logs.

- By default the restore is a complete restore. You can optionally include `--type all` on the command line to specify a complete restore, but the flag is not required, as a complete restore is performed by default. Note that the complete restore uses the `priorityList` configuration setting that you specified in [Configuring backup settings for the Developer Portal subsystem](#).

- To restore just the Portal system configuration, run the following command:

```
apicup subsys restore ptl --type system --system-name arg
```

where `arg` can be a `.tgz` name or also accepts `backup ID` if `TYPE=system` and `CR TYPE=record` from the `list-backups` command.

Note that if Portal system configuration information exists on the current stack, running this command will overwrite that configuration.

- To restore just the Portal sites, run the following command:

```
apicup subsys restore ptl --type site --site-name arg
```

where `arg` can be the site backup `tgz` file name or URL, to restore a particular site by using the specified backup ID (or the latest backup file found if using a URL). Or you can use the argument `all` to restore all of the Portal sites that have backup files on the remote server. Note that if any of the backed up sites are already installed on the current stack, then they are reinstalled by using the backup (the sites are overwritten by the backup).

```
apicup subsys restore portal -h
Restore portal subsystem
```

```
Usage:
 restore SUBSYS [flags]
```

```
Flags:
 --debug Enable debug logging
 --dry-run Runs a dry run of the command, returning the actions that will be taken.
 -h, --help help for restore
 --site-name string File to restore site from which should exist on the pod's local filesystem or the remote
server. Also accepts backup ID if TYPE=site and CR TYPE=record.
 --system-name string File to restore system from which should exist on the pod's local filesystem or the remote
server. Also accepts backup ID if TYPE=system and CR TYPE=record.
 --timestamp string In 'YYYYMMDD.HHMMSS' format, specify a timestamp to retrieve the backup from. The nearest
backup, searching backwards from this timestamp, is used. (default "now")
 --type string Type of restore to take ['system' (restore Portal System), 'site' (restore Portal Site),
'all' (complete restore)] (default "all")
 --wait Wait for the operation to complete or fail.
 --wait-timeout duration Command timeout in seconds. (default 40s)
```

4. To view your restores and their statuses, run:

```
apicup subsys list-restores <subsys_name> <flags>
```

Help output:

```
apicup subsys list-restores -h
List restores of the subsystem
```

```
Usage:
 apicup subsys list-restores SUBSYS [flags]
```

```
Flags:
 -h, --help help for list-restores
 --timeout duration Command timeout in seconds. (default 40s)
```

```
Global Flags:
 --accept-license Accept the license for API Connect
 --debug Enable debug logging
```

5. To list the Portal backup sites, use the Portal CLI command. See [Using the sites commands](#).
6. To list the Portal system sites, use the Portal CLI command. See [Using the platforms commands](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Backing up and restoring the Analytics database on VMware

The IBM® API Connect Analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required; for example, IBM Cloud Object Storage.

---

### About this task

Begin by configuring your backup configuration, which optionally includes a schedule if you want to automate your backups. You can run backups manually as needed. To restore a backup, review the set of available backups, and then restore the selected backup.

- [Configuring backup settings for Analytics](#)  
Use the `apicup` utility to configure backup settings for the Analytics database in your VMware environment.
- [Running a backup of the Analytics database](#)  
Initiate a backup of the IBM API Connect Analytics database on VMware.
- [Restoring the Analytics database](#)  
Restore a selected backup of the IBM API Connect Analytics database on VMware.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Configuring backup settings for Analytics

Use the `apicup` utility to configure backup settings for the Analytics database in your VMware environment.

### About this task

The Analytics database can be backed up and restored from an S3 repository. S3-compatible object storage is required; for example, IBM Cloud Object Storage.

Note:

- Only host-style S3 backups are supported. Path-style S3 backups are not supported.
- If you are using a self-managed S3 backup server, check that you have a DNS hostname entry and matching TLS certificate for your S3 backup endpoint.

### Procedure

1. Use the `apicup` utility to configure the backup settings.  
Configure each setting by running the following command with the key and value from Table 1 that you want to apply:

```
apicup subsys set <analytics_subsystem> <key> <value>
```

Table 1 shows the supported backup settings with the default value (if any) and a description of each setting.

Table 1. Analytics backup settings

| Key                                     | Default value | Description                                                                                                                                                                                                                                                                                   |
|-----------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>analytics-backup-auth-pass</code> |               | Server password for Analytics backups.                                                                                                                                                                                                                                                        |
| <code>analytics-backup-auth-user</code> |               | Server user name for Analytics backups.                                                                                                                                                                                                                                                       |
| <code>analytics-backup-host</code>      |               | The S3 endpoint with the corresponding S3 region in the format:<br><code>s3.s3region.s3domain</code><br>For example:<br><code>s3.eu-gb.cloud-object-storage.appdomain.cloud</code><br>Attention: The path-style host value (formatted as <code>S3endpoint/S3region</code> ) is not supported. |

| Key                                                  | Default value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>analytics-backup-certs</code>                  |               | <p>The name of a custom certificate that contains your upstream custom S3 CA certificate. Supported beginning with 10.0.1.2-eus.</p> <p>This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be <code>ca.crt</code> and the value is the base64-encoded value of the CA certificate.</p> <p>If the server certificate that is presented by your S3/object-store endpoint is signed by a well known CA and includes any intermediate certificates in the chain, then you do not need to provide the CA certificate using this feature because the Portal subsystem already trusts the server certificate. You can test this by configuring the Portal backup to your S3/object-store server without providing the CA certificate.</p> <p>If you do need to provide the CA certificate then you must provide the entire chain in the <code>ca.crt</code> member of the secret, as follows:</p> <pre>intermediate-certificate-1 intermediate-certificate-2 . . . intermediate-certificate-n root-certificate</pre> <p>Where the first certificate in the <code>ca.crt</code> member (intermediate-certificate-1) is the issuer of the S3/object-store server certificate, and each subsequent certificate in the <code>ca.crt</code> member is the issuer of the preceding certificate. The root certificate in the <code>ca.crt</code> member must be self-signed.</p> <p>If there are no intermediate certificates involved, then the <code>ca.crt</code> member contains only the root certificate.</p> <p>The following sample bash script creates a Kubernetes secret:</p> <pre>cat &gt;customs3ca.yaml &lt;&lt;EOF apiVersion: v1 data:   ca.crt: \$(base64 &lt;path-to-ca-certificate&gt;   tr -d '\n' ) kind: Secret metadata:   name: custom-server-ca type: generic EOF</pre> <pre>kubectl apply -f customs3ca.yaml -n &lt;namespace&gt;</pre> |
| <code>analytics-backup-path</code>                   |               | A combination of the S3 bucket and the base path within the bucket, using the format: <code>bucket_name/path</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>analytics-backup-chunk-size</code>             | 1GB           | (Optional) Specifies how large files are stored. Large files can be stored as chunks when the snapshot is created. This setting specifies the size of the chunks as GB, MB, or KB.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>analytics-backup-schedule</code>               | 0 2 * * *     | (Optional) Determines how often backups will be invoked automatically. The format for the schedule is any valid <code>cron</code> string. The timezone for backups is UTC. Backing up once a day is probably sufficient; remember that the more frequently you run backups, the more storage space you need.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>analytics-enable-compression</code>            | true          | (Optional) Determines whether metadata files are stored in compressed format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>analytics-enable-server-side-encryption</code> | false         | (Optional) Determines whether files are encrypted. When set to true, files are encrypted on the server side using AES256.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

2. Validate the backup settings by running the following command:

```
apicup subsys get <analytics_subsystem> --validate
```

3. Apply the backup settings to the Analytics subsystem by reinstalling with the following command:

```
apicup subsys install <analytics_subsystem>
```

Note: The `apicup subsys install` command automatically runs `apicup health-check` prior to installing the new configuration. An error is displayed if a problem is found that will prevent successful reconfiguration.

In some scenarios, after you fix the problem, the health check might continue to fail. In this case, you can use the `--skip-health-check` flag to suppress the automatic health check:

```
apicup subsys install <subsystem_name> --skip-health-check
```

4. Verify that the backup settings were successfully applied by running the following command:

```
apicup subsys health-check <analytics_subsystem>
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Running a backup of the Analytics database

Initiate a backup of the IBM® API Connect Analytics database on VMware.

### About this task

## Procedure

---

1. Perform a health check of your Analytics system by running the following command:

```
apicup subsys health-check <analytics_subsystem>
```

If successful, the command returns silently with exit code 0.

2. Start the backup by running the following command and including the appropriate flags:

```
apicup subsys backup <analytics_subsystem>
```

View the list of supported flags by running the `backup` command with the `-h` (help) flag, as shown in the following example:

```
apicup subsys backup analytics -h
Backup analytics subsystem
```

```
Usage:
 backup SUBSYS [flags]
```

**Flags:**

```
--comment string Comment to add to the backup CR before creation
--debug Enable debug logging
-h, --help help for backup
--ignore-unavailable If false, the backup will fail if an index is missing. If true, missing indices will be
skipped and the backup will continue.
--indices strings Indice(s) you'd like to backup (all/apievents/ui/config). It can be set to any combination
of indice(s) (eg. ui or config,apievents) (default [all])
--wait Wait for the operation to complete or fail.
--wait-timeout duration Command timeout in seconds. (default 40s)
```

3. Optionally view a list of available backups, and the status of each, by running the following command:

```
apicup subsys list-backups <analytics_subsystem>
```

View the list of supported flags by running the `list-backups` command with the `-h` (help) flag, as shown in the following example:

```
apicup subsys list-backups -h
List backups of the subsystem
```

```
Usage:
 apicup subsys list-backups SUBSYS [flags]
```

**Flags:**

```
-h, --help help for list-backups
--timeout duration Command timeout in seconds. (default 40s)
```

**Global Flags:**

```
--accept-license Accept the license for API Connect
--debug Enable debug logging
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Restoring the Analytics database

Restore a selected backup of the IBM® API Connect Analytics database on VMware.

### About this task

---

Use the `apicup` utility to view the list of available backups for the Analytics database, and then restore a selected backup.

## Procedure

---

1. Retrieve a list of available backups, and the status of each, by running the following command:

```
apicup subsys list-backups <analytics_subsystem>
```

View the list of supported flags by running the `list-backups` command with the `-h` (help) flag, as shown in the following example:

```
apicup subsys list-backups -h
List backups of the subsystem
```

```
Usage:
 apicup subsys list-backups SUBSYS [flags]
```

**Flags:**

```
-h, --help help for list-backups
--timeout duration Command timeout in seconds. (default 40s)
```

**Global Flags:**

```
--accept-license Accept the license for API Connect
--debug Enable debug logging
```

The response includes the unique ID of each backup. Note the ID of the backup that you want to restore, so you can use it in the next step.

2. Restore a backup by running the following command with the appropriate flags:

```
apicup subsys restore <analytics_subsystem>
```

Use the `--id string` flag to specify which backup you want to restore.

View the complete list of supported flags by running the `restore` command with the `-h` (help) flag, as shown in the following example:

```
apicup subsys restore analytics -h
Restore analytics subsystem
```

Usage:

```
restore SUBSYS [flags]
```

Flags:

```
--debug Enable debug logging
-h, --help help for restore
--id string ID of the backup to restore
--ignore-unavailable If false, the restore will fail if an index is missing. If true, missing indices will be
skipped and the restore will continue.
--indices strings Indice(s) you'd like to restore (all/apievents/ui/config). It can be set to any
combination of indice(s) (eg. ui or config,apievents) (default [all])
--override If set to true, then the restore operation will override existing indices.
--wait Wait for the operation to complete or fail.
--wait-timeout duration Command timeout in seconds. (default 40s)
```

Note: By default, the `--override` parameter is set to `false` to prevent you from accidentally replacing existing indices. If `--override` is set to `false` and you specify indices that already exist in the database that you are restoring, then the restore fails. The failure prevents you from accidentally replacing or losing data that exists in the current database.

3. Optionally view a list of available restores, and the status of each, by running the following command:

```
apicup subsys list-restores <analytics_subsystem>
```

View the list of supported flags by running the `list-restores` command with the `-h` (help) flag, as shown in the following example:

```
apicup subsys list-restores -h
List restores of the subsystem
```

Usage:

```
apicup subsys list-restores SUBSYS [flags]
```

Flags:

```
-h, --help help for list-restores
--timeout duration Command timeout in seconds. (default 40s)
```

Global Flags:

```
--accept-license Accept the license for API Connect
--debug Enable debug logging
```

Important:

For deployment profiles with fewer than 3 storage nodes, the restore process is never marked as **Complete**. The storage cluster status is expected to be yellow and to have more than 0 unassigned shards. In this situation, the restore process is likely to be complete when there are 0 initializing shards.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Backing up and restoring (10.0.0.0 or 10.0.1.0-eus)

You can backup and restore API Connect subsystems. Use these instructions for 10.0.0.0 or 10.0.1.0-eus.

- You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.
- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.
- When restoring, the Gateway and all deployed subsystems (Management, Analytics, and Developer Portal) must be at the same version level.
- The API Connect backup and restore procedures back up all of the state required by API Connect but do not include the underlying infrastructure software or other internal state. In some scenarios, you may want to perform backups and disaster recovery at an infrastructure layer. You can do this by taking snapshots of the virtual machines or underlying storage volumes. See [Using VM snapshots for infrastructure backup and disaster recovery](#).
- [Backing up and restoring the management subsystem on VMware](#)  
You can backup and restore the management subsystem.
- [Backing up and restoring the Developer Portal in a VMware environment](#)  
You can back up and restore your Developer Portal service in your VMware environment.
- [Backing up and restoring the analytics database on VMware](#)  
The IBM® API Connect Analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required; for example, IBM Cloud Object Storage.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

# Backing up and restoring the management subsystem on VMware

You can backup and restore the management subsystem.

See the following topics:

- [Backing up the Management subsystem in a VMware environment](#)  
You can back up and restore your Management subsystem in your VMware environment.
- [Verify configuration for s3 backup](#)  
Verify that the configuration for s3 backups succeeded.
- [Restoring the management subsystem on VMware](#)  
You can restore your Management subsystem in your VMware environment.
- [Modifying the DatabaseBackup configuration on VMware](#)  
You can modify the `DatabaseBackup` configuration in the Management Cluster CR.
- [Using an sftp server for backup files on VMware](#)  
The sftp backup script enables you to upload and download Postgres backups for the Management Subsystem to and from an sftp server.
- [Workaround for scheduling and retaining local backups on management subsystem on VMware](#)  
Use an extra-values file to schedule local backups and set retention parameters for the management subsystem on VMware deployments.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Backing up the Management subsystem in a VMware environment

You can back up and restore your Management subsystem in your VMware environment.

### About this task

---

The Backup and Restore solution supports Backup and Restore to and from remote cloud-based S3 storage, such as IBM Cloud Object Storage, or AWS S3, and also to and from Local Backups. Local Backups can be stored remotely on an sftp server, and retrieved later from the sftp server for restore operations. For steps on uploading local-backup files to an sftp server, and for downloading local-backup files from a sftp server for the purposes of a restore, see [Using an sftp server for backup files on VMware](#).

Important: For S3 backups of the management subsystem, do not use retention features provided by Cloud-based S3 storage providers. Use of such features can result in periodic deletion of archived backups, which can cause backup corruptions which can cause database restores to fail.

Restoring a backup restores the registration credentials (`client_ID`, `client_secret`) that were in use at the time that the selected backup was created. For information on the registration credentials, see [Changing the registration client\\_id and client\\_secret for applications](#).

Note: You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.

### Procedure

---

- Configure your Management subsystem backup
  1. Create a file `management-extra-values.yaml` with the following content

```
spec:
 databaseBackup:
 s3provider: ibm
 host: s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard
 path: apic-backup
 retries: 0
 credentials: mgmt-backup-secret
 schedule: "0 3 * * *"
```

- All of your settings must be added in the `spec` section of the file; if the section doesn't exist, create it now.
- `s3provider`: is the name of the S3 provider to use. This supports either `aws` or `ibm`.
- `host`: is the S3 endpoint with the corresponding S3 region in the format `<S3endpoint>/<S3region>`.
- `path`: is the name of your S3 bucket to store backup data.

Note:

- The use of subdirectories in the bucket name is not supported.
- Ensure that `bucket-name/folder` is empty. If the folder was previously used for backups, the folder will not be empty, and stanza create might encounter an error.

**Explanation:** Once a folder is used, `archive.info` and `backup.info` files are created. During stanza creation, the process compares the database version and database system id between the two info files and the current Postgres database cluster. Stanza creation fails if there is a mismatch. To prevent this possibility, remove all files from the folder before configuring.

- `retries`: is the number of times `ibm-apiconnect` reattempts backups if a SFTP backup fails.
- `credentials`: is the name of the Kubernetes secret that contains your S3 Access Key and S3 Access Key Secret that you created.
- `schedule`: is the schedule for how often automatic Management subsystem backups are run. The format for the schedule is any valid cron string. The timezone for backups is UTC.

Note: For local-storage backups only, `s3provider`, `host`, `path`, and `credentials` can be omitted.

2. Execute the following command to add the extra values file to the subsystem:

```
apicup subsys set <management_subsystem> extra-values-file <path_to_management-extra-values.yaml_file>
```

3. Complete the remainder of the installation steps for the management subsystem, and create an ISO file. See [Deploying the Management subsystem](#).

4. Create your Management subsystem backup secret.

The backup secret is a Kubernetes secret that contains your username and password for your backup database (sftp/s3). Only password-based authentication is supported for sftp and s3, not authentication based on public certificates and private keys. Password-based authentication for s3 requires that you generate an access key and secret. For example:

- IBM (Cloud Object Storage): [Service credentials](#).
  - AWS: [Managing access keys](#).
- a. Enter the following command to connect to the management subsystem using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.

b. Select Yes to continue connecting, and once connected:

```
sudo -i
```

c. The secret can be created with the following command:

```
$ kubectl create secret generic mgmt-backup-secret --from-literal=key='<YOUR ACCESS KEY>' --from-literal=keysecret='<YOUR ACCESS KEY SECRET>'
```

5. When configuring s3 type backups, verify that the configuration succeeded. See [Verify configuration for s3 backup](#).

- How to configure a scheduled backup.

1. Connect to the management subsystem using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.

2. Get necessary credentials:

```
sudo -i
```

3. Edit the `schedule` option in your `management-extra-values.yaml` file to specify the time that you want the backup to be taken. The format for the `schedule` option is any valid cron string.

```
spec:
 databaseBackup:
 s3provider: ibm
 host: s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard
 path: apic-backup
 retries: 0
 credentials: mgmt-backup-secret
 schedule: "0 3 * * *"
```

Note: All scheduled Management subsystem backups are of type `full` only.

- How to generate a manual backup.

You can use these steps to configure a Management subsystem with backups that use IBM's Cloud Object Storage S3 or AWS S3.

Decide which of the two types of manual backups you want to do:

- `full`: backs up the entire Management subsystem database.
- `incr`: backs up any data that has not been backed up since the last `full` or `incr` backup.

1. Connect to the management subsystem using SSH:

```
ssh ip_address -l apicadm
```

2. Get necessary credentials:

```
sudo -i
```

3. You generate a backup manually by creating a `databaseBackup custom` resource which is detected by the `ibm-apiconnect` operator that then triggers the backup process.

You can use `mgmtbackup_cr.yaml` in the `helper_files` directory as an example:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementBackup
metadata:
 generateName: mgmt-backup-
spec:
 type: full
 crType: create
 clusterName: management
```

- `type`: is the type of backup to be done. Valid arguments are:
  - `full`
  - `incr`
- `crType`: Specifies the type of backup CR to be created: `create` or `record`. Use `create` to trigger a backup process. When the backup is created, the operator generates another backup CR with `crType: record`, which represents the actual stored backup that you can use for a restore operation.
- `clusterName`: is the name of the target ManagementCluster you want to backup.

4. Create the `databaseBackup custom` resource in the `namespace` of your Management subsystem to trigger the backup process:

```
$ kubectl create -f mgmtbackup_cr.yaml -n <ns-of-mgmt-subsystem>
```

5. Optional: You can list current backups by using the command:

```
$ kubectl get managementbackup -n <ns-of-mgmt-subsystem> --sort-by=.metadata.creationTimestamp
```

Here is an example of some possible output:

| NAME              | STATUS   | ID               | CLUSTER              | SUBSYSTEM | TYPE | CR TYPE | AGE   |
|-------------------|----------|------------------|----------------------|-----------|------|---------|-------|
| mgmt-backup-29gfl | Complete | 20200518-134003F | m1-240a96a9-postgres | m1        | full | record  | 3m28s |
| mgmt-backup-4tnnh | Complete | 20200518-131002F | m1-240a96a9-postgres | m1        | full | create  | 3m31s |

6. Optional: You can get a detailed view of a specific backup by using the command:

```
$ kubectl get managementbackup <bup-name> -n <ns-of-mgmt-subsystem> -o yaml
```

Here is an example of some possible output:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementBackup
metadata:
 creationTimestamp: "2020-05-12T18:23:00Z"
 generateName: mgmt-backup-
 generation: 1
 name: mgmt-backup-4nrpq
 namespace: default
 resourceVersion: "11918"
 selfLink: /apis/management.apiconnect.ibm.com/v1beta1/namespaces/default/managementbackups/mgmt-backup-4nrpq
 uid: a16498cc-b233-49df-a8c1-6b6c251c8e04
spec:
 crType: record
 type: full
status:
 clusterName: m1-6dc5fa49-postgres
 conditions:
 - lastTransitionTime: "2020-05-12T18:25:36Z"
 message: Complete
 status: "True"
 type: Ready
 id: 20200512-182307F
 info:
 id: 20200512-182307F
 range: 2020-05-12 19:23:07 +0100 IST - 2020-05-12 19:25:05 +0100 IST
 rangeEnd: 1589307905
 rangeStart: 1589307787
 size: 56.3 MB
 totalsize: 56.3 MB
 type: full
 subsysName: m1
```

- How to restore a Management subsystem.  
To restore from a backup, see [Restoring the management subsystem on VMware](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Verify configuration for s3 backup

Verify that the configuration for s3 backups succeeded.

### About this task

When you configure Management subsystem backups, the operator runs a `stanza-create` job. This job creates the stanza (Postgres cluster configuration) on the upstream S3 server, which is used for backup and archive procedures. The job also brings up the necessary pod.

### Procedure

1. SSH into the management appliance.
2. Check the status of the `stanza-create` job:

```
kubectl get jobs -n <namespace> | grep stanza
```

- On success:
  - The `stanza-create` job status is 1/1:
 

```
kubectl get jobs | grep stanza
m1-b722e361-postgres-stanza-create 1/1 5s 127m
```

- The `stanza-create` job shows `status: "True"` and `type:`  
`Complete:`

```
kubectl get job m1-b722e361-postgres-stanza-create -o yaml

status:
 completionTime: "2021-04-13T18:38:50Z"
 conditions:
 - lastProbeTime: "2021-04-13T18:38:50Z"
 lastTransitionTime: "2021-04-13T18:38:50Z"
 status: "True"
 type: Complete
```

```
startTime: "2021-04-13T18:38:45Z"
succeeded: 1
```

- The `stanza-create` pod is in `Completed` state:

```
kubectl get pods | grep stanza
ml-b722e361-postgres-stanza-create-q4fvp 0/1 Completed 0 127m
```

- Exec into the pod:

```
kubectl exec -it <backrest-shared-repo-pod> -- bash
```

- The `pgbackrest` command returns the S3 contents in valid JSON:

```
pgbackrest info --output json --repo1-type s3
```

```
"backup": {"held": false}, "message": "ok"}] [pgbackrest@ml-b722e361-postgres-backrest-shared-repo-69cdfdfd5-rs882 /
```

- On failure, see [Troubleshooting failure of stanza-create job for S3 backup configuration](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Restoring the management subsystem on VMware

You can restore your Management subsystem in your VMware environment.

### Before you begin

You must have backups of the management subsystem in order to restore. See [Backing up the Management subsystem in a VMware environment](#).

### About this task

To trigger a restore, you will create a `ManagementRestore` custom resource. When the `ibm-apiconnect` operator detects the new CR, it starts the restore process.

- Ensure that the backup method that you used is complete before you attempt a restore. The backup data that is stored in the remote server is used for restoring the Management subsystem data back to a previous state. Ensure that these backups are on your remote server before you attempt a restore, and that the backup ID in the selected backup exists in remote storage.
- Restoring a backup restores the registration credentials (`client_ID`, `client_secret`) that were in use at the time that the selected backup was created. For information on the registration credentials, see [Changing the registration client id and client secret for applications](#).
- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.

Note: There is a known issue where sometimes a restore from the Management subsystem's SFTP backup succeeds but the data is not restored. If this happens, run the restore again.

### Procedure

1. Connect to the management subsystem using SSH:

```
ssh ip_address -l apicadm
```

2. Get necessary credentials:

```
sudo -i
```

3. Obtain a list of the available backups, and decide which one to restore your Management subsystem:

```
kubectl get mgmtb -n <your-namespace>
```

For example:

```
$ kubectl get mgmtb
NAME STATUS ID CLUSTER TYPE CR TYPE AGE
management-3aa3bebf Ready 20200929-152150F management full record 10h
management-3c4ca8df Ready 20200929-115520F management full record 20h
management-5tbxj Ready 20200929-224349F management full create 17h
management-f10af337 Ready 20200925-133703F management full record 5d2h
management-jt1cd Ready 20200929-224349F management full create 25h
management-zxjtz Ready 20200929-224349F management full create 28h
```

Attention: You can restore the Management subsystem from any backup where the STATUS is Ready; however, you should avoid restoring to the initial system backup. During installation, the Management database is used for an initial system backup before certain database schema jobs are complete. Restoring to this backup will result in an unstable system.

You will use one of the values in the `NAME` column.

4. Optional: If a local-backup file stored on an sftp server is to be used for the restore operation, the file must be downloaded to the Management Subsystem first. See [Downloading backup files from an sftp server](#).
5. Trigger a restore by creating the `ManagementRestore` custom resource.

Note that the Management subsystem must be deployed with the databaseBackup subsection configured in order for the ibm-apiconnect operator to detect ManagementRestore and then trigger the restore process.

- a. Identify the backup you wish to restore to by running the following command:

```
kubectl get mgmtb -n <your-namespace>
```

```
$ kubectl get mgmtb -n apic
```

| NAME                | STATUS | ID               | CLUSTER    | TYPE | CR TYPE | AGE  |
|---------------------|--------|------------------|------------|------|---------|------|
| management-3aa3bebf | Ready  | 20200929-152150F | management | full | record  | 10h  |
| management-3c4ca8df | Ready  | 20200929-115520F | management | full | record  | 20h  |
| management-5tbxj    | Ready  | 20200929-224349F | management | full | create  | 17h  |
| management-f10af337 | Ready  | 20200925-133703F | management | full | record  | 5d2h |
| management-jtlcd    | Ready  | 20200929-224349F | management | full | create  | 25h  |
| management-zxjtz    | Ready  | 20200929-224349F | management | full | create  | 28h  |

Note: You can restore the Management subsystem from any backup where the **STATUS** is **Ready**.  
Select the backup to restore and get the Point-in-Time-Recovery target for the selected backup:

```
$ kubectl get mgmtb management-3aa3bebf -o jsonpath="{.status.info.range}"
2020-09-29 15:21:50 +0000 UTC - 2020-09-29 15:30:56 +0000 UTC
```

The target for recovery is the second half of the **range** value in the backup custom resource, such as 2020-09-29 15:30:56 +0000.

To get a valid **pitrTarget**, it must be later than the value obtained above (for example, +1 second) and in the format **YYYY-MM-DD HH:MM:SS+Z**.

For example, 2020-09-29

15:30:56 +0000 in **range** becomes 2020-09-29 15:30:57+00 as **pitrTarget**.

- b. You can use mgmtrestore\_cr.yaml in the helper\_files directory as an example:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementRestore
metadata:
 generateName: management-
spec:
 backupName: management-3aa3bebf
 pitrTarget: "2020-09-30 13:53:21+00"
```

- **backupName**: is the name of backup custom resource you want to restore to.
- **pitrTarget**: is the time you want to restore to in format **YYYY-MM-DD HH:MM:SS+Z**

6. Create the ManagementRestore custom resource in the namespace of the Management Subsystem to trigger the restore process:

```
$ kubectl create -f mgmtrestore_cr.yaml -n <your-namespace>
```

7. You can list current restores using the following command:

```
$ kubectl get managementrestore -n <your-namespace> --sort-by=.metadata.creationTimestamp
```

Here is an example of some possible output:

| NAME             | STATUS   | BACKUP            | CLUSTER | PITR                   | AGE |
|------------------|----------|-------------------|---------|------------------------|-----|
| management-6nzjr | Complete | mgmt-backup-dg4s4 | m1      | 2020-01-05 19:05:00+01 | 14m |

8. Note that the operator creates an upgrade CR when the postgres database is restarted during restore.

Example message:

```
managementdbupgrade.management.apiconnect.ibm.com/m1-up-zqkk5 Complete Fresh install is Complete (DB Schema/data are up-to-date)
63s5s
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Modifying the DatabaseBackup configuration on VMware

You can modify the **DatabaseBackup** configuration in the Management Cluster CR.

### About this task

Modifying the **DatabaseBackup** configuration requires a reconfiguration of the database and a brief downtime.

### Procedure

1. Connect to the management subsystem using SSH:

```
ssh ip_address -l apicadm
```

2. Get necessary credentials:

```
sudo -i
```

### 3. Edit the management CR

```
protocol: objstore
databaseBackup:
s3provider: ibm
host: s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard
path: apic-backup
credentials: mgmt-backup-secret
schedule: "0 3 * * *"
restartDB:
 accept: true
```

Note:

If you have an APICoconnectCluster custom resource installed, do not modify the ManagementCluster CR. Instead, modify the APICoconnectCluster CR.

You can verify if you have an `apiconnectcluster` CR with the command

```
$ kubectl get apiconnectcluster -n <your-namespace>
```

- A new parameter `restartDB` is required when changing the backup configuration.
- When `accept` is `true` and the new configuration differs, the Operator stops the database and any dependent services, applies the change, and restarts the stopped components.
- `restartDB` is not required for initial deployments, only for modifications after the cluster is deployed.
- Operator restarts the database with new backup configurations.
- Operator creates an upgrade CR because postgres db is re-created as part of database backup configuration change.
- The new upgrade CR goes to completed as soon postgres comes up.
- For example:

When you change database backup configurations after upgrading API Connect, the operator restarts all components related to the postgres database. The operator also creates an upgrade CR, and reaches the completed state as soon as all postgres database components, such as `pgbouncer` and the postgres database, are in `Running` state

| NAME                                                          | STATUS   | MESSAGE                                                   |
|---------------------------------------------------------------|----------|-----------------------------------------------------------|
| A                                                             |          |                                                           |
| GE                                                            |          |                                                           |
| managementdbupgrade.management.apiconnect.ibm.com/m1-up-g6lcb | Complete | Upgrade is Complete (DB Schema/data are up-to-date)       |
| 1                                                             |          |                                                           |
| 6m                                                            |          |                                                           |
| managementdbupgrade.management.apiconnect.ibm.com/m1-up-zqkk5 | Complete | Fresh install is Complete (DB Schema/data are up-to-date) |

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Using an sftp server for backup files on VMware

The sftp backup script enables you to upload and download Postgres backups for the Management Subsystem to and from an sftp server.

The script resides on the Postgres Backrest Repo Pod known as the Backup and Restore Pod. The script is invoked by using the Kubernetes interactive shell (`exec`) on the script with appropriate parameters. The script can use password or SSH key for sftp server authentication.

Backup files stored on the sftp server are named according to ID of the **latest** backup available in:

```
/backrestrepo/<pg cluster>-backrest-shared-repo/backup/db/.
```

The names of these backups align with IDs found in `kubectl get mgmtb` lists. For example:

```
$ kubectl get mgmtb
NAME STATUS ID CLUSTER SUBSYSTEM TYPE CR TYPE AGE
mgmt-backup-8hqgq Ready 20200826-161301F m1-dc1-postgres m1 full record 127m
mgmt-backup-fbz6w Ready 20200826-162422F m1-dc1-postgres m1 full record 116m
mgmt-backup-1lhqz Ready 20200826-154646F m1-dc1-postgres m1 full record 153m
mgmt-backup-rwgp2 Ready 20200826-160010F m1-dc1-postgres m1 full record 140m
mgmt-backup-tfj95 Ready 20200826-152658F m1-dc1-postgres m1 full record 173m
```

```
$ ls -l /backrestrepo/m1-dc1-postgres-backrest-shared-repo/backup/db/
total 8
drwxr-s--- 3 pgbackrest 26 72 Aug 26 15:27 20200826-152658F
drwxr-s--- 3 pgbackrest 26 72 Aug 26 15:47 20200826-154646F
drwxr-s--- 3 pgbackrest 26 72 Aug 26 16:00 20200826-160010F
drwxr-s--- 3 pgbackrest 26 72 Aug 26 16:13 20200826-161301F
drwxr-s--- 3 pgbackrest 26 72 Aug 26 16:24 20200826-162422F
drwxr-s--- 3 pgbackrest 26 18 Aug 26 15:27 backup.history
-rw-r----- 1 pgbackrest 26 3288 Aug 26 16:24 backup.info
-rw-r----- 1 pgbackrest 26 3288 Aug 26 16:24 backup.info.copy
lrwxrwxrwx 1 pgbackrest 26 16 Aug 26 16:24 latest -> 20200826-162422F
```

In this example, the file stored on the sftp server is `20200826-162422F.tar`.

The script also has the ability to list the backup files available on the sftp server.

When the script is invoked to download a selected file, the contents of the `/backrestrepo` directory in the Backup and Restore Pod are replaced with the contents of the backup file. A `ManagementRestore` custom resource can be created, pointing to the relevant backup name that relates to the backup ID, in order to perform a restore.

For example:

```
$ cat mgmtrestore_cr.yaml
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementRestore
metadata:
 generateName: mgmt-restore-
spec:
 backupName: mgmt-backup-fbz6w

$ kubectl create -f mgmtrestore_cr.yaml
```

The sftp backup script has the following parameters:

```
$ /sftp/backup.sh --help
usage: backup.sh ACTION OPTIONS...
ACTION:
 [-l|--list] list backup files available remotely
 [-d|--download] download backup file from remote system
 [-u|--upload] upload backup file to remote system (default)
OPTIONS:
 -H|--host host to upload backup to
 [-P|--port] port for upload protocol. (default 22)
 -d|--DIRECTORY directory to upload to
 -u|--username username to use for upload
 [-p|--password] password to use for upload
 [-k|--key] ssh key to use for upload
 [-r|--retries] number of retries if there is a failure
 [-n|--name] name of the backup compressed file (default last backup-id)
 [-h|--help] help
```

There is error checking to ensure that the script cannot be invoked while there is a Postgres backup already in progress, or if the sftp script is already in use.

- [Setting up the backup script](#)  
You can prepare for using the backup script by setting up a private key for the sftp session and setting environment variables.
- [Listing backup files on the sftp server](#)  
You can list the available backup files on the sftp server.
- [Uploading backup files to an sftp server](#)  
You can upload backup files from the Backup and Restore Pod to the sftp server.

You can download a specific backup file from the sftp server to the Backup and Restore Pod.
- [Removing a backup file from the listing](#)  
You can remove a backup file from the list of backup files available for downloading for restore.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Setting up the backup script

You can prepare for using the backup script by setting up a private key for the sftp session and setting environment variables.

### Procedure

---

1. Run the following command to connect to the management subsystem as the API Connect administrator.

```
ssh ip_address -l apicadm
```

2. Select Yes to continue connecting, and once connected, get necessary credentials:

```
sudo -i
```

3. Setup a Private Key for sftp Session.
  - a. Create an RSA SSH key. For example, the following command can be used to generate an SSH key with the required RSA encryption:

```
ssh-keygen -t rsa -m pem
```

Note the directory in which the generated `id_rsa` and `id_rsa.pub` files reside.

The generated key needs to be uploaded to the Backup and Restore Pod by adding the key to the `postgres-backrest-repo-config` Kubernetes secret.

- b. Use the following command to determine the name of the secret:

```
kubectl get secrets -n <namespace> | grep postgres-backrest-repo-config | awk '{print $1}'
```

Replace `<namespace>` with the namespace where the Management Subsystem resides. If you are using the default namespace, you can omit `-n <namespace>`.

- c. Use the following command to add the key to the secret:

- MacOS

```
kubectl patch secret <postgres-backrest-repo-config secret name> \
-p="{\"data\":{\"sftp-key\": \"$(cat <path-to-key>/id_rsa | base64)\"}}\" \
-n <namespace>
```

- Linux

```
kubectl patch secret <postgres-backrest-repo-config secret name> \
 -p="{\"data\":{\"sftp-key\": \"$(cat <path-to-key>/id_rsa | base64 -w0)\"} }\" \
 -n <namespace>
```

Note that on Linux an extra `-w0` flag is required to the base64 script to ensure that there are no extra line breaks added to the property.

The SSH key will be automatically uploaded to the Backup and Restore Pod as file `/sshd/sftp-key`. This can take a few seconds.

- d. The `id_rsa.pub` file needs to be added to the `authorized_keys` file, on the sftp server, for the username that the sftp session uses. **SSH** to the sftp server with the following command:

```
ssh <sftp username>@<sftp server>
```

Enter the password when prompted.

Change to the `.ssh` directory of the sftp user. For example, `cd /root/.ssh`.

Append the contents of the `id_rsa.pub` to the `authorized_keys` file.

4. Complete the following setup steps for the sftp script:
- Determine the name of the Backup and Restore Pod, using the following command:

```
export POD=$(kubectl get pods -n <namespace> | grep backrest-shared-repo | awk '{print $1}')
```

- Set the following environment parameters either on the client machine or in the Pod:

```
export HOST=<sftp server hostname>
export DIRECTORY=<sftp backup directory on sftp server>
export USERNAME=<sftp session username>
export PASSWORD=<sftp session password> # if ssh key is not being used
```

## Results

You can now use the sftp script:

- [Listing backup files on the sftp server](#)
- [Uploading backup files to an sftp server](#)
- [Downloading backup files from an sftp server](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Listing backup files on the sftp server

You can list the available backup files on the sftp server.

## Procedure

- Run the following command to connect to the management subsystem as the API Connect administrator.

```
ssh ip_address -l apicadm
```

- Select Yes to continue connecting, and once connected, get necessary credentials:

```
sudo -i
```

- Authenticate by using the sftp key:

```
kubectl exec $POD -n <namespace> -- bash -c "/sftp/backup.sh -L -H $HOST -u $USERNAME -k /sshd/sftp-key -d $DIRECTORY"
```

- Alternatively, authenticate using username/password:

```
kubectl exec $POD -n <namespace> -- bash -c "/sftp/backup.sh -L -H $HOST -u $USERNAME -p $PASSWORD -d $DIRECTORY"
```

- Alternatively, if running within the interactive shell of the Backup and Restore Pod:

```
/sftp/backup.sh -L -H $HOST -u $USERNAME -k /sshd/sftp-key -d $DIRECTORY
/sftp/backup.sh -L -H $HOST -u $USERNAME -p $PASSWORD -d $DIRECTORY
```

## Example

```
$ /sftp/backup.sh -L -H $HOST -u $USERNAME -k /sshd/sftp-key -d $DIRECTORY
drwxr-xr-x 2 root root 90 Aug 26 09:21 .
drwxrwxrwt 10 root root 198 Aug 26 09:45 ..
-rw-r--r-- 1 root root 13092333 Aug 26 08:56 20200826-154646F.tgz
-rw-r--r-- 1 root root 18703758 Aug 26 09:10 20200826-160010F.tgz
-rw-r--r-- 1 root root 24318561 Aug 26 09:21 20200826-161301F.tgz
```

These files correspond to the IDs of `mgmtb` backup instances.

## What to do next

[Downloading backup files from an sftp server](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Uploading backup files to an sftp server

You can upload backup files from the Backup and Restore Pod to the sftp server.

### About this task

For a description of the full process for generating backups, see [Configuring backup settings for fresh install of the Management subsystem \(10.0.1.1-eus or later\)](#).

### Procedure

- Run the following command to connect to the management subsystem as the API Connect administrator.

```
ssh ip_address -l apicadm
```

- Select Yes to continue connecting, and once connected, get necessary credentials:

```
sudo -i
```

- Authenticate using the sftp key:

```
kubectl exec $POD -n <namespace> -- bash -c "/sftp/backup.sh -U -H $HOST -u $USERNAME -k /sshd/sftp-key -d $DIRECTORY"
```

- Alternatively, authenticate using username/password:

```
kubectl exec $POD -n <namespace> -- bash -c "/sftp/backup.sh -U -H $HOST -u $USERNAME -p $PASSWORD -d $DIRECTORY"
```

- Alternatively, if running within the interactive shell of the Backup and Restore Pod:

```
/sftp/backup.sh -U -H $HOST -u $USERNAME -k /sshd/sftp-key -d $DIRECTORY
/sftp/backup.sh -U -H $HOST -u $USERNAME -p $PASSWORD -d $DIRECTORY
```

### Example

```
$ /sftp/backup.sh -U -H $HOST -u $USERNAME -k /sshd/sftp-key -d $DIRECTORY
Starting upload of backup 20200826-162422F.tgz using protocol sftp
% Total % Received % Xferd Average Speed Time Time Time Current
 Dload Upload Total Spent Left Speed
0 0 0 0 0 32.7M 0 11.4M ---:--:-- 0:00:02 ---:--:-- 11.4M
0 0 0 0 0 32.7M 0 11.4M ---:--:-- 0:00:02 ---:--:-- 11.4M
Finished uploading backup
Successful backup
```

File 20200826-162422F.tgz relates to the backup instance with that ID.

```
$ kubectl get mgmtb | grep 20200826-162422F
mgmt-backup-fbz6w Ready 20200826-162422F m1-dc1-postgres m1 full record 165m
```

The backup file for backup with ID 20200826-162422F can now be found on the sftp server:

```
$ /sftp/backup.sh -L -H $HOST -u $USERNAME -k /sshd/sftp-key -d $DIRECTORY
drwxr-xr-x 2 root root 118 Aug 26 12:04 .
drwxrwxrwt 10 root root 198 Aug 26 09:45 ..
-rw-r--r-- 1 root root 13092333 Aug 26 08:56 20200826-154646F.tgz
-rw-r--r-- 1 root root 18703758 Aug 26 09:10 20200826-160010F.tgz
-rw-r--r-- 1 root root 24318561 Aug 26 09:21 20200826-161301F.tgz
-rw-r--r-- 1 root root 34315393 Aug 26 12:04 20200826-162422F.tgz
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Downloading backup files from an sftp server

You can download a specific backup file from the sftp server to the Backup and Restore Pod.

### About this task

In the following commands, note that you use the `-n <backup file name>` parameter to specify a particular backup file.

## Procedure

- Run the following command to connect to the management subsystem as the API Connect administrator.

```
ssh ip_address -l apicadm
```

- Select Yes to continue connecting, and once connected, get necessary credentials:

```
sudo -i
```

- Authenticate using the sftp key:

```
kubectl exec $POD -n <namespace> -- bash -c "/sftp/backup.sh -D -H $HOST -u $USERNAME \
-k /sshd/sftp-key -d $DIRECTORY -n <backup file name>"
```

- Alternatively, authenticate using username/password:

```
kubectl exec $POD -n <namespace> -- bash -c "/sftp/backup.sh -D -H $HOST -u $USERNAME \
-p $PASSWORD -d $DIRECTORY -n <backup file name>"
```

- Alternatively, if running within the interactive shell of the Backup and Restore Pod:

```
/sftp/backup.sh -D -H $HOST -u $USERNAME -k /sshd/sftp-key \
-d $DIRECTORY -n <backup file name>
/sftp/backup.sh -D -H $HOST -u $USERNAME -p $PASSWORD \
-d $DIRECTORY -n <backup file name>
```

## Example

This example restore an earlier backup from the sftp server and makes it available for restore. Use the `pgbackrest info` command within the Backup and Restore Pod to list the available backups known to Postgres Backrest Repo:

```
$ pgbackrest info
stanza: db
 status: ok
 cipher: none

db (current)
 wal archive min/max (12-1): 000000010000000000000001/000000050000000000000097

 full backup: 20200826-152658F
 timestamp start/stop: 2020-08-26 15:26:58 / 2020-08-26 15:27:23
 wal start/stop: 000000010000000000000002 / 000000010000000000000002
 database size: 31MB, backup size: 31MB
 repository size: 3.7MB, repository backup size: 3.7MB

 full backup: 20200826-154646F
 timestamp start/stop: 2020-08-26 15:46:46 / 2020-08-26 15:47:11
 wal start/stop: 000000020000000000000006 / 000000020000000000000006
 database size: 31MB, backup size: 31MB
 repository size: 3.7MB, repository backup size: 3.7MB

 full backup: 20200826-160010F
 timestamp start/stop: 2020-08-26 16:00:10 / 2020-08-26 16:00:36
 wal start/stop: 000000030000000000000009 / 000000030000000000000009
 database size: 31MB, backup size: 31MB
 repository size: 3.7MB, repository backup size: 3.7MB

 full backup: 20200826-161301F
 timestamp start/stop: 2020-08-26 16:13:01 / 2020-08-26 16:13:29
 wal start/stop: 00000004000000000000000C / 00000004000000000000000C
 database size: 31MB, backup size: 31MB
 repository size: 3.7MB, repository backup size: 3.7MB

 full backup: 20200826-162422F
 timestamp start/stop: 2020-08-26 16:24:22 / 2020-08-26 16:24:48
 wal start/stop: 00000005000000000000000F / 00000005000000000000000F
 database size: 31MB, backup size: 31MB
 repository size: 3.7MB, repository backup size: 3.7MB
```

The last full backup is 20200826-162422F.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Removing a backup file from the listing

You can remove a backup file from the list of backup files available for downloading for restore.

## Procedure

1. Run the following command to connect to the management subsystem as the API Connect administrator.

```
ssh ip_address -l apicadm
```

2. Select Yes to continue connecting, and once connected, get necessary credentials:

```
sudo -i
```

3. List the available Backup Files on the sftp server:

```
$/sftp/backup.sh -L -H $HOST -u $USERNAME -k /sshd/sftp-key -d $DIRECTORY
drwxr-xr-x 2 root root 118 Aug 26 12:04 .
drwxrwxrwt 10 root root 198 Aug 26 09:45 ..
-rw-r--r-- 1 root root 13092333 Aug 26 08:56 20200826-154646F.tgz
-rw-r--r-- 1 root root 18703758 Aug 26 09:10 20200826-160010F.tgz
-rw-r--r-- 1 root root 24318561 Aug 26 09:21 20200826-161301F.tgz
-rw-r--r-- 1 root root 34315393 Aug 26 12:04 20200826-162422F.tgz
```

The last full backup is 20200826-162422F. In this example, we will remove this file from the valid backup list.

4. Choose and download 20200826-161301F.tgz from the available backup files on the sftp server.

Note that this backup file does not include 20200826-162422F, which is the one to be removed:

```
$/sftp/backup.sh -D -H $HOST -u $USERNAME -k /sshd/sftp-key -d $DIRECTORY -n 20200826-161301F.tgz
Starting download of backup 20200826-161301F.tgz using protocol sftp
% Total % Received % Xferd Average Speed Time Time Time Current
 Dload Upload Total Spent Left Speed
100 23.1M 100 23.1M 0 0 15.9M 0 0:00:01 0:00:01 --:--:-- 15.9M
100 23.1M 100 23.1M 0 0 15.9M 0 0:00:01 0:00:01 --:--:-- 15.9M
Successful download
```

The contents of the /backrestrepo directory in the Backup and Restore Pod will now be replaced with the contents of the 20200826-161301F.tgz backup file.

5. Run pgbackrest info within the Backup and Restore Pod to show the backups:

```
$ pgbackrest info
stanza: db
status: ok
cipher: none

db (current)
wal archive min/max (12-1): 000000010000000000000001/000000040000000000000002

full backup: 20200826-152658F
timestamp start/stop: 2020-08-26 15:26:58 / 2020-08-26 15:27:23
wal start/stop: 00000001000000000000000002 / 00000001000000000000000002
database size: 31MB, backup size: 31MB
repository size: 3.7MB, repository backup size: 3.7MB

full backup: 20200826-154646F
timestamp start/stop: 2020-08-26 15:46:46 / 2020-08-26 15:47:11
wal start/stop: 00000002000000000000000006 / 000000020000000000000006
database size: 31MB, backup size: 31MB
repository size: 3.7MB, repository backup size: 3.7MB

full backup: 20200826-160010F
timestamp start/stop: 2020-08-26 16:00:10 / 2020-08-26 16:00:36
wal start/stop: 00000003000000000000000009 / 000000030000000000000009
database size: 31MB, backup size: 31MB
repository size: 3.7MB, repository backup size: 3.7MB

full backup: 20200826-161301F
timestamp start/stop: 2020-08-26 16:13:01 / 2020-08-26 16:13:29
wal start/stop: 0000000400000000000000000C / 00000004000000000000000C
database size: 31MB, backup size: 31MB
repository size: 3.7MB, repository backup size: 3.7MB
```

Backup 20200826-162422F is no longer an option for restoration.

A ManagementRestore custom resource can now be created to perform a Restore to any of these backups. For more information, see [Restoring the management subsystem \(10.0.1.1-eus or later\)](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Workaround for scheduling and retaining local backups on management subsystem on VMware

Use an extra-values file to schedule local backups and set retention parameters for the management subsystem on VMware deployments.

### About this task

You cannot use the apicup utility to specify the schedule or the retention parameters for local backups for the management subsystem on VMware. You can use an extra-values file to workaround this limitation.

## Procedure

1. Create, or edit if one already exists, a subsystem extra-values file in the **apicup** management project directory, and enter the following configuration details:

```
spec:
 databaseBackup:
 schedule: <value>
 repoRetentionFull: <value>
```

The **schedule** field specifies when backups are run. The **repoRetentionFull** property specifies the number of backups to retain. For more information, see [Configuring backup settings during initial installation of the management subsystem \(10.0.1.1-eus or greater\)](#).

2. Save the extra-values file with a filename of your choice, but it must have a .yaml or .yml extension.
3. Use **apicup** to update the VMware **extra-values-file** attribute to point to the new or updated management subsystem extra-values file:

```
apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
```

Where:

- **<mgmt\_subsystem\_name>** is the name of the subsystem that you are configuring.
- **<extra\_values\_file\_path\_and\_name>** is the fully qualified path and name of your extra-values file.

For example:

```
apicup subsys set ds10-management extra-values-file /workspace/v10011/my_extra_values.yaml
```

4. Verify that the configuration settings are valid in the apiconnect-up.yaml by running the following command:

```
apicup subsys get <mgmt_subsystem_name> --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.

5. Update the management VMware with the updated setting.

```
apicup subsys install <subsystem_name>
```

6. Monitor the health-check output until the management subsystem is healthy by running the following command:

```
apicup subsys health-check <mgmt_subsystem_name>
```

When all of the health criteria are successfully met, the command displays no output, and exits with a status of 0.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Backing up and restoring the Developer Portal in a VMware environment

You can back up and restore your Developer Portal service in your VMware environment.

### About this task

Note: You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.

To complete a backup and restore of your Developer Portal, you must have a file portal-extra-values.yaml that is configured with the **portalBackup** subsection.

Backups can be scheduled or generated manually (on-demand). You can then list what backups are available and then use one to restore your Developer Portal if required.

The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

---

## Procedure

- Configure your Developer Portal subsystem backup.
  1. Create a file portal-extra-values.yaml with the following content:

```
spec:
 portalBackup:
 credentials: portal-backup-secret
 host: s3.eu-gb.cloud-object-storage.apdomain.cloud/eu-standard
 path: test-bucket/restore-test
 port: 443
 protocol: objstore
 schedule: '* /5 * * * *'
```

- All of your settings must be added in the **spec**: section of the file.
- **host**: is the S3 endpoint with the corresponding S3 region in the format **<S3endpoint>/<S3region>**.
- **path**: is the name of your S3 bucket to store backup data.
- **port**: is the port for the protocol to connect to the host.
- **protocol**: is the protocol that is used to communicate with your remote backup endpoint. Specify one of the following values:

- **sftp** - for secure file transfer protocol.
- **objstore** - for S3 compatible object storage.
- **schedule** - is the schedule for how often automatic Developer Portal backups are run. The format for the schedule is any valid cron string. The timezone for backups is UTC.
- **credentials** - is the name of the secret you created.

Note: If edits to the **portalBackup** section are needed after installation, you can modify the `portal-extra-values.yaml` file and apply the changes to the Appliance cluster by using the command:

```
apicup subsys install portal_subsystem
```

2. Run the following command to add the extra values file to the subsystem:

```
apicup subsys set portal_subsystem extra-values-file path_to_portal-extra-values.yaml_file
```

3. Complete any remaining installation steps for your Developer Portal subsystem, and create an ISO file. For more information, see [Deploying the Developer Portal](#).

4. Create your Developer Portal subsystem backup secret.

The backup secret is a Kubernetes secret that contains your username and password for your backup database (sftp/s3). Only password-based authentication is supported for sftp and s3, not authentication based on public certificates and private keys. Password-based authentication for s3 requires that you generate an access key and secret. For example:

- IBM (Cloud Object Storage): [Service credentials](#).
  - AWS: [Managing access keys](#).
- a. Enter the following command to connect to the Developer Portal subsystem by using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of `apicadm`, which is the API Connect ID that has administrator privileges.

- b. Select Yes to continue connecting, and when connected:

```
sudo -i
```

- c. The secret can be created with the following command:

```
$ kubectl create secret generic portal-backup-secret --from-literal=username='<YOUR ACCESS KEY>' --from-literal=password='<YOUR ACCESS KEY SECRET>'
```

- How to configure a scheduled backup.

1. Edit the **schedule** option in your `portal-extra-values.yaml` file to be the time that you want the backup to be taken. The format for the **schedule** option is any valid cron string.

```
spec:
 portalBackup:
 credentials: portal-backup-secret
 host: s3.eu-gb.cloud-object-storage.apptomain.cloud/eu-standard
 path: test-bucket/restore-test
 port: 443
 protocol: objstore
 backupCerts: <custom-s3-server-CA-cert>
 schedule: '*/5 * * * *'
```

- How to generate a manual backup.

You can use these steps to configure a Developer Portal with backups that use IBM's Cloud Object Storage S3 or AWS S3.

Decide which of the three types of manual backups you want to do:

- **all**: backs up the Developer Portal system and all its sites to the remote server
- **system**: backs up the Developer Portal system to the remote server
- **site**: backs up a Developer Portal site to the remote server

1. Connect to the Developer Portal subsystem by using SSH:

```
ssh ip_address -l apicadm
```

2. Get necessary credentials:

```
sudo -i
```

3. You generate a backup manually by creating a **portalBackup custom resource** that is detected by the **ibm-apiconnect** operator that then triggers the backup process.

You can use `portalbackup_cr.yaml` in the `helper_files` directory as an example:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalBackup
metadata:
 generateName: portal-bup-
spec:
 type: all
 crType: create
 comment: "test comment"
```

- **type**: is the type of backup to be done. Valid arguments are:
  - **all**
  - **system**
  - **site**
- **crType**: Use **create** to trigger a backup process. When the backup is created, the operator generates another backup CR with **crType**: **record**, which represents the stored backup that you can use for a restore operation.
- **comment**: you can optionally add a comment to the CR before you create a backup.
- **siteName**: used only when you take a site backup. Valid arguments are:

- site uuid or url - back up that site only to the remote server
- **installed** - backups all installed sites to the remote server

4. Create the `PortalBackup custom resource` in the `namespace` of your Developer Portal to trigger the backup process:

```
kubectl create -f portalbackup_cr.yaml
```

5. Optional: You can list current backups by using the command:

```
kubectl get portalbackup
```

Here is an example of some possible output:

| NAME         | ID              | STATUS   | TYPE   | CR TYPE | AGE   | COMMENT |
|--------------|-----------------|----------|--------|---------|-------|---------|
| p1-bup-gqz8f | 20200526.142449 | Complete | system | record  | 55m   |         |
| p1-bup-jx4vc | 20200526.142458 | Complete | site   | record  | 54m   |         |
| p1-bup-st412 |                 | Complete | all    | create  | 56m   | y       |
| p1-bup-th2dm |                 | Complete | all    | create  | 4h51m | y       |

Tip: If you want to order your `portalbackups` by ID, you can use the Kubernetes keyword `--sort-by`. For example:

```
kubectl get pb --sort-by=.status.backupId
```

6. Optional: You can get a detailed view of a specific backup by using the command:

```
kubectl get portalbackup <bup-name> -o yaml
```

Here is an example of some possible output:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalBackup
metadata:
 creationTimestamp: "2020-05-26T14:24:37Z"
 generateName: portal-bup-

- How to list available Developer Portal backups on remote server.

1. Connect to the portal subsystem by using SSH:

```
ssh ip_address -l apicadm
```

2. Get necessary credentials:

```
sudo -i
```

3. Run the command:

```
kubectl get portalbackups
```

Here is an example of some possible output:

```
kubectl get portalbackup
```

| NAME         | ID              | STATUS   | TYPE   | CR TYPE | AGE   | COMMENT |
|--------------|-----------------|----------|--------|---------|-------|---------|
| p1-bup-gqz8f | 20200526.142449 | Complete | system | record  | 55m   |         |
| p1-bup-jx4vc | 20200526.142458 | Complete | site   | record  | 54m   |         |
| p1-bup-st412 |                 | Complete | all    | create  | 56m   | y       |
| p1-bup-th2dm |                 | Complete | all    | create  | 4h51m | y       |

Note: You can only restore the Portal subsystem from backups where the `CR TYPE` is `record`.

Optionally, if you need more information, such as the name of the `.tgz` file that you can run, use command:

```
kubectl get portalbackups <bup-name> -o yaml
```

Here is an example of some possible output:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalBackup
metadata:
 creationTimestamp: "2020-05-26T18:21:24Z"
 generateName: portal-bup-

```

- How to restore a Developer Portal subsystem.

Ensure that the backup method that you used is complete before you attempt a restore. The backup data that is stored in the remote server is used for restoring the Developer Portal subsystem data back to a previous state. Ensure that these backups are on your remote server before you attempt a restore.

There are three types of restores:

- **all**: restores the Developer Portal system and all the sites that are found on the remote server by using the latest backup.
- **system**: restores the Developer Portal system to the remote server
- **site**: restores the Developer Portal site from the remote server

1. Connect to the portal subsystem by using SSH:

```
ssh ip_address -l apicadm
```

2. Get necessary credentials:

```
sudo -i
```

3. Decide on the options to use for your **PortalRestore custom resource**. The **PortalRestore custom resource** is detected by the **ibm-apiconnectoperator** that then triggers the backup process.

You can use `portalrestore_cr.yaml` in the `helper_files` directory as an example:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalRestore
metadata:
 generateName: portal-restore-
spec:
 type: all
 dryRun: true
 timestamp: now
```

- **type**: is the type of restore to be done. Valid arguments are:
  - **all**
  - **system**
  - **site**
- **siteName**: used only when you took a site backup. Valid arguments are:
  - **ID**, for example `20200526.142458`: the backup ID of a portal backup CR. The ID must be taken from a portal backup that is of **type site**, and **crType record**.
  - **site-1234.tgz**: restore the site by using this file name that exists on the local file system or remote server.
  - **myportal.com**: find the latest backup for this URL (locally or remotely) and restore it.
  - **all**: restore all sites that are found on the remote server by using the latest backup.
  - **site** **uuid** or **url** - back up that site only to the remote server
  - **installed** - backups all installed sites to the remote server.
- **systemName** - Valid arguments are:
  - **ID**, for example `20200526.142449`: the backup ID of a portal backup CR. The ID must be taken from a portal backup that is of **type system**, and **crType record**.
  - **system\_backup-1234.tgz**: restores the system from the given file that exists on the pod's local file system or the remote server.
  - **latest**: restores from latest system backup that is found from either local file system or remote server.
- **timestamp** - Valid arguments are:
  - **now**: use the latest backups available.
  - **< TIMESTAMP >**: in '**YYYY-MM-DD HH:MM:SS**' format, specify a timestamp to retrieve the backup from. The nearest backup, searching backwards from this timestamp, is used.

Note: From IBM® API Connect Version 10.0.1.4-ifix1-eus, the timestamp format changed to **YYYYMMDD.HHMMSS**. For Version 10.0.1.2-eus and earlier, the timestamp format is **YYYY-MM-DD HH:MM:SS**.
- **dryRun** - Valid arguments are:
  - **true**: runs a dry run of the command, returning the actions that will be taken. These actions can be found in the custom resource by following step 4.
  - **false**: runs the command, restoring and replacing the system files and all sites. Any existing sites are reinstalled.

Table 1. The options that are needed for each Developer

## Portal restore

|            | all | system | site |
|------------|-----|--------|------|
| type       | X   | X      | X    |
| siteName   |     |        | X    |
| systemName |     | X      |      |
| timestamp  | X   |        |      |
| dryRun     | X   |        |      |

4. Create the `PortalRestore` custom resource in the namespace of the Developer Portal subsystem to trigger the restore process:

```
kubectl create -f portalrestore_cr.yaml
```

5. Optional: You can list current restores by using the command:

```
kubectl get portalrestore
```

Here is an example of some possible output:

```
NAME READY AGE
portal-restore-twjrp Running 28s
```

6. Optional: You can get a detailed view of a specific restore by using the command:

```
kubectl get portalrestore <restore-name> -o yaml
```

Here is an example of some possible output:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalRestore

```

- Troubleshooting

1. Connect to the portal subsystem by using SSH:

```
ssh ip_address -l apicadm
```

2. Get necessary credentials:

```
sudo -i
```

3. Check the Developer Portal backup CR or restore CR.

Use command:

```
kubectl get <portalbackup/portalrestore> <bup-name/restore-name> -o yaml
```

Here is an example of some possible output:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalRestore
metadata:
 creationTimestamp: "2020-05-26T13:10:46Z"
 generateName: portal-restore-
 generation: 1
 name: portal-restore-x2bf9
 namespace: default
 resourceVersion: "1493471"
```

```
selfLink: /apis/portal.apiconnect.ibm.com/v1beta1/namespaces/portal/portalrestores/portal-restore-x2bf9
uid: 9f6ale22-55ab-4595-8b98-bdfaec40d58c
spec:
 type: site
status:
 backupId: ""
 commentLeft: ""
 conditions:
 - lastTransitionTime: "2020-05-26T13:10:49Z"
 message: |
 Please provide a site to restore. To restore all sites use value 'all' in the CR
 status: Failed
 type: Ready
 fullBackupName: ""
 id: ""
 message: ""
```

Read the message inside the conditions of the Developer Portal backup CR or the restore CR.

#### 4. Retrieving logs

Look for information in the logs of the `ibm-apiconnect` pod:

- Locate the `ibm-apiconnect` pod with:

```
kubectl get pods
```

- View the logs with:

```
kubectl logs <ibm-apiconnect-pod-NAME>
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Backing up and restoring the analytics database on VMware

The IBM® API Connect Analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required; for example, IBM Cloud Object Storage.

### About this task

Before you can initiate a backup or restore operation, you must update the Analytics CR (custom resource) to configure your settings. Generating a backup for Analytics can be performed on a scheduled basis or manually as needed. You can deploy a restore CR to start the restoration of a previously generated backup. To work with CRs, you need to log in to the virtual machine with an SSH tool.

- [Configuring backup settings for Analytics](#)  
Configure the IBM API Connect Analytics subsystem on VMware to support backing up and restoring the Analytics database.
- [Running a backup of the Analytics database](#)  
Deploy the `analyticsbackup_cr.yaml` CR to initiate a backup of the IBM API Connect Analytics database on VMware.
- [Restoring the Analytics database](#)  
Deploy the `analyticsrestore_cr.yaml` CR to initiate restoration of a backup of the IBM API Connect Analytics database on VMware.
- [Troubleshooting Analytics backup and restore](#)

If you encounter problems when backing up or restoring the IBM API Connect Analytics database on VMware, review the following troubleshooting tips.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Configuring backup settings for Analytics

Configure the IBM® API Connect Analytics subsystem on VMware to support backing up and restoring the Analytics database.

### About this task

The Analytics database can be backed up and restored from an S3 repository. S3-compatible object storage is required; for example, IBM Cloud Object Storage. Generating a backup for Analytics is performed on demand by creating the a backup CR (custom resource). You can create a restore CR to start the restoration of a previously generated backup.

Note: You can only run one backup or restore process at a time.

### Procedure

1. Use SSH to log into the virtual machine:
  - a. Run the following command to connect as the API Connect administrator.

```
ssh ip_address -l apicadm
```

b. When prompted, select Yes to continue connecting.

2. Create the analytics backup secret for your S3-compatible storage:

a. Obtain an access key and corresponding access key secret from your S3 provider.

For example, you might obtain the key and secret from one of the following providers, using the instructions found on their sites:

- [IBM Cloud Object Storage](#)
- [AWS](#)

b. Create the Kubernetes secret by running the following command and filling in your access key, access key secret, and namespace:

```
kubectl create secret generic analytics-backup-secret --from-literal=username='Your_Access_Key' --from-literal=password='Your_access_key_secret' -n Namespace_of_Analytics_Subsystem
```

3. Use the `apicup` utility with an extra-values file to configure backup settings:

a. On the server where you run the `apicup` utility, create a file named `analytics-extra-values.yaml` with the following content:

```
spec:
 databaseBackup:
 credentials: analytics-backup-secret
 host: s3.eu-gb.cloud-object-storage.appdomain.cloud
 path: my-s3-bucket/apic-analytics-backups
 backupCerts: <custom-s3-server-CA-cert>
 schedule: "0 2 * * *"
 enableCompression: true
 chunkSize: 1GB
 enableServerSideEncryption: false
```

where:

- `credentials` is the name of the Kubernetes secret you created in step 1

- `host` is the S3 endpoint with the corresponding S3 region in the format:

```
s3.s3region.s3domain
```

Attention: A path style host value (formatted as `S3endpoint/S3region`) is not supported.

- `path` is a combination of the S3 bucket and the base path within the bucket, using the format: `bucket_name/path`

- (S3 storage only) `backupCerts` is the name of a custom certificate that contains your upstream custom S3 CA certificate. Supported beginning with 10.0.1.2-eus.

Used only when `s3Provider` is set to `custom`. Most of the custom S3 providers are created based on custom CA certificates.

This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be `ca.crt` and the value is the base64-encoded value of the CA certificate.

If the server certificate that is presented by your S3/object-store endpoint is signed by a well known CA and includes any intermediate certificates in the chain, then you do not need to provide the CA certificate using this feature because the Analytics subsystem already trusts the server certificate. You can test this by configuring the Analytics backup to your S3/object-store server without providing the CA certificate.

If you do need to provide the CA certificate then you must provide the entire chain in the `ca.crt` member of the secret, as follows:

```
intermediate-certificate-1
intermediate-certificate-2
.
.
intermediate-certificate-n
root-certificate
```

Where the first certificate in the `ca.crt` member (`intermediate-certificate-1`) is the issuer of the S3/object-store server certificate, and each subsequent certificate in the

`ca.crt` member is the issuer of the preceding certificate. The root certificate in the `ca.crt` member must be self-signed.

If there are no intermediate certificates involved, then the `ca.crt` member contains only the root certificate.

The following sample bash script creates the Kubernetes secret:

```
cat >customs3ca.yaml <<EOF
apiVersion: v1
data:
 ca.crt: $(base64 <path-to-ca-certificate> | tr -d '\n')
kind: Secret
metadata:
 name: custom-server-ca
type: generic
EOF

kubectl apply -f customs3ca.yaml -n <namespace>
```

- Optional: `schedule` determines how often backups will be invoked automatically. The format for the schedule is any valid `cron` string. The timezone for backups is UTC.

- Optional: `enableCompression` determines whether metadata files are stored in compressed format. Default value is true.

- Optional: `chunkSize` specifies how large files are stored. Large files can be stored as chunks when the snapshot is created. This setting specifies the size of the chunks as GB, MB, or KB. Default value is 1GB.

- Optional: `enableServerSideEncryption` determines whether files are encrypted. When set to true, files are encrypted on the server side using AES256. Default value is false.

b. Run the following command to add the `analytics-extra-values.yaml` file to your system:

```
apicup subsys set <analytics_subsystem> extra-values-file <path_to_analytics-extra-values.yaml_file>
```

c. Run the following command to propagate the modified settings to the Appliance cluster:

```
apicup subsys install <analytics_subsystem>
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Running a backup of the Analytics database

Deploy the analyticsbackup\_cr.yaml CR to initiate a backup of the IBM® API Connect Analytics database on VMware.

### Before you begin

---

[Configure backup settings for Analytics.](#)

### About this task

---

A backup is triggered by creating the analyticsbackup\_cr.yaml CR. The new CR is detected by the `ibm-apiconnect` operator, which requests a new backup.

### Procedure

---

1. Connect to the management subsystem using SSH:
  - a. Run the following command to connect as the API Connect administrator.

```
ssh ip_address -l apicadm
```

- b. When prompted, select Yes to continue connecting.
- c. Get the necessary credentials:

```
sudo -i
```

2. Create the `AnalyticsBackup` CR for your deployment in a file called `analyticsbackup_cr.yaml`.  
The following code shows the sample `analyticsbackup_cr.yaml`, which is stored in the `helper_files` directory:

```
apiVersion: analytics.apiconnect.ibm.com/v1beta1
kind: AnalyticsBackup
metadata:
 generateName: a7s-bup-
spec:
 crType: create
 comment: "test comment"
 indices:
 - ui
 enableIgnoreUnavailable: true
```

3. In your copy of the CR, update the following settings:
  - `crType` - set `create` to trigger a backup process. When the backup is created, the operator generates another backup CR with `crType: record`, which represents the stored backup that you can use for a restore operation.
  - Optional: `indices` - A list of index names or keywords, indicating which indices you want to back up. If no indices are specified, then all indices are backed up. The following supported keywords are mapped to indices or aliases in Elasticsearch:
    - `all` - Backup all data. This is equivalent to listing all of the remaining keywords (`apievents`, `ui`, `config`).
    - `apievents` - Backup all analytics data.
    - `ui` - Backup all UI visualizations and dashboards.
    - `config` - Backup all configuration information, such as the retention period.
  - Optional: `enableIgnoreUnavailable` - Default value is `false`. If set to `false`, the backup fails if a specified index is not present. If set to `true`, missing indices are skipped and the backup continues.
4. Deploy your CR by running the following command to create it in the namespace for your Analytics subsystem:

```
kubectl create -f analyticsbackup_cr.yaml -n namespace
```

where `namespace` is the name of the Analytics namespace.

The backup's name and ID are generated when the backup operation runs.

5. To get a list of available backups, run the following command:

```
kubectl get analyticsbackup -n namespace
```

The response looks like the following example:

| NAME                | STATUS | ID                                   | CR TYPE | INDICES               | AGE | COMMENT |
|---------------------|--------|--------------------------------------|---------|-----------------------|-----|---------|
| a7s-bup-266p8       | Ready  |                                      | create  | [all]                 | 20h | y       |
| a7s-bup-pffdh       | Ready  |                                      | create  | [all]                 | 34h | y       |
| analytics-bup-kxwq5 | Ready  | analytics-all-2020-09-07t03:49:15utc | record  | [ui apievents config] | 34h |         |
| analytics-bup-p29z8 | Ready  | analytics-all-2020-09-07t18:04:03utc | record  | [ui apievents config] | 20h |         |

6. Display the details for a particular backup by running the following command:  
Use the backup name from the results in step 4.

```
kubectl get analyticsbackup backup_NAME -n namespace -o yaml
```

The result looks like the following example:

```
apiVersion: analytics.apiconnect.ibm.com/v1beta1
kind: AnalyticsBackup
metadata:
 creationTimestamp: "2020-05-20T16:18:05Z"
 generateName: a7s-bup-
 generation: 1

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Restoring the Analytics database

Deploy the analyticsrestore\_cr.yaml CR to initiate restoration of a backup of the IBM® API Connect Analytics database on VMware.

---

### Before you begin

[Create a backup.](#)

---

### About this task

A restore operation is triggered by creating the analyticsrestore\_cr.yaml CR. The new CR is detected by the `ibm-apiconnect` operator, which requests a restore of the specified backup.

Note: You can only run one backup or restore process at a time.

---

### Procedure

1. Connect to the management subsystem using SSH:
  - a. Run the following command to connect as the API Connect administrator.

```
ssh ip_address -l apicadm
```

- b. When prompted, select Yes to continue connecting.
- c. Get the necessary credentials:

```
sudo -i
```

2. Get a list of available backups by running the following command:

```
kubectl get analyticsbackup -n namespace
```

where `namespace` is the name of the Analytics namespace.

The response looks like the following example. Note down the ID of the backup that you want to restore.

| NAME                | STATUS | ID                                   | CR TYPE | INDICES               | AGE | COMMENT |
|---------------------|--------|--------------------------------------|---------|-----------------------|-----|---------|
| a7s-bup-266p8       | Ready  |                                      | create  | [all]                 | 20h | y       |
| a7s-bup-pffdh       | Ready  |                                      | create  | [all]                 | 34h | y       |
| analytics-bup-kxwq5 | Ready  | analytics-all-2020-09-07t03:49:15utc | record  | [ui apievents config] | 34h |         |
| analytics-bup-p29z8 | Ready  | analytics-all-2020-09-07t18:04:03utc | record  | [ui apievents config] | 20h |         |

3. Get the ID of the backup that you want to restore:

Note: You can only restore the Analytics subsystem from backups where the `CR TYPE` is `record`.

```
kubectl describe a7b analytics-bup-kxwq5 -n namespace
```

where:

- `analytics-bup-kxwq5` is the NAME of a backup of CR type `record`
- `namespace` is the name of the Analytics namespace

The response looks like the following example. Note down the ID.

```
Successful: 7}}}
```

```
Id: analytics-all-2020-09-07t03:49:15utc
Phase: Ready
State:
```

4. Create the `AnalyticsRestore` CR for your deployment in a file called `analyticsrestore_cr.yaml`. The following code shows the sample `analyticsrestore_cr.yaml`, which is stored in the `helper_files` directory:

```
apiVersion: analytics.apiconnect.ibm.com/v1beta1
kind: AnalyticsRestore
metadata:
 generateName: a7s-restore-
spec:
 indices:
 - ui
 backupID: analytics-all-2020-09-07t03:49:15utc
 enableIgnoreUnavailable: true
 enableOverride: false
```

5. In your copy of the CR, update the following settings:
  - `indices` - A list of index names or keywords, indicating which indices you want to back up. If no indices are specified, then all indices are backed up. The following supported keywords are mapped to indices or aliases in Elasticsearch:
    - `all` - Restore all data. This is equivalent to listing all of the remaining keywords (`apievents`, `ui`, `config`).
    - `apievents` - Restore all analytics data.
    - `ui` - Restore all UI visualizations and dashboards.
    - `config` - Restore all configuration information, such as the retention period.
  - `backupID` - The ID of the backup to be restored, which you obtained in step 3.
  - `enableIgnoreUnavailable` - Default value is `false`. If set to `false`, the restore fails if a specified index is not present in the backup identified by the `backupID`. If set to `true`, missing indices are skipped and the restore continues.
  - `enableOverride` - Default value is `false`. If set to `true`, then the restore overrides existing indices.
6. Deploy your CR by running the following command to create it in the namespace for your Analytics subsystem:

```
kubectl create -f analyticsrestore_cr.yaml -n Namespace_of_Analytics_Subsystem
```

The restore name is generated when the restore operation runs.

7. To get a list of restores, run the following command:

```
kubectl get analyticsrestore -n namespace
```

The response looks like the following example.

| NAME              | STATUS  | ID                                   | AGE |
|-------------------|---------|--------------------------------------|-----|
| a7s-restore-9z4fr | Warning | analytics-all-2020-09-07t03:49:15utc | 47h |

8. Display the details for a particular restore by running the following command: Use the restore name from the results in step 6.

```
kubectl get analyticsrestore restore_NAME -n namespace -o yaml
```

The result looks like the following example:

```
apiVersion: analytics.apiconnect.ibm.com/v1beta1
kind: AnalyticsRestore
metadata:
 creationTimestamp: "2020-10-21T15:06:03Z"
 generateName: a7s-restore-
 generation: 1
 name: a7s-restore-9z4fr
 namespace: my-namespace
 resourceVersion: "975152"
 selfLink: /apis/analytics.apiconnect.ibm.com/v1beta1/namespaces/my-namespace/analyticsrestores/a7s-restore-9z4fr
 uid: fdda9105-17ab-44ac-83de-852620a4dcde
spec:
 backupID: analytics-all-2020-09-07t03:49:15utc
 enableIgnoreUnavailable: false
 enableOverride: true
 indices:
 - ui
status:
 conditions:
 - lastTransitionTime: "2020-10-21T18:07:05Z"
 message: WARNING
 status: Warning
 type: Ready
 details: |
 &{NumberOfDataNodes:1
 Status:yellow
 ActivePrimaryShards:23
 ActiveShards:23
 RelocatingShards:0
 InitializingShards:0
```

```
UnassignedShards:40
PendingTasks:0}
id: analytics-all-2020-09-07t18:04:03utc
```

When the restore is successfully started, the **status: condition** section displays **Running**. If the restore does not start correctly, the **status: condition** section displays **Failed**.

The restore process is successful when the storage cluster status is green, there are no unassigned shards, and there are no initializing shards. At that time the **status: condition** section displays **Complete**. If **status: Complete** is not achieved after 3 hours, the status changes to **Warning** and the details are no longer updated.

Attention:

- For deployment profiles with fewer than 3 storage nodes, the restore process is never marked as **Complete**. The storage cluster status is expected to be yellow and to have more than 0 unassigned shards. In this situation, the restore process is likely to be complete when there are 0 initializing shards.
- When you restore v2018 data after upgrading the development profile, there will be a short delay before the restored data displays in the Analytics user interfaces.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Troubleshooting Analytics backup and restore

If you encounter problems when backing up or restoring the IBM® API Connect Analytics database on VMware, review the following troubleshooting tips.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

### Check the CR status

---

Look for messages in the **status** section of the backup or restore CR by running the following command:

```
kubectl get analytics[backup|restore] restore|backup_NAME -n namespace -o yaml
```

where:

- You specify whether to retrieve the **analyticsbackup** CR or the **analyticsrestore** CR
- **restore|backup\_NAME** is the name that is generated when you initially deploy the backup or restore CR.
- **namespace** is the namespace where Analytics is deployed.

For example:

```
kubectl get analyticsbackup a7s-bup-gb6s5 -n analytics -o yaml
```

### Check the logs

---

Look for information in the logs of the **ibm-apiconnect** pod:

1. Run the following command to connect as the API Connect administrator.

```
ssh ip_address -l apicadm
```

2. Locate the **ibm-apiconnect** pod by running the following command:

```
kubectl get pods -n namespace
```

3. View the logs with:

```
kubectl logs ibm-apiconnect-pod-NAME -n namespace
```

If there is a problem with your **databaseBackup** configuration, there are messages with the label "error" to indicate the problem

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Troubleshooting management subsystem backups on VMware

You can troubleshoot failures of the management subsystem backups.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its

associated management server, but the Git information is based on where it was downloaded from.  
See:

- [Troubleshooting resiliency issues](#)  
Resolve resiliency issues with API Connect management system backups.
- [Troubleshooting stanza-create job for S3 backup configuration](#)  
Troubleshoot configuration of s3 backups when the stanza-create job fails.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Troubleshooting resiliency issues

Resolve resiliency issues with API Connect management system backups.

---

### pgbackrest-shared-repo resiliency problems

If the Kubernetes node hosting pgbackrest-shared-repo pod is down and the PVC attached to the pod has strict zone requirements (for example, in AWS or other clouds) or if the storage class is set to `local-storage`, then pgbackrest-shared-repo pod will not get rescheduled to another Kubernetes node.

As a result, there is a single point of failure and the following conditions might occur:

- Backups of the management database fails
- Disk space fills with accumulated Postgres WAL (Write-Ahead Logging) files

To avoid this problem, monitor the disk usage: [Monitoring Postgres disk usage](#).

When the Kubernetes node comes back up, the pod is scheduled and all the processes should resume properly.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Troubleshooting stanza-create job for S3 backup configuration

Troubleshoot configuration of s3 backups when the stanza-create job fails.

When you configure Management subsystem backups for s3 providers, the operator runs a `stanza-create` job. This job creates the stanza (Postgres cluster configuration) on the upstream S3 server, which is used for backup and archive procedures. The job also brings up the necessary pod.

SSH into the appliance VM, and check the status of the `stanza-create` job:

```
kubect1 get jobs -n <namespace> | grep stanza
```

On failure:

- `stanza-create` pods fail, and job status is 0/1:

```
kubect1 get jobs | grep stanza
m1-3bfe12ac-postgres-stanza-create 0/1 32m 32m
```

- Listing all pods brought up by `stanza-create` job shows multiple pods because a job tries `backoffLimit` times to complete the job. By default, there will be 7 pods in error state:

```
kubect1 get pods | grep stanza
m1-3bfe12ac-postgres-stanza-create-726z4 0/1 Error 0 11m
m1-3bfe12ac-postgres-stanza-create-9vq4n 0/1 Error 0 22m
m1-3bfe12ac-postgres-stanza-create-gbtgb 0/1 Error 0 30m
m1-3bfe12ac-postgres-stanza-create-g15g5 0/1 Error 0 17m
m1-3bfe12ac-postgres-stanza-create-q8qhw 0/1 Error 0 26m
m1-3bfe12ac-postgres-stanza-create-t84zs 0/1 Error 0 8m54s
m1-3bfe12ac-postgres-stanza-create-z8tfs 0/1 Error 0 12m
```

Note: In some cases, the pods are cleaned by Kubernetes and the logs of these pods can be lost.

- Pod log errors show a reason for the failure. For example, when a hostname is not valid:

```
kubect1 logs m1-3bfe12ac-postgres-stanza-create-gbtgb

time="2021-04-13T20:01:19Z" level=info msg="pgo-backrest starts"
time="2021-04-13T20:01:19Z" level=info msg="debug flag set to false"
time="2021-04-13T20:01:19Z" level=info msg="backrest stanza-create command requested"
time="2021-04-13T20:01:19Z" level=info msg="s3 flag enabled for backrest command"
time="2021-04-13T20:01:19Z" level=info msg="command to execute is [pgbackrest stanza-create --db-host=192.1.2.3 --db-path=/pgdata/m1-3bfe12ac-postgres --repo1-type=s3]"
```

```
time="2021-04-13T20:01:19Z" level=info msg="command is pgbackrest stanza-create --
db-host=192.1.1.2.3 --db-path=/pgdata/m1-3bfe12ac-postgres --repol-type=s3 "
time="2021-04-13T20:05:21Z" level=error msg="command terminated with exit code 49"
time="2021-04-13T20:05:21Z" level=info msg="output=[] "
```

- Job status is set to `type: Failed` and `status: "True"`, with reason: `BackoffLimitExceeded`:

```
kubectl get job m1-3bfe12ac-postgres-stanza-create -o yaml

status:
 conditions:
 - lastProbeTime: "2021-04-13T20:28:03Z"
 lastTransitionTime: "2021-04-13T20:28:03Z"
 message: Job has reached the specified backoff limit
 reason: BackoffLimitExceeded
 status: "True"
 type: Failed
 failed: 7
 startTime: "2021-04-13T20:01:18Z"
```

- If pod logs are lost, you can execute a command inside the `backrest-shared-repo` pod:
  1. Obtain the `backrest-shared-repo` pod name:

```
kubectl get pods -n <namespace> | grep backrest-shared-repo
```

For example:

```
kubectl get pods | grep backrest-shared-repo
m1-eb8edc18-postgres-backrest-shared-repo-98dd46cc6-tw195 1/1 Running
```

2. Exec into the pod:

```
kubectl exec -it <backrest-shared-repo-pod> -- bash
```

3. Run:

```
pgbackrest info --output json --repol-type s3
```

For example, for invalid hostname:

```
ERROR: [049]: unable to get address for 'test1-v10-backup.s3.exampleaws.com': [-2] Name or service not knownCopy
```

The exact **ERROR**: will vary depending on the misconfiguration. Common errors:

- Invalid access key
- Invalid access key secret
- Invalid bucket region
- Invalid bucket or folder path

- To fix the incorrect settings, see:
  - For 10.0.1.1-eus or greater: [Reconfiguring backup settings for the management subsystem \(10.0.1.1-eus or greater\)](#)
  - For 10.0.1.0-eus or earlier: [Backing up the Management subsystem in a VMware environment](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Disaster recovery

Prepare for disaster events and recover API Connect on VMware if a disaster event occurs.

You must complete preparation steps prior to a disaster in order to recover API Connect on VMware.

The backups that you create for disaster recovery are for recovery of the API Connect subsystems in the same environment that the backups were taken, or in a different environment that has the same network configuration, API Connect form factor and deployment topology. You cannot use backups to move an API Connect installation to a different environment that has different endpoints.

Note: For information about how to maintain a two data center deployment, including failover and recovery procedures, see [Maintaining a two data center deployment](#).

- [Preparing for a disaster](#)  
Prepare your API Connect deployment for disaster recovery in a VMware environment.
- [Recovering from a disaster](#)  
Recover the API Connect subsystems on VMware.
- [Using VM snapshots for infrastructure backup and disaster recovery](#)  
You can use VM snapshots to backup and restore the infrastructure used by API Connect on VMware, and also for infrastructure disaster recovery.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Preparing for a disaster

Prepare your API Connect deployment for disaster recovery in a VMware environment.

- Successful disaster recovery of API Connect depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. The preparation steps for Management subsystem differ for each v10.x version of API Connect, and also for backup types (S3 or SFTP). Use the instructions for your version and backup type.
- The preparation steps for the Developer Portal subsystem are the same for all v10 versions.
- The preparation steps for the Analytics subsystem are the same for all v10 versions.
- [Preparing the management subsystem for disaster recovery on VMware](#)  
Prepare the API Connect Management subsystem for disaster recovery in a VMware environment.
- [Preparing the Developer Portal subsystem for disaster recovery on VMware](#)  
Prepare a Developer Portal subsystem for disaster recovery by taking specific steps immediately after the installation of the subsystem.
- [Preparing the Analytics subsystem for disaster recovery on VMware](#)  
Prepare the API Connect Analytics subsystem for disaster recovery in a VMware environment.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Preparing the management subsystem for disaster recovery on VMware

Prepare a Management subsystem for disaster recovery by taking specific steps before and after the installation of the subsystem.

### About this task

---

- This task must be performed before any disaster event occurs, and also prior to the installation of a replacement Management subsystem during the recovery process. Best practice is to complete these steps immediately after initial configuration of a management subsystem during your original v10 deployment.
- Any **local** backups are presumed to have been lost in the disaster scenario and are non-recoverable in this procedure.

Note: This procedure is for API Connect version 10.0.1.2-eus or higher. For 10.0.1.1-eus, see [Preparing the management subsystem for disaster recovery on VMware using S3 backups \(10.0.1.1-eus\)](#). For 10.0.1.0-eus, see [Preparing the management subsystem for disaster recovery on VMware \(10.0.1.0-eus\)](#).

Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

### Procedure

---

1. Download `v10_ova_dr_files-<version>.tgz` from IBM Fix Central.
2. Uncompress this file to access `dr-preparation-py.zip`. Uncompress the zip, which contains a Python script that you will use to capture important information. For example:

```
$ unzip dr-preparation.py.zip
```

3. Copy (`scp`) the Python script to the management system, and run it:

```
python3 dr-preparation
```

The script creates the output file `apicup-commands.txt` with commands that you will use later to create the secrets necessary to recover the management subsystem.

Example output when the script runs without error:

```
apicup certs set management atm-credential --encoded-string '<encoded_string>'
apicup certs set management consumer-toolkit-credential --encoded-string '<encoded_string>'
apicup certs set management designer-credential --encoded-string '<encoded_string>'
apicup certs set management toolkit-credential --encoded-string '<encoded_string>'
apicup certs set management juhu-credential --encoded-string '<encoded_string>'
apicup certs set management consumer-ui-credential --encoded-string '<encoded_string>'
apicup certs set management ui-credential --encoded-string '<encoded_string>'
apicup certs set management encryption-secret --encoded-string '<encoded_string>'
apicup subsys set management site-name='<site_name>'
```

Note: If any of the secrets are missing, the script will display an error message. You must resolve the errors before continuing, or you cannot successfully recover from a disaster event.

4. Save the `apicup-commands.txt` to your local machine for later reference.

5. Backup your version 10 management subsystem:

- For backup configuration, see [Configuring backup settings during initial installation of the management subsystem \(10.0.1.1-eus or greater\)](#).
- If scheduled backups were configured during backup configuration, you should have access to a backup on the specified cloud storage.
- You can perform a manual backup at any time by creating a manual backup CR. See [Backing up the management subsystem](#).

6. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVA's and restoring from normal backups.

Important: VM snapshots are not an alternative to the standard backups that are described in the previous steps, and which must be taken in order to use the API Connect restore feature.

## What to do next

You should now complete the preparation steps for the Developer Portal subsystem; see [Preparing the Developer Portal subsystem for disaster recovery on VMware](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Preparing the management subsystem for disaster recovery on VMware using S3 backups (10.0.1.1-eus)

Prepare a Management subsystem for disaster recovery from S3 backups by taking specific steps before and after the installation of the subsystem.

### About this task

- This task must be performed before any disaster event occurs, and also prior to the installation of a replacement Management subsystem during the recovery process. Best practice is to complete these steps immediately after initial configuration of a management subsystem during your original version 10 deployment.
- This procedure is designed to work with S3 backup storage only. To prepare for disaster recovery using SFTP backups, see [Preparing the management subsystem for disaster recovery on VMware using SFTP backups \(10.0.1.1-eus\)](#).
- Any `local` backups are presumed to have been lost in the disaster scenario and are non-recoverable in this procedure.

Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

### Procedure

1. Confirm that you have access to the Kubernetes cluster on your Management Appliance:

a. Log onto a Management Appliance node:

```
ssh -i ~/.ssh/id_rsa -o CheckHostIP=no apicadm@example.hostname.com
sudo -i
```

b. Confirm you are able to run `kubectl` commands against your Kubernetes cluster

```
$ kubectl get nodes
NAME STATUS ROLES AGE VERSION
apimdevr0050 Ready master 6h17m v1.16.8
apimdevr0068 Ready master 6h13m v1.16.8
apimdevr0089 Ready master 6h10m v1.16.8
```

2. After installation, you must back up essential Kubernetes secrets that are used by the Management subsystem.

The Kubernetes secrets are created during installation. You must save these in case a restore is needed after a disaster has occurred. At that time, you will use them in the setup of the restored Management subsystem:

- a. Obtain and save the Management database encryption secret.  
Use the following command to find the name of the secret in the status of the Management Subsystem. Replace `<namespace>` with the namespace used for the subsystem installation:

```
kubectl get mgmt -n <namespace> -o yaml | grep encryption
```

The output of this command shows the name of the Kubernetes secret storing the database encryption key, for example:

```
encryptionSecret: management-enc-key
```

In this case, the name of the Management database encryption secret is `management-enc-key`. Use the following command to back up this secret locally:

```
kubectl get secret management-enc-key -n <namespace> -o yaml > management_enc_key.yaml
```

The secret is stored in a file called `management_enc_key.yaml`, located in the present working directory.

- b. Obtain and save the Management client application credential secrets.  
As part of [Installing the Management subsystem](#), you must store a set of credentials for Disaster Recovery. These credentials are required to ensure that users can log in to API Connect after recovering the database, as these credentials cannot be reconstituted by a new Management subsystem.

Important: If you do not have these credentials, Disaster Recovery is not possible.

- i. Use the following command to find the names of the secrets in the status of the Management subsystem:

```
kubectl get mgmt -n <namespace> -o yaml | grep CredentialSecret
```

The output of this command shows the names of the Kubernetes Secrets used to store the various client application credentials. For example:

```
atmCredentialSecret: management-atm-cred
consumerToolkitCredentialSecret: management-ccli-cred
consumerUICredentialSecret: management-cui-cred
designerCredentialSecret: management-dsgr-cred
juhuCredentialSecret: management-juhu-cred
toolkitCredentialSecret: management-cli-cred
uiCredentialSecret: management-ui-cred
```

Here, for example, the name of the ATM Client Application Credential Secret is `management-atm-cred`.

- ii. Next, back up all of the secrets locally. Use the following command for each listed Credential Secret, replacing `<secret_name>` with the secret name listed each time:

```
kubectl get secret <secret_name> -n <namespace> -o yaml > <secret_name>.yaml
```

For example, use the following command to backup the ATM Client Credential Secret:

```
kubectl get secret management-atm-cred -n <namespace> -o yaml > management-atm-cred.yaml
```

- iii. Once you have saved each of these client application Credential Secrets locally, open each of the YAML files saved for each secret in turn. Remove both the `ownerReferences` subsection and the `selfLink` property. Re-save the file.

For example, the `ownerReferences` and `selfLink` properties to be removed appear in the YAML files similar to the following:

```
ownerReferences:
- apiVersion: management.apiconnect.ibm.com/v1beta1
 blockOwnerDeletion: true
 controller: true
 kind: ManagementCluster
 name: management
 uid: 623e6b20-7eb8-46ce-94ac-6b64cd71afc4
selfLink: /api/v1/namespaces/default/secrets/management-atm-cred
```

- c. Ensure that all of these YAML files that contain the various backed-up Secrets are stored persistently and safely.

Important: If the files are lost, you cannot restore after a disaster event.

- d. Obtain the endpoints of your Management subsystem.

In Disaster Recovery, the endpoints of the old Management installation *must* match that of the new Management installation:

```
kubectl get managementcluster management -o jsonpath="{..apiManagerEndpoint.hosts[0].name}"
```

```
kubectl get managementcluster management -o jsonpath="{..cloudManagerEndpoint.hosts[0].name}"
```

```
kubectl get managementcluster management -o jsonpath="{..consumerAPIEndpoint.hosts[0].name}"
```

Save this output to a safe place.

- e. Take note of the following values in the Management subsystem CR. You will need them to restore the Management subsystem.

Table 1. Management subsystem CR settings

| Setting                                | Example value                           |
|----------------------------------------|-----------------------------------------|
| <code>name</code>                      | <code>management</code>                 |
| <code>siteName</code>                  | <code>82b290a2</code>                   |
| <code>databaseBackup.protocol</code>   | <code>objstore</code>                   |
| <code>databaseBackup.s3provider</code> | <code>aws</code> or <code>ibm</code>    |
| <code>databaseBackup.host</code>       | <code>s3.amazonaws.com/eu-west-1</code> |
| <code>databaseBackup.path</code>       | <code>my-bucket/mgmt</code>             |
| <code>databaseBackup.schedule</code>   | <code>0 3 * * *</code>                  |

- The values `name` and `siteName` form the name of the database cluster name, such as `management-82b290a2-postgres` and is needed to synchronize the backups from your old Management subsystem to your new one.
- The `databaseBackup.host` and `databaseBackup.path` settings must be identical to what was configured on your old Management subsystem. This is the location of your old Management subsystem backups from where we will recover from.
- Take note of `databaseBackupschedule`. The schedule will be included during the restoration.

3. Make sure that you have a backup that can be used in case of a disaster event:

- For backup configuration, see [Configuring backup settings during initial installation of the management subsystem \(10.0.1.1-eus or greater\)](#).

- If scheduled backups were configured during backup configuration, you should have access to a backup on the specified cloud storage.
  - You can perform a manual backup at any time by creating a manual backup CR. See [Backing up the management subsystem](#).
4. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVA's and restoring from normal backups.
- Important: VM snapshots are not an alternative to the standard backups that are described in the previous steps, and which must be taken in order to use the API Connect restore feature.

## What to do next

You should now complete the preparation steps for the Developer Portal subsystem; see [Preparing the Developer Portal subsystem for disaster recovery on VMware](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

# Preparing the management subsystem for disaster recovery on VMware using SFTP backups (10.0.1.1-eus)

Prepare a Management subsystem for disaster recovery from SFTP backups by taking specific steps before and after the installation of the subsystem.

## About this task

- This task must be performed before any disaster event occurs, and also prior to the installation of a replacement Management subsystem during the recovery process. Best practice is to complete these steps immediately after initial configuration of a management subsystem during your original version 10 deployment.
- This procedure is designed to work with SFTP backup storage only. For S3 backup storage, see [Preparing the management subsystem for disaster recovery on VMware using S3 backups \(10.0.1.1-eus\)](#).
- Any `local` backups are presumed to have been lost in the disaster scenario and are non-recoverable in this procedure.

Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

## Procedure

1. Confirm that you have access to the Kubernetes cluster on your Management Appliance:
  - a. Log onto a Management Appliance node:

```
ssh -i ~/.ssh/id_rsa -o CheckHostIP=no apicadm@example.hostname.com
sudo -i
```

- b. Confirm you are able to run `kubectl` commands against your Kubernetes cluster

```
$ kubectl get nodes
NAME STATUS ROLES AGE VERSION
apimdevr0050 Ready master 6h17m v1.16.8
apimdevr0068 Ready master 6h13m v1.16.8
apimdevr0089 Ready master 6h10m v1.16.8
```

2. After installation, you must back up essential Kubernetes secrets that are used by the Management subsystem. The Kubernetes secrets are created during installation. You must save these in case a restore is needed after a disaster has occurred. At that time, you will use them in the setup of the restored Management subsystem:

- a. Obtain and save the Management database encryption secret.

Use the following command to find the name of the secret in the status of the Management Subsystem. Replace `<namespace>` with the namespace used for the subsystem installation:

```
kubectl get mgmt -n <namespace> -o yaml | grep encryption
```

The output of this command shows the name of the Kubernetes secret storing the database encryption key, for example:

```
encryptionSecret: management-enc-key
```

In this case, the name of the Management database encryption secret is `management-enc-key`. Use the following command to back up this secret locally:

```
kubectl get secret management-enc-key -n <namespace> -o yaml > management_enc_key.yaml
```

The secret is stored in a file called `management_enc_key.yaml`, located in the present working directory.

- b. Obtain and save the Management client application credential secrets.

As part of [Installing the Management subsystem](#), you must store a set of credentials for Disaster Recovery. These credentials are required to ensure that users can log in to API Connect after recovering the database, as these credentials cannot be reconstituted by a new Management subsystem.

Important: If you do not have these credentials, Disaster Recovery is not possible.

- i. Use the following command to find the names of the secrets in the status of the Management subsystem:

```
kubectl get mgmt -n <namespace> -o yaml | grep CredentialSecret
```

The output of this command shows the names of the Kubernetes Secrets used to store the various client application credentials. For example:

```
atmCredentialSecret: management-atm-cred
consumerToolkitCredentialSecret: management-ccli-cred
consumerUICredentialSecret: management-cui-cred
designerCredentialSecret: management-dsgr-cred
juhuCredentialSecret: management-juhu-cred
toolkitCredentialSecret: management-cli-cred
uiCredentialSecret: management-ui-cred
```

Here, for example, the name of the ATM Client Application Credential Secret is `management-atm-cred`.

- ii. Next, back up all of the secrets locally. Use the following command for each listed Credential Secret, replacing `<secret_name>` with the secret name listed each time:

```
kubectl get secret <secret_name> -n <namespace> -o yaml > <secret_name>.yaml
```

For example, use the following command to backup the ATM Client Credential Secret:

```
kubectl get secret management-atm-cred -n <namespace> -o yaml > management-atm-cred.yaml
```

- iii. Once you have saved each of these client application Credential Secrets locally, open each of the YAML files saved for each secret in turn. Remove both the `ownerReferences` subsection and the `selfLink` property. Re-save the file.

For example, the `ownerReferences` and `selfLink` properties to be removed appear in the YAML files similar to the following:

```
ownerReferences:
- apiVersion: management.apiconnect.ibm.com/v1beta1
 blockOwnerDeletion: true
 controller: true
 kind: ManagementCluster
 name: management
 uid: 623e6b20-7eb8-46ce-94ac-6b64cd71afc4
 selfLink: /api/v1/namespaces/default/secrets/management-atm-cred
```

- c. Ensure that all of these YAML files that contain the various backed-up Secrets are stored persistently and safely.

Important: If the files are lost, you cannot restore after a disaster event.

- d. Obtain the endpoints of your Management subsystem.

In Disaster Recovery, the endpoints of the old Management installation *must* match that of the new Management installation:

```
kubectl get managementcluster management -o jsonpath="{..apiManagerEndpoint.hosts[0].name}"
```

```
kubectl get managementcluster management -o jsonpath="{..cloudManagerEndpoint.hosts[0].name}"
```

```
kubectl get managementcluster management -o jsonpath="{..consumerAPIEndpoint.hosts[0].name}"
```

Save this output to a safe place.

- e. Take note of the following values in the Management subsystem CR. You will need them to restore the Management subsystem.

Table 1. Management subsystem CR settings

| Setting                                 | Example value                                   |
|-----------------------------------------|-------------------------------------------------|
| <code>name</code>                       | <code>management</code>                         |
| <code>siteName</code>                   | <code>82b290a2</code>                           |
| <code>databaseBackup.protocol</code>    | <code>sftp</code>                               |
| <code>databaseBackup.host</code>        | <code>&lt;SFTP-host-name&gt;</code>             |
| <code>databaseBackup.path</code>        | <code>&lt;SFTP-path&gt;</code>                  |
| <code>databaseBackup.schedule</code>    | <code>0 3 * * *</code>                          |
| <code>databaseBackup.credentials</code> | <code>secret-containing-SFTP-credentials</code> |

- The values `name` and `siteName` form the name of the database cluster name, such as `management-82b290a2-postgres` and is needed to synchronize the backups from your old Management subsystem to your new one.
- The `databaseBackup.host` and `databaseBackup.path` settings must be identical to what was configured on your old Management subsystem. This is the location of your old Management subsystem backups from where we will recover from.
- Take note of `databaseBackupschedule`. The schedule will be included during the restoration.

3. Make sure that you have a backup that can be used in case of a disaster event:

- If scheduled backups were configured as part of [Configuring backup settings during initial installation of the management subsystem \(10.0.1.1-eus or greater\)](#), backups to the specified cloud storage will take place as scheduled.
- You can also perform a manual backup at any time by creating a manual backup CR. See [Backing up the management subsystem](#).

4. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVA's and restoring from normal backups.

Important: VM snapshots are not an alternative to the standard backups that are described in the previous step, and which must be taken in order to use the API Connect restore feature.

## What to do next

You should now complete the preparation steps for the Developer Portal subsystem; see [Preparing the Developer Portal subsystem for disaster recovery on VMware](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

# Preparing the management subsystem for disaster recovery on VMware (10.0.1.0-eus)

Prepare a Management subsystem for disaster recovery on 10.0.1.0-eus by taking specific steps before and after the installation of the subsystem.

## About this task

Note: This procedure applies to API Connect 10.0.1.0-eus only. For 10.0.1.1-eus, see [Preparing the management subsystem for disaster recovery on VMware using SFTP backups \(10.0.1.1-eus\)](#). For 10.0.1.2-eus, see [Preparing the management subsystem for disaster recovery on VMware using SFTP backups](#).

Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

## Procedure

1. Ensure that you configured backups for your management database. See [Backing up the Management subsystem in a VMware environment](#)

2. After installation, you must back up essential Kubernetes secrets that are used by the Management subsystem.

The Kubernetes secrets are created during installation. You must save these in case a restore is needed after a disaster has occurred. At that time, you will use them in the setup of the restored Management subsystem:

- a. Obtain and save the Management database encryption secret.

Use the following command to find the name of the secret in the status of the Management Subsystem. Replace `<namespace>` with the namespace used for the subsystem installation:

```
kubectl get mgmt -n <namespace> -o yaml | grep encryption
```

The output of this command shows the name of the Kubernetes secret storing the database encryption key, for example:

```
encryptionSecret: management-enc-key
```

In this case, the name of the Management database encryption secret is `management-enc-key`. Use the following command to back up this secret locally:

```
kubectl get secret management-enc-key -n <namespace> -o yaml > management_enc_key.yaml
```

The secret is stored in a file called `management_enc_key.yaml`, located in the present working directory.

- b. Obtain and save the Management client application credential secrets.

Use the following command to find the names of the secrets in the status of the Management subsystem:

```
kubectl get mgmt -n <namespace> -o yaml | grep CredentialSecret
```

The output of this command shows the names of the Kubernetes Secrets used to store the various client application credentials. For example:

```
atmCredentialSecret: management-atm-cred
consumerToolkitCredentialSecret: management-ccli-cred
consumerUICredentialSecret: management-cui-cred
designerCredentialSecret: management-dsgr-cred
juhuCredentialSecret: management-juhu-cred
toolkitCredentialSecret: management-cli-cred
uiCredentialSecret: management-ui-cred
```

Here, for example, the name of the ATM Client Application Credential Secret is `management-atm-cred`.

Next, back up all of the secrets locally. Use the following command for each listed Credential Secret, replacing `<secret_name>` with the secret name listed each time:

```
kubectl get secret <secret_name> -n <namespace> -o yaml > <secret_name>.yaml
```

For example, use the following command to backup the ATM Client Credential Secret:

```
kubectl get secret management-atm-cred -n <namespace> -o yaml > management-atm-cred.yaml
```

Once you have saved each of these client application Credential Secrets locally, open each of the YAML files saved for each secret in turn. Remove both the `ownerReferences` subsection and the `selfLink` property. Re-save the file.

For example, the `ownerReferences` and `selfLink` properties to be removed appear in the YAML files similar to the following:

```
ownerReferences:
- apiVersion: management.apiconnect.ibm.com/v1beta1
 blockOwnerDeletion: true
 controller: true
 kind: ManagementCluster
 name: management
 uid: 623e6b20-7eb8-46ce-94ac-6b64cd71afc4
 selfLink: /api/v1/namespaces/default/secrets/management-atm-cred
```

- c. Ensure that all of these YAML files that contain the various backed-up Secrets are stored persistently and safely.

Important: If the files are lost, you cannot restore after a disaster event.

- d. Obtain the endpoints of your Management subsystem.

In Disaster Recovery, the endpoints of the old Management installation *must* match that of the new Management installation:

```
kubectl get managementcluster management -o jsonpath="{..apiManagerEndpoint.hosts[0].name}"
```

```
kubectl get managementcluster management -o jsonpath="{..cloudManagerEndpoint.hosts[0].name}"
```

```
kubectl get managementcluster management -o jsonpath="{..consumerAPIEndpoint.hosts[0].name}"
```

Save this output to a safe place.

e. Note the `siteName` that is being used.

The `siteName` is either be a randomly generated alphanumeric ID, or a custom name that was specified by the administrator in the Management Subsystem CR helper YAML file at deploy time. Use the following command to get the `siteName`:

```
kubectl get mgmt -o yaml -n <namespace> | grep siteName
```

For example:

```
siteName: a2a5e6e2
```

Save this name persistently and safely. It is needed to successfully restore.

3. Complete either a manual backup or scheduled backup of the Management subsystem.  
After the backup has completed, ensure you have a valid backup. To get started, list the available backups. See [Listing backup files on the sftp server](#).
4. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVA's and restoring from normal backups.  
Important: VM snapshots are not an alternative to the standard backups that are described in the previous steps and which must be taken in order to use the API Connect restore feature.

## Results

---

With stored Backups, Secrets and `siteName` saved, the stack is now ready for a restore after a disaster event.

## What to do next

---

You should now complete the preparation steps for the Developer Portal subsystem; see [Preparing the Developer Portal subsystem for disaster recovery on VMware](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

# Preparing the Developer Portal subsystem for disaster recovery on VMware

Prepare a Developer Portal subsystem for disaster recovery by taking specific steps immediately after the installation of the subsystem.

## About this task

---

- Perform this task before any disaster event occurs, and also prior to the installation of a replacement Developer Portal subsystem for the recovery process.
  - Best practice is to complete these steps immediately after initial configuration of a Developer Portal subsystem during your original version 10 deployment.
  - Any **local** backups are presumed to have been lost in the disaster scenario and are non-recoverable in this procedure.
  - Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. For information about preparing the Management subsystem, see [Preparing the management subsystem for disaster recovery on VMware](#).
- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

## Procedure

---

1. Before the initial installation, configure the Developer Portal subsystem for database backups. See [Backing up and restoring](#) and select the Developer Portal backup instructions for your version of API Connect.
2. Ensure you create a backup:
  - You can perform a manual backup at any time. For API Connect 10.0.1.1-eus or later, see [Backing up the Developer Portal subsystem](#), or for API Connect 10.0.0.0 or 10.0.1.0-eus see [Backing up and restoring the Developer Portal in a VMware environment](#).
  - If you configure scheduled backups, the backups to the specified cloud storage will take place at the configured time.
3. Ensure that you have a backup of the original project directory, stored in a location from where it can always be retrieved.  
The original project directory created with APICUP during the initial product installation (for example, myProject), is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. Note that the endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored or upgraded system.
4. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVA's and restoring from normal backups.  
Important: VM snapshots are not an alternative to the standard Developer Portal backups that are described in the previous steps, and which must be taken in all circumstances.

## What to do next

---

To restore the Developer Portal on VMware after a disaster, see [Recovering the Developer Portal subsystem on VMware](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Preparing the Analytics subsystem for disaster recovery on VMware

Prepare the API Connect Analytics subsystem for disaster recovery in a VMware environment.

### About this task

Preparing for disaster recovery involves backing up analytics data and your project directory.

### Procedure

1. [Perform a backup of the Analytics database.](#)  
Scheduling automatic backups ensures that a recovery includes recent updates. For more information on configuring backups, see [Configuring backup settings for Analytics](#).
2. Ensure that you have a backup of your project directory.  
The original project directory that was created with the `apicup` command during the initial product installation is required for disaster recovery, see: [First steps for deploying in a VMware environment](#). The project directory contains the yaml files that describe your deployment, encryption keys, and deployment ISO files. It is not possible to restore the subsystem databases on a deployment that uses a new or different project directory.
3. Ensure that you have a backup of the `analytics-extra-values.yaml` file if you created one: [Creating the analytics-extra-values file](#). This file might be included in the project directory backup if you kept it there.
4. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVAs and restoring from normal backups.  
Important: VM snapshots are not an alternative to the standard backups that are described in the previous steps, and which must be taken in order to use the API Connect restore feature.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Recovering from a disaster

Recover the API Connect subsystems on VMware.

- [Recovering the management subsystem on VMware](#)  
Recover the management subsystem on VMware.
- [Recovering the Developer Portal subsystem on VMware](#)  
Recover the Developer Portal on VMware.
- [Recovering the Analytics subsystem on VMware](#)  
Recover the API Connect Analytics subsystem in a VMware environment.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Recovering the management subsystem on VMware

Recover the management subsystem on VMware.

The recovery procedures for the management subsystem are specific to each version of API Connect plus the type of backup. Use the instructions for your version and backup type:

- [Recovering the management subsystem on VMware](#)  
Recover the management subsystem from backups after a disaster event.
- [Recovering the management subsystem from S3 backups after a disaster event on VMware \(10.0.1.1-eus\)](#)  
Recover the management subsystem from S3 backups after a disaster event on 10.0.1.1-eus.
- [Recovering the management subsystem from SFTP backups after a disaster event on VMware \(10.0.1.1-eus\)](#)  
Recover the management subsystem from SFTP backups after a disaster event on 10.0.1.1-eus
- [Restoring the management subsystem on VMware after a disaster \(10.0.1.0-eus\)](#)  
Restore the management subsystem after a disaster event.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

# Recovering the management subsystem on VMware

Recover the management subsystem from backups after a disaster event.

## Before you begin

To successfully recover the management subsystem, you must have previously completed the steps in [Preparing the management subsystem for disaster recovery on VMware](#).

You must use the same project directory that you used for your original deployment, or a restore of your project directory backup, to ensure that configuration and secret information is transferred to the replacement deployment.

In a clustered deployment, if any one VM is corrupted then all of the VMs in the cluster must be redeployed. You cannot replace just a single corrupted VM in a cluster.

Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

## Procedure

1. Determine which backup to restore from.

a. Obtain a list of the available backups for your backup type:

• s3 backups

• For IBM's Cloud Object Storage, you can check currently stored backups in the COS console. Select Buckets > Objects. See the Object Names displayed on the `<cos_name>/backup/db` panel. For example:

```
20200605-105429F
20200605-100008F
20200605-11040F
```

• For Amazon's AWS, you can check currently stored backups in the S3 console For example, under Amazon S3 > `cluster_name` > old cluster > backup > db:

```
20200606-144315F
20200606-145011F
```

• SFTP backups

View the SFTP backups available on your remote storage site:

```
--rw-r--r-- 1 root root 13092333 Aug 26 08:56 20200826-154646F.tgz
--rw-r--r-- 1 root root 18703758 Aug 26 09:10 20200826-160010F.tgz
--rw-r--r-- 1 root root 24318561 Aug 26 09:21 20200826-161301F.tgz
```

b. Select the backup ID of the backup you want to restore. For example, in the sample SFTP backup list, for the Aug 26 09:21 backup, the backup ID is `20200826-161301F`.

Each filename contains the date, time, and type of the backup stored. The format of the backup ID is `YYYYMMDD-HHMMSS<F|I>`. Full backups are denoted with a suffix `F` on the ID. Incremental backups are denoted with a suffix `I` on the ID. For incremental backups, ensure each incremental backup has its prior full backup also present in storage. You can check this by examining the ID `<prior-backup-id>_<backup-id>`.

2. Make sure you know the management database cluster name. You can get this name from the original management subsystem CR.

If you are not able to recover the original management subsystem CR, you can obtain the name from your backup configuration. Use the following steps applicable to your backup type:

| Backup type | How to obtain database cluster name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| s3          | <p>a. Open your IBM Cloud Object Storage or AWS S3 console and proceed to the bucket location where the old Management subsystem backups are located.</p> <p>b. Download <code>backup/db/&lt;backup-id&gt;/pg_data/postgresql.conf.gz</code>. Open <code>postgresql.conf</code> to view the database cluster name:</p> <ul style="list-style-type: none"><li>IBM Cloud Object Storage<pre>cluster_name = 'm1-a6287572-postgres'</pre><ul style="list-style-type: none"><li>m1 - Management subsystem name</li><li>a6287572 - site name</li></ul></li><li>AWS S3<pre>cluster_name = 'm1-c91dc0b9-postgres'</pre><ul style="list-style-type: none"><li>m1 - Management subsystem name</li><li>c91dc0b9 - site name</li></ul></li></ul> |

| Backup type | How to obtain database cluster name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SFTP        | <p>a. Recover the Management database cluster name and siteName by examining the SFTP backup tar. Download or move the SFTP backup tar file and decompress (untar) it.</p> <p>b. Open <code>&lt;management-subsystem-name&gt;-&lt;siteName&gt;-postgres-backrest-shared-repo/backup/db/&lt;backup-id&gt;/pg_data/postgresql.conf.gz</code> which contains the management subsystem name and siteName. For example:</p> <pre># Do not edit this file manually! # It will be overwritten by Patroni! include 'postgresql.base.conf'  archive_command = 'source /opt/cpm/bin/pgbackrest/pgbackrest-set-env.sh &amp;&amp; pgbackrest archive-push "%p"' archive_mode = 'True' archive_timeout = '60' autovacuum_vacuum_cost_limit = '1000' autovacuum_vacuum_scale_factor = '0.01' cluster_name = 'm1-f785a3e3-postgres'</pre> <p>In this example:</p> <ul style="list-style-type: none"> <li><code>cluster_name</code> has both the management subsystem name and siteName</li> <li><code>m1</code> - Management subsystem name</li> <li><code>f785a3e3</code> - site name</li> </ul> |

- Run the commands in `apicup-commands.txt` to restore the saved (extracted) data:  
You created `apicup-commands.txt` when you ran `dr-preparation.py` as part of [Preparing the management subsystem for disaster recovery on VMware](#). The commands in the file create the necessary secrets

Be sure to:

- Use an `apicup` binary from the version of API Connect that you want to restore to.
- Use your prior existing project directory (or a restore of your project directory backup). The directory contains `apiconnect-up-v10.yml`, which has your configuration.

When the commands in `apicup-commands.txt` complete successfully, the Management subsystem configuration is complete.

- Use your prior existing project directory (or a restore of your project directory backup) to install the Management subsystem:
  - Create your ISO files

```
apicup subsys install mgmt --out mgmtplan-out
```

The `--out` parameter and value are required.

In this example, the ISO file is created in the `myProject/mgmtplan-out` directory.

Note: If your original ISO files are still available, and you haven't upgraded from the original installation, you can reuse your original files. However, if you have upgraded your original deployment, you must create your ISO files by using the version of `apicup` that corresponds to the version of API Connect that you want to restore to.

- Deploy the files into the replacement VMs. See [Deploying the management subsystem OVA file](#).
- Verify the deployment. See [Verify installation of the management subsystem](#).

Important:

For S3, the recovery remains in an intermediate state until the restore is complete, and Postgres wal files might cause serious disk issues. To avoid this possibility, continue immediately with the next step.

Note that if you delay completion of the restore:

- Health check might fail. In this case, you can still proceed to the next step and perform a restore.
- Postgres wal files might cause problems by consuming all disk space. In this case, you must either:
  - Re-install the system, prepare again for disaster recovery, and perform the restore.
  - Or increase disk space so that the system returns to a stable state, and then proceed with the restore.

- Once your Management subsystem is ready, confirm the backup ID noted in Step 1 is present on the sftp or s3 server.
- After a few moments, confirm there is a `ManagementBackup` of type `record` and it's backup ID matches with the backup ID noted in Step 1.  
You can list the management backups using:

```
apicup subsys list-backups <subsystem_name>
```

For example:

| NAME              | STATUS | ID               | CLUSTER                      | SUBSYSTEM  | TYPE | CR TYPE | AGE |
|-------------------|--------|------------------|------------------------------|------------|------|---------|-----|
| mgmt-backup-8hqgg | Ready  | 20200826-161301F | management-82b290a2-postgres | management | full | record  | 40s |

- Perform a Management Restore using the name of the backup CR that has the ID you want to restore.  
For example, for ID `20200826-161301F` the backup CR name is `mgmt-backup-8hqgg`.

For instructions on how to restore, see [Restoring the management subsystem](#).

Once the Management Restore has completed and the database is running again, the data of the old Management subsystem will be successfully restored onto the new Management subsystem. Manual and scheduled backups should perform as normal once again.

## What to do next

You should now complete the recovery steps for the Developer Portal subsystem on VMware, see [Recovering the Developer Portal subsystem on VMware](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#), for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

# Recovering the management subsystem from S3 backups after a disaster event on VMware (10.0.1.1-eus)

Recover the management subsystem from S3 backups after a disaster event on 10.0.1.1-eus.

## Before you begin

To successfully recover the management subsystem, you must have previously completed the steps in [Preparing the management subsystem for disaster recovery on VMware using S3 backups \(10.0.1.1-eus\)](#).

You must use the same project directory that you used for your original deployment, to ensure that configuration and secret information is transferred to the replacement deployment.

Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

## Procedure

1. Determine which backup to restore from.

- For IBM's Cloud Object Storage, you can check currently stored backups in the COS console. Select Buckets > Objects. See the Object Names displayed on the `<cos_name>/backup/db` panel. For example:

```
20200605-105429F
20200605-100008F
20200605-11040F
```

- For Amazon's AWS, you can check currently stored backups in the S3 console. For example, under Amazon S3 > `cluster_name` > old cluster > backup > db:

```
20200606-144315F
20200606-145011F
```

The format of the backup ID is `YYYYMMDD-HHMMSS<F|I>`

Take note of the ID of the backup you wish to restore to. Each ID contains the date, time, and type of the backup stored. This will be used later in the procedure.

- Incremental backups are denoted with a suffix `I` on the ID, ensure each incremental backup has its prior backup also present in storage. You can check this by examining the ID `<prior-backup-id>_<backup-id>`.
- Full backups are denoted with a suffix `F` on the ID.

2. Make sure you know the management database cluster name.

You can get this name from the original management subsystem CR. You made note of this name in Step 2.e in [Preparing the management subsystem for disaster recovery on VMware using S3 backups \(10.0.1.1-eus\)](#).

If you are not able to recover the original management subsystem CR, use the following steps to recover the Management database cluster name:

- Open your IBM Cloud Object Storage or AWS S3 console and proceed to the bucket location where the old Management subsystem backups are located.
- Download `backup/db/<backup-id>/pg_data/postgresql.conf.gz`. Open `postgresql.conf` to view the database cluster name:

- IBM Cloud Object Storage

```
.
.
cluster_name = 'm1-a6287572-postgres'
.
.
```

- `m1` - Management subsystem name
- `a6287572` - site name

- AWS S3

```
.
.
cluster_name = 'm1-c91dc0b9-postgres'
.
.
```

- `m1` - Management subsystem name
- `c91dc0b9` - site name

3. From your new project directory, install the Management subsystem as per [Deploying the Management subsystem](#)

Important:

- The hostnames of the Endpoints cannot be changed, and must remain the same in the Management subsystem used for installation now as they were for the original installation.
- The Management subsystem name must remain the same in the new installation as the original.

4. Before you restore onto new management subsystem, complete the following steps:

- SSH onto your Management appliance and remove the Management subsystem if it is already present.

```
kubectl get managementcluster
NAME READY STATUS VERSION RECONCILED VERSION AGE
management 16/16 Running 10.0.1.1 10.0.1.1-706 5h28m
```

```
kubectl delete managementcluster management
managementcluster.management.apiconnect.ibm.com "management" deleted
```

b. Apply the YAML file that contains the Management Database Encryption Secret into the cluster. For example, where `encryption-bin-secret.yaml` is the local YAML file containing the backup-up encryption secret:

```
kubectl create -f encryption-bin-secret.yaml -n <namespace>.
```

Replace `<namespace>` with the namespace being used for the management subsystem installation.

This command re-creates the original Management Database encryption secret on the cluster. It will be named as the original name of the secret.

c. For each of the saved YAML Files that contain the Management Client Application Credential Secrets, apply each file into the cluster using the following command:

```
kubectl create -f <secret_name>.yaml -n <namespace>
```

where `<secret_name>` is the local YAML file containing one of the backed-up Credential Secrets.

Repeat this for each of the backed-up Credential Secrets. These are the secrets you saved in Step 2.b of [Preparing the management subsystem for disaster recovery on VMware using S3 backups \(10.0.1.1-eus\)](#).

These commands will re-create the original Management Client Application Credential Secrets on the cluster. Each will be named as the original name of the Secret.

d. In your project directory, create the `management-extra-values.yaml` file for the Management subsystem.

- Add the `encryptionSecret` subsection to the `spec`, which is the name of the newly created secret on the cluster containing the original Management Database Encryption Secret from the previous step.
- Add the `siteName` property to the `spec`, where in this example, `82b290a2` is the original `siteName` that was noted after the installation of the original Management Subsystem
- Add the `customApplicationCredentials` subsection to the `spec`. For each named credential above, the `secretName` is given as the corresponding name of the newly created Secret from Step 4.c above for each of the above Credential Secrets.

```
spec:
 customApplicationCredentials:
 - name: atm-cred
 secretName: management-atm-cred
 - name: ccli-cred
 secretName: management-ccli-cred
 - name: cli-cred
 secretName: management-cli-cred
 - name: cui-cred
 secretName: management-cui-cred
 - name: dsgr-cred
 secretName: management-dsgr-cred
 - name: juhu-cred
 secretName: management-juhu-cred
 - name: ui-cred
 secretName: management-ui-cred
 encryptionSecret:
 secretName: management-enc-key
 siteName: 82b290a2
```

e. Set the `management-extra-values` file in your Management subsystem

```
apicup subsys set [SUBSYS_NAME] extra-values-file management-extra-values.yaml
```

5. Prepare your backup configuration before fresh install.

The following settings can be configured via `apicup subsys set [SUBSYS_NAME] [setting]=[value]`:

```
database-backup-auth-pass
database-backup-auth-user
database-backup-host
database-backup-path
database-backup-protocol objstore (default)
database-backup-s3provider aws/ibm
database-backup-schedule 0 0 * * * (default)
```

You can view all the management subsystem settings with the command:

```
apicup subsys get [SUBSYS_NAME] --validate
```

To review backup configuration, see [Configuring backup settings during initial installation of the management subsystem \(10.0.1.1-eus or greater\)](#).

6. Install the Management subsystem using `apicup` with the flag `--skip-health-check`:

```
apicup subsys install [SUBSYS_NAME] --skip-health-check
```

7. Once your Management subsystem is ready, confirm the backup ID noted in Step 1 is present on the sftp server.

8. After a few moments, confirm there is a `ManagementBackup` of type `record` and it's backup ID matches with the backup ID noted in Step 1.

You can list the management backups using:

```
apicup subsys list-backups [SUBSYS_NAME]
```

For example:

| NAME              | STATUS | ID               | CLUSTER                      | SUBSYSTEM  | TYPE | CR TYPE | AGE |
|-------------------|--------|------------------|------------------------------|------------|------|---------|-----|
| mgmt-backup-8hqqg | Ready  | 20200826-161301F | management-82b290a2-postgres | management | full | record  | 40s |

9. Perform a Management Restore using the name of the backup CR that has the ID you want to restore.

For example, for ID `20200826-161301F` the backup CR name is `mgmt-backup-8hqqg`.

For instructions on how to restore, see [Restoring the management subsystem](#).

Once the Management Restore has completed and the database is running again, the data of the old Management subsystem will be successfully restored onto the new Management subsystem. Manual and scheduled backups should perform as normal once again.

## What to do next

You should now complete the recovery steps for the Developer Portal subsystem on VMware, see [Recovering the Developer Portal subsystem on VMware](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

# Recovering the management subsystem from SFTP backups after a disaster event on VMware (10.0.1.1-eus)

Recover the management subsystem from SFTP backups after a disaster event on 10.0.1.1-eus

## Before you begin

To successfully recover the management subsystem, you must have previously completed the steps in [Preparing the management subsystem for disaster recovery on VMware using SFTP backups \(10.0.1.1-eus\)](#).

You must use the same project directory that you used for your original deployment, to ensure that configuration and secret information is transferred to the replacement deployment.

**Important:** Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

## Procedure

1. Determine which backup to restore from.

View the SFTP backups available on your remote storage site:

```
-rw-r--r-- 1 root root 13092333 Aug 26 08:56 20200826-154646F.tgz
-rw-r--r-- 1 root root 18703758 Aug 26 09:10 20200826-160010F.tgz
-rw-r--r-- 1 root root 24318561 Aug 26 09:21 20200826-161301F.tgz
```

Take note of the backup ID of the backup you wish to restore to. Each filename contains the date, time, and type of the backup stored. This will be used later in the procedure.

The format of the backup ID is **YYYYMMDD-HHMMSS<F|I>**. For example, if we want to use the Aug 26, 09:21 backup, its backup ID will be **20200826-161301F**

- a. Incremental backups are denoted with a suffix **I** on the ID, ensure each incremental backup has its prior backup also present in storage. You can check this by examining the ID **<prior-backup-id>\_<backup-id>**.
- b. Full backups are denoted with a suffix **F** on the ID.

2. Make sure you know the management database cluster name.

You can get this name from the original management subsystem CR. You made note of this name in Step [2.e](#) in [Preparing the management subsystem for disaster recovery on VMware using SFTP backups \(10.0.1.1-eus\)](#).

If you are not able to recover the original management subsystem CR, you can also recover the Management database cluster name and siteName by examining the SFTP backup tar:

- a. Download or move the SFTP backup tar file and decompress (untar) it.
- b. Open **<management-subsystem-name>-<siteName>-postgres-backrest-shared-repo/backup/db/<backup-id>/pg\_data/postgresql.conf.gz** which contains the management subsystem name and siteName. For example:

```
Do not edit this file manually!
It will be overwritten by Patroni!
include 'postgresql.base.conf'

archive_command = 'source /opt/cpm/bin/pgbackrest/pgbackrest-set-env.sh && pgbackrest archive-push "%p"'
archive_mode = 'True'
archive_timeout = '60'
autovacuum_vacuum_cost_limit = '1000'
autovacuum_vacuum_scale_factor = '0.01'
cluster_name = 'm1-f785a3e3-postgres'
```

In this example:

- **cluster\_name** has both the management subsystem name and siteName
- **m1** - Management subsystem name
- **f785a3e3** - site name

3. From your new project directory, install the Management subsystem as per [Deploying the Management subsystem](#)

**Important:**

- The hostnames of the Endpoints cannot be changed, and must remain the same in the Management subsystem used for installation now as they were for the original installation.
- The Management subsystem name must remain the same in the new installation as the original.

4. Before you restore onto new management subsystem, complete the following steps:

- a. SSH onto your Management appliance and remove the Management subsystem if it is already present.

```
kubectl get managementcluster
NAME READY STATUS VERSION RECONCILED VERSION AGE
management 16/16 Running 10.0.1.1 10.0.1.1-706 5h28m
```

```
kubectl delete managementcluster management
managementcluster.management.apiconnect.ibm.com "management" deleted
```

- b. Apply the YAML file that contains the Management Database Encryption Secret into the cluster. For example, where `encryption-bin-secret.yaml` is the local YAML file containing the backup-up encryption secret:

```
kubectl create -f encryption-bin-secret.yaml -n <namespace>.
```

Replace `<namespace>` with the namespace being used for the management subsystem installation.

This command re-creates the original Management Database encryption secret on the cluster. It will be named as the original name of the secret.

- c. For each of the saved YAML Files that contain the Management Client Application Credential Secrets, apply each file into the cluster using the following command:

```
kubectl create -f <secret_name>.yaml -n <namespace>
```

where `<secret_name>` is the local YAML file containing one of the backed-up Credential Secrets.

Repeat this for each of the backed-up Credential Secrets. These are the secrets you saved in Step 2.b of [Preparing the management subsystem for disaster recovery using SFTP backups](#).

These commands will re-create the original Management Client Application Credential Secrets on the cluster. Each will be named as the original name of the Secret.

- d. In your project directory, create the `management-extra-values.yaml` file for the Management subsystem.

- Add the `encryptionSecret` subsection to the `spec`, which is the name of the newly created secret on the cluster containing the original Management Database Encryption Secret from the previous step.
- Add the `siteName` property to the `spec`, where in this example, `82b290a2` is the original `siteName` that was noted after the installation of the original Management Subsystem
- Add the `customApplicationCredentials` subsection to the `spec`. For each named credential above, the `secretName` is given as the corresponding name of the newly created Secret from Step 4.c above for each of the above Credential Secrets.

```
spec:
 customApplicationCredentials:
 - name: atm-cred
 secretName: management-atm-cred
 - name: cli-cred
 secretName: management-ccli-cred
 - name: cli-cred
 secretName: management-cli-cred
 - name: cui-cred
 secretName: management-cui-cred
 - name: dsgr-cred
 secretName: management-dsgr-cred
 - name: juhu-cred
 secretName: management-juhu-cred
 - name: ui-cred
 secretName: management-ui-cred
 encryptionSecret:
 secretName: management-enc-key
 siteName: 82b290a2
```

- e. Set the `management-extra-values` file in your Management subsystem

```
apicup subsys set [SUBSYS_NAME] extra-values-file management-extra-values.yaml
```

5. Prepare your backup configuration before fresh install.

The following settings can be configured via `apicup subsys set [SUBSYS_NAME]`

`[setting]=[value]`:

```
database-backup-auth-pass
database-backup-auth-user
database-backup-host
database-backup-path
database-backup-port 22 (default)
database-backup-protocol sftp (default)
database-backup-retries 0 (default)
database-backup-schedule 0 0 * * * (default)
```

You can view all the management subsystem settings with the command:

```
apicup subsys get [SUBSYS_NAME] --validate
```

To review backup configuration, see [Configuring backup settings during initial installation of the management subsystem \(10.0.1.1-eus or greater\)](#).

6. Install the Management subsystem using `apicup` with the flag `--skip-health-check`:

```
apicup subsys install [SUBSYS_NAME] --skip-health-check
```

7. Once your Management subsystem is ready, confirm the backup ID noted in Step 1 is present on the sftp server.

8. After a few moments, confirm there is a `ManagementBackup` of type `record` and it's backup ID matches with the backup ID noted in Step 1.

You can list the management backups using:

```
apicup subsys list-backups [SUBSYS_NAME]
```

For example:

| NAME              | STATUS | ID               | CLUSTER                      | SUBSYSTEM  | TYPE | CR TYPE | AGE |
|-------------------|--------|------------------|------------------------------|------------|------|---------|-----|
| mgmt-backup-8hqgg | Ready  | 20200826-161301F | management-82b290a2-postgres | management | full | record  | 40s |

- Perform a Management Subsystem Restore using the name of the backup CR that has the ID you want to restore. For example, for ID 20200826-161301F the backup CR name is `mgmt-backup-8hqgg`.

For instructions on how to restore, see [Restoring the management subsystem](#).

Once the Management Restore has completed and the database is running again, the data of the old Management subsystem will be successfully restored onto the new Management subsystem. Manual and scheduled backups should perform as normal once again.

## What to do next

You should now complete the recovery steps for the Developer Portal subsystem on VMware, see [Recovering the Developer Portal subsystem on VMware](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Restoring the management subsystem on VMware after a disaster (10.0.1.0-eus)

Restore the management subsystem after a disaster event.

### Before you begin

In a disaster recovery scenario where an install of a new Management subsystem is required, the following steps will guide you through how to recover your previous Management subsystem's data onto the new Management subsystem.

This task should be performed *before* the install of the new Management subsystem.

Note:

This procedure is designed to work with SFTP backup storage only. Any backups not in remote storage prior to disaster are presumed to have been lost and are non-recoverable in this procedure.

Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

### Procedure

- Locate the saved credentials for the Management subsystem:

Warning:

- If you do not have the credentials, Disaster Recovery is not possible.
- During installation of API Connect, you were required to store a set of credentials for Disaster Recovery. These credentials are required in this restore procedure to ensure that users can login into API Connect after recovering the database. Note that these credentials cannot be reconstituted by a new Management subsystem.
- The Kubernetes Secrets for the following credentials should have been exported and saved as YAML files as part of the backup-procedure before the disaster event. See [Preparing the management subsystem for disaster recovery on VMware \(10.0.1.0-eus\)](#). The set of Management Client Application Credentials required are as follows:

- `atm-cred` (Test & Monitor Credential)
- `ccli-cred` (Consumer Toolkit Credential)
- `cli-cred` (Toolkit Credential)
- `cui-cred` (Consumer UI Credential)
- `dsgr-cred` (Designer Credential)
- `juhu-cred` (Juhu Credential)
- `ui-cred` (UI Credential)

- The Management Database Encryption Secret is also required, which also should have been exported and saved a YAML file as part of the backup-procedure before the disaster event. See [Preparing the management subsystem for disaster recovery on VMware \(10.0.1.0-eus\)](#).

- Determine which backup to use when restoring.

Ensure you have a backup available in remote storage to restore from. Restoring your Management subsystem's data requires a backup containing the data you wish to restore.

Note:

Avoid restoring to initial system backup. During install, Management db will take an initial system backup before certain database schema jobs are complete. Restoring to this backup will result in an unstable system.

For more information on remote sftp backups, see [Using an sftp server for backup files on VMware](#)

List the backup files available: For example:

```
$ /sftp/backup.sh -l -H $HOST -u $USERNAME -p $PASSWORD -d $DIRECTORY
drwxr-xr-x 2 root root 90 Aug 26 09:21 .
drwxrwxrwt 10 root root 198 Aug 26 09:45 ..
-rw-r--r-- 1 root root 13092333 Aug 26 08:56 20200826-154646F.tgz
-rw-r--r-- 1 root root 18703758 Aug 26 09:10 20200826-160010F.tgz
-rw-r--r-- 1 root root 24318561 Aug 26 09:21 20200826-161301F.tgz
```

Take note of the filename of the backup you wish to restore to. Each filename contains the date, time, and type of the backup stored. This will be used later in the procedure.

3. Determine the old Management subsystem database name

Take note of the following values belonging to the old Management subsystem CR. They will be needed to recover that data from your old Management subsystem.

Table 1. Management database values

| Value    | Example    |
|----------|------------|
| name     | management |
| siteName | 82b290a2   |

The Management subsystem `name` and `siteName` property is also required, which is used to form the name of the database cluster name. (for example: `management-82b290a2-postgres`) and is needed to synchronize the backups from your old Management subsystem to your new one.

For `sitename`, see [Preparing the management subsystem for disaster recovery on VMware \(10.0.1.0-eus\)](#)

4. From your new project directory, install the Management subsystem. See [Deploying the Management subsystem](#)

Warning:

- If the disaster event only affects Management appliances, it is safe to reuse the existing project for Installation of Management subsystem. In the event all appliances are affected and the project itself is lost, a new project will be required for the install of new subsystems.
- Ensure that the Management subsystem name remains the same in the new installation as the original installation.
- Ensure that the hostnames of the endpoints remain the same in the Management subsystem used for installation now as they were for the original installation. The hostnames for the endpoints cannot be changed.

5. Confirm you are able to run `kubect1` commands against your Kubernetes cluster.

- a. Log onto a Management Appliance node

```
ssh -i ~/.ssh/id_rsa -o CheckHostIP=no apicadm@example.hostname.com
sudo -i
```

- b. Run `kubect1`:

```
$ kubect1 get nodes
NAME STATUS ROLES AGE VERSION
apimdevr0050 Ready master 6h17m v1.16.8
apimdevr0068 Ready master 6h13m v1.16.8
apimdevr0089 Ready master 6h10m v1.16.8
```

6. Complete the following steps before you restore onto new management subsystem:

- a. SSH onto your Management appliance and remove the Management subsystem:

```
root@apimdev0076:/# kubect1 get managementcluster
NAME READY STATUS VERSION RECONCILED VERSION AGE
management 16/16 Running 10.0.1.1 10.0.1.1-706 5h28m

root@apimdev0076:/# kubect1 delete managementcluster management
managementcluster.management.apiconnect.ibm.com "management" deleted
```

- b. Apply the saved YAML file that contains the Management Database Encryption Secret into the cluster. For example:

```
kubect1 create -f encryption-bin-secret.yaml
```

where `encryption-bin-secret.yaml` is the local YAML file containing the backup-up encryption secret.

This command re-creates the original Management Database Encryption Secret on the cluster. It is named as the original name of the Secret.

- c. Apply into the cluster each of the saved YAML files that contain the Management Client Application Credential Secrets:

```
kubect1 create -f <secret_name>.yaml
```

The parameter `<secret_name>` is the local YAML file containing one of the backed-up Credential Secrets.

Repeat this command for each of the backed-up Credential Secrets. These commands re-create the original Management Client Application Credential Secrets on the cluster. Each will be named as the original name of the Secret.

- d. In your project directory, create the `management-extra-values.yaml` file for the Management subsystem.

- Add the `encryptionSecret` subsection to the `spec`, which is the name of the newly created secret on the cluster containing the original Management Database Encryption Secret from the previous step.
- Add the `siteName` property to the `spec`, where in this example, `82b290a2` is the original `siteName` that was noted after the installation of the original Management Subsystem
- Add the `customApplicationCredentials` subsection to the `spec`. For each named credential above, the `secretName` is given as the corresponding name of the newly created Secret from Step [6.c](#) for each of the above Credential Secrets.

```
spec:
 customApplicationCredentials:
 - name: atm-cred
 secretName: management-atm-cred
 - name: cli-cred
 secretName: management-ccli-cred
 - name: cli-cred
 secretName: management-cli-cred
 - name: cui-cred
 secretName: management-cui-cred
 - name: dsgr-cred
 secretName: management-dsgr-cred
 - name: juhu-cred
 secretName: management-juhu-cred
 - name: ui-cred
 secretName: management-ui-cred
```

```
encryptionSecret:
 secretName: management-enc-key
 siteName: 82b290a2
```

e. Set the `management-extra-values` file in your Management subsystem:

```
$ apicup subsys set management extra-values-file management-extra-values.yaml
```

7. Install the Management subsystem using `apicup` with the flag `--skip-health-check`:

```
$ apicup subsys install management --skip-health-check
```

8. Confirm the backup file you identified in step 2 is present in the sftp server.

9. Download the backup onto the Management subsystem. See [Downloading backup files from an sftp server](#).

10. Confirm there is a `ManagementBackup` of type `record` your downloaded backup:

```
$ kubectl get ManagementBackup
kubectl get mgmtb

NAME	STATUS	ID	CLUSTER	SUBSYSTEM	TYPE	CR TYPE	AGE
mgmt-backup-8hqgq	Ready	20200826-154646F	management-82b290a2-postgres	management	full	record	40s

```

11. Perform a Management Restore using the name of the backup that has the ID we want to restore to.

- For example, for ID `20200826-154646F` the backup name is `mgmt-backup-8hqgq`.
- For how to perform the Management Restore, see [Restoring the management subsystem on VMware](#).

Once the Management Restore has completed and the database is running again, the data of the old Management subsystem will be successfully restored onto the new Management subsystem.

## Results

The Management subsystem will be restored to its state prior to the disaster event.

## What to do next

You should now complete the recovery steps for the Developer Portal subsystem on VMware, see [Recovering the Developer Portal subsystem on VMware](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

# Recovering the Developer Portal subsystem on VMware

Recover the Developer Portal on VMware.

## Before you begin

Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. If you must recover a deployment due to a disaster, you must first complete [Recovering the management subsystem on VMware](#), and then immediately recover the Developer Portal.

Recovery of the Portal subsystem is also dependent on prior completion of the preparation steps: [Preparing the Developer Portal subsystem for disaster recovery on VMware](#).

## About this task

- In a disaster recovery scenario, an installation of a new Developer Portal subsystem is required.
- In a clustered deployment, if any one VM is corrupted then all of the VMs in the cluster must be redeployed. You cannot replace just a single corrupted VM in a cluster.
- You must use the same project directory that you used for your original Portal deployment, or a restore of your project directory backup, to ensure that configuration and secret information is transferred to the replacement deployment. The `apiconnect-up-v10.yaml` file contains Portal configuration.

Use the following steps to recover the data from your previous Developer Portal subsystem.

## Procedure

1. Use your prior existing project directory, or a restore of your project directory backup, to install the replacement Portal subsystem:

a. Create your ISO files.

```
apicup subsys install portal-subsystem-name --out mgmtplan-out
```

The `--out` parameter and value are required.

In this example, the ISO file is created in the `myProject/portal-subsystem-nameplan-out` directory.

Note: If your original ISO files are still available, and you haven't upgraded from the original installation, you can reuse your original files. However, if you have upgraded your original deployment, you must create your ISO files by using the version of `apicup` that corresponds to the latest release of API Connect that you deployed.

b. Deploy the files into the replacement VMs. See [Deploying the Developer Portal subsystem OVA file](#).

c. Verify the deployment. See [Verifying deployment of the Developer Portal subsystem](#).

2. View the available backups and their status:

```
apicup subsys list-backups [subsystem_name] [flags]
```

Optional flags:

```
./apicup subsys list-backups -h
List backups of the subsystem
Usage:
 apicup subsys list-backups SUBSYS [flags]
Flags:
 -h, --help help for list-backups
 --timeout duration Command timeout in seconds. (default 40s)
Global Flags:
 --accept-license Accept the license for API Connect
 --debug Enable debug logging
```

3. Perform a Developer Portal restore.

Run the following command, and attach any flags as appropriate.

```
apicup subsys restore [SUBSYS_NAME] [flags]
```

- To restore your Portal service, run the following command:

```
apicup subsys restore ptl --timestamp [now|YYYYMMDD.HHMMSS]
```

where `--timestamp` can be `now`, so the latest backup file that is available is used. Or you can specify a timestamp in the format of `YYYYMMDD.HHMMSS` to retrieve the nearest backup file to a specified time, searching backwards from the timestamp given. This command executes the portal restore process, which downloads the system backup and all of the site backups from the remote server, and installs them within the Portal stack. This process will then restore the system configuration from the found backup, and restore all of the sites. Note that if a backed up site is already installed on the current stack, then the site is reinstalled by using the backup (the site is overwritten by the backup). If there are multiple sites to restore, then these sites are queued for restoring. You can track the restoration process within the Portal `www admin` logs.

Note: From IBM® API Connect Version 10.0.1.4-ifix1-eus, the timestamp format changed to `YYYYMMDD.HHMMSS`. For Version 10.0.1.2-eus and earlier, the timestamp format is `YYYY-MM-DD HH:MM:SS`.

- For a disaster recovery scenario, it is advised that you restore all sites and systems. By default the restore is a complete restore. You can optionally include `-type all` on the command line to specify a complete restore, but the flag is not required, as a complete restore is performed by default. Note that the complete restore uses the `priorityList` configuration setting that you specified in [Configuring backup settings for the Developer Portal subsystem](#).
- For more information, see [Restoring the Developer Portal subsystem](#)

## Results

When the Developer Portal restore CR is marked as **Ready**, the Disaster recovery is complete for the Developer Portal.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Recovering the Analytics subsystem on VMware

Recover the API Connect Analytics subsystem in a VMware environment.

### About this task

Recovering the Analytics subsystem involves deploying a new installation of the Analytics subsystem and then restoring the Analytics database from a back-up copy.

You must use the same project directory that you used for your original deployment, or a restore of your project directory backup, to ensure that configuration and secret information is transferred to the replacement deployment.

In a clustered deployment, if any one VM is corrupted then all of the VMs in the cluster must be redeployed. You cannot replace just a single corrupted VM in a cluster.

### Procedure

1. Use your prior existing project directory, or a restore of your project directory backup, to install the replacement Analytics subsystem:
  - a. Create your ISO files:

```
apicup subsys install install-subsystem-name --out analytplan-out
```

The `--out` parameter and value are required.

In this example, the ISO files are created in the `myProject/analytplan-out` directory.

Note: If your original ISO files are still available, and you haven't upgraded from the original installation, you can reuse your original files. However, if you have upgraded your original deployment, you must create your ISO files by using the version of `apicup` that corresponds to the version of API Connect that you want to restore to.

- b. Deploy the files into the replacement VMs. See [Deploying the Analytics subsystem OVA file](#).
  - c. Verify the deployment. See [Verifying deployment of the Analytics subsystem](#).
2. Restore the Analytics data from backup, as explained in [Restoring the Analytics database](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

# Using VM snapshots for infrastructure backup and disaster recovery

You can use VM snapshots to backup and restore the infrastructure used by API Connect on VMware, and also for infrastructure disaster recovery.

Backup and restore procedures for the databases used by IBM API Connect on VMware are described in [Backing up and restoring \(10.0.1.1-eus or later\)](#). The procedures back up all of the state required by API Connect but do not include the underlying infrastructure software or other internal state.

In some scenarios, you may want to perform backups and disaster recovery at an infrastructure layer. You can do this by taking snapshots of the virtual machines or underlying storage volumes, providing that you follow the constraints described here.

Note that performing backups at the infrastructure layer differs from the standard approach in that not only is the database state backed up, but also the precise state of the software. This approach can be useful, for example, when testing upgrades of production systems.

VM snapshots should not be used as an alternative to taking normal backups. Ideal times to take VM snapshots are after initial install and configuration, and before and after upgrades. In the event of a disaster, reverting to the last snapshot taken and then restoring the standard daily backup can be faster than redeploying OVA's and restoring the backup.

- Requirements for taking a consistent backup of an API connect system at the infrastructure level
  - An API Connect system can be approximated by the following diagram:

Table 1. API Connect Installation

- The system comprises multiple Virtual Machine images which are running Kubernetes, multiple databases, with the API Connect micro services running on top. There is transactional communication between the virtual machines which is occurring at all levels of this stack. This communication occurs all the time, even if the system is seemingly idle.
- Within the system there are multiple stateful or database layers on the software that maintain a consistency protocol. For example `etcd` upon which Kubernetes is based uses the [Raft](#) consensus algorithm. These algorithms depend for consistency on the basic assertion that time flows forwards on all systems together. If one or more of the virtual machine's state were to move backwards relative to the others by even the smallest quantum of time then consistency would be lost and the system might behave badly.

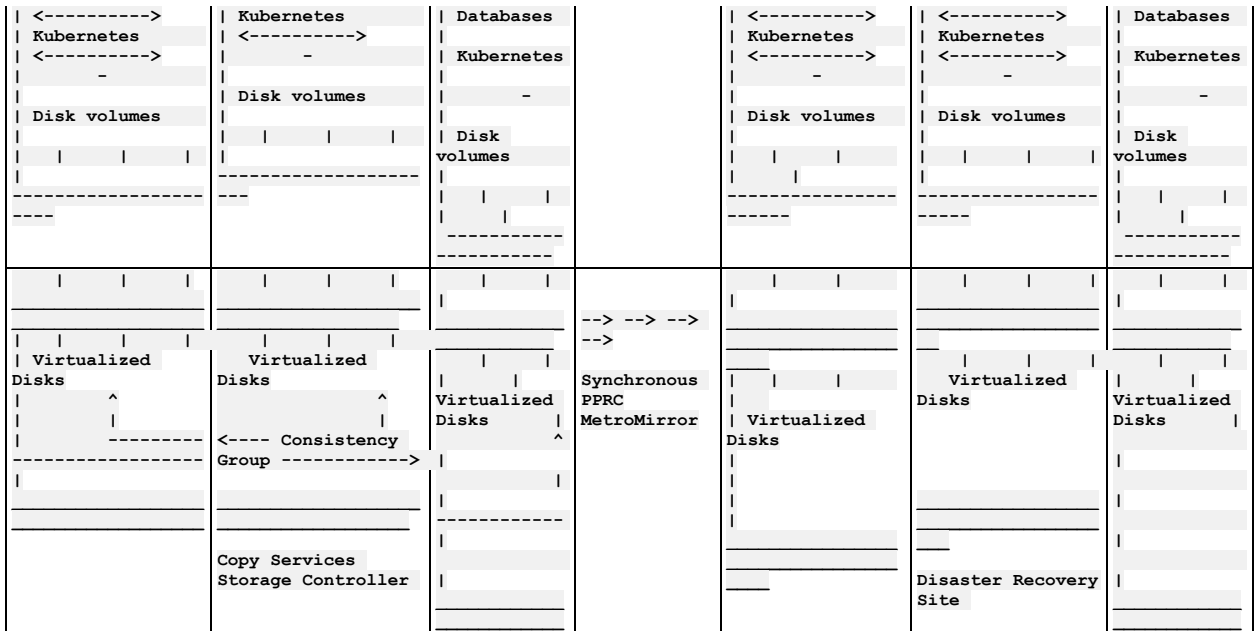

Clearly, if Virtual Machine snapshots are taken across multiple virtual machines it is certain that these snapshots will not be taken at precisely the same time. The result will be a backup that contains a system state that contains data from snapshots taken at slightly different times. It is possible that such a backup system may be restored and may appear to work correctly but hidden deep within it there may be undetected inconsistencies that will cause strange unpredictable errors and inconsistencies later. These issues can be extremely difficult to diagnose.

It is also possible that you can test this procedure successfully multiple times and see no apparent problem occurring. Irrespective of the apparent success of tests, corruption can be occurring in the system state. For this reason, taking VM snapshots or clones of a running API Connect system is not supported.

- How to take a consistent backup of an API connect system at the infrastructure level
  - The only way to take a consistent backup of an API connect system using VM snapshots and clones is to shut down ALL of the virtual machines comprising the system before taking the snapshot or clone.
  - Once the virtual machines are stopped at the VM level, time is effectively frozen. Then a snapshot can be taken on all the VMs. A clone can be made from the snapshot taken on each VM. This set of clones represent a valid, consistent state that the API Connect system was in when it was shut down.
  - Once all of the snapshots and clones have been taken the original API Connect system can be restarted.
- Restoring an API Connect System from VM clones
  - The Cloned VMs represent a valid state of the original API Connect system. They will restart in exactly the same way as the original system restarted.
  - If the objective is to stand up another instance of the cloned API connect system for testing or DR purposes, the following must be true:
    - The original system and the cloned system must be isolated from one another. The clone will be using the same hostnames and IP addresses as the original and so must be stood up in a separate virtual machine hosting environment with Network Address Translation between itself and any network to which the original system is stood up.
    - The cloned system must be stood up in an identical environment in terms of its hardware, software and network.
- Disaster Recovery approaches using Disk Replication:
  - A common DR approach used by enterprises is to use disk based replication. In this case, a storage controller such as IBM's San Volume Controller provides [Copy Services](#). You can use Copy Services to create a completely consistent copy of a set of disks. IBM calls this feature *Synchronous Remote Copy* or *MetroMirror*. Other storage vendors have similar features.
  - If you use Remote Copy to synchronize disk images to a DR site then IBM will support API connect used with these systems so long as the copy at the DR site is completely consistent. Ensuring this consistency is the responsibility of the storage controller and its configuration. It is **critically important** to ensure that ALL of the disk volumes for all of the VMs or nodes in the entire API Connect system are in the same [remote copy consistency group](#) as shown below. This ensures that DR scenarios do not create inconsistent volumes. If the disks are not in the same consistency group then the copy will not be managed consistently and the system will not be supported.

Table 2. API Connect Installation and corresponding Disaster Recovery site

- Infrastructure based backup of API Connect using vSphere
  - The following procedure outlines steps to clone a VMware instance of API Connect, using the following topology:
    - 3 Management Nodes
    - 3 Portal Nodes
    - 3 Analytics Nodes
    - 3 Gateways
  - Each of these components has a load balancer with its own IP address. The load balancers all sit on a single VM. The cluster is installed and configured on 13 VMs in VMware. In this example, the system was populated with data and APIs. These should first be tested to ensure that all published APIs respond as expected. Once this is done, use vSphere UI to complete the following steps:
    1. Power off VMs
 

To power off the VMs in sync, schedule a “shutdown guest OS” such that all the VMs shutdown at the same time. Although the shutdown does not occur at exactly the same instant, this does allow the shutdown for every machine to be as close in time as possible.
    2. Take snapshots
 

Take snapshots of each VM after shutdown. Using the scheduling feature in the UI, schedule a snapshot of all the VMs at the same instant. If cloning should adversely affect the system in any way then the original VMs can be reverted back to these snapshots.
    3. Clone VMs
 

Use the clone feature of the UI to create a clone of each VM. This VM should sit in the same resource pool as the original cluster. This is simply an exact copy of the disks of the original machine. The clones and originals are in no way coupled.
    4. Power on clones
 

Schedule the power-on for each clone VM such that all the clone VMs power on simultaneously. Once this is done, test the cluster to ensure that the APIs respond as expected. For the example cluster topology shown earlier on this page, it can take a couple of hours after power-on for all the APIs to respond as expected.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
 For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Disabling the Analytics subsystem on VMware

Disable the Analytics subsystem by shutting down the VM that hosts it.

### Before you begin

Disabling the Analytics subsystem stops the collection and storage of data as well as making the subsystem unavailable. If you just want to pause data collection without disabling the entire subsystem (for example, while renewing certificates), see [Stopping Analytics data collection](#).

### About this task

When you disable Analytics, there will be no data in either the API Manager Dashboards or third-party offloads.

### Procedure

1. Back up your Analytics data.  
 For information, see the backup instructions for your version of API Connect:

- 10.0.1.1-eus or later: [Backing up and restoring the Analytics database on VMware](#)
  - 10.0.0.0 or 10.0.1.0-eus: [Backing up and restoring the analytics database on VMware](#)
2. Disable shard allocation for storage.
- Disabling shard allocation is optional, but is recommended because it prevents new shards from being created for replication when a node is unavailable, and helps avoid corruption issues in full system restarts.

a. Connect to the virtual machine as the API Connect administrator by completing the following steps:

i. Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```

ii. When prompted, select Yes to continue connecting.

iii. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

b. Disable shard allocation for storage by running the following command:

```
kubectl -n namespace exec -it storage-master|shared_pod -- curl_es _cluster/settings -XPUT -d '{"persistent":{"cluster.routing.allocation.enable":"none"}}'
```

where:

- `namespace` is the namespace where the Analytics subsystem is installed.
- `storage-master|shared_pod` is the name of any storage-master or storage-shared pod. You can get the name of your storage pods by running the following command and substituting in the namespace where Analytics is installed:

```
kubectl -n namespace get po
```

When you disable shard allocation, the response looks like the following example:

```
{"acknowledged":true,"persistent":{"cluster":{"routing":{"allocation":{"enable":"none"}}},"transient":{}}
```

Leave the connection open for the next step.

3. Perform a synced flush of storage.

Flushing the storage is optional, but is recommended because it helps to avoid losing the data that was not yet written to disk. This step flushes all current index operations synchronously and attempts to write everything that is in flux to disk. Perform a synced flush of storage by running the following command:

```
kubectl -n namespace exec -it storage-master|shared_pod -- curl_es _flush/synced -XPOST
```

When you flush storage, the response looks like the following example:

```
{"_shards":{"total":33,"successful":13,"failed":0},".export-status":{"total":1,"successful":1,"failed":0},".apic-config":{"total":1,"successful":1,"failed":0},".kibana-6":{"total":1,"successful":1,"failed":0},"apic-api-2020.06.19-000002":{"total":15,"successful":5,"failed":0},"apic-api-2020.06.18-1":{"total":15,"successful":5,"failed":0}}
```

The operation often fails, and it is safe to rerun it multiple times until it passes and there are all "failed" counts are zero. If it continues to fail after running multiple attempts over the span of a couple minutes, you can proceed to the next step.

4. Shut down the Analytics VMs.

You can shut down the VMs using one of the following methods:

- Use the VMware console
- `ssh` into the images and run the `shutdown` command

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Maintaining a two data center deployment

How to maintain a two data center disaster recovery (DR) deployment on VMware, including information about normal operation, failure handling, and recovery.

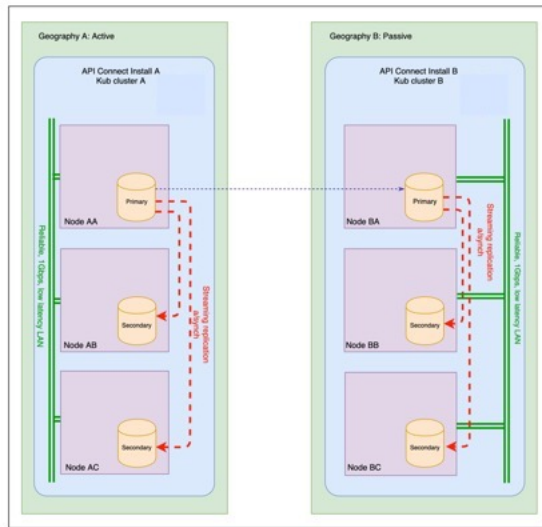

The following information explains how the data flows between the two API Connect subsystems, the API Manager and the Developer Portal, when the two data center DR deployment is running in normal operational mode. Both subsystems have a different internal topology and operate in a slightly different way, and therefore are described separately.

For a general overview of how endpoints and the traffic between ingresses flow in API Connect, see [Deployment overview for endpoints and certificates](#).

Ensure that you understand the concepts of a two data center disaster recovery deployment in API Connect. For more information, see [A two data center deployment strategy on VMware](#).

## Normal operation for the API Manager

In normal operation each data center contains an API Manager service which includes one primary database pod, and some (usually two) secondary pods. As well as the cluster replication that occurs within the data center from the primary to the secondary pods, there is also a Publish/Subscribe logical replication of changes from the active data center to the passive one, as shown in the following diagram.

#### API Manager data flows

The following data flows exist to and from the API Manager.

- Data traffic from the API Manager to the DataPower® gateway director to publish APIs to the gateway via webhooks, as well as to update the gateway with consumer subscriptions, credentials, and so on. This connection does not use mutual TLS (mTLS) by default, but it can be enabled; see [TLS profiles overview](#) for more information.
- Data traffic from the API Manager to the Developer Portal director endpoint. This traffic contains both REST calls to create and delete Portal sites, and also webhook traffic to send the Portal updated data when changes are made in API Manager. This connection is secured by mTLS.
- Incoming data traffic to the consumer API endpoint of the API Manager, in order to carry out consumer actions such as login authentication, create a new application, subscribe to a product, and so on. These calls could come from the Portal, or from direct REST calls made by a consumer or a custom application.
- Incoming data traffic to the platform API endpoint of the API Manager. These calls could come from the Portal, the gateway, and possibly from custom applications.
- Incoming web UI data traffic to the Cloud and Manager UI endpoints of the API Manager.

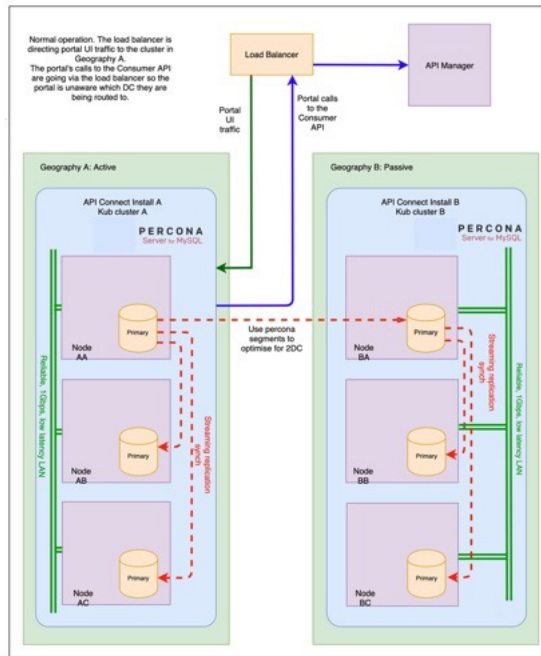

## Normal operation for the Developer Portal

An API Connect deployment can have multiple Developer Portal services, each of which can be deployed to the primary data center, or the secondary data center, or to both. Obviously if the Developer Portal service is only deployed to a single data center, there is no disaster recovery strategy. So, on the assumption that the Portal service is deployed to both data centers, then there will be multiple Portal pods in each data center. The ideal configuration is to have two or three Portal pods in each data center; any more than three and the costs of data replication outweigh any benefits in additional load handling.

The Developer Portal cluster replication has two components: a database and a filesystem. These components are independent, and both replicate in a star model whereby each pod replicates changes to every other pod. The database also has the added advantage of supporting segment replication, which can be used to optimize the replication across data centers. However, the filesystem replication, which uses CSync2, does not currently support segments.

As all Developer Portal pods are active primary servers, there is no need to be concerned if any writes occur in the passive data center. If any traffic does get routed to the passive data center, this traffic is replicated back to the active data center, and data consistency is maintained.

The following diagram gives an overview of the normal operation for the Developer Portal.

### Developer Portal data flows

The following data flows exist to and from the Developer Portal.

- Data traffic from the API Manager to the Developer Portal director endpoint. This traffic contains both REST calls to create and delete Portal sites, and also webhook traffic to send the Portal updated data when changes are made in API Manager. This connection is secured by mTLS.
- Data traffic from the Developer Portal to the consumer API endpoint of the API Manager, in order to carry out consumer actions such as login authentication, create a new application, subscribe to a product, and so on.
- Data traffic from the Developer Portal to the Analytics client endpoint, in order to display the Portal consumer analytics. However, if there is more than one analytics service in use on a Catalog, then Portal consumer analytics is automatically disabled.
- There is no data traffic from the Developer Portal to the DataPower Gateway, or vice versa.
- Incoming web UI data traffic to the Developer Portal on the Portal UI endpoint. This data is user traffic from the browsers of Developer Portal consumers.
- All calls between the API Manager and the Developer Portal (in either direction), must go via a dynamic router in order to allow for either service to have independent failover between the data centers.

## Backup and restore considerations for a two data center deployment

Points to consider when backing up and restoring a two data center disaster recovery (DR) deployment on VMware.

Full instructions about backing up and restoring your API Connect deployment are contained in the following topics:

- [Backing up the Management subsystem in a VMware environment](#)
- [Restoring the management subsystem on VMware](#)

- [Backing up and restoring the Developer Portal in a VMware environment](#)

Follow the steps in these topics to back up and restore your two data center DR deployment. However, there are some additional considerations to bear in mind if you have a two data center DR deployment, and these considerations are listed in the [General considerations](#) section that follows.

For general information about two data center disaster recovery in API Connect, see [A two data center deployment strategy on VMware](#).

## General considerations

---

- Best practice is to take regular, scheduled backups of the subsystems in the primary (active) data center, as this is the data center that contains the most valid data.
- Before you configure S3 backup settings you must first disable 2DCDR on both sites, and then re-enable 2DCDR after reconfiguring your backup settings.

1. Disable 2DCDR for the management subsystems on both sites:

```
apicup subsys set <management subsystem> multi-site-ha-enabled=false
apicup subsys install <management subsystem>
```

2. Configure your S3 backup settings.
3. Enable 2DCDR for the management subsystems on both sites:

```
apicup subsys set <management subsystem> multi-site-ha-enabled=true
apicup subsys install <management subsystem>
```

You do not need to do this for SFTP or local backups.

- The subsystems in the secondary (passive) data center should be backed up only when key updates are made, for example when first deploying a passive data center, and then again before and after applying fix packs. This ensures that all of the endpoints in the deployment remain consistent.
- If a subsystem or entire data center needs to be restored, the data will be retrieved from the backups of the subsystems in the active data center.
- If a passive data center fails, you can either restore before you enable the multi-site HA setting on that site. Or, restore your passive data center, then trigger a re-sync of the databases.

Important: If the passive data center is offline for more than 24 hours, there can be issues with the disk space on the active data center so you must revert your deployment to a single data center topology. To revert to a single data center topology, you must change the `multi-site-ha-enabled` setting to `false` on the active data center. When the passive site has been redeployed, the `multi-site-ha-enabled` setting can be reapplied to the active site.

- You can trigger the passive data center to re-sync its databases with the active data center by disabling the multi-site HA setting of the passive data center, and then enabling the multi-site HA setting again. This action triggers a re-sync with the active data center, to ensure that the passive data center contains the latest data. On VMware, this involves the following steps:

1. Run `apicup` to change the `multi-site-ha-enabled` property to `false` on the passive data center, for example:

```
apicup subsys set service_name multi-site-ha-enabled=false
```

where `service_name` is the name of the management or portal service that you want to disable, for example `mgmt_dc2`.

2. Run `apicup` to update the settings in the deployed passive subsystem, for example:

```
apicup subsys install service_name
```

3. Run `apicup` to change the `multi-site-ha-enabled` property back to `true` on the passive data center, for example:

```
apicup subsys set service_name multi-site-ha-enabled=true
```

4. Run `apicup` to update the settings in the deployed passive subsystem again, for example:

```
apicup subsys install service_name
```

# Failure handling of a two data center deployment

How to detect failures, and perform service failover, in a two data center disaster recovery deployment on VMware.

## Before you begin

---

Ensure that you understand the concepts of a two data center disaster recovery deployment in API Connect. For more information, see [A two data center deployment strategy on VMware](#).

## About this task

---

Failure handling comprises of two main concepts; failure detection, and failover of services.

Failure detection is about detecting that a failure has happened, and then alerting the relevant administrator for them to take action. Failure detection is different from system monitoring. Failure detection checks are run often and fast (for example, every 5 seconds). As such they are normally more limited in what they check. In API

Connect, failure checks detect only whether the database and web server are online, and nothing more. Whereas monitoring checks typically are run less frequently, but are more likely to check for things like CPU, memory, and disk space usage. The results of these checks can then be recorded to perform historical trend analysis to spot memory leaks for example.

If a failure is detected by the system administrator, or any automated monitoring that you are running, it's important to make sure that the cluster or service is definitely offline. So, for example, if data center one (DC1) appears to have an outage, and the plan is to failover to data center two (DC2), then it's important to make sure that the pods in DC1 really are offline. If the DC1 pods are actually still running, then they might continue to send data to DC2, which would lead DC2 to think it wasn't the active deployment, and then that could lead to split-brain. A fast way to ensure that the cluster or service really is offline, is to drop the network link to those pods in your VMware infrastructure, and then delete them.

The failure detection endpoint must be location specific and must be exempt from any traffic routing, so that it's possible to explicitly check the health of each data center regardless of how traffic is being routed.

You can failover a specific service, for example `portal_service_1`, or all of the services that are running in a particular data center. The following sections describe how failover is achieved.

The operational states of an API Manager service:

| Operational state      | Description                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------|
| progressing to active  | Pods are progressing to the active state, but none are capable of serving traffic.                |
| active                 | All of the pods are ready and in the correct disaster recovery state for the active data center.  |
| progressing to passive | Pods are progressing to the passive state, but none are capable of serving traffic.               |
| passive                | All of the pods are ready and in the correct disaster recovery state for the passive data center. |

The operational states of a Developer Portal service:

| Operational state                          | Description                                                                                           |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------|
| progressing to active                      | Pods are progressing to the active state, but none are capable of serving traffic.                    |
| progressing to active (ready for traffic)  | At least one pod of each type is ready for traffic. The dynamic router can be linked to this service. |
| active                                     | All of the pods are ready and in the correct disaster recovery state for the active data center.      |
| progressing to passive                     | Pods are progressing to the passive state, but none are capable of serving traffic.                   |
| progressing to passive (ready for traffic) | At least one pod of each type is ready for traffic.                                                   |
| passive                                    | All of the pods are ready and in the correct disaster recovery state for the passive data center.     |
| progressing to down                        | Pods are moving from passive state to down.                                                           |
| down                                       | The multi-site HA mode is deleted from the passive data center.                                       |

You can run the following command to check the operational state of a service:

```
kubect1 describe ServiceName
```

Where `ServiceName` is the name of the API Manager or Developer Portal service.

Important:

- If the active data center is offline, do not change the `multi-site-ha-enabled` setting to `false` on the passive data center, as this action deletes all the data from the databases. If you want to revert to a single data center topology, you must change the `multi-site-ha-enabled` setting to `false` on the active data center, and then redeploy the passive data center. If the active data center is offline, you must first change the passive data center to be active, and then change the `multi-site-ha-enabled` setting to `false` on the now active data center.
- If the passive data center is offline for more than 24 hours, there can be issues with the disk space on the active data center so you must revert your deployment to a single data center topology. To revert to a single data center topology, you must change the `multi-site-ha-enabled` setting to `false` on the active data center. When the passive site has been redeployed, the `multi-site-ha-enabled` setting can be reapplied to the active site.

## Procedure

### • API Manager service failover

To initiate a failover from DC1 to DC2 you first must set DC1 to passive, before making the passive data center active. This action is needed to prevent split-brain, as there cannot be two active services or clusters at the same time. If the failover is being done because the current active data center has had a complete outage, then you should ensure that the network links to that data center are dropped in your VMware infrastructure, in order to avoid the potential for split-brain occurring. The offline data center must be set to passive before the network links are restored. The following instructions show how to failover DC1 to DC2 for the API Manager service.

1. Set DC1 (in this example, located in Dallas) to be passive.

Run `apicup` to change the `multi-site-ha-mode` property to `passive` on the Dallas data center, for example:

```
apicup subsys set mgmt_dallas multi-site-ha-mode=passive
```

where

- `mgmt_dallas` is the name of the management service on DC1.

Note: If DC1 is completely down, and you cannot set it to be passive at this point, you must ensure that the network links to DC1 are removed before continuing to set DC2 to be active. You must then not restore the network links to DC1 until you can set DC1 to be passive.

2. Run `apicup` to update the settings on DC1, for example:

```
apicup subsys install mgmt_dallas
```

3. Log in to the virtual machine management subsystem on DC1 by using an SSH tool, and run the following command to check that the API Manager service is ready for traffic:

```
kubect1 describe ServiceName
```

The service is ready for traffic when the `Ha mode` part of the `Status` object is set to `passive`. For example:

```
Status:
...
Ha mode: passive
...
```

4. Set DC2 (in this example, located in Raleigh) to be active.

Run `apicup` to change the `multi-site-ha-mode` property to `active` on the Raleigh data center, for example:

```
apicup subsys set mgmt_raleigh multi-site-ha-mode=active
```

where

- `mgmt_raleigh` is the name of the management service on DC2.

5. Run `apicup` to update the settings on the services on DC2.

For example:

```
apicup subsys install mgmt_raleigh
```

6. Update your dynamic router to redirect all traffic to DC2 instead of DC1. Note that until the DC2 site becomes `active`, the UIs might not be operational.

7. Log in to the virtual machine management subsystem on DC2 by using an SSH tool, and run the following command to check that the API Manager service is ready for traffic:

```
kubect1 describe ServiceName
```

The service is ready for traffic when the `Ha mode` part of the `Status` object is set to `active`. For example:

```
Status:
...
Ha mode: active
...
```

#### • Developer Portal service failover

To initiate a failover for the Developer Portal from DC1 to DC2 you first must ensure that the existing DC1 is passive, before making the passive data center active, in order to prevent split-brain. The following instructions show how to failover DC1 to DC2 for the Developer Portal service. You must repeat these steps for each Developer Portal service that you want to failover.

Note:

- Switching a Developer Portal service to passive mode instantly restarts all of its `portal-db` and `portal-www` pods at the same time. Therefore, if you don't have an active Developer Portal service that is online, there will be an outage of the Developer Portal web sites until the passive data center is ready to accept traffic.
- If you want to monitor the failover process, you can run the following command to check the status of the Portal pods in the `PortalService` CR file:

```
kubect1 describe ServiceName
```

For more details about the status information in a `PortalCluster` CR file, see the [Example](#) section.

- Do not edit the `PortalService` CR file during the failover process.

1. Set DC1 (in this example, located in Dallas) to be passive.

Run `apicup` to change the `multi-site-ha-mode` property to `passive` on the Dallas data center, for example:

```
apicup subsys set port_dallas multi-site-ha-mode=passive
```

where

- `port_dallas` is the name of the Portal service on DC1.

Note: If DC1 is completely down, and you cannot set it to be passive at this point, you must ensure that the network links to DC1 are removed before continuing to set DC2 to be active. You must then not restore the network links to DC1 until you can set DC1 to be passive.

2. Run `apicup` to update the settings on DC1, for example:

```
apicup subsys install port_dallas --skip-health-check
```

Important: You must not wait for the active DC `Status` to become `passive`, before failing over the passive DC to become `active`. You should change the DC1 `multi-site-ha-mode` to `passive`, and then run the `kubect1 describe ServiceName` command, and as soon as the `haMode` is set to `progressing to passive`, you must change DC2 to be `active`.

3. Set DC2 (in this example, located in Raleigh) to be active.

Run `apicup` to change the `multi-site-ha-mode` property to `active` on the Raleigh data center, for example:

```
apicup subsys set port_raleigh multi-site-ha-mode=active
```

where

- `port_raleigh` is the name of the Portal service on DC2.

4. Run `apicup` to update the settings on the services on DC2.

For example:

```
apicup subsys install port_raleigh --skip-health-check
```

5. Update your dynamic router to redirect all traffic to DC2 instead of DC1.

6. Log in to the virtual machine management subsystem on DC2 by using an SSH tool, and run the following command to check that the Developer Portal service is ready for traffic:

```
kubect1 describe ServiceName
```

The service is ready for traffic when the `haMode` part of the `Status` object is set to `active`. For example:

```
Status:
...
haMode: active
...
```

#### • Entire data center failover

To failover an entire datacenter, follow the previous steps to failover the API Manager service, followed by the steps to failover each Developer Portal service in that data center.

How long it takes to complete the failover varies, and depends on hardware speed, network latency, and the size of the databases. However, here are some approximate timings:

For API Manager:

- `passive` to `active` approximately 5 minutes

- **active to passive** approximately 15 minutes
- For Developer Portal:
- **passive to active** 15 - 40 minutes
  - **active to passive** approximately 10 minutes

## Example

Example of the status section of a `PortalCluster` CR file for an active data center that you can view by running the `kubectl describe PortalService` command:

```
status:
 conditions:
 - lastTransitionTime: "2020-04-27T08:00:25Z"
 message: 4/6
 status: "False"
 type: Ready
 customImages: true

 reconciled: 10.0.0.0-1038
```

Meaning of the `haMode` for the active data center:

- **active** - this is the active data center, or the only data center, and all pods are ready and accepting traffic.
- **progressing to active** - this is the active data center, or the only data center, and there are no pods ready yet.
- **progressing to active (ready for traffic)** - this is the active data center, or the only data center, and there is at least one pod of each type, www, db, and nginx, ready, so the data center is accepting traffic.

Example of the status section of a `PortalCluster` CR file for a passive data center that you can view by running the `kubectl describe PortalService` command:

```
status:
 conditions:
 - lastTransitionTime: "2020-04-21T10:54:54Z"
 message: 6/6
 status: "True"

 reconciled: 10.0.0.0-1038
```

Meaning of the `haMode` for the passive data center:

- **passive** - this is the passive data center, and all pods are ready and accepting traffic.
- **progressing to passive** - this is the passive data center, and there are no pods ready yet.
- **progressing to passive (ready for traffic)** - this is the passive data center, and there is at least one pod of each type, www, db, and nginx, ready, so the data center is accepting traffic.

## What to do next

---

As soon as a failure on a data center has been resolved, the failed data center should be brought back online and re-linked to the currently active data center in order to maintain the highest availability; see [Recovering from a failover of a two data center deployment](#) for more information.

# Recovering from a failover of a two data center deployment

How to recover a two data center disaster recovery deployment on VMware.

## Before you begin

---

Ensure that you understand the concepts of a two data center disaster recovery deployment in API Connect. For more information, see [A two data center deployment strategy on VMware](#).

## About this task

---

After a failure has been resolved, the failed data center can be brought back online and re-linked to the currently active data center. It's important to do this as soon as possible, in order to reinstate disaster recovery. Otherwise, if another failure occurred before the failed data center is brought back online, there could be a complete outage.

The failed data center can be brought back online as the new active primary data center, or it can be brought back as a passive secondary data center and the currently active data center kept as the primary one. This decision will be based on your own company policies about recovering from a failure.

The amount of data that is sent when recovering from a failover, will depend on how long the outage lasted, and how much activity there was during that period.

Important:

- If the active data center is offline, do not change the `multi-site-ha-enabled` setting to `false` on the passive data center, as this action deletes all the data from the databases. If you want to revert to a single data center topology, you must change the `multi-site-ha-enabled` setting to `false` on the active data center, and then redeploy the passive data center. If the active data center is offline, you must first change the passive data center to be active, and then change the `multi-site-ha-enabled` setting to `false` on the now active data center.
- If the passive data center is offline for more than 24 hours, there can be issues with the disk space on the active data center so you must revert your deployment to a single data center topology. To revert to a single data center topology, you must change the `multi-site-ha-enabled` setting to `false` on the active data center. When the passive site has been redeployed, the `multi-site-ha-enabled` setting can be reapplied to the active site.

## Procedure

### • Recovering from an API Manager failover

The following instructions show how to bring data center one (DC1) back as the primary (**active**) data center, and assume that DC1 is now online and in the passive state. If you prefer, you can keep DC1 as the secondary data center, and leave data center two (DC2) as the primary (**active**) data center.

1. Set DC2 (in this example, located in Raleigh) to be passive.

Run **apicup** to change the **multi-site-ha-mode** property to **passive** on the Raleigh data center, for example:

```
apicup subsys set mgmt_raleigh multi-site-ha-mode=passive
```

where

- **mgmt\_raleigh** is the name of the management service on DC2.

2. Run **apicup** to update the settings on DC2, for example:

```
apicup subsys install mgmt_raleigh
```

3. Log in to the virtual machine management subsystem on DC2 by using an SSH tool, and run the following command to check that the API Manager service is ready for traffic:

```
kubectl describe ServiceName
```

The service is ready for traffic when the **Ha mode** part of the **Status** object is set to **passive**. For example:

```
Status:
...
Ha mode: passive
...
```

You must also ensure that the database in DC2 has replicated over completely before proceeding.

4. Set DC1 (in this example, located in Dallas) to be active.

Run **apicup** to change the **multi-site-ha-mode** property to **active** on the Dallas data center, for example:

```
apicup subsys set mgmt_dallas multi-site-ha-mode=active
```

where

- **mgmt\_dallas** is the name of the management service on DC1.

5. Run **apicup** to update the settings on DC1.

For example:

```
apicup subsys install mgmt_dallas
```

6. Update the dynamic router to redirect all traffic to DC1 instead of DC2. Note that until the DC1 site becomes **active**, the UIs might not be operational.

7. Log in to the virtual machine management subsystem on DC1 by using an SSH tool, and run the following command to check that the API Manager service is ready for traffic:

```
kubectl describe ServiceName
```

The service is ready for traffic when the **Ha mode** part of the **Status** object is set to **active**. For example:

```
Status:
...
Ha mode: active
...
```

### • Recovering from a Developer Portal failover

When recovering from a Developer Portal failover, how much data is sent from the now passive data center (in this example, DC2) back to the newly recovered active data center (in this example, DC1) varies depending on how much time has passed and how many changes have been made in the meantime.

If possible, the Portal sends an Incremental State Transfer (IST), which is a replay of the transactions that have happened since the failed data center, DC1, became unreachable. The IST can grow to be up to 3 GB in size. If the IST grows larger than 3 GB, then the Portal sends a State Snapshot Transfer (SST) instead, which is basically a full copy of the whole database. How long this process takes depends on how many Portal sites there are, how much content in each of those sites, how active they are (as in number of transactions), and how fast the network speed is between the data centers. However, it is likely to take in the range 5 - 60 minutes.

You can check whether the Developer Portal servers are in sync by running the **status** command in the **portal-www** pod admin container. If all servers show as **primary**, then they are in sync and traffic can be directed wherever needed. For information about running the status command, see [Verifying deployment of the Developer Portal subsystem](#).

Note:

- If you want to monitor the recovery process, you can log in to the virtual machine Portal subsystem by using an SSH tool, and run the following command to check the status of the Portal pods in the **PortalService** CR file:

```
kubectl describe ServiceName
```

For more details about the status information in a **PortalCluster** CR file, see the [Example](#) section.

- Do not edit the **PortalService** CR file during the recovery process.

The following instructions show how to bring DC1 back as the active primary data center, and switch DC2 to be the passive secondary data center. Again, you can keep DC2 as the active primary data center if you prefer, and leave DC1 to be passive.

1. Set DC2 (in this example, located in Raleigh) to be passive.

Run **apicup** to change the **multi-site-ha-mode** property to **passive** on the Raleigh data center, for example:

```
apicup subsys set port_raleigh multi-site-ha-mode=passive
```

where

- **port\_raleigh** is the name of the Portal service on DC2.

2. Run **apicup** to update the settings on the services on DC2.

For example:

```
apicup subsys install port_raleigh --skip-health-check
```

Important: You must not wait for the active DC **Status** to become **passive**, before changing the passive DC to become **active**. You should change the DC2 **multi-site-ha-mode** to **passive**, and then run the `kubect1 describe ServiceName` command, and as soon as the **haMode** is set to **progressing** to **passive**, you must change DC1 to be **active**.

3. Set DC1 (in this example, located in Dallas) to be active.

Run `apicup` to change the **multi-site-ha-mode** property to **active** on the Dallas data center, for example:

```
apicup subsys set port_dallas multi-site-ha-mode=active
```

where

- `port_dallas` is the name of the Portal service on DC1.

4. Run `apicup` to update the settings on the services on DC1.

For example:

```
apicup subsys install port_dallas --skip-health-check
```

5. Update the dynamic router to redirect all traffic to DC1 instead of DC2.

6. Log in to the virtual machine Portal subsystem on DC1 by using an SSH tool, and run the following command to check that the Developer Portal service is ready for traffic:

```
kubect1 describe ServiceName
```

The service is ready for traffic when the **Ha mode** part of the **Status** object is set to **active**. For example:

```
Status:
...
Ha mode: active
...
```

# Removing a two data center deployment

You can remove your two data center disaster recovery deployment on VMware.

## Before you begin

Ensure that you understand the concepts of a two data center disaster recovery deployment in API Connect. For more information, see [A two data center deployment strategy on VMware](#).

## About this task

If you decide to remove your two data center disaster recovery (DR) deployment, you go from two data centers to one. The active data center remains as the only working system. The passive one loses all data as part of the process.

Warning: If the active data center is offline, do not remove the multi-site HA CR section from the passive data center, as this action deletes all the data from the databases. As part of the installation, you configured the **multi-site-ha** settings on each data center, as described in the following table:

Table 1. The **multi-site-ha** settings

| Setting                       | Description                                                                                                                                                                                                                                                                                 |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>multi-site-ha-enabled</b>  | Indicates whether two data center DR deployment is enabled. Set to <b>true</b> to enable two data center DR. Set to <b>false</b> to disable two data center DR. The default value is <b>false</b> .                                                                                         |
| <b>multi-site-ha-mode</b>     | The state of the data center in the context of the two data center deployment. Valid values are: <ul style="list-style-type: none"><li>• <b>active</b> - indicates the primary data center</li><li>• <b>passive</b> - indicates the standby data center</li></ul>                           |
| <b>management-replication</b> | Required only for the Management subsystem. The external ingress name for the Management subsystem in the current data center in the two data center deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center. |
| <b>portal-replication</b>     | Required only for the Portal subsystem. The external ingress name for the Portal subsystem in the current data center in the two data center deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.         |
| <b>replication-peer-fqdn</b>  | The ingress hostname for the other data center in the two data center deployment. This information is required so that the two data centers can communicate with each other.                                                                                                                |

If you want to revert to a single data center topology, or temporarily remove the passive data center from DR, you must disable the `multi-site-ha` configuration on the active data center, and then remove the passive data center. If the active data center is offline, you must first change the passive data center to be active, and then disable the `multi-site-ha` configuration on the now active data center.

## Procedure

---

- Disable the `multi-site-ha` configuration on the Management subsystem of the active data center. For example:

```
apicup subsys set mgmt multi-site-ha-enabled=false
apicup subsys install mgmt
```

- Disable the `multi-site-ha` configuration on the Portal subsystem of the active data center. For example:

```
apicup subsys set ptl multi-site-ha-enabled=false
apicup subsys install ptl
```

- You can now power off and shut down your passive data center.

# Upgrading a two data center deployment

How to upgrade a two data center disaster recovery (DR) deployment on VMware.

Full instructions about how to upgrade your API Connect deployment are contained in the following topic:

- [Upgrading API Connect](#)

However, there are some important additional instructions if you have a two data center DR deployment; see the following sections:

- [Key points when upgrading a two data center DR deployment](#)
- [How to upgrade when one data center is down](#)

For general information about two data center disaster recovery in API Connect, see [A two data center deployment strategy on VMware](#).

## Key points when upgrading a two data center DR deployment

---

Both data centers must be using the same version of API Connect, including down to the specific fix pack and iFix level, as appropriate. Each data center is effectively an identical deployment instance, so they must be kept on identical code level bases. Therefore, both data centers must be upgraded in the same maintenance window.

You must upgrade each subsystem in a specific order, upgrading it on the `passive` (standby) data center first, and then upgrading it on the `active` (primary) data center. This ordering of the upgrade is important, as the replication between the primary and the standby subsystems might fail if the `passive` subsystem is older than the `active` subsystem. Use the following instructions to upgrade your subsystems, paying particular attention to the detailed instructions for the Management subsystem.

Note:

- DO NOT reboot any of the virtual machines until the end of the upgrade, even if you're instructed to do so by the `apicup subsys health-check` during the upgrade process.
- To run the `kubect1` commands you need to SSH into the appropriate subsystem.
- Download [The API Connect operations tool: apicops](#) and copy it to your management VMs. The `apicops` tool must be run as root user.

### 1. The Management subsystem cluster:

- a. Run a health check on both clusters to ensure the deployment is in a good state. For example:

```
apicup subsys health-check <mgmt_cluster>
```

- b. Determine the current version of API Connect (what you are upgrading from).

You will need to specify the correct version number in the next step. To get the version, `ssh` into a subsystem and run the following command:

```
apic version
```

In the response, the `-`

`subsystem-<subsystem-name>` statement displays the installed version. In the following example, the response indicates that the installed version is 10.0.1.2-ifix2-eus:

```
root@ip-192-168-122-240:~# apic version
INFO[0000] Log level: info
```

```
Control plane: 1.20.0
Appliance base 3.0.0
GitCommitSha:10.0.1.2
Packages:
- appliance-base:3.0.0
- appliance-runtime-3.0.0:1.0.0
- subsystem-management:1:10.0.1.2-ifix2-eus
```

Important: If you are upgrading from a source version of 10.0.1.x, you must append "-eus" to the end of all references to that version number; for example 10.0.1.2-ifix2-eus.

- c. Create an extra-values.yaml file in a directory that `apicup` can access, and add the `version` setting with the current API Connect version that you just determined (or add the snippet to an existing file if you have one); for example:

```
spec:
 version: "10.0.1.2-ifix2-eus"
 imageRegistry: 127.0.0.1:8675/10.0.1.2-ifix2-eus
```

- d. Using the new `apicup` binary, run the following command to set the `extra-values` in the project folder for both the `active` and `passive` clusters.

```
apicup subsys set <mgmt> extra-values-file=<extra-values-file-path>
```

If you want to validate your `<extra-values-file-path>`, and the settings, before proceeding, you can run the following command:

```
apicup subsys get <mgmt> --validate
```

- e. If necessary, download any Control Plane files that are needed from the Fix Pack page to your computer. Control Plane files provide support for specific Kubernetes versions. An upgrade from the most recent API Connect version to the current version does not need a separate Control Plane file. However, when upgrading from older versions of API Connect, you must install one or more control plane files to ensure that all current Kubernetes versions are supported. Consult the following table to see if your deployment needs one or more separate Control Plane files.

Table 1. Control Plane files needed for upgrading to 10.0.1.7-eus

| Version to upgrade from                                                                                        | Control Plane files required for upgrading to 10.0.1.7-eus                                                                                                               |
|----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>• 10.0.1.6-eus and iFixes</li> <li>• 10.0.1.5-eus and iFixes</li> </ul> | Download: <ul style="list-style-type: none"> <li>• <code>appliance-control-plane-1.22.x.tgz</code></li> </ul>                                                            |
| Releases prior to 10.0.1.5-eus                                                                                 | Download: <ul style="list-style-type: none"> <li>• <code>appliance-control-plane-1.22.x.tgz</code></li> <li>• <code>appliance-control-plane-1.21.x.tgz</code></li> </ul> |

- f. If you are upgrading to a target version that is earlier than 10.0.1.9 or 10.0.5.1, you must save the images of that source version from the local docker registry at `/var/lib/apiconnect-subsystem/registry/<source_version>` to a secure location that won't be overwritten, for example, the root directory. Back up the images on both the `active` and `passive` clusters: first SSH into the management subsystem, and then run the following command:

```
cp /var/lib/apiconnect-subsystem/registry/<source_version> <secure-file-path>
```

- g. Now upgrade both the `active` and `passive` clusters to the latest version in parallel, with the new setting. For example:

```
apicup subsys install mgmt mgmt_upgrade_tar_archive
```

- h. For both clusters, wait for the Management subsystem status to become `Running`. Note that the new operator should reconcile the old version operand, and this may take some time. For example:

```
kubectl get mgmt -n mgmt_cluster
NAME READY STATUS VERSION RECONCILED VERSION AGE
management 16/16 Running 10.0.1.2-ifix2-eus 10.0.1.2-ifix2-100-eus 5h2m
```

The `RECONCILED VERSION/VERSION` should be the `source_version` that you retrieved in Step 1.b, and then will be updated to the target version in Step 1.r.

Note: If you are upgrading to a target version that is earlier than 10.0.1.9 or 10.0.5.1, some pods on the `active` or `passive` data center will have a status of `imagePullBackoff`, because the source version images were overwritten by the target version images. You must move the source version images back to the directory `/var/lib/apiconnect-subsystem/registry/<source_version>` where they were saved originally, and run the following command:

```
systemctl restart appliance-manager
```

This command will restart the local docker registry to pick up the source version images. However, if some pods remain in the `imagePullBackoff` state, it's because the image path is incorrect. To correct the image path, run the following commands:

- `kubectl edit deploy <deploy>` - Run this command on every deployment of pods that have the `imagePullBackoff` state, and change the image path to the source version.
- `kubectl edit pod <stancluster-pod>` - Run this command directly on the `<stancluster-pod>` and change the image path to the source version.

- i. Use the latest version of `apicops` to validate the certificates. For information on the `apicops` tool, see [The API Connect operations tool: apicops](#).

- i. Run the following command:

```
apicops upgrade:stale-certs -n <namespace>
```

- ii. Delete any stale certificates that are managed by cert-manager.

If a certificate failed the validation and it is managed by cert-manager, you can delete the stale certificate secret, and let cert-manager regenerate it. Run the following command:

```
kubectl delete secret <stale-secret> -n <namespace>
```

- iii. Restart the corresponding pod so that it can pick up the new secret.

To determine which pod to restart, see the following topics:

- [List of external certificates](#)
- [List of internal certificates](#)

- j. Disable the multi-site HA configuration on the `passive` Management subsystem. For example:

```
apicup subsys set passive_mgmt_cluster multi-site-ha-enabled=false
```

k. Run `apicup` to update the settings. For example:

```
apicup subsys install passive_mgmt_cluster
```

As soon as the multi-site HA configuration is disabled, the `passive` Management subsystem converts itself to an independent cluster where you can see all the microservices. Run a health check to ensure the deployment is in a good state; for example:

```
apicup subsys health-check mgmt_cluster
```

l. Wait for the Management subsystem status to become `Running` on the `passive` Management subsystem. For example:

```
kubect1 get mgmt -n passive_mgmt_cluster
NAME READY STATUS VERSION RECONCILED VERSION AGE
management 16/16 Running 10.0.1.2-ifix2-eus 10.0.1.2-ifix2-100-eus 5h2m
```

Note: If you are upgrading from a source version that is earlier than 10.0.4.0.0 or 10.0.1.4-eus, some pods on the data center will have a status of `imagePullBackoff`, because the source version images were overwritten by the target version images. See the previous [Note](#) for the instructions on how to correct the pod status.

m. Disable the multi-site HA configuration on the `active` Management subsystem. For example:

```
apicup subsys set active_mgmt_cluster multi-site-ha-enabled=false
```

n. Run `apicup` to update the settings. For example:

```
apicup subsys install active_mgmt_cluster
```

As soon as the multi-site HA configuration is disabled, the `active` Management subsystem converts itself to an independent cluster where you can see all the microservices.

o. Wait for the Management subsystem status to become `Running` on the `active` Management subsystem. For example:

```
kubect1 get mgmt -n active_mgmt_cluster
NAME READY STATUS VERSION RECONCILED VERSION AGE
management 16/16 Running 10.0.1.2-ifix2-eus 10.0.1.2-ifix2-100-eus 5h2m
```

The `RECONCILED VERSION/VERSION` should be the `source_version` that you retrieved in Step [1.b](#), and then will be updated to the target version in Step [1.r](#).

At this point you have two independent Management clusters.

p. Remove the `spec: version` snippet from the `extra-values.yaml` file that you added in Step [1.c](#):

```
spec:
 version: "10.0.1.2-ifix2-eus"
```

Alternatively, if there are no additional settings in the `extra-values.yaml` file that you want to keep, you can run the following command to unset the file:

```
apicup subsys set mgmt extra-values-file=
```

q. Using the updated `apicup` binary, run the `install` command on both the `active` and `passive` clusters (can be run in parallel). For example:

```
apicup subsys install mgmt
```

r. For both clusters, wait for the Management subsystem status to become `Running`. For example:

```
kubect1 get mgmt -n mgmt_cluster
NAME READY STATUS VERSION RECONCILED VERSION AGE
management 16/16 Running 10.0.1.5-eus 10.0.1.5-xxxx-eus 5h46m
```

The `RECONCILED VERSION/VERSION` now displays the target version that you upgraded to.

s. Run a health check on both clusters to ensure that the upgrade completed. For example:

```
apicup subsys health-check mgmt_cluster
```

t. Now, enable the multi-site HA configuration on the previously `active` Management subsystem. For example:

```
apicup subsys set active_mgmt_cluster multi-site-ha-enabled=true
```

u. Run `apicup` to update the settings. For example:

```
apicup subsys install active_mgmt_cluster
```

v. Wait for the Management subsystem status to become `Running` on the `active` Management subsystem. For example:

```
kubect1 get mgmt -n active_mgmt_cluster
NAME READY STATUS VERSION RECONCILED VERSION AGE
management 17/17 Running 10.0.1.5-eus 10.0.1.5-2807-eus 5h56m
```

The `RECONCILED VERSION/VERSION` now displays the target version that you upgraded to.

w. Enable the multi-site HA configuration on the previously `passive` Management subsystem. For example:

```
apicup subsys set passive_mgmt_cluster multi-site-ha-enabled=true
```

x. Run `apicup` to update the settings. For example:

```
apicup subsys install passive_mgmt_cluster
```

y. Wait for the Management subsystem status to become `Running` on the `passive` Management subsystem. For example:

```
kubect1 get mgmt -n passive_mgmt_cluster
NAME READY STATUS VERSION RECONCILED VERSION AGE
management 7/7 Running 10.0.1.5-eus 10.0.1.5-xxxx-eus 5h46m
```

You should see a limited set of microservices on the `passive` Management subsystem, for example 7/7.

z. Run the following command on the **active** Management subsystem to check that the API Manager service is ready for traffic:

```
kubectl describe ServiceName
```

The service is ready for traffic when the **Ha mode** part of the **Status** object is set to **active**. For example:

```
Status:
...
Ha mode: active
...
```

Note:

- It will take time for the **passive** site to sync with the **active** site.
- You can now run the `apicup subsys health-check` on the Management subsystem, and reboot if instructed to do so.

2. The Gateway subsystem cluster.

3. The Portal subsystem cluster: **passive** followed by **active**.

Note: If you upgrade from before Version 10.0.1.1-eus to Version 10.0.1.1-eus or later, you must upgrade the passive and active sites in parallel. This method means that both sites are down and then they restart their pods at the new versions in parallel so that they can cluster together. If you do not upgrade the passive and active sites in parallel, you might need to pass the `--skip-health-check` flag to `apicup` to do the second site. This flag might be needed because of an incompatibility between pods from before Version 10.0.1.1-eus, and pods of Version 10.0.1.1-eus, and later.

4. The Analytics subsystem cluster.

You must verify that each subsystem has been updated successfully on both the **passive** and the **active** data centers before upgrading the next subsystem.

The Developer Portal upgrade takes place in two stages. Firstly, the system is upgraded, which updates the internal deployment scripts, packages, and so on. Then, as soon as the system upgrade is complete, the individual Portal sites are upgraded to the new level of the Portal UI code. This second stage, the Portal site upgrades, doesn't start until the first stage is complete and all of the pods (in both data centers) have been upgraded to the new version. The upgrade of the sites then starts automatically, a few at a time, spread across both data centers to allow the upgrade to run in parallel.

## How to upgrade when one data center is down

---

In this scenario, one data centre is down and you have to failover to the other data center in your deployment. So, you are now running a two data center deployment, but only one data center is online and is in active mode. However, a critical fix must be applied before you can recover the failed data center. In this instance, you must apply the upgrade to the remaining active data center. Then, when you are ready to bring the failed data center back online, you must first disable the multi-site HA setting from the failed data center, and then enable the multi-site HA setting again and make that data center passive. This action triggers a re-sync with the active data center, and ensures that the passive data center contains the latest data.

Note: If one data center is completely down, and you cannot set it to be passive, you must ensure that the network links to that data center are removed before continuing to set your other data center to be active. You must then not restore the network links to the failed data center until you can set it to be passive.

On VMware, this involves the following steps:

1. Run `apicup` to change the `multi-site-ha-enabled` property to `false` on the failed data center, for example:

```
apicup subsys set service_name multi-site-ha-enabled=false
```

where `service_name` is the name of the management or portal service that you want to disable, for example `mgmt_dc1`.

2. Run `apicup` to update the settings in the subsystem, for example:

```
apicup subsys install service_name
```

3. Run the following commands to change the `multi-site-ha-enabled` property back to `true` and to set the `mode` to `passive` on the failed data center, for example:

```
apicup subsys set service_name multi-site-ha-enabled=true
```

```
apicup subsys set service_name multi-site-ha-mode=passive
```

4. Run `apicup` to update the settings in the subsystem again, for example:

```
apicup subsys install service_name
```

---

## Monitoring and health checks

Monitor your deployment and complete health checks on subsystems.

See:

- [Checking cluster health on VMware](#)  
You can use `apicup` to check the health of the API Connect clusters in your VMware deployment.
- [Monitoring Postgres disk usage](#)  
Monitor disk usage by the Postgres database in the management subsystem.
- [Obtaining simple health check data of Developer Portal sites by using a REST API call](#)  
Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.
- [Monitoring the network with SNMP](#)  
Presents a table of OID trees that you can poll using SNMP Get.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Checking cluster health on VMware

You can use `apicup` to check the health of the API Connect clusters in your VMware deployment.

The `health-check` command checks a number of criteria to determine the health of their cluster. When all criteria are successfully met, the command displays no output, and exits with a status of 0. When one or more criteria are not met, the command stops processing and displays a message with the failure and exits with a status of 1.

The command takes no arguments. The only option is the `--verbose` flag. If `--verbose` is set the command prints all checks that were performed.

The `health-check` is run against the namespace that is specified in `apiconnect-up.yaml`.

The health check is run on the specified subsystem.

The command verifies that for the specified subsystem:

- The `apicup` version matches the API Connect release version.
- All cluster members are running the same API Connect release version.
- All cluster members have a deployment status of **Done**.
- Docker is running.
- `kubelet` is running
- All Kubernetes-defined nodes are running.
- The Kubernetes Control Plane pods are running:
  - `etcd/kube-apiserver`
  - `kube-system.kube-controller`
  - `kube-scheduler`
  - `kube-apiserver-proxy`
- The add-on Kubernetes Deployments are fulfilled:
  - `coredns`
  - `metrics-server`
- The add-on Kubernetes DaemonSets are fulfilled:
  - `calico-node`
  - `ingress-nginx-ingress-controller`
  - `kube-proxy`

Syntax:

```
Usage:
 apicup subsys health-check <SUBSYS> [flags]
```

```
Flags:
 -h, --help help for health-check
 --kubeconfig string (optional) absolute path to the kubeconfig file (default "/Users/<username>/.kube/config")
 -v, --verbose Verbose output
```

```
Global Flags:
 --accept-license Accept the license for API Connect
 --debug Enable debug logging
```

Example usage, for a subsystem named `mgmt`:

```
../apicup subsys health-check mgmt
```

Note:

- The command flag `--kubeconfig string` does not apply to deployments on VMware.
- In a multi-node OVA cluster, the `apicup subsys health-check` command does not return status information if a majority of the nodes are down. To obtain status information, start more nodes. Status is returned only when a quorum is achieved.
- **Version 10.0.1.2-eus Known Limitation:** Running `apicup subsys health-check` on 10.0.1.2-eus may result in some warning messages. The warnings are harmless and can be ignored. The warnings occur because the CRD version for some Kubernetes resources has been deprecated, but the resources have not been removed so are still supported. For example:

```
INFO[0000] Log level: info
W0218 08:17:32.224850 424979 warnings.go:70] apiextensions.k8s.io/v1beta1 CustomResourceDefinition is deprecated in v1.16+, unavailable in v1.22+; use apiextensions.k8s.io/v1 CustomResourceDefinition
W0218 08:17:32.232455 424979 warnings.go:70] rbac.authorization.k8s.io/v1beta1 Role is deprecated in v1.17+, unavailable in v1.22+; use rbac.authorization.k8s.io/v1 Role
```

```

W0218 08:17:32.237079 424979 warnings.go:70] rbac.authorization.k8s.io/v1beta1 RoleBinding is deprecated in v1.17+,
unavailable in v1.22+; use rbac.authorization.k8s.io/v1 RoleBinding
W0218 08:17:32.401830 424979 warnings.go:70] apiextensions.k8s.io/v1beta1 CustomResourceDefinition is deprecated in
v1.16+, unavailable in v1.22+; use apiextensions.k8s.io/v1 CustomResourceDefinition
W0218 08:17:34.959226 424979 warnings.go:70] admissionregistration.k8s.io/v1beta1 MutatingWebhookConfiguration is
deprecated in v1.16+, unavailable in v1.22+; use admissionregistration.k8s.io/v1 MutatingWebhookConfiguration
W0218 08:17:34.962512 424979 warnings.go:70] admissionregistration.k8s.io/v1beta1 ValidatingWebhookConfiguration is
deprecated in v1.16+, unavailable in v1.22+; use admissionregistration.k8s.io/v1 ValidatingWebhookConfiguration
W0218 08:17:35.666316 424979 warnings.go:70] rbac.authorization.k8s.io/v1beta1 ClusterRole is deprecated in v1.17+,
unavailable in v1.22+; use rbac.authorization.k8s.io/v1 ClusterRole

```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Monitoring Postgres disk usage

Monitor disk usage by the Postgres database in the management subsystem.

Postgres Database is the core database used in Management Subsystem. It is important to monitor the Postgres disk usage.

In 10.0.1.4-eus and greater, the APICconnect operator tracks the current disk usage of the Postgres components, and regularly updates `apic health-check` command.

APICconnect operator regularly updates the `ManagementCluster` instance status which is reflected in the `apic health-check` command.

`apic health-check` command reports WARNING state when disk utilization reaches 50%.

`apic health-check` command reports ERROR state when disk utilization reaches 70% and Postgres is brought down.

See:

- [Management Cluster disk stats](#)
- [Warning condition is populated at 50% usage](#)
- [Error condition is populated at 70% usage](#)

## Management Cluster disk stats

The `ManagementCluster` instance has `.status.postgresDataStats` where the operator prints the current disk usage of Postgres components. Use `kubect1` to view the status.

To use `kubect1`, first ssh into the appliance as `root`.

```

kubect1 get mgmt m1 -o json | jq .status.postgresDataStats
[

 "pvcUsedPercentage": 0
 }
]

```

## Warning condition is populated at 50% usage

When one of the Postgres components occupy 50% usage, the operator marks the overall status of the **ManagementCluster** to **Warning** with an appropriate warning message, which is included in the output from `apic health-check` command.

The warning condition explains why the warning condition was set.

To use `apic`, first ssh into the appliance as `root`.

```
apic health-check
```

```

FATA[0007] Cluster not in good health:
ManagementCluster is not Ready or Complete | State: 17/17 Phase:
Warning Message: Current WAL disk usage of nihar-stac-3955b42d-sitel-postgres is 51 percent.
DATABASE SHUTDOWN starts at 70 percent utilization. Please contact IBM Support immediately

```

If you encounter the warning, contact IBM support to fix the root cause.

## Error condition is populated at 70% usage

An error condition is populated when the operator brings down Postgres because it is using 70% of available disk space. Postgres is brought down to avoid problems, such as disk corruption, that can occur if the disk becomes completely filled.

To use `apic`, first ssh into the appliance as `root`.

```
apic health-check
```

```

FATA[0011] Cluster not in good health:
ManagementCluster is not Ready or Complete | State: 17/17 Phase:
Error Message: Current WAL disk usage of nihar-stac-3955b42d-sitel-postgres is more than 70 percent,
initiating DATABASE SHUTDOWN

```

If you encounter the error, contact IBM support to fix the root cause.

Important:

On VMware, because the entire disk is allocated to the worker node, in some cases before the operator reacts to 70% usage, , Kubernetes itself can face disk pressure and starts evicting pods. In these cases, increase the disk allocated to worker node in order to stabilize the worker node. See [Adding disk space to a VMware appliance](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Obtaining simple health check data of Developer Portal sites by using a REST API call

Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.

### About this task

You can use the site health REST API to determine whether a particular Developer Portal site is running. The site health API returns the current system time of the site if both the database and web server are running. This API is fast and puts no load on the system, so it is ideal for use with load balancers to help them determine where to route traffic.

### Procedure

To call the site health REST API, append `/health` to the end of your Developer Portal site URL in your web browser, as follows:

`site_url/health`

Where `site_url` is the URL of the Developer Portal site that you want to check.

If both the database and web server of the site are running, the web browser returns the current system time. For example:

1511367695

If either the database or the web server of the site is not running, the web browser returns an error that the site can't be reached.

If you do get an error from the `/health` endpoint, refer to the [must gather logs page](#) and obtain the `portal-www web` logs, so that you can see more information on the error.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Monitoring the network with SNMP

Presents a table of OID trees that you can poll using SNMP Get.

Simple Network Management Protocol (SNMP) collects information from network devices, such as servers, printers, hubs, switches, and routers on an Internet Protocol (IP). SNMP employs addresses for network devices using a hierarchical numbering system called Object Identifiers (OID). The following table provides OID addresses for polling in SNMP to monitor API Connect servers.

Note:

- Only SNMP v2 and SNMP v3 are supported. However, it is not recommended to enable SNMP v2. Instead, configure SNMPv3 as shown in [Configuring SNMPv3](#), and then enable it as shown in [Enabling SNMP](#).
- If the server has two or more network interfaces, the SNMP request is sent only to the first network interface.
- SNMP is disabled by default for all hosts.
- This information applies to API Connect deployments in VMware environments. It does not apply to Kubernetes deployments.

Each entry in the table represents many individual items. Use `snmpwalk` or another SNMP polling utility to see the complete list. You can poll the following OID trees:

Table 1. Default SNMPv2 configuration

| OID                  | SNMP Name                     | Notes                                                                                                                                                          |
|----------------------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| .1.3.6.1.2.1.1       | SNMPv2-MIB::system            |                                                                                                                                                                |
| .1.3.6.1.2.1.2       | IF-MIB::interfaces            |                                                                                                                                                                |
| .1.3.6.1.2.1.4       | IP-MIB::ip                    |                                                                                                                                                                |
| .1.3.6.1.2.1.5       | IP-MIB::icmp.                 |                                                                                                                                                                |
| .1.3.6.1.2.1.6       | TCP-MIB::tcp                  |                                                                                                                                                                |
| .1.3.6.1.2.1.7       | UDP-MIB::udp                  |                                                                                                                                                                |
| .1.3.6.1.2.1.11      | SNMPv2-MIB::snmp              |                                                                                                                                                                |

## Configuring SNMPv3

From an OVA shell prompt as root edit the file `/etc/snmp/snmpd.conf` so that its content is:

```
createUser readOnlyUser SHA authpassphrase AES privpassphrase
rouser readOnlyUser
agentAddress udp:161,udp6[::1]:161
```

- Replace `authpassphrase` with the passphrase to be used for authentication,
- Replace `privpassphrase` with the passphrase to be used for privacy (encryption) of the communications.

## Enabling SNMP

It is not recommended to start SNMP without first configuring it for SNMPv3. See [Configuring SNMPv3](#).

Enable SNMP on each individual OVA node with the following commands from an OVA shell prompt as root:

```
systemctl start snmpd
systemctl enable snmpd
```

Sample output:

```
root@mgmt:~# systemctl start snmpd
root@mgmt:~# systemctl enable snmpd
snmpd.service is not a native service, redirecting to systemd-sysv-install
Executing /lib/systemd/systemd-sysv-install enable snmpd
```

```
insserv: warning: current start runlevel(s) (empty) of script `snmpd' overrides LSB defaults (2 3 4 5).
insserv: warning: current stop runlevel(s) (0 1 2 3 4 5 6) of script `snmpd' overrides LSB defaults (0 1 6).
```

## Disabling SNMP

---

Disable SNMP on each individual OVA node with the following commands from an OVA shell prompt as root:

```
systemctl stop snmpd
systemctl disable snmpd
```

Sample output:

```
root@mgmt:~# systemctl stop snmpd
root@mgmt:~# systemctl disable snmpd
snmpd.service is not a native service, redirecting to systemd-sysv-install
Executing /lib/systemd/systemd-sysv-install disable snmpd
insserv: warning: current start runlevel(s) (empty) of script `snmpd' overrides LSB defaults (2 3 4 5).
insserv: warning: current stop runlevel(s) (0 1 2 3 4 5 6) of script `snmpd' overrides LSB defaults (0 1 6).
```

## Checking SNMP status

---

Check whether SNMP is enabled on each individual OVA node with the following commands from an OVA shell prompt:

```
systemctl status snmpd
```

Sample output when SNMP is enabled and running:

```
apicadm@mgmt:~$ systemctl status snmpd
snmpd.service - LSB: SNMP agents
 Loaded: loaded (/etc/init.d/snmpd; bad; vendor preset: enabled)
 Active: active (running) since Wed 2019-02-06 03:53:02 UTC; 2 days ago
 Docs: man:systemd-sysv-generator(8)
 Tasks: 1
 Memory: 6.0M
 CPU: 3min 1.641s
 CGroup: /system.slice/snmpd.service
 └─1366 /usr/sbin/snmpd -Lsd -Lf /dev/null -u snmp -g snmp -I -smux mteTrigger mteTriggerConf -p /run/snmpd.pid
...

```

Sample output when SNMP is stopped and disabled:

```
root@mgmt:~# systemctl status snmpd
snmpd.service - LSB: SNMP agents
 Loaded: loaded (/etc/init.d/snmpd; bad; vendor preset: enabled)
 Active: inactive (dead)
 Docs: man:systemd-sysv-generator(8)
...

```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Logging

Configure logging for your deployment on VMware.

See:

- [Configuring remote logging for a VMware deployment](#)  
Logging collection is required for IBM Support to assist with troubleshooting. You can configure fluent-bit to collect and forward logs to a remote Syslog server.
- [Gathering logs for a VMware environment](#)  
The `generate_postmortem.sh` script gathers all logs for troubleshooting and diagnostics.
- [Changing logging levels](#)  
You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Configuring remote logging for a VMware deployment

Logging collection is required for IBM Support to assist with troubleshooting. You can configure fluent-bit to collect and forward logs to a remote Syslog server.

### Before you begin

---

Beginning in version 10.0.1.9-eus, API Connect uses [fluent-bit](#) to collect log files for appliance-based deployments using OVA and forward the logs to a remote syslog server.

In API Connect 10.0.1.11-eus or later, the fluent-bit service is already installed on the appliances and is configured to forward container logs to `/var/log/syslog` on the local machine. For best results, upgrade to API Connect 10.0.1.11-eus or later to take advantage of the included fluent-bit service.

Important: This article refers to third-party software that IBM does not control. As such, the software may change and this information might become outdated. In addition, the fluent-bit service was tested only for simple container log routing to local and remote Syslog servers as configured in the instructions that follow. Any customization of other fluent-bit settings (for example, to set up parsers or filters) is at your own risk and should be performed with caution by referring to the [fluent-bit documentation](#).

## About this task

Remote logs created with fluent-bit use the following format:

```
Mar 1 00:38:44 apicdev1147 calico-node-gqbv_42428a8ade169ad3 2023-03-01 00:38:44.684 [INFO][208] felix/int_dataplane.go 1245: Applying dataplane updates
```

Where:

- `Mar 1 00:38:44` is the time the log arrived on the remote server.
- `apicdev1147` is the hostname of the log source.
- `calico-node-gqbv_42428a8ade169ad3` is a portion of the pod name/container\_id where the log is coming from.
- `2023-03-01 00:38:44.684` is the timestamp at which the logged event actually took place within the container.
- The rest of the log is the log message itself.

Logs posted to your local server look different, as in this example:

```
Feb 28 23:47:03 apicdev1147 fluent-bit[2332273]: [2] kube.var.log.containers.kqn2-management-portal-proxy-647b96b89f-pkz5w_default_portal-proxy-74a1723512574fdc23fb9c014b80c7e83aff225b9d44d995736251eddl8c49b4.log: [1677628023.503190040, {"_p"=>"F", "log"=>"Tue, 28 Feb 2023 23:47:03 GMT express:router expressInit : /healthz", "tag"=>"kqn2-management-74a1723512574fdc", "time"=>"2023-02-28T23:47:03.503190005Z", "stream"=>"stderr"}]
```

On the local log, the whole fluent-bit JSON object is logged, which provides slightly more information (for example, the full file name of the log file) than in the remote log.

Use the appropriate instructions for your deployed version of API Connect:

- [API Connect 10.0.1.11-eus and later: Configuring remote logging](#)
- [API Connect 10.0.1.11-eus and later: Update the remote logging configuration](#)
- [API Connect 10.0.1.9-eus: Installing and configuring remote logging](#)
- [API Connect 10.0.1.9-eus: Update the remote logging configuration](#)

## API Connect 10.0.1.11-eus and later: Configuring remote logging

### About this task

The fluent-bit service is already installed on the appliance and is configured to forward container logs to `/var/log/syslog` on the local machine. If you want to change the output destination to a remote Syslog server, complete the following steps:

### Procedure

1. Create the `/etc/fluent-bit/append-tag.lua` file.
  - a. Paste the following code into the new file:

```
function append_tag(tag, timestamp, record)
 new_record = record
 local pod_name = string.sub(string.match(tag, "^kube%.var%.log%.containers%. (.+)$"), 1, 16)
 local container_id = string.sub(string.match(tag, "-([^-]+)%.log$"), 1, 16)

 new_record["tag"] = pod_name .. "-" .. container_id
 return 1, timestamp, new_record
end
```

- b. Save and close the file.

2. Create the `/etc/fluent-bit/fluent-bit-override.conf` file.

- a. Add the following statements to the new file::

Replace the variables in the `[OUTPUT]` section with values for your deployment:

```
[SERVICE]
 Daemon Off
 Flush 1
 Log_Level info
 Parsers_File parsers.conf
 HTTP_Server On
 HTTP_Listen 0.0.0.0
 HTTP_Port 2021
 Health_Check On

[INPUT]
 Name tail
 Path /var/log/containers/*.log
 multiline.parser docker, cri
 Tag kube.*
 Mem_Buf_Limit 5MB
 Skip_Long_Lines On

[INPUT]
 Name systemd
```

```

Tag host.*
Systemd_Filter _SYSTEMD_UNIT=kubelet.service
Read_From_Tail On

[FILTER]
Name kubernetes
Match kube.*
Merge_Log On
Keep_Log Off
K8S-Logging.Parser On
K8S-Logging.Exclude On

[FILTER]
Name lua
Match *
Script /etc/fluent-bit/append-tag.lua
call append_tag

[OUTPUT]
Name syslog
Match *
Host <host>
port 514
mode udp
syslog_format rfc5424
syslog_maxsize 2048
syslog_hostname_key hostname
syslog_hostname_preset <hostname of local machine/log source>
syslog_appname_key tag
syslog_message_key log

```

Note: The default values shown in the [OUTPUT] section can be modified as explained in the [fluent-bit documentation](#).

b. Save and close the file.

3. Run the following command to restart the fluent-bit service so it picks up the configuration changes:

```
systemctl restart appliance-manager && systemctl restart fluent-bit
```

## API Connect 10.0.1.11-eus and later: Update the remote logging configuration

To update the fluent-bit configuration, complete the following steps:

### Procedure

1. Run the following command to edit the configuration file:

```
vim /etc/fluent-bit/fluent-bit-override.conf
```

2. Complete your configuration changes, then save and close the file.

3. Run the following command to restart the appliance-manager:

```
systemctl restart appliance-manager
```

## API Connect 10.0.1.9-eus: Installing and configuring remote logging

### About this task

Download Debian packages from IBM Fix Central to install fluent-bit by completing the following steps:

### Procedure

1. If you previously performed a Helm installation of fluent-bit, uninstall it by running the following command:

```
helm uninstall fluent-bit
```

2. Download the following files from IBM Fix Central:

- [libpq5\\_12.13-0ubuntu0.20.04.1\\_amd64.deb](#)
- [fluent-bit\\_2.0.6\\_amd64.deb](#)

3. Install libpq5 by running the following command:

```
apt install <path-to-libpq5_12.13-0ubuntu0.20.04.1_amd64.deb>
```

4. Install fluent-bit by running the following command:

Be sure to install libpq5 first because it is a prerequisite for fluent-bit.

```
apt install <path-to-fluent-bit_2.0.6_amd64.deb>
```

5. Create the /etc/fluent-bit/append-tag.lua file.

a. Paste the following code into the new file:

```

function append_tag(tag, timestamp, record)
 new_record = record
 local pod_name = string.sub(string.match(tag, "^kube%.var%.log%.containers%.(.+$)", 1, 16)
 local container_id = string.sub(string.match(tag, "-([^-]+).log$", 1, 16)

 new_record["tag"] = pod_name .. "-" .. container_id
 return 1, timestamp, new_record
end

```

b. Save and close the file.

6. Configure the input and output settings for the configuration file, so that fluent-bit forwards logs to Syslog:

- a. Run the following command to edit the configuration:

```
vim /etc/fluent-bit/fluent-bit.conf
```

- b. Replace the contents of the file with the following information:

- For a local Syslog:

```
[SERVICE]
 flush 1
 daemon Off
 log_level info
 parsers_file parsers.conf
 plugins_file plugins.conf
 http_server Off
 http_listen 0.0.0.0
 http_port 2020
 storage.metrics on

[INPUT]
 Name tail
 Path /var/log/containers/*.log
 Parser cri
 Mem_Buf_Limit 5MB
 Skip_Long_Lines On

[OUTPUT]
 name stdout
 match *
```

- For a remote Syslog:

Replace the variables in the [OUTPUT] section with values for your deployment:

```
[SERVICE]
 Daemon Off
 Flush 1
 Log_Level info
 Parsers_File parsers.conf
 HTTP_Server On
 HTTP_Listen 0.0.0.0
 HTTP_Port 2021
 Health_Check On

[INPUT]
 Name tail
 Path /var/log/containers/*.log
 multiline.parser docker, cri
 Tag kube.*
 Mem_Buf_Limit 5MB
 Skip_Long_Lines On

[INPUT]
 Name systemd
 Tag host.*
 Systemd_Filter _SYSTEMD_UNIT=kubelet.service
 Read_From_Tail On

[FILTER]
 Name kubernetes
 Match kube.*
 Merge_Log On
 Keep_Log Off
 K8S-Logging.Parser On
 K8S-Logging.Exclude On

[FILTER]
 Name lua
 Match *
 Script /etc/fluent-bit/append-tag.lua
 call append_tag

[OUTPUT]
 Name syslog
 Match *
 Host <host>
 port 514
 mode udp
 syslog_format rfc5424
 syslog_maxsize 2048
 syslog_hostname_key hostname
 syslog_hostname_preset <hostname of local machine/log source>
 syslog_appname_key tag
 syslog_message_key log
```

Note: The default values shown in the [OUTPUT] section can be modified as explained in the [fluent-bit documentation](#).

- c. Save and close the file.

7. Run the following commands to start the fluent-bit service:

- a. Enable fluent-bit to start after a system restart:

```
systemctl enable fluent-bit
```

- b. Start fluent-bit:

```
systemctl start fluent-bit
```

## API Connect 10.0.1.9-eus: Update the remote logging configuration

---

To update the fluent-bit configuration, complete the following steps:

### Procedure

1. Run the following command to edit the configuration file:

```
vim /etc/fluent-bit/fluent-bit.conf
```

2. Complete your configuration changes, then save and close the file.

3. Run the following command to restart the fluent-bit service:

```
systemctl restart fluent-bit
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Gathering logs for a VMware environment

The `generate_postmortem.sh` script gathers all logs for troubleshooting and diagnostics.

### Before you begin

You can download the `generate_postmortem.sh` script directly to the OVA. If the OVA does not have internet access, first download the script to another machine and then transfer it to the OVA.

### About this task

When contacting IBM Support, several logs are required to assist in troubleshooting or diagnostics. The `generate_postmortem.sh` script gathers all the required logs using a single shell script.

### Procedure

1. Connect to the target appliance via SSH then switch to the `root` user with the following commands:

```
ssh apicadm@{ova appliance hostname}
sudo -i
```

2. Download the `generate_postmortem.sh` script. Enter the following command:

```
curl -s -o generate_postmortem.sh https://raw.githubusercontent.com/ibm-apiconnect/v10-postmortem/master/generate_postmortem.sh
```

3. Add execute permissions to the `generate_postmortem.sh` script. Enter the following command:

```
chmod +x generate_postmortem.sh
```

4. Run the postmortem tool using the following command:

```
./generate_postmortem.sh --ova --pull-appliance-logs
```

5. (Optional) Currently, log generation is supported for Portal and Management subsystems. Specify either management or portal, or all subsystems. Enter the following arguments:

```
Portal: ./generate_postmortem.sh --ova --diagnostic-portal --pull-appliance-logs
Management: ./generate_postmortem.sh --ova --diagnostic-manager --pull-appliance-logs
```

6. (Optional) If there are errors when running the `generate_postmortem.sh` script, enter the following command:

```
./generate_postmortem.sh --ova --debug &>debug.log
```

For more documentation on the script, see <https://github.com/ibm-apiconnect/v10-postmortem>.

Note: Offboarding the logs to an external server is the recommended best practice for long term storage of log data. See [Configuring remote logging for a VMware deployment](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Changing logging levels

You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

## About this task

---

For apim-v2 pods, the default logging settings do not include entry and exit trace and logging of large payloads.

Logging of large payloads is typically needed if you are logging `apim:webhookPayload` or other processes that log large variables.

You can also set the debug level without needing to restart the pods.

You can enable the settings through either the APIM deployment YAML file, the toolkit, or the REST APIs. Note, you must use the toolkit or REST API to set the debug level without restarting the pods.

## Procedure

---

- Updating the settings in the APIM deployment YAML file

Note: This action causes a pod restart.

- The `DEBUG` variable works the same as prior releases.

```
- env:
 - name: DEBUG
 value:
audit,bhendi:error,bhendi:probe,bhendi:flags,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:*
```

To enable entry and exit trace, add `trace:*` to the start of the debug string:

```
- env:
 - name: DEBUG
 value: trace:*,audit,bhendi:error,bhendi:probe,bhendi:flags,bhendi:webhookAudit,bhendi:cassandra-transactions,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:*,apim:taskmanager:info
```

- To enable large object logging:

```
- env:
 - name: VELOX_LOG_FULL_PAYLOAD
 value: "true"
```

- Updating the settings by using the toolkit

Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

```
apic log-spec:get
apic log-spec:update LOG_SPEC_FILE
```

Where the spec file contains:

```
{"specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error", "large_objects": true}
```

- Updating the settings by using the REST API

Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

```
GET /cloud/api/log-spec
PUT /cloud/api/log-spec
```

For example, to set debug level and large objects logging:

```
curl -k https://172.16.140.212:3003/api/cloud/log-spec -X PUT -H "Authorization: Bearer $BEARER"
-H "Accept: application/json" -d '{"specification":
"apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error","large_objects": true}'
-H "Content-Type: application/json"
```

The command responds with:

```
{
 "specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error",
 "large_objects": true,
 "message": "Successfully changed the log specification on all apim-v2 pods. Success on IP(s): 172.16.140.212,
172.16.140.213"
}
```

Note: The response might include the following warning, which can be ignored:

```
WARNING: Could not change the log specification on all apim-v2 pods. Success on IP(s): 4.5.6.7 Failed on IP(s): 1.2.3.4
```

To view the REST APIs for logging, go to [API Connect REST APIs](#), and select IBM API Connect Platform - Cloud Management API 2.0.0 reference\_2.Resource: Log Spec.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Troubleshooting

Troubleshoot your deployment on VMware.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.  
See:

- [Recreating a calico pod that is in the CrashLoopBackOff state](#)  
If you complete an upgrade and find that one or more of the calico pods are in the `CrashLoopBackOff` state, you can delete the pod to recreate it.
- [Running a filesystem check on a VMware root partition](#)  
You can run a filesystem check on the appliance root filesystem at boot time.
- [Increasing the PostgreSQL archive timeout on VMware](#)  
Increase change the `archive_timeout` to 3600 (seconds) so that accumulated wal files do not cause a disk-space issue during a network outage.
- [Troubleshooting the management database](#)  
You can troubleshoot the API Connect management database

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Recreating a calico pod that is in the `CrashLoopBackOff` state

If you complete an upgrade and find that one or more of the calico pods are in the `CrashLoopBackOff` state, you can delete the pod to recreate it.

Complete the following steps:

1. Get the names of the calico pods:

```
kubectl -n kube-system get pods | grep calico
```

2. Recreate each pod by deleting it with the following command:

```
kubectl -n kube-system delete pod <calico_pod_name>
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Running a filesystem check on a VMware root partition

You can run a filesystem check on the appliance root filesystem at boot time.

---

### About this task

If the appliance root filesystem is mounted read-only because it is corrupt, use the following steps to run `fsck` on root partition:

---

### Procedure

1. Access to the VMware console for the Appliance, and after causing it to reboot, make sure to bring up a console to the appliance (as needed to give focus to the window by clicking the mouse into it), and press the `Esc` key repeatedly.

You will see a boot screen similar to the following:

```
GNU GRUB v2.02
.
.
- Ubuntu
- Advanced options for Ubuntu
.
.
.
Press Enter to boot the selected OS, 'e' to edit the commands
before booting or 'c' for a command-line
```

2. Press `e` to edit the commands before booting, and add the lines `fsck.mode=force` and `fsck.repair=yes`.  
For example, the boot screen contents resemble:

```
GNU GRUB v2.02
.
.
set params 'Ubuntu'
fsck.mode=force
fsck.repair=yes
.
.
.
```

```
Press Ctrl-x or F10 to boot
```

3. Press F10 to boot.
4. The following command should show that **fsck** was run recently:

```
root@ip-230:~# sudo tune2fs -l /dev/sda1 | grep "Last checked"
Last checked: Wed Jul 1 19:32:25 2020
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Increasing the PostgreSQL `archive_timeout` on VMware

Increase change the `archive_timeout` to 3600 (seconds) so that accumulated wal files do not cause a disk-space issue during a network outage.

### About this task

PostgreSQL sends its wal archives to the backup location (S3 or local PVC) whenever the configured `archive_timeout` period elapses. By default, the `archive_timeout` is set to 60 seconds. During a network outage, the files cannot be transferred and instead accumulate on the current server, and could cause a disk-space issue. Increasing the `archive_timeout` value helps to mitigate this issue by creating archive files less frequently.

For information on tracking the Postgres disk space, see [Monitoring Postgres disk usage](#).

Complete the following steps to increase the PostgreSQL `archive_timeout` value.

### Procedure

1. SSH into the server by completing the following steps:
  - a. Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```
  - b. When prompted, select Yes to continue connecting.
  - c. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

2. Get the name of the `pgha` config map by running the following command:

```
kubectl -n <namespace> get cm -l pgha-config=true'
```

The response looks like the following example:

| NAME                                             | DATA | AGE |
|--------------------------------------------------|------|-----|
| apis-produ-d18f3f0-0d18f3f0-postgres-pgha-config | 5    | 22d |

3. Edit the config map by running the following command:

```
kubectl -n <namespace> edit configmap <config-map-name>
```

In the command, replace `<config-map-name>` with the `NAME` returned in step 1.

4. Change the `archive_timeout` value to 3600.  
The value must be an integer, and represents the number of seconds that must elapse before the archive file is generated.
5. Save the file and exit the editor.  
The configuration is updated automatically; archives will be generated and pushed every 3600 seconds.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Troubleshooting the management database

You can troubleshoot the API Connect management database

### Database Replica Pods stuck in Unknown or Pending state

In certain scenarios, a postgres replica pod may not recover to a healthy state when a restore completes, a node outage occurs, or after a fresh install or upgrade. In these cases, a postgres pod remains in a **Unknown** or a **Pending** state after a number of minutes. The pod fail to get into a **Running** state.

This situation occurs when the replicas do not initialize properly. You can use the `patronictl reinit` command to reinitialize the replica. Note that this command syncs the replica's volume data from the current Primary pod.

Use the following steps to get the pod back into a working state:

1. SSH into the appliance as `root`.
2. Exec onto the failing pod:

```
kubectl exec -it <postgres_replica_pod_name> -n <namespace> -- bash
```

3. List the cluster members:

```
patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+-----+
| Member | Host | Role | State | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+
| fxpk-management-01191b80-postgres-586f899fdf-6s25b | 172.16.172.244 | | start failed | | unknown |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51 | Leader | running | 3 | |
| fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m | 172.16.53.68 | | running | 3 | 0 |
+-----+-----+-----+-----+-----+-----+
```

In the example shown above `fxpk-management-01191b80-postgres-586f899fdf-6s25b` is not in running state.

Note the `clusterName` and `replicaName` which are not up:

- `clusterName` - `fxpk-management-01191b80-postgres`
- `replicaName` - `fxpk-management-01191b80-postgres-586f899fdf-6s25b`

4. Run:

```
patronictl reinit <clusterName> <replicaName-which-is-not-running>
```

Example:

```
patronictl reinit fxpk-management-01191b80-postgres fxpk-management-01191b80-postgres-586f899fdf-6s25b
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+-----+
| Member | Host | Role | State | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+
| fxpk-management-01191b80-postgres-586f899fdf-6s25b | 172.16.172.244 | | start failed | | unknown |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51 | Leader | running | 3 | |
| fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m | 172.16.53.68 | | running | 3 | 0 |
+-----+-----+-----+-----+-----+-----+
Are you sure you want to reinitialize members fxpk-management-01191b80-postgres-586f899fdf-6s25b? [y/N]: y
Success: reinitialize for member fxpk-management-01191b80-postgres-586f899fdf-6s25b
```

5. Run `patronictl list` again.

You may also observe that the replica is on a different Timeline (TL) and possibly have a Lag in MB. It may take a few minutes for the pod to switch onto the same TL as the others and the Lag should slowly go to 0.

For example:

```
bash-4.2$ patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+-----+
| Member | Host | Role | State | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+
| fxpk-management-01191b80-postgres-586f899fdf-6s25b | 172.16.172.244 | | running | 1 | 23360 |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51 | Leader | running | 3 | |
| fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m | 172.16.53.68 | | running | 3 | 0 |
+-----+-----+-----+-----+-----+-----+
```

6. The pod that previously was in an `Unknown` or `Pending` state or `(0/1) Running` state is now in `(1/1) Running` state.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Troubleshooting Analytics on VMware

If your API Connect Analytics subsystem encounters problems, review the following topics for help resolving the issue.

- [Analytics start-up issues on VMware](#)  
If you receive an error starting the Analytics service after installing, upgrading, or recovering from a catastrophic failure of IBM® API Connect on VMware, you might be able to resolve it by completing this task.
- [Analytics offload issues on VMware](#)  
If your Analytics offload fails, you can perform checks to help determine the cause. Common causes for an offload failure are connection or security-related issues.
- [Empty Analytics display on Kubernetes](#)  
If your API Connect analytics data doesn't display in the Analytics dashboard, complete the following steps to determine the cause of the problem.
- [Analytics running out of disk space on VMware](#)  
If your Analytics data is taking up too much disk space, complete the following steps to resolve the problem.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

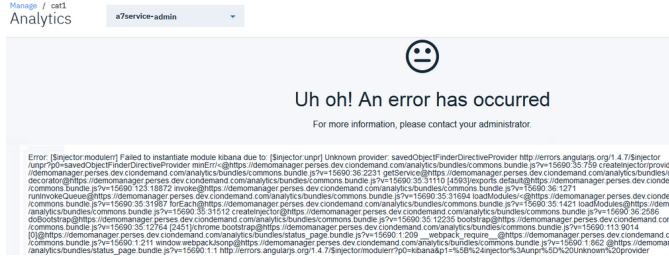

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Analytics start-up issues on VMware

If you receive an error starting the Analytics service after installing, upgrading, or recovering from a catastrophic failure of IBM® API Connect on VMware, you might be able to resolve it by completing this task.

## Uh oh! An error has occurred

In rare cases, the Kibana index can fail and the following message displays:

This error typically indicates that the index was corrupted. Complete the following steps to verify the problem and delete the corrupted index.

- SSH into the server:
  - Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```
  - When prompted, select Yes to continue connecting.
  - When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

- Get the names of a storage-coordinating pod and a client pod:

Determine the names of one of the deployment's storage-coordinating pods (called `analytics-storage-coordinating-pod` in the steps that follow) and one of the client pods (called `analytics-client-pod` in the steps). To see the pod names, run the following command:

```
kubectl get pods
```

In the following sample output, a storage-coordination pod is named `r70eaala0f2-analytics-storage-coordinating-5d87d4c76-btqfq` and a client pod is named `r70eaala0f2-analytics-client-68c499d5f9-7g7vm`:

| NAME                                                       | READY | STATUS    | RESTARTS | AGE |
|------------------------------------------------------------|-------|-----------|----------|-----|
| r70eaala0f2-analytics-client-68c499d5f9-7g7vm              | 1/1   | Running   | 0        | 37m |
| r70eaala0f2-analytics-client-68c499d5f9-hjx22              | 1/1   | Running   | 0        | 82m |
| r70eaala0f2-analytics-cronjobs-retention-1559698200-7tjjh  | 0/1   | Completed | 0        | 18h |
| r70eaala0f2-analytics-cronjobs-rollover-1559762100-fnhnd   | 0/1   | Completed | 0        | 24m |
| r70eaala0f2-analytics-ingestion-7f5d748759-5cgrs           | 1/1   | Running   | 0        | 83m |
| r70eaala0f2-analytics-ingestion-7f5d748759-wjvkd           | 1/1   | Running   | 0        | 83m |
| r70eaala0f2-analytics-mtls-gw-6988bd8cbf-g88p5             | 1/1   | Running   | 0        | 83m |
| r70eaala0f2-analytics-mtls-gw-6988bd8cbf-xxzvb             | 1/1   | Running   | 0        | 83m |
| r70eaala0f2-analytics-operator-747f75c4f-7965r             | 1/1   | Running   | 0        | 83m |
| r70eaala0f2-analytics-storage-coordinating-5d87d4c76-btqfq | 1/1   | Running   | 0        | 83m |
| r70eaala0f2-analytics-storage-coordinating-5d87d4c76-sr9mg | 1/1   | Running   | 0        | 83m |
| r70eaala0f2-analytics-storage-coordinating-5d87d4c76-t8djr | 1/1   | Running   | 0        | 82m |
| r70eaala0f2-analytics-storage-data-0                       | 1/1   | Running   | 0        | 70m |
| r70eaala0f2-analytics-storage-data-1                       | 1/1   | Running   | 0        | 76m |
| r70eaala0f2-analytics-storage-data-2                       | 1/1   | Running   | 0        | 80m |
| r70eaala0f2-analytics-storage-master-0                     | 1/1   | Running   | 0        | 72m |
| r70eaala0f2-analytics-storage-master-1                     | 1/1   | Running   | 0        | 75m |
| r70eaala0f2-analytics-storage-master-2                     | 1/1   | Running   | 0        | 80m |

- Verify that you have both the `.kibana` and `.kibana-6` indexes by running the following command:

```
kubectl exec -it analytics-storage-coordinating-pod -- curl_es /_cat/indices?v
```

In the `index` column of the response, look for `.kibana` and `.kibana-6`:

```
health status index uid pri rep docs.count docs.deleted store.size pri.store.size
green open .kibana-6 2KX9GwpTEKESlVwEa3-g 1 2 39 0 239.1kb 79.7kb
green open .kibana 3AC2HDCATLuKRLvmbT0A 1 2 1 0 9.3kb 3.1kb
green open .spic-config WLMq7241ST6YRjLEp3Vp1Q 1 2 1 0 14.6kb 4.8kb
green open .export-status 2lh3Bwn-T4GFWPmHnBDG3w 1 2 0 0 573b 191b
green open spic-api-2019.06.05-000002 4uv15SRWRlWq-lsum1-Kry 5 2 148889 0 350.2mb 116.8mb
green open spic-api-2019.06.04-1 0WC8p1uQeKHvU5SjgRdGQ 5 2 8000 0 24.7mb 8.2mb
```

If the response includes both indexes, it indicates a problem with the index creation. Proceed to the next step.

Note: If you received the "Uh oh! An error has occurred" page and the response to this command only includes the `.kibana-6` index, then something else is wrong with the cluster and you should contact IBM Support for assistance.

- Set the `.kibana` index to be read-and-write enabled by running the following command, replacing `analytics-storage-coordinating-pod` with the name of the storage-coordinating pod that you determined at the beginning of this task:

```
kubectl exec -it analytics-storage-coordinating-pod -- curl_es -XPUT .kibana/_settings -d '{"index.blocks.write":false}'
```

When you see the following response: `{"acknowledged": true}`, continue to the next step.

Note: If you see a different response, make sure the request was correct and try again. If the command still does not work, then something else is wrong with the cluster and you should contact IBM Support for assistance.

- Delete the `.kibana-6` index by running the following command:

```
kubectl exec -it analytics-storage-coordinating-pod -- curl_es -XDELETE .kibana-6
```

When you see the following response: `{"acknowledged": true}` to indicate that the deletion was successful, continue to the next step.

Note: If you see a different response, then the index was not deleted. Make sure the request was correct and try again. If the delete operation still fails, then something else is wrong with the cluster and you should contact IBM Support for assistance.

- Restart a single analytics client pod by running the following command and replacing `analytics-client-pod` with the name of the pod (which you determined at the beginning of this task):

```
kubectl delete pod analytics-client-pod
```

Sample response: pod "analytics-client-pod" deleted

Wait for the response to ensure that the pod was successfully deleted. Then wait a few minutes for a new pod to start automatically. To check the status of the pods, run the following command:

```
kubectl get pods
```

- Navigate to the Analytics page and refresh to verify that the dashboard now displays correctly.
- (Optional) If you have a backup of `ui` or `.kibana-6`, you can restore it now as explained in [Restoring the Analytics database](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Analytics offload issues on VMware

If your Analytics offload fails, you can perform checks to help determine the cause. Common causes for an offload failure are connection or security-related issues.

When you save the configuration files, their syntax is first validated to verify that it can be applied. However, this does not confirm that other parts of your analytics collection ecosystem are trouble-free, for example, that your endpoints are running, or that the TLS certificates are validated. Errors in these areas may also result in no data output.

To verify issues you will need to examine the logs for one of your Kubernetes analytics ingestion pods. (Note that it may take a few minutes for the pods to pick up changes in the configuration files after edits are applied.)

For information on obtaining logs, refer to [Configuring remote logging for a VMware deployment](#) and [Configuring logging for a Kubernetes deployment](#).

Following are some common checks you can make to troubleshoot the offload:

- Verify that the specified URL or the host and port values for the target system are accurate.
- Verify that the server or cluster of servers in the target system are running and reachable. If applicable, also verify that the connection problems are not caused by firewall settings.
- If you are using Transport Layer Security (TLS) to establish a private and secure communication channel to the target system, investigate whether the issue is caused by SSL certificate errors; for example, untrusted server certificates, certificates that have expired or are not yet valid, or missing intermediate (or chain) certificates. For more information on using TLS, see [Creating a TLS profile](#).
- If offloading to an Elasticsearch or Kafka target, verify that your configuration settings are valid; for example, the user credentials for authenticating to Elasticsearch or the Kafka topic name.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Empty Analytics display on Kubernetes

If your API Connect analytics data doesn't display in the Analytics dashboard, complete the following steps to determine the cause of the problem.

### Procedure

---

- SSH into the server:
  - Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```

- When prompted, select Yes to continue connecting.
- When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

- Run the following command to check the logs of the `mtls-gw` pod:

```
kubectl logs analyt-mtls-gw-7665f5d445-4cx4n -n <APIC_namespace>
```

The response looks like the following example:

```
10.254.6.1 -- [22/Sep/2021:18:05:54 +0000] "POST /x2020/v1/apievent/_bulk HTTP/1.1" 200 2 "-" "-" 2841 0.072 0.070
```

- Check the response for any `_bulk` request coming from the gateway, as shown in the example.  
If there are no `_bulk` requests, then the problem is with the gateway and the `wsm-agent`, which is not sending bulk requests to the Analytics server.

- b. If you see the `_bulk` request., then check the return code in the response.  
If `_bulk` requests are processed successfully you will see a return code 200 (as in the example), which indicates that the bulk request has been ingested.
- c. If it is any other return code, check the ingestion pod logs for any errors, which will indicate any issues during ingestion:

```
oc logs analyt-ingestion-78d7cff7f7-6pktd
```

3. If everything with the data flow looks fine, and if you are unable to see analytics data, then check the health of Analytics by executing into one of the storage pods:

```
kubectl exec -it <storage_pod> - bash
```

```
d.bash-4.4$ curl_es _cluster/health?pretty=1
```

For example:

```
{
 "cluster_name" : "apic-analytics-cluster",
 "status": "yellow",
 "timed_out": false,
 "number_of_nodes": 3,
 "number_of_data_nodes": 1,
 "active_primary_shards": 258,
 "active_shards": 258,
 "relocating_shards": 0,
 "initializing_shards": 0,
 "unassigned_shards": 510,
 "delayed_unassigned_shards": 0,
 "number_of_pending_tasks": 0,
 "number_of_in_flight_fetch": 0,
 "task_max_waiting_in_queue_millis": 0,
 "active_shards_percent_as_number": 33.59375
}
```

- a. Check the status of the cluster (red, yellow, green) in the response.  
In the example, the status is set to yellow.
  - Green indicates all indices are fine.
  - Yellow indicates there are some unassigned shards, which might still be replicating.
  - Red indicates there is a problem with one or more of the indices.
- b. Run the following command to get a list of indices:

```
bash-4.4$ curl_es _cat/indices?v
```

- c. In the list, find the red indices.
- d. Delete each red index by running the following command:

```
bash-4.4$ curl_es -XDELETE <index_name>
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Analytics running out of disk space on VMware

If your Analytics data is taking up too much disk space, complete the following steps to resolve the problem.

### About this task

Analytics indices taking up too much space

### Procedure

1. SSH into the server:
  - a. Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:
 

```
ssh ip_address -l apicadm
```
  - b. When prompted, select Yes to continue connecting.
  - c. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:
 

```
sudo -i
```
2. Run the following command to display the indices:
 

```
curl_es _cat/indices?v
```
3. Find the old and large indices that can be deleted, and delete each index using the following command:
 

```
curl_es -XDELETE <index_name>
```
4. Reduce the retention period from the Cloud manager:
  - a. Open Cloud Manager and click Topology, Analytics Service, Advanced analytics configuration, Storage.
  - b. Locate the Oldest Api Call Data Kept field and set it to the lowest feasible value.

5. Verify that the index is rotating as scheduled.
  - a. Open Cloud Manager and click Topology, Analytics Service, Advanced analytics configuration, Storage.
  - b. Click Index Roll Over, Max age and Max Documents.  
Check the rotation time and number of documents.
6. Verify that the retention and rollover jobs are running properly.  
Run the following command to check the age of the job and the logs, to see whether there is any issue:

```
kubect1 get jobs
```

The output looks like the following example:

| NAME                           | COMPLETIONS | DURATION | AGE |
|--------------------------------|-------------|----------|-----|
| analyt-cj-retention-1632965400 | 1/1         | 17s      | 21h |
| analyt-cj-rollover-1633040100  | 1/1         | 10s      | 15m |

7. Apply a filter to reduce the index size is by excluding large fields, such as `response_body`, from being saved in the index.  
For example:

```
filter {
 if "apicapievent" in [tags] {
 mutate {
 remove_field => ["response_body"]
 }
 }
}
```

For information on creating filters for Analytics data, see [Modifying your analytics data](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Migrating a Version 5 deployment

Use the Migration Utility to automate the migration of a version 5 deployment to a version 10 deployment.

### Supported versions

- You can migrate APIC Connect Version 5.0.8.7 (or later point release) to API Connect Version 10.0.1 (or later point release). We always recommend migrating to the latest point release when possible.
  - If your Version 5 system is older than the minimum, you must first upgrade it to the minimum version.
  - Tip: For installations of API Connect 10.0.1 on VMware, we recommend migrating to 10.0.1.2-ifix1-eus or later because the virtual machine for 10.0.1.2-eus is based on a required version of the Ubuntu operating system. If you migrate to an older version of API Connect, such as 10.0.1.1-eus your VMware deployment will be on a down-level Ubuntu operating system which will force a complex operating system upgrade.
- The migration utility version must match the API Connect and DataPower version. Observe the following Version 10 API Connect requirements:
  - For Kubernetes, the installation operator version must match the API Connect version.
  - For VMware, the `apicup` utility version must match the API Connect version.

### Obtaining the API Connect Migration Utility

Download the API Connect Migration Utility (AMU) from IBM Fix Central. For a link to the latest files on Fix Central, see [What's new in the latest release](#).

- [Migration overview](#)  
The migration process provides tools to extract v5 data, arrange it for v10 formats, and load it onto a v10 system.
- [Migration steps](#)  
Plan the migration, install a new v10 deployment, and move data from v5 to v10.
- [Converting APIs to DataPower API Gateway](#)
- [Migration mapping files](#)  
You can use mapping files to map the name of a v5 object to a corresponding v10 object that has a different name.
- [Migrating OAuth Providers and OAuth secured APIs](#)  
You can migrate v5 OAuth Providers and OAuth secured APIs to your v10 API Connect deployment.
- [Migrating custom policies](#)  
The migration utility migrates API Connect Version 5 user-defined custom policies to API Connect Version 10. After migration, the v5 custom policies run on a v5-compatible DataPower Gateway or the DataPower API Gateway. Custom policies can be migrated to API Gateway with limitations.
- [Migrating gateway extensions](#)  
Use the appropriate procedure for migrating extensions to either a v10 DataPower® Gateway (v5 compatible) or a v10 DataPower API Gateway.
- [Migration considerations](#)  
You can optimize the migration process by reviewing the migration considerations and taking any actions that apply to your deployment.
- [Migration troubleshooting](#)  
If you run migration and observe error messages in your log output, you can take troubleshooting steps, and run the migration again.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Migration overview

The migration process provides tools to extract v5 data, arrange it for v10 formats, and load it onto a v10 system.

**Important:** The migration utility allows migration from v5 to a v10 v5-compatible gateway or v10 API Gateway. References to conversion of v5-compatible artifacts to v10 API Gateway refer to the v5-compatible artifacts that were initially from a v5 environment and were unpacked by the migration utility.

The migration model is centered around using tooling to bring the contents of Version 5 catalogs onto a Version 10 deployment that is set up to import them. The tooling migrates provider organization configuration information, including APIs, Catalogs, Products, Consumers, subscriptions, user registries and more.

You use a v5 extract command to gather the v5 data, and then use a migration unpack command to convert the data into Version 10 format. This extraction will generate a `c1oud` directory where your v5 data will be represented as YAML files. By viewing the contents of the `c1oud` folder, you can see which structures, such as provider organizations, are needed to support your catalog.

The model recognizes that not all v5 data is applicable to a new Version 10 deployment. To optimize your v10 deployment, you may use a text editor to remove unneeded or obsolete v5 configurations from the converted file. When you install and configure your v10 management server, you manually create those structures. You can then use migration tooling to load the v5 data into the prepared v10 system.

During the migration process you can keep your existing v5 system active while you install and configure a parallel (side-by-side) v10 system. You must have system administrator privileges to complete a migration. You should be familiar with IBM API Connect Version 5 architecture and requirements, and with the deployment configuration that you want to migrate.

The migration process supports migrating v5 data to both v10 DataPower Gateway (v5-compatible) and v10 DataPower® API Gateway.

The following sections in this topic review each step in the migration process. See also [Migration considerations](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Migration steps

Plan the migration, install a new v10 deployment, and move data from v5 to v10.

---

### About this task

At the highest level, the migration steps are:

- Plan your migration.
- Install and configure a v10 system to best meet current needs and integrate v5 data.
- Backup your v5 data and migrate the data to your new v10 deployment.

---

### Procedure

Complete the following steps:

1. Plan your migration:
  - Read [Migration overview](#).
  - Ensure you have supported versions of the software. See [Supported versions](#).
  - Plan your new v10 deployment. When moving from v5 to v10, use the opportunity to review your topology, user registries, provider organizations, etc. You might want to look at the existing data on the v5 system, and do some cleanup before running the extract. This will help ensure only objects that are required in v10 are migrated over.
  - If you are migrating to DataPower API Gateway, migrate a proof-of-concept deployment before migrating your entire v5 backup. Migrate 10 to 20 of your most commonly used v5 APIs and test them to determine which migration utility settings you may need to convert your APIs to DataPower API Gateway.
2. Install and configure a v10 system.

Install and deploy v10 with usage of the incoming v5 data in mind. Before you push your v5 data to v10, your v10 system must be up and running, with gateway services, provider organizations, user registries, etc, ready to receive the data.

  - For the v10 deployment, install the API Connect subsystems. Use the normal installation and configuration processes as shown in the documentation:
    - [Installing and maintaining IBM API Connect](#)
    - [Configuring and managing your server environment](#)

**Important:**

Verify that you completed the following steps as part of deploying your v10 environment:

- Ensure that you create the same number of API Managers as on the v5 deployment.
- Use the Cloud Manager to configure topology. See [Defining your topology](#).
- If your v10 topology uses identical names and quantities of gateway services as v5, the migration utility automatically maps configuration information. If your v10 configuration uses different names or a different number, you must manually map the v5 gateway services to v10 gateway services. You will be guided to map gateway services in a later step. To review the mapping requirement, see [Mapping a gateway service](#).
- Review Gateway types and configurations:

API Connect v10 supports two types of gateway services: DataPower Gateway (v5-compatible) and DataPower API Gateway. The DataPower API Gateway type is not supported for API Connect v5. When you register your gateway service on your v10 system, you must select the gateway service type. If you select API Gateway, your migration process must include a step to convert (port) the v5 API Definitions from the DataPower Gateway (v5-compatible) format to the DataPower API Gateway format. The migration utility provides an option to do the porting. Command line instructions are provided in a later step.

If migrating to datapower-api-gateway, confirm xml-manager is enabled in default domain of all gateways.

To review gateway types and configuration, see [API Connect gateway types](#) and [Registering a gateway service](#).

- Create the provider organizations. If your v10 configuration for provider organizations uses different names or a different quantity, you must manually map the v5 provider organizations to v10 provider organizations. You will be guided to map provider organizations in a later step. To review the mapping requirement, see [Mapping a provider organization](#).
  - When migrating catalog spaces in an provider organization that uses a local user registry (LUR), ensure that the LUR is configured with the visibility setting of either **Public** or **Custom**. If set to Custom, ensure that the provider organization is selected. For information on configuring visibility, see [Setting visibility for a user registry](#).
  - Configure user registries such as LDAP, as needed to match the user registries used for v5 users.
  - The migration process includes migration of users. Configuration of users into API Connect includes sending email to users to set up their accounts. The recommended way to do this during an automated migration is to set up a temporary SMTP server. One open source option for SMTP is MailHog. See <https://github.com/mailhog/MailHog>. When the migration process is complete, be sure to replace your temporary SMTP server with the permanent SMTP server for your API Connect v10 deployment.
  - Create the Portal services that you want to use with the Catalogs that you plan to migrate. You will configure the catalogs to the Portals after the migration data is pushed to the v10 system.
3. Backup your v5 data and migrate the data to your new v10 deployment.
- a. Download the migration utility. See [Obtaining the API Connect Migration Utility](#).
  - b. Determine if your v5 system contain catalogs that user a Portal Delegated User Registry (PDUR).  
Use of the PDUR was optional in v5. Migration of systems that use PDUR is very similar to migration of systems that do not use PDUR, however a few additional steps are needed. If you are not sure if your v5 catalogs use PDUR, check your v5 registry settings. See [Selecting the Portal Delegated User Registry](#).
  - c. Continue with instructions that apply to your deployment:
    - [Migration steps with PDUR](#)
    - [Migration steps without PDUR](#)
- [Migration steps with PDUR](#)  
Complete the following steps to migrate from v5 to v10 when your v5 catalogs use Portal Delegated User Registries (PDUR).
  - [Migration steps without PDUR](#)  
Complete the following steps to migrate from v5 to v10 when your v5 catalogs do not use Portal Delegated User Registries (PDUR).
  - [Logging in to a management server with an OIDC registry](#)  
Logging in with an OIDC registry involves several steps, in which you obtain a temporary token and pass it to the toolkit to ensure it can communicate securely with the management server.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Migration steps with PDUR

Complete the following steps to migrate from v5 to v10 when your v5 catalogs use Portal Delegated User Registries (PDUR).

### Before you begin

Important: If your v5 deployment does **not** use Portal Delegated User Registry (PDUR), do not use these instructions. See [Migration steps without PDUR](#).

- Ensure you planned your migration, obtained the migration utility, and installed a v10 deployment, as described in [Migration steps](#)
- Review [Migration considerations](#).
- Ensure you have system administrator privileges.
- To use `apicm` to convert the API definitions, you must have Node version 14.21.3 (or greater) installed.

### About this task

Tip:

To achieve a smooth and successful migration, we recommend these best practices:

- Before you push your v5 data to v10, your v10 system must be up and running, with gateway services, provider organizations, user registries, etc, ready to receive the data.
- Plan to do several test iterations of migration. You can use the `--dry-run` option to do iterations of the migration push, to test for any errors or warnings to address before the actual data push.
- Use the `apicm <command> --help` command to review the command options and their purpose. To see the list of commands you can run: `apicm help`.
- Complete all the steps in this topic in the order listed, unless the step is marked optional and does not apply to your scenario. You can push provider orgs as many times as needed.

The migration of v5 catalogs that use PDUR to a v10 deployment contains all of the steps for migration a non-PDUR v5 deployment to a v10 deployment (as described in [Migration steps without PDUR](#)) plus additional steps that are needed to migrate Portal Delegated User Registry data.

In IBM API Connect Version 5, when Portal Delegated User Registry (PDUR) was selected for a Catalog, the user management was delegated from the management server to the Developer Portal. The site administrator within the Portal site then performed the configuration. The management server recorded that the delegation had taken place, and stored a record of the users which existed in the catalog. However, the management service maintained no information about the configuration of the specific registries or how users mapped to them.

PDUR in IBM API Connect v5 was highly configurable. A single Portal site (catalog) could be configured to use multiple different registry types or different registries of the same type. Details of this configuration, and which users map to which registry, is all stored in the Portal.

However, IBM API Connect Version 10 and later supports new registries, and no longer needs the PDUR. Instead, functionally equivalent registries can be configured in v10 and used. To migrate the PDUR user registries and users from v5 to v10, we must gather configuration information from both the management server and the Portal node.

PDUR supported 4 different types of user registries. The following table shows the mapping of these types to the v10 equivalents:

Table 1. Mapping of Registry types

| v5 PDUR Registry          | v10 Equivalent Registry   |
|---------------------------|---------------------------|
| LDAP                      | LDAP                      |
| OIDC                      | OIDC                      |
| HybridAuth                | OIDC                      |
| Local User Registry (LUR) | Local User Registry (LUR) |

In this scenario, if you want to migrate users from an IBM API Connect V5 Developer Portal to an IBM API Connect v10 Developer Portal, you must export the user information that is stored in the Developer Portal local database. This information can then be used by the migration tooling to migrate the PDUR user registry. You complete this action after you have exported the v5 configuration database for the management server.

## Procedure

1. Log in to the command line interface of the v5 appliance. Use the following command to create a tar.gz export of the v5 configuration database and place it on an **sftp** server:

```
config dbextract sftp <host_name> user <user_name> file <path/name>
```

- Specify a name of your choice for the compressed file to contain the dbextract. For example, `v5mgmt_data.tgz`.
- If you are not familiar with the v5 appliance CLI, see [The Command Line Interface](#). For information on `config dbextract`, see [Configuration commands](#).

2. Log in to Developer Portal CLI to export Portal Delegated User Registry user information for all of the sites on a Developer Portal server. Use the following command to create a `*.tgz` file:

```
pdur_user_export
```

The status of the export is displayed. For example:

```
admin@apimxxx123:~$ pdur_user_export
portal123.company.com/api-provider/production: Exporting pdur users
portal123.company.com/api-provider/preprod: Exporting pdur users
portal123.company.com/api-provider/uat: Exporting pdur users
portal123.company.com/api-provider/development: Skipping as not a pdur enabled site
portal123.company.com/api-provider/sandbox: Skipping as not a pdur enabled site
~/pdurexport ~
5c20b903e4b0485cbbd81775.5c20bf43e4b0485cbbd81795.json
5c20b903e4b0485cbbd81775.5c2cddb4e4b0485cbbd818a0.json
5c20b903e4b0485cbbd81775.5c335211e4b0485cbbd8196e.json
~
Output can be found in /home/admin/pdurexport.tgz
```

Results:

- When the command completes, you can see the output `*pdurexport.tgz` in `/home/admin/pdurexport.tgz`.
  - This compressed file contains all of the JSON user-mapping files for that server. Each `.json` file contains a list of all of the PDUR user information that is stored in the Developer Portal local database. The naming convention used for the individual user-mapping files is `<provider_org_id>.<catalog_id>.json`.
  - The user information for all of the user registration methods that are used in the specific Developer Portal are included in the same file. For example, local user registry, LDAP user registry, third-party authentication, OpenID Connect, and any custom user registration method.
  - If a site doesn't contain any PDUR data, that site is skipped. The example output shows that there was one provider organization on the server, and that organization had five Developer Portal sites, three of which contained PDUR user information. The PDUR user information for all of the sites on the server is exported into a `pdurexport.tgz` file.
3. Optional: Setup a temporary SMTP server.  
During migration, if subscription approval is needed to enable an application to subscribe to a plan, notifications are sent to all users, within the organization, who have subscription approval permission. In some cases, this results in a large number of emails. To avoid the sending of these emails, set up a temporary email server prior to running the migration, and use it to collect all notifications rather than sending them to users' email accounts.  
  
If subscription approvals are not needed during your migration, you can skip this step.
  4. Optional: If necessary, set up a temporary LDAP server. This can be needed if you are temporarily behind a firewall.
    - a. Install a server:

```
git clone https://github.com/veo-labs/ldap-server-mock
```

```
npm install
```

- b. Creating the configuration files:

- `ldap-server-mock-conf.json`

```
{
 "port": 3004,
 "userLoginAttribute": "cn",
 "searchBase": "dc=test",
 "searchFilter": "(&(objectclass=person)(cn={username}))"
}
```

- `users.json`

```
[
 {
 "dn": "cn=user,dc=test",
 "cn": "user-login"
 }
]
```

```
}
]
```

c. Run the LDAP server:

```
node server.js --conf=./ldap-server-mock-conf.json --database=./users.json
```

d. Modifying a current LDAP provider.

The following file is a dummy user registry file that maps to a read-only test server. The fields in bold font (**admin\_dn** and **endpoint**) have been changed to fit the dummy server configuration. Change these on all user registries that need to be fixed.

```
api_version: 2.0.0
configuration:
 admin_dn: cn=user,dc=test
 admin_password: xxxx
 authenticated_bind: "true"
 authentication_method: search_dn
 bind_prefix: ""
 bind_suffix: ""
 protocol_version: "3"
 search_dn_base: ""
 search_dn_filter_prefix: (examplelegacyuid=
 search_dn_filter_suffix:)
 search_dn_scope: sub
endpoint:
 endpoint: ldap://172.20.20.11:3004
 tls_client_profile_url: idurl://..\..\..\..\admin-org\tls-client-profiles\tls-profile-for-ldap-1.0.0.yml
integration_url: file://..\..\..\..\integrations\user_registry\ldap.yml
metadata:
 v5_id: xxxxxxx40cf2fc09a9ba0d6c
 v5_scope: '["api"]'
 v5_type: ldap
name: xxxxxxxxxxxxxxxx
title: xxxxxxxxxxxxxxxxxxxxxxxx
type: user_registry
```

5. Unpack both the v5 management data backup and the PDUR tar file.

Important: Migration on Windows 10

Windows has path length limits that can interfere with large extracts. It is recommended that you keep the initial path for migration on Windows as short as possible. The AMU must be run in a command window with administrative privileges on Windows. Running from a Linux VM on your Windows system may be a better option for doing migration.

a. Copy the v5 extract tar file (**<v5mgmt\_data>.tgz**) and the PDUR extract file (**pdurexport.tgz**) from the sftp server to the location where you have v10 migration utility installed.

b. Run **apicm archive:unpack** command from the directory where you downloaded the v5 extract file.

When you invoke **apicm** for the first time, you are prompted to accept the license. Accept the license to continue.

You can optionally limit the unpack to only specific provider orgs. See [Table 2](#).

```
./apicm archive:unpack <v5_extract_file>.tgz pdurexport.tgz
```

Table 2. **apicm archive:unpack** command options

| Parameters                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&lt;v5_extract_file&gt;</b> | Can be compressed file (.tgz, tar.gz) or uncompressed file (.tar). Use any file name of your choosing. Example:<br><b>v5_DBextract_data.tgz</b>                                                                                                                                                                                                                                                                                                                                            |
| <b>pdurexport.tgz</b>          | The Portal Delegated User Registry export file generated by the <b>pdur_user_export</b> utility. Example:<br><b>pdurexport.tgz</b>                                                                                                                                                                                                                                                                                                                                                         |
| <b>--provider-orgs</b>         | One or more provider orgs to unpack. This flag is optional. Use it when you want to unpack only specific provider orgs rather than the entire archive. Example:<br><b>./apicm archive:unpack v5_DBextract_data.tgz pdurexport.tgz --provider-orgs=&lt;pOrg1_name&gt;</b><br><br>Use a comma-separated list to specify multiple provider orgs:<br><b>./apicm archive:unpack v5_archive_data.tgz pdurexport.tgz --provider-orgs=&lt;pOrg1_name&gt;,&lt;pOrg2_name&gt;,&lt;pOrg3_name&gt;</b> |

Note:

- You can avoid the license prompt by adding **--accept-license** to the command line.
- The unpack command ensures that catalog names and API properties contain only valid characters. Any invalid characters are mapped to '-'. See [Parity between Version 5 and Version 10](#).
- The unpack command issues warning messages for APIs and Products that fail validation against the OpenAPI specification. See the limitations section in [Migration considerations](#).
- For troubleshooting tips, see [Migration troubleshooting](#)
- The unpack command might return error messages related to PDUR, such as:

```
ERRO[3414] PDUR backup data for IDP PortalDelegatedIdentityProvider-123b81f8e4b06de411580e2e
(123b81f8e4b06de411580e2f) not provided: not found
ERRO[3414] PDUR backup data for IDP PortalDelegatedIdentityProvider-123b820de4b06de411580e32
(123b820ee4b06de411580e33) not provided: not found
```

The error means that when the migration utility unpacked **pdurexport.tgz**, it could not find all the specified Portal user registries. To resolve the errors, re-run **pdur\_user\_export** and re-run the unpack..

When the command completes, the data is unpacked to the **/cloud** directory. The **/cloud** directory is located in the same directory as **apicm**, and populated with yaml files representing the configuration objects in the export. The unpack processes produce output in the format required for v10 configuration.

Note: The unpack directory must be named `/cloud`. Do not rename the directory.  
 Example output in `/cloud` for provider-org:

```

```

6. If the v5 Developer Portal used LDAP, HybridAuth, or OIDC (such as social login through Google, GitHub, or Slack) user registries, you must manually configure them in v10 before using `apicm archive:push` to migrate PDUR. See the following instructions for your registry type:

- LDAP

- Manually configure LDAP

The user registries which are required in the target v10 system are described in the `user-registry.yml` file. Where possible the configuration for the v10 registries is complete in these files. However, for LDAP the configuration of the registry is not possible due to differences in the way the v5 Portal (Drupal) and v10 API Manager (`apim`) specify user registry configuration.

For LDAP with v10, create a user registry manually, using the same LDAP server and configuration as used with v5. Where it is possible, the v5 configuration is provided as helpful information in the `metadata.v5_config` property. To view the v10 configuration instructions, see [Configuring an LDAP user registry](#).

For example: An `ldap.tar.gz` file, when unpacked, creates the following directory hierarchy, for an LDAP directory `example`:

```

└─ user-registries
 └─ example-5c38556de4b0c5f69db90ee0
 └─ user-registry.yml
 └─ users
 └─ testuser1.yml
 └─ testuser2.yml

```

You can create an LDAP user registry for the PDUR by either modifying `user-registry.yml` or by creating the registry in the UI:

- Modify the `user-registries/example-5c38556de4b0c5f69db90ee0/user-registry.yml` file directly and add the required LDAP fields based on the extracted info provided in the metadata. Remove the metadata after you are done. The modification of `user-registry.yml` is preferred over using the UI. This method enables any APIs that depend on the user registry to be satisfied when the migration command `apicm archive:push` is run in Step [10](#).
- Create the registry in the UI. The creation of the registry in the UI requires more manual setup of the organization and catalog. In addition, you must provide a mapping file to map from the `example-5c38556de4b0c5f69db90ee0` to the ID of the registry that was created manually.

- Create a mapping file entry for the LDAP user registry.  
In the `/cloud` directory, go to `provider-org/<provider-org>/user-registry/<PDUR_LDAP_User_registry>` and create a mapping file to tell migration utility the name of the migration endpoint for the LDAP user registry used with v5 PDUR:

```
user-registry:
 name: <pdur-ldap-v10-name>
```

To determine which name to use for the v10 LDAP registry, go to the management user interface, click on **Resources** -> **User Registries** then use **Name** not **Title**.

For more information on how to create mapping files, see [Migration mapping files](#).

- OIDC

- Manually configure OIDC
  - Note that v10 supports OAuth 2.0 but does not support OAuth 1.0. Deployments, such as Twitter, which use OAuth 1.0 with APIC version 5, can not use OAuth 1.0 when migrating to v10.
  - Automatic migration is not supported for the OIDC user registries which you use in your v5 Portal. Thus if you are using OIDC OAuth 2.0, e.g., Google, GitHub, or Slack, please complete the following manual steps.
  - The OIDC data from the Portal Delegated User registry does not contain the `client_id` and `client_secret` that are needed to migrate a user registry automatically. You must obtain the data and update the user registry manually if you are using `client_id` and `client_secret`.

On the Version 10 system:

- Edit `user-registry.yml`. For example, for GitHub:  
`cloud/provider-orgs/test-user1-org1/user-registries/git-hub-5c5xyz6ee4b0c5f69db94xxxx-a339/user-registry.yml`

```
api_version: 2.0.0
configuration:
 client_id: ""
 client_secret: ""
 authorization_endpoint: https://github.com/login/oauth/authorize
 provider_type: github
 token_endpoint:
 endpoint: https://github.com/login/oauth/access_token
integration_url: file://../../../../integrations/user_registry/oidc.yml
metadata:
 v5_id: 5c5xyz6ee4b0c5f69db94xxxx
 name: git-hub-5c5xyz6ee4b0c5f69db94xxxx-a339
 registry_type: oidc
 title: GitHub
 type: user_registry
```

- Insert the values for `client_id` and `client_secret`. Once the client id and client secrets have been updated in the `user-registry.yml` file just described, the `apim archive:push` can be successfully executed.  
Upon creation and configuration of the Developer Portal, you can log in by using, as in this example, an account such as a GitHub account.

To verify that the manual configuration succeeded, view the log file for entries for the users after you run `apim archive:push` in Step [10](#).

- Example success message:

```
INFO[0012] User registry git-hub-5c5xyz6ee4b0c5f69db94xxxx-a339 created
INFO[0013] User test-user1-4d48 created
```

- Example error message:

```
ERRO[0010] unable to create User registry git-hub-5c5xyz6ee4b0c5f69db94xxxx-a339
ERRO[0010] git-hub-5c5xyz6ee4b0c5f69db94xxxx-a339: The properties client_id, client_secret are required.
```

- Create a mapping file entry for the OIDC user registry.  
In the `/cloud` directory, go to `provider-org/<provider-org>/user-registry/<PDUR_OIDC_User_registry>` and create a mapping file to tell migration utility the name of the migration endpoint for the OIDC user registry used with v5 PDUR:

```
user-registry:
 name: <pdur-OIDC-v10-name>
```

For more information on how to create mapping files, see [Migration mapping files](#).

## 7. Remove unneeded configuration objects.

Inspect the set of configuration objects and their attributes, and remove the ones that are not needed. In many cases, some of the configuration objects present in the v5 system are not needed in the new v10 environment. For example, there is no value in preserving inactive users, obsolete apps, obsolete consumer organizations, and so on.

When deleting objects, make sure that you do not delete objects that have other dependent objects, such as products with subscriptions on them or users that are active. If you delete a consumer organization make sure you also delete all apps and subscriptions associated with that consumer org. Be aware of any groups that include these consumer orgs or visibility settings that include the consumer orgs.

## 8. Map v5 object names to v10 object names.

Most deployments adjust the names or quantities of gateway services, provider organizations, and user registries when setting up a new environment for v10. Be sure to specify any changed v10 destinations for the v5 data in a migration mapping file so that the migration utility can automatically move the data.

Complete the following, as needed. You can skip the steps for any objects that are unchanged from v5 to v10.

- [What is a mapping file?](#)
- [Mapping a gateway service](#)
- [Mapping a provider organization](#)

- Optional: If your v10 deployment uses a **DataPower API Gateway**, convert the v5 API definitions to v10 DataPower® API Gateway.  
To convert API definitions using the default migration configuration, use the following syntax.

```
./apicm archive:port-to-apigw <path>
```

Important: Ensure that the DataPower Gateway version that you are using with your API Connect v10 deployment is compatible with the version of the migration utility that you are using. For details, see the version compatibility information in [Configuring and managing your server environment](#).

Important: If you are running the migration utility in Windows, Administrator privileges are required to complete this step.

Table 3. Parameter for archive:port-to-apigw

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <path>    | <p>Specify the unpacked <code>cloud</code> directory as input:</p> <pre>./apicm archive:port-to-apigw /cloud</pre> <p>By specifying <code>/cloud</code>, <code>apicm</code> ports all artifacts within the directory, including APIs, Products, OAuth providers, custom policies, subscriptions and so on. Running a subsequent <code>archive:push</code> pushes all the artifacts to API Gateway.</p> <p>Running <code>archive:port-to-apigw</code> on any subdirectory within the unpacked <code>/cloud</code> directory could leave the directory in an inconsistent state, and cause the subsequent <code>archive:push</code> of artifacts to API Gateway to fail. Custom policies and OAuth providers are not migrated if a directory other than <code>/cloud</code> is specified.</p> <p>Note: However, if you decide to rewrite one API at a time, to migrate them to API Gateway, you can use:</p> <pre>./apicm archive:port-to-apigw &lt;path&gt;</pre> <p>where <code>&lt;path&gt;</code> is a single API file, or a directory that contains only APIs or Products.</p> <p>In this case, you cannot use <code>archive:push</code> to push artifacts to API Gateway. All the ported APIs and Products must be pushed (or imported) into API Manager by either the toolkit or UI.</p> |

Usage notes:

- The conversion produces a draft output YAML file. Review the entire draft output YAML file for conformance, performance, and errors. Review the log files for messages about any manual actions that might be needed. For more information, see [Reviewing APIs converted to DataPower API Gateway](#).
- By default, all changes that the migration utility makes when rewriting APIs are logged as comments within the API YAML file. You can use the `enable-api-logging` parameter to disable logging of these changes.

```
./apicm archive:port-to-apigw <folder> --enable-api-logging=false
```

- You can also specify migration configuration parameters using either a YAML configuration file or from the command line, but not both. For information about configuration options and DataPower requirements for certain configuration parameters, see [Configuring migration options for DataPower API Gateway](#).
- Multiple runs of `./apicm archive:port-to-apigw` on the same `/cloud` folder will skip artifacts that have already been converted to DataPower® API Gateway.
- If your v10 deployment uses DataPower MultiProtocol Gateway (v5-compatible) you do not need to convert the API definitions.

10. Use `apicm` commands to push the Cloud Manager admin organization data onto your v10 Management Server.

- Log in to the Cloud Manager on the destination v10 Management Server as an Owner of the admin organization:

```
./apicm login --server <cloud_manager_endpoint> --realm admin/identity_provider --username admin --password admin_password
```

Important: You must be logged in as an Owner of the admin organization to be able to migrate Cloud Manager admin organization data.

See [Table 4](#) to review how to obtain each parameter.

Example commands:

- API Connect v10 standalone

```
./apicm login --server cloud-admin-ui.mgmt.dev.apic10-stack.example.test --realm admin/default-idp-1 --username admin --password 'myadminpassword'
```

Note: If you want to login using an OIDC user registry, see [Logging in to a management server with an OIDC registry](#).

Table 4. `apicm login` command parameters

| Parameters                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--server &lt;cloud_manager_endpoint&gt;</code> | <p>The endpoint on the management server for communication with the Cloud Manager user interface.</p> <p>v10 standalone</p> <p>Example:</p> <pre>cloud-admin-ui.mgmt.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the management subsystem was installed. View the <code>apiconnect_api</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory that you created for initial deployment of v10.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>VMware: see the <code>cloud-admin-ui</code> endpoint in <a href="#">Deployment overview for endpoints and certificates</a>.</li> <li>Kubernetes: see the <code>admin</code> endpoint in <a href="#">Deployment overview for endpoints and certificates</a>.</li> </ul> |

| Parameters                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--realm admin/default-idp-1</code> | <p>The <code>apicm login</code> example shows the expected <code>--realm</code> parameter values for a default API Connection administration organization. The default user is <code>admin</code> and the identity provider is <code>default-idp-1</code>.</p> <p>You can determine which identity provider to use in the <code>--realm</code> parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):</p> <pre>apicm identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm</pre> <p>For example:</p> <pre>apicm identity-providers:list --scope admin --server myserver.com --fields title,realm total_results: 2 results: - title: Cloud Manager User Registry   realm: admin/default-idp-1 - title: Corporate LDAP user registry   realm: admin/corporate-ldap</pre> <p>The <code>title</code> value should enable you to determine which identity provider to use; you can then copy the corresponding <code>--realm</code> parameter directly from the displayed <code>realm</code> value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is <code>default-idp-1</code>.</p> |
| <code>--username admin</code>            | Administrative user with permissions to modify API Connect admin-org. The default user is <code>admin</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>--password myadminpassword</code>  | Administrative user password.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

3

Note:

The `apicm login` obtains a token that expires after eight hours. If the token expires while `apicm archive:push` is running, `apicm` generates errors due to lack of the necessary access permissions. In this case, log in again and re-run `apicm archive:push`. The token is refreshed every time you log in. See also [Token expiration](#) in [Migration troubleshooting](#)

- b. Run `/apicm archive:push` to migrate data for the Cloud Manager administrative org (admin-org).

Tip: First run the command with the optional flag `--dry-run` to test for errors or warnings. Review the command parameters, examples and guidance that follow before you run it.

```
./apicm archive:push <cloud_manager_endpoint> <path_to_admin_org> [optional flags]
```

Example:

```
./apicm archive:push cloud-admin-ui.mgmt.dev.apic10-stack.example.test cloud/admin-org
```

Table 5. `apicm archive:push` command

| Parameters                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;cloud_manager_endpoint&gt;</code> | <p>The endpoint on the management server for communication with the Cloud Manager user interface.</p> <p>v10 standalone<br/>Example:</p> <pre>cloud-admin-ui.mgmt.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the management subsystem was installed. View the <code>apiconnect_api</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory that you created for initial deployment of v10.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>VMware: see the <code>cloud-admin-ui</code> endpoint in <a href="#">Deployment overview for endpoints and certificates</a>.</li> <li>Kubernetes: see the <code>admin</code> endpoint in <a href="#">Deployment overview for endpoints and certificates</a>.</li> </ul> |
| <code>&lt;path_to_admin_in_org&gt;</code>   | Must be <code>cloud/admin-org</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>--dry-run</code>                      | <p>You can test the Admin org migration output first view by using the <code>--dry-run</code> option.</p> <pre>./apicm archive:push &lt;cloud_manager_endpoint&gt; &lt;consumer_api_endpoint&gt; &lt;path_to_admin_org&gt; --dry-run</pre> <p>Note: Type the command on a single line.</p> <p>This option creates a project directory similar to <code>cloud</code>, titled <code>.workdir-&lt;apim_admin_server&gt;</code> where you can view how the data will be loaded into your new system. The option also displays the objects that will fail due to existing already or missing dependencies. Use this option to view the resolved URLs for where the data will be loaded, without creating resources on the new system. See <a href="#">apicm command line help</a>.</p>                                    |
| <code>--apigw-only</code>                   | <p>Optional flag. Use when migrating to a DataPower API Gateway. For example:</p> <pre>./apicm archive:push &lt;cloud_manager_endpoint&gt; &lt;path_to_admin_org&gt; --apigw-only</pre> <p>Note: Type the command on a single line.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

Important: Usage notes:

- Run `/apicm archive:push` in the same directory where you ran `apicm archive:unpack`.
- If you run migration and observe error messages in your log output, you can take troubleshooting steps, and run the migration again. See [Migration troubleshooting](#).
- An alternative method of viewing endpoints is to run `kubectl get ingress` and get the values from the output. For example, see the values in **bold** in the following sample output:

|                                        |                                             |         |     |
|----------------------------------------|---------------------------------------------|---------|-----|

11. Migrate the API Manager provider organizations.

- If you have not already done so, create the provider organizations on your API Connect v10 deployment.
- Use `apicm` to log in to the API Manager user interface as an Owner of the provider organization that you want to migrate. If you want to login using an OIDC user registry, see [Logging in to a management server with an OIDC registry](#).

Important: You cannot migrate a provider organization while you are logged in with the Cloud Manager admin organization. You must be logged in as an Owner of the provider organization to be able to migrate that organization's data.

API Connect v10 standalone

```
./apicm login --server <api-manager-ui-endpoint> --realm provider/identity_provider --username org_owner --password org_password
```

Example:

```
./apicm login --server api-manager-ui.dev.apic10-stack.example.test --realm provider/default-idp-2 --username org_owner1@example.com --password myorgpassword
```

Table 6. `apicm login` parameters for logging in to provider orgs on API Connect v10 standalone

| Parameters                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--server &lt;api-manager-ui-endpoint&gt;</code> | API Manager URL endpoint on the management server for communication with the API Manager user interface.<br>For example:<br><code>api-manager-ui.dev.apic10-stack.example.test</code><br><br>The endpoint was specified when the management subsystem was installed. To verify your endpoint setting you can: <ul style="list-style-type: none"> <li>View the <code>apiconnect-apim-ui</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory.</li> <li>In the Cloud Manager UI, select Settings &gt; Endpoints and view <b>API Manager URL</b>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>--realm provider/identity_provider</code>       | The <code>apicm login</code> example shows the expected <code>realm</code> parameter values for a default API Connection provider organization. The default user is <code>provider</code> and the identity provider is <code>default-idp-2</code> .<br>You can determine which identity provider to use in the <code>--realm</code> parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):<br><code>apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm</code><br><br>For example:<br><code>apic identity-providers:list --scope provider --server myserver.com --fields title,realm</code><br>total_results: 2<br>results:<br>- title: Cloud Manager User Registry<br>realm: provider/default-idp-2<br>- title: Corporate LDAP user registry<br>realm: provider/corporate-ldap<br><br>The <code>title</code> value should enable you to determine which identity provider to use; you can then copy the corresponding <code>--realm</code> parameter directly from the displayed <code>realm</code> value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is <code>default-idp-2</code> . |
| <code>--username &lt;org_owner&gt;</code>             | A user with permissions to modify the provider organization. Typically this is the owner of the organization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>--password &lt;org_owner_password&gt;</code>    | Organization owner password.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

- Run `./apicm archive:push` to migrate data for the Provider organization. Review the command parameters, examples and guidance that follow before you run it.

Tip: First run the command with the optional flag `--dry-run` to test for errors or warnings.

```
./apicm archive:push <api-manager-ui-endpoint> cloud/provider-orgs/<pOrg_name> [optional flags]
```

For example:

```
./apicm archive:push api-manager-ui.mgmt.dev.apic10-stack.example.test cloud/provider-orgs/production_Org
```

Table 7. `apicm archive:push` command parameters for Provider orgs

| Parameters | Description |
|------------|-------------|
|------------|-------------|

| Parameters                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;api-manager-ui-endpoint&gt;</code>       | <p>API Connect v10 standalone<br/>API Manager URL endpoint on the management server for communication with the API Manager user interface. For example:</p> <pre>api-manager-ui.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the management subsystem was installed. To verify your endpoint setting you can:</p> <ul style="list-style-type: none"> <li>View the <code>apiconnect_api</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory.</li> <li>In the Cloud Manager UI, select Settings, Endpoints and view <b>API Manager URL</b>.</li> </ul>                                                                                                             |
| <code>cloud/provider-orgs/&lt;pOrg_name&gt;</code> | <p>The location of your Provider org within the <code>/cloud</code> file hierarchy you created when you ran <code>apicm archive:unpack</code>.</p> <pre>cloud/provider-orgs/production_Org</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>--catalogs=&lt;name&gt;</code>               | <p>Optionally, you can push data for only specified Catalogs if you don't want to push the entire Provider organization. Use this flag to specify the name of the Catalog you want to push:</p> <pre>./apicm archive:push &lt;api-manager-ui-endpoint&gt; cloud/provider-orgs/&lt;pOrg_name&gt; --catalogs=&lt;catalog_name&gt;</pre> <p>Note: Type the command on a single line.<br/>When a catalog is mapped, specify the mapped new catalog name.</p> <p>To specify multiple catalogs, use a comma-separated list:</p> <pre>./apicm archive:push &lt;api-manager-ui-endpoint&gt; cloud/provider-orgs/&lt;pOrg_name&gt; --catalogs=catalog_name1,catalog_name2,catalog_name3</pre> <p>Note: Type the command on a single line.</p>                      |
| <code>--dry-run</code>                             | <p>You can test the Provider org migration output first view by using the <code>--dry-run</code> option. This will create a project directory similar to <code>cloud</code>, titled <code>.workdir-&lt;apim_admin_server&gt;</code> where you can view how the data will be loaded into your new system. The option also displays the objects that will fail due to existing already or missing dependencies. Use this option to view the resolved URLs for where the data will be loaded, without creating resources on the new system. See <a href="#">apicm command line help</a>.</p> <pre>./apicm archive:push &lt;api-manager-ui-endpoint&gt; cloud/provider-orgs/&lt;pOrg_name&gt; --dry-run</pre> <p>Note: Type the command on a single line.</p> |
| <code>--no-drafts</code>                           | <p>Do not push any Draft APIs or Products. Draft objects are objects that have not been published.</p> <pre>./apicm archive:push &lt;cloud_manager_endpoint&gt; &lt;path_to_provider_org&gt; --no-drafts</pre> <p>Note: Type the command on a single line.<br/>This option can be used with or without <code>--catalogs=a,b,c</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>--overwrite</code>                           | <p>When this option is used, draft products, draft APIs, published products and their APIs, and OAuth Providers that are already on the v10 system will be overwritten. When this option is not used these artifacts will be skipped.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Important: Usage notes

- Run `/apicm archive:push` in the same directory where you ran `apicm:archive:unpack`.
- If you run migration and observe error messages in your log output, you can take troubleshooting steps, and run the migration again. See [Migration troubleshooting](#).
- An alternative method of viewing endpoints is to run `kubectl get ingress` and get the values from the output. See [kubectl example](#).

12. When migration finishes, complete the following steps:

- If a user in a Local User Registry is owner of a Consumer Organization, the user must reset their password.
- If applicable, reapply any customized configurations from your v5 deployment. See [Customizations to recreate](#).
- Optional: If necessary, switch the provider organization ownership to the identity that owned it in v5.  
This step might be necessary if you created and migrated the provider organization using a different identity (such as administrative account) than the user identity of the v5 provider org. Note that the UI does not provide this function, but you can use the API `/orgs/{org}/transfer-owner` to switch ownership.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Migration steps without PDUR

Complete the following steps to migrate from v5 to v10 when your v5 catalogs do not use Portal Delegated User Registries (PDUR).

### Before you begin

Important: Do not use these instructions if your v5 catalogs use Portal Delegated User Registry. Instead, see [Migration steps with PDUR](#).

- Ensure you planned your migration, obtained the migration utility, and installed a v10 deployment, as described in [Migration steps](#)
- Review [Migration considerations](#).
- Ensure you have system administrator privileges.
- To use `apicm` to convert the API definitions, you must have Node version 14.21.3 (or greater) installed.

## About this task

Use the `apicm` utility to migrate your API Connect v5 data to a new API Connect v10 installation.

Tip:

To achieve a smooth and successful migration, we recommend these best practices:

- Before you push your v5 data to v10, your v10 system must be up and running, with gateway services, provider organizations, user registries, etc, ready to receive the data.
- Plan to do several test iterations of migration. You can use the `--dry-run` option to do iterations of the migration push, to test for any errors or warnings to address before the actual data push.
- Use the `apicm <command> --help` command to review the command options and their purpose. To see the list of commands you can run: `apicm help`.
- Complete all the steps in this topic in the order listed, unless the step is marked optional and does not apply to your scenario. You can push provider orgs as many times as needed.

## Procedure

1. Log in to the command line interface of the v5 appliance. Use the following command to create a tar.gz export of the v5 configuration database and place it on an `sftp` server:

```
config dbextract sftp <host_name> user <user_name> file <path/name>
```

- Specify a name of your choice for the compressed file to contain the dbextract. For example, `v5mgmt_data.tar.gz`.
- If you are not familiar with the v5 appliance CLI, see [The Command Line Interface](#). For information on `config dbextract`, see [Configuration commands](#).

2. Optional: Setup a temporary SMTP server.

During migration, if subscription approval is needed to enable an application to subscribe to a plan, notifications are sent to all users, within the organization, who have subscription approval permission. In some cases, this results in a large number of emails. To avoid the sending of these emails, set up a temporary email server prior to running the migration, and use it to collect all notifications rather than sending them to users' email accounts.

If subscription approvals are not needed during your migration, you can skip this step.

3. Optional: If necessary, set up a temporary LDAP server. This can be needed if you are temporarily behind a firewall.

- a. Install a server:

```
git clone https://github.com/veo-labs/ldap-server-mock
```

```
npm install
```

- b. Creating the configuration files:

- `ldap-server-mock-conf.json`

```
{
 "port": 3004,
 "userLoginAttribute": "cn",
 "searchBase": "dc=test",
 "searchFilter": "(&(objectclass=person)(cn={username}))"
}
```

- `users.json`

```
[
 {
 "dn": "cn=user,dc=test",
 "cn": "user-login"
 }
]
```

- c. Run the LDAP server:

```
node server.js --conf=./ldap-server-mock-conf.json --database=./users.json
```

- d. Modifying a current LDAP provider.

The following file is a dummy user registry file that maps to a read-only test server. The fields in bold font (`admin_dn` and `endpoint`) have been changed to fit the dummy server configuration. Change these on all user registries that need to be fixed.

```
api_version: 2.0.0
configuration:
 admin_dn: cn=user,dc=test
 admin_password: xxxx
 authenticated_bind: "true"
 authentication_method: search_dn
 bind_prefix: ""
 bind_suffix: ""
 protocol_version: "3"
 search_dn_base: ""
 search_dn_filter_prefix: (examplelegacyuid=
 search_dn_filter_suffix:)
 search_dn_scope: sub
endpoint:
 endpoint: ldap://172.20.20.11:3004
 tls_client_profile_url: idurl://...\\admin-org\\tls-client-profiles\\tls-profile-for-ldap-1.0.0.yml
integration_url: file://...\\integrations\\user_registry\\ldap.yml
metadata:
 v5_id: xxxxxx40cf2fc09a9ba0d6c
 v5_scope: '["api"]'
 v5_type: ldap
name: xxxxxxxxxxxxxxxx
title: xxxxxxxxxxxxxxxxxxxxxxxx
type: user_registry
```

4. Unpack the V5 configuration data onto the local filesystem.

Important: Migration on Windows 10

Windows has path length limits that can interfere with large extracts. It is recommended that you keep the initial path for migration on Windows as short as possible. The AMU must be run in a command window with administrative privileges on Windows. Running from a Linux VM on your Windows system may be a better option for doing migration.

- a. Copy the v5 extract tar file from the sftp server to the location where you have v10 migration utility installed.
- b. Run `apicm archive:unpack` command from the directory where you downloaded the v5 extract file.

```
./apicm archive:unpack <v5_extract_file>.tgz
```

When you invoke `apicm` for the first time, you are prompted to accept the license. Accept the license to continue.

You can optionally limit the unpack to only specific provider orgs. See [Table 1](#).

Table 1. `apicm archive:unpack` command options

| Parameters                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;v5_extract_file&gt;</code> | Can be compressed file (.tgz, tar.gz) or uncompressed file (.tar). Use any file name of your choosing. Example:<br><br><code>./apicm archive:unpack v5_DBextract_data.tgz</code>                                                                                                                                                                                                                                                                                                 |
| <code>--provider-orgs</code>         | One or more provider orgs to unpack. This flag is optional. Use it when you want to unpack only specific provider orgs rather than the entire archive. Example:<br><br><code>./apicm archive:unpack v5_DBextract_data.tgz --provider-orgs=&lt;pOrg1_name&gt;</code><br><br>Use a comma-separated list to specify multiple provider orgs:<br><br><code>./apicm archive:unpack v5_archive_data.tgz --provider-orgs=&lt;pOrg1_name&gt;,&lt;pOrg2_name&gt;,&lt;pOrg3_name&gt;</code> |

Note:

- **Important:** Any Warnings or Errors that occur during `archive:unpack` should be investigated for remediation. See [Migration troubleshooting](#)
- You can avoid the license prompt by adding `--accept-license` to the command line.
- The unpack command ensures that catalog names and API properties contain only valid characters. Any invalid characters are mapped to '-'. See [Parity between Version 5 and Version 10](#).
- The unpack command issues warning messages for APIs and Products that fail validation against the OpenAPI specification. See the limitations section in [Migration considerations](#).
- For troubleshooting tips, see [Migration troubleshooting](#)
- The unpack command might return error messages related to PDUR, such as:

```
ERRO[3414] PDUR backup data for IDP PortalDelegatedIdentityProvider-123b81f8e4b06de411580e2e (123b81f8e4b06de411580e2f) not provided: not found
ERRO[3414] PDUR backup data for IDP PortalDelegatedIdentityProvider-123b820de4b06de411580e32 (123b820ee4b06de411580e33) not provided: not found
```

If you are not migrating PDUR backup data, and your command did not include a `<pdur_user_export>.tgz`, the error indicates that you do in fact have a PDUR registry, and that you should have included a PDUR backup. Follow the migration instructions in [Migration steps with PDUR](#).

When the command completes, the data is unpacked to the `/cloud` directory. The `/cloud` directory is located in the same directory as `apicm`, and populated with yaml files representing the configuration objects in the export. The unpack processes produce output in the format required for v10 configuration.

Note: The unpack directory must be named `/cloud`. Do not rename the directory.

Example output in `/cloud` for `admin-org`:

```
cloud
├── admin-org

```

5. Remove unneeded configuration objects.

Inspect the set of configuration objects and their attributes, and remove the ones that are not needed. In many cases, some of the configuration objects present in the v5 system are not needed in the new v10 environment. For example, there is no value in preserving inactive users, obsolete apps, obsolete consumer organizations, and so on.

When deleting objects, make sure that you do not delete objects that have other dependent objects, such as products with subscriptions on them or users that are active. If you delete a consumer organization make sure you also delete all apps and subscriptions associated with that consumer org. Be aware of any groups that include these consumer orgs or visibility settings that include the consumer orgs.

6. Map v5 object names to v10 object names.

Most deployments adjust the names or quantities of gateway services, provider organizations, and user registries when setting up a new environment for v10. Be sure to specify any changed v10 destinations for the v5 data in a migration mapping file so that the migration utility can automatically move the data.

Complete the following, as needed. You can skip the steps for any objects that are unchanged from v5 to v10.

- a. [What is a mapping file?](#)
- b. [Mapping a gateway service](#)
- c. [Mapping a provider organization](#)

7. Optional: If your v10 deployment uses a **DataPower API Gateway**, convert the v5 API definitions to v10 DataPower® API Gateway.

To convert API definitions using the default migration configuration, use the following syntax.

```
./apicm archive:port-to-apigw <path>
```

Important: Ensure that the DataPower Gateway version that you are using with your API Connect v10 deployment is compatible with the version of the migration utility that you are using. For details, see the version compatibility information in [Configuring and managing your server environment](#).

Important: If you are running the migration utility in Windows, Administrator privileges are required to complete this step.

Table 2. Parameter for archive:port-to-apigw

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <path>    | <p>Specify the unpacked <code>cloud</code> directory as input:</p> <pre>./apicm archive:port-to-apigw /cloud</pre> <p>By specifying <code>/cloud</code>, <code>apicm</code> ports all artifacts within the directory, including APIs, Products, OAuth providers, custom policies, subscriptions and so on. Running a subsequent <code>archive:push</code> pushes all the artifacts to API Gateway.</p> <p>Running <code>archive:port-to-apigw</code> on any subdirectory within the unpacked <code>/cloud</code> directory could leave the directory in an inconsistent state, and cause the subsequent <code>archive:push</code> of artifacts to API Gateway to fail. Custom policies and OAuth providers are not migrated if a directory other than <code>/cloud</code> is specified.</p> <p>Note: However, if you decide to rewrite one API at a time, to migrate them to API Gateway, you can use:</p> <pre>./apicm archive:port-to-apigw &lt;path&gt;</pre> <p>where <code>&lt;path&gt;</code> is a single API file, or a directory that contains only APIs or Products.</p> <p>In this case, you cannot use <code>archive:push</code> to push artifacts to API Gateway. All the ported APIs and Products must be pushed (or imported) into API Manager by either the toolkit or UI.</p> |

Usage notes:

- The conversion produces a draft output YAML file. Review the entire draft output YAML file for conformance, performance, and errors. Review the log files for messages about any manual actions that might be needed. For more information, see [Reviewing APIs converted to DataPower API Gateway](#).
  - By default, all changes that the migration utility makes when rewriting APIs are logged as comments within the API YAML file. You can use the `enable-api-logging` parameter to disable logging of these changes.
 

```
./apicm archive:port-to-apigw <folder> --enable-api-logging=false
```
  - You can also specify migration configuration parameters using either a YAML configuration file or from the command line, but not both. For information about configuration options and DataPower requirements for certain configuration parameters, see [Configuring migration options for DataPower API Gateway](#).
  - Multiple runs of `./apicm archive:port-to-apigw` on the same `/cloud` folder will skip artifacts that have already been converted to DataPower® API Gateway.
  - If your v10 deployment uses DataPower MultiProtocol Gateway (v5-compatible) you do not need to convert the API definitions.
8. Use `apicm` commands to push the Cloud Manager admin organization data onto your v10 Management Server.
- a. Log in to the Cloud Manager on the destination v10 Management Server as an Owner of the admin organization:

```
./apicm login --server <cloud_manager_endpoint> --realm admin/identity_provider --username admin --password admin_password
```

Important: You must be logged in as an Owner of the admin organization to be able to migrate Cloud Manager admin organization data. See [Table 3](#) to review how to obtain each parameter.

Example commands:

- API Connect v10 standalone

```
./apicm login --server cloud-admin-ui.mgmt.dev.apic10-stack.example.test --realm admin/default-idp-1 --username admin --password 'myadminpassword'
```

Note: If you want to login using an OIDC user registry, see [Logging in to a management server with an OIDC registry](#).

Table 3. `apicm login` command parameters

| Parameters                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>--server &lt;cloud_manager_endpoint&gt;</pre> | <p>The endpoint on the management server for communication with the Cloud Manager user interface.</p> <p>v10 standalone</p> <p>Example:</p> <pre>cloud-admin-ui.mgmt.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the management subsystem was installed. View the <code>apiconnect_api</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory that you created for initial deployment of v10.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>VMware: see the <code>cloud-admin-ui</code> endpoint in <a href="#">Deployment overview for endpoints and certificates</a>.</li> <li>Kubernetes: see the <code>admin</code> endpoint in <a href="#">Deployment overview for endpoints and certificates</a>.</li> </ul> |

| Parameters                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--realm admin/default-idp-1</code> | <p>The <code>apicm login</code> example shows the expected <code>--realm</code> parameter values for a default API Connection administration organization. The default user is <code>admin</code> and the identity provider is <code>default-idp-1</code>.</p> <p>You can determine which identity provider to use in the <code>--realm</code> parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):</p> <pre>apicm identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm</pre> <p>For example:</p> <pre>apicm identity-providers:list --scope admin --server myserver.com --fields title,realm total_results: 2 results: - title: Cloud Manager User Registry   realm: admin/default-idp-1 - title: Corporate LDAP user registry   realm: admin/corporate-ldap</pre> <p>The <code>title</code> value should enable you to determine which identity provider to use; you can then copy the corresponding <code>--realm</code> parameter directly from the displayed <code>realm</code> value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is <code>default-idp-1</code>.</p> |
| <code>--username admin</code>            | Administrative user with permissions to modify API Connect admin-org. The default user is <code>admin</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>--password myadminpassword</code>  | Administrative user password.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

3

Note:

The `apicm login` obtains a token that expires after eight hours. If the token expires while `apicm archive:push` is running, `apicm` generates errors due to lack of the necessary access permissions. In this case, log in again and re-run `apicm archive:push`. The token is refreshed every time you log in. See also [Token expiration](#) in [Migration troubleshooting](#).

- b. Run `/apicm archive:push` to migrate data for the Cloud Manager administrative org (admin-org).

Tip: First run the command with the optional flag `--dry-run` to test for errors or warnings. Review the command parameters, examples and guidance that follow before you run it.

```
./apicm archive:push <cloud_manager_endpoint> <path_to_admin_org> [optional flags]
```

Example:

```
./apicm archive:push cloud-admin-ui.mgmt.dev.apic10-stack.example.test cloud/admin-org
```

Table 4. `apicm archive:push` command

| Parameters                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;cloud_manager_endpoint&gt;</code> | <p>The endpoint on the management server for communication with the Cloud Manager user interface.</p> <p>v10 standalone<br/>Example:</p> <pre>cloud-admin-ui.mgmt.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the management subsystem was installed. View the <code>apiconnect_api</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory that you created for initial deployment of v10.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>VMware: see the <code>cloud-admin-ui</code> endpoint in <a href="#">Deployment overview for endpoints and certificates</a>.</li> <li>Kubernetes: see the <code>admin</code> endpoint in <a href="#">Deployment overview for endpoints and certificates</a>.</li> </ul> |
| <code>&lt;path_to_admin_in_org&gt;</code>   | Must be <code>cloud/admin-org</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>--dry-run</code>                      | <p>You can test the Admin org migration output first view by using the <code>--dry-run</code> option.</p> <pre>./apicm archive:push &lt;cloud_manager_endpoint&gt; &lt;consumer_api_endpoint&gt; &lt;path_to_admin_org&gt; --dry-run</pre> <p>Note: Type the command on a single line.</p> <p>This option creates a project directory similar to <code>cloud</code>, titled <code>.workdir-&lt;apim_admin_server&gt;</code> where you can view how the data will be loaded into your new system. The option also displays the objects that will fail due to existing already or missing dependencies. Use this option to view the resolved URLs for where the data will be loaded, without creating resources on the new system. See <a href="#">apicm command line help</a>.</p>                                    |
| <code>--apigw-only</code>                   | <p>Optional flag. Use when migrating to a DataPower API Gateway. For example:</p> <pre>./apicm archive:push &lt;cloud_manager_endpoint&gt; &lt;path_to_admin_org&gt; --apigw-only</pre> <p>Note: Type the command on a single line.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

Important: Usage notes:

- Run `/apicm archive:push` in the same directory where you ran `apicm archive:unpack`.
- If you run migration and observe error messages in your log output, you can take troubleshooting steps, and run the migration again. See [Migration troubleshooting](#).
- An alternative method of viewing endpoints is to run `kubectl get ingress` and get the values from the output. For example, see the values in **bold** in the following sample output:

|                                        |                                             |         |     |
|----------------------------------------|---------------------------------------------|---------|-----|

9. Migrate the API Manager provider organizations.

- If you have not already done so, create the provider organizations on your API Connect v10 deployment.
- Use `apicm` to log in to the API Manager user interface as an Owner of the provider organization that you want to migrate. If you want to login using an OIDC user registry, see [Logging in to a management server with an OIDC registry](#).

Important: You cannot migrate a provider organization while you are logged in with the Cloud Manager admin organization. You must be logged in as an Owner of the provider organization to be able to migrate that organization's data.

API Connect v10 standalone

```
./apicm login --server <api-manager-ui-endpoint> --realm provider/identity_provider --username org_owner --password org_password
```

Example:

```
./apicm login --server api-manager-ui.dev.apic10-stack.example.test --realm provider/default-idp-2 --username org_owner1@example.com --password myorgpassword
```

Table 5. `apicm login` parameters for logging in to provider orgs on API Connect v10 standalone

| Parameters                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--server &lt;api-manager-ui-endpoint&gt;</code> | API Manager URL endpoint on the management server for communication with the API Manager user interface.<br>For example:<br><code>api-manager-ui.dev.apic10-stack.example.test</code><br><br>The endpoint was specified when the management subsystem was installed. To verify your endpoint setting you can: <ul style="list-style-type: none"> <li>View the <code>apiconnect-apim-ui</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory.</li> <li>In the Cloud Manager UI, select Settings &gt; Endpoints and view <b>API Manager URL</b>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>--realm provider/identity_provider</code>       | The <code>apicm login</code> example shows the expected <code>realm</code> parameter values for a default API Connection provider organization. The default user is <code>provider</code> and the identity provider is <code>default-idp-2</code> .<br>You can determine which identity provider to use in the <code>--realm</code> parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):<br><code>apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm</code><br><br>For example:<br><code>apic identity-providers:list --scope provider --server myserver.com --fields title,realm</code><br>total_results: 2<br>results:<br>- title: Cloud Manager User Registry<br>realm: provider/default-idp-2<br>- title: Corporate LDAP user registry<br>realm: provider/corporate-ldap<br><br>The <code>title</code> value should enable you to determine which identity provider to use; you can then copy the corresponding <code>--realm</code> parameter directly from the displayed <code>realm</code> value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is <code>default-idp-2</code> . |
| <code>--username &lt;org_owner&gt;</code>             | A user with permissions to modify the provider organization. Typically this is the owner of the organization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>--password &lt;org_owner_password&gt;</code>    | Organization owner password.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

- Run `./apicm archive:push` to migrate data for the Provider organization. Review the command parameters, examples and guidance that follow before you run it.

Tip: First run the command with the optional flag `--dry-run` to test for errors or warnings.

```
./apicm archive:push <api-manager-ui-endpoint> cloud/provider-orgs/<pOrg_name> [optional flags]
```

For example:

```
./apicm archive:push api-manager-ui.mgmt.dev.apic10-stack.example.test cloud/provider-orgs/production_Org
```

Table 6. `apicm archive:push` command parameters for Provider orgs

| Parameters | Description |
|------------|-------------|
|------------|-------------|

| Parameters                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;api-manager-ui-endpoint&gt;</code>       | <p>API Connect v10 standalone<br/>API Manager URL endpoint on the management server for communication with the API Manager user interface. For example:</p> <pre>api-manager-ui.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the management subsystem was installed. To verify your endpoint setting you can:</p> <ul style="list-style-type: none"> <li>View the <code>apiconnect_api</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory.</li> <li>In the Cloud Manager UI, select Settings &gt; Endpoints and view <b>API Manager URL</b>.</li> </ul>                                                                                                         |
| <code>cloud/provider-orgs/&lt;pOrg_name&gt;</code> | <p>The location of your Provider org within the <code>/cloud</code> file hierarchy you created when you ran <code>apicm archive:unpack</code>.</p> <pre>cloud/provider-orgs/production_Org</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>--catalogs=&lt;name&gt;</code>               | <p>Optionally, you can push data for only specified Catalogs if you don't want to push the entire Provider organization. Use this flag to specify the name of the Catalog you want to push:</p> <pre>./apicm archive:push &lt;api-manager-ui-endpoint&gt; cloud/provider-orgs/&lt;pOrg_name&gt; --catalogs=&lt;catalog_name&gt;</pre> <p>Note: Type the command on a single line.<br/>When a catalog is mapped, specify the mapped new catalog name.</p> <p>To specify multiple catalogs, use a comma-separated list:</p> <pre>./apicm archive:push &lt;api-manager-ui-endpoint&gt; cloud/provider-orgs/&lt;pOrg_name&gt; --catalogs=catalog_name1,catalog_name2,catalog_name3</pre> <p>Note: Type the command on a single line.</p>                      |
| <code>--dry-run</code>                             | <p>You can test the Provider org migration output first view by using the <code>--dry-run</code> option. This will create a project directory similar to <code>cloud</code>, titled <code>.workdir-&lt;apim_admin_server&gt;</code> where you can view how the data will be loaded into your new system. The option also displays the objects that will fail due to existing already or missing dependencies. Use this option to view the resolved URLs for where the data will be loaded, without creating resources on the new system. See <a href="#">apicm command line help</a>.</p> <pre>./apicm archive:push &lt;api-manager-ui-endpoint&gt; cloud/provider-orgs/&lt;pOrg_name&gt; --dry-run</pre> <p>Note: Type the command on a single line.</p> |
| <code>--no-drafts</code>                           | <p>Do not push any Draft APIs or Products. When this option is not used these artifacts will be skipped.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Important: Usage notes

- Run `/apicm archive:push` in the same directory where you ran `apicm:archive:unpack`.
- If you run migration and observe error messages in your log output, you can take troubleshooting steps, and run the migration again. See [Migration troubleshooting](#).
- An alternative method of viewing endpoints is to run `kubectl get ingress` and get the values from the output. See [kubectl example](#).

10. When migration finishes, complete the following steps:

- If a user in a Local User Registry is owner of a Consumer Organization, the user must reset their password.
- If applicable, reapply any customized configurations from your v5 deployment. See [Customizations to recreate](#).
- Optional: If necessary, switch the provider organization ownership to the identity that owned it in v5.  
This step might be necessary if you created and migrated the provider organization using a different identity (such as administrative account) than the user identity of the v5 provider org. Note that the UI does not provide this function, but you can use the API `/orgs/{org}/transfer-owner` to switch ownership.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Logging in to a management server with an OIDC registry

Logging in with an OIDC registry involves several steps, in which you obtain a temporary token and pass it to the toolkit to ensure it can communicate securely with the management server.

Attention: If you want to log in using a non-OIDC registry, see the login steps in [Migration steps without PDUR](#) or [Migration steps with PDUR](#).

To log in, complete the following steps:

- Enter the following command on the command line:

```
apicm login --server mgmt_endpoint_url --sso
```

where `mgmt_endpoint_url` is the endpoint URL. When you log in with a Cloud admin or Provider organization, specify one of the following URLs:

- platform API endpoint URL

- management API manager URL

These endpoint URLs are configured during the installation of API Connect, as described in [Installing the Management subsystem into a Kubernetes environment](#) and [Deploying the Management subsystem in a VMware environment](#). If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in [Viewing platform and UI endpoints](#), ignoring any segments at the end of the displayed URLs. If you are not sure of the endpoint URL, ask your administrator.

2. When the toolkit prompts for the context, type `provider`:

```
Context? provider
```

3. The server responds with the following message:

```
Please copy and paste the url https://mgmt_endpoint_url/auth/manager/sign-in/?from=TOOLKIT to a browser to start the authentication process.
Do you want to open the url in default browser? [y/n]: y
```

Take one of the following actions:

- If you want to use your default browser to log in to API Manager, type `y` and press Enter. The API Manager sign-in page opens in a new browser tab.
  - If you don't use to use your default browser, type `n` and press Enter.
    - Copy the URL from the command window.
    - Open a browser, paste the URL, and press Enter. The API Manager sign-in page displays.
4. On the API Manager sign-in page, select the OIDC registry and then log in to API Connect. After you log in, API Connect displays the "You are authenticated!" message and provides a temporary token. Copy the token.
  5. Return to the command window. Paste the token at the `API Key?` prompt and press Enter.

When the token is validated and you are successfully logged in to the toolkit, the following message displays:

```
Logged into mgmt_endpoint_url successfully
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Converting APIs to DataPower API Gateway

You can convert API Connect v5-compatible APIs to v10 DataPower® API Gateway.

### Before you begin

Use the migration utility command `apicm archive:port-to-apigw` to convert v5-compatible APIs to DataPower API Gateway. For instructions on installing the migration utility, see [Installing the migration utility](#).

You can convert your API definitions as part of the migration workflow, or as a separate task. Use these instructions to convert YAML source files separately. For instructions on converting APIs during migration, see [Migration steps without PDUR](#).

The following steps are required before converting v5-compatible APIs to DataPower API Gateway. For detailed instructions on all of these tasks, see [Migration steps without PDUR](#).

- Download the latest IBM API Connect® Migration Utility (AMU) from [IBM® Fix Central](#). The migration utility requires Installer Version 5.0.0 or later. However, if you intend to use it to convert APIs, use Installer Version 7.0.1 or later.
- Ensure that the AMU version that you are using is supported by your versions of DataPower API Gateway and API Connect. For more information, see [Configuring migration options for DataPower API Gateway](#).
- Converting APIs using the migration utility requires Node version 14.21.3. Ensure that you have that version installed.
- Run `archive:unpack` to unpack the V5 dbextract into v5-compatible artifacts.
- Map v5 object names to v10 object names. If the names are preserved exactly between the v5 and v10 environments, this step can be skipped. The gateway service must be mapped to a DataPower API Gateway. For more information, see [Migration mapping files](#).

For information about the differences between gateway types available in API Connect, see [API Connect gateway types](#).

### About this task

The migration utility command `apicm archive:port-to-apigw` provides assistance in converting v5-compatible APIs to DataPower API Gateway, rather than full migration. It generates an output API that is supported on API Gateway v10.

The conversion process annotates the YAML file and logs with information regarding the artifacts that it attempts to convert. For cases where additional information is available or further action is required, the YAML input file and logs contain links to documentation.

Because of differences between the programming models of v5-compatible APIs and DataPower API Gateway APIs, the command might not be able to convert all items. You might need to port these items to the API Gateway. In these cases, messages generated by the `apicm archive:port-to-apigw` command provide links to documentation that provides more details about changes you must make for these items to be compatible with DataPower API Gateway.

## Procedure

Run the conversion command from the directory where you downloaded the utility.  
Command syntax:

```
./apicm archive:port-to-apigw path
```

The path is the full path to the YAML file or directory. You can specify to convert a single YAML file or the contents of an entire directory.

The migration utility produces an output YAML file with the results of the conversion process.

## What to do next

Review the output YAML file and make any necessary changes to ensure that your APIs are compatible with DataPower API Gateway. For more information, see [Reviewing APIs converted to DataPower API Gateway](#).

Push the converted YAML files to the v10 deployment. For details, see [Migration steps without PDUR](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Configuring migration options for DataPower API Gateway

If you are converting APIs to DataPower API Gateway, you can accept the default migration configuration or specify configuration parameters.

You can specify migration configuration parameters using either a YAML configuration file or from the command line, but not both. The `config.yml` file must be located in the same directory as the migration utility. Use of this file is specified when the migration utility is invoked using the `apicm` command with the `port-to-apigw` option, as in the following example.

```
./apicm archive:port-to-apigw <path> --use-config-file=true
```

If use of the configuration file is not specified, the migration utility uses parameters specified on the command line. If no parameters are specified, then the default parameters are used.

Some of these `port-to-apigw` configuration parameters depend upon a specific DataPower implementation to function. See the information in the following table to ensure that you have the correct version of DataPower for the parameters you want to use.

Table 1. Migration configuration options

| Parameter                              | Valid values                                                                                                        | DataPower version required                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>use-config-file</b>                | <b>true / false</b><br>The default value is <b>false</b> .                                                                 | 10.0.0.0+                                                                                          | Use the <b>config.yml</b> file that is in the same directory as the <b>apicm</b> binary file that is being executed. If this file is used, configuration options cannot be set using the command line. The purpose of the config file is to specify the command inputs given on this page, but in an easy-to-read file format (YAML).                                                                                                                                                                                                                                                                       |
| <b>v5-request-headers</b>             | <b>true / false</b><br>The default value is <b>true</b> .                                                                  | 10.0.1.2+,<br>10.0.2.0+                                                                            | When set to <b>true</b> , the following v5-compatible request headers are set: <b>Via</b> , <b>X-Global-Transaction-ID</b> , <b>X-Client-IP</b> . When set to <b>false</b> , these request headers are not set.                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>validate-username-token-policy</b> | <b>validate-username-token_1.0.0</b><br>The default value is empty.                                                        | 10.0.1.3+,<br>10.0.2.0+                                                                            | Defines whether or not to use the <b>validate-username-token</b> v5 emulation policy when the migration utility rewrites the API assembly. When empty, the migration utility takes no action on the policy.                                                                                                                                                                                                                                                                                                                                                                                                 |

| Parameter                | Valid values                                                                                                                           | DataPower version required | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>xslt-policy</code> | One of the following values:<br><code>xslt_1.0.0</code> ,<br><code>xslt_2.0.0</code><br>The default value is <code>xslt_1.0.0</code> . | 10.0.0.0+                  | Defines which gatewayscript policy the migration utility uses when rewriting the API assembly.<br><br><code>xslt_1.0.0</code> : A user-defined policy created by the migration utility. This policy uses the v5 MPGW processing rule. Use <code>xslt_1.0.0</code> if the xslt policy is dependent on v5 MPGW capabilities, such as load balancer groups or XML Manager settings.<br><br><code>xslt_2.0.0</code> : The migration utility rewrites the existing API to xslt 2.0.0. Specifying <code>xslt_2.0.0</code> can cause migration errors or run-time errors. Use <code>xslt_2.0.0</code> if you are able to review and verify all changes made by the migration utility in the API YAML file. |

## Example migration configurations

The following examples show configuration options using the `config.yml` file or the `apicm` command.

- The following example uses the `config.yml` file to specify the migration configuration.

```

custom-policies-scope: global
emulate-v4-plan-rate-limit: false
deploy-policies:
- proxy_1.5.0
- redact_1.5.0
- invoke_1.5.0
- xslt_2.0.0
- gatewayscript_1.0.0
- switch_2.0.0
rewrite-apis:
 enable-api-logging: false
 proxy-policy: proxy_1.5.0
 redact-policy: redact_1.5.0
 invoke-policy: invoke_1.5.0
 xslt-policy: xslt_2.0.0
 gatewayscript-policy: gatewayscript_1.0.0
 if-policy: switch_2.0.0
 switch-policy: switch_2.0.0
 optimize-gws: false
 no-retitle: true

```

Use the `use-config-file` parameter when running the `apicm` command to specify that the `config.yml` file is used for migration configuration values.

```
./apicm archive:port-to-apigw <path> --use-config-file=true
```

- The following example uses the `apicm` command to specify the same settings as in the previous example.

```

./apicm archive:port-to-apigw <path> --custom-policies-scope: global --emulate-v4-plan-rate-limit: false --deploy-policies="proxy_1.5.0,redact_1.5.0,invoke_1.5.0,xslt_2.0.0,gatewayscript_1.0.0,switch_2.0.0" --enable-api-logging=false --proxy-policy="proxy_1.5.0" --redact-policy="redact_1.5.0" --invoke-policy="invoke_1.5.0" --xslt-policy="xslt_2.0.0" --gatewayscript-policy="gatewayscript_1.0.0" --if-policy="switch_2.0.0" --switch-policy="switch_2.0.0" --optimize-gws=true --no-retitle=true

```

- The following example uses the `apicm` command to specify that the default migration configuration values are used.

```
./apicm archive:port-to-apigw <path>
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

## Reviewing APIs converted to DataPower API Gateway

The migration utility command `apicm archive:port-to-apigw`, which assists in the conversion of v5 APIs for use with the v10 DataPower® API Gateway, provides draft output YAML files containing the results of the conversion process.

### Procedure

- Review the entire output YAML files for conformance, performance, and errors.  
The conversion process annotates the YAML file and logs with information regarding the artifacts that are converted. For cases where additional information is available or further action is required, the YAML file and logs contain links to documentation.
- Make any necessary changes to port APIs to DataPower API Gateway.
  - [Messages generated during conversion of APIs to DataPower API Gateway](#)  
Reference information about the messages generated by the migration utility command `apicm archive:port-to-apigw`.
  - [Parse actions added to the API assembly after migration](#)  
The migration utility command `apicm archive:port-to-apigw` adds parse actions to the API assembly depending on the policies specified in your migration configuration.
  - [Fine-tuning APIs after migration](#)  
After running the migration utility command `apicm archive:port-to-apigw`, review the converted APIs to determine if any of the changes made by the migration utility can be modified to enhance performance and usability.

- [Frequently asked questions about migrating to API Gateway](#)  
Answers to some of the most frequently asked questions about migrating APIs to API Gateway.

**ACT01** Converted ``activity-log`` policy to API Gateway ``activity-log`` policy.

### Explanation

An `activity-log` policy was found. The API Gateway activity log is not a policy and is provided in the base API configuration.

### Response

Review the activity log configuration to ensure that the activity logging is consistent with the v5 API.

### Severity

info

**ACT02** Removed ``title`` property from ``activity-log`` policy to conform to the API Gateway specification.

### Explanation

An `activity-log` policy was found. The API Gateway activity log is not a policy and is provided in the base API configuration.

**Response**

Review the activity log configuration to ensure that the activity logging is consistent with the v5 API.

**Severity**

info

**ACT03 Removed `version` property from `activity-log` policy to conform to the API Gateway specification.**

**Explanation**

An `activity-log` policy was found. The API Gateway activity log is not a policy and is provided in the base API configuration.

**Response**

Review the activity log configuration to ensure that the activity logging is consistent with the v5 API.

**Severity**

info

**ACT04 More than one `activity-log` policy was found. Only the first `activity-log` policy found will be used.**

**Explanation**

The API Gateway activity log is provided in the API configuration, but it is not a policy. Some v5 APIs might have used multiple policies to conditionally specify the analytics logging in the API, but this is not supported in the API Gateway. This message will be output for each additional `activity-log` policy found in the YAML input file.

**Response**

Review the v5 API to ensure that the desired activity log configuration will be used.

**Severity**

error

**ACT08 Removed `description` property from `activity-log` policy to conform to the API Gateway specification.**

**Explanation**

See message text.

**Severity**

info

**API01 The specified API YAML input file is of gateway type `datapower-api-gateway`. This utility accepts only v5-compatible APIs of gateway type `datapower-gateway`.**

**Explanation**

The input API YAML file must be of gateway type `datapower-gateway`. If the gateway type is `datapower-api-gateway`, the API does not need to be converted. Any other gateway type is not supported.

**Response**

Review your input file to confirm that it is v5 compatible.

**Severity**

error

**API02 Input API policy is already version 2.0.0. This version is reserved for API Gateway policies only. Skipping conversion of this policy.**

**Explanation**

The input API YAML file must be of gateway type `datapower-gateway`. Every policy within that API must be version 1.0.0. Version 2.0.0 policies are reserved for the API Gateway, which should be included only in APIs with gateway type `datapower-api-gateway`. No conversion is performed for this policy.

**Severity**

error

**API03 Suffix `%s` appended to API `title` and `x-ibm-name`.**

**Explanation**

As the v5 and API Gateway policy can reside in the same API Manager, a suffix can be provided to ensure a unique name of the API Gateway version of the v5 API.

**Response**

Consider incrementing the API version to accommodate converting to the API Gateway.

**Severity**

info

**API04 Added missing `/` to the front of the basepath.**

**Explanation**

A v5 API with a `basepath` property value that does not start with a `/` will have the character `/` added at the beginning of the `basepath` property of the API Gateway.

**Severity**

info

**API05 Trailing slashes (`/`) removed from the `basepath` to conform to the API Gateway specification.****Explanation**

A v5 API with a `basepath` property value that is not a `/` but ends with the `/` character will have the ending `/` character removed in the `basepath` property of the API Gateway.

**Response**

Calls to the API might need to be updated to conform to the new `basepath`.

**Severity**

warn

**API06 Changed gateway type to `datapower-api-gateway`.****Explanation**

See message text.

**Severity**

info

**API07 Moved `assembly request` into `assembly execute`.****Explanation**

Older v5 APIs might include the `execute` property within an `assembly request` property. This `execute` property is moved to the API Gateway `assembly` property.

**Severity**

info

**API08 Moved `assembly implementation` into `assembly execute`.****Explanation**

Older v5 APIs might include the `execute` property within an `assembly implementation` property. This `execute` property is moved to the API Gateway `assembly` property.

**Severity**

info

**API09 Moved `assembly response` into `assembly execute`.****Explanation**

Older v5 APIs might have the `execute` property within an `assembly response` property. This `execute` property is moved to the API Gateway `assembly` property.

**Severity**

info

**API10 Removed `x-ibm-gateway-invoke-v4-nomap-emulation` API property and replaced it with a `gatewayscript` policy to conform to the API Gateway specification.****Explanation**

This v5 API property applies only to the `invoke` policy. In API Gateway, this property has been replaced by a `gatewayscript` policy that will modify the `invoke` policy response in a similar fashion.

**Severity**

warn

**API11 The API property `x-ibm-gateway-sourcecode-resolve-apic-variables` does not exist in the API Gateway. The property has been removed from the YAML file.****Explanation**

This v5 API property is not supported by the API gateway and has been removed. If the `x-ibm-gateway-map-resolve-apic-variables` property is not set, then the original value of this property will be set into the map option `mapResolveApicVariables` automatically.

### Severity

error

**API12 The API property `x-ibm-gateway-reencode-request-params-slash` does not exist in the API Gateway. The property has been removed from the YAML file.**

### Explanation

This v5 API property only applies to the `invoke` and `proxy` policies. In the API Gateway, the functionality of this property has been implemented as an option in the `invoke` policy.

This change was made for the following reasons.

- The option is now clearly visible in the `invoke` policy, making it easy to identify available options.
- Each use of the `invoke` policy can now have a different setting.

### Severity

error

**API13 The API property `x-ibm-gateway-framework-legacy-json-encoding` does not exist in the API Gateway. The property has been removed from the YAML file.**

### Explanation

This v5 API property is not supported by the API gateway and has been removed. If the value of the `x-ibm-gateway-framework-legacy-json-encoding` property is present, it will be used by the migration utility when migrating `xslt`, `gatewayscript`, and `map` policy source code to produce the same result as v5 would have produced based upon the property value.

### Severity

error

**API14 Converted v5-compatible policies to the API Gateway and updated policy versions to 2.0.0.**

### Explanation

See message text.

### Severity

info

**API15 The `x-ibm-gateway-api-enforce-response-limits` API property is enabled. Appended `parse` policy to the end of the assembly to parse the JSON response.**

### Explanation

The v5 API property `x-ibm-gateway-api-enforce-response-limits` ensures that a JSON response payload is within the defined JSON parser limits. This functionality is emulated in API Gateway by adding a `parse` policy at the end of the assembly.

### Severity

info

**API16 Removed the `x-ibm-gateway-api-enforce-response-limits` API property and replaced it with a `parse` policy to conform to the API Gateway specification.**

### Explanation

The v5 API property `x-ibm-gateway-api-enforce-response-limits` ensures that a JSON response payload is within the defined JSON parser limits. This functionality is emulated in API Gateway by replacing it with a `parse` policy.

### Severity

info

**API17 Setting `x-ibm-soap` to `%s`.**

### Explanation

The v5 API path does not have a `x-ibm-soap` property with a `soap-action` child property, but the schema referenced by this path is for a SOAP document. The `x-ibm-soap` property is added with a child property of `soap-action` into this path of the API gateway. The `soap-action` property will be determined from the schema encountered.

### Severity

info

**API18 This `set-variable` policy is used to add the client identification header to the message headers for use by a subsequent `invoke` policy.**

### Explanation

Typically, the client identification header as defined by the security definition is `x-IBM-Client-Id`. This header will be removed from the message headers at the start of the API. A `set-variable` policy will add this header back into the message headers, as the v5 API specifies not to suppress this header from being sent by subsequent `invoke` policies.

### Severity

info

**API19 Skipping appending of a `parse` policy for the `x-ibm-gateway-api-enforce-response-limits` API property, as this `parse` policy already exists at the end of the assembly and contains the same `input` and `output` values.**

### Explanation

See message text.

### Severity

info

**API20 Added `parse` policy to the beginning of the assembly to parse incoming data.**

### Explanation

The v5-compatible implementation implicitly parses messages. However, by requiring explicit parsing for every assembly wherever parsing is required, the API Gateway provides greater control over when and how parsing is performed.

The `parse` policy is added in API Gateway for the following purposes.

- To explicitly control when parsing occurs.
- To determine which threat protection settings to apply to a parse.
- To determine which kinds of output to allow.
- To determine how to gather metadata from the parse.

By separating the parsing time from the processing time of the assembly, explicit parsing can also enhance performance.

API Gateway has no implicit parsing. The assembly must explicitly parse when parsing is desired, which ensures that the correct limits and input checks are done.

### Response

You should retain the added `parse` policy for any of the following reasons.

- You need non-well-formed XML or JSON documents to abort and call the `catch`.
- The data is still streaming and you need to keep a copy of the data for various reasons.
- You need to use the payload data with another policy.

If you do not need the `parse` policy, remove it. If you retain the `parse` policy, consider the following questions.

- Which threat protection settings do you want to enforce with this `parse` policy?
- Does the use of this `parse` policy remove the need for an additional `parse` policy?
- Do you want to use the metadata from the parse, such as document size and complexity?

### Severity

info

**API21 Moved catalog specific `x-ibm-gateway-\*` API Property: `%s` under catalog: `%s` to API level for further processing.**

### Explanation

`x-ibm-gateway` catalog-level properties are not supported in API Gateway. The properties have been moved to the top-level properties section in the API for further processing by the migration utility.

### Severity

info

**API22 Skipped adding `parse` policy since an adjacent parse of the same properties was already added.**

### Explanation

The `invoke` policy might add a `parse` policy next to it in the assembly. If this `parse` policy is detected, another parse is not added because it would result in duplicate parses in the assembly. This prevention of duplicate parses applies only if both parses are found to have the same properties.

### Severity

info

**API23 Removed redundant `parse` policy from end of the assembly.**

### Explanation

The tool added a duplicate `parse` policy to the end of the assembly. The duplicate policy has been removed as it performs the same action as another `parse` policy in the assembly.

### Severity

info

### API24 Removed redundant `parse` policy from the beginning of the assembly.

### Explanation

The tool added a duplicate `parse` policy to the beginning of the assembly. The duplicate policy has been removed as it performs the same action as another `parse` policy in the assembly.

### Severity

info

### API25 Removed unsupported `name` property from the Swagger info property.

### Explanation

An empty `name` property under the `info` property is not supported in API Gateway. If an API is published with an empty `name` property, an error is generated. Therefore, the migration utility removes the empty `name` property if it is found.

### Severity

info

### API26 Removed empty `description` property from the Swagger info property.

### Explanation

An empty `description` property is not supported in API Gateway. If an API is published with an empty `description` property, an error is generated. Therefore, the migration utility removes the empty `description` property if it is found.

### Severity

info

### API27 Removed empty `security` property from the Swagger file.

### Explanation

An empty object `security` property is not supported in API Gateway. If an API is published with an empty object `security` property, an error is generated. Therefore, the migration utility removes the empty object `security` property if it is found.

### Severity

info

### API28 Moved `%s` from API properties to this policy option `%s` and set to [%s].

### Explanation

In the API Gateway, the functionality of this property has been implemented as a policy option.

### Severity

info

### API29 Preserved API Property `%s` in YAML.

### Explanation

The API property was preserved because there is a 1.0.0 or 1.5.0 policy that requires it.

### Severity

info

### API30 Removed API Property `%s` from YAML.

### Explanation

This property is obsolete and has been removed from the YAML file.

### Severity

info

**API31 The API property `x-ibm-gateway-custom-policy-with-gws-action` does not exist in the API Gateway. The property has been removed from the YAML file.**

**Explanation**

In v10, this property is not required to control the behavior of a custom policy that includes a GatewayScript action, as both `true` and `false` scenarios are handled as expected.

**Severity**

error

**API32 The `\$ref %s` was not found in the swagger.**

**Explanation**

A `$ref` could not be dereferenced because the reference content was not found in the v5 YAML.

**Response**

Review the v5 file to confirm that the `$ref` references are valid and exist in the YAML.

**Severity**

warn

**API33 Found usage of inline parameters: `%s` in `%s` policy.**

**Explanation**

API Gateway does not support inline parameters in the GatewayScript 2.0.0 or XSLT 2.0.0 policies.

**Response**

Modify the policy to use context variables instead of inline parameters. The following tables show examples of inline parameters in v5 and how they can be rewritten to use context variables in API Gateway.

Table 1. GatewayScript 2.0.0 examples

| v5                                                                     | API Gateway                                                 |
|------------------------------------------------------------------------|-------------------------------------------------------------|
| If <code>test.data</code> is a variable:<br><code>\$(test.data)</code> | <code>context.get('test.data');</code>                      |
| If <code>test.body</code> is a message:<br><code>\$(test.body)</code>  | <code>context.getMessage('test').body;</code>               |
| <code>{test.example}</code>                                            | <code>context.get('request.parameters.test.example')</code> |

For more GatewayScript 2.0.0 examples, see [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.](#)

Table 2. XSLT 2.0.0 example

| v5                                          | API Gateway                                                                                                             |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>\$(request.parameters.example)</code> | <code>apigw:get-variable('request.parameters.example')</code><br>Note: Be sure to use the <code>apigw</code> namespace. |
| <code>{example}</code>                      | <code>apigw:get-variable('request.parameters.example')</code>                                                           |

For more XSLT 2.0.0 examples, see [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.](#)

**Severity**

error

**API34 Found `x-ibm-gateway-\*` catalog specific property: `%s` under catalog section: `%s`, within an unpublished API.**

**Explanation**

The API was most likely found under the drafts folder of an organization. Because it is not published to a specific catalog, the migration utility cannot determine which API to apply the properties to.

**Response**

Apply the `x-ibm-gateway-*` properties to the policies of the assembly manually before publishing.

**Severity**

info

**API35 Found `x-ibm-gateway-\*` catalog specific property: `%s` under catalog section: `%s`. This API is published under catalog: `%s`**

**Explanation**

The API is published to a specific catalog, and other catalog-specific `x-ibm-gateway-*` properties were found under other catalogs.

**Response**

If you want to move this API to other catalogs, apply these properties manually to the policies in the assembly.

### Severity

info

**API36 `x-ibm-gateway-\*` API Property: `%s` found to have invalid value: `%s`.**

### Explanation

See message text.

### Response

Check the API to ensure that the API property has the correct value. For more information on the API property, see the appropriate section of the IBM API Connect Knowledge Center.

### Severity

error

**API37 JSON Schema contains an invalid reference.**

### Explanation

See message text.

### Response

Confirm that your schema definitions are valid. If you find errors, fix them.

### Severity

info

**API38 XSD generation ignoring references beyond limit set by property.**

### Explanation

XSD generation from JSON schema uses the `x-ibm-gateway-schema-definition-reference-limit` property value to determine how many recursions to go in circular references.

### Response

### Severity

info

**API39 An error occurred while generating the XSD for `%s` definition.**

### Explanation

See message text.

### Response

Confirm that your JSON schema is valid before continuing.

### Severity

warn

**API40 Skipping JSON Schema definition: `%s` with multiple roots or not intended for XML data.**

### Explanation

See message text.

### Severity

info

**API41 Set `chunked-uploads` value to `false` to emulate v5 behavior.**

### Explanation

For information about the Allow chunked uploads property in the Invoke policy, see [Invoke](#).

### Severity

info

**API42 Input option `chunked-uploads` set to `true`, which is the API Gateway `chunked-uploads` default. All invoke and proxy 1.5.0 and 2.0.0 policies will use this default value.**

**Explanation**

For information about the Allow chunked uploads property in the Invoke policy, see [Invoke](#).

**Severity**

info

**API43 Created `compatibility:` section for API-wide toggles set by migration utility.**

**Explanation**

The migration utility generates a compatibility section that allows DataPower to read in custom settings to for compatibility between v5 and API Gateway.

**Severity**

info

**API44 Set compatibility toggle `%s` to value: `%s`.**

**Explanation**

See message text.

**Severity**

info

**API45 Compatibility toggle: `%s` set to value: `%s`, which is the same as the API Gateway default.**

**Explanation**

The migration utility input specified to set a compatibility toggle to a value that is already the default. Therefore, no change was made in the API as the default will automatically be used.

**Severity**

info

**API46 Updated `securityDefinition`: `%s` with new name: `%s` as specified in toggle input: `%s`.**

**Explanation**

See message text.

**Severity**

info

**API47 `application-authentication` was found to be set, adding `application-authentication-source` and `custom-header-name` defaults.**

**Explanation**

In v5, `application-authentication-source` does not exist. In API Gateway, it is a new option that must be set if authentication is set. Therefore, the migration utility automatically sets `application-authentication-source` to its most-compatible default, and as a result also sets `custom-header-name`. If `application-authentication` is not set in the v5 API, the migration utility does not set `application-authentication-source` and `custom-header-name`.

**Severity**

info

**API48 `%s` found in API definition `%s`, changing the value to a string null.**

**Explanation**

See message text.

**Severity**

info

**API49 Changed `\$(request.body\*)` to `\$(request.parsed\_body\*)` in: `%s` to use parsed copy of data.**

**Explanation**

In the API Gateway, the `request.body` context is never parsed and cannot be evaluated. The parse policy added to the beginning of the assembly automatically copies `request.body` into `request.parsed_body` and parses that copy. The reference to `request.body` has been changed to use this new context.

**Severity**

warn

**API51 Added missing path parameter definition for path ` %s ` operation ` %s ` parameter ` %s `.**

**Explanation**

See message text.

**Severity**

info

**API52 Added missing path parameter reference for path ` %s ` operation ` %s ` parameter ` %s `.**

**Explanation**

See message text.

**Severity**

info

**API53 A path parameter reference ` %s ` is not a path parameter.**

**Explanation**

See message text.

**Severity**

warn

**API54 A parameter reference ` %s ` is not defined.**

**Explanation**

See message text.

**Severity**

warn

**API55 Definition: %s is missing property 'Body' or 'properties', this is an invalid SOAP definition.**

**Explanation**

The structure of the SOAP definition is invalid. For example, if the definition contains a SOAP fault that is not within the SOAP body, then the definition is invalid.

**Severity**

error

**API56 Catalog specific API Property found without a corresponding default property: %s for catalog: %s, created empty string default property at the API level.**

**Explanation**

See message text.

**Severity**

info

**API57 Definition reference: %s is incorrect, and should be of form '#/definitions/foo'**

**Explanation**

See message text.

**Response**

For example, the following reference is invalid:

```
moreDetails:
 $ref: '#definitions/MoreDetails'
```

To make this a valid reference, use the following form:

```
moreDetails:
 $ref: '#/definitions/MoreDetails'
```

**Severity**

warn

**API58** `securityDefinition` property encountered without a `security` property. An empty `security` property is added.

**Explanation**

See message text.

**Severity**

info

**API59** The missing referenced definition `%s` was added to the swagger.

**Explanation**

See message text.

**Severity**

info

**API60** The API property name `%s` is invalid and has been removed from the swagger.

**Explanation**

API properties with an invalid characters such as \$ and parentheses are ignored.

**Severity**

info

**API61** Set buffering property to true.

**Explanation**

APIs will always have buffering enabled, as v5 did not support streaming.

**Severity**

info

**API62** A query based security definition `%s` was present. A new security definition `%s` was created to match implicit v5 behavior.

**Explanation**

The security definitions in v5 for an API key that was specified as a query parameter were configured using the key names `client_id` and `client_secret`. However, this behavior implicitly provided the ability to also use query parameters `app_id` and `app_secret`. The specification of `app_id` and `app_secret` must be done explicitly in v10.

**Severity**

info

**API63** A security set was created with security definition references `%s` to match implicit v5 behavior.

**Explanation**

The security definitions in v5 for an API key that was specified as a query parameter were configured using the key names `client_id` and `client_secret`. However, this behavior implicitly provided the ability to also use query parameters `app_id` and `app_secret`. The specification of `app_id` and `app_secret` must be done explicitly in v10.

**Severity**

info

**API64** Suffix %s appended to API `x-ibm-name`.

**Explanation**

See message text.

**Severity**

info

**API65** The referenced definition %s was changed to %s.

**Explanation**

The referenced definition contained a / character in the name and was not defined in the API. The / character has been removed to allow the API to publish during `archive:push`.

### Severity

info

**API66 Security has been removed as there are no associated security definitions.**

### Explanation

The API security is extraneous without associated security definitions.

### Severity

info

**API67 The API property `x-ibm-gateway-framework-preserve-escaped-reverse-solidus` does not exist in the API Gateway. The property has been removed from the YAML file.**

### Explanation

This v5 API property is not supported by the API gateway and has been removed. If the `x-ibm-gateway-framework-preserve-escaped-reverse-solidus` API property is present with a `true` value, it will be used by the migration utility when migrating `xslt`, `gatewayscript`, and `map` policy source code to produce the same result as v5 would have produced.

**GWS02 This `gatewayscript` policy was added before the newly converted `switch` policy in the assembly to assist with the condition logic.**

#### Explanation

A conditional policy from a v5 API is converted to a `switch` policy in the API Gateway. The v5 API uses GatewayScript for the `if` and `switch` policies, whereas the API Gateway condition syntax is JSONata based. These conditions have been moved into a `gatewayscript` policy that will execute immediately before the `switch` policy. The switch conditions will use results from the `gatewayscript` policy to execute the correct assembly path.

#### Response

Review the changes to ensure that the `switch` policy result will be consistent with the v5 API.

#### Severity

info

**GWS04 Found `gatewayscript` policy. Porting might be required.**

#### Explanation

Review the `gatewayscript` policy and make any necessary changes. The following list includes examples of some of the differences between `gatewayscript` code in v5-compatible APIs and API Gateway.

- Calls that reference the `request.parameters` context variable in v5-compatible APIs might not produce the same results in API Gateway. For example, consider the following call in a v5-compatible API.

```
apim.getvariable('request.parameters.org_name')
```

This call is not equivalent to the following call in an API Gateway API.

```
context.get('request.parameters.org_name')
```

The `context.get()` call in API Gateway supports multiple occurrences of the same parameter variable. Therefore, it returns structured JSON for retrieving parameters, as in the following example return.

```
{"locations":["query"],"values":["sandbox-test-org"]}
```

For this example, the `apim.getvariable` call should be changed to the following call in API Gateway.

```
((context.get('request.parameters.org_name') || {}).values || []).slice(-1)[0]
```

- Access to `header-metadata` is not supported in API Gateway. In some cases, the call can be edited to conform to the API Gateway specification. For example, the call `hm.current.remove("Accept-Encoding")`; can be replaced in API Gateway with `context.message.header.remove("message.headers.Accept-Encoding")` or `context.clear("message.headers.Accept-Encoding")`. However, if you are using `header-metadata` to set the response message header before the `proxy` policy, you must add a `gatewayscript` policy after the `invoke` policy to set the header on the response message.
- In v5 and in v10 API Gateway, `apim.getvariable()` returns an XML node set if an XML node set was set in the variable being retrieved. In v10 API Gateway, `context.get()` always returns an XML document, even if an xml node set was set in the variable. The API may require modification to work properly.
- In both v5 and v10 API Gateway, using the `apim.getvariable()` function on XML data returns an XML NodeList object. In v10 API Gateway, using the `context.get()` function on XML data returns an XML document. Consider this change before switching to `context.get()` using the `optimize-gws` migration configuration option, as API behavior may change as a result.

#### Severity

warn

### GWS05 Added `require('apim')` function to `gatewayscript` policy to conform to the API Gateway specification.

#### Explanation

See message text.

#### Response

Review the changes to ensure that the `gatewayscript` policy result will be consistent with the v5 API.

#### Severity

info

### GWS06 Found `require('header-metadata');` in the `gatewayscript` source.

#### Explanation

The `header-metadata` module is not supported in the API Gateway. All API context variables in the API Gateway are in the global context module. You can access the context variables directly using `context.set()` or `context.get()`.

For more information about using context variables in `gatewayscript` policies in API Gateway, see [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#).

#### Response

For better performance, either use the `--optimize-gws=true` toggle when running the migration utility, or use the context module for native API Gateway performance. For more information about `header-metadata`, see [Access to the headers object](#) in the IBM DataPower Gateways documentation.

#### Severity

info

### GWS07 Replaced `require('local:///isp/policy/apim.custom.js')` with `require('apim')` to conform to the API Gateway specification.

#### Explanation

The v5 `gatewayscript` compatibility module does not exist on the local file system in the API Gateway. The `require` function for this module was present in the `gatewayscript` code and has been changed for API Gateway compatibility.

#### Severity

info

### GWS08 Empty source `gatewayscript` found.

#### Explanation

See message text.

#### Response

Consider updating the empty `gatewayscript` policy or remove it from the assembly for better performance.

**Severity**

warn

**GWS09 Found `require('fs')` in the `gatewayscript` source.**

**Explanation**

The `fs` module is supported in the API Gateway. Some API Gateway configuration folders have restricted access.

**Severity**

info

**GWS10 Found `require('service-metadata')` in the `gatewayscript` source.**

**Explanation**

See message text.

**Response**

The Gatewayscript examples in the following table show how the service variables map to API Gateway metric functions. To obtain the metric data, use the `getMetricData()` API of the `context.metric` object in DataPower API Gateway, as in the following example.

```
var md = context.metric.getMetricData();
```

For more information about the `context.metric` object, see [context.metric object for API Gateway services](#) in the IBM DataPower Gateways documentation.

| v5 MPGW service variable                                         | Gatewayscript example                                                               | Description                                                |
|------------------------------------------------------------------|-------------------------------------------------------------------------------------|------------------------------------------------------------|
| <code>dp:variable('var://service/time-response-complete')</code> | <code>md.filter(n =&gt; n.type === 'assembly-invoke').slice(-1).endTime</code>      | The end time of the last assembly-invoke metric data.      |
| <code>dp:variable('var://service/time-elapsed')</code>           | <code>md.slice(-1).endTime</code>                                                   | The end time of the last element in the metric data array. |
| <code>dp:variable('var://service/time-forwarded')</code>         | <code>md.filter(n =&gt; n.type === 'assembly-invoke').slice(-1).requestTime</code>  | The request time of the last assembly-invoke metric data.  |
| <code>dp:variable('var://service/URL-out')</code>                | <code>md.filter(n =&gt; n.type === 'assembly-invoke').slice(-1).targetURL</code>    | The target URL of the last assembly-invoke metric data.    |
| <code>dp:variable('var://service/mpgw/request-size')</code>      | <code>md.filter(n =&gt; n.type === 'assembly-invoke').slice(-1).requestSize</code>  | The request size of the last assembly-invoke metric data.  |
| <code>dp:variable('var://service/mpgw/response-size')</code>     | <code>md.filter(n =&gt; n.type === 'assembly-invoke').slice(-1).responseSize</code> | The response size of the last assembly-invoke metric data. |

**Severity**

info

**GWS11 Found `require('mgmt')` in the `gatewayscript` source.**

**Explanation**

The `mgmt` module is not supported in the API Gateway.

**Response**

Remove use of the `mgmt` module from the source code.

**Severity**

error

**GWS12 Found `require('policy/policy-utility')` or `require('policy/policy-utility.js')` in the `gatewayscript` source.**

**Explanation**

`policy-utility` is a DataPower module that is not supported in the API Gateway.

**Response**

Remove use of the `policy-utility` module from the source code.

**Severity**

error

**GWS18 Found `gatewayscript` containing session function: `%s` and replaced with API Gateway native `%s`**

**Explanation**

See message text.

**Severity**

info

**GWS19 Invalid `gatewayscript` found. The gateway script could not be parsed due to `%s`**

**Explanation**

See message text.

**Severity**

warn

**GWS20 Found `gatewayscript` containing apim function: `%s`. No replacement was performed. The closest match is '%s', but it may not work in all situations.**

**Explanation**

See message text.

**Severity**

warn

**GWS21 Found `gatewayscript` containing session context function: `%s`. No replacement was performed. The closest match is '%s', but it may not work in all situations.**

**Explanation**

See message text.

**Severity**

warn

**GWS22 Found `gatewayscript` containing: `%s` and replaced with API Gateway equivalent context var of: `%s`**

**Explanation**

The following context variable names differ between v5 and v10 API Gateway. The migration utility replaces the v5 variable name with the equivalent v10 API Gateway variable name. For more information, see [API Connect context variables](#).

| v5 context variable | v10 API Gateway context variable |
|---------------------|----------------------------------|
| env.path            | api.catalog.path                 |
| env.name            | api.catalog.name                 |
| client.app.type     | client.app.lifecycle-state       |

**Severity**

info

**GWS24 Found gatewayscript policy containing api.document. Adding a gatewayscript policy to populate the api.document context.**

**Explanation**

The migration utility added a gatewayscript policy before the gatewayscript policy that contains `api.document`. The additional gatewayscript policy is required to populate the `api.document` context.

**Severity**

info

**GWS25 Replaced TLS Profile name `webapi-sslcli-mgmt` or `api-sslcli-all` with default TLS profile name `api-ssl-client-all` to conform to the API Gateway specification.**

**Explanation**

See message text.

**Severity**

info

**GWS26 Removed %s `\\` characters to conform to the API Gateway specification.**

**Explanation**

The processing of v5 API metadata would implicitly remove extraneous \\ characters. The source property of the gatewayscript policy has been changed to removed these characters as they would have been removed in v5.

**Severity**

info

**INV01 Moved `x-ibm-gateway-decode-request-params` from API properties to each `invoke` policy.**

**Explanation**

This v5 API property only applies to the `invoke` and `proxy` policies. In API Gateway, the functionality of this property is implemented as an option in the `invoke` policy. This change was made for the following purposes.

- The option is now clearly visible in the `invoke` policy, making it easy to identify available options.
- Each use of the `invoke` policy can now have a different setting.

**Severity**

info

**INV02 Moved `x-ibm-gateway-invoke-keep-payload` from API properties to the `keep-payload` `invoke` property where applicable.**

**Explanation**

This v5 API property applies only to the `invoke` policy. In API Gateway, the functionality of this property is implemented as an option in the `invoke` policy. This change was made for the following purposes:

- The option is now clearly visible in the `invoke` policy, making it easy to identify available options.
- Each use of the `invoke` policy can now have a different setting.

**Severity**

warn

**INV03 Moved `x-ibm-gateway-queryparam-encode-plus-char` from API properties to each `invoke` policy.**

**Explanation**

This API property only applies to the `Invoke` policy. In API gateway, this property is an option in the `Invoke` policy. This change was made for the following purposes:

- The option is now clearly visible on the `invoke` policy, making it easy to identify available options.
- Each use of the `invoke` policy can now have a different setting.

**Severity**

info

**INV04 Added `parse` policy immediately after the `invoke` policy to parse the `invoke` output.**

**Explanation**

The `invoke` policy output context in the API Gateway is not parsed. For compatibility with the v5 API, the `invoke` policy output context will be explicitly parsed by a `parse` policy that has been added to execute immediately after the `invoke` policy.

**Severity**

info

**INV05 Removed `x-ibm-gateway-invoke-suppress-clientid` API property from the YAML file and replaced it with allowlists and blocklists to conform to the API Gateway specification.**

**Explanation**

This v5 API property applies only to the `invoke` policy. In API Gateway, the functionality of this property is implemented as an option in the `invoke` policy. This change was made for the following purposes:

- The option is now clearly visible in the `invoke` policy, making it easy to identify available options.
- Each use of the `invoke` policy can now have a different setting.

**Severity**

warn

**INV06 Found `invoke` policy. Converted to API Gateway `invoke` policy.**

**Explanation**

See message text.

**Severity**

info

**INV07 The API property `x-ibm-gateway-invoke-emulate-v4-soap-error` does not exist in the API Gateway.**

**Explanation**

A `x-ibm-gateway-invoke-emulate-v4-soap-error` property was found. This property does not exist in the API gateway.

**Response**

Remove the `x-ibm-gateway-invoke-emulate-v4-soap-error` property from the API.

**Severity**

error

**INV08 Incorrect timeout value of `%s` found in `%s` policy, updated to `60` seconds.**

**Explanation**

The `timeout` property of the v5 `invoke` policy is invalid. It must be a numeric data type. It has been set to the default value of `60`.

**Response**

Correct the timeout value if the default value does not satisfy the requirements of the policy.

**Severity**

info

**INV09 Renamed the `keepPayload` property in the `invoke` policy to `keep-payload`.**

**Explanation**

See message text.

**Severity**

info

**INV10 `X-IBM-Client-Id` HTTP header suppressed using header-control blocklist, as the `x-ibm-gateway-invoke-suppress-clientid` property is undefined or not set in the v5-compatible YAML input file.**

**Explanation**

The v5 default behavior was to not send the `X-IBM-Client-Id` HTTP header to the invoke target. The `x-ibm-gateway-invoke-suppress-clientid` is not provided, so the header will not be sent. The API Gateway accomplishes this behavior by adding the header to the `invoke` policy header-control blocklist.

**Severity**

info

**INV11 `X-IBM-Client-Id` HTTP header suppressed using header-control blocklist, as the `x-ibm-gateway-invoke-suppress-clientid` property is set to `true` in the v5-compatible YAML input file.**

**Explanation**

The v5 default behavior was to not send the `X-IBM-Client-Id` HTTP header to the invoke target. The `x-ibm-gateway-invoke-suppress-clientid` property is provided with a value of `true`, so the header will not be sent. The API Gateway accomplishes this behavior by adding the header to the `invoke` policy header-control blacklist.

**Severity**

info

**INV12 Removed `x-ibm-gateway-optimize-invoke` API property from the YAML file and converted the `invoke` policy to conform to the API Gateway specification.**

**Explanation**

This v5 API property is not supported by the API Gateway.

**Severity**

info

**INV13 Added `set-variable` policy to preserve `X-IBM-Client-Id` HTTP header before the `invoke` policy, as `x-ibm-gateway-invoke-suppress-clientid` is set to `false` in the v5c YAML input file.**

**Explanation**

By default in the API Gateway, the `X-IBM-Client-Id` HTTP header is not copied from the inbound request headers to the message context headers used by the `invoke` policy. This request header will be copied to the message context headers so that it will be available to be sent by the `invoke` policy.

**Severity**

warn

**INV14 Added `gatewayscript` policy for `x-ibm-gateway-invoke-v4-nomap-emulation` as the property is set to `true` in the v5-compatible YAML input file.**

**Explanation**

The v5 `invoke` policy used this property internally, but this behavior is not supported by the API Gateway `invoke` policy. A `gatewayscript` policy that implements the behavior of this v5 API property has been added to execute after the `invoke` policy.

**Severity**

info

**INV15 Invoke `keep-payload` property has been set to the value of the API property `x-ibm-gateway-invoke-keep-payload`.**

**Explanation**

Although not supported by the v5 UI, a `keep-payload` property in the `invoke` policy is always used if present to control this behavior. If not present in the policy, the API property is used instead. The policy property is not present, but the API property is present, therefore the `keep-payload` property in the API Gateway will use the v5 API property.

**Severity**

info

**INV16 Set `keep-payload` setting to `true`.**

**Explanation**

The `keep-payload` setting is set based on the following conditions:

- For an `invoke` policy that meets all of the following criteria, the `keep-payload` property is always set to `true`.
  - The policy is at the end of the assembly.
  - The API property `x-ibm-gateway-optimize-invoke` is not set to `false`.
  - The `invoke` policy does not contain a `stop-on-error` property.
- For an `invoke` policy that does not meet the above criteria, the `keep-payload` property is set to one of the following values, in order of precedence.
  - The value of `keepPayload` property, if it is set.
  - The value of the API property `x-ibm-gateway-invoke-keep-payload`, if it is set.
- For an `invoke` policy that meets none of the above criteria, the `keep-payload` property is not set at all.
- For a `proxy` policy, the `keep-payload` property is always set to `true` after it is converted to an `invoke` policy.

**Severity**

info

**INV17 Invoke policy set to `invoke_1.5.0`, converting `invoke` to `invoke_1.5.0`**

**Explanation**

See message text.

**Severity**

info

**INV18 Set `final-action` parameter on `invoke\_1.5.0`**

**Explanation**

If the `invoke_1.5.0` policy is last in the assembly, the migration utility adds the `final-action` parameter, which ensures that the policy sends output to the message context. If `invoke_1.5.0` is not last in the assembly, the policy adds a `parse` after the wrapper policy to parse the output.

**Severity**

info

**JSON-to-XML policy messages**

- [J2X01](#)
- [J2X02](#)

**J2X01 Added a `parse` policy to execute before the `json-to-xml` policy.**

**Explanation**

A v5 `json-to-xml` policy must have the current API Gateway context parsed explicitly prior to execution. The `parse` policy has been added to execute before the `json-to-xml` policy.

**Severity**

info

**J2X02 Found `json-to-xml` policy and converted to API Gateway `json-to-xml`.**

**Explanation**

info

**LTPA-Generate policy messages**

- [LTPA01](#)

## LTPA01 Found v5-compatible `ltpa-generate` policy. Because this policy does not exist in the API Gateway, it is unchanged.

### Explanation

The `ltpa-generate` policy is not available in the API Gateway.

### Response

Remove the `ltpa-generate` policy from the API.

### Severity

error

## Map policy messages

- [MAP01](#)
- [MAP02](#)
- [MAP03](#)
- [MAP04](#)
- [MAP05](#)
- [MAP06](#)

## MAP01 "Moved `%s` from API properties to each `map` policy as map option: `%s`."

### Explanation

This v5 API property applies only to the `map` policy. In API Gateway, the functionality of this property is implemented as an option in the `map` policy. This change was made for the following purposes.

- The option is now clearly visible on the `map` policy, making it easy to identify available options.
- Each use of the `map` policy can now have a different setting.

### Severity

info

## MAP02 Replaced %s with %s to conform to the API Gateway syntax specification.

### Explanation

API Connect Version 5 treats a map value property with a string quoted with `"` or `\"` as the same, specifically as a double quote. This is not supported in the API Gateway. The `\"` is converted to a single `"`.

### Severity

info

## MAP03 Converted `map` to API Gateway `map` for conformance."

### Explanation

See message text.

### Severity

info

## MAP04 Set `map` option of `mapResolveApicVariables` to previous default of `true` for compatibility.

### Explanation

If a map policy is found to not have `mapResolveApicVariables` set, the option is set to true to maintain backwards compatibility.

### Severity

info

## MAP05 Set `map` option of `mapParseXMLOutput` to `true` for compatibility.

### Explanation

This property is always set by the migration utility to maintain compatibility with v5. If XML data is output from the `map_2.0.0` policy, then the data is parsed before it reaches `<output>.body`.

### Severity

info

## MAP06 Removed %s `\"` characters to conform to the API Gateway specification.

#### Explanation

The processing of v5 API metadata would implicitly remove extraneous \\ characters. The value properties of the map policy action have been changed to remove these characters as they would have been removed in v5.

#### Severity

info

#### Proxy policy messages

#### **PRX01 Found `proxy` policy and converted to API Gateway `invoke` policy, as `proxy` does not exist in the API Gateway.**

#### Explanation

A `proxy` policy was found. The policy was converted to an `invoke` policy in the API gateway.

#### Response

Review the changes to ensure that the `invoke` policy result will be consistent with the v5 API. Alternatively, you can specify that the migration utility convert `proxy` policies to `proxy_1.5.0`, which is a backward-compatible policy available in the API Gateway.

#### Severity

info

#### **PRX02 Removed `x-ibm-gateway-proxy-suppress-clientid` API property from the YAML file and replaced it with allowlists and blocklists to conform to the API Gateway specification.**

#### Explanation

This v5 API property applies only to the `proxy` policy. In the API Gateway, this property is represented by the header control and parameter control options in the `invoke` policy to either allow or restrict the `X-IBM-Client-Id` header or `client_id` parameter being sent to the backend server. This change was made for the following reasons.

- The option is now clearly visible in the `invoke` policy, making it easy to identify available options.
- Each use of the `invoke` policy can now have a different setting.

#### Severity

warn

#### **PRX03 Set policy `title` to `invoke` as this is now an `invoke` policy.**

#### Explanation

The functionality of the v5 `invoke` and `proxy` policies has been merged into the API Gateway `invoke` policy. The `title` property of the policy was changed to `invoke`.

#### Severity

info

#### **PRX04 Proxy: Changed `No-Cache` to lowercase `no-cache`.**

#### Explanation

#### Severity

info

#### **PRX05 Proxy: Changed `Time-to-Live` to lowercase `time-to-live`.**

**Explanation**

See message text.

**Severity**

info

**PRX06 Proxy: Changed `Protocol-Based` to lowercase `protocol`.****Explanation**

See message text.

**Severity**

info

**PRX07 `client\_id` query parameter suppressed using parameter-control blocklist, as `x-ibm-gateway-proxy-suppress-clientid` is set to `true` in the v5-compatible YAML input file.****Explanation**

The v5 default behavior is to send the `client_id` query parameter to the proxy target. The `x-ibm-gateway-proxy-suppress-clientid` property was provided with a value of `true`, indicating not to send this query parameter. The API Gateway accomplishes this behavior by adding this query parameter name to the parameter-control blocklist of the policy.

**Severity**

info

**PRX08 `X-IBM-Client-Id` HTTP header suppressed using header-control blocklist, as `x-ibm-gateway-proxy-suppress-clientid` is set to `true` in the v5-compatible YAML input file.****Explanation**

The v5 default behavior was to not send the `X-IBM-Client-Id` HTTP header to the proxy target. The `x-ibm-gateway-proxy-suppress-clientid` property was provided with a value of `true`, indicating not to send this HTTP header. The API Gateway accomplishes this behavior by adding this header name to the header-control blocklist of the policy.

**Severity**

info

**PRX09 `X-IBM-Client-Id` HTTP header suppressed using header-control blocklist, as `x-ibm-gateway-proxy-suppress-clientid` is undefined or not set in the v5-compatible YAML input file.****Explanation**

The v5 default behavior was to not send the `X-IBM-Client-Id` HTTP header to the proxy target. The `x-ibm-gateway-proxy-suppress-clientid` property was not provided, indicating not to send this HTTP header. The API Gateway accomplishes this behavior by adding this header name to the header-control blocklist of the policy.

**Severity**

info

**PRX10 `client\_id` not suppressed in query parameter, as `x-ibm-gateway-proxy-suppress-clientid` is undefined or not set in the v5-compatible YAML input file.****Explanation**

The v5 default behavior was to send the `client_id` query parameter to the proxy target. The `x-ibm-gateway-proxy-suppress-clientid` property was not provided, indicating to send this query parameter. No API Gateway `invoke` policy configuration is required to emulate this behavior.

**Severity**

warn

**PRX11 `output` deleted as this policy is the last policy in the assembly flow.****Explanation**

The v5 `proxy` API can specify an output context that makes the `proxy` response available for subsequent policies, but that response was also made available as the API response, should a subsequent policy not update the message context. When the `proxy` policy is the last policy in the v5 assembly, this output is removed, which allows the API Gateway `invoke` response to be returned to the client.

**Severity**

info

## PRX12 Added `gatewayscript` policy to copy the proxy policy headers, status, and output to `message` context.

### Explanation

A v5 `proxy` policy that specifies an output response context name is not the last policy in the assembly flow. A `gatewayscript` policy has been added after the API Gateway `invoke` policy. The `gatewayscript` policy copies the contents of the response context to the message context to emulate v5 behavior.

### Severity

warn

## PRX13 Added `set-variable` policy to preserve `X-IBM-Client-Id` HTTP header immediately before the proxy as `x-ibm-gateway-proxy-suppress-clientid` was set to `false` in the V5-compatible YAML input file.

### Explanation

By default in the API Gateway, the `X-IBM-Client-Id` HTTP header is not copied from the inbound request headers to the message context headers used by the `invoke` policy. This request header will be copied to the message context headers so that it will be available to be sent by the `invoke` policy.

### Severity

info

## PRX14 Proxy policy set to `proxy_1.5.0`, converting proxy to `proxy_1.5.0`

### Explanation

See message text.

### Severity

info

## PRX15 Set `final-action` parameter on `proxy_1.5.0`

### Explanation

If the `proxy_1.5.0` policy is last in the assembly, the migration utility adds the `final-action` parameter, which ensures that the policy sends output to the message context. If `proxy_1.5.0` is not last in the assembly, the policy adds a parse after the wrapper policy to parse the output.

### Severity

info

## Redact policy messages

- [RE10](#)
- [RE11](#)
- [RE12](#)
- [RE13](#)
- [RE14](#)

## RE01 This API Gateway `redact` policy is added to contain all v5-compatible `redact` paths targeted against the `request`.

### Explanation

To redact the request body, an API Gateway `redact` policy is placed at the front of the assembly in order to redact incoming data. All redactions in v5c that are not found within a `switch`, `if`, or `operation-switch` component will be moved to this single `redact` policy.

### Response

Review to confirm that this change meets the purpose of the API.

### Severity

warn

## RE02 API Gateway `redact` policy added to contain all v5-compatible `redact` paths targeted against `response`, `logs`, and `all`.

### Explanation

In the API Gateway, `response` and `logs` data must be redacted at the end of the assembly. This API Gateway `redact` policy was added to the end of the assembly to conform to the specification. If `logs` or `all` is the v5-compatible target for the `redact` policy, then a new `log` policy will be added in `gather-only` mode to populate the `log` API context.

The API Gateway emulates the v5-compatible redact on response and logs by adding a redact action at the end of the assembly to redact the response. All redactions in v5c that are not found inside of a `switch`, `if`, or `operation-switch` component will be moved to this single `redact` policy.

**Response**

Review to confirm that this change meets the purpose of the API.

**Severity**

warn

**RE03 Found v5-compatible `redact` policy. `action:path` pairs from this policy will be sorted into one or both leading and trailing API Gateway `redact` policies to conform to the API Gateway specification.**

**Explanation**

To emulate the v5 redact on `request` and `response`, some of the `redact` policies must be moved to either the end of the assembly or beginning of the assembly. This change is necessary because the `redact` policy now works directly on the API context, so it must be placed in a specific order so that it can redact data either before it enters the assembly or after it exits the assembly.

**Response**

Review the changes to ensure that the `redact` policy result will be consistent with the v5 API.

**Severity**

warn

**RE04 Found duplicate v5-compatible `redact` path of the same `redact` type. Duplicate item will not be added.**

**Explanation**

Because multiple redactions are consolidated into the leading or trailing `redact` policy, there might be some paths that are duplicates of current paths in the consolidated `redact` policy. These paths are not added as they are redundant.

**Response**

Review the changes to ensure that the `redact` policy result will be consistent with the v5 API.

**Severity**

warn

**RE05 Redaction on `request` was found in the v5-compatible YAML input file. Added first API Gateway `redact` policy to the front of the assembly after the `parse` policy to perform this redaction.**

**Explanation**

To redact the request body, an API Gateway `redact` policy is placed at the front of the assembly in order to redact incoming data. All redactions in v5c that are not found within a `switch`, `if`, or `operation-switch` component will be moved to this single `redact` policy.

**Response**

Review to confirm that this change meets the purpose of the API.

**Severity**

info

**RE06 Redact on `response`, `logs`, or `all` was found in the v5-compatible YAML input file. Added second API Gateway `redact` to the end of the assembly to perform this redaction. `log` policy also added if redact on `logs` or `all` was found.**

**Explanation**

In the API Gateway, `response` and `logs` data must be redacted at the end of the assembly. This API Gateway `redact` policy was added to the end of the assembly to conform to the specification. If `logs` or `all` is the v5-compatible target for the `redact` policy, then a new `log` policy will be added in `gather-only` mode to populate the `log` API context.

The API Gateway emulates the v5-compatible redact on response and logs by adding a redact action at the end of the assembly to redact the response. All redactions in v5c that are not found inside of a `switch`, `if`, or `operation-switch` component will be moved to this single `redact` policy.

**Response**

Review to confirm that this change meets the purpose of the API.

**Severity**

warn

### RE07 Potential JSON v5-compatible `redact` path detected.

#### Explanation

A v5 `redact` path has been detected that is highly likely to be targeted against JSON data. It has been converted to a JSONata path because the `redact` policy in the API Gateway uses JSONata to specify `path`:

#### Response

Review to confirm that the path is meant for JSON data and it is formed properly.

#### Severity

warn

### RE08 XML v5-compatible `redact` path detected. Converted to `redact` XPath: `%s` to JSONata: `%s`.

#### Explanation

A v5-compatible `redact` path has been detected that is highly likely to be targeted against XML data. It has been converted to JSONata to meet the API Gateway specification. The `redact` policy in the API Gateway uses JSONata for `path`:

#### Response

Review to confirm that the path is meant for XML data and it is formed properly. Note that a malformed XPath may still publish on API Connect v10 API Gateway, but will fail subsequent API calls with a **404 API Not found** error. The API Definition DataPower object will also be in the `[down]` state because of the invalid XPath. It is also possible for an invalid XPath to work on v5 but fail on API Gateway. For example, the XPath `/test/path/` is invalid because of the trailing slash. However, this XPath will work in v5, and fail with the above scenario in v10 API Gateway.

#### Severity

warn

### RE09 Common `redact` XPath `%s` replaced with JSONata `%s` to adhere to the API Gateway `redact` specification.

#### Explanation

The `redact` policy in API Gateway uses JSONata to specify the `path`:. All v5-compatible `redact` paths are converted to JSONata.

#### Response

Review to confirm that the changes conform to the purpose of the `redact` policy.

#### Severity

info

### RE10 Invalid redact action: `%s` found.

#### Explanation

A v5-compatible `redact` policy was found to contain an invalid `action` type. Valid types include `redact` or `remove`.

#### Response

Review the `action` type in the `redact` policy and update to either `redact` or `remove`.

#### Severity

error

### RE11 Added `log` policy to populate the `log` API context, because a v5-compatible `redact` policy was found targeted against `logs` or `all`. An API Gateway `redact` policy will be appended after this policy to redact the outgoing `log` data.

#### Explanation

The API Gateway specification requires a `log` policy in the assembly to populate the `log.request_body` and `log.response_body` context variables. After the `log` policy, the `redact` policy will then redact the contents of `log.request_body` and `log.response_body`.

#### Severity

warn

### RE12 Added `parse` policy before `redact` policy to parse incoming data.

#### Explanation

The incoming data must be parsed for the `redact` policy to work properly. For example, if the incoming data contains unparsed but well-formed XML data, the `redact` policy does nothing and the data passes through. With this added `parse` policy, the XML data is parsed properly and the redaction works as expected.

**Response**

Review the changes to ensure that the `redact` policy result will be consistent with the v5 API.

**Severity**

warn

**RE13 Found v5-compatible `redact` policy inside of a `switch` policy. Converted all paths to JSONata.**

**Explanation**

If a v5-compatible `redact` policy is found within a `switch`, `if`, or `operation-switch` component, it will be left in place. If the redaction is on the response and there is an `invoke` policy at the end of the assembly, problems could arise.

**Response**

Review and confirm that this redaction conforms to the purpose of the API.

**Severity**

warn

**RE14 Invalid `redact` action found: path is empty.**

**Explanation**

The v5-compatible `redact` policy was found to have an empty path. This configuration is invalid

**Response**

To make the API functional, update the path in the `redact` policy.

**Severity**

error

**SW01 Found `operation-switch\_1.0.0` and converted to API Gateway `operation-switch\_2.0.0`.**

**Explanation**

See message text.

**Severity**

info

**SW03 Found `switch` policy and converted to the API Gateway `switch` policy.**

**Explanation**

A **switch** policy from a v5 API is converted to an API Gateway **switch** policy. The v5 API uses GatewayScript syntax for conditions, whereas the API Gateway uses JSONata syntax. The conditions have been moved to a **gatewayscript** policy that will execute immediately before the **switch** policy. The **switch** conditions will use results from the **gatewayscript** policy to execute the correct assembly path.

**Response**

Review the changes to ensure that the **switch** policy result will be consistent with the v5 API.

**Severity**

info

**SW04 Found `if` policy and converted to API Gateway `switch` policy.**

**Explanation**

An **if** policy from a v5 API is converted to an API Gateway **switch** policy. The v5 API uses GatewayScript syntax for conditions, whereas the API Gateway uses JSONata syntax. The conditions have been moved to a **gatewayscript** policy that will execute immediately before the **switch** policy. The **switch** conditions will use results from the **gatewayscript** policy to execute the correct assembly path.

**Severity**

info

**SW05 Found `switch` condition: `%s` and converted it to JSONata: `%s` to conform to the API Gateway specification.**

**Explanation**

A v5 **switch** policy condition was converted directly into a JSONata condition. This condition does not require a **gatewayscript** policy that would be executed prior to the switch.

**Severity**

warn

**SW06 `switch` condition: `%s` could not be converted to JSONata. (Error code: `%d`).**

**Explanation**

Cannot convert an **if/switch** condition to JSONata. A GatewayScript policy will be added to handle the Switch logic instead. Changes are needed only if highest performance is desired. See the Response section for more details on performance. This message can appear for the following reasons.

| Error code | Explanation                                                             |
|------------|-------------------------------------------------------------------------|
| 1          | The auto-generated JSONata mapping file was not found.                  |
| 2          | The condition was not found in the auto-generated JSONata mapping file. |
| 3          | The condition resolved to empty.                                        |
| 4          | An unknown error occurred                                               |

**Response**

To improve performance, review the condition in the v5 API and provide the JSONata for this condition.

If an **indexOf()** method is used to determine whether a substring is present in a value, consider using the **\$contains()** JSONata string function. If **indexOf()** is used to get a substring before or after the match, consider using the **substringBefore()** or **substringAfter()** JSONata string functions.

For more information about using JSONata to write switch conditions, see [Writing switch condition scripts - DataPower API Gateway](#).

**Severity**

warn

**SW07 `switch` condition: `%s` could not be converted to JSONata or handled by `gatewayscript`.**

**Explanation**

The **if/switch** condition cannot be converted to JSONata. This error can occur for the following reasons:

- A condition contains invalid Javascript.
- The condition contains multiple expressions.

**Response**

Review the contents of the condition and edit as necessary.

- [VAL08](#)

**VAL01 Found v5-compatible `validate-usernametoken` policy. This policy does not exist in the API Gateway. No action has been taken.**

**Explanation**

A `validate-usernametoken` policy was found. This policy does not exist in the api gateway and has been ignored.

**Response**

Remove the `validate-usernametoken` policy from the API.

**Severity**

error

**VAL02 Converted `validate` policy into an API Gateway `validate` policy.**

**Explanation**

A `validate` policy was found.

**Response**

Review the changes to ensure that the `validate` policy result will be consistent with the v5 API.

**Severity**

info

**VAL03 Found `definition: request` and replaced it with `validate-against: body-param`.****Explanation**

The `definition` property in the v5 `validate` policy contained a value of `request`. This value has been changed to a value of `body-param` in the `validate-against` property of the API Gateway `validate` policy.

**Severity**

info

**VAL04 Found `definition: response` and replaced it with `validate-against: response-param`.****Explanation**

The `definition` property of the v5 `validate` policy contained a value of `request`. This value has been changed to a value of `response-param` in the `validate-against` property of the API Gateway `validate` policy.

**Severity**

info

**VAL05 Found `soap-env` `validate` definition and converted it to the API Gateway `xml-schema` property.****Explanation**

The `definition` property in the v5 `validate` policy references an OpenAPI definition. The definition referenced is for a SOAP document. This value has been changed to a value of `url` in the `validate-against` property in the API Gateway `validate` policy. The `definition` property value has been moved to the `xml-schema` property.

**Severity**

info

**VAL06 Set `xml-validation-mode` to `soap-body`.****Explanation**

The `definition` property in the v5 `validate` policy references an OpenAPI definition. The definition referenced is for a SOAP document. This value has been changed to a value of `url` in the `validate-against` property in the API Gateway `validate` policy. The `xml-validation-mode` property value has been set to `soap-body`.

**Severity**

info

**VAL07 Set `validate-against` to `%s`.****Explanation**

The `definition` property in the v5 `validate` policy references an OpenAPI definition. This value has been changed to conform to the API Gateway `validate` policy property `validate-against` with a value of `definition` or `url`.

**Severity**

info

**VAL08 Added `parse` policy before `validate` policy.****Explanation**

A v5 `validate` policy that is configured to validate the current context payload against a schema definition must have the input of the current API Gateway context parsed explicitly prior to execution. The `parse` policy has been added to execute before the `validate` policy.

- [XSLT02](#)
- [XSLT03](#)
- [XSLT04](#)
- [XSLT05](#)
- [XSLT06](#)

**XSLT01 Replaced `apim.custom`, `apim.setvariable`, and `webapi-util` with `apim.custom.xsl` within `xsl import` and `xsl include` statements.**

**Explanation**

The v5 `xslt` policy code that contains an `xsl import` or `xsl include` of v5 framework stylesheets that were found in the local directory of the file system have been changed to use the v5-compatible stylesheet in the store directory of the file system.

**Severity**

info

**XSLT02 Added `parse` policy to execute before the `xslt` policy.**

**Explanation**

A v5 `xslt` policy that is configured to use the current context payload as input to the stylesheet must have the current API Gateway context parsed explicitly prior to execution. The `parse` policy has been added to execute before the `xslt` policy.

**Severity**

info

**XSLT03 Found `xslt` policy. Porting might be required.**

**Explanation**

Review the `xslt` policy and make any changes required for use in API Gateway.

**Response**

If you want to use v5-compatible XSLT code in API Gateway, use the API Gateway extension elements and functions to ensure compatibility with API Gateway. Depending on the content of your code, you may need to make the following changes.

- Remove the `apim:setvariable-impl.xsl` stylesheet from the XSLT code. This stylesheet is not used in API Gateway. Instead, use the API Gateway extension functions to manipulate the assembly context.
- Use API Gateway extension elements to manipulate values in the assembly context. The following example uses the `apigw:set-header` extension element to set the value of the request header.

```
<apigw:set-header name="'request'" value="$request" />
```

- Use of `dp:variable` and `dp:set-variable` functions is not supported in API Gateway. These functions should be changed to `apim:getVariable` and `apim:setVariable`. Access to session, service, and system metadata is restricted.

For more information about the API Gateway extension elements and functions, see the IBM DataPower Gateway documentation.

**Severity**

warn

**XSLT04 `xslt` policy set to `xslt\_1.0.0`, converting xslt to `xslt\_1.0.0`.**

**Explanation**

See message text.

**Severity**

info

**XSLT05 Replaced TLS Profile name `webapi-sslcli-mgmt` or `api-sslcli-all` with default TLS profile name `api-ssl-client-all` to conform to the API Gateway specification.**

**Explanation**

See message text.

**Severity**

info

**XSLT06 Removed %s `\\` characters to conform to the API Gateway specification.**

**Explanation**

The processing of v5 API metadata would implicitly remove extraneous `\\` characters. The source property of the `xslt` policy has been changed to remove these characters as they would have been removed in v5.

info

## Migration utility messages

---

- [Catalog property updated with catalog name](#)

**Catalog property updated with catalog name Message API: `{{.APIFile}}`, pOrg: `{{.ProviderOrg}}`: Updated catalogs: property: `{{.OldCatalogName}}` with catalog name: `{{.NewCatalogName}}` based on matching catalog title: `{{.FoundCatalogTitle}}` since API Gateway requires catalog name instead of catalog title in `catalogs:`**

**Explanation**

In v5, the `catalogs` property uses names based on the Catalog Title. In API Gateway, the Catalog Name must be used. The Migration Utility attempted to find a matching Catalog Title in the same provider-org as the API, and succeeded. The `catalogs` property that formerly used the Catalog Title has been automatically updated by the Migration Utility to use the Catalog Name of the Catalog instead.

## Response

Review your API to confirm that the Catalog Name used in the `catalogs` property is correct.

## Parse actions added to the API assembly after migration

The migration utility command `apicm archive:port-to-apigw` adds parse actions to the API assembly depending on the policies specified in your migration configuration.

Review the API assembly to determine if any of the parse actions or other actions added by the migration utility can be removed. For more information, see [Fine-tuning APIs after migration](#).

Parse actions are added to the assembly according to the rules in the following tables.

Table 1. Parse actions added to the API assembly after conversion of policies to 1.0.0 or 2.0.0

| Policy                                                                                           | Where the parse action is added                                                 |
|--------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| If a <b>POST</b> , <b>PUT</b> , <b>DELETE</b> , <b>OPTIONS</b> , or <b>PATCH</b> method is found | As the first action in the assembly                                             |
| invoke 2.0.0                                                                                     | After the invoke action, except when invoke is the last action in the assembly. |
| json-to-xml 2.0.0                                                                                | Before the json-to-xml action                                                   |
| proxy 2.0.0                                                                                      | After the proxy action                                                          |
| validate 2.0.0                                                                                   | Before the validate action                                                      |
| xml-to-json 2.0.0                                                                                | Before the xml-to-json action                                                   |
| xslt 1.0.0 or 2.0.0                                                                              | Before the xslt action                                                          |

Table 2. Parse actions added to the API assembly after conversion of invoke and proxy policies to 1.5.0

| Policy       | Where the parse action is added                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| invoke 1.5.0 | A parse action is added after the invoke if any of the following are true: <ul style="list-style-type: none"><li>• <code>stop-on-error</code> is specified</li><li>• <code>final-action</code> is set to <code>false</code>. This is the default setting.</li><li>• <code>x-ibm-gateway-optimize-invoke</code> is explicitly set to <code>false</code></li></ul> The parse action is added because there can be a subsequent use of the output. |
| proxy 1.5.0  | A parse action is added after the proxy if <code>final-action</code> is set to <code>false</code> .                                                                                                                                                                                                                                                                                                                                             |

## Fine-tuning APIs after migration

After running the migration utility command `apicm archive:port-to-apigw`, review the converted APIs to determine if any of the changes made by the migration utility can be modified to enhance performance and usability.

If the migration utility makes any of the following changes to your APIs, consider making the suggested changes.

- If the last policy in the assembly has output that is set to a variable that is not used afterward, remove the output set or the entire policy.
- Remove any unnecessary parse actions that the migration utility adds to the assembly. For information about the parse actions added by the migration utility, see [Parse actions added to the API assembly after migration](#).
- If the assembly contains redact policies, verify that these policies are necessary. Delete any unnecessary redact policies.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

- [What is the difference between the 1.5.0 and 2.0.0 versions of the invoke and proxy policies, and the 1.0.0 and 2.0.0 versions of the gatewayscript policy? Why isn't the 2.0.0 version the default version?](#)
- [Should I rewrite my Gatewayscript policies?](#)
- [What is the optimize-gws option?](#)
- [What is the gateway-extension.zip file and how does it work?](#)
- [How does the migration utility migrate custom policies?](#)
- [Should I set the custom-policies-scope option to global or catalog?](#)
- [Why are my custom policies not showing up in the Assembly Editor policy palette?](#)

What is `port-to-apigw`?

`port-to-apigw` is a command in the API Connect migration utility that converts all APIs, products, subscriptions, OAuth providers, and custom policies into v10 native API Gateway artifacts. These newly created artifacts live side-by-side with the original v5-compatible artifacts, and have `-apigw` appended to the end of the filename.

For more information, see [Converting APIs to DataPower API Gateway](#).

When is it necessary to run the `port-to-apigw` command, and how do I use it?

Run this command if you are migrating to a v10 native API Gateway. Follow the migration steps that are appropriate for your v5 environment. For instructions on running the `port-to-apigw` command, see [Migration steps](#). For information on configuring migration options, see [Configuring migration options for DataPower API Gateway](#). For other information to help you optimize migration, see [Migration considerations](#).

Additional information is available in the [API Connect Migration Utility \(AMU\) for Version 10 Technical Run Book](#).

Why is the `port-to-apigw` command needed for migrating to v10 API Gateway?

The required fields, properties, settings, and configuration in v10 native API Gateway differs from v5-compatible mode. The `port-to-apigw` step in the migration process is needed to convert the artifacts to conform to the changes.

What is the difference between these terms: "porting to API Gateway", `port-to-apigw`, and "migration"?

"Porting to API Gateway" describes what the `port-to-apigw` command does in the migration utility. "Migration" is the overall purpose of the migration utility. The `port-to-apigw` step is necessary for migrating to a v10 native API Gateway. Migration can be completed without the `port-to-apigw` step if you are migrating to a v10 deployment that uses only the v5-compatible DataPower Gateway.

What is v5 policy emulation and how does it work?

The v5 policy emulation layer allows both custom policies and the 1.0.x policies to run on the native v10 API Gateway. It is deployed automatically by the API Connect migration utility to the `local:///isp` folder of the DataPower appliance when a custom policy is found in the v5 backup, or if you specify a 1.0.x policy in the policy option for the `port-to-apigw` command. The deployment is first staged by the `port-to-apigw` command, and pushed by the `archive:push` command. Follow the steps as outlined in [Migration steps](#).

Note that 1.5.x policies do not use v5 policy emulation, and exist only as native wrappers to the 2.0.0 implementation.

What is the purpose of the policy parameter options in `port-to-apigw`?

Input options allow you to customize your migration. If you want to use the native policies, such as `invoke_2.0.0` instead of the default `invoke_1.5.0-compatible` option, you can select the appropriate option. However, using these options can result in migration errors that require manual changes to get your APIs up and running. If you want to be up and running quickly, it is best to use the default options for the input. The default options convert APIs in a way that is most backwards compatible with v5.

For more information about the migration configuration options, see [Configuring migration options for DataPower API Gateway](#). For explanations of errors and other messages generated during migration and suggestions for manual changes to APIs, see [Messages generated during conversion of APIs to DataPower API Gateway](#).

How do the v5 emulated policies `invoke_1.5.0`, `proxy_1.5.0`, `xslt_1.0.0`, and `gatewayscript_1.0.0` work?

When the push step of the migration utility is completed, these policies will exist on the DataPower Gateway as assembly function objects. The 1.0.x policies call the v5 policy emulation layer in order to function as if they were v5 policies. The 1.5.x policies are wrapper policies to the 2.0.0 implementation. They call the 2.0.0 policies and exist only as a compatibility layer between the original v5 policy and the new 2.0.0 policy.

What is the difference between the 1.5.0 and 2.0.0 versions of the `invoke` and `proxy` policies, and the 1.0.0 and 2.0.0 versions of the `gatewayscript` policy? Why isn't the 2.0.0 version the default version?

The 1.5.x policy implementations are native wrappers to the underlying 2.0.0 implementation. They exist only to create a compatibility layer between the v5 policy and the APIGW native policy. The `gatewayscript_1.0.0` policy uses v5 policy emulation to run as if it were on a v5 environment. The performance of the 1.0.x v5 emulation layer policies in API Gateway is the same or slightly better than the v5 and v5-compatible versions. The performance of 1.5.x policies is slightly slower than their corresponding 2.0.0 policies. You can inspect the 1.5.x wrapper implementation in Assembly Functions in DataPower Gateway.

Should I rewrite my Gatewayscript policies?

Most Gatewayscript policies do not require rewriting, as the native v10 API Gateway contains an enhanced compatibility layer that accepts most of the `apim` functions without modification. In most cases, Gatewayscript policies require rewriting when they contain any of the following:

- inline parameters
- `require('service-metadata')` and service variables associated with it
- `require('mgmt')`
- `require('fs')`
- OAuth context variables

What is the `optimize-gws` option?

The `optimize-gws` migration option converts certain v5 gatewayscript functions to the native API Gateway implementation. This setting is optional because the compatibility layer already handles processing of original v5 gatewayscript functions. If set to true, the migration utility makes the following conversions:

- `apim.getvariable()` is converted to `context.get()`
- `apim.setvariable()` is converted to `context.set()`
- `hm.current.remove()` is converted to `context.clear()`

What is the `gateway-extension.zip` file and how does it work?

After running the `port-to-apigw` command, a `gateway-extension.zip` file is located in the `cloud/admin-org/availability-zones/default-availability-zone/gateway-services/<gateway-service>` folder. This file is automatically generated by the migration utility during the processing of the `port-to-apigw` command. It contains a `manifest.json` file, and every custom policy under the gateway service that came from the v5 backup. The `manifest.json` file contains a list of custom policies to push, and backwards-compatible policies to advertise and make available for use by APIs. These backwards-compatible policies include `invoke_1.5.0`, `proxy_1.5.0`, `xslt_1.0.0`, and `gatewayscript_1.0.0`. During the `archive:push` steps of the migration process, this zip file is pushed to the API Manager as a gateway extension.

For more information, see [Gateway extensions manifest](#).

How does the migration utility migrate custom policies?

Custom policies are migrated in multiple steps, depending on whether the `custom-policies-scope` option is set to `global` or `catalog`. Once custom policies are pushed to the DataPower Gateway, they use the `v5 policy emulation` layer that was unpacked into the `local:///isp` folder in order to run on the native v10 API Gateway.

When `port-to-apigw` is run, the following steps are performed depending on the `custom-policies-scope` setting.

- If `custom-policies-scope` is set to `global`, and there are no duplicate custom policies with differing implementations, the custom policies under each gateway service are bundled in a `gateway-extension.zip` file. This zip file contains a `manifest.json` file that describes the contents. The `gateway-extension.zip` file is copied to the `admin-org gateway-service` folder. These steps are performed automatically when `port-to-apigw` is run. Next, you must push the `admin-org` during the `archive:push` step, which pushes the `gateway-extension.zip` bundles (one per gateway) to the API Manager using an internal `APIC Toolkit gateway-extensions:create` call. The custom policies within the bundle are advertised on the API Manager. The custom policies and compatible legacy policies are shown in the policy pallet in the API Manager Assemble UI. These custom policies are also in the DataPower filesystem in the `local:///` folder. Note that if duplicate custom policies with the same name, version, and differing underlying implementation are found, the migration utility logs a message and automatically falls back to `catalog` scope to prevent the migration from failing.
- If `custom-policies-scope` is set to `catalog`, the custom policies under each gateway service are bundled in a `gateway-extension.zip` zip file. This zip file contains a `manifest.json` file that describes the contents. The `gateway-extension.zip` file is then copied to the `admin-org gateway-service` folder. The custom policy definition files under each catalog are copied into the `catalog-scoped-staging` folder, where their gateway type is set to `datapower-api-gateway`. Next, you must push the `admin-org` during the `archive:push` step, which pushes the `gateway-extension.zip` bundles (one per gateway) to the API Manager using an internal `APIC Toolkit gateway-extensions:create` call. Note that the custom policies and compatible legacy policies are not visible in the policy pallet in the UI. You can see the custom policies in the DataPower filesystem in the `local:///` folder. Before you can publish APIs that use these policies, you must push your `provider-orgs` during the `archive:push` step. The custom policy definitions as described earlier from the `catalog-scoped-staging` folder are then pushed to the API Manager automatically using an internal `APIC Toolkit policies:create` call. The APIs containing the newly migrated catalog-scoped custom policies are then published.

Note: The folders and zip files are created automatically, and you should not need to modify them. For instructions on the tasks you must perform, see [Migration steps](#).

Should I set the `custom-policies-scope` option to `global` or `catalog`?

Global scope custom policies are visible to every catalog and org on the gateway. Catalog scope custom policies are visible only to the catalog that they were migrated from. If you plan to migrate to v10 with the intention of custom policy availability the same as it is on v5, then use the default `catalog` setting.

Why are my custom policies not showing up in the Assembly Editor policy palette?

See the following troubleshooting information: [Custom policies not appearing in the policy palette after migration](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Migration mapping files

You can use mapping files to map the name of a v5 object to a corresponding v10 object that has a different name.

The API Connect migration process allows you to make modifications to the configuration information after it has been extracted from the source v5 system and before it is uploaded to the target v10 system.

The names of some structures may not match exactly between v5 and v10. Since the names of some high-level objects may be intentionally different in the v10 environment, you can substitute values so that references to v5 object names (user registries, gateway services etc.) can be bound to the newly created objects in v10.

Note: If the names are preserved exactly between the v5 and v10 environments, you do not need to map any names.

- [What is a mapping file?](#)
- [Mapping a gateway service](#)
- [Mapping a migrated OAuth shared secret key](#)
- [Mapping SNI settings](#)
- [Mapping a provider organization](#)

---

## What is a mapping file?

What does a mapping file do?

Mapping files are simple yaml files that may be placed at any level in the directory structure produced by the `apicm archive:unpack` command where there is a yaml file describing a configuration object. A mapping file contains yaml `key: value` pairs that provide the values to apply in place of the original configuration values.

- You can use mapping files to override any values within the `.yaml` files.
- Common mappings can be specified in `mapping.yaml`.
- Server specific mappings can be provided in `mapping.<servername/ip>.yaml`. For example: `mapping.hostname.com.yaml` for `hostname.com` server.

What kinds of settings can I map?

You can override any values within a `.yaml` files. The most common mappings for v5 migrations are:

- Gateway service names
- Provider organization names
- User registry names

What does a mapping file contain?

A mapping entry consists of a minimum of two lines:

- The first line of the mapping entry should be the file name you want to override, without the `.yaml` extension. For example, when overriding a value in `provider-org.yaml`, the first line of the mapping is `provider-org`.
- Additional lines have `key: value` pairs that override `key: value` pairs found in the main `.yaml` file. The most common usage is for overriding the name. To do this include the `name:` setting, followed by the new value for v10. For example, if you have a v5 provider organization `myv5porg`, and you want to map it to `myv10porg`, the second line is `name: myv10porg`.

```
provider-org:
 name: myv10porg
```

- There are a few exceptions for some additional fields with special meaning in the mapping file for gateway services. See [Mapping a gateway service](#).

Where do I create mapping files

Examine the `/cloud` directory hierarchy that you created when you ran `apicm`

`archive:unpack`. Locate the directory that has the `.yaml` file with the v5 value you want to overwrite. In that same directory, create a new file named `mapping.yaml`. For a detailed example, see the [Mapping tutorial](#).

## Mapping a gateway service

You can use a mapping file to tell the migration program the name of the target gateway service in v10 to use when migrating from v5 gateway service data to v10 gateway service data. You might want to map a v5 gateway service name to a v10 gateway service if the names do not match, or if the number of gateway services does not match.

Note: You can map a v5 gateway service to a v10 DataPower API Gateway. In this case, the mapping definition requires a `gateway-type` field. See the [Mapping tutorial](#). After you unpack the v5 data, you can find each of v5 gateway services in `cloud/admin-org/availability-zones/availability-zone-default/gateway-services/`.

For example, the following `cloud/admin-org/availability-zones/availability-zone-default/gateway-services/` hierarchy shows entries for three v5 gateways named: `gateway-2536`, `gateway-2537`, and `gateway-2538`.

Figure 1. Example admin-org with entries for three v5 gateway services

```
admin-org
├── availability-zones
│ ├── availability-zone-default
│ │ ├── availability-zone.yaml
│ │ └── gateway-services
│ │ ├── gateway-2536
│ │ │ ├── gateway-service.yaml
│ │ │ └── gateway-2537
│ │ ├── gateway-2537
│ │ │ ├── gateway-service.yaml
│ │ │ └── gateway-2538
│ │ └── gateway-2538
│ │ ├── gateway-service.yaml
```

## Mapping a migrated OAuth shared secret key

Information about migrated OAuth shared secret keys is contained in your `gateway-service.yaml` file. When you map a gateway to a new name, you must ensure that the OAuth shared secret key is associated with mapped gateway name.

Note: Make sure you only migrate one OAuth shared secret key per gateway service. You will get an error if you attempt to map more than one to the same gateway service.

1. Determine if your `gateway-service.yaml` includes information for an OAuth Shared Secret Key (`oauth_shared_secret:`). For example:

```
api_version: 2.0.0
metadata:
 v5_created_at: 2018-12-01 17:43:03.065 +0000 UTC
 v5_created_by: admin
 v5_id: 5c02c827e4b0e816d3874747
 v5_updated_at: 2018-12-04 15:59:03.282 +0000 UTC
 v5_updated_by: admin
name: gw3-cf31
oauth_shared_secret: 0xF2DB3AE67A7988C06FF1EBA5C2B51F04ABC5D3D1192B4C994CA00C79FAB5ADAD
type: gateway_service
```

2. If `oauth_shared_secret:` is found, add `migrate_oauth_shared_secret:` `true` to the mapping `.yaml`. For example:

```
gateway-service:
 name: gateway-10-1
 migrate_oauth_shared_secret: true
```

## Mapping SNI settings

You can include Server Name Indication (SNI) settings in the mapping file. When enabled, these settings, which include the host and TLS Server Profile pairs, are included in the migration of gateway services.

Note: You can migrate only one set of SNI settings for a v10 gateway service. If you are mapping multiple v5 gateway services to a single v10 gateway service, only the first set of SNI settings is migrated and warnings are generated for the additional mappings.

1. Determine whether your `gateway-service.yaml` file contains SNI settings to migrate, as in the following example.

```
api_version: 2.0.0
gateway_service_type: datapower-gateway
metadata:
 v5_created_at: 2022-02-02 20:07:29.566 +0000 UTC
```

```

v5_created_by: admin
v5_id: 61fae481e4b0b16dad38691a
v5_updated_at: 2022-02-02 20:07:29.566 +0000 UTC
v5_updated_by: admin
name: gateway-service6-fabd
oauth_shared_secret: 0x014D004DC0A32EF091C17FEFCF10A621C36A92CE88BCE0F8FC2463B096D72D99
sni:
- host: internal.apic.ibm.com
 tls_server_profile_url: idurl://../../../../tls-server-profiles/gatewaytlsprofile-1.0.0.yml
- host: partner.apic.ibm.com
 tls_server_profile_url: idurl://../../../../tls-server-profiles/default-ssl-profile-1.0.0.yml
type: gateway_service

```

- If SNI settings are found, add `migrate_sni: true` to the `mapping.yml`. For example:

```

gateway-service:
 name: gateway-10-1
 migrate_sni: true

```

## Mapping tutorial

You create and bring up a new gateway service in v10 called `gateway-10-1`. You want the data (e.g Catalogs) associated with the v5 gateway `gateway-2536` to be migrated to the v10 gateway named `gateway-10-1`.

- Go to the `/cloud` hierarchy and locate the `gateway-2536/` directory.

```

├── gateway-services
│ └── gateway-2536
│ └── gateway-service.yml

```

- Open the `gateway-service.yml` and verify that the `name:` entry specifies the v5 gateway service that you want to map.

```

api_version: 2.0.0
v5_id: 5c0icef4e45816d32290fb
name: gateway-2536
type: gateway-service

```

- To map `name: gateway-2536` to a new value, use a text editor to create a **new** file named `mapping.yml`.
  - On a new line, enter `gateway-service:`.

How do I know what to enter on the first line?

Enter the name of the file that you are overriding, without the `.yml` suffix. In this case, you are overwriting `gateway-service.yml`, so you enter `gateway-service:`.

- On the next line, indent two spaces (as required for valid yaml), and enter `name:`  
`gateway-10-1`.

```

gateway-service:
 name: gateway-10-1

```

How do I know which name to use when mapping the v10 gateway-service?

In the v10 Cloud Manager UI, go to the Topology page. In the Default Availability Zones table, locate the Service column and click the gateway service entry. On the Edit DataPower Gateway Service page, in the Gateway Details section, locate the value in the **Name** field. Use this value.

Note: Do not use the value in the **Title** field. The value in the **Name** field is slugified to contain only characters that are supported in v10, and thus might differ from the value in the **Title** field.

- If the new v10 gateway service `gateway-10-1` is a DataPower API Gateway, add a third line to specify the gateway type:

```

gateway-service:
 name: gateway-10-1
 gateway-type: datapower-api-gateway

```

If the new v10 gateway service `gateway-10-1` is a v5-compatible gateway, do not specify `gateway-type`. When `gateway-type` is not specified, the mapping defaults to v5-compatible.

- The mapping is complete. Save the file in the same directory.

The following diagram shows the location of the new `mapping.yml` file in the `cloud/` hierarchy for `admin-org`. Note that it is in the same directory as the `gateway-service.yml` file for the v5 service it applies to (`gateway-2536`).

Figure 2. Example `admin-org` with `mapping.yml` for `gateway-2536` gateway service entry

```

admin-org
├── availability-zones
│ ├── availability-zone-default
│ │ ├── availability-zone.yml
│ │ └── gateway-services
│ │ ├── gateway-2536
│ │ │ ├── gateway-service.yml
│ │ │ └── mapping.yml
│ │ ├── gateway-2537
│ │ │ └── gateway-service.yml
│ │ ├── gateway-2538
│ │ │ └── gateway-service.yml

```

When the mapping utility (`apicm archive:push`) runs, it automatically uses the new `name:` value found in `mapping.yml` to overwrite the `v5` value found in `gateway-service.yml`. Note that the gateway service on `v10` must be up and running

Do I have to edit the existing `gateway-service.yml`?

No, just create a new `mapping.yml` file and add it to the same directory as `gateway-service.yml`.

What if I want to map several `v5` gateway-services to one `v10` gateway-service?

If you have several `v5` gateway services, and you want to map each of them to the same `v10` gateway service, `gateway-10-1`, you can copy your newly edited `mapping.yml` into the directory for each gateway service. Under each gateway entry, place a copy of your new `mapping.yml`.

The following diagram shows the locations of the three copies of `mapping.yml` files (one each for `gateway-2536`, `gateway-2537`, and `gateway-2538`) in the `cloud/` hierarchy for `admin-org`.

Figure 3. Example `admin-org` with `mapping.yml` files for three `v5` gateway services

## Mapping a provider organization

The `apicm archive:unpack` command produces a directory structure that includes a subdirectory for each provider organization in the original system. A provider organization named `onlinebanking` would be represented by a directory name `cloud/provider-orgs/onlinebanking`, containing a file named `provider-org.yml`:

```
api_version: 2.0.0
name: onlinebanking
org_type: provider
state: enabled
title: OnlineBanking
summary: migrated onlinebanking
metadata:
 v5_id: 5c0ebfd4e4b007df531ffe40
...
```

To override the organization name (indicated by the `name` property), create a file named `mapping.yml` in the same directory as the `provider-org.yml` file, and include the new name to apply to the organization. Example `mapping.yml`:

```
provider-org:
 name: digitalbanking
```

Here, the result of the override is to cause a provider organization named `digitalbanking` to be used as the target provider organization for the contents originally extracted from the `onlinebanking` organization.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Migrating OAuth Providers and OAuth secured APIs

You can migrate `v5` OAuth Providers and OAuth secured APIs to your `v10` API Connect deployment.

In `v5` OAuth Providers are a specialized type of API that are published within products. In `v10` OAuth Providers are first class objects that are directly published in the provider organization. This is applicable for both DataPower Gateway (`v5-compatible`) and DataPower API Gateway.

Also, `v10` adds tight coupling between the API using OAuth and the OAuth provider object. Hence an API using OAuth security must link to the corresponding OAuth Provider object. For a review of how API Connect `v10` uses OAuth Providers, see [OAuth Provider overview](#).

The API Connect Migration Utility (AMU) migrates all OAuth Provider APIs from `v5` to the first-class OAuth provider objects on both DataPower Gateway (`v5-compatible`) and DataPower API Gateway.

In addition, the AMU uses logic to determine which OAuth provider is used by a given API and populates it in the newly added field `x-ibm-configuration` of API security definitions. If the AMU is unable to find a match between an API using OAuth and the OAuth provider, it prints out error messages. See [Common errors with OAuth Providers](#).

- To ensure that APIs that use OAuth security definitions are mapped to the corresponding OAuth Provider APIs in `v10`, make sure that either the Authorization URL or the Token URL defined in OAuth Security Definitions of APIs that use OAuth correctly point to the base path of the OAuth Provider API. Note that the AMU uses logic to map Consumer APIs to Provider APIs, and adds `x-ibm-oauth-provider` in the OAuth Security Definition of the consumer API.
- To verify whether OAuth Provider APIs are migrated correctly, ensure that all the APIs that use OAuth Security Definition have the new field `x-ibm-oauth-provider` added. Check the value of that field and make sure it points to a correct OAuth Provider resource object that was created and configured in the catalog to which the API is published.
- As mentioned earlier, in `v5` OAuth Providers are a specialized type of API that are published within products. In `v10` OAuth Providers are instead first class objects that are directly published in the provider organization, and are not APIs that are published within products. Because of this, it is possible that you may have some

v5 products that only contained OAuth Provider APIs. Since these products do not contain any Open API definitions in v10, they will not be published as all products in v10 must contain at least one Open API definition.

Note: Conflicting OAuth provider names or base paths are not migrated. If the migration utility encounters conflicting names or base paths for OAuth providers, the provider is not migrated.

## Migrating OAuth token revocation information

In v5, token revocation could be enabled either using native token management system (TMS) or using external TMS. For migration to v10:

- Native TMS migration
  - DataPower Gateway (v5-compatible)

After setting up a v10 DataPower Gateway instance, follow these steps to configure the v10 DataPower Gateway quota enforcement server (QES) to use the same QES on both v5 and v5-compatible. You must configure the QES and verify that it is enabled and functional before migrating from v5 to v10. For more details about configuring the QES, see the DataPower Gateway documentation topic *Configuring the quota enforcement server*.

    1. Log into the graphical interface of the DataPower Gateway instance in the default domain.
    2. Cluster the v5 MPGWS with the v10 DataPower Gateway QES.
      - a. In DataPower Gateway, navigate to Objects > System Settings > Quota Enforcement Server.
      - b. Specify the password alias, data storage location, and the server and monitor port numbers.

If your v10 DataPower Gateway is a Docker instance, configure the QES to store data in memory. For more information about RAID and Docker, see the DataPower Gateway documentation topic *RAID and a DataPower Docker image*.
      - c. Enable Peer group mode.
      - d. Specify the IP address of the DataPower Gateway.

The IP address can be the IP address on any interface of the current appliance and must be accessible by other peers in the peer group.
      - e. Specify the IP addresses of the v5-compatible gateways to add them as peers.

The appliance connects to each peer in the order in which the peers are added in the list.
      - f. Apply and save the configuration.
    3. As a test, revoke a token on the v5 MPGWS server.

Revocation data will replicate to v10 DataPower Gateway QES.
    4. Migrate the v5 APIs to the v10 DataPower Gateway QES.
    5. Send a request to the v10 DataPower Gateway QES with previously revoked token, which should fail as expected.

The expected failure indicates that the APIs were migrated and revocation data was replicated.
  - DataPower API Gateway

When migrating to API Gateway, QES is not used for native token management and revocation. A new set of objects called *Gateway Peering objects* are created on API Gateway. This means that any existing revocation information on QES is not available for API Gateway.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Migrating custom policies

The migration utility migrates API Connect Version 5 user-defined custom policies to API Connect Version 10. After migration, the v5 custom policies run on a v5-compatible DataPower Gateway or the DataPower API Gateway. Custom policies can be migrated to API Gateway with limitations.

## Overview of the custom policy file format

Review your custom policies in the `/cloud` hierarchy that is created by the migration upack. The path to custom policies in the `/cloud` hierarchy structure is:

```
provider-orgs -> <provider-org-name> -> catalogs -> <catalog-name> -> configured-gateway-services -> <gateway-name> -> policies
```

The following example from a `/cloud` hierarchy shows custom policies for the catalog `policy-and-vendor-ext-test` listed under the gateway service `g-w-1-8f82`:

```
./provider-orgs/onlinebanking/catalogs/policy-and-vendor-ext-test/configured-gateway-services/
├── g-w-1-8f82
│ ├── configured-gateway-service.yml
│ └── policies
│ ├── client-i-p-filter-policy-9d58-1.0.doc.yml
│ ├── client-i-p-filter-policy-9d58-1.0.meta.yml
│ ├── client-i-p-filter-policy-9d58-1.0.zip
│ ├── client-i-p-filter-policy-9d58-2.0.doc.yml
│ ├── client-i-p-filter-policy-9d58-2.0.meta.yml
│ ├── client-i-p-filter-policy-9d58-2.0.zip
│ ├── validate-auto-xsd-jsv-1.0.0.doc.yml
│ ├── validate-auto-xsd-jsv-1.0.0.meta.yml
│ ├── validate-auto-xsd-jsv-1.0.0.zip
│ ├── validate-username-token-5.0.0.doc.yml
│ ├── validate-username-token-5.0.0.meta.yml
│ └── validate-username-token-5.0.0.zip
```

File naming legend:

- `*.doc.yml` - the policy definition files

- `*.meta.yml` - metadata used only by the migration utility.
- `*.zip` - the custom policy zip files

## Migrating custom policies to a v5-compatible gateway

---

A Version 5 custom policy definition is a zip file containing the yaml description of the policy (its name and configuration parameters) and the implementation zip of DataPower configuration that runs on the gateway. The zip file is pushed onto the gateway service used by any catalog that has APIs that make use of the policy. For more information on v5 custom policies, see [User-defined policies in API Connect](#).

The migration utility migrates both the zip file and the yaml description file. After migration, the v5 custom policies run on a v5-compatible DataPower Gateway. Note that the structure of the custom policy zip file is the same in v5-compatible gateway as in v5. The v5-compatible gateway runtime will run any custom policy that a v5 gateway runs.

## Migrating custom policies to API Gateway

---

Important: When migrating custom policies to v10 API Gateway, the v5-emulation layer is used to ease compatibility. For more information, see [v5 policy emulation limitations](#).

You can migrate v5 custom policies to API Gateway using the v5-emulation layer. The migration utility bundles custom policies and groups them by gateway service during the port step. During the push step, the custom policies are pushed to the Gateway Service with instructions for DataPower to enable the v5-emulation layer, along with any v5-emulated or wrapped policies that were specified during the port step, such as `invoke_1.5.0` or `gatewayscript_1.0.0`.

v5 policy emulation is deployed by the API Connect Gateway Service using a Gateway extensions manifest. For more information, see [Gateway extensions manifest](#).

Note: If porting to API Gateway using the `custom-policies-scope=catalog` parameter, and spaces are contained in the v5 backup, then any duplicate custom policies found will be discarded. The final remaining custom policy out of the duplicates when pushed using `archive:push` will be pushed to all spaces within the same catalog. This is the correct behavior of the v10 API migration utility. For more details about pushing custom policies at the catalog (space) scope, see [Importing a user-defined policy into a Catalog](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Migrating gateway extensions

Use the appropriate procedure for migrating extensions to either a v10 DataPower® Gateway (v5 compatible) or a v10 DataPower API Gateway.

## Migrating gateway extensions to a v10 DataPower Gateway (v5 compatible)

---

### About this task

Follow these steps to migrate gateway extensions to a v10 DataPower Gateway (v5 compatible).

### Procedure

Follow all migration utility steps to migrate to a v5-compatible DataPower Gateway. For instructions, see [Migration steps](#).

The gateway extensions are automatically extracted as part of the `archive:unpack` step. No further manual steps are required.

### Results

The v5 extension zip file is pushed to the DataPower Gateway (v5 compatible) service.

Note: Only one gateway extension per gateway service can be used.

## Migrating gateway extensions to a v10 DataPower API Gateway

---

### Before you begin

Note: When migrating v5 extensions to v10 API Gateway, the v5-emulation layer is used to ease compatibility for any pre-request or post-response global assemblies it contains. For more information, see [v5 policy emulation limitations](#).

The following limitations apply to migrating gateway extensions to a v10 DataPower API Gateway.

- Post-request assemblies are not compatible with the API Gateway and cannot be migrated using this process. Pre-request, post-response, and post-error can be migrated using these steps.
- Any modifications to the DataPower v5 Multiprotocol Gateway cannot be migrated using these steps because the API Gateway does not use a Multiprotocol Gateway. The modifications will still be in the `gateway-extension.zip` that is pushed to API Manager, and the artifacts might still be imported to DataPower. These artifacts can be deleted from the DataPower appliance.
- Any load-balancer modifications cannot be migrated using these steps as the load-balancer DataPower object is not used in the same manner in the API Gateway. These artifacts can be deleted from the DataPower appliance.

### About this task

You can migrate pre-request and post-response global assemblies contained within v5 extensions to API Gateway using the v5-emulation layer. The migration utility bundles the entire v5 extension file and groups them by gateway service during the `port` step. During the `push` step, the v5 extensions are pushed to the Gateway Service, and pre-hook and post-hook global assemblies are enabled using global policy files that were generated previously during the `port-to-apigw` step. DataPower object modifications or additions that are not v5 framework changes or load-balancer changes are also automatically imported during this step.

Global assemblies that are pre-request or post-response are utilized through the v5-emulation layer as an Assembly Function. They are referenced by the global policy files auto-generated by the migration utility during the `port-to-apigw` step.

## Results

The `gateway-extension.zip` file is pushed to the DataPower API Gateway service.

Note: Only one gateway extension per gateway service can be used at a time. However, the manifest extension allows a vector of multiple extensions contained within the single `gateway-extension.zip` that is pushed to the single gateway service.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Migration considerations

You can optimize the migration process by reviewing the migration considerations and taking any actions that apply to your deployment.

Review the following information:

- [Limitations and workarounds](#)
- [Version 5 data that is not migrated](#)
- [Parity between Version 5 and Version 10](#)
- [Customizations to recreate](#)

---

## Limitations and workarounds

- For an **Admin organization**, you must be logged in as `admin` in order to migrate TLS profiles, OAuth providers, and user registries.
- The `apicm` login token expires after eight hours. If the token expires while `apicm archive:push` is running, `apicm` generates errors due to lack of the necessary access permissions. There are two workarounds:
  - Log in again and re-run `apicm archive:push`. The token is refreshed with each new login.
  - Extend the token expiration time by logging in again with an optional argument: `-expireHours=<number_of_hours>`. See [Token expiration](#).
- When migrating catalog spaces in a provider organization that uses a local user registry (LUR), ensure that the LUR is configured with the visibility setting of either **Public** or **Custom**. If set to Custom, ensure that the provider organization is selected. For information on configuring registries, see [Setting visibility for a user registry](#).
- Migration of version 5 username token policy for authenticating the username token is not supported.
- Unable to publish, on version 10, products that contain an API with a Swagger property using **regex** that includes "?" in the characters for the pattern. You can expect to see an error message similar to the following:

```
(? The preceding token is not quantifiable
```

- The migration utility validates Products and APIs against the OpenAPI specification. The `archive:unpack` command issues warnings for any Product or API that fails validation. To resolve warnings, fix the Product or API and re-run the `unpack` command. Validation is not performed on draft Products and draft APIs. Example warning:

```
WARN[0019] Error validating product cloud/provider-orgs/onlinebanking/catalogs/test/products/clientipfilter-policy-test-api-1.0.0.yml:
Validation errors:
Error validating API cloud/provider-orgs/onlinebanking/catalogs/test/products/api123-1.0.0.api.yml
- Must validate one and only one schema (oneOf) (context: (root).securityDefinitions, line: 36, col: 3)
- securityDefinitions.authorizationUrl Does not match format 'uri' (context: (root).securityDefinitions.authorizationUrl, line: 0, col: 0)
```

- OAuth Provider APIs:
  - To ensure that APIs that use OAuth security definitions are mapped to the corresponding OAuth Provider APIs in version 10, make sure that either the Authorization URL or the Token URL defined in OAuth Security Definitions of APIs that use OAuth correctly point to the base path of the OAuth Provider API. Note that the Migration tool uses that logic to map Consumer APIs to Provider APIs, and adds `x-ibm-oauth-provider` in the OAuth Security Definition of the consumer API.
  - To verify whether OAuth Provider APIs are migrated correctly, ensure that all the APIs that use OAuth Security Definition have the new field `x-ibm-oauth-provider` added. Check the value of that field and make sure it points to a correct OAuth Provider resource object that was created and configured in the catalog to which the API is published.
  - In version 5 OAuth Providers are a specialized type of API that are published within products. In version 10, OAuth Providers are first class objects that are directly published in the provider organization and are not APIs that are published within products. Because of this, it is possible that you may have some version 5 products that only contained OAuth Provider APIs. Since these products do not contain any Open API definitions in version 10, they will not be published because all products in version 10 must contain at least one Open API definition.
- Automatic migration of vendor extensions is not supported. The version 5 `dbextract` output includes the original content of vendor extensions, but this output is not automatically unpacked by the `apicm archive:unpack` command. You must use your original zip files when manually configuring vendor extensions in a version 10 environment. Use the CLI to create the extensions you need. See the reference page for `apic extensions:create`: [apic extensions:create](#).
- Portal Delegated User Registry migration limitations
  - Automated migration is not supported for some version 5 PDUR OIDC registries. You must manually supply the `client_id` and `client_secret`. See Step 6 in [Migration steps with PDUR](#).
  - LDAP User Registry - automated configuration of the registry is not supported. You can configure manually. See Step 6 in [Migration steps with PDUR](#).
- The SCIM (System for Cross-domain Identity Management) user registry type was supported in Version 4 but was deprecated for Version 5. The SCIM user registry type is not supported in version 10. If data with a SCIM identity provider type is detected during migration of version 5 data, the migration utility logs an error message:

```
WARN[0614] manual fix required for cloud/provider-orgs/apimteam/user-registries/scimcv/user-registry.yml:
The SCIM user registry type is no longer supported
```

Any v5 data with a SCIM identity provider type must be manually migrated. For version 10, you can use OIDC with a backend user registry that supports SCIM. You must develop custom code to complete the data flow between the OIDC provider and your backend user registry. The API Connect built-in OIDC registry interacts with your OIDC provider.

- Roles limitations  
Previously, in API Connect 5, it was possible to create a role (and associated permissions) at the organization level. This same role was inherited by the catalogs within this org. With the version 5 inheritance model it was possible to modify the inherited role and add/remove permissions from it.  
  
In API Connect 10 the inheritance model has changed. It is no longer possible to remove permissions from an inherited role. Because of this design change, it becomes difficult to perform a true 1-to-1 migration keeping the original parent-child relationships. For example, in version 5 it was possible for an inherited role to contain less permissions than its parent role. This is parent-child relationship is not allowed to exist for roles in API Connect 10.  
  
In order to work-around this restriction, the parent-child relationship is purposely decoupled during migration. The child-level roles are treated as individual roles, separate from the original parent. However, the child-level roles cannot exist by themselves without a parent role. So, to satisfy this restriction a new artificial parent role is created for each of the children roles.
- Modifications made to default roles in version 5 are not migrated to version 10.
- If the version 5 settings `server_name_indication` and `limit_renegotiation` are not specified, the value defaults to `true`. However if they are specified with value of `false` that value is changed to `true`. Thus the settings are always `true`.
- Custom policies and Version 5 emulated policies  
For custom policies and Version 5 emulated policies, such as the Invoke 1.5.0 policy, to be available for migrated API or OAuth provider assemblies, the Sandbox Catalog in the target provider organizations must have the associated DataPower® API Gateway service enabled; see [Creating and configuring Catalogs](#).
- Subscriptions on staged products are not be automatically migrated because in version 10 staged products cannot have subscriptions on them. In order to save those subscriptions you must change the state of the product to either deprecated or published before doing the `archive:push`. You can do this either in version 5 before running `dbextract`, or you can do it after the `dbextract` through mapping or editing of the product metadata and modifying the state of the product. If you have already pushed the staged product then you can publish the product in your version 10 environment and rerun `archive:push` in order to migrate the subscriptions.
- The migration utility appends `-apigw` to the end of the `x-ibm-name` of APIs to maintain uniqueness from the original version 5 artifacts. Therefore, custom backend services that rely on the `x-ibm-name` of the APIs to be matched must be updated to look for `-apigw` in the new API name. Alternatively, the custom backend service can be modified to strip `-apigw` from the API name.

## Version 5 data that is not migrated

- APIs with LTPA policies are not migrated as this policy is not supported in version 10.
- Configuration in version 5 for gateway type `Microgateway` is not migrated because `Microgateway` is not supported in version 10.
- Transient or conflicting configuration data is not migrated
  - Tasks that are still active are not included in the Version 5 backup. For example, lifecycle approvals or subscription approvals that have been requested but not granted.
  - Drafts on version 5 that are local are not migrated. If you have draft APIs or draft products that you want migrated to version 10, use `apic drafts:push` to upload them prior to starting migration. See [Working with drafts](#).
  - Pending invitees in user registries are not migrated.
  - Pending invitations for ownership of provider organization. Consumer organizations with pending ownership are migrated. If the Version 5 owner received an invitation for ownership but never accepted it, the owner identity is not migrated. This causes the organization to not be migrated. To avoid this issue, check for any unaccepted invitations prior to migration, and ensure they are accepted.
  - Conflicting user names within the same identity provider are not migrated.
  - Conflicting OAuth provider names or base paths. If the migration utility encounters conflicting names or base paths for OAuth providers, the provider is not migrated.
- OAuth Shared secret keys are not migrated unless you explicitly map them in the mapping.yml file for the gateway.
- Organizations without an active owner (user identity) are not migrated

On the Version 5 deployment, verify that the owners of provider organizations and consumer organizations are current user identities. If the user identities of the owners no longer exist the identities are not migrated. One effect of this is that if the original owner of the organization is an identity that was not migrated, the provider organization or consumer organization cannot be migrated.

- Version 5 Analytics data is not migrated

If you want to retain Version 5 analytics data, offload your Analytics prior to migrating to Version 10. Note that in Version 5 the analytics data is retained only for 90 days. For more information on Version 5 support for archiving Analytics data, see [Viewing and exporting analytics and API event data](#).

## Parity between Version 5 and Version 10

- The migration utility slugifies the names and versions of some elements when moving from version 5 to version 10 to ensure that each element in version 10 passed Open API schema validation and that each is uniquely named. For the names of API properties, Catalogs, Provider Orgs, Consumer Orgs, Spaces, and some other elements, any character other than `a-z`, `0-9`, or `-`, is converted to `-` and a unique suffix based on the checksum of the name or version is added. Uppercase letters are changed to lowercase, with `-` added between words. Leading `-` characters are removed, and multiple consecutive `-` characters are reduced to a single `-`. For versions of similar elements, the `.` (period) character is also allowed. Examples:

| Version 5 name | Example migrated name on version 10                             |
|----------------|-----------------------------------------------------------------|
| abc-def        | abc-def (no change)                                             |
| Abc            | abc-a2c6                                                        |
| AbcDef         | abc-def-dfc                                                     |
| Abc Def        | abc-def-1e82<br>With <code>slugify-no-checksum</code> : abc-def |
| abc_def        | abc-def-c2bb                                                    |
| abc--def       | abc-def-813d                                                    |
| -abc-def       | abc-def-abb                                                     |
| ABC-DEF        | abc-def-d1e                                                     |

| Version 5 version | Example version on version 10 |
|-------------------|-------------------------------|
| 1.0.0             | 1.0.0 (no change)             |
| 1.0_2             | 1.0-2-3933                    |
| 1.0 2             | 1.0-2-913                     |
| 1.0--2            | 1.0-2-5410                    |

| Version 5 version | Example version on version 10 |
|-------------------|-------------------------------|
| -1.0-2            | 1.0-2-26cf                    |

You can use `apicm sluggify <arg>` to view how a name or version will be sluggified:

```
$./apicm sluggify Abc
abc-a2c6
$./apicm sluggify -v 1.0_2
1.0-2-3933
$./apicm sluggify --version '1.0 2'
1.0-2-913
```

- Version 10 does not support Spaces within the Sandbox Catalog. Spaces in Sandbox Catalogs are not migrated from Version 5 to Version 10. The names of Spaces found in Version 5 Sandbox Catalogs are logged in the migration output log. You can use a mapping file to rename the Sandbox Catalogs in order to preserve Spaces.
- In version 10, publish of an API will fail if `enforced` is set to `true`, and `phase` is set to either `Specified` or `Identified` instead of `Realized`. During migration the phase will be set to `Realized` in this case, so that the API can be successfully published.
- Enforcement of user subscription to an API is handled differently between version 5 and version 10. In version 5, subscription to a product is **not** allowed in the following scenario: An API is created with `enforced` set to `false`. The API is associated with a product, the product is published, and a user attempts to subscribe to a Product or Plan from the Developer Portal. In version 10, the subscription **is** allowed for this scenario. This change can affect migration because a version 5 Product that could not be subscribed to in version 5 can be subscribed to in version 10. Note that the change in behavior for version 10 accommodates the scenario where Products or Plans have multiple APIs, some of which are enforced and some of which are not enforced. The new behavior allows such Products or Plans to be subscribed to.
- In version 10, the API Manager handles all authentication methods. This change eliminates the need for configuration of a catalog with a Portal Delegated User Registry (PDUR). See [Migration steps with PDUR](#).
- If `OpenAPI.info.contact.email` contains more than one email address, only the first email is used by migration. If the email is not in valid RFC5322 email format then it is removed during migration.
- Provider-side applications  
In API Connect, registered applications are a fundamental concept representing an application identity known to the system. Applications have their own credential sets in the form of client ID and client secret pairs, and access to published API endpoints is governed by subscriptions associated with registered applications. Most commonly, registered applications are created by app developers belonging to a consumer organization in the context of a developer portal.

However, API Connect 5 also provides the ability for provider organizations to register and manage applications, independent of any consumer organization. Provider-owned apps behave in the same way as consumer-owned apps and carry credentials and subscriptions in exactly the same way. Customers use provider-owned applications for API testing or for cases where the app and API are owned and managed directly by the same team.

The API Connect 10.x platform API does not support the creation of provider-side apps, so migration of provider-side apps is only possible if they are converted to consumer-side apps. Each provider-side app is migrated as follows by the API Connect migration utility:

- An instance of the app including its credentials (sets of client ID and secret) is created in each catalog belonging to the provider organization.
- The app is owned by a consumer organization which is the existing Sandbox Test Organization (for the provider organization's automatically created sandbox catalog) or a consumer organization named `Catalog-name Test Organization` (for other catalogs).
- The consumer organization's owner is a user named `test-user`. This user name already exists in the context of a provider organization's automatically created sandbox catalog.
- The consumer organization's owning user belongs to a user registry named `catalog-name-test-org`.
- The subscriptions belonging to the original provider-side app are retained.

These definitions are added to the relevant locations subordinate to the `cloud/` directory that is produced by the `apicm archive:unpack` command. When an `apicm archive:push` is performed, the definitions are propagated to the target system as part of the overall configuration.

## Customizations to recreate

Version 5 provides methods to customize some configurations. After you complete the automated migration, manually reapply the following customizations.

- Customized email templates  
Customized email templates are not migrated from Version 5. You can customize email templates in Version 10 with greater flexibility and precision. See [Customizing email templates](#).
- Developer Portal customizations are not migrated to a new Drupal version  
For the Developer Portal, none of the customizations are migrated because the Version 10 Drupal 9 baseline differs greatly from the Version 5 Drupal 7 baseline. This means that custom portal themes, custom modules, custom fields, custom blocks, custom pages, and more, cannot be migrated. For more information, see [Migrating your Developer Portal from Version 5 to Version 10](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Migration troubleshooting

If you run migration and observe error messages in your log output, you can take troubleshooting steps, and run the migration again.

- [apicm command line help](#)
- [Log files for apicm](#)
- [Common errors](#)
- [Common errors with OAuth Providers](#)
- [Error messages and warnings from archive:unpack](#)
- [Error messages and warnings from archive:push](#)
- [Troubleshooting tips](#)

- [Failure to convert API definitions to API Gateway](#)
- [Custom policies not appearing in the policy palette after migration](#)

## apicm command line help

You can use command line help to review usage syntax for **apicm**. For example:

```
./apicm help
APIConnect migration toolkit

Usage:
 apicm [command]

Available Commands:
 archive:port-to-apigw Port artifacts to apigw
 archive:push Push catalog archive content to APIConnect server
 Locate PLATFORM_API_ENDPOINT in the apiconnect-up.yml file used during apic install
 archive:unpack Unpack a V5 management/portal archive
 help Help about any command
 login Log in to IBM API Connect
 version APIConnect migration toolkit version
```

```
Flags:
 -h, --help help for apicm
```

Use "apicm [command] --help" for more information about a command.

Example usage for more information about a command:

```
$./apicm archive:push help

Usage:
 apicm archive:push PLATFORM_API_ENDPOINT ARTIFACT_PATH [flags]

Flags:
 --apigw-only Only attempt to push APIGW artifacts
 --dry-run Prepare the working directory but do not push to server
 -h, --help help for archive:push
 -f, --overwrite Delete and re-push resource if it exists on server
```

## Log files for apicm

The **apicm** command creates log files that you can use to review messages produced by the **unpack** and **push** actions. All logs are saved in the **logs** directory. Unique files are saved for each run. All default log names can be overridden via the command line.

### Error log

Includes all warning and error level messages. Default file:

```
logs/ErrorMsg<timestamp>.log
```

You can optionally give the file a different name:

```
apicm --saveErrorMsg= '<filename>'
```

For example:

```
apicm archive:unpack apic33-2020-02-19-1650.tar.gz --saveErrorMsg= 'unpack.txt'
```

This command creates a file **unpack.txt** in the logs directory:

```
~/example/migration-cli/logs/unpack.txt
```

### Info Log

Includes all info, warning and error level messages. Default file:

```
logs/InfoLog<timestamp>.log
```

You can optionally give the file a different name:

```
apicm --saveInfoLog= '<filename>'
```

For example:

```
apicm archive:unpack apic33-2020-02-19-1650.tar.gz --saveInfoLog= 'unpack_info.txt'
```

This will create a file **unpack\_info.txt** in the logs directory:

```
~/example/migration-cli/logs/unpack_info.txt
```

### Debug Log

Includes all info, warning, error and debug level messages. If you encounter errors or limitations that are not documented on this page, access the **DebugLog<timestamp>.log** which located in the directory where you extracted **apicm**. Contact your IBM representative for help with using the Debug log.

```
logs/Debug/DebugLog<timestamp>.log
```

## Common errors

You can use the **--saveErrorMsg** flag to specify that all the errors are saved in a file in **logs** folder, as described in [Saving the error log](#). Common errors:

- API Validation Failed:

This error occurs when an API within the v5 extract does not conform to the Open API specification. Due to stricter validation on v10, the API must be corrected to get added to the new system in v10. Use the error message and particular files references to resolve the API issue. The error is usually caused by a missing property definition default or invalid default value.

Example:

```
time="2020-01-27T18:15:24-08:00" level=error msg="unable to create Product access-points:1.0.0"
time="2020-01-27T18:15:24-08:00" level=error msg="access-points:1.0.0: API property 'authURL' does not have default value."
time="2020-01-27T18:15:24-08:00" level=error msg="access-points:1.0.0: The multipart 'openapi' field contains an OpenAPI definition accesspointsoap:1.0.0 (AccessPointSoap) that has validation errors."
```

Following is the section of the AccessPointSoap API definition for the concerned API where the field in question exists:

```
EFS-PerfTest:
 properties:
 authURL:https://test1.example.com/test-icdc/efs-perftest/reststub/25
 invokeURL:https://test1.example.com/test-icdc/efs-perftest/fivekbsoap/650
```

The backend does not expect `authURL` field as a part of the properties and hence is validation fails.

- Long chain of error messages hours into a **push**:  
This scenario typically occurs due to expiration of an authentication token. To resolve this issue, either reauthenticate and or extend the token timeout. See [Token expiration](#).
- Unable to find User Registry when migrating (pushing) a provider-org:  
Occurs when the `admin-org` user registry artifacts are not shared prior to pushing provider organization artifacts. To resolve the issue, use the cloud admin account to change the visibility of the registry to `public`, and **push** the provider organization again.
- Unable to find `xxxx` when migrating (pushing) a provider organization:  
Occurs when `admin-org` artifacts are not pushed prior to pushing provider organization artifacts. Ensure that all of admin org data is pushed without errors, and then **push** your provider organization again.
- `Object.PropertyName` does not match format `uri`  
This error occurs during artifact validation when a specific property does not match a proper URI identifier. Check the mentioned field and change it to its proper URI format (<https://example.com/optionalPath>)
- Unable to create an identity provider portal-delegated-identity-provider `xxxx` because the PDUR backup data is not provided.  
This error occurs if certain Portal delegated user registries are missing from the PDUR extract provided. If the missing user registries are not no longer used, they can be skipped. If they are still used, you must create a fresh backup of the PDUR.
- Unable to create product `xxxx`. The OpenAPI definition `<xyz>` requires the policy `<sample-policy>` that is not configured on the gateway-service `<sample-gateway>`:  
This error occurs when the specified policy is not configured on the gateway for the catalog that contains the product. To resolve this, you must configure, on the v5 system, the specified policy on the gateway for the catalog, and re-extract the data.
- Fixing API Errors  
When encountering API issues, you might see the following error:  

```
WARN[0100] skipping product "EXAMPLE/FILE/PATH" one or more OpenAPI definitions are invalid
```

  
Prior to this error, you will see some additional lines that detail the particular issues with the OpenAPI definition.  
  
For example:  

```
WARN[0100] - Additional property bakonline.backend.url is not allowed (context:
(root).x-ibm-configuration.catalogs.properties, line: 0, col: 0)
```

  
In this example, the property `bakonline.backend.url` with element at `x-ibm-configuration.catalogs.properties` in the OpenAPI spec is broken. Remove or correct the incorrect property.
- For `apicm archive:push:Error: A resource of type gateway_extension with the key <key_value> already exists.`  
When multiple v5 gateway services are mapped to the same API Gateway, then custom policies of only the first gateway service are migrated. Note, that if custom policies are not used, the following error is generated, but can be ignored:  

```
An error occurred while attempting to push
.workdir-api.example.com-1589574253/cloud/admin-org/availability-zones/availability-zone-default/gateway-services/dp612-upgrade/gateway-extension.zip.
Error code: 409, Reason: [A resource of type gateway_extension with the key
cf763bf9-9827-4fb6-92d7-7d9a5eae14be:eed7875b-036f-43de-ad82-dc34ee6670df:b67614e2-e27b-4e46-9a4d-2b8bab879164 already exists.]
```
- v5 emulated policies and custom policies not deployed to gateway. Make sure the following was done during the migration steps:
  - xml-manager is enabled in default domain of all gateways
  - Mapping of gateways was done before the porting step
  - gateway-extension.zip shows up under `cloud/admin-org/availability-zones/availability-zone-default/gateway-services/<gw-name>/gateway-extension.zip`
  - Ensure push of admin-org is done after all of the above is verified

## Common errors with OAuth Providers

- Message: `Multiple OAuth Providers matching basePath: <X> and scopes: <Y>....`  
Occurs when the migration utility attempts to match an OAuth Provider to an API but cannot determine a single matching OAuth Provider. In this case, the utility lists all of the matching OAuth Providers and selects the first one. If this selection is not correct, you must manually set the OAuth Provider in the `.ym1` file for the API.

- **Message: Could not find an OAuth Provider that matches calculated basePath: <X> but did find one to match the Scopes: <Y>**  
Occurs when the migration utility could not properly calculate the basePath from the TokenURL or AuthorizationURL of the API, but was able to find an OAuth Provider based upon matching Scopes. In this case, the TokenURL or AuthorizationURL is overridden with a working value. Verify that the match and calculated values in the API are correct.
- **Message: Could not find an OAuth Provider than matches calculated basePath: <X> but did find multiple that match the Scopes: <Y>**  
Occurs when the migration utility could not properly calculate the basePath from the TokenURL or AuthorizationURL of the API, but found multiple OAuth Providers based upon matching Scopes. In this case, the TokenURL or AuthorizationURL are overridden with a working value, and all matching OAuth Providers are listed, and the utility selects the first one. If this selection is not correct, you must manually set the OAuth Provider in the .yaml file for the API.
- **Messages Unable to find an OAuth Provider to extract from Token URL or Authorization URL %s with basePath %s and scopes %s**  
Occurs when the migration utility could not match the basePath and Scope to an existing OAuth Provider. The utility creates a placeholder OAuth Provider value for the API in the .yaml file. You must replace it with the appropriate OAuth Provider. In the .yaml file, you must also set the TokenURL or AuthorizationURL and the scopes to acceptable values. This error message can occur when the appropriate OAuth Provider was not migrated.

## Error messages and warnings from archive:unpack

- "AMUUAU000E": "The migration tool failed to initialize."  
The migration utility could not access files or directories needed to establish its working environment. Ensure that file permissions allow write access to the current working directory and that the cloud directory is empty or non-existent.
- "AMUUAU001E": "The {{.Type}} {{.Name}} contains content that could not be unpacked and will not be included."  
The migration utility is unable to read the API Connect v5 representation of an object in the migration archive. This content is skipped and will not appear in the unpacked migration data.
- "AMUUAU002F": "The archive content at {{.DocPath}} cannot be read."  
The migration utility is unable to read the internal contents of a collection in the API Connect v5 migration archive. This is likely to indicate a corrupt migration archive file. The archive:unpack operation cannot be completed.
- "AMUUAU003E": "The portal delegated user registry file {{.File}} cannot be unpacked and will be skipped."  
The migration utility is unable to read a PDUR archive. User information associated with this user registry will not be included in the unpacked migration contents.
- "AMUUAU004E": "The archive content at {{.FilePath}} cannot be read and will not be unpacked."  
The migration utility is unable to read the internal contents of an individual file in the API Connect v5 migration archive. This is likely to indicate a corrupt migration archive file. This content is skipped and will not appear in the unpacked migration data.
- "AMUUAU005W": "{{.Type}} {{.Name}} requires updating before it can be pushed to a target system."  
The migration utility has unpacked a configuration object for which modifications are required because the content is incorrect or missing information required by a target API Connect v10 system. The unpacked file must be updated by the user before it can be published successfully to the target system.
- "AMUUAU006W": "The {{.Type}} {{.Name}} has been linked to OAuth provider {{.Provider}}. Please update the security definition {{.Security}} if another OAuth Provider should be used instead."  
The migration utility has added a reference from an OAuth security definition in the named API to an OAuth provider resource. The migration utility uses the authorization URL, token URL and scope information where possible to determine which OAuth provider resource is to be used with each OAuth-secured API. In some cases, the migration utility cannot accurately determine which OAuth provider is intended for use with a particular API. The OAuth provider reference can be modified if needed by editing the security definition in the unpacked API file and changing the x-ibm-oauth-provider property value to match the intended OAuth provider resource. The reference value is a relative file path that identifies an unpacked OAuth provider resource.
- "AMUUAU007W": "The {{.Type}} {{.NameVersion}} could not be linked to an OAuth provider. Please update the security definition {{.Security}} to select an OAuth provider."  
The migration utility has been unable to add a reference from an OAuth security definition in the named API to an OAuth provider resource.  
  
The migration utility uses the authorization URL, token URL and scope information where possible to determine which OAuth provider resource is to be used with each OAuth-secured API. In some cases, the migration utility cannot accurately determine which OAuth provider is intended for use with a particular API. The OAuth provider reference can be added by editing the security definition in the unpacked API file and setting the x-ibm-oauth-provider property value to match the intended OAuth provider resource. The reference value is a relative file path that identifies an unpacked OAuth provider resource.
- "AMUUAU008W": "{{.Type}} {{.Name}} could not be introspected for OAuth provider API references."  
The migration utility has attempted to determine which OAuth providers should be configured in support of an API product, but a reference to an OAuth provider API in the product cannot be correlated with an OAuth provider resource.
- "AMUUAU009W": "{{.Type}} {{.Name}} contains invalid content that cannot be unpacked."  
The migration utility has encountered an entry in the API Connect v5 migration archive that contains unexpected or corrupt data. This content is skipped and will not appear in the unpacked migration data.
- "AMUUAU010E": "{{.Type}} {{.Name}} cannot be unpacked to the local filesystem."  
The migration utility has attempted to unpack an entry in the API Connect v5 migration archive that could not be written to the local filesystem during the archive:unpack operation. This may be the result of a local file permissions problem, an unexpectedly long file name resulting from the unpack, or a shortage of space on the local filesystem.
- "AMUUAU011E": "{{.Type}} {{.Name}} contains a {{.Target}} reference that cannot be resolved."  
The migration utility has encountered a SOAP API entry in the API Connect v5 archive that refers to a WSDL definition that cannot be found in the archive. This entry will not be included in the unpacked content.
- "AMUUAU012W": "The {{.Type}} {{.Name}} contains a {{.Target}} reference that cannot be resolved."  
The migration utility has encountered an entry in the API Connect v5 archive that refers to another entry that cannot be found in the archive. This entry will not be included in the unpacked content.
- "AMUUAU013E": "Portal delegated user registry information could not be loaded for user registry {{.Name}}."  
The migration utility has encountered a portal delegated user registry definition in the API Connect v5 archive for which no PDUR file name has been provided as an argument to the archive:unpack command. The user registry contents will not be included in the unpacked content.
- "AMUUAU014E": "The migration tool failed to load content for the admin organization."

The migration utility was unable to find the admin organization while unpacking provider organization information in the API Connect v5 archive. This is likely to result in further errors while unpacking the provider organization contents.

"AMUUAU015E": "The migration tool failed to load provider organization contents."  
 The migration utility was unable to find the load provider organization contents while unpacking the API Connect v5 archive. This message indicates an internal error with the migration utility.

"AMUUAU016E": "The {{.Type}} information belonging to organization {{.Org}} could not be unpacked."  
 The migration utility was unable to process the provider organization contents while unpacking the API Connect v5 archive. This message indicates an internal error with the migration utility.

"AMUUAU017W": "The settings update for {{.Type}} {{.Name}} could not be completed."  
 The migration utility was unable to update the settings for a configuration object while unpacking the API Connect v5 archive.

"AMUUAU018E": "Apps belonging to provider organization {{.Org}} could not be converted to consumer apps."  
 The migration utility was unable to convert registered applications belonging to the provider organization into applications in each catalog. The conversion occurs because the representation of applications differs between API Connect v5 and API Connect v10. This message indicates an internal error in the migration utility.

"AMUUAU019W": "User registry {{.UserRegistryName}} must be migrated to a different user registry type."  
 The migration utility has encountered a user registry in the API Connect v5 migration archive that is not directly supported in API Connect v10. User entries can be migrated if a mapping file is used to override the user registry name and refer to another user registry that has been created in the target API Connect v10 environment.

"AMUUAU020W": "User {{.User}} in portal delegated user registry {{.Registry}} is not associated with any OIDC provider and will be skipped."  
 The migration utility has encountered a user entry in the API Connect v5 migration archive that belongs to a portal delegated user registry but cannot be associated with any backing identity provider. This can occur if no PDUR export file has been provided, or if the user entry information is incomplete.

"AMUUAU021W": "The TLS profile {{.Name}} includes an unsupported protocol {{.Protocol}} that will not be included in the configuration."  
 The migration utility has encountered a TLS profile entry in the API Connect v5 migration archive that uses a protocol that is not supported in the API Connect v10 environment. This protocol will be omitted from the unpacked entry for the TLS profile.

"AMUUAU022W": "User {{.UserName}} ({{.ID}}) will need a password reset"  
 The migration utility has encountered a user entry in the API Connect v5 migration archive that is associated with a local user registry but does not have a password configured. The user entry will be migrated, but the user's password reset must be reset before logging in. This may occur when user registry mappings are used to migrate users to a local user registry from some other user registry type.

"AMUUAU023W": "Uniqueness of names cannot be guaranteed when using the --sluggify-no-checksum option during unpack"  
 The archive:unpack command has been invoked with an option that could in unusual cases result in duplicate names being used for different unpacked entries. This is likely only for names with near-identical spelling but differ only in their use of upper and lower case letters or symbols that are converted to a hyphen during the unpack process. If duplicate names appear for entries of the same type in the same context, further messages indicating problems with the duplicate will appear.

"AMUUAU024E": "The stats summary could not be generated"  
 The migration utility was unable to produce information listing the total numbers of entries of different types that were unpacked from the API Connect v5 migration archive. This message indicates an internal error in the migration utility.

"AMUUAU025I": "The {{.Type}} {{.Name}} contains an invalid value that will be removed."  
 The migration utility has encountered an entry in the API Connect v5 migration archive that contains a value that is not valid for the property in which it appears. The invalid value is automatically removed. This can occur with values such as email or URL properties that contain values that do not match the required format.

"AMUUAU026I": "The {{.Type}} {{.Name}} contains an invalid value that will be replaced."  
 The migration utility has encountered an entry in the API Connect v5 migration archive that contains a value that is not valid for the property in which it appears. The invalid value is automatically corrected. This can occur with values such as email or URL properties that contain values that do not match the required format.

"AMUUAU027W": "The product subscription {{.Name}} cannot be pushed to the target system."  
 The migration utility has encountered a subscription entry in the API Connect v5 migration archive that refers to a product that is in a state that does not allow subscriptions. The subscription is removed and will not appear in the unpacked data.

"AMUUAU028E": "The migration tool failed to create default roles for {{.Type}} {{.Name}}."  
 The migration utility has encountered an error while attempting to create the default roles for an organization, catalog, or space. This may be the result of a local file permissions problem or a shortage of space on the local filesystem.

"AMUUAU029W": "The OAuth provider {{.OAuthProvider}} with base path {{.BasePath}} could not be unpacked."  
 The migration utility has failed to create an OAuth Provider with a particular base path. This can occur if there is an OAuth provider of this name with a different base path that has already been created in this provider organization. In API Connect v5, OAuth providers existed at the catalog level. In API Connect v10, they exist at the provider organization level, which can cause this issue to occur.

## Error messages and warnings from archive:push

"AMUAP001E": "The {{.Type}} {{.Name}} contains nested content that cannot be published."  
 The migration utility is unable to read or load nested configuration content during the archive:push operation. After the migration unpack has been completed, some configuration objects are comprised of a directory with one or more nested files. For example, information about catalogs in their unpacked form consists of a directory with a name matching the catalog name, and a nested catalog.yml and catalog-settings.yml file. This message indicates that one or more of these files cannot be opened or loaded.

"AMUAP002E": "The {{.Type}} {{.Name}} cannot be published."  
 The migration utility is unable to read or load configuration content during the archive:push operation. This message indicates that the file representing the named configuration object is unreadable or contains unexpected content.

"AMUAP003W": "Skipping mapping file {{.Name}}."  
 The migration utility found a mapping file (mapping.yml) with invalid contents. The archive:push operation proceeds as if this mapping file were not present.

"AMUAP004E": "The file {{.Filepath}} could not be loaded and will not be published."  
 The migration utility is unable to read or load configuration content during the archive:push operation. This message indicates that the file representing a configuration object cannot be read or loaded.

"AMUAP005E": "The file {{.Filepath}} contains references that could not be loaded and will not be published."  
 The migration utility is unable to read or load configuration content during the archive:push operation. This message indicates that the file representing a configuration object cannot be read or loaded.

"AMUAP006E": "Unable to update reference to {{.Path}} in file {{.File}}."  
 The migration utility is unable to resolve a reference in the named file to another configuration object. This message indicates that the content in the file refers to other objects that are not found in the unpacked content, or the referenced content is not of the expected format.

"AMUAP007E": "The {{.Type}} {{.Name}} cannot be published because of a missing prerequisite."  
 The migration utility is unable to publish the named object because it refers to another object that cannot be found in the target API Connect system. This message indicates that the object contains an incorrect reference, or that the referenced object has not been successfully created or has been deleted from the target system.

"AMUAP008W": "The update to the {{.Type}} {{.Name}} could not be verified and may not have been successful."  
 The archive:push operation has attempted to update an object in the target API Connect system, but the results of the update were not received or indicated an error. This can occur in the event of a network interruption or timeout between the migration utility and the target API Connect system. If this occurs, it is safe to

retry the `archive:push` operation; the same update will be attempted.

"AMUAP009E": "The `{{.Type}}` `{{.Name}}` was not published because it could not be checked in the target system."

The migration utility has attempted to check the existence of an object in the target API Connect system, but the check did not complete successfully. The migration utility will not overwrite objects in the target system if it cannot successfully determine whether or not a conflict will occur.

"AMUAP010W": "The creation of the `{{.Type}}` `{{.Name}}` could not be verified and may not have been successful."

The migration utility has attempted to create an object in the target API Connect system, but the results of the creation were not received or indicated an error. This can occur in the event of a network interruption or timeout between the migration utility and the target API Connect system. If this occurs, it is safe to retry the `archive:push` operation; if the named object was created, then it will subsequently be skipped unless the overwrite option is used.

"AMUAP011W": "The deletion of the `{{.Type}}` `{{.Name}}` could not be verified and may not have been successful."

The migration utility has attempted to delete an object in the target API Connect system, but the results of the deletion were not received or indicated an error. This can occur in the event of a network interruption or timeout between the migration utility and the target API Connect system. If this occurs, it is safe to retry the `archive:push` operation.

"AMUAP012W": "The ownership transfer of the `{{.Type}}` `{{.Name}}` could not be verified and may not have been successful."

The migration utility has attempted to transfer ownership of an object in the target API Connect system, but the results of the ownership transfer were not received or indicated an error. This can occur in the event of a network interruption or timeout between the migration utility and the target API Connect system. If this occurs, it is safe to retry the `archive:push` operation.

"AMUAP013E": "The endpoint settings for catalog `{{.Name}}` could not be updated."

The migration utility has attempted to update the endpoint settings for a catalog in the target API Connect system, but the update was not successful. This can occur if the catalog settings refer to a gateway service for which the configuration cannot be found in the unpacked migration contents.

"AMUAP014E": "The `{{.Type}}` `{{.NameVersion}}` could not be `{{.Action}}` in the target system."

The migration utility has attempted to create or modify an object in the target API Connect system, but the target system returned an error. The reason associated with the message indicates the error returned by the server.

"AMUAP015E": "The gateway extension for the gateway service `{{.Name}}` could not be published."

The migration utility has attempted to publish a gateway extension zip to the target API Connect system, but the target system returned an error. The reason associated with the message indicates the error returned by the server.

"AMUAP016W": "The `{{.Type}}` for the gateway service `{{.Name}}` could not be updated."

The migration utility has attempted to update the OAuth shared secret or SNI items for a gateway service in the target API Connect system, but an OAuth shared secret or SNI items were previously set. The migration utility will not overwrite an OAuth shared secret or SNI items that have already been set.

"AMUAP017W": "The product `{{.NameVersion}}` could not be validated and may contain errors."

The migration utility has attempted to validate a product before publishing, but the validation operation did not complete successfully. If validation errors are present in the product file, then the publish to the target API Connect system will not be successful.

"AMUAP018W": "The product `{{.NameVersion}}` contains API `{{.APIName}}` that could not be validated and may contain errors."

The migration utility has attempted to validate the APIs in a product before publishing, but the validation operation did not complete successfully. If validation errors are present in the API file, then the publish to the target API Connect system will not be successful.

"AMUAP019W": "The product `{{.NameVersion}}` contains validation errors: `{{.Errors}}`"

The migration utility has validated the content of a product before publishing, and the validation revealed errors in the product file contents. The product cannot be published to the target API Connect system unless the validation errors in the product file are corrected.

"AMUAP020W": "The product `{{.NameVersion}}` contains an API `{{.APINameVersion}}` with validation errors: `{{.Errors}}`"

The migration utility has validated the content of a product and its associated APIs before publishing, and the validation revealed errors in the API file contents. The product cannot be published to the target API Connect system unless the validation errors in the API file are corrected.

"AMUAP021W": "The product `{{.NameVersion}}` contains API content that could not be updated."

The migration utility has attempted to update the state of an API in the named product, but the metadata file (`*.api.meta.yml`) containing extra API attributes could not be read or contained unexpected content.

"AMUAP022W": "Subscription `{{.Name}}` will not be published."

The migration utility has encountered a subscription for which the subscribed product cannot be found. The subscription cannot be created in the target API Connect system.

"AMUAP023W": "The user registry `{{.Name}}` cannot be published."

The migration utility has encountered a user registry object that cannot be published to the target API Connect system. This can occur for user registry types that may appear in an API Connect v5 system but are not directly supported in API Connect v10. A mapping file in the unpacked user registry directory may be used to identify an alternative user registry into which user entries can be migrated.

"AMUAP024I": "Subscriptions for the product `{{.NameVersion}}` will not be published."

The migration utility has encountered a product that contains no subscribable APIs. This can occur when a product originating in API Connect v5 contains one or more OAuth provider APIs, and no REST or SOAP APIs. OAuth provider APIs are converted to OAuth provider resources by the `archive:unpack` operation, and do not appear as APIs in API Connect v10. OAuth provider instances in API Connect v10 use subscription information associated with the REST or SOAP APIs that refer to the OAuth provider in a security definition.

"AMUAP025E": "Non-fatal errors were found while running the preflight check: `{{.Errors}}`"

The migration utility encountered a non-fatal error during its preflight check before the start of `archive:push`. The details of any of these errors will be reported back here and the `archive:unpack` will continue.

## Troubleshooting tips

- The migration utility may have issues when running across a VPN. The connection might fail if you use a corporate VPN to attempt to access an API Connect subsystem (API Manager UI) located behind an internet firewall. To workaround this problem, add the IP addresses of the API Connect management server and API manager to your local `/etc/hosts`.
- Token expiration: By default, the `apicm` login token expires after eight hours. If the token expires while `apicm archive:push` is running, `apicm` generates errors due to lack of the necessary access permissions. In this case, log in again and re-run `apicm archive:push`. (The token is refreshed every time you log in.) Optionally, you can extend the token expiration time when logging in as the admin user:

```
apicm login --expireHours=<number_of_hours>
```

The `expireHours` flag overrides the default authentication token expiration of 8 hours. Use this flag when pushing data sets that take longer than 8 hours to complete. Note that the revised value persists after the session ends. Best practice is to revert the value to the default (8 hours) after migration.

- If your prior migration created an incorrect artifact on v10, you must manually remove the artifact before re-running migration.
- When you re-run migration, the utility will not recreate any artifacts that already exist on v10. If a collision occurs, the older artifact takes priority. Also, the utility will not delete any artifacts from v10. Thus, you can re-run migration to cover any gaps in artifact creation on v10 without affecting existing artifacts.
- The steps you need to take depend on whether you need to change the v5 export data. For example, if you need to publish or replace a v5 API, you need to export the v5 data and run `unpack` again. If you do not need to change the v5 data, you can skip those steps.

Example 1: Re-using the v5 export data

For example, your v5 export data is accurate and current, but you migrated a consumer-org that is no longer needed on v10, and you mapped a catalog to an incorrect name. Complete the following steps:

1. Delete the incorrect artifacts from the v10 deployment /`ccloud` directory. For this example, delete the unneeded consumer-org and the incorrectly named catalog.
2. Edit the contents of the /`ccloud` directory as needed. For example, remove the unneeded consumer-org entry.
3. Edit your mapping entries as needed. For example, remap the catalog name.
4. Run `apicm archive:push <server> <project_directory>`.

Example 2: Revising v5 export data

In this example your v5 export data is not current because you want to publish or replace a v5 API and then migrate it to v10. Complete the following steps:

1. In the v10 /`ccloud` directory, delete the incorrect artifacts created by the migration. For this example, delete the API you want to replace.
2. On v5, recreate the export data: `config dbextract sftp <host_name> user <user_name> file <path/name>`
3. On v10, delete the /`ccloud` directory.
4. Run `apicm archive:unpack` to create the v10 hierarchy in /`ccloud` directory.
5. Recreate any edits you made to the /`ccloud` directory.
6. Recreate any mappings.
7. Run `apicm archive:push <server> <project_directory>`.

## Failure to convert API definitions to API Gateway

When you change gateway types from DataPower Gateway (v5-compatible) to DataPower API Gateway, you use `./apicm archive:port-to-apigw <path>` to convert API definitions to API Gateway format. The conversion requires Node version 14.21.3 or greater. If Node is not installed, this error is displayed:

```
ERRO[0000] Error getting node version: exec: "node": executable file not found in $PATH
```

If an unsupported version of Node is installed, an error is displayed as in the following example:

```
ERRO[0000] Node version installed must be >=14.21.3. Currently installed version: 4.9.1.
```

To resolve the error, install Node and re-run the command.

To view the conversion step, see [Migration steps without PDUR](#) or [Migration steps with PDUR](#). For information about the conversion, see [Reviewing APIs converted to DataPower API Gateway](#).

## Custom policies not appearing in the policy palette after migration

If you are migrating to v10.0.1.3 or earlier, or v10.0.2.0 or earlier, follow these steps to have custom policies appear in the policy palette in the API Manager Assembly UI.

1. Open `gateway-extension.zip` in the `cloud/admin-org/.../<gateway-service>` folder that is generated in `admin-org` after `port-to-apigw` is run.
2. Open the `manifest.json` file.
3. Edit the `manifest.json` file to specify the implementation files for the custom policies to push to the sandbox catalog.  
Add entries for the sandbox catalog for all provider-orgs using the format `<provider-org>_<catalog-name>`. The filename can remain the same for each respective provider-org, as it will be the same custom policy. Ensure that the actual file that the filename is pointing to in the .zip file exists. The same filename can be re-used multiple times in the `manifest.json` to add the sandbox entries for the custom policy. Only the `manifest.json` must be edited. You do not need to edit any of the .zip files in the `gateway-extension.zip` package.
4. Save the `manifest.json` file and zip it.
5. If the `archive:push` was already performed before step 1, then delete the `gateway-extension.zip` file from the gateway using the API Connect toolkit command `apic gateway-extensions:delete`.
6. Push `admin-org`, which pushes the updated `gateway-extension.zip` file.
7. Follow these steps to ensure that the API Manager advertises the custom policy that is being pushed.
  - a. In each of the provider orgs in the cloud folder, navigate to the `catalog-scoped-staging` folder and log in to the API Connect toolkit as a provider-org user.
  - b. Run this command on every .zip file that you want to appear in the policy palette in the v10 UI:

```
apic policies:create -c sandbox --configured-gateway-service -o -s $API_SERVER_URL --scope catalog .zip
```

The `gateway-service` name is under Topology. `$API_SERVER_URL` is the same one you use to log in to the API Connect toolkit. The custom policy zip filename will appear in the `catalog-scoped-staging` folder.

8. Navigate to the API Manager UI and check the assembly policy palette. The custom policies should now appear in the list. You do not need to push the provider orgs.

If you are migrating to v10.0.1.4 or later, v10.0.3.0 or later, follow these steps to have custom policies appear in the policy palette in the API Manager Assembly UI.

1. After the migration of `admin-org` and `provider-orgs` has completed, navigate to the API Manager UI.
2. While editing a draft API, click the gear icon next to the offline button. A pop-up should appear.
3. Select the target-catalog to publish the draft API to. The target-catalog must already have the custom policies pushed to it.
4. Select the Application to use for the API.
5. Click Save.
6. Navigate to the Assembly policy palette. The custom policies for that specific target-catalog should now appear. For more details about these steps, see [Specifying the testing preferences for an API](#).

When artifacts such as provider org, space or catalog are mapped, any warning or error messages for artifacts in subdirectories underneath those may have the location incorrect. The location will include the mapped artifact location instead of the original location.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

# Replacing passwords, keys, and certificates

Ensure the security of your API Connect deployment by replacing compromised passwords, keys, and certificates.

## About this task

---

Each subsystem uses one or more passwords, database keys, and registration secrets. In some cases, an update takes effect immediately or on the next log-in, but some components require a restart to apply the update. Follow the procedure for updating each subsystem to ensure that you complete all required steps.

All subsystems use TLS certificates to encrypt communications both within each subsystem, between subsystems, and with clients. The procedure for renewing a certificate depends on whether you use IBM Certificate Manager. After you replace a certificate in a subsystem, you must restart all pods that are affected by the certificate, so there will be a service interruption.

The instructions in this section are written for deployments on Kubernetes and details for other platforms appear at the end of the section. Before you begin updating passwords, keys, and certificates, review the entire section to ensure you understand the procedures and are aware of any platform-specific differences that affect your deployment.

Attention: Before you change any passwords, keys, or certificates, you should disable scheduled backups for the Management subsystem and disable data collection for the Analytics subsystem as explained in this section. After the updates are complete, enable backups and data collection.

- [Disabling backups before updating secrets and certificates](#)  
Disable scheduled backups to ensure that you don't update secrets and certificates while a backup is running in your API Connect deployment.
- [Stopping Analytics data collection](#)  
When you renew secrets and certificates for the Analytics subsystem in your API Connect deployment, you must restart Analytics pods. Data cannot be moved to storage while pods are unavailable and if you do not stop collection, that data is lost.
- [Management subsystem: updating the password, keys, and secrets](#)  
Update the cloud administrator password, the key for encrypted database fields, and the `client_ID` and `client_secret` values for the Management subsystem in an API Connect deployment.
- [Gateway subsystem: updating the password and secret](#)  
Update the administrator password and the `client_secret` values for the Gateway subsystem in an API Connect deployment.
- [Portal subsystem: updating keys and secrets](#)  
Update the database passwords, keys, and the `client_secret` values for the Portal subsystem in an API Connect deployment.
- [Analytics subsystem: replacing the TLS profile and keys](#)  
Update the Analytics subsystem's TLS profile and keys for backup and restore operations in your API Connect deployment.
- [Renewing TLS certificates](#)  
Renew TLS certificates in your API Connect deployment.
- [Management subsystem: restarting pods](#)  
Restart Management subsystem pods in your API Connect deployment.
- [Gateway subsystem: restarting pods](#)  
Restart Gateway subsystem pods and components in your API Connect deployment.
- [Portal subsystem: restarting pods](#)  
Restart Portal subsystem pods in your API Connect deployment.
- [Analytics subsystem: restarting endpoints and pods](#)  
Restart the pods that support the Analytics service and endpoints in your API Connect deployment.
- [Re-enabling scheduled backups](#)  
If you disabled scheduled backups before updating keys, secrets, or passwords, enable the backups again for your API Connect deployment.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

# Disabling backups before updating secrets and certificates

Disable scheduled backups to ensure that you don't update secrets and certificates while a backup is running in your API Connect deployment.

## About this task

---

Manually disable any configured backup schedule prior to updating and passwords, keys, profiles, secrets, or certificates. If a backup is taken while an update is running, then that backup should be considered potentially corrupted.

## Procedure

---

1. Disable backups by completing the following steps:
  - a. Open the management cluster CR for editing by running the following command:

```
kubectl -n namespace edit CR-name
```

where:

- `namespace` is the namespace where the Management subsystem is installed.
- `CR-name` is the name of the CR that was used to install the Management subsystem.

- b. In the `databaseBackup` section of the CR, remove the `schedule` entry.
  - c. Save and close.
2. Verify that no backups are running by completing the following steps:

- a. List all your Management backups by running the following command:

```
kubectl -n namespace get managementbackup
```

where `namespace` is the namespace where the Management subsystem is installed.

- b. In the results, check the STATUS column to ensure that all backups are listed as **Ready**. If any backups are still running, wait for them to complete before proceeding to the next topic. The **Ready** status indicates that the backup was finished successfully. If the status is **Failed** then the backup did not complete successfully.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Stopping Analytics data collection

When you renew secrets and certificates for the Analytics subsystem in your API Connect deployment, you must restart Analytics pods. Data cannot be moved to storage while pods are unavailable and if you do not stop collection, that data is lost.

### About this task

---

Complete the following steps to stop the collection of Analytics data and write to disk any data that is currently in the pipeline.

### Procedure

---

1. Disable shard allocation for storage by running the following command:

Disabling shard allocation is optional, but is recommended because it prevents new shards from being created for replication when a node is unavailable, and helps avoid corruption issues in full system restarts.

```
kubectl -n namespace exec -it storage-master|shared_pod -- curl -es _cluster/settings -XPUT -d '{"persistent":{"cluster.routing.allocation.enable":"none"}}'
```

where:

- `namespace` is the namespace where the Analytics subsystem is installed.
- `storage-master|shared_pod` is the name of any storage-master or storage-shared pod. You can get the name of your storage pods by running the following command and substituting in the namespace where Analytics is installed:

```
kubectl -n namespace get po
```

When you disable shard allocation, the response looks like the following example:

```
{"acknowledged":true,"persistent":{"cluster":{"routing":{"allocation":{"enable":"none"}}},"transient":{}}
```

2. Unassociate Analytics service from the Gateway service.

Unassociating the services is optional but is recommended because it prevents new data from entering the pipeline while the Analytics pods are unavailable, and helps avoid corruption issues in full system restarts.

Unassociate the Analytics service from all Gateway services as explained in step 7 in the topic, [Associating an analytics service with a gateway service](#).

3. Perform a synced flush of storage by running the following command:

Flushing the storage is optional, but is recommended because it helps to avoid losing the data that was not yet written to disk before you restart pods. This step flushes all current index operations synchronously and attempts to write everything that is in flux to disk.

```
kubectl -n namespace exec -it storage-master|shared_pod -- curl -es _flush/synced -XPOST
```

where:

- `namespace` is the namespace where the Analytics subsystem is installed.
- `storage-master|shared_pod` is the name of any storage-master or storage-shared pod. You can get the name of your storage pods by running the following command and substituting in the namespace where Analytics is installed:

```
kubectl -n namespace get po
```

When you flush storage, the response looks like the following example:

```
{"_shards":{"total":33,"successful":13,"failed":0},"_export-status":{"total":1,"successful":1,"failed":0},"_apic-config":{"total":1,"successful":1,"failed":0},".kibana-6":{"total":1,"successful":1,"failed":0},"_apic-api-2020.06.19-000002":{"total":15,"successful":5,"failed":0},"_apic-api-2020.06.18-1":{"total":15,"successful":5,"failed":0}}
```

The operation often fails, and it is safe to rerun it multiple times until it passes and there are all "failed" counts are zero. If it continues to fail after running multiple attempts over the span of a couple minutes, you can proceed to the next step.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Management subsystem: updating the password, keys, and secrets

Update the cloud administrator password, the key for encrypted database fields, and the `client_ID` and `client_secret` values for the Management subsystem in an API Connect deployment.

## About this task

---

- [Changing the cloud administrator password](#)  
Update the cloud administrator password for the Management subsystem using the Cloud Manager UI, the toolkit CLI, or an API call.
- [Changing the database encryption key](#)  
Replace the value of the secret that is used for encrypting database fields in the Management subsystem.
- [Changing the registration client\\_id and client\\_secret for applications](#)  
Change the registration credentials (the `client_id` and `client_secret`) for applications provided by the Management subsystem.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Changing the cloud administrator password

Update the cloud administrator password for the Management subsystem using the Cloud Manager UI, the toolkit CLI, or an API call.

### About this task

---

In the Management subsystem for an API Connect on-premises deployment, the administrator is called the *cloud administrator* and works with the management server to configure the deployment of the local server cloud. Updating the cloud administrator password for the Management subsystem requires no service interruption because the change takes place immediately.

You can change the cloud administrator's password using any of the following methods.

Note: Passwords must contain eight or more characters, with at least one character from three of the following categories: lowercase letters, uppercase letters, numerals, and punctuation (for example: ! \$ # %). The same character cannot be used more than twice consecutively.

Cloud Manager UI

1. [Log in to the Cloud Manager UI](#).
2. [Change your Cloud Manager password](#).

Toolkit CLI

1. Run the `apic login` command to [log in to a management server](#).
2. Run the `apic me:change-password` command to [change your password](#).

API call

1. Run the `apic login` command to [log in to a management server](#).  
You must log in to a management server with the toolkit CLI before you can call the API Connect APIs.
2. Execute the `/api/me/change-password` API call, as explained in the "Resource: Me" section of the IBM API Connect Platform - Cloud Management API.

The next time that you log in as the cloud administrator, you must use the new password.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Changing the database encryption key

Replace the value of the secret that is used for encrypting database fields in the Management subsystem.

### About this task

---

This update does not require an outage; however some operations might take longer than usual due to database locking.

### Procedure

---

1. Create a secret rotation CR that specifies the name of your management cluster.  
You can optionally specify the name of a secret containing the new `encryption_secret.bin` as shown in the following example, or you can omit it so that a new key is generated automatically.

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementSecretRotation
metadata:
 name: rotate-secret
```

```
spec:
 managementCluster: management
 rotateEncryptionSecret:
 rotate: true
 # encryptionSecret: name_of_secret
```

Note: If you upgraded from V2018, the database encryption key was carried forward and is called `managementUpgradeName-encryption-secret`.  
 2. Run the following command to apply the CR and change the secret:

```
kubectl -n namespace create -f rotate_secret.yaml
```

where:

- `namespace` is the namespace where you installed the Management subsystem.
  - `rotate_secret.yaml` is the name of the file containing the CR. Notice that the file name does not have to match the value of the `name` specified in the CR.
3. Verify that the secret was generated using one of the following methods:
- Run the `kubectl get job` command and verify that the results include a job for the new CR. The job is named based on the management cluster name and the CR name, using the following format: `managementCluster-crName`. For the example CR `rotate-secret` created for the `management` cluster, the job is named `management-rotate-secret`.
  - Look in the pod logs of the `apiconnect` operator and locate the record with the name that you specified in the `kind` field in the CR, and check its progress. For the example CR, the `kind` value is "ManagementSecretRotation". You can also use the log to verify that database tables were updated.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
 For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Changing the registration `client_id` and `client_secret` for applications

Change the registration credentials (the `client_id` and `client_secret`) for applications provided by the Management subsystem.

### About this task

Update the application registration `client_id` and `client_secret` by changing the Kubernetes secret containing them. The `apim` file-watcher detects the change and automatically updates the following secrets in the database:

- toolkit: `management-cli-cred` (Customer facing)  
 When you update the secret for the toolkit, users must download and install new toolkit credentials as explained in [Installing the toolkit](#).
- consumer-toolkit: `management-ccli-cred` (Customer facing)  
 When you update the secret for the toolkit, users must download and install new toolkit credentials as explained in [Installing the toolkit](#).
- designer: `management-dsgr-cred` (Customer facing)  
 When you update the secret for API Designer, users must download and install new credentials as explained in [Installing the toolkit](#).
- atm: `management-atm-cred` (Internal)
- consumer-ui: `management-cui-cred` (Internal)
- juhu: `management-juhu-cred` (Internal)
- ui: `management-ui-cred` (Internal)  
 The API Manager and Cloud Manager read the credentials from the back-end on start-up.

When you update registration credentials, the registration name that is associated with the updated secret changes. Table 1 lists the registration secrets with the default registration name and the pattern used for generating updated registration names for each secret. The new registration names follow the patterns shown in the table. The second and subsequent updates append a number to the name; for example, `toolkit-application-registration`, `toolkit-application-registration0` and then `toolkit-application-registration1`.

Table 1. Secret names and the corresponding default, and new, registration names for each secret

| Secret                            | Default registration name             | New registration name pattern                           |
|-----------------------------------|---------------------------------------|---------------------------------------------------------|
| <code>management-cli-cred</code>  | <code>toolkit-default</code>          | <code>toolkit-application-registration*</code>          |
| <code>management-ccli-cred</code> | <code>consumer-toolkit-default</code> | <code>consumer-toolkit-application-registration*</code> |
| <code>management-dsgr-cred</code> | <code>designer-default</code>         | <code>designer-registration*</code>                     |
| <code>management-atm-cred</code>  | <code>atm-default</code>              | <code>atm-default*</code>                               |
| <code>management-cui-cred</code>  | <code>consumer-ui-default</code>      | <code>consumer-ui-default*</code>                       |
| <code>management-juhu-cred</code> | <code>juhu-default</code>             | <code>juhu-default*</code>                              |
| <code>management-ui-cred</code>   | <code>ui-default</code>               | <code>ui-default*</code>                                |

### Procedure

1. To renew an internal certificate, complete the following steps:
  - a. Create a ManagementSecretRotation CR (for example, `operationcr.yaml`) with contents similar to the following example, and list the secrets that you want to update:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementSecretRotation
metadata:
 name: rotate-credentials
spec:
 managementCluster: management
```

```

rotateClientIDandSecret:
 secrets:
 - management-ui-cred
 - management-cui-cred
 - management-juhu-cred
 - management-atm-cred

```

b. Apply the CR by running the following command:

```
kubectl create -f operationcr.yaml -n namespace
```

where:

- `namespace` is the namespace where you installed the Management subsystem
- `operationcr.yaml` is the file that contains the CR

Applying the resource updates the credential for the specified secrets with new values.

2. To update customer-facing credentials, complete the following steps:

a. For each of the credential secrets, run the following command to update the `client_id` and `client_secret`:

```
kubectledit secret credential_secret_name -n namespace
```

where:

- `namespace` is the namespace where the Management subsystem is installed.
- `credential_secret_name` is the name of the secret that you want to update.

The response opens the secret in a text editor as shown in the following example:

```

apiVersion: v1
data:
 credential.json:
eyAiaWQiOiAiNTY3MTYyNjYtZDE0Zi00ODZmLWI0MmYtZTE3MzZkZTg3NjE0IiwgInNlY3JldCI6ICJmYjU5MDdhNy0zMjZjLTQ4ZWYtYjQ0ZC1hMTI5ZmZkMzNiMTEiIH0=

```

In the secret, the value of `credential.json` is a base64 encoded string of the following JSON format. Decode it first, modify the values of `id` and `secret`, and encode back as base64 and paste it in the secret. (Note that either `id` or `secret` or both can be updated, but if the credentials have been compromised then it's recommended to update both `id` and `secret`). For example:

b. Decode the value of `credential.json`.

To decode the value, copy it from the secret in step 2a, and paste it between the quotation marks as the `encoded_value` in the following command:

```
echo "encoded_value" | base64 --decode
```

Using the value returned in step 1, the command looks like the following example:

```

echo
"eyAiaWQiOiAiNTY3MTYyNjYtZDE0Zi00ODZmLWI0MmYtZTE3MzZkZTg3NjE0IiwgInNlY3JldCI6ICJmYjU5MDdhNy0zMjZjLTQ4ZWYtYjQ0ZC1hMTI5ZmZkMzNiMTEiIH0=" | base64 --decode

```

The response displays decoded values of the `id` and `secret`, as in the following example:

```
{ "id": "56716266-d14f-486f-b41f-e1736de87614", "secret": "fb5907a7-326c-48ef-b44d-a129ffd33b11" }
```

c. Update the values of `id` and `secret`.

You can use any string that meets the following requirements:

- The `id` (it becomes `client_id`) must be unique across all credentials in your entire deployment.
- The values must be enclosed in straight quotation marks. To make sure you use the correct character, create the values in a plain text editor.

d. Encode the updated `id` and `secret` as base64 by running the following command:

```
echo -n '{ "id": "new_id", "secret": "new_secret" }' | base64
```

Replace `new_id` and `new_secret` with your updated values. For example:

```
echo -n '{ "id": "21034840-b439-a393-4482-a948bcb39603", "secret": "43450ab9-4038-acf0-0498-793b29ade396" }' | base64
```

Returns the following base64-encoded value:

```
aWQ6IDIxMDM0ODQwLWI0MmYtZTE3MzZkZTg3NjE0IiwgInNlY3JldCI6ICJmYjU5MDdhNy0zMjZjLTQ4ZWYtYjQ0ZC1hMTI5ZmZkMzNiMTEiIH0=
```

e. Paste the newly coded value for `credential.json` into the secret.

f. Save the secret.

When you save the secret, the logs in the `apim` pods indicate that a new registration was created. For example, if the `client_id` changed, the display looks similar to the following messages

```

2020-09-14T09:55:58.331Z bhendi:audit [ce64fd50-e4de-4cfb-baa7-7379a892b2c9] Created internal resource "Registration"

2020-09-14T11:00:52.377Z audit [866bb70b-3bb5-4ac3-9a59-0b60ade7feb2] Creating a new registration for type, ui, with
client_id: ui-client-id.
```

g. If the response shows any errors, you must correct the errors.

When the logs show no errors, the saved values are updated in the Management subsystem's database.

h. Confirm that the new registration exists in the registrations list by running the following toolkit CLI command:

```
apic --server server registrations:list
```

where `server` is the Management server endpoint URL.

i. Verify that the updated registration is now in effect by running the following toolkit CLI command:

```
apic --server server registrations:get new_registration_name --output -
```

where:

- `server` is the Management server endpoint URL
- `new_registration_name` is the new registration name (including any numeric suffix) following the patterns in Table 1.

j. Save the old registration (refer to Table 1 to determine the previous registration's file name) in case you need it when restoring an older backup.

Restoring a backup restores the registration credentials (`client_ID`, `client_secret`) that were in use at the time that the selected backup was created.

k. If you updated the registration credentials for API Designer or the toolkit, inform users so they can download new credentials.

Users can download and set up new credentials as explained in [Installing the toolkit](#). Other credentials are updated automatically and require no actions from the user.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Gateway subsystem: updating the password and secret

Update the administrator password and the `client_secret` values for the Gateway subsystem in an API Connect deployment.

### About this task

- [Changing the Gateway administrator password](#)  
Change the Gateway administrator password by updating the CR and reinstalling the subsystem.
- [Changing the Gateway client secret](#)  
The Gateway subsystem receives its `client_secret` from the Management subsystem.
- [Changing the secret for Gateway peering](#)  
Update the secret that protects gateway-peering communications within a Gateway cluster in your API Connect deployment.
- [Updating the TLS profile for Gateway](#)  
Update the TLS profile that secures communications with the Gateway subsystem in your API Connect deployment.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Changing the Gateway administrator password

Change the Gateway administrator password by updating the CR and reinstalling the subsystem.

### About this task

Updating the administrator password for the Gateway subsystem requires no measurable reduction in API enforcement performance (gateways remain "up"); however, services such as SNMP will experience a disconnect until the password is updated on all pods.

## Procedure

---

1. Determine the name of the secret that is used in the Gateway CR by running the following command:

```
kubectl -n namespace get gatewaycluster gw-cluster-name -o yaml
```

where `namespace` is the namespace where you installed the Gateway subsystem.

In the resource, the Gateway's `secretName` is in the `adminUser` section.

2. Update the secret by running the following command to edit the resource:

```
kubectl -n namespace edit secret secretName
```

where `namespace` is the namespace where you installed the Gateway subsystem.

Change the value of `.data.password` to be the base64-encoded value of a new password. The new password can be any string you want but you must encode it to base64.

3. Save and close.

The Gateway pods automatically restart, one at a time, until all pods are using the new secret.

4. To verify that the Gateway subsystem(s) are fully installed, run the following command:

Replace `namespace` with the appropriate namespace.

```
kubectl -n namespace get GatewayCluster
```

where `namespace` is the namespace where you installed the Gateway subsystem.

The update is complete when the `READY` status is `True`, and the `SUMMARY` reports that all services are online ( `2/2` ) for all the Gateway subsystems that were updated. Example:

| NAME | READY | SUMMARY | VERSION  | RECONCILED VERSION | AGE   |
|------|-------|---------|----------|--------------------|-------|
| gwv5 | True  | 2/2     | 10.0.0.0 | 10.0.0.0-1219      | 7m31s |
| gwv6 | True  | 2/2     | 10.0.0.0 | 10.0.0.0-1219      | 7m32s |

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Changing the Gateway `client_secret`

The Gateway subsystem receives its `client_secret` from the Management subsystem.

### About this task

---

If you changed the `client_secret` on the Management subsystem, force a dynamic reconfiguration and reregistration (DRR) as explained in [How can I force re-population of the configuration data?](#) On completion, the Gateway subsystem uses the new `client_secret` in its communications with the Management subsystem.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Changing the secret for Gateway peering

Update the secret that protects gateway-peering communications within a Gateway cluster in your API Connect deployment.

### About this task

---

You can update the secret for an appliance-based gateway or a Kubernetes-based gateway. This task causes a disruption in API transactions because the secret must be changed on all gateways at the same time, and all gateways must be restarted.

## Procedure

---

1. Appliance only: Manually update the Gateway Peering Identification Credential and Validation Credential objects.

Attention: If your Gateway is not deployed on an appliance, skip to step 2.

As soon as you begin this process, nodes will be out of sync. The nodes will remain out of sync until the entire process is complete. If the nodes do not recover from the out-of-sync condition, you might need to perform a DRR. For information about dynamic reregistration and reconfiguration and (DRR), see [Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment](#).

2. Kubernetes only: If your Gateway is deployed on Kubernetes, update the secret by completing the following steps.
- Determine the name of your Gateway cluster by running the following command:

```
kubectl -n namespace get gatewayCluster
```

where `namespace` is the namespace where the Gateway subsystem is deployed.

- Determine the name of the secret currently being used for gateway peering by running the following command:

```
kubectl -n namespace describe gatewayCluster gateway-cluster
```

where:

- `namespace` is the namespace where the Gateway subsystem is deployed.
- `gateway-cluster` is the name that you obtained in step 2a.

In the response, the name of the secret currently being used displays after the heading **Apic Gateway Peering TLS** as shown in the following example:

```
Spec:
 Admin User:
 Secret Name: datapower-admin-credentials
 API Debug Probe: true
 API Debug Probe Expiration Minutes: 60
 API Debug Probe Max Records: 1000
 Apic Gateway Peering TLS:
 Secret Name: gateway-peering
```

- Show the age of the secret currently being used by running the following command:

```
kubectl -n namespace get secret gateway-peering-secret
```

where:

- `namespace` is the namespace where the Gateway subsystem is deployed.
- `gateway-peering-secret` is the secret name that you obtained in step 2b.

- Delete the secret and then immediately delete all of the Gateway pods in the Gateway cluster by running the following two commands:

```
kubectl -n namespace delete secret gateway-peering-secret
kubectl -n namespace delete pod gw-pod1 gw-pod2 gw-pod3
```

where:

- `namespace` is the namespace where the Gateway subsystem is deployed.
- `gateway-peering-secret` is the secret name that you obtained in step 2b.

When you delete the secret and the pods, the following events occur automatically:

- The cert-manager recreates the secret.
- The DataPower operator recreates the gateway pods.
- Dynamic reconfiguration re-installs the API metadata onto the gateways.

For information about dynamic reregistration and reconfiguration and (DRR), see [Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment](#).

- To verify the update, show the age of the new gateway peering secret by running the following command:

```
kubectl -n namespace get secret gateway-peering-secret
```

where:

- `namespace` is the namespace where the Gateway subsystem is deployed.
- `gateway-peering-secret` is the secret name that you obtained in step 2b.

Make sure that the secret is new and does not show the same age as previously.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Updating the TLS profile for Gateway

Update the TLS profile that secures communications with the Gateway subsystem in your API Connect deployment.

### Procedure

---

- Appliance only: update the TLS profile by modifying the configuration of the REST management interface.  
Attention: If your Gateway is not deployed on an appliance, skip to step 2.  
For information on the REST management interface commands, see [REST Management Interface commands](#) in the DataPower Gateway documentation.
- Kubernetes only: update the TLS profile using the Domain API, which is exposed in the GatewayCluster CRD.  
The update requires a change the `rest-mgmt` service in the `default` domain. For information, see [Domain API](#) in the DataPower Operator documentation. For information on updating the domain definition, see [Domain configuration](#) in the same documentation.

Note: The Gateway's API call SNI endpoint already supports replacing customer-provided keys and certifications as explained in [Binding a TLS server profile to a gateway service](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Portal subsystem: updating keys and secrets

Update the database passwords, keys, and the `client_secret` values for the Portal subsystem in an API Connect deployment.

### About this task

---

- [Changing the secret for Portal data and system tools](#)  
Replace the encryption key that generates the secret used for securing the database and system tools that are used by the Portal subsystem.
- [Changing the Portal client secret](#)  
Change the `client_secret` for the Portal subsystem to keep it in sync with the Management subsystem.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Changing the secret for Portal data and system tools

Replace the encryption key that generates the secret used for securing the database and system tools that are used by the Portal subsystem.

### Before you begin

---

If you are using a stand-alone, single data center deployment, you can update the encryption key with the PortalSecretRotation CR, as explained in [Using a PortalSecretRotation CR to update the portal CA](#). The PortalSecretRotation CR is not supported for a two data center configuration or a Cloud Pak for Integration deployment, so you must update the key manually as explained in the following steps.

### About this task

---

The Portal subsystem uses a database plus several system tools to manage storage, hot backups, and cluster synchronization. The following services are all secured with the secret that is generated by the Portal CR during installation:

- MySQL root account for each Portal site
- Csync2 cluster synchronization service

Updating the portal-encryption-secret will make the following changes to your deployment:

- Change the root MySQL password
- Generate a new, site-specific MySQL password for each site
- Generate a new csync2 cluster key
- Re-encrypt all `client_ids` and `client_secrets` in the portal database

If you change the secret, the update is applied to all of the listed services. You can change the secret by generating a new value and restarting pods to pick up the new value. In a two data center deployment, you must manually copy the new secret to the other site.

### Procedure

---

Generate a new secret and apply it to the deployment using the appropriate steps for your environment:

- Single data center

Run the following command to generate a new secret and apply it to the deployment:

```
kubectl -n namespace patch secret portal-enc-key -p '{"data": {"encryption_secret": "$(head -c72 /dev/urandom | base64 -w0 | base64 -w0) \\"}}'
```

where *namespace* is the namespace where you installed the Portal subsystem.

The `portal-enc-key` was generated during installation and added to the CR as the `encryptionSecret` setting. When you generate a new secret, the value is updated automatically. If you saved the secret in a file after the [Portal installation](#) as recommended, be sure to update that file now.

- Two data centers

a. Generate the new secret on DC1 by running the following command:

```
head -c72 /dev/urandom | base64 -w0 | base64 -w0 > secret.txt
```

The `portal-enc-key` was generated during installation and added to the CR as the `encryptionSecret` setting. When you generate a new secret, the value is updated automatically. If you saved the secret in a file after the [Portal installation](#) as recommended, be sure to update that file now.

b. Open a terminal to each DC in the same working directory where you saved `secret.txt` (or, copy the file to somewhere you can open a terminal to each DC).

c. In each terminal, verify that you can access `secret.txt` by typing the following command:

```
echo $(<secret.txt)
```

d. In each terminal, type the following command -- but do not press Enter yet:

```
kubectl -n namespace patch secret portal-enc-key -p "{\"data\": {\"encryption_secret\": \"$(cat secret.txt)\"}}"
```

where *namespace* is the namespace where you installed the Portal subsystem.

e. Press Enter in both terminals at the same time (or as close in time as possible).

There is a 5-minute time-out that starts as soon as any of the pods has the new secret mounted by Kubernetes. All pods will get the secret at slightly different times, but within about a minute of each other. If the 5-minute time-out expires before all pods across both DCs have the new secret, then the pods will rotate the new secret in at different times, resulting in errors in the logs and some down time for various pods, until they manage to rotate the new secret into use and recover.

## Results

When pods restart, the new secret is used to secure the services. The `portal-www` admin logs display messages as the new secret is used to re-encrypt the database. The following example shows sample log messages when the updated secret is applied to the database:

```
[upgrade stdout] 2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: NEW k8s encryption key detected on this system!
Reencrypting portal data
[upgrade stderr] 2954 888ec0:73add2:7fcelb 2020-08-06 13:16:21: refresh_encryption_key: Command Started:
/opt/ibm/bin/refresh_encryption_key
FEgX8F5MxtwvoJ8Wpxw5DB/6Mkk/qPKfRt5FaId3jy5IjbpXL8wi3/33q3KOySh8/zh1lrVNFZTlzRnVfkGheLr9Le/Pb9jq
[upgrade stdout] 2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: No portal service exists! Simply overriding the key
[upgrade stdout] 2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: New key installed
(FEgX8F5MxtwvoJ8Wpxw5DB/6Mkk/qPKfRt5FaId3jy5IjbpXL8wi3/33q3KOySh8/zh1lrVNFZTlzRnVfkGheLr9Le/Pb9jq)
[upgrade stderr] 2954 888ec0:73add2:7fcelb 2020-08-06 13:16:21: refresh_encryption_key: Command Finished:
/opt/ibm/bin/refresh_encryption_key
FEgX8F5MxtwvoJ8Wpxw5DB/6Mkk/qPKfRt5FaId3jy5IjbpXL8wi3/33q3KOySh8/zh1lrVNFZTlzRnVfkGheLr9Le/Pb9jq with RC 0
[upgrade stderr] 2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: Command Finished: /opt/ibm/bin/sysupgrade with RC 0
```

If there is a Portal service registered and Developer Portal sites installed, then this task re-encrypts that data as well. When the site encryption is complete, the log displays a "Command Finished" message for the `refresh_encryption_key` command, as shown in the following example:

```
Command Finished: /opt/ibm/bin/refresh_encryption_key <KEY> with RC 0
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Changing the Portal `client_secret`

Change the `client_secret` for the Portal subsystem to keep it in sync with the Management subsystem.

### About this task

The Portal subsystem uses the same `client_secret` as the Management subsystem. If you change the `client_secret` on the Management subsystem, update the Portal subsystem by pulling the credential from the Management subsystem.

Note: If you did not deploy the Portal subsystem, skip this task.

### Procedure

1. On a Portal pod, run the following command to pull the Portal service's `client_secret` from the Management subsystem:

```
kubectl -n namespace exec -t portal-mydc-www-0 -- bash -ic refresh_cloud_credentials
```

where *namespace* is the namespace where you installed the Portal subsystem.

2. Then, run the following command to update the credential for the Portal sites:

Note: If you did not deploy any Portal sites, skip this step.

```
kubectl -n namespace exec -t portal-mydc-www-0 -- bash -ic "refresh_site_credentials -a"
```

where *namespace* is the namespace where you installed the Portal subsystem.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Analytics subsystem: replacing the TLS profile and keys

Update the Analytics subsystem's TLS profile and keys for backup and restore operations in your API Connect deployment.

- [Updating the TLS profile for Analytics](#)  
Update the TLS Profile for the Analytics service in your API Connect deployment.

- [Updating the Analytics backup/restore secret](#)

Update the secret that secures backed-up data for the Analytics subsystem in an API Connect deployment.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Updating the TLS profile for Analytics

Update the TLS Profile for the Analytics service in your API Connect deployment.

### Procedure

---

1. Unassociate Analytics service from the Gateway service.  
Unassociate the Analytics service from all gateway services as explained in step 7 in the topic, [Associating an analytics service with a gateway service](#).
2. Update the TLS Profile for the Analytics service.  
See step 3 in the topic, [Registering an analytics service](#).
3. Associate the Analytics service with the Gateway service.  
See [Associating an analytics service with a gateway service](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Updating the Analytics backup/restore secret

Update the secret that secures backed-up data for the Analytics subsystem in an API Connect deployment.

### About this task

---

When you configure S3 storage for backing up Analytics data, you encrypt the S3 provider's access key and save it as a Kubernetes secret for your Analytics deployment. If the S3 access key or your Kubernetes secret is compromised, obtain a new key from the S3 provider and use it to generate a new Kubernetes secret.

Important: When you invalidate a key, be sure to save a copy of it with a notation listing the dates when it was used. If you need to restore a backup that was created with the invalidated key, you will need to use that key to access the data. One method of saving the key is to create a new version of the CR every time you change the key, so that you can easily refer to the settings and key that were used for each backup.

This task assumes that you have already [configured the backup settings for your Analytics subsystem](#) and now want to replace the Kubernetes secret that is specified as the `analytics-backup-secret` in the Analytics CR.

### Procedure

---

1. Update the secret for your S3 storage:
  - a. Obtain a new access key and corresponding access key secret from your S3 provider.
  - b. Invalidate the previous credentials that were specified in the Analytics CR.
2. Verify that the secret is now invalid by running the following command:

```
kubectl -n namespace exec -it storage_master/shared_pod -- curl_es_snapshot/apic-analytics/_verify -XPOST
```

where:

- `namespace` is the namespace where Analytics is deployed.
- `storage-master/storage-shared_pod` the name of any one of the storage master or shared pods.  
You can retrieve the list of storage pod names by running the following command:

```
kubectl get po -n namespace
```

A successful invalidation operation returns a `repository_verification_exception` message as in the following example:

```
{ "error": { "root_cause": [{ "type": "repository_verification_exception", "reason": "[apic-analytics] path is not accessible on master node" }, { "type": "repository_verification_exception", "reason": "[apic-analytics] path is not accessible on master node", "caused_by": { "type": "i_o_exception", "reason": "Unable to upload object [tests-5PQ7Hm0zRs6ryr6wm_ZA1A/master.dat-temp] using a single upload", "caused_by": { "type": "amazon_s3_exception", "reason": "The AWS Access Key ID you provided does not exist in our records. (Service: Amazon S3; Status Code: 403; Error Code: InvalidAccessKeyId; Request ID: 8ea5a567-e1dd-4959-bc1a-5933a8a559c6; S3 Extended Request ID: null) } } }, "status": 500 }
```

If the invalidation was not successful, then the secret is still valid and the response includes the names of the analytics-storage pods, as in the following example:

```
{ "nodes": { "NsrFYadiQhumJBb-6XuQUw": { "name": "analytics-storage-master-0" }, "uoXoBx4KQH00bhi-yqWekQ": { "name": "analytics-storage-data-0" } }
```

Attention: Make sure that you successfully invalidate the current secret to prevent unauthorized access to your data.

3. Delete the invalidated Kubernetes secret by running the following command:

```
kubectl -n namespace delete secret name
```

where:

- **namespace** is the namespace where Analytics is deployed.
- **name** is the name of the current (invalidated) Kubernetes secret, which is specified in the **credentials** setting in the **databaseBackup** section of the Analytics CR. Every time you update the secret, you must assign it a new name.

4. Create a new Kubernetes secret by running the following command and filling in your access key, access key secret, and namespace:

```
kubectl -n namespace create secret generic new_secret_name --from-literal=username='S3_access_key' --from-literal=password='S3_access_key_secret'
```

where:

- **namespace** is the namespace where Analytics is deployed.
- **new\_secret\_name** is a new name for storing the new Kubernetes secret. Every time you update the secret, you must assign it a new name.
- **S3\_access\_key** and **S3\_access\_key\_secret** are the values that you received from the S3 provider.

5. Edit the Analytics CR file and replace the invalidated secret with the new secret.

- a. In the CR, locate the **credentials** setting in the **databaseBackup** section.
- b. Replace the invalidated secret name with the name of the new secret that you just generated.
- c. Save and close the CR file.

6. Run the following command to apply the updated CR so that the new secret takes effect:

```
kubectl -n namespace apply -f path/to/analytics-cr
```

where:

- **namespace** is the namespace where Analytics is deployed.
- **path/to/analytics-cr** is the path and file name of the Analytics CR.

7. After the pods restart, run the following command to verify that the new secret is valid and in use:

This step uses the same command as step 2 to determine whether a key is valid, but this time you want to ensure that the new key is valid.

```
kubectl -n namespace exec -it storage_master/shared_pod -- curl -es _snapshot/apic-analytics/_verify -XPOST
```

where:

- **namespace** is the namespace where Analytics is deployed.
- **storage-master/storage-shared\_pod** the name of any one of the storage master or shared pods. You can retrieve the list of storage pod names by running the following command:

```
kubectl get po -n namespace
```

If the new secret is valid and in use, the response includes the names of the analytics-storage pods, as in the following example:

```
{ "nodes": { "NsrFYadiQhumJBb-6XuQUw": { "name": "analytics-storage-master-0" }, "uoXoBx4KQH00bhi-yqWekQ": { "name": "analytics-storage-data-0" } } }
```

If the new secret is not valid, the response indicates a **repository\_verification\_exception** as in the following example:

```
{ "error": { "root_cause": [{ "type": "repository_verification_exception", "reason": "[apic-analytics] path is not accessible on master node" }], "type": "repository_verification_exception", "reason": "[apic-analytics] path is not accessible on master node", "caused_by": { "type": "i_o_exception", "reason": "Unable to upload object [tests-5PQ7Hm0zRs6ryr6wm_ZA1A/master.dat-temp] using a single upload", "caused_by": { "type": "amazon_s3_exception", "reason": "The AWS Access Key ID you provided does not exist in our records. (Service: Amazon S3; Status Code: 403; Error Code: InvalidAccessKeyId; Request ID: 8ea5a567-e1dd-4959-bc1a-5933a8a559c6; S3 Extended Request ID: null)" } } }, "status": 500 }
```

In this case, wait 1 minute and then run the command again. If the response still indicates an invalid secret, new S3 access key and secret are valid before repeating the procedure.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Renewing TLS certificates

Renew TLS certificates in your API Connect deployment.

### About this task

When you install API Connect, the deployment uses Kubernetes cert-manager to create *issuers*, *CA certificates*, *server certificates*, and *client certificates*. You can accept the certificates generated during deployment, or create custom certificates. For information on creating certificates for your deployment, see [Certificates in a Kubernetes environment](#).

If you use Kubernetes cert-manager to generate and manage certificates (both default certificates and custom certificates), you can easily renew them with as explained in this section. If you used a different application to create certificates, you are responsible for renewing them manually. This section provides instructions for renewing certificates, as well as lists of the certificates to renew. The next section explains how to restart subsystems to apply the new certificates.

Note: The topics in this section use variables to represent the subsystem name in each certificate name, to indicate that the name is based on the name you provide in the Kubernetes Custom Resource (CR) for each subsystem instance. For example, the CA for the Management subsystem is referred to as *management\_CR-ca* to indicate that the name depends on the value you provided in the management CR.

- [Renewing certificates with cert-manager](#)  
Use Kubernetes cert-manager to renew the issuers, CA certificates, and derived certificates that it manages for your API Connect deployment.
- [Renewing custom certificates](#)  
If you did not use cert-manager to generate certificates for your API Connect deployment, you must renew them manually.
- [Renewing the postgres-pgbouncer-secret](#)
- [List of Issuers, CA certificates, and secrets](#)  
A summary of certificate issuers, with the CA issued by each, and the corresponding secret used to sign certificates in an API Connect deployment..
- [List of external certificates](#)  
A summary of certificates used for communications between subsystems and clients in an API Connect deployment.
- [List of internal certificates](#)  
A summary of certificates used for communications within subsystems in an API Connect deployment.
- [V2018 upgrade: List of certificates to update manually](#)  
If you upgraded to API Connect V10 from V2018, some external certificates are carried over from the V2018 deployment and are not managed by cert-manager. When you update any of the retained certificates, you must restart the affected pods manually.
- [Certificate lists for Cloud Pak for Integration](#)  
When you deploy API Connect as an IBM Cloud Pak for Integration (CP4I) capability, certificates receive different names. Refer to the tables in this section for the names used on issuer, internal, and external certificates.
- [Renewing certificates on VMware](#)  
Replacing passwords, keys, and certificates and then restarting the subsystems requires some differences in the procedures and commands on VMware in your API Connect deployment..
- [Renewing certificates in a two data center deployment on Kubernetes and OpenShift](#)  
Renewing TLS certificates in an API Connect two data center disaster recovery deployment requires you to copy some updated information between data centers while ensuring that the shared information is not overwritten during the remaining updates.
- [Renewing certificates in a two data center deployment on VMware](#)  
How to renew the Portal encryption secret in an API Connect two data center disaster recovery deployment.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Renewing certificates with cert-manager

Use Kubernetes cert-manager to renew the issuers, CA certificates, and derived certificates that it manages for your API Connect deployment.

### Before you begin

Kubernetes cert-manager can only renew the certificates that it stores and manages. If you created custom certificates using a different application, you must renew them manually.

If you configured automatic renewal of certificates with cert-manager, you must still restart the pods affected by the updated certificates. For more information, see [Automatic renewal with cert-manager](#).

For lists of the different certificates used in an API Connect deployment, see the following topics:

- [List of Issuers, CA certificates, and secrets](#)
- [List of external certificates](#)
- [List of internal certificates](#)

### About this task

The following steps explain how to renew certificates using Kubernetes cert-manager. The instructions also apply to renewing internal certificates on VMware. For information on renewing other certificates on VMware, see [Renewing certificates on VMware](#).

If you are using a single data center configuration with a stand-alone API Connect deployment, you can update the CA certificate for the following subsystems using the appropriate secret-rotation CR:

- Management subsystem: Update the CA certificate with the ManagementSecretRotation CR, as explained in [Using a ManagementSecretRotation CR to update the management CA](#) (not supported for a two data center configuration or Cloud Pak for Integration).
- Portal subsystem: Update the CA certificate with the PortalSecretRotation CR, as explained in [Using a PortalSecretRotation CR to update the portal CA](#) (not supported for a two data center configuration or Cloud Pak for Integration).

The CA certificate for the Analytics and Gateway subsystems can only be updated using step 2 in the following procedure.

Beginning with version 10.0.2, the end certificates (issued by the cert-manager), have a default duration of 2 years, and the CA certificates have a default duration of 10 years.

### Procedure

1. VMware only: Connect to the virtual machine as the API Connect administrator by completing the following steps:
  - a. Run the following command to connect as the API Connect administrator, replacing *ip\_address* with the appropriate IP address:

```
ssh ip_address -l apicadm
```

- b. When prompted, select Yes to continue connecting.
- c. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

- To renew a CA certificate or an issuer (for example, `ingress-ca`, `management_CR-ca`, `analytics_CR-ca`, or `portal_CR-ca`), complete the following steps:
  - Run the following command to list of all the certificate names, with the status and the date and time of the last update for each certificate:

```
kubectl get certificate -o wide
```

- Add the `duration` and `renewBefore` fields if needed.

If the certificate was generated in a version of API Connect earlier than 10.0.1.2, it might not include these fields. Before you renew the certificate, add the fields by completing the following steps:

- Run the following command to open the `ingress-ca` certificate for editing:

```
kubectl -n <namespace> edit certificate ingress-ca
```

- Add the `duration` and `renewBefore` fields under the `spec` field as shown in the following example:

```
.
.
.
spec:
 duration: 87600h # 10 years
 renewBefore: 720h # 30 days
.
.
```

- Save the certificate and then exit the editor.

- Run the following command to renew the CA certificate:

```
kubectl get certificate certificate_name -o=jsonpath='{.spec.secretName}' | xargs kubectl delete secret
```

where `certificate_name` is the name of the CA certificate that you want to renew, and will be one of the following: `ingress-ca`, `management_CR-ca`, `analytics_CR-ca`, or `portal_CR-ca`.

Tip: For the `management_CR-ca`, you can optionally create a special CR (Custom Resource) to renew the CA certificate and its dependent certificates, then restart the dependent pods. For instructions, see [Using a ManagementSecretRotation CR to update the management CA](#), later in this topic.

- Proceed to step 3 and renew each of the end-entity certificates that were issued by the Cert-Manager Issuer based on the CA certificate.

- Renew an end-entity certificate by running the following command:

```
kubectl get certificate certificate_name -o=jsonpath='{.spec.secretName}' | xargs kubectl delete secret
```

where `certificate_name` is the name of the certificate that you want to renew.

Refer to the following topics to see the list of certificates that need renewing based on the CA certificate that you renewed in step 1:

- [List of internal certificates](#)
- [List of external certificates](#)

- For each updated certificate, restart all of the pods that are affected by that certificate.

To see which pods are affected by each certificate, see the following topics:

- [List of external certificates](#)
- [List of internal certificates](#)

Then, see the following topics for instructions for restarting pods:

- [Management subsystem: restarting pods](#)
- [Gateway subsystem: restarting pods](#)
- [Analytics subsystem: restarting endpoints and pods](#)
- [Portal subsystem: restarting pods](#) for a two data center configuration or Cloud Pak for Integration

If you are using a single data center configuration with a stand-alone API Connect deployment, the Portal subsystem pods pick up the new certs and restart any internal processes automatically. Changing the portal-server or portal-client certificates will be a zero downtime operation. However, changing the portal-ca certificate will cause downtime because all portal-db pods need to restart MySQL to allow for the certificate to update. The pods will not restart, but they will all go non-ready and then ready again, which will take a few minutes.

Note: Due to a known issue, when the `ingress-ca` is renewed, it is possible that [Analytics in the Developer Portal](#) might stop working. If this happens, complete the following steps to ensure that certificate changes take effect:

- Log in to the Cloud Manager user interface.
- In the navigation list, click  Topology.
- Edit the Analytics service.
- On the Analytics page, edit the Summary field to force a change; for example, by adding a space to the end of a sentence.
- Click Save.

- If you have subsystems in different namespaces, you need to update the renewed CA secrets to be the same those namespaces. The following example shows how to do this for the `ingress-ca` where the gateway is in a different namespace:

- Export the management namespace `ingress-ca` secret as a yaml:

```
kubectl -n <management namespace> get secret ingress-ca -o yaml > ingress-ca.yaml
```

- Edit the `ingress-ca.yaml` file to remove all annotations, labels, `creationTimestamp`, `managedFields`, `manager`, `operation`, `time`, `resourceVersion`, `selfLink`, and `uid`. Update the `namespace` field to that of your gateway namespace.

- Apply the updated the `ingress-ca.yaml` in the namespace of the other subsystem:

```
kubectl -n <gateway namespace> apply -f ingress-ca.yaml
```

- Use the following commands to confirm that the `ingress-ca` certificates are the same, in both namespaces run:

```
kubectl -n <management namespace> get secrets ingress-ca -o yaml | grep tls.crt | grep -v 'f:tls' | awk '{print $2}' |
base64 -d > /tmp/ingress.pem.dc1

kubectl -n <gateway namespace> get secrets ingress-ca -o yaml | grep tls.crt | grep -v 'f:tls' | awk '{print $2}' |
base64 -d > /tmp/ingress.pem.dc2
```

e. To see the differences run:

```
diff /tmp/ingress.pem.dc1 /tmp/ingress.pem.dc2
```

The files should be the same.

f. Repeat steps 3 and 4 to renew the end-entity certificates in the other namespace.

- [Using a ManagementSecretRotation CR to update the management CA](#)
- [Using a PortalSecretRotation CR to update the portal CA](#)
- [Automatic renewal with cert-manager](#)

If TLS certificates are automatically renewed in your API Connect deployment, you must restart the pods that are affected by the updated certificates.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Using a ManagementSecretRotation CR to update the management CA

### About this task

Applying the `ManagementSecretRotation` CR (Custom Resource) is an alternative method for renewing the `management_CR-ca` and its dependencies, and then restarting the dependent pods. This option applies only to the `management_CR-ca`.

Restriction: The `ManagementSecretRotation` CR can only be used with a stand-alone deployment using a single data center. Do not attempt to use it with a two data center configuration or a Cloud Pak for Integration deployment.

### Procedure

1. Create a `ManagementSecretRotation` CR (for example, `operationcr.yaml`) with contents similar to the following example:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementSecretRotation
metadata:
 name: rotate-issuer
spec:
 managementCluster: management_CR_name
 rotateCertificates:
 certificates:
 - management_CR-ca
```

where `management_CR_name` is the name of the management CR that the system was deployed with.

2. Apply the CR by running the following command:

```
kubectl create -f operationcr.yaml -n namespace
```

where:

- `namespace` is the namespace where you installed the Management subsystem
- `operationcr.yaml` is the file that contains the CR

Applying the CR updates the `management_CR-ca`, along with any certificates that are signed by it. To view a list of the updated certificates, run the following command and check the `status` block of the CR:

```
kubectl get managementsecretrotation rotate-issuer -n namespace
```

In the command, replace `namespace` with the namespace where you installed the Management subsystem.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Using a PortalSecretRotation CR to update the portal CA

### About this task

Applying the `PortalSecretRotation` CR (Custom Resource) is an alternative method for renewing the `portal_CR-ca` and its dependencies, and then restarting the dependent pods. This option applies only to the `portal_CR-ca`.

Restriction: The `PortalSecretRotation` CR can only be used with a stand-alone deployment using a single data center. Do not attempt to use it with a two data center configuration or a Cloud Pak for Integration deployment.

### Procedure

1. Create a `PortalSecretRotation` CR (for example, `portal-secret-cr.yaml`) with contents similar to the following example:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalSecretRotation
metadata:
 name: portal-rotate-secret
spec:
 # Name of the portal cluster's secrets you want to rotate.
 portalCluster: portal
 # List of certificates you want to rotate (Listing an issuer will rotate any certs issued by the issuer e.g listing just
 # portal-ca will rotate portal-ca, portal-client and portal-server)
 rotateCertificates:
 certificates:
 - portal-ca
 rotateEncryptionSecret:
 # Set to true if you want to rotate the encryption secret.
 rotate: true
 # Optional value to set the encryption secret to, if supplied secret exists in the env. If not supplied the rotated
 # secret will be random.
 encryptionSecret: new-encryption-secret
```

If you set `rotate: true` in the `rotateEncryptionSecret` section, the `portal-encryption-secret` will be updated and the following changes will be made:

- Change the root MySQL password
- Generate a new, site-specific MySQL password for each site
- Re-encrypt all `client_ids` and `client_secrets` in the portal database

2. Apply the CR by running the following command:

```
kubectl create -f portal-secret-cr.yaml -n namespace
```

where:

- `namespace` is the namespace where you installed the Portal subsystem
- `portal-secret-cr.yaml` is the file that contains the CR

Applying the CR updates the `portal_CR-ca`, along with any certificates that are signed by it. To view a list of the updated certificates, run the following command and check the `status` block of the CR:

```
kubectl get portalsecretrotation portal-rotate-secret -n namespace
```

In the command, replace `namespace` with the namespace where you installed the Portal subsystem.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Automatic renewal with cert-manager

If TLS certificates are automatically renewed in your API Connect deployment, you must restart the pods that are affected by the updated certificates.

### About this task

When you renew TLS certificates in your API Connect deployment, you must restart the pods that use the renewed certificates so the pods can use the updated certificates. If you configured your deployment so that TLS certificates are renewed by cert-manager automatically based on expiry-time and `renewBefore` settings, it's important to monitor the certificates so that you can restart affected pods when the certificates are renewed and avoid problems caused by outdated certificates.

### Procedure

1. Monitor the deployment for automatically renewed certificates.

Tip: You can monitor the cert-manager logs manually as explained in the following steps, but you will be less likely to overlook a certificate renewal if you set up a logs-based alerting mechanism that informs you when cert-manager renews any certificate.

- To determine when a particular certificate is due for renewal, complete the following steps:

- Retrieve the list of certificate names by running the following command:

```
kubectl get certs
```

- From the list of certificates, choose the one you want to know about and run the following command:

```
kubectl get cert certificate_name -o yaml
```

The output looks like the following example:

```
apiVersion: cert-manager.io/v1alpha1
kind: Certificate
metadata:
 ...
spec:
 commonName: management-server
 ...
 duration: 12720h0m0s
 ...
 renewBefore: 24h0m0s
 secretName: management-server
status:
```

```
...
notAfter: "2022-06-21T16:28:47Z"
...
```

In the example, you can see that the certificate will expire by 2022-06-21T16:28:47Z (`status.notAfter`) and the renewal will take place 24 hours (`spec.renewBefore`) before that time. This can be used to keep track of which certs will be renewing when to perhaps to have a better idea of when to lookout for renewals for each cert in the cert-manager logs.

- To determine when a certificate was renewed, complete the following steps:
  - Run the following command to display the cert-manager log:

```
kubectl logs Cert-manager_pod_name -n cert-manager
```

- In the log output, look for lines similar to the following example:

```
I0108 14:23:18.001074 1 controller.go:129] cert-manager/controller/certificates "level"=0 "msg"="syncing
item" "key"="default/test-cert"
I0108 14:23:18.009940 1 issue.go:109] cert-manager/controller/certificates/certificates/issue "level"=0
"msg"="certificate issued" "related_resource_kind"="Secret" "related_resource_name"="test-cert"
"related_resource_namespace"="default"
I0108 14:23:18.018664 1 sync.go:331] cert-manager/controller/certificates/certificates "level"=0
"msg"="certificate scheduled for renewal" "duration_until_renewal"="-5.018566857s"
"related_resource_kind"="Secret" "related_resource_name"="test-cert" "related_resource_namespace"="default"
I0108 14:23:18.019070 1 controller.go:135] cert-manager/controller/certificates "level"=0 "msg"="finished
processing work item" "key"="default/test-cert"
```

The 4 statements (shown in the example) indicate when a certificate is about to be renewed, and when the renewal is complete a few seconds later.

2. If a CA certificate was renewed, renew all of the certificates issued by that CA's issuer.  
For the list of CA certificates and issuer, see [List of Issuers, CA certificates, and secrets](#).

3. Restart pods affected by the renewed certificates.

When the logs show that a certificate was renewed, restart the pods that use the secret based on that certificate, so that the pods can load the renewed secret.

- a. Determine which pods are affected by the updated certificate by reviewing the following topics:

- [List of external certificates](#)
- [List of internal certificates](#)

- b. Restart the pods affected by the certificate as explained in the following topics:

- [Management subsystem: restarting pods](#)
- [Gateway subsystem: restarting pods](#)
- [Analytics subsystem: restarting endpoints and pods](#)
- [Portal subsystem: restarting pods](#) for a two data center configuration or Cloud Pak for Integration

If you are using a single data center configuration with a stand-alone API Connect deployment, the Portal subsystem pods pick up the new certs and restart any internal processes automatically. Changing the portal-server or portal-client certificates will be a zero downtime operation. However, changing the portal-ca certificate will cause downtime because all portal-db pods need to restart MySQL to allow for the certificate to update. The pods will not restart, but they will all go non-ready and then ready again, which will take a few minutes.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Renewing custom certificates

If you did not use cert-manager to generate certificates for your API Connect deployment, you must renew them manually.

### About this task

You can recreate custom certificates that you generated, or that were generated by the operator during installation. After you renew certificates, restart the affected pods to ensure that the updated certificates are used.

### Procedure

1. Renew the certificates that you generated:

Use one of the following methods to renew the certificates that you created:

- Update the secret
- Delete and then recreate the secret
- Update the CR to reference a different secret name

2. Renew the certificates that were generated by the operator:

To renew the certificates generated by the operator, delete each certificate so that it can be recreated by the operator.

3. Restart the affected pods so they can pick up the renewed certificates.

For information on which pods are associated by each certificate, see the following topics:

- [List of external certificates](#)
- [List of internal certificates](#)

For instructions on restarting pods, see the following topics:

- [Restarting Analytics pods and data collection](#)
- [Management subsystem: restarting pods](#)

- [Gateway subsystem: restarting pods](#)
- [Portal subsystem: restarting pods](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Renewing the `postgres-pgbouncer-secret`

### About this task

Note: These steps are not required from v10.0.1.7 onwards, where pgbouncer secrets are updated automatically.  
The `postgres-pgbouncer-secret` depends on several certificates and secrets, which are listed in Table 1. In the table, the names of items use the variable `management_CR`, which should be replaced with the name of CR that was used for installing the Management subsystem.  
Whenever any of the listed certificates is updated, the `postgres-pgbouncer-secret` is updated automatically. After the secret is updated, you must restart the `postgres-pgbouncer` pod.

Table 1. `postgres-pgbouncer-secret` dependencies

| Secret                                                      | Depends on                                                                                                                                                                                                                                                                                                                            | Pods                            |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| <code>management_CR-random-postgres-pgbouncer-secret</code> | <ul style="list-style-type: none"> <li>• <code>management_CR-ca</code></li> <li>• <code>management_CR-db-client-pgbouncer</code></li> <li>• <code>management_CR-&lt;random&gt;-postgres-pgbouncer</code></li> <li>• <code>management_CR-db-client-postgres</code></li> <li>• <code>management_CR-db-client-apicuser</code></li> </ul> | <code>postgres-pgbouncer</code> |

### Procedure

1. Update all of the secrets that `postgres-pgbouncer-secret` depends on by deleting those secrets.  
Note: Deleting the `management_CR-ca` secret will mean you also need to update all other secrets that depend on it: [Renewing certificates with cert-manager](#)
2. Restart all of the pods that are affected by the updated certificates. See [List of internal certificates](#)
3. Wait for the `postgres-pgbouncer-secret` to be updated.
  - Wait until you see the "updating pgbouncer secret" message in the `ibm-apiconnect` operator log, as in the following example:

```
{ "level": "info", "ts": "2020-08-20T14:29:03.503Z", "logger": "controller_management_cluster", "msg": "Certificate has changed", "cert": "postgres-pgbouncer.crt" }
{ "level": "info", "ts": "2020-08-20T14:29:03.503Z", "logger": "controller_management_cluster", "msg": "Certificate has changed", "cert": "postgres-pgbouncer.key" }
{ "level": "info", "ts": "2020-08-20T14:29:03.503Z", "logger": "controller_management_cluster", "msg": "Certificate has changed", "cert": "pgbouncer.crt" }
{ "level": "info", "ts": "2020-08-20T14:29:03.503Z", "logger": "controller_management_cluster", "msg": "Certificate has changed", "cert": "pgbouncer.key" }
{ "level": "info", "ts": "2020-08-20T14:29:03.503Z", "logger": "controller_management_cluster", "msg": "updating pgbouncer secret", "secret": "management-a7239c78-postgres-pgbouncer-secret" }
```

Watch the `postgres-pgbouncer-secret` for update

Note: If the `postgres-pgbouncer` pod is restarted too soon, the `apim`, `taskmanager`, and `lur` pods will not work correctly and will restart repeatedly. Correct the problem by ensuring that the `postgres-pgbouncer-secret` is updated before proceeding to step 4 to restart the `postgres-pgbouncer` pod.

4. Restart the `postgres-pgbouncer` pod by running the following command:

```
kubectl -n namespace rollout restart deployment/deployment_name
```

where:

- `namespace` is the namespace where you installed the Management subsystem.
- `deployment_name` is the name of the Management subsystem deployment.

You can determine the deployment name by running the following command:

```
kubectl -n namespace get deployment | grep CR_name
```

where:

- `namespace` is the namespace where you installed the Management subsystem.
- `CR-name` is the name of the CR used for installing the Management subsystem.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## List of Issuers, CA certificates, and secrets

A summary of certificate issuers, with the CA issued by each, and the corresponding secret used to sign certificates in an API Connect deployment..

Table 1 presents a list of the certificate issuers used in an API Connect deployment, with the CA issued by each, and the corresponding secret used to sign certificates. The `selfsigning-issuer` is used only for creating CAs, and does not have a corresponding certificate or secret of its own. The certificates generated by the issuers in

Table 1 use the custom-certs-external.yaml template.

Table 1. Issuers, CAs, and secrets

| Issuer                          | CA certificate                                                          | Secret                        |
|---------------------------------|-------------------------------------------------------------------------|-------------------------------|
| <code>selfsigning-issuer</code> | N/A                                                                     | N/A                           |
| <code>ingress-issuer</code>     | <code>ingress-ca</code> issued by <code>selfsigning-issuer</code>       | <code>ingress-ca</code>       |
| <code>analytics_CR-ca</code>    | <code>analytics_CR-ca</code> issued by <code>selfsigning-issuer</code>  | <code>analytics_CR-ca</code>  |
| <code>management_CR-ca</code>   | <code>management_CR-ca</code> issued by <code>selfsigning-issuer</code> | <code>management_CR-ca</code> |
| <code>portal_CR-ca</code>       | <code>portal_CR-ca</code> issued by <code>selfsigning-issuer</code>     | <code>portal_CR-ca</code>     |

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## List of external certificates

A summary of certificates used for communications between subsystems and clients in an API Connect deployment.

### Ingress (front-end) certificates

Table 1 presents a list of ingress certificates (issued by `ingress-issuer`) with the corresponding secret and affected pods. The certificates in Table 1 use the custom-certs-external.yaml template.

Table 1. Ingress certificates, secrets, and affected pods

| Issuer / CA certificate     | Certificate                           | Usage                       | Secret                                | Pods                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|---------------------------------------|-----------------------------|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ingress-issuer</code> | <code>analytics_CR-ac-endpoint</code> | <code>ingress-issuer</code> | <code>analytics_CR-ac-endpoint</code> | <code>analytics_CR-mtls-gw</code><br>Restart the pod with the following command:<br><code>kubectl -n &lt;namespace&gt; rollout restart deploy analytics_CR-mtls-gw</code>                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>ingress-issuer</code> | <code>analytics_CR-ai-endpoint</code> | <code>ingress-issuer</code> | <code>analytics_CR-ai-endpoint</code> | <code>analytics_CR-mtls-gw</code><br>Restart the pod with the following command:<br><code>kubectl -n &lt;namespace&gt; rollout restart deploy analytics_CR-mtls-gw</code>                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>ingress-issuer</code> | <code>*-api-endpoint-*</code>         | <code>ingress-issuer</code> | <code>*-api-endpoint-*</code>         | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

### Subsystem communication certificates

Table 2 lists all of the common subsystem communication certificates (issued by `ingress-issuer`), with the usage, corresponding secret, and affected pods. The certificates in Table 2 use the custom-certs-external.yaml template.

When any certificate is renewed, the corresponding pods must be restarted.

Table 2. Subsystem certificates, secrets, and affected pods

| Issuer / CA certificate     | Certificate                             | Usage  | Secret                                  | Pods                                                                                                                                                                                                                                                          |

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## List of internal certificates

A summary of certificates used for communications within subsystems in an API Connect deployment.

Table 1 presents a list of certificates used for microservice-to-microservice communications with the corresponding secret and affected pods. The certificates in Table 1 must be specified using cert-manager. The issuer can be any cert-manager issuer (default is `selfsigning-issuer`) using the `custom-certs-internal.yaml` template.

Note: When any certificate is renewed, the corresponding pods must be restarted unless otherwise noted in Table 1. If the `postgres-pgbouncer` pod is listed for a certificate, restart that pod by running the following command:

```
kubectl rollout restart deployment/deployment_name
```

For more information, see [Renewing the postgres-pgbouncer-secret](#).

Table 1. Internal certificates, secrets, and affected pods

| Issuer / CA Certificate | Certificate         | Usage  | Secret                           | Pods <sup>1</sup>                                                                                                                                                          |

<sup>1</sup> Note that some of these pods might not exist on your deployment, depending on what features are installed.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## V2018 upgrade: List of certificates to update manually

If you upgraded to API Connect V10 from V2018, some external certificates are carried over from the V2018 deployment and are not managed by cert-manager. When you update any of the retained certificates, you must restart the affected pods manually.

### Ingress (front-end) certificates

Table 1 presents a list of the ingress certificates that were carried forward when you upgraded from V2018, and the pods that you must restart when you update each certificate.

If multiple Portal web ingress endpoints have been configured, then the certificates for those additional endpoints must be updated manually as well.

Table 1. V2018 ingress certificates and affected pods

| Certificate and Secret                      | Pods                                     |
|---------------------------------------------|------------------------------------------|
| <i>client-tls-xxxxxxxxxx</i>                | • <i>analytics-mtls-gw-hashed-suffix</i> |

### Subsystem communication certificates

Table 2 presents a list of the subsystem communication certificates that were carried forward when you upgraded from V2018, and the pods that you must restart when you update each certificate.

Table 2. V2018 subsystem communication certificates and affected pods

| Usage  | Certificate and Secret                                  | Pods                                                                                                                                                                                                                           |
|--------|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| client | <i>managementUpgradeName-analytics-client-client</i>    | <ul style="list-style-type: none"> <li>• <i>management-analytics-proxy</i></li> <li>• <i>management-apim</i></li> <li>• <i>management-taskmanager</i></li> <li>• <i>portal-www</i> (via webhook, no restart needed)</li> </ul> |
| client | <i>managementUpgradeName-analytics-ingestion-client</i> | <ul style="list-style-type: none"> <li>• <i>management-apim</i></li> <li>• <i>management-taskmanager</i></li> <li>• <i>gateway</i> (via webhook, no restart needed)</li> </ul>                                                 |

## Database encryption key

The database encryption key is carried forward from V2018, and uses the name: *managementUpgradeName-encryption-secret*. You can update the value of this secret as explained in [Changing the database encryption key](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Certificate lists for Cloud Pak for Integration

When you deploy API Connect as an IBM Cloud Pak for Integration (CP4I) capability, certificates receive different names. Refer to the tables in this section for the names used on issuer, internal, and external certificates.

- [CP4I: List of Issuers, CA certificates, and secrets](#)  
A summary of certificate issuers, with the CA issued by each, and the corresponding secret used to sign certificates in an API Connect deployment with IBM Cloud Pak for Integration (CP4I).
- [CP4I: List of external certificates](#)  
A summary of certificates used for communications between subsystems and clients in an API Connect deployment with IBM Cloud Pak for Integration (CP4I).
- [CP4I: List of internal certificates](#)  
A summary of certificates used for communications within subsystems in an API Connect deployment with IBM Cloud Pak for Integration (CP4I).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## CP4I: List of Issuers, CA certificates, and secrets

A summary of certificate issuers, with the CA issued by each, and the corresponding secret used to sign certificates in an API Connect deployment with IBM Cloud Pak for Integration (CP4I).

Table 1 presents a list of the certificate issuers used in an API Connect deployment, with the CA issued by each, and the corresponding secret used to sign certificates. In the table, the names of items use the variable *APIC\_instance\_name*, which should be replaced with the name of your deployed API Connect instance.

The *APIC\_instance\_name-self-signed* is used only for creating CAs, and does not have a corresponding certificate or secret of its own.

Table 1. Issuers, CAs, and secrets

| Issuer                                   | CA certificate                                                                       | Secret                                                                                                                                                                                  |
|------------------------------------------|--------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>APIC_instance_name-self-signed</i>    | N/A                                                                                  | N/A                                                                                                                                                                                     |
| <i>APIC_instance_name-ingress-issuer</i> | <i>APIC_instance_name-ingress-ca</i> issued by <i>APIC_instance_name-self-signed</i> | <i>APIC_instance_name-ingress-ca</i><br>Attention: If you change the <i>ingress-ca</i> secret in a 2 data center deployment, you must change it to the same value in both data centers. |
| <i>APIC_instance_name-a7s-ca</i>         | <i>APIC_instance_name-a7s-ca</i> issued by <i>APIC_instance_name-self-signed</i>     | <i>APIC_instance_name-a7s-ca</i>                                                                                                                                                        |
| <i>APIC_instance_name-mgt-ca</i>         | <i>APIC_instance_name-mgt-ca</i> issued by <i>APIC_instance_name-self-signed</i>     | <i>APIC_instance_name-mgt-ca</i>                                                                                                                                                        |
| <i>APIC_instance_name-ptl-ca</i>         | <i>APIC_instance_name-ptl-ca</i> issued by <i>APIC_instance_name-self-signed</i>     | <i>APIC_instance_name-ptl-ca</i>                                                                                                                                                        |

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

## CP4I: List of external certificates

A summary of certificates used for communications between subsystems and clients in an API Connect deployment with IBM Cloud Pak for Integration (CP4I).

## Ingress (front-end) certificates

Table 1 presents a list of ingress certificates (issued by *APIC\_instance\_name-ingress-issuer*) with the corresponding secret and affected pods. In the table, the names of items use the variable *APIC\_instance\_name*, which should be replaced with the name of your deployed API Connect instance. Pods are listed for convenience;

when you update certificates the pods are restarted automatically and do not require a manual restart.

Table 1. Ingress certificates, secrets, and affected pods

| Issuer / CA certificate                        | Certificate                                         | Secret                                              | Pods                                                                                          |
|------------------------------------------------|-----------------------------------------------------|-----------------------------------------------------|-----------------------------------------------------------------------------------------------|
| <code>APIC_instance_name-ingress-issuer</code> | <code>APIC_instance_name-a7s-ac-endpoint</code>     | <code>APIC_instance_name-a7s-ac-endpoint</code>     | <ul style="list-style-type: none"> <li><code>APIC_instance_name-a7s-mtls-gw</code></li> </ul> |

Note: IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## CP4I: List of internal certificates

A summary of certificates used for communications within subsystems in an API Connect deployment with IBM Cloud Pak for Integration (CP4I).

Table 1 presents a list of certificates used for microservice-to-microservice communications (issued by `APIC_instance_name-ingress-issuer`) with the corresponding secret and affected pods. In the table, the names of items use the variable `APIC_instance_name`, which should be replaced with the name of your deployed API Connect instance. Pods are listed for convenience; when you update certificates the pods are restarted automatically and do not require a manual restart.

The certificates in Table 1 must be specified using cert-manager. The issuer can be any cert-manager issuer (default is `APIC_instance_name-self-signed`).

Table 1. Internal certificates, secrets, and affected pods

| Issuer / CA Certificate | Certificate | Usage | Secret | Pods |
|-------------------------|-------------|-------|--------|------|
|-------------------------|-------------|-------|--------|------|

| Issuer / CA Certificate                | Certificate                                                   | Usage        | Secret                                                        | Pods                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Renewing certificates on VMware

Replacing passwords, keys, and certificates and then restarting the subsystems requires some differences in the procedures and commands on VMware in your API Connect deployment..

Attention:

The instructions in this section apply only to the Management, Portal, and Analytics subsystems. For Gateway appliance-specific instructions, see [Configuring the API Connect Gateway Service](#) in the *DataPower Gateway* documentation.

## Using SSH to connect to the server so you can run Kubernetes commands

If the instructions in a referenced topic require you to run `kubectl` commands directly on servers, you must first log in to the virtual machine (appliance) as follows:

1. Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```

2. When prompted, select Yes to continue connecting.

3. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

Then, you can follow the instructions in each topic and run `kubectl` commands as needed.

## Determining which certificates are due for renewal

To determine which certificates are due to expire and must be renewed, SSH into the server as explained in the previous section. Then, run the following command and check the EXPIRATION column in the results:

```
kubectl get certificate
```

- [VMware: Renewing internal certificates with cert-manager](#)  
On VMware OVA/Appliance, the internal certificates are managed using Kubernetes cert-manager.
- [VMware: Renewing external certificates with apicup](#)  
On VMware OVA/Appliance, the external public-facing and the cross-subsystem certificates are managed with the `apicup` utility.
- [VMware: Renewing the postgres-pgbouncer-secret](#)  
Renew the `postgres-pgbouncer-secret` that is used by the Management subsystem in an API Connect deployment.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## VMware: Renewing internal certificates with cert-manager

On VMware OVA/Appliance, the internal certificates are managed using Kubernetes cert-manager.

### About this task

The subsystem CR is configured with `microServiceSecurity` set to `CertManager`, and the `certManagerIssuer` is pointing to a `selfsigning-issuer` as in the following example:

```
microServiceSecurity: certManager
 certManagerIssuer:
 name: selfsigning-issuer
 kind: Issuer
```

Note: Cert-manager is only used for renewing internal certificates. For the list of internal certificates that must be renewed with cert-manager, see [List of internal certificates](#). For information on renewing other certificates, see [Renewing certificates on VMware](#)

## Procedure

Follow the instructions in [Renewing certificates with cert-manager](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## VMware: Renewing external certificates with `apicup`

On VMware OVA/Appliance, the external public-facing and the cross-subsystem certificates are managed with the `apicup` utility.

### About this task

When API Connect is deployed on VMware, the public-facing external certificates, as well as some internal cross-subsystem certificates, are managed with `apicup` but are stored as Kubernetes secrets. Complete the following steps to renew certificates that are managed with `apicup` and restart the affected pods.

### Procedure

1. Renew the certificates as explained in [Replacing custom certificates](#).  
For information on setting up new certificates, see [Setting custom certificates](#).
2. Use Tables 1 and 2 to determine which certificates to renew and which pods to restart:  
Table 1 presents a list of secrets for external (ingress/front-end certificates) with the corresponding pod that must be restarted when the secret changes.

Table 1. External (ingress/front-end) secrets and affected pods

| Secret                                   | Pods                           |
|------------------------------------------|--------------------------------|

| <code>portal-client</code>                                                                               | <ul style="list-style-type: none"> <li><code>management-apim</code></li> <li><code>management-taskmanager</code></li> <li><code>management-portal-proxy</code></li> </ul>                                                                      |
| Site-dependent names.<br>Example: <code>management-replication-ingress/dc2-mgmt-replication</code>       | <ul style="list-style-type: none"> <li><code>management-tunnel</code></li> </ul>                                                                                                                                                               |
| Site-dependent names.<br>Example: <code>management-replication-client/dc2-mgmt-replication-client</code> | <ul style="list-style-type: none"> <li><code>management-remote-sitename-postgres</code> (on passive site in 2DC-HA config)</li> </ul>                                                                                                          |
| Site-dependent names.<br>Example: <code>portal-replication-ingress/dc2-pt1-replication</code>            | <ul style="list-style-type: none"> <li><code>portal-tunnel</code></li> </ul>                                                                                                                                                                   |
| Site-dependent names.<br>Example: <code>portal-replication-client/dc2-pt1-replication-client</code>      | <ul style="list-style-type: none"> <li><code>portal-remote-sitename-db-X</code></li> <li><code>portal-remote-sitename-www-X</code></li> </ul>                                                                                                  |

- Restart the pods listed in the corresponding row for each certificate that you renewed.

For instructions for restarting pods, see the following topics:

- [Management subsystem: restarting pods](#)
- [Gateway subsystem: restarting pods](#)
- [Portal subsystem: restarting pods](#)
- [Analytics subsystem: restarting endpoints and pods](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## VMware: Renewing the `postgres-pgbouncer-secret`

Renew the `postgres-pgbouncer-secret` that is used by the Management subsystem in an API Connect deployment.

### Before you begin

---

Renewing the `postgres-pgbouncer-secret` on VMware uses the same steps as on Kubernetes, but you must SSH into the server first.

### Procedure

---

- SSH into the server:
  - Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```
  - When prompted, select Yes to continue connecting.
  - When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```
- Follow the instructions in [Renewing the postgres-pgbouncer-secret](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Renewing certificates in a two data center deployment on Kubernetes and OpenShift

Renewing TLS certificates in an API Connect two data center disaster recovery deployment requires you to copy some updated information between data centers while ensuring that the shared information is not overwritten during the remaining updates.

### About this task

---

Begin the process by updating certificates as needed on data center 1 (DC1). Then, copy the `ingress-ca` from DC1 to data center 2 (DC2) before updating certificates on DC2. Finally, you will copy encryption keys for the Management and Portal subsystem from DC1 to DC2.

### Procedure

---

Complete the following steps in the sequence shown to ensure that you do not overwrite information that was copied from DC1 while updating DC2.

- DC1: Renew TLS certificates as explained in [Renewing TLS certificates](#).
- DC2: Complete the following steps to copy the `ingress-ca` from DC1:
  - On DC1, export the `ingress-ca` secret to a YAML file by running the following command:

```
kubectl -n namespace get secret ingress-ca -o yaml > ingress-ca.yaml
```
  - Still on DC1, edit the `ingress-ca.yaml` file to remove all labels, annotations, `creationTimestamp`, `resourceVersion`, `uid`, and `selfLink`.
  - Copy the `ingress-ca.yaml` to DC2.
  - On DC2, apply the `ingress-ca.yaml` file by running the following command:

```
kubectl -n namespace apply -f ingress-ca.yaml
```
- Validate that the `ingress-ca` on DC2 matches the `ingress-ca` on DC1:
  - On DC1, run the following command to save the original `ingress-ca` as a PEM file:

```
kubectl -n namespace get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d > /tmp/ingress.pem.dc1
```
  - On DC2, run the following command to save the copied `ingress-ca` as a PEM file:

```
kubectl -n namespace get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d > /tmp/ingress.pem.dc2
```

- iii. Copy `/tmp/ingress.pem.dc1` from DC1 and store it in the `/tmp` folder on DC2.
- iv. On DC2, run the following command to compare the two files and verify that there are no differences:

```
diff /tmp/ingress.pem.dc1 /tmp/ingress.pem.dc2
```

- 3. DC2: Update all external certificates that are based on the `ingress-ca` (see [List of external certificates](#)).
  - 4. DC2: Update all of the internal certificates (see [List of internal certificates](#)).
- At this point, DC1 and DC2 have the same `ingress-ca` secrets. Next, copy the encryption keys for the Management and Portal subsystems from DC1 to DC2.

- 5. Copy the encryption key for the Management subsystem to DC2 by completing the following steps:
  - a. On DC1, copy the management encryption key:
    - i. Get the name of the management encryption key by running the following command:

```
$ kubectl -n namespace get mgmt -o yaml | grep enc
```

The response looks like the following example:

```
encryptionSecret: dallas-enc-key
```

Make a note of the secret name for the next step. In the example, the key's name is `dallas-enc-key`.

- ii. Retrieve the secret from the encryption key by running the following command (substitute in the name of the key from the previous step):

```
kubectl get secret dallas-enc-key -o yaml
```

The output looks like the following example:

```
apiVersion: v1
data:
 encryption_secret.bin:
VKBNFj7sAOizxvE1H6i+9P31oJHvWwsO+x*****EGe/K+x6b3D7FEWGgoyG1WBUJKB4+T21My2iR5rBTov
pyLiY5g*****tSiRcQKegMPNBPg1829SVBCxuv3I=
kind: Secret
metadata:
 creationTimestamp: "2020-08-28T12:53:41Z"
 labels:
 app.kubernetes.io/instance: m1
 app.kubernetes.io/managed-by: ibm-apiconnect
 app.kubernetes.io/name: dallas-enc-key
 name: dallas-enc-key
 namespace: default
 resourceVersion: "43039"
 selfLink: /api/v1/namespaces/default/secrets/m1-enc-key
 uid: 46c92395-9cc2-4421-b2c4-48e472c0cbb1
type: Opaque
```

- iii. Copy the output and save it in a YAML file; for example `dc1-enc-key.yaml`.
- iv. Edit the file and make the following changes:
  - Delete the contents of the `metadata:` section (retain the section).
  - In the `metadata:` section, add in a `name:` attribute, with `dc1-enc-key` as the value.

The following example shows the updated file:

```
apiVersion: v1
data:
 encryption_secret.bin:
VKBNFj7sAOizxvE1H6i+9P31oJHvWwsO+x*****EGe/K+x6b3D7FEWGgoyG1WBUJKB4+T21My2iR5rBTov
pyLiY5g*****tSiRcQKegMPNBPg1829SVBCxuv3I=
kind: Secret
metadata:
 name: dc1-enc-key
type: Opaque
```

- v. Copy the updated file (`dc1-enc-key.yaml`) to the `/tmp` folder on DC2.
- b. On DC2, run the following command to create a secret from the encryption key file (`dc1-enc-key.yaml`) that you copied from DC1:

```
$ kubectl -n namespace create -f /tmp/dc1-enc-key.yaml
```

The response looks like the following example:

```
secret/dc1-enc-key created
```

- 6. Update the encryption key for the Portal subsystem on DC1 and then copy it to DC2 as explained in [Changing the secret for Portal data and system tools](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Renewing certificates in a two data center deployment on VMware

How to renew the Portal encryption secret in an API Connect two data center disaster recovery deployment.

### About this task

Complete the following steps to renew the Portal encryption secret in a two data center disaster recovery deployment on VMware.

## Procedure

Complete the following steps in the sequence shown to ensure that you do not overwrite information that was copied from the **active** data center, in this example DC1, while updating the **passive** data center, in this example DC2.

1. Run a health check on DC1 to ensure the deployment is in a good state. For example:

```
apicup subsys health-check dc1_portal
```

2. Run a health check on DC2 to ensure the deployment is in a good state. For example:

```
apicup subsys health-check dc2_portal
```

3. List the certificates on DC1:

```
apicup certs list dc1-portal
```

4. List the certificates on DC2:

```
apicup certs list dc2-portal
```

5. Clear the certificates on DC1:

```
apicup certs set dc1-portal encryption-secret --clear
```

6. Clear the certificates on DC2:

```
apicup certs set dc2-portal encryption-secret --clear
```

7. Generate new certificates on DC1:

```
apicup certs generate dc1-portal
```

8. Copy the new certificates on DC1:

```
apicup certs get dc1-portal encryption-secret -t key > new_port-encryption-secret
```

9. Set the new certificates from DC1 onto DC2:

```
apicup certs set dc2-portal encryption-secret new_port-encryption-secret
```

10. Install the certificates on both the **active** and **passive** data centers at the same time:

```
apicup subsys install dc1-portal
apicup subsys install dc2-portal
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Management subsystem: restarting pods

Restart Management subsystem pods in your API Connect deployment.

### About this task

This section describes how to restart Management subsystem pods.

## Procedure

1. Determine the deployment name by running the following command:

```
kubectl -n namespace get deployment | grep CR_name
```

where:

- **namespace** is the namespace where the Management subsystem is installed.
- **CR-name** is the name of the CR used for installing the Management subsystem.

2. Restart pods by running the appropriate **kubectl** commands, shown in Table 1.

Use the deployment name that you obtained in step 1.

Table 1. Management pods and the commands to restart them

| Pod name                           | Restart command                                                                                                                                                |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| management-analytics-proxy         | <code>kubectl rollout restart deployment/<i>deployment_name</i> -n &lt;namespace&gt;</code>                                                                    |
| management-apim                    | <code>kubectl rollout restart deployment/<i>deployment_name</i> -n &lt;namespace&gt;</code><br>A manual restart is not needed when the certificate is updated. |
| management-client-downloads-server | <code>kubectl rollout restart deployment/<i>deployment_name</i> -n &lt;namespace&gt;</code><br>A manual restart is not needed when the certificate is updated. |
| management-hub                     | <code>kubectl rollout restart deployment/<i>deployment_name</i> -n &lt;namespace&gt;</code>                                                                    |

| Pod name                             | Restart command                                                                                                                                                                                                             |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| management-juhu                      | <code>kubectl rollout restart deployment/<i>deployment_name</i> -n &lt;namespace&gt;</code>                                                                                                                                 |
| management-ldap                      | <code>kubectl rollout restart deployment/<i>deployment_name</i> -n &lt;namespace&gt;</code><br>A manual restart is not needed when the certificate is updated.                                                              |
| management-lur                       | <code>kubectl rollout restart deployment/<i>deployment_name</i> -n &lt;namespace&gt;</code><br>A manual restart is not needed when the certificate is updated.                                                              |
| management-natscluster               | Execute for each <code>natscluster</code> pod, one at a time:<br><code>kubectl exec management-natscluster-n -- bash -c "kill -HUP 1"</code><br>A manual restart is not needed when the certificate is updated.             |
| postgres-operator                    | <code>kubectl rollout restart deployment postgres-operator -n &lt;namespace&gt;</code>                                                                                                                                      |
| management-random-postgres*          | Rollout restart all the postgres deployments:<br><code>kubectl -n &lt;namespace&gt; get deploy -o name   grep postgres   egrep -v "backrest pgbouncer operator"   xargs kubectl -n &lt;namespace&gt; rollout restart</code> |
| management-random-postgres-pgbouncer | <code>kubectl rollout restart deployment/<i>deployment_name</i> -n &lt;namespace&gt;</code><br>A manual restart is not needed when the certificate is updated.                                                              |
| management-portal-proxy              | <code>kubectl rollout restart deployment/<i>deployment_name</i> -n &lt;namespace&gt;</code><br>A manual restart is not needed when the certificate is updated.                                                              |
| management-stancluster               | Execute for each <code>stancluster</code> pod, one at a time:<br><code>kubectl delete pod management-stancluster-n -n &lt;namespace&gt;</code><br>A manual restart is not needed when the certificate is updated.           |
| management-taskmanager               | <code>kubectl rollout restart deployment/<i>deployment_name</i> -n &lt;namespace&gt;</code><br>A manual restart is not needed when the certificate is updated.                                                              |
| management-tunnel                    | <code>kubectl rollout restart deployment/<i>deployment_name</i> -n &lt;namespace&gt;</code>                                                                                                                                 |
| management-turnstile                 | <code>kubectl rollout restart deployment/<i>deployment_name</i> -n &lt;namespace&gt;</code>                                                                                                                                 |
| management-ui                        | <code>kubectl rollout restart deployment/<i>deployment_name</i> -n &lt;namespace&gt;</code>                                                                                                                                 |
| management-remote-sitename-postgres  | <code>kubectl rollout restart deployment/<i>deployment_name</i> -n &lt;namespace&gt;</code>                                                                                                                                 |

3. Verify that all Management pods are ready by running the following command:

```
kubectl -n namespace get po
```

where *namespace* is the namespace where the Management subsystem is installed.

The restart is complete when all pods are **Running** and **Ready**.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Gateway subsystem: restarting pods

Restart Gateway subsystem pods and components in your API Connect deployment.

### About this task

When you update Gateway subsystem secrets and certificates, the pods restart automatically.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Portal subsystem: restarting pods

Restart Portal subsystem pods in your API Connect deployment.

### Procedure

1. If you are restarting pods after updating the `portal-ca`, complete the following steps:

a. Delete all of the portal pods with the following command:

In the command, **namespace** is the namespace where the Portal subsystem is installed:

- For a development profile:

```
kubectl delete pods portal-sitename-db-0 portal-sitename-www-0 -n namespace
```

- For a production profile:

```
kubectl delete pods portal-sitename-db-0 portal-sitename-db-1 portal-sitename-db-2 portal-sitename-www-0 portal-sitename-www-1 portal-sitename-www-2 -n namespace
```

b. Reload the NGINX configuration by running the following command:

```
kubectl -n namespace exec -it portal-tunnel -- openresty -s reload
```

2. If you updated any other certificate, you can perform a rolling restart on the pods by completing the following steps:

a. Determine the statefulset names by running the following command:

```
kubectl -n namespace get statefulset | grep CR_name
```

Where:

- **namespace** is the namespace where the Portal subsystem is installed.
- **CR-name** is the name of the CR used for installing the Portal subsystem.

b. Restart pods by running the appropriate **kubectl** commands, which are shown in Table 1.

Use the statefulset name that you obtained in step 2a.

Table 1. Portal pods and the commands to restart them

| Pod name                                          | Restart command                                      |
|---------------------------------------------------|------------------------------------------------------|
| portal-local_sitename-db                          | kubectl rollout restart statefulset/statefulset_name |
| portal-local_sitename-www                         | kubectl rollout restart statefulset/statefulset_name |
| portal-tunnel                                     | kubectl rollout restart statefulset/statefulset_name |
| portal-remote_sitename-db                         | kubectl rollout restart statefulset/statefulset_name |
| portal-remote_sitename-www                        | kubectl rollout restart statefulset/statefulset_name |
| portal-nginx<br>Attention: Restart this pod last. | kubectl rollout restart statefulset/statefulset_name |

3. Verify that all Portal pods are ready by running the following command:

```
kubectl -n namespace get po
```

where **namespace** is the namespace where the Portal subsystem is installed.

The restart is complete when all pods are **Running** and **Ready**.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Analytics subsystem: restarting endpoints and pods

Restart the pods that support the Analytics service and endpoints in your API Connect deployment.

- [Restarting the Analytics client endpoint](#)  
Restart the pods that support the Analytics client endpoint in your API Connect deployment.
- [Restarting the Analytics ingestion endpoint](#)  
Restart the pods that support the Analytics ingestion endpoint in your API Connect deployment.
- [Restarting Analytics pods and data collection](#)  
Restart the pods that support the internal communications within the Analytics subsystem in your API Connect deployment.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Restarting the Analytics client endpoint

Restart the pods that support the Analytics client endpoint in your API Connect deployment.

---

### About this task

The client endpoint contains the external certificates that secure communications with the Analytics subsystem. The default names of the secrets for these certs are **ingress-ca**, **analytics-ac-endpoint** (server), and **analytics-client-client** (client).

When you refresh the certificates for the client endpoint, restart the NGINX configuration and the Analytics pods by completing the following steps.

## Procedure

---

1. Reload the NGINX configuration in the `analytics-mtls-gw` pod by running the following command:

```
kubectl -n namespace exec analytics-mtls-gw -- openresty -s reload
```

where:

- `namespace` is the namespace where Analytics is installed.
- `analytics-mtls-gw` is the name of the `analytics-mtls-gw` pod.

2. Restart the analytics-proxy pods by running the following command:

```
kubectl -n namespace delete po -l app.kubernetes.io/name=analytics-proxy,app.kubernetes.io/instance=CR_name
```

where:

- `namespace` is the namespace where Analytics is installed.
- `CR_name` is the name of the CR used for installing the Management subsystem (default is `management`).

3. Verify that the Analytics subsystem is working correctly by opening the Analytics user interface in both Portal and API Manager services.  
Note: Due to a known issue, when the `ingress-ca` is renewed, it is possible that [Analytics in the Developer Portal](#) might stop working. If this happens, complete the following steps to ensure that certificate changes take effect:
  - a. Log in to the Cloud Manager user interface.
  - b. In the navigation list, click  Topology.
  - c. Edit the Analytics service.
  - d. On the Analytics page, edit the Summary field to force a change; for example, by adding a space to the end of a sentence.
  - e. Click Save.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Restarting the Analytics ingestion endpoint

Restart the pods that support the Analytics ingestion endpoint in your API Connect deployment.

### About this task

---

The ingestion endpoint contains the external certificates that secure communications with the Analytics subsystem. The default names of these of the secrets for these certificates are `ingress-ca`, `analytics-ai-endpoint` (server), and `analytics-ingestion-client` (client).

When you refresh the certificates for the ingestion endpoint, restart the Analytics pods by completing the following steps.

## Procedure

---

1. Reload the NGINX configuration in the `analytics-mtls-gw` pod by running the following command:

```
kubectl -n namespace exec analytics-mtls-gw -- openresty -s reload
```

where:

- `namespace` is the namespace where Analytics is installed.
- `analytics-mtls-gw` is the name of the `analytics-mtls-gw` pod.

The Management and Gateway subsystems pick up the change automatically and do not require a restart.

2. Verify that the Analytics service is working by completing the following steps:
  - a. Invoke an API on your gateway that uses the associated Analytics subsystem.
  - b. Use the Analytics user interface to confirm that new data was posted to the Analytics service.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Restarting Analytics pods and data collection

Restart the pods that support the internal communications within the Analytics subsystem in your API Connect deployment.

### About this task

---

The internal certificates are used for all Analytics microservices to communicate with each other within the subsystem. The default names of the secrets for these are `analytics-client`, `analytics-server`, and `analytics-ca`.

When you refresh the internal certificates for the Analytics subsystem, restart the Analytics pods by completing the following steps.

## Procedure

1. If you did not already [stop Analytics data collection](#), complete that task now.  
Data cannot be moved to storage while pods are unavailable and if you do not stop collection before restarting Analytics pods, that data is lost.
2. Restart all of the Analytics pods by running the following command:

```
kubectl -n namespace delete po -l app.kubernetes.io/instance=CR_name
```

where:

- `namespace` is the namespace where the Analytics subsystem is installed.
- `CR_name` is the name of the CR for installing the Analytics subsystem (default name: `analytics`).

3. Verify that all Analytics pods are ready by running the following command:

```
kubectl -n namespace get po
```

where `namespace` is the namespace where the Analytics subsystem is installed.

Make sure that every pod is **Running** and **Ready**.

4. If you [disabled shard allocation](#), check the storage cluster's health by running the following command:  
Note: If you did not disable shard allocation, skip this step. If you stopped shard allocation, check the cluster's health before re-enabling shard allocation.

```
kubectl -n namespace exec -it storage-master|shared_pod -- curl_es _cluster/health?pretty
```

where:

- `namespace` is the namespace where the Analytics subsystem is installed.
- `storage-master|shared_pod` is the name of any storage-master or storage-shared pod. You can get the name of your storage pods by running the following command:

```
kubectl get po -n namespace
```

When you check the cluster's health, the response looks like the following example:

```
{
 "cluster_name" : "apic-analytics-cluster",
 "status" : "yellow",
 "timed_out" : false,
 "number_of_nodes" : 1,
 "number_of_data_nodes" : 1,
 "active_primary_shards" : 318,
 "active_shards" : 318,
 "relocating_shards" : 0,
 "initializing_shards" : 0,
 "unassigned_shards" : 630,
 "delayed_unassigned_shards" : 0,
 "number_of_pending_tasks" : 0,
 "number_of_in_flight_fetch" : 0,
 "task_max_waiting_in_queue_millis" : 0,
 "active_shards_percent_as_number" : 33.54430379746836
}
```

If you have a single node cluster, wait for the status to be **yellow** before proceeding to the next step. If you have a three node cluster, wait for the status to be **green**.

Note: Single node analytics clusters never show **green** in the health output. Green indicates that the data is replicated to at least one other node, and since there are no other nodes in a single node cluster it remains as **yellow**.

5. Associate the Analytics service with the Gateway service.  
Note: If you did not unassociate the Analytics service from the Gateway, skip this step.  
See [Associating an analytics service with a gateway service](#).

6. Enable shard allocation by running the following command:  
Note: If you did not disable shard allocation, skip this step.

```
kubectl -n namespace exec -it storage-master|shared_pod -- curl_es _cluster/settings -XPUT -d '{"persistent": {"cluster.routing.allocation.enable": "all"}}'
```

where:

- `namespace` is the namespace where the Analytics subsystem is installed.
- `storage-master|shared_pod` is the name of any storage-master or storage-shared pod. You can get the name of your storage pods by running the following command:

```
kubectl get po -n namespace
```

When you enable shard allocation, the response looks like the following example:

```
{"acknowledged": true, "persistent": {"cluster": {"routing": {"allocation": {"enable": "all"}}}}, "transient": {}}
```

7. Check the storage cluster's health again and wait until the status is **green**.
8. Verify that the Analytics service is working by completing the following steps:
  - a. Invoke an API on your gateway that uses the associated Analytics subsystem.
  - b. Use the Analytics user interface to confirm that new data was posted to the Analytics service.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Re-enabling scheduled backups

If you disabled scheduled backups before updating keys, secrets, or passwords, enable the backups again for your API Connect deployment.

### About this task

---

### Procedure

---

1. Open the management cluster CR for editing by running the following command:

```
kubectl -n namespace edit CR-name
```

where:

- `namespace` is the namespace where the Management subsystem is installed.
- `CR-name` is the name of the CR that was used to install the Management subsystem.

2. In the `databaseBackup` section of the CR, replace the `schedule` entry that you removed earlier when you disabled scheduled backups.
3. Save and close the file.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## The API Connect operations tool: apicops

Use the apicops operations tool to check the health, troubleshoot, and run maintenance operations on your API Connect installation.

The API Connect apicops tool is in active development and is available to download from [github.com](#). It is available for Linux® and macOS. All suggestions, feedback, and bug reports can be raised in this repository.

### Installing

---

Download the binary for your operating system from [latest release](#). Rename the file to `apicops`, and give it execute permission: `chmod +x apicops`.

### Running apicops

---

Apicops requires access to your Kubernetes or OpenShift environment. For more information about using apicops, see: [Requirements for running apicops](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Configuring and managing your server environment

You configure and manage the servers that comprise your IBM® API Connect on-premises cloud by using the Cloud Manager user interface.

The Cloud Manager user interface is the part of IBM API Connect that enables a Cloud Administrator to define and manage the API Connect on-premises cloud.

You can use the Cloud Manager to define the API Connect cloud by performing the following tasks:

- Create Provider organizations and invite users to serve as the owner
- Create and manage user roles and role defaults
- Create availability zones for services
- Register the relevant servers that will provide the gateway, analytics, and portal services
- Associate an analytics service with a gateway to enable reports for API Events
- Configure resources for user authentication, TLS security, and OAuth providers and make the resources visible to all or selected provider organizations
- Connect to an existing SMTP mail server and edit templates for system-generated emails
- Set the default gateway service for catalogs

- [Cloud Manager configuration checklist](#)

A summary, with links, of the key initial configuration tasks that you must complete in the Cloud Manager user interface after installing and deploying IBM API Connect, and further supplementary tasks.

- [Activating your Cloud Manager user account](#)

If you have been invited to be an administrator of your API Connect cloud, you must activate your account by using the activation link that was sent by another administrator. You can then access the Cloud Manager user interface.

- [Accessing the Cloud Manager user interface](#)

How to navigate to and log in to the Cloud Manager user interface.

- [Defining your Cloud Manager topology](#)

To define your API Connect on-premises cloud, you define availability zones and register services within those zones to securely create, promote, and track APIs.

The installation procedure provides initial configuration of an Availability Zone containing the Management service.

- [Managing authentication and security](#)  
Secure Cloud Manager and API Manager as well as your Catalogs with a user registry. Secure your APIs with OAuth. Create TLS profiles to ensure that information you share among web servers will not be stolen or tampered with.
- [Configuring the cloud settings](#)  
Before you can add a provider organization to your cloud, you must specify your cloud settings to configure an email server for notifications as well as user registry options and catalog defaults.
- [Administering provider organizations](#)  
Manage the provider organizations who have accounts to publish APIs in your API Connect cloud.
- [Administering members and roles](#)  
Cloud Administrators can add members and assign them roles to enable them to work in Cloud Manager. The Cloud and Topology Administrators can also create roles and role defaults. You can also delete users to prevent them from accessing Cloud Manager.
- [Monitoring the cloud](#)  
API Connect generates events to monitor the status of your cloud.
- [Changing your Cloud Manager password and profile information](#)  
You can change your Cloud Manager password and update your profile information.
- [Resolving login problems by increasing HTTP header size](#)  
You can resolve login problems for the Cloud Manager UI by increasing the maximum HTTP client header size.
- [Onboarding a new admin for Cloud Pak for Integration](#)  
Use the API Connect toolkit CLI to create a new admin account for use with Cloud Pak for Integration.
- [Extending the Gateway server behavior](#)  
To support your enterprise requirements, you can extend the Gateway servers within IBM API Connect to provide extra enforcement behavior.
- [Cloud Manager Tutorials](#)  
Tutorials for using the Cloud Manager user interface in IBM API Connect.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Cloud Manager configuration checklist

A summary, with links, of the key initial configuration tasks that you must complete in the Cloud Manager user interface after installing and deploying IBM® API Connect, and further supplementary tasks.

### Key initial tasks

| Task                                                                   | Description                                                                                                                                                                                                                                                                                   |
|------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Log in to the Cloud Manager user interface</a>             | A default admin user account is provided for you to begin your configuration tasks.                                                                                                                                                                                                           |
| <a href="#">Configure an email server for notifications</a>            | The email server sends registration invitations and other event-driven emails. You must configure the email server before you add any provider organizations or register a Portal service.                                                                                                    |
| <a href="#">Specify your email server as the notification server</a>   | Select the email server to be used as the notification server, and configure the sender name and email address to be included in the emails.                                                                                                                                                  |
| <a href="#">Register a Gateway service</a>                             | A Gateway service represents a cluster of gateway servers that host published APIs and provide the API endpoints used by client applications. Gateways execute API proxy invocations to backend systems and enforce API policies including client identification, security and rate limiting. |
| <a href="#">Register an Analytics service</a>                          | The Analytics service collects API event data from the Gateway service.                                                                                                                                                                                                                       |
| <a href="#">Associate the Analytics service with a Gateway service</a> | You must associate an Analytics service with each of the Gateway services from which you want to collect API event data.                                                                                                                                                                      |
| <a href="#">Register a Portal service</a>                              | The Portal service provides a developer portal used by application developers to discover APIs and onboard consumers.                                                                                                                                                                         |
| <a href="#">Create a provider organization</a>                         | For developers to be able to publish APIs, and for API managers to be able to manage the API lifecycle, they must be a member of a provider organization. You must create a least one provider organization specifying the owner, who can add further members.                                |

### Further supplementary tasks

| Task                                                  | Description                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Configure authentication and security</a> | API Connect provides default local user registries, but you can configure your own user registries, of various types, for user interface and API access control. You can also configure TLS profiles for securing data transmission over HTTPS, and OAuth providers for securing third-party website or application access to APIs.                     |
| <a href="#">Create an Availability Zone</a>           | An Availability Zone is a logical or physical set of data centers containing one or more API Connect services. Availability Zones provide redundancy and failover in the event of network issues. A default Availability Zone is provided when you install API Connect but you can add further Availability Zones to reflect your data center topology. |
| <a href="#">Administer members and roles</a>          | You can add further users as members of the administration organization, and control their permissions by assigning predefined roles. You can also create your own custom roles.                                                                                                                                                                        |
| <a href="#">Monitor your API Connect cloud</a>        | API Connect generates events to allow you to monitor the status of your cloud.                                                                                                                                                                                                                                                                          |

## Related concepts

---

- [Cloud Manager Tutorials](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Activating your Cloud Manager user account

If you have been invited to be an administrator of your API Connect cloud, you must activate your account by using the activation link that was sent by another administrator. You can then access the Cloud Manager user interface.

### Before you begin

---

A cloud administrator invited you to join API Connect .

### Procedure

---

1. Complete the following steps to activate your Cloud Manager account:

If the Identity Provider uses LDAP

An invitation email with an activation link is sent. Click the activation link, or paste it in a browser, to log in directly with your LDAP user credentials. Upon authentication, the API Connect user record is updated from the backend identity provider.

If the Identity Provider uses a local registry

An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your first name, last name and password. Passwords must have a minimum of 8 characters and contain characters from at least three of the four following categories:

- Uppercase letters
- Lowercase letters
- Numbers
- Special characters (for example: ! # \$ %)

Note:

- The email address that you enter on the sign up page must match the email address to which the invitation email was sent, otherwise the account activation fails.
- If you previously had an account that was removed, and you are being invited again, you must re-activate your account by using the Sign In option on the page, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail.

If the Identity Provider uses an authentication URL

An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your credentials, which then become your user name and password. Upon authentication, the API Connect user record is updated from the backend identity provider.

If multiple user registries are available for selection on the sign up page, then make sure that the correct registry for your Cloud Manager account is selected. You might need to ask your administrator which user registry is appropriate for your account.

For information on configuring user registries and making them available for Cloud Manager login, see [User registries overview](#) and [Selecting user registries for Cloud Manager and API Manager](#).

2. Click Sign up to complete your registration, then click Sign in to open the Cloud Manager login page.

### Results

---

You have created your API Connect administrator account.

### What to do next

---

Log in to the Cloud Manager user interface and, depending on your role, start to manage the cloud topology, and work with provider organizations and cloud resources. To access the Cloud Manager login page in the future, use the following URL:

```
https://host/admin
```

where *host* is the fully qualified host name or IP address of the Management server.

## Accessing the Cloud Manager user interface

How to navigate to and log in to the Cloud Manager user interface.

### Before you begin

---

To open the Cloud Manager user interface, enter the URL for the <cloud-admin-ui> endpoint that is entered during installation, followed by `/admin`. The <cloud-admin-ui> endpoint is configured in the Management subsystem by using the following command: `apicup subsys set mgmt cloud-admin-ui <endpoint>`.

The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You are prompted to change the Cloud Administrator password and email address.

### Procedure

---

1. Open a browser and enter the URL for the cloud-admin-ui endpoint followed by `/admin`. Note that this is secure connection that uses HTTPS, for example:  
`https://<cloud-admin-ui>/admin`.
2. Enter the Cloud Administrator user name and password.
  - Kubernetes and VMware  
If you are logging in for the first time, enter `admin` for the user name and `7iron-hide` for the password. Otherwise, enter `admin` for the user name and your own password.
  - OpenShift  
The default user name is `admin`. Run the following words to retrieve the default password, which is generated automatically during deployment:

```
oc get secret -n <namespace> | grep mgmt-admin-pass
oc get secret -n <namespace> <secret_name_from_previous_command> -o jsonpath="{.data.password}" | base64 -d && echo
""
```
3. If your cloud contains multiple user registries, as configured on the Settings\_>User Registries screen, then choose the user registry that contains your login credentials. You might need to ask your administrator which user registry is appropriate for your account.
4. Click Sign In.  
Important: The first time that you access the cloud console, you must, for security reasons, enter a new password and your email address. If you forget your password and request a password reset, the notification email is sent to this email address. The email is sent by the email server that is configured in the **Notifications** section of the cloud **Settings**.

### Results

---

The Cloud Manager user interface opens to the home page, as shown in the following screen capture:

## What to do next

Configure the email server so you can reset your password if needed and send other notifications. See [Tutorial: Configuring the Cloud](#).

Configure your topology by registering services. See [Tutorial: Configuring the Cloud](#).

Create a Provider Organization. See [Tutorial: Creating a Provider Organization](#).

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Defining your Cloud Manager topology

To define your API Connect on-premises cloud, you define availability zones and register services within those zones to securely create, promote, and track APIs. The installation procedure provides initial configuration of an Availability Zone containing the Management service.

## About this task

The Cloud Manager topology consists of Availability Zones that contain the API Connect services (management, gateway, analytics and portal services). Availability Zones can contain one or more gateway services, analytics service, and portal service, but there is one management service that spans all Availability Zones. When configuring your Availability Zones and Services, the recommended practice is that the gateway, analytics, and portal services do not communicate across Availability Zones. Only the management service can span across Availability Zones.

The following diagram illustrates the topology for services and Availability Zones in an API Connect network:

One of the following roles is required to register and manage services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

Following are the tasks involved in defining the API Connect topology:

- Create one or more Availability Zones.
- Register one or more Gateway, Analytics, and Portal services in each Availability Zone
- Associate an Analytics service with each Gateway service
- Set the visibility for the services

There are two types of deployment scenarios:

1. Appliance-based deployment using .ova files on Virtual Machines
2. Container-based deployment using Docker and Kubernetes clusters

The configuration of the Management service will differ depending upon the deployment scenario. For both, a Management service is added to the Default Availability Zone by the installation utility.

Once the cloud is defined and an email server has been configured, you invite other users to access API Manager to create APIs. You expose these APIs to the development community through the Developer Portal user interface.

To define the API Connect cloud, complete the following tasks:

- **Configuring the Management service**  
A Management service is configured in the Default Availability Zone by the installation script. For an appliance-based deployment on VMs, additional Management services may be configured using the .ova file. For a container-based deployment, only one Management service is configured for the cloud.
- **Creating an Availability Zone**  
An Availability Zone is a logical or physical set of data centers containing one or more API Connect services. Availability Zones provide redundancy and failover in the event of network issues. The Default Availability Zone is created during installation; it includes a Management service.
- **Registering a gateway service**  
A gateway service is required to handle incoming traffic for APIs.
- **Registering an analytics service**  
Configure at least one analytics service in your API Connect on-premises cloud. The analytics service is always associated with a gateway service, from which it collects API event data.
- **Registering a Portal service**  
Define one or more Portal services in your API Connect on-premises cloud.
- **Associating an analytics service with a gateway service**  
To collect data about your API usage and other statistics, you must associate an analytics service with each gateway service. You can associate multiple gateway services with one analytics service, but each gateway can be associated with only one analytics service.
- **Setting visibility for a service**  
The visibility setting determines which provider organizations can access a service.

---

## Configuring the Management service

A Management service is configured in the Default Availability Zone by the installation script. For an appliance-based deployment on VMs, additional Management services may be configured using the .ova file. For a container-based deployment, only one Management service is configured for the cloud.

## Before you begin

---

You must complete the following tasks:

- Run the Install Assist installation program to configure the Default Availability Zone that contains the Management service. See [Installing API Connect into a Kubernetes environment](#) and [Deploying the Management OVA file](#).

## About this task

---

The Management service is added to your cloud by the installation script. It will be added to the Default Availability Zone. You cannot add or configure Management services using the Cloud Manager user interface.

The Management service is handled differently depending on the deployment option:

- Appliance-based deployment: API Connect Services are deployed on VMs using an .ova configuration file. Multiple Management services may be deployed, but each Availability Zone can have only one Management service.
- Container-based deployment: Services are deployed in Docker containers and managed in Kubernetes clusters. One Management service is deployed for the entire cloud using the installation script.

## Results

---

One or more Management services are configured.

## What to do next

---

## Creating an Availability Zone

An Availability Zone is a logical or physical set of data centers containing one or more API Connect services. Availability Zones provide redundancy and failover in the event of network issues. The Default Availability Zone is created during installation; it includes a Management service.

## Before you begin

---

You must complete the following task:

- Run Install Assist to configure the Default Availability Zone that contains the Management service. See [Installing API Connect into a Kubernetes environment](#) or [Deploying the Management OVA file](#).

## About this task

Availability zones organize API Connect operations based upon your business needs. Availability zones are sets of logical or physical data centers containing one or more API Connect services. Multiple availability zones in your cloud provide redundancy and fail over in the event of network issues. Availability zones can be organized by region, for global separation, or for physical or logical separation of data centers.

The Default Availability Zone is created during the installation process. It contains the Management service that was configured by Install Assist. You register one or more gateway, analytics, and portal services in the availability zones to configure your API Connect cloud topology.

Note: For appliance-based deployments, additional management services may be added (one per availability zone) using the installation script. However, for container-based deployments using Docker and Kubernetes, only one management service is allowed. No additional management services can be added if you are using container-based deployment.

When you create an availability zone, you should provide a descriptive title; a name is generated automatically for internal identification. For example:

Table 1. Example availability zones

| Title                          | Name                           |
|--------------------------------|--------------------------------|
| US Availability Zone           | us-availability-zone           |
| Hampshire Availability Zone    | hampshire-availability-zone    |
| Newport Availability Zone      | newport-availability-zone      |
| London South Availability Zone | london-south-availability-zone |

One of the following roles is required to add and manage Availability Zones:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

## Procedure

Follow these steps to add one or more additional Availability Zones to your on-premises cloud:

1. In the Cloud Manager, click  Topology.
2. You will see the current Availability Zones configured in your cloud. The Default Availability Zone is created by the installation script, and includes the Management service. To add another Availability Zone, choose Create Availability Zone.
3. Enter the following values:

| Field              | Description                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------|
| Title (required)   | Enter a descriptive title for the availability zone. This title will display on the screen. |
| Name (required)    | This field is auto-populated by the system and used as the internal field name.             |
| Summary (optional) | Enter a brief description.                                                                  |

4. Click Create to complete the operation.

## Results

The availability zone will be added on the Services page. You can now add gateway, analytics, and portal services to the availability zone.

## Related tasks

- [Registering an analytics service](#)
- [Registering a Portal service](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Registering a gateway service

A gateway service is required to handle incoming traffic for APIs.

## Before you begin

Before registering a Gateway service in Cloud Manager, the DataPower® API Connect Gateway Service has to either be installed as a subsystem in your Kubernetes cluster or enabled on the DataPower appliance. For a Kubernetes environment, see [DataPower Gateway subsystem on Kubernetes](#). For appliances, see [Configuring the API Connect Gateway Service](#) in the appropriate version of the [DataPower documentation](#).

Also complete the following task:

- [Configuring the Management service](#)

## About this task

A Gateway service represents a cluster of gateway servers that host published APIs and provide the API endpoints used by client applications. Gateways execute API proxy invocations to backend systems and enforce API policies including client identification, security and rate limiting.

One of the following roles is required to register and manage a gateway services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

Note: You can also register, and manage, gateway services by using the developer toolkit CLI; for details, see [apic gateway-services](#).

## Procedure

Complete the following steps to configure a Gateway service for your cloud:

1. In the Cloud Manager, click  Topology.
2. From the Availability Zone that will contain the Gateway service, select Register Service.
3. On the Configure Service page, select DataPower Gateway as the service type. Select the Gateway type that you want to create, either DataPower Gateway (v5 compatible) or DataPower API Gateway. For a description of the gateway types, see [API Connect gateway types](#)
4. Enter the values to configure the Gateway service. You will need to obtain the endpoints from your deployment configuration. For a Kubernetes environment, the endpoints are configured by the following values in the CR (custom resource) file. For an appliance, the endpoint is configured in DataPower.

| Field                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)                                                           | Enter a descriptive title for the gateway service. This title will be displayed on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Name (required)                                                            | This field is auto-populated by the system and used as the internal field name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Summary (optional)                                                         | Enter a brief description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Management endpoint on the gateway service: Endpoint (required)            | Enter the API Connect Gateway Service endpoint. <ul style="list-style-type: none"> <li>• For a Kubernetes environment, the Management Endpoint is the endpoint created in the CR (custom resource). See <a href="#">DataPower Gateway subsystem on Kubernetes</a> for more information.</li> <li>• For an appliance, the Management Endpoint is the <i>Management address</i> to the API Connect Gateway Service shown in the <a href="#">gateway service connection diagram</a>. For one gateway, this takes the form <i>http://&lt;ip-address-for-gateway&gt;:3000</i>. For multiple gateways, it would be the address:port of the load balancer</li> </ul>                          |
| Management endpoint on the gateway service: TLS client profile (required)  | Specify the TLS Client profile to use when contacting the gateway through the management endpoint.<br>Note: The default value is Gateway management client TLS client profile:1.0.0. If you are using a DataPower Gateway in a Kubernetes deployment, with mutual TLS enabled, use this setting. For any other gateway, if the gateway is not configured with the correct TLS credentials the gateway registration will fail with this setting. To prevent registration failure, select either Default TLS client profile:1.0.0 or your own custom TLS client profile. For information on configuring a custom TLS client profile, see <a href="#">Creating a TLS Client Profile</a> . |
| API invocation endpoint: API endpoint base (required)                      | Enter the base portion of the URL that maps to the base portion of the URL for incoming API traffic. It is a public FQDN with additional paths that are specific to your API calls. For example: <b>https://api.mycompany.com</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| API invocation endpoint: Server Name Indication (SNI) - Host name          | For supporting Server Name Indication (SNI) at the API Endpoint Base. The default hostname of '*' is required to allow all hosts. Enter other host names as needed. Wild card format is supported. The SNI capability enables you to serve multiple TLS secure host names through the same Gateway service, using the same IP address and port, without requiring them to use the same TLS profile.<br>Note: To allow requests from clients that don't support SNI, you <b>must</b> include a host name value of '*'.                                                                                                                                                                  |
| API invocation endpoint: Server Name Indication (SNI) - TLS server profile | The TLS server profile that supports the given hostname for SNI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| OAuth shared secret (optional)                                             | For sites using native OAuth providers, enter the shared secret that will be used by all API calls going through the gateway.<br>Note: The specified shared secret must be 64 characters (64 bytes) in length, prefixed with <b>0x</b> , and must consist only of hexadecimal characters.<br>For example: <b>0xa354282f227c10250511ae9c9e8c7ed9f4f1bd0d7c04cb6d5bd178f8c62296e3</b>                                                                                                                                                                                                                                                                                                    |

The following diagram illustrates the gateway service connection:

---

## Management layer

5. When you are finished, click Save.

---

## Results

The Gateway service is added to the appropriate Availability Zone for your cloud.

---

## What to do next

Add additional gateway services. Add one or more analytics services. Add one or more portal services. Associate the gateway service with an analytics service. Set the visibility for the gateway.

---

## Related tasks

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Registering an analytics service

Configure at least one analytics service in your API Connect on-premises cloud. The analytics service is always associated with a gateway service, from which it collects API event data.

---

## Before you begin

You must complete the following tasks:

- [Creating an Availability Zone](#)
- [Registering a gateway service](#)

---

## About this task

The Analytics service collects API event data from the Gateway service. In Cloud Manager, you configure the Analytics service and then associate it with one or more Gateways. You can have multiple Gateways associated with a single Analytics service, but each Gateway can be associated with only one Analytics service. Using the Analytics service, you can filter, sort, and aggregate the API event data and view the results on a dashboard.

One of the following roles is required to register and manage Analytics services:

- Administrator
- Topology Administrator
- Owner

- A custom role with the **Topology:Manage** permission

## Procedure

Complete the following steps to configure the Analytics services for your cloud:

1. In the Cloud Manager, click  Topology.
2. In the Availability Zone that will contain the Analytics service, select Register Services > Analytics.
3. Enter the values to configure the Analytics service:

| Field                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Title (required)                                                               | Enter a descriptive title for the Analytics service. This title will display on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Name (required)                                                                | This field is auto-populated by the system and used as the internal field name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Summary (optional)                                                             | Enter a brief description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Management endpoint on the analytics service: Endpoint (required)              | Enter the fully-qualified domain name for the Analytics client endpoint that you defined during installation.<br>Note: If you disabled internal storage for Analytics, provide the ingestion endpoint instead. <ul style="list-style-type: none"> <li>• In a Kubernetes deployment, the client endpoint (or ingestion endpoint) is defined in the CR with the <code>\$STACK_HOST</code> variable. For more information, see step 2 in <a href="#">Creating the Analytics CR</a>.</li> <li>• In a VMware deployment, the client endpoint (or ingestion endpoint) is defined with an <code>apicup</code> command during installation. For more information, see step 7 in <a href="#">Deploying the Analytics subsystem</a>.</li> </ul> |
| TLS client profile (required)                                                  | Select the TLS Client Profile that will be used to communicate with the Analytics service. The Client Profile applies to the Endpoint that you specified in the previous row.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Advanced analytics configuration (available when editing an analytics service) | Configure advanced parameters in Kibana.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

4. Click Save to complete the operation.

## Results

The Analytics service is added to your cloud settings.

## What to do next

Associate the Analytics service one or more Gateway services. For more information, see [Associating an analytics service with a gateway service](#).

## Related tasks

- [Registering a gateway service](#)
- [Registering a Portal service](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Registering a Portal service

Define one or more Portal services in your API Connect on-premises cloud.

## Before you begin

You must complete the following tasks:

- [Creating an Availability Zone](#)
- [Registering a gateway service](#)
- [Configuring an email server for notifications](#)
- [Setting up notifications](#)

Note:

When you create or register a Developer Portal service, the Portal subsystem checks that the Portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the `portal-ww` pod, admin container logs, if the endpoint cannot be reached:

```
An error occurred contacting the provided portal web endpoint: example.com
The provided Portal web endpoint example.com returned HTTP status code 504
```

From API Connect 10.0.1.8-eus and later, you can disable the Portal web endpoint check so that the Developer Portal service can be created successfully. To disable the endpoint check, complete one of the following updates depending on your platform:

On Kubernetes, OpenShift, and IBM® Cloud Pak for Integration  
Add the following section to the Portal custom resource (CR) template:

```
spec:
 template:
 - containers:
 - env:
 - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
 value: "true"
 name: admin
 name: www
```

On VMware

In your `apicup` project, create a file called `ptl-extra-values.yaml` (or edit the file if one already exists), and add the following section:

```
spec:
 template:
 - containers:
 - env:
 - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
 value: "true"
 name: admin
 name: www
```

Run the following commands:

```
apicup subsys set <ptl_subsys> extra-values-file <path-to-ptl-extra-values-yaml-file>
apicup subsys install <ptl_subsys>
```

## About this task

Each Availability Zone contains one or more Portal services. The Portal service provides a Developer Portal used by application developers to discover APIs and onboard consumers. An email server must be configured and set as the email server for the cloud before registering a Portal service. One of the following roles is required to register and manage Portal services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Important: It's not recommended to have more than 100 sites per Developer Portal service. Note that it's not necessary to have a Portal site for every Catalog, for example Catalogs that are only for API Developers don't need a Portal site, as the APIs can be tested by using credentials from the API Manager. If more than 100 sites are required, you should configure additional Developer Portal services.

## Procedure

Complete the following steps to configure the Portal services for your cloud:

1. In the Cloud Manager, click  Topology.
2. In the Availability Zone that will contain the Portal service, select Register Services > Portal.
3. Enter the values to configure the Portal service.

| Field                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)                                                         | Enter a descriptive title for the portal service. This title will display on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Name (required)                                                          | This field is auto-populated by the system and used as the internal field name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Summary (optional)                                                       | Enter a brief description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Management endpoint on the portal service: Endpoint (required)           | Enter the IP address, fully-qualified host name, service, or ingress name. Used for communication with API Manager. <ul style="list-style-type: none"> <li>• In a Kubernetes deployment, the endpoint is defined in the CR by <code>api.portal.\$STACK_HOST</code>. See <a href="#">Developer Portal subsystem on Kubernetes</a>.</li> <li>• If configured during installation in a VMware environment, it is the <code>apicup subsys set portal portal-admin</code> value.</li> </ul>                                                                                                                                                                                                                                                              |
| Management endpoint on the portal service: TLS client profile (optional) | Select the TLS Client Profile that will be used to communicate with the portal service. The profile applies to the Management Endpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Portal website URL (required)                                            | The URL that will be used for public access to the portal. <ul style="list-style-type: none"> <li>• In a Kubernetes deployment, the endpoint is defined in the CR by <code>portal.\$STACK_HOST</code>. See <a href="#">Developer Portal subsystem on Kubernetes</a>.</li> <li>• If configured during installation in a VMware environment, it is the <code>apicup subsys set portal portal-www &lt;portal&gt;.&lt;hostname&gt;.&lt;domainname&gt;</code> value.</li> </ul> <p>Multiple <code>portal-www</code> endpoints may be configured, as described here in these topics: <a href="#">Defining multiple portal endpoints for a Kubernetes environment</a> and <a href="#">Defining multiple portal endpoints for a VMware environment</a>.</p> |

4. When you are finished, click Save.

## Results

The Portal service is configured in your cloud and can be used to publish APIs.

## Associating an analytics service with a gateway service

To collect data about your API usage and other statistics, you must associate an analytics service with each gateway service. You can associate multiple gateway services with one analytics service, but each gateway can be associated with only one analytics service.

---

### Before you begin

You must complete the following tasks:

- Run Install Assist to configure the Default Availability Zone that contains the Management service.
- Register a gateway service and an analytics service.

---

### About this task

Each gateway service is associated with an analytics service. Each gateway service can be associated with only one analytics service (a one-one relationship), however, each analytics service can be associated with one or more gateway services (a one-many relationship). The associated analytics service collects API event data from the gateway service.

In order to associate an analytics service with a gateway, you must first configure at least one analytics service and one gateway service.

One of the following roles is required to associate an analytics service with a gateway service:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

Follow these steps to associate an analytics service with a gateway service:

---

### Procedure

1. In the Cloud Manager, click  Topology.
2. In the section for the Availability Zone you want to work on, locate the Gateway service that requires an Analytics service in the SERVICE column.
3. Locate the ASSOCIATED ANALYTICS SERVICE column.
4. If an Analytics service has been configured, the Associate Analytics service link is enabled for each Gateway service. Click Associate Analytics Service in the same row as the Gateway service that requires an Analytics service.
5. In Associate Analytics Service, you will see the name of the Gateway service and a list of Analytics services that have been configured in your cloud.
6. Select the Analytics service to associate with the Gateway service by adding a checkmark, then click Associate.
7. To remove the associated Analytics service, select Unassociate analytics service from the actions menu. Note that when there is no Analytics service associated with a Gateway service, all analytics collection will be disabled and there will be no data in either the API Manager Dashboards or third-party offloads.

---

### Results

The Analytics service is associated with a Gateway service and will collect API event data for that Gateway.

## Setting visibility for a service

The visibility setting determines which provider organizations can access a service.

## Before you begin

---

You must complete the following tasks:

- Run Install Assist to configure the Default Availability Zone that contains the Management service
- Create additional availability zones if needed, see [Creating an Availability Zone](#)
- Register at least one gateway service, see [Registering a gateway service](#)
- Register other services

## About this task

---

The visibility setting controls which provider organizations can use a service. The default visibility setting is Public.

One of the following roles is required to set the visibility for services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

## Procedure

---

Follow these steps to set the visibility for the services in your on-premises cloud:

1. In the Cloud Manager, click  Topology.
2. From the list of Services, choose Set visibility from the actions menu next to the name of the service that requires the visibility setting.
3. Select the visibility setting for the service. The options are:
  - Private - the service is not visible and cannot be used by any provider organization
  - Public - the service is visible and can be used by all provider organizations
  - Custom - the service is visible only to the provider organizations designated by you
4. For Custom visibility, select the provider organizations that will be able to use the service.
5. Click Make visible to complete the operation.

## Results

---

For Private, the service cannot be used by any provider organizations. For Public, the service can be used by all provider organizations. For Custom, the service can be used by the provider organizations that you designate.

---

## Managing authentication and security

---

Secure Cloud Manager and API Manager as well as your Catalogs with a user registry. Secure your APIs with OAuth. Create TLS profiles to ensure that information you share among web servers will not be stolen or tampered with.

As Cloud Administrator or Topology Administrator (or with a custom role that contains the `Settings:Manage` permission), you can configure the following authentication and security mechanisms:

- User registries to authenticate users of Cloud Manager and API Manager and of your Catalogs and APIs.
- OAuth providers to provide protection for APIs.
- TLS profiles to secure transmission of data through the Gateway to external web sites and among web servers.

The following topics describe how to configure user registries, OAuth providers, and TLS profiles:

- [User registries overview](#)  
API Connect supports several types of user registries for authenticating users. The credentials for all users of Cloud Manager, API Manager, and the Developer Portal must be stored in a user registry.
- [TLS profiles overview](#)  
API Connect supports TLS Profiles for securing data transmission over HTTPS.
- [OAuth Provider overview](#)  
API Connect supports OAuth Specification 2.0, for both Native and Third party implementations.

---

---

## User registries overview

API Connect supports several types of user registries for authenticating users. The credentials for all users of Cloud Manager, API Manager, and the Developer Portal must be stored in a user registry.

## Introduction to user registries

---

A user registry holds unique user account credentials, primarily usernames and passwords, which are accessed during authentication for logging into Cloud Manager, API Manager, the Developer Portal, and also for calling APIs (if the API is configured to use Basic Authentication in the Security Definition). The Cloud Administrator configures user registries to ensure that all users are successful at logging in.

User registries also provide security when calling APIs. For information on configuring Security Definitions for APIs, see [Creating a basic authentication security definition](#).

User registries are configured as Resources. Once the user registry has been configured as a resource in Resources, the next step is indicate the active user registries for your cloud in Settings, User registries. The user registry must be made active in your cloud in order to make it available for authentication. When a user logs into Cloud Manager or API Manager, the specified user registry is queried for credentials to confirm the user's identity. To make a user registry available to the Developer Portal, you must define the registry for consumer onboarding in the associated Catalog. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Settings, Onboarding; for more information see [Creating and configuring Catalogs](#).

In Cloud Manager and API Manager, a registry cannot be changed after a user is invited to be the owner of a provider organization, even if the invitation is not yet accepted.

User registries in API Connect serve the following primary functions:

- To authenticate a user at login time based upon username and password.
- To store basic profile information such as first name, last name, and email address.
- To provide secure access to Catalogs.
- To provide Basic Authentication for APIs when called by an application.

In order to log in to Cloud Manager, API Manager, the Developer Portal, or access a catalog, a user must have valid credentials (username and password) stored in a user registry that is configured in API Connect.

The Security Definition for an API can be configured to require a username and password, called the Basic Authentication method. With Basic Authentication, the username and password are included in the HTTP authorization header, and the credentials are verified through user registry.

User registries that are configured in Cloud Manager have the following characteristics:

- They are available to Cloud Manager, API Manager, the Developer Portal, and for Basic Authentication for APIs.
- They are available to provider organizations, as determined by the visibility setting.
- They can be edited and deleted only in Cloud Manager.

User registries that are configured in API Manager have the following characteristics:

- They are available to the Developer Portal (for Catalogs) and for Basic Authentication for APIs.
- They are available only to the Provider Organization that created them.

## User registries supported by API Connect

---

API Connect integrates with several types of user registries to accommodate all security solutions. You can use your corporate LDAP registry, an Authentication URL, or an LUR to provide secure access to Cloud Manager, API Manager, the Developer Portal, and APIs. API Connect includes two internal databases that serve as local user registries, or LURs. The Providers LUR supports credentials for Provider organizations and the Admin LUR supports credentials for the Administrator organization. Multiple registries may be configured.

The following user registry types can serve as a resource in API Connect:

- Local user registry (LUR) - An internal database of usernames and passwords stored on the local server. Contains the Admin user account which may not be modified or deleted.
- LDAP - A user registry definition that points to an existing corporate LDAP directory. May be set up as case-sensitive.
- Authentication URL - Accesses a URL that points to a service for validating user credentials.
- OpenID Connect (OIDC).
- [Configuring an Authentication URL user registry](#)  
An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.
- [Configuring an LDAP user registry in the Cloud Manager](#)  
You can use the Cloud Manager UI to configure an LDAP user registry as a shared resource to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.
- [Configuring a Local User Registry](#)  
A Local User Registry (LUR) can be configured to provide user authentication for both Cloud Manager and API Manager.
- [Configuring an OIDC user registry](#)  
Configure a shared OIDC user registry for user onboarding and authentication when multi-factor authentication (MFA) is required.
- [Setting visibility for a user registry](#)  
The visibility setting determines which provider organizations can access a resource, for example, user registries.
- [Deleting a user registry](#)  
As the Cloud Manager administrator, you can delete user registries.
- [Removing a user from a user registry](#)  
As an API Connect user, you can remove yourself from an API Connect user registry. As an administrative user, you can remove other users from an API Connect user registry.

## Configuring an Authentication URL user registry

An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.

### About this task

This topic describes how to configure a new Authentication URL user registry as a Resource in your cloud. After the user registry is configured, you must select it for use in your cloud in Settings > User Registries. See [Selecting user registries for Cloud Manager and API Manager](#).

One of the following roles is required to configure user registries.:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note:

API Connect issues an HTTP `GET` call to the Authentication URL endpoint, sending the user's credential. The following example shows a call made to an Authentication URL identity provider with an endpoint defined as `https://myauthurl.example.com/user/authenticate`:

```
GET /user/authenticate HTTP/1.1
Host: myauthurl.example.com
Authorization: Basic c3Bvb246Zm9yaw=
```

If the Authentication URL endpoint returns an HTTP status code of `200`, the user authenticates successfully. An HTTP status code other than `200` indicates a failed login attempt. API Connect forwards any HTTP Header starting with `X-` (with the exception of `X-Client-Certificate`), and `Cookie` to the Authentication URL identity provider, to aid the authentication decision; for example:

```
GET /user/authenticate HTTP/1.1
Host: myauthurl.example.com
Authorization: Basic c3Bvb246Zm9yaw=
X-Forwarded-For: 8.8.9.9
X-Custom-Header-From-Customer: special
Cookie: MyCookie=VGhpc0lzV2lja2VkQWlhbmhluZw==
```

When a user is presented with the form for completing their API Connect user registration, which fields are pre-populated depends on which fields are returned in the response from the Authentication URL identity provider. If any of the following fields are returned, they will be pre-populated in the registration form:

- `username`
- `email`
- `first_name`
- `last_name`

If the `username` field is not returned, the registration form displays the user name that was provided by the user. The pre-population capability requires that the response from the Authentication URL identity provider satisfies the following conditions:

- The `Content-Type` must be `application/json`.
- The response body format must be JSON.

A sample response is as follows:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache

{
 "username": "myuser",
 "email": "myuser@example.com",
 "first_name": "My",
 "last_name": "User"
}
```

### Procedure

1. In the Cloud Manager, click .
2. Select User Registries to see the list of current user registries in your cloud.
3. Click Create in the User Registries section.

**Important:** Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the

Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

4. Select Authentication URL User Registry and enter the following parameters:

| Field                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)              | Enter a descriptive name to use on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Name (required)               | The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see <a href="#">apic user-registries</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Summary (optional)            | Enter a brief description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Display Name (required)       | The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see <a href="#">Accessing the Cloud Manager user interface</a> , <a href="#">Accessing the API Manager user interface</a> , and <a href="#">Activating your API Manager user account</a> .<br><br>Note: The Developer Portal uses the <b>Title</b> of the User Registries when rendering them at the login page, rather than the <b>Display Name</b> .                                                         |
| URL (required)                | Enter the URL for the authentication service. When establishing authentication, API Connect makes a GET call to the URL. The call includes the user name and password it has collected from the user in its authorization header. Either 200 OK or 401 Unauthorized will be returned.                                                                                                                                                                                                                                                                                                                           |
| TLS Client Profile (optional) | Select a TLS Client Profile to allow secure authentication with a specific web server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Case sensitive                | To ensure proper handling of user name capitalization, you <b>must</b> ensure that your case-sensitivity setting here matches the setting on your backend Authentication URL server: <ul style="list-style-type: none"><li>• <b>Only</b> select Case sensitive if your backend server supports case-sensitivity.</li><li>• Do <b>not</b> select Case sensitive if your backend server does not support case-sensitivity.</li></ul> Note: The Developer Portal does not support case sensitive usernames.<br>Note: After at least one user has been onboarded into the registry, you cannot change this setting. |
| Email required                | Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding.<br>Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.                                                                                                                                                                                                           |
| Unique email address          | Select this checkbox if email addresses must be unique within the user registry.<br>Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.                                                                                                                                                                                                                                                                                                                                              |

5. Click Save.

## Results

The Authentication URL user registry is saved and is available to be selected as a user registry for Cloud Manager or API Manager by selecting it in Settings > User Registries. It can also be used for Basic Authentication in the Security Definition for an API.

# Configuring an LDAP user registry in the Cloud Manager

You can use the Cloud Manager UI to configure an LDAP user registry as a shared resource to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

## Before you begin

To configure an LDAP user registry as a shared resource in the Cloud Manager, the LDAP directory must be created for use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, to authenticate users to the Cloud Manager and the API Manager, or for securing a Catalog to authenticate Developer Portal users.

Important: If you are using an LDAP registry to secure APIs, the STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.

One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the Settings: Manage permissions

## About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for authenticating Developer Portal users in a specific provider organization. While a shared LDAP user registry can be used across the Cloud Manager, the API Manager, and the Developer Portal components in your environment.

This topic describes how to configure a shared LDAP user registry that is available to all of the provider organizations in your API Connect environment. If you want to create an organization-specific registry, see [Creating an LDAP user registry in API Manager](#) for more information. Note also that the visibility of a user registry is set to **shared** by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see [Setting visibility for a user registry](#).

Note:

- If you configure your LDAP user registry to be writable (by selecting the User Managed check box on the registry), you can use the Developer Portal UI for onboarding and authenticating new Developer Portal users, as well as those users that already exist in the LDAP database. A writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
- You can also create and manage LDAP user registries by using the developer toolkit CLI (see [Using the CLI to configure a shared LDAP user registry](#)), and by using the API Connect REST APIs (see the [API Connect REST API documentation](#)).
- If you are using the DataPower® API Gateway, LDAP group authentication is not supported.

You create an LDAP user registry by configuring a set of properties in the Cloud Manager UI. If you want to enable writable LDAP, you must complete the Attribute Mapping section by selecting the User Managed checkbox, and providing the mapping of your source LDAP attribute names to the target API Connect values. You can also change a registry to be read-only again by clearing the User Managed checkbox. After configuring the user registry, you must set it as active in Settings > User Registries. To make the registry available to the Developer Portal, you must define the registry for consumer onboarding in the associated Catalog. To secure APIs with an LDAP registry, you must configure security definitions.

For general information about authenticating with LDAP, see [LDAP authentication](#).

## Procedure

Follow these steps to configure a new LDAP user registry as a shared resource in the Cloud Manager UI.

1. In the Cloud Manager, click  Resources.
2. Click Create in the User Registries section.

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

3. Select LDAP User Registry for the user registry type, and enter the following information:

| Field                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title                                  | Enter a descriptive name to display on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Name                                   | The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see <a href="#">apic user-registries</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Display Name (required)                | The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see <a href="#">Accessing the Cloud Manager user interface</a> , <a href="#">Accessing the API Manager user interface</a> , and <a href="#">Activating your API Manager user account</a> .<br>Note: The Developer Portal uses the <b>Title</b> of the User Registries when rendering them at the login page, rather than the <b>Display Name</b> .                                                         |
| Summary (optional)                     | Enter a brief description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Address                                | Enter the IP address or host name of the LDAP server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Port                                   | Enter the Port number that API Connect can use to communicate with the LDAP registry. For example, 389.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Select a TLS Client Profile (optional) | Select the TLS Client Profile the LDAP server requires.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Select an LDAP protocol version        | Select the version number for the LDAP protocol that you are using.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Case-sensitivity                       | To ensure proper handling of user name capitalization, you <b>must</b> ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: <ul style="list-style-type: none"><li>• <b>Only</b> select Case sensitive if your backend LDAP server supports case-sensitivity.</li><li>• <b>Do not</b> select Case sensitive if your backend LDAP server does not support case-sensitivity.</li></ul> Note: The Developer Portal does not support case sensitive usernames.<br>Note: After at least one user has been onboarded into the registry, you cannot change this setting. |
| Email required                         | Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding.<br>Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.                                                                                                                                                                                                       |
| Unique email address                   | Select this checkbox if email addresses must be unique within the user registry.<br>Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.                                                                                                                                                                                                                                                                                                                                          |

4. Click Next and enter the authentication information, which will vary depending on the selected Authentication Method. The choices are:
  - Compose DN - Select this format if you can compose the user LDAP Distinguished Name (DN) from the user name. For example, **uid=<username>,ou=People,dc=company,dc=com** is a DN format that can be composed from the user name. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, Compose DN is not supported with the DataPower API Gateway.
  - Compose UPN - Select this format if your LDAP directory supports binding with User Principal Names such as **john@acme.com**. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, Compose UPN is not supported with the DataPower API Gateway.

- Search DN - Select this format if you cannot compose the user LDAP Distinguished Name from the user name; for example, if the base DN's of the users are different. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.

For all of the authentication methods:

If you are creating an LDAP registry to authenticate users of an API, you can specify an LDAP authorization group to restrict API access. To be able to call an API that is secured by the LDAP registry, a user must successfully authenticate with their LDAP user ID and password **and** they must be a member of the specified authorization group. The authorization group can be a Static Group or Dynamic Group. A static group is one in which the individual members of the group are explicitly listed. A dynamic group is one which is defined according to the set of attributes that the group members share in common.

5. For authentication method Compose DN, enter the following:

| Field                               | Description                                                                                                                                                                                                                                      |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bind Method                         | Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.                                                          |
| Admin DN                            | For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example <code>cn=admin,dc=company,dc=com</code> .                                                                       |
| Admin Password                      | For Authenticated Bind, enter the user password for the Admin DN.                                                                                                                                                                                |
| Prefix                              | Specify the prefix to the DN. For example <code>(uid=</code> .                                                                                                                                                                                   |
| Suffix                              | Specify the suffix to the DN. For example <code>)</code> .                                                                                                                                                                                       |
| Base DN (optional)                  | Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN.                                                                                                                                       |
| Use group authentication (optional) | Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.<br>Note: If you are using the DataPower API Gateway, LDAP group authentication is not supported. |

6. For authentication method Compose UPN, enter the following:

| Field                               | Description                                                                                                                                                                             |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bind Method                         | Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind. |
| Admin DN                            | For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example <code>cn=admin,dc=company,dc=com</code> .              |
| Admin Password                      | For Authenticated Bind, enter the user password for the Admin DN.                                                                                                                       |
| Suffix                              | Enter the domain part of the user principal name. For example, <code>@acme.com</code> .                                                                                                 |
| Use group authentication (optional) | Enter the Filter condition for the group.<br>Note: If you are using the DataPower API Gateway, LDAP group authentication is not supported.                                              |

7. For authentication method Search DN, enter the following:

| Field                               | Description                                                                                                                                                                                                                                      |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bind Method                         | Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.                                                          |
| Admin DN                            | For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example <code>cn=admin,dc=company,dc=com</code> .                                                                       |
| Admin Password                      | For Authenticated Bind, enter the user password for the Admin DN.                                                                                                                                                                                |
| Prefix                              | Specify the prefix to the DN. For example <code>(uid=</code> .                                                                                                                                                                                   |
| Suffix                              | Specify the suffix to the DN. For example <code>)</code> .                                                                                                                                                                                       |
| Base DN (optional)                  | Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN.                                                                                                                                       |
| Use group authentication (optional) | Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.<br>Note: If you are using the DataPower API Gateway, LDAP group authentication is not supported. |

8. Optional: Click Test configuration to test the settings for your LDAP user registry. Enter valid credentials to ensure that you can access the LDAP database.

9. Optional: If you want to make your LDAP user registry writable, select the User Managed checkbox in the Attribute Mapping section, and provide the mapping of your source LDAP attribute names to the target API Connect values. Click Add to add each name/value pair, specified as follows:

- LDAP ATTRIBUTE NAME - is the name of the source LDAP attribute.
- API CONNECT VALUE - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in [ ] with the value that the user supplies when signing up.

The default user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`, as shown in the following example:

| LDAP ATTRIBUTE NAME       | API CONNECT VALUE                                      |
|---------------------------|--------------------------------------------------------|
| <code>dn</code>           | <code>uid=[username],ou=users,dc=company,dc=com</code> |
| <code>cn</code>           | <code>{first_name} {last_name}</code>                  |
| <code>sn</code>           | <code>{last_name}</code>                               |
| <code>mail</code>         | <code>{email}</code>                                   |
| <code>userPassword</code> | <code>{password}</code>                                |

You must ensure that you enter the correct attribute mapping values for your LDAP configuration, to enable API Connect to access the LDAP database. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.

10. Click Create.

Your new LDAP registry is shown in the list of User Registries on the Resources page.

## What to do next

To make the LDAP registry available for user authentication in the Cloud Manager and the API Manager, you must set it as active in the Settings > User Registries section. See [Selecting user registries for Cloud Manager and API Manager](#) for more information.

If you want to make the LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Settings > Onboarding. In the Catalog User Registries section, click Edit, select the user registry, and click Save. For more information, see [Creating and configuring Catalogs](#).

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see [Creating a basic authentication security definition](#).

- To use for authentication in the User Security configuration for a native OAuth provider, see [Configuring user security for a native OAuth provider](#).
- **Using the CLI to configure a shared LDAP user registry**  
You can use the developer toolkit CLI to configure an LDAP user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

# Using the CLI to configure a shared LDAP user registry

You can use the developer toolkit CLI to configure an LDAP user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

---

## Before you begin

To configure an LDAP user registry as a resource in the Cloud Manager, the LDAP directory must be created and available to use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, or for authenticating users to the Cloud Manager, the API Manager, and the Developer Portal.

Important: If you are using an LDAP registry to secure APIs, the STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.

One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

---

## About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for onboarding and authenticating Developer Portal users, while a shared LDAP user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure a shared LDAP user registry. If you want to create an organization-specific registry, see [Using the CLI to create an organization-specific LDAP user registry](#) for more information. Note also that the visibility of a user registry is set to **shared** by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see [Setting visibility for a user registry](#).

Note:

- If the LDAP user registry is configured as writable (by enabling the `user-managed` property on the registry), you can use the Developer Portal UI for onboarding and authenticating new Developer Portal users, as well as those users that already exist in the LDAP database. A writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
- You can also create LDAP user registries by using the Cloud Manager UI (see [Configuring an LDAP user registry in the Cloud Manager](#)), and by using the API Connect REST APIs (see the [API Connect REST API documentation](#)).
- If you are using the DataPower® API Gateway, LDAP group authentication is not supported.

You configure an LDAP user registry by first defining the registry details in a configuration file. You then use a developer toolkit CLI command to create the registry, passing the configuration file as a parameter. Finally, to make the registry available for user authentication, you need to configure the registry in the management server, or in the appropriate Catalog, or both, depending on your requirements. To secure APIs with an LDAP registry, you must configure security definitions. You can use the following instructions to create a writable or a read-only LDAP user registry.

For general information about authenticating with LDAP, see [LDAP authentication](#).

---

## Logging in to the management server CLI

Before you can define the LDAP user registry configuration, you must log in to your management server from the developer toolkit CLI as a member of the cloud administration organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
- title: Cloud Manager User Registry
 realm: admin/default-idp-1
- title: Corporate LDAP user registry
 realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.

For full details of the login command, see [Logging in to a management server](#).

For more information about how to use the CLI, see [Installing the toolkit](#), and [Overview of the command-line tool](#).

## Defining your LDAP configuration

You define the configuration of your LDAP user registry in an `ldap_config_file.yaml` file, as shown in the following example. Note that the actual contents of your YAML file will vary depending on the authentication method of your LDAP server, and this is explained in the following tables.

```
name: registry_name
title: "display_title"
integration_url: LDAP_integration_url
user_managed: true_or_false
user_registry_managed: false
case_sensitive: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
- name: provider_name
 title: provider_title
endpoint:
 endpoint: "ldap_server_url_and_port"
configuration:
 authentication_method: authentication_method
 authenticated_bind: "true_or_false"
 admin_dn: "admin_dn"
 admin_password: admin_password
 search_dn_base: "search_dn_base"
 search_dn_scope: search_dn_scope
 search_dn_filter_prefix: prefix
 search_dn_filter_suffix: suffix
 attribute_mapping:
 dn: "distinguished_name"
 cn: "common_name"
 sn: "last_name"
 mail: "email_address"
 userPassword: "password"
```

The registry properties that are common to each authentication method are described in the following table:

| Property                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>                  | The name of the registry. This name is used in CLI commands.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>title</code>                 | A descriptive name to display in a graphical user interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>integration_url</code>       | The LDAP integration URL in your API Connect configuration. You can determine the LDAP integration URL by using the following CLI command:<br><code>apic integrations:list --server mgmt_endpoint_url --subcollection user-registry</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>user_managed</code>          | Determines whether your user registry is writable or not. Must be set to <code>true</code> for writable LDAP. You can change this setting to <code>false</code> if you don't want the registry to be writable; see the Switching your LDAP registry between writable and read-only section at the end of this topic for details. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.                                                                                                                                                                                                                                                                                                                                |
| <code>user_registry_managed</code> | Must be set to <code>false</code> for LDAP. Determines whether API Connect manages your user registry. Only LUR registries are managed by API Connect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>case_sensitive</code>        | Determines whether your user registry is case-sensitive. Valid values are: <ul style="list-style-type: none"> <li><code>true</code></li> <li><code>false</code></li> </ul> <p>To ensure proper handling of user name capitalization, you <b>must</b> ensure that your case-sensitivity setting here matches the setting on your backend LDAP server:</p> <ul style="list-style-type: none"> <li><b>Only</b> set <code>case_sensitive</code> to <code>true</code> if your backend LDAP server supports case-sensitivity.</li> <li>Set <code>case_sensitive</code> to <code>false</code> if your backend LDAP server does not support case-sensitivity.</li> </ul> <p>Note: After at least one user has been onboarded into the registry, you cannot change this setting.</p> |

| Property                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>email_required</code>        | <p>Determines whether an email address is required as part of the user onboarding process. Valid values are:</p> <ul style="list-style-type: none"> <li><code>true</code></li> <li><code>false</code></li> </ul> <p>If set to <code>true</code>, the source identity provider must supply the email address as part of the authentication process during onboarding.<br/> Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.</p> |
| <code>email_unique_if_exist</code> | <p>Determines whether email addresses must be unique within the user registry. Valid values are:</p> <ul style="list-style-type: none"> <li><code>true</code></li> <li><code>false</code></li> </ul> <p>Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.</p>                                                                                                                                                         |
| <code>identity_providers</code>    | <p>An array containing the details of your LDAP server, where:</p> <ul style="list-style-type: none"> <li><code>name</code> - is the name of the LDAP server and is the name that is used in CLI commands</li> <li><code>title</code> - is the display name of the LDAP server</li> </ul>                                                                                                                                                                                                                                                          |
| <code>endpoint</code>              | <p>The endpoint of your LDAP server, made up of the url and port, for example:</p> <p><code>"ldap://server.com:389"</code></p>                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>tls_profile</code>           | <p>Optionally set the TLS Client Profile that the LDAP server requires.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>protocol_version</code>      | <p>Optionally set the version number for the LDAP protocol that you are using. Valid values are:</p> <ul style="list-style-type: none"> <li><code>2</code></li> <li><code>3</code></li> </ul> <p>Defaults to <code>3</code> if not explicitly set.</p>                                                                                                                                                                                                                                                                                             |

The properties in the configuration section will vary depending on the selected authentication method. The three authentication methods are:

- `compose_dn` - Set this format if you can compose the user LDAP Distinguished Name (DN) from the user name. For example, `uid=<username>,ou=People,dc=company,dc=com` is a DN format that can be composed from the user name. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, `compose_dn` is not supported with the DataPower API Gateway.
- `compose_upn` - Set this format if your LDAP directory supports binding with User Principal Names such as `john@acme.com`. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, `compose_upn` is not supported with the DataPower API Gateway.
- `search_dn` - Select this format if you cannot compose the user LDAP Distinguished Name from the user name; for example, if the base DN of the users are different. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.

For authentication method `compose_dn`, set the following configuration properties:

| Properties                         | Description                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>authentication_method</code> | <code>compose_dn</code>                                                                                                                                                                                                                                                                                                                                   |
| <code>authenticated_bind</code>    | <p>The bind method. Valid values are:</p> <ul style="list-style-type: none"> <li><code>"true"</code> - authenticated bind</li> <li><code>"false"</code> - anonymous bind</li> </ul> <p>If specific permissions are not needed to search the registry, select <code>"false"</code>. If specific permissions are necessary, select <code>"true"</code>.</p> |
| <code>admin_dn</code>              | <p>If <code>authenticated_bind</code> is set to <code>"true"</code>, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example:</p> <p><code>"cn=admin,dc=company,dc=com"</code></p>                                                                                                                  |
| <code>admin_password</code>        | <p>If <code>authenticated_bind</code> is set to <code>"true"</code>, enter the user password for the <code>admin_dn</code>.</p>                                                                                                                                                                                                                           |
| <code>search_dn_base</code>        | <p>Optionally set a base DN, for example:</p> <p><code>"dc=company,dc=com"</code></p>                                                                                                                                                                                                                                                                     |
| <code>bind_prefix</code>           | <p>Set the prefix to the DN, for example:</p> <p><code>(uid=</code></p>                                                                                                                                                                                                                                                                                   |
| <code>bind_suffix</code>           | <p>Set the suffix to the DN, for example:</p> <p><code>)</code></p>                                                                                                                                                                                                                                                                                       |

| Properties               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>attribute_mapping</b> | <p>If <b>user_managed</b> is set to <b>true</b>, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows:</p> <pre>ldap_registry_attribute_name: "apic_ldap_attribute_value"</pre> <p>Where:</p> <ul style="list-style-type: none"> <li><code>ldap_registry_attribute_name</code> - is the name of the source LDAP attribute</li> <li><code>apic_ldap_attribute_value</code> - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in [ ] with the value that the user supplies when signing up.</li> </ul> <p>The user profile properties that API Connect requires during user registration are <b>username</b>, <b>first_name</b>, <b>last_name</b>, <b>email</b>, and <b>password</b>. The following extract shows an example of an attribute mapping:</p> <pre>attribute_mapping: dn: "uid=[username],ou=users,dc=company,dc=com" cn: "[first_name] [last_name]" sn: "[last_name]" mail: "[email]" userPassword: "[password]"</pre> |

For authentication method **compose\_upn**, set the following configuration properties:

| Properties                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>search_dn_base</b>        | <p>Optionally set a base DN, for example:</p> <pre>"dc=company,dc=com"</pre>                                                                                                                                                                                                                                                      |
| <b>search_dn_scope</b>       | <p>Optionally set the search DN scope. The scope determines which part of the directory information tree is examined. Possible values are:</p> <ul style="list-style-type: none"> <li><b>base</b></li> <li><b>one</b></li> <li><b>sub</b></li> </ul>                                                                              |

| Property                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>search_dn_filter_prefix</code> | Set the prefix to the DN, for example:<br><code>(uid=</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>search_dn_filter_suffix</code> | Set the suffix to the DN, for example:<br><code>)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>attribute_mapping</code>       | <p>If <code>user_managed</code> is set to <code>true</code>, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows:</p> <pre>ldap_registry_attribute_name: "apic_ldap_attribute_value"</pre> <p>Where:</p> <ul style="list-style-type: none"> <li><code>ldap_registry_attribute_name</code> - is the name of the source LDAP attribute</li> <li><code>apic_ldap_attribute_value</code> - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in [ ] with the value that the user supplies when signing up.</li> </ul> <p>The user profile properties that API Connect requires during user registration are <code>username</code>, <code>first_name</code>, <code>last_name</code>, <code>email</code>, and <code>password</code>. The following extract shows an example of an attribute mapping:</p> <pre>attribute_mapping: dn: "uid=[username],ou=users,dc=company,dc=com" cn: "[first_name] [last_name]" sn: "[last_name]" mail: "[email]" userPassword: "[password]"</pre> |

Save your `ldap_config_file.yaml` so it can be accessed by the `user-registries:create` command in the following section. See the [Example](#) section for an example configuration file.

## Creating your LDAP user registry

To create your shared LDAP user registry, run the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org admin ldap_config_file.yaml
```

where:

- `mgmt_endpoint_url` is the platform API endpoint URL.
- `--org admin` means that the registry will be created in the admin organization, which is required for a user registry to be shared.
- `ldap_config_file` is the name of the YAML file that defines the configuration of your LDAP user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

The `registry_name` is derived from the `name` property in the configuration YAML file. The `registry_url` is the URL with which the registry resource can be accessed. Your shared LDAP user registry is now created; see the following sections for instructions on how to make the registry available to users.

## Configuring your LDAP registry for Cloud Manager or API Manager login

If you want to make your LDAP registry available for authenticating Cloud Manager and API Manager users, you must configure it on the management server.

- Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

- Determine what the current user registries are, because you will need to confirm these as well as add your new LDAP registry:

```
apic user-registry-settings:get --server mgmt_endpoint_url --output -
```

This command outputs a list of all the current user registries in your environment, similar to the following example:

```
type: user_registry_setting
api_version: 2.0.0
name: user-registry-setting
admin_user_registry_default_url: >-
 https://server.com/api/user-registries/xxxxx/xxxxx-1234
admin_user_registry_urls:
- >-
 https://server.com/api/user-registries/xxxxx/xxxxx-1234
provider_user_registry_default_url: >-
 https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
provider_user_registry_urls:
- >-
 https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
created_at: '2019-09-30T12:22:19.467Z'
updated_at: '2019-10-17T10:05:37.867Z'
url: 'https://server.com/api/cloud/settings/user-registries'
```

- Enter the following command to update your user registries (the terminating hyphen character means that the command takes input from the command line):

```
apic user-registry-settings:update --server mgmt_endpoint_url -
```

The following message is output:

```
Reading USER_REGISTRY_SETTING_FILE arg from stdin
```

- If you want to make your LDAP registry available for authenticating Cloud Manager users, enter the following data, followed by a new line:

```
admin_user_registry_urls:
- >-
 current_admin_user_registry_urls
- new_ldap_user_registry_url
```

where:

- `current_admin_user_registry_urls` are the current admin user registry URLs, as listed in Step 2 in the `admin_user_registry_urls` section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
  - `new_ldap_user_registry_url` is the URL of your new LDAP user registry, as determined in Step 1.
5. If you want to make your LDAP registry available for authenticating API Manager users, enter the following data, followed by a new line:

```
provider_user_registry_urls:
- >-
 current_provider_user_registry_urls
- new_ldap_user_registry_url
```

where:

- `current_provider_user_registry_urls` are the current provider organization user registry URLs, as listed in Step 2 in the `provider_user_registry_urls` section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
  - `new_ldap_user_registry_url` is the URL of your new LDAP user registry, as determined in Step 1.
6. Press **CTRL D** to terminate the input. A confirmation message is output, for example:

```
user-registry-setting https://server.com/api/cloud/settings/user-registries
```

where `server.com` is your management server endpoint.

## Configuring your LDAP registry in a Catalog

If you want to make your LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

2. Log in to the management server as a member of a provider organization by entering the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

For full details of the `apic login` command, see [Logging in to a management server](#).

3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
```

where `catalog_name` is the value of the `name` property of the required Catalog. The command returns:

```
Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
```

4. Enter the following data, followed by a new line:

```
user_registry_url: ldap_registry_url
```

where `ldap_registry_url` is the URL of your LDAP registry, obtained in step 1.

5. Press **CTRL D** to terminate the input.

## Switching your LDAP registry between writable and read-only

After an LDAP user registry has been created, it can be switched between writable and read-only by updating the `user_managed` property in the registry configuration. Complete the following steps.

1. Determine the name or ID of the LDAP user registry that you want to update, by running the following command (or you can use the summary from the registry creation):

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

The command returns a list of all the user registries on that server, shown by name followed by their registry URL. The registry ID is located at the end of the URL, for example `https://company.com/api/user-registries/x-x-x-x-x/registry_id`.

2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic user-registries:update --server mgmt_endpoint_url --org admin registry_name_or_id -
```

where `registry_name_or_id` is the name or ID of the LDAP user registry that you want to update (as determined in the previous step). The command returns:

```
Reading USER_REGISTRY_FILE arg from stdin
```

3. Enter the following data, followed by a new line:

```
user_managed: true_or_false
```

where `true` makes the registry writable, and `false` makes the registry read-only.

4. Press **CTRL D** to terminate the input.

Note that if you are changing your registry from read-only to writable, you must also set the `attribute_mapping` configuration, as described in the previous registry property tables.

## Using an LDAP user registry to secure APIs

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see [Creating a basic authentication security definition](#).
- To use for authentication in the User Security configuration for a native OAuth provider, see [Configuring user security for a native OAuth provider](#).

For details of all the `apic user-registries` and `apic configured-catalog-user-registries` commands, see [apic user-registries](#) and [apic configured-catalog-user-registries](#).

## Example

The following example shows a configuration file that uses the Search DN authentication method for setting up writable LDAP:

```
name: sdn-ldap
title: "SDN LDAP User Registry"
integration_url: https://mycompany.com/api/cloud/integrations/user-registry/xxx-xxx-xxx
user_managed: true
user_registry_managed: false
case_sensitive: false
identity_providers:
- name: ldap
 title: "SDN LDAP Identity Provider"
endpoint:
 endpoint: "ldap://mycompany.com:389"
configuration:
 authentication_method: search_dn
 authenticated_bind: "true"
 admin_dn: "cn=admin,dc=company,dc=com"
 admin_password: xxxx
 search_dn_base: "dc=company,dc=com"
 search_dn_scope: sub
 search_dn_filter_prefix: (uid=
 search_dn_filter_suffix:)
 attribute_mapping:
 dn: "uid=[username],ou=users,dc=company,dc=com"
 cn: "[first_name] [last_name]"
 sn: "[last_name]"
 mail: "[email]"
 userPassword: "[password]"
```

## Configuring a Local User Registry

A Local User Registry (LUR) can be configured to provide user authentication for both Cloud Manager and API Manager.

### About this task

Local User Registries (LURs) are the default user registries included in API Connect. LURs are local databases included with API Connect. Two default LURs are installed and configured during installation of API Connect. They cannot be deleted. The default Admin user account is stored in the Provider LUR.

You can create and configure a new LUR. After you create it, you must set it as active in Settings > User Registries. See [Selecting user registries for Cloud Manager and API Manager](#).

One of the following roles is required to configure user registries:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

## Procedure

Follow these steps to configure a new LUR:

1. In the Cloud Manager, click .
2. Click Create in the User Registries section.  
Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

3. Select Local User Registry as the type for the user registry and enter the following information:

| Field                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)        | Enter a descriptive name for use on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Name (required)         | The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see <a href="#">apic user-registries</a> .                                                                                                                                                                                                                                                                                                                                                                         |
| Display Name (required) | The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see <a href="#">Accessing the Cloud Manager user interface</a> , <a href="#">Accessing the API Manager user interface</a> , and <a href="#">Activating your API Manager user account</a> .<br>Note: The Developer Portal uses the <b>Title</b> of the User Registries when rendering them at the login page, rather than the <b>Display Name</b> . |
| Summary (optional)      | Enter a brief description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Case sensitive          | Select this setting if user names are case-sensitive.<br>Note: The Developer Portal does not support case sensitive usernames.<br>Note: After at least one user has been onboarded into the registry, you cannot change this setting.                                                                                                                                                                                                                                                                                                               |
| Email required          | Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding.<br>Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.                                                                                                                                               |
| Unique email address    | Select this checkbox if email addresses must be unique within the user registry. For new Local User Registries, this setting is always selected; so if email addresses are contained in the user record, they must be unique. However, for existing Local User Registries this setting can be edited.<br>Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.                                                             |

4. Click Save.

## Results

The user registry is saved and is available to be configured for user authentication in Cloud Manager or API Manager by selecting it in Settings > User Registries. See [Selecting user registries for Cloud Manager and API Manager](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Configuring an OIDC user registry

Configure a shared OIDC user registry for user onboarding and authentication when multi-factor authentication (MFA) is required.

You can create an OIDC user registry that is specific to a provider organization, or that is shared and available to all the provider organizations in your API Connect environment. An organization-specific OIDC user registry is used for onboarding and authenticating Developer Portal users, while a shared OIDC user registry can be used for onboarding and authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to create a shared registry. For information on how to create an organization-specific registry, see [Creating an OIDC user registry](#).

Important: If you are using Twitter as your OIDC provider, API Connect supports only the OAuth 1.0a method, so your Twitter application must be configured to use OAuth 1.0a. Other OIDC providers support OAuth 2.0.

API Connect provides two methods for creating an OIDC user registry in Cloud Manager, as described in the following sections:

- [Using the UI to configure an OIDC user registry](#)
- [Using the CLI to configure an OIDC user registry](#)

## Using the UI to configure an OIDC user registry

Use the Cloud Manager application's user interface to configure a shared OIDC user registry when multi-factor authentication (MFA) is required.

1. In the Cloud Manager navigation pane, click  Resources.
2. Click User Registries.
3. Click Create and select OIDC User Registry.

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same

backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

- On the Create OIDC User Registry page, use the fields in each of the following sections to configure the registry settings, and then click Create. Many of the registry settings are preconfigured to simplify the configuration steps.

#### Provider Type

Use the settings in Table 1 to define the provider type.

Table 1. Provider Type settings

| Field                | Description                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Provider Type        | OIDC provider. Select one of the following supported OIDC providers: <ul style="list-style-type: none"> <li>Facebook</li> <li>GitHub</li> <li>Google</li> <li>LinkedIn</li> <li>Slack</li> <li>Twitter</li> <li>Windows Live</li> <li>Standard OIDC (default value allows you to specify another provider)</li> </ul>                                                                                 |
| Title                | Provide a descriptive name for display purposes.                                                                                                                                                                                                                                                                                                                                                      |
| Name                 | Automatically generated. This name is used in CLI commands to reference the registry. For details of the CLI commands for managing user registries, see the <a href="#">apic user registries</a> topic in the Command Line tool reference section of this documentation.                                                                                                                              |
| Summary              | Provide a brief description of the new registry.                                                                                                                                                                                                                                                                                                                                                      |
| Email required       | Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding.<br>Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal. |
| Unique email address | Select this checkbox if email addresses must be unique within the user registry.<br>Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.                                                                                                                                    |

#### Provider Endpoint

Automatically generated for most supported providers. In the Authorization Endpoint field, type the URL of the provider's authorization endpoint.

#### Token Endpoint

Fill in the settings as described in Table 2.

Table 2. Token Endpoint settings

| Field | Description                                                                                                                       |
|-------|-----------------------------------------------------------------------------------------------------------------------------------|
| URL   | Preconfigured for most of the supported OIDC providers. Type the URL of the provider's token endpoint.                            |
| TLS   | Select the TLS Client Profile for the token endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile. |

#### UserInfo Endpoint

Fill in the settings as described in Table 3.

Table 3. UserInfo Endpoint settings

| Field | Description                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------------------|
| URL   | Preconfigured for most of the supported OIDC providers. Type the URL of the provider's userinfo endpoint.                            |
| TLS   | Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile. |

#### JWKS Endpoint

Fill in the settings as described in Table 4.

Table 4. JWKS Endpoint settings

| Field | Description                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------------------|
| URL   | Type the URL of the read-only endpoint that contains the public keys' information in JWKS format.                                    |
| TLS   | Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile. |

#### Logout

Fill in the settings as described in Table 5.

Table 5. Logout

| Field           | Description                                                                                                                                                                                                                                                                      |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Logout redirect | Optionally, give a logout redirect URL, allowing APIC to initiate an https 302 redirect to the configured endpoint.<br>Note: When the Developer Portal uses this feature, it does not retain control afterwards. Instead, the content is presented from the redirected endpoint. |

#### Client Information

Fill in the settings as described in Table 6.

Table 6. Client Information settings

| Field                        | Description                                                                                                                                                                                                                                                    |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Client ID                    | Provide the client ID of the application that is registered with the selected OIDC provider.                                                                                                                                                                   |
| Client Secret                | Provide the client secret of the application that is registered with the selected OIDC provider.                                                                                                                                                               |
| Response Type                | Preconfigured for most of the supported OIDC providers. Specify the data type of the response that will be received from the OIDC provider.                                                                                                                    |
| Scopes                       | Preconfigured for most of the supported OIDC providers. Specify the access scope for the OIDC provider.                                                                                                                                                        |
| Client Authentication Method | Preconfigured for most of the supported OIDC providers. Select the authentication method to be used with the OIDC provider.<br>Options are: <ul style="list-style-type: none"> <li>Http basic authentication schema</li> <li>Data encoded form body</li> </ul> |

#### Additional Support

Optional. Select the additional security parameters described in Table 7.

Table 7. Additional security options

| Security parameter                 | Setting name for CLI | Description                                                                                                            |
|------------------------------------|----------------------|------------------------------------------------------------------------------------------------------------------------|
| NONCE                              | <code>nonce</code>   | Enable the NONCE extension to prevent compromised requests from being used again (replayed).                           |
| Proof Key for Code Exchange (PKCE) | <code>pkce</code>    | Enable the PKCE extension to allow public clients to mitigate the threat of having the authorization code intercepted. |

#### Advanced Features

Optional. Select the advanced features described in Table 8.

Table 8. Advanced features

| Feature / UI Label                                        | Setting name for CLI                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------------|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Auto onboard                                              | <code>auto_onboard</code>              | Allow users to execute calls to APIs without logging in first, provided they present a valid token issued by the OIDC provider.<br>Note: Does not apply to consumer organizations.                                                                                                                                                                                                                                                                                         |
| Always use the userinfo endpoint                          | <code>userinfo</code>                  | Configures the OIDC user registry to always fetch user data from the userinfo endpoint, if populated.                                                                                                                                                                                                                                                                                                                                                                      |
| Use Portal as Endpoint for external OIDC provider traffic | <code>proxy_redirect</code>            | When authenticating users, redirect the external OIDC provider to communicate with the Developer Portal instead of API Manager.                                                                                                                                                                                                                                                                                                                                            |
| Return third-party access token                           | <code>proxy_access_token</code>        | Include the third-party OIDC access token in the response.<br>Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an <code>ERR_HTTP2_PROTOCOL_ERROR</code> or <code>ERR_CONNECTION_CLOSED</code> error. |
| Return third-party id_token                               | <code>proxy_id_token</code>            | Include the third-party OIDC id_token in the response.<br>Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an <code>ERR_HTTP2_PROTOCOL_ERROR</code> or <code>ERR_CONNECTION_CLOSED</code> error.     |
| Token Relay                                               | <code>token_relay</code>               | Allow <code>access_token/refresh_token</code> to send in 302 redirect for logout                                                                                                                                                                                                                                                                                                                                                                                           |
| Userinfo POST                                             | <code>post_userinfo</code>             | If supported by your OIDC provider, by using HTTP POST method when contacting userinfo endpoint.<br>Note: Not all OIDC providers support POST. Ensure that your OIDC provider supports this before you enable the feature.                                                                                                                                                                                                                                                 |
| Use IBM APIC token expiration setting from cloud          | <code>override_provider_ttl</code>     | Override the OIDC provider's token expiration setting with the access token and refresh token expiration settings that are configured in API Connect. For information on configuring the access token and refresh token expiration settings in API Connect, see <a href="#">Configuring timeouts for access tokens and refresh tokens</a> .                                                                                                                                |
| Disable hash verification (CLI only)                      | <code>disable_hash_verification</code> | Disable <code>at_hash, c_hash</code>                                                                                                                                                                                                                                                                                                                                                                                                                                       |

#### User Mapping

Fill in the settings as described in Table 9.

Note:

The User Mapping fields are preconfigured for most of the supported OIDC providers to minimize potential errors; use care when changing the settings. For the Standard OIDC option, contact your OIDC provider to obtain the details of the fields.

Table 9. User mapping settings

| Field      | Description                                                                                                                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username   | The name of the field in the response token that contains the user's user name.<br>Note: The username field must be unique for this OIDC registry, because it identifies the user in the system and cannot be changed. |
| Email      | The name of the field in the response token that contains the user's email address.                                                                                                                                    |
| First name | The name of the field in the response token that contains the user's given name.                                                                                                                                       |
| Last name  | The name of the field in the response token that contains the user's surname.                                                                                                                                          |

#### Redirect URI

The Redirect URI section lists the endpoints to which the OIDC authorization server will redirect the authorization code. There is one endpoint for each API Connect organization type: Cloud administration, Provider organization, and Consumer organization. The redirect endpoint is required when a user registers their application with the OIDC provider. For example, if this OIDC user registry is used by a provider organization, the user must register the provider organization's redirect endpoint with the OIDC provider. These read-only fields are provided for you to copy the endpoint values as required.

### Enabling the OIDC user registry

Complete the following steps to enable the new user registry for Cloud Manager, API Designer, or both.

1. On the navigation pane, click  Settings.
2. Click User Registries, > Edit.
3. Click Edit in the section that corresponds to the application for which you are enabling the new user registry.
4. Select the new OIDC user registry.
5. When you have finished enabling the registry, click Save.

## Using the CLI to configure an OIDC user registry

Use the developer toolkit CLI to configure a shared OIDC user registry when multi-factor authentication (MFA) is required.

You configure an OIDC user registry by first defining the registry details in a configuration file. You then use a CLI command to create the registry, passing the configuration file as parameter. To make the registry available to the Developer Portal, you must enable the registry in the associated Catalog.

Note:

- An OIDC registry, in common with a Local User Registry, cannot be used to secure APIs on the gateway.
- Because the interaction with the third party OIDC provider is handled by the Management server, the Management server is the application from the point of view of the third party OIDC provider. Your OIDC redirection endpoint, which is used by authorization server to send the token to the Management server, must be accessible to the OIDC provider through your firewall. When you register your application with the third party OIDC provider, you are required to supply the associated OIDC redirect URI, `https://consumer.mycompany.com/consumer-api/oauth2/redirect` for example. However, this information is not available until you have created your OIDC user registry in API Connect. You must therefore first register your application without this information, then update it later, as detailed in the instructions on this page.

## Logging in to the Management server

Before you can create an OIDC user registry, you must log in to your management server from the CLI. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
- title: Cloud Manager User Registry
 realm: admin/default-idp-1
- title: Corporate LDAP user registry
 realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`. For full details of the `apic login` command, see [Logging in to a management server](#).

## Defining your OIDC registry configuration

You define the configuration of your OIDC user registry in a YAML file. As a minimum, the YAML file must have the following content:

```
title: registry_title
integration_url: oidc_integration_url
case_sensitive: case_sensitivity_setting
email_required: true_or_false
email_unique_if_exist: true_or_false
configuration:
 client_id: 'app_client_id'
 client_secret: 'my-client-secret'
 provider_type: oidc_provider_type
```

where:

- `registry_title` is your chosen descriptive title for the user registry.
- `oidc_integration_url` is the OIDC integration URL in your API Connect configuration. You can determine the OIDC integration URL by using the following CLI command:

```
apic integrations:list --server mgmt_endpoint_url --subcollection user-registry
```

- `case_sensitivity_setting` determines whether your user registry is case-sensitive. Valid values are:
  - `true`
  - `false`

To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on the backend OIDC provider:

- **Only** set `case_sensitive` to `true` if the backend OIDC provider supports case-sensitivity.
  - Set `case_sensitive` to `false` if the backend OIDC provider does not support case-sensitivity.
- Note: After at least one user has been onboarded into the registry, you cannot change this setting.
- `email_required` determines whether an email address is required as part of the user onboarding process. Valid values are:
    - `true`
    - `false`

If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding.

Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.

- `email_unique_if_exist` determines whether email addresses must be unique within the user registry. Valid values are:
  - `true`
  - `false`

Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

- `app_client_id` is the client ID of the application that is registered with the OIDC server, and must be in string format.
- `my-client-secret` is the client secret of the application that is registered with the OIDC server, and must be in string format.
- `oidc_provider_type` is the type of OIDC provider; specify one of the following values:
  - `facebook`
  - `github`
  - `google`
  - `linkedin`
  - `slack`
  - `twitter`
  - `windows_live`

- **standard**

Use the **standard** provider type for any OIDC provider that is compliant with the OIDC standard.

Note: If the provider type is **standard**, you must include the following additional properties in the **configuration** section of your YAML file:

```
authorization_endpoint: 'oidc_auth_endpoint'
token_endpoint:
 endpoint: 'oidc_token_endpoint'
```

where:

- `oidc_auth_endpoint` is the authorization endpoint on the OIDC server, and must be in string format.
- `oidc_token_endpoint` is the token endpoint on the OIDC server, and must be in string format.

## Default OIDC configurations

For each OIDC provider type, API Connect assumes a default configuration, but you can override the default configuration properties in your YAML file. The default configurations are as follows:

- Facebook

```
authorization_endpoint: 'https://www.facebook.com/v3.1/dialog/oauth'
token_endpoint:
 endpoint: 'https://graph.facebook.com/v3.1/oauth/access_token'
userinfo_endpoint:
 endpoint: 'https://graph.facebook.com/me'
scope: email public_profile
field_mapping:
 username: email
 email: email
 last_name: last_name
 first_name: first_name
```

- Github

```
authorization_endpoint: 'https://github.com/login/oauth/authorize'
token_endpoint:
 endpoint: 'https://github.com/login/oauth/access_token'
userinfo_endpoint:
 endpoint: 'https://api.github.com/user'
scope: 'read:user user:email'
field_mapping:
 username: login
 email: email
 last_name: name
 first_name: name
```

- Google

```
authorization_endpoint: 'https://accounts.google.com/o/oauth2/v2/auth'
token_endpoint:
 endpoint: 'https://www.googleapis.com/oauth2/v4/token'
scope: openid profile email
field_mapping:
 username: email
 email: email
 last_name: family_name
 first_name: given_name
```

- LinkedIn

```
authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'
token_endpoint:
 endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'
userinfo_endpoint:
 endpoint: 'https://api.linkedin.com/v1/people/~:(id,first-name,last-name,picture-url,public-profile-url,email-address)?
format=json'
scope: r_basicprofile r_emailaddress
field_mapping:
 username: emailAddress
 email: emailAddress
 last_name: lastName
 first_name: firstName
credential_location: form_body
```

- Slack

```
authorization_endpoint: 'https://slack.com/oauth/authorize'
token_endpoint:
 endpoint: 'https://slack.com/api/oauth.access'
userinfo_endpoint:
 endpoint: 'https://slack.com/api/users.identity'
scope: identity.basic identity.email
field_mapping:
 username: user.email
 email: user.email
 last_name: user.name
 first_name: user.name
```

- Twitter

```
request_endpoint: https://api.twitter.com/oauth/request_token'
authorization_endpoint: https://api.twitter.com/oauth/authenticate'
token_endpoint:
 endpoint: 'https://api.twitter.com/oauth/access_token'
userinfo_endpoint:
```

```

 endpoint: 'https://api.twitter.com/1.1/account/verify_credentials.json'
 oauth_signature_method: 'HMAC-SHA1'
 field_mapping:
 email: email
 first_name: name
 last_name: name
 username: screen_name

```

- Windows Live

```

authorization_endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/authorize'
token_endpoint:
 endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/token'
 scope: openid offline_access profile email
 field_mapping:
 email: email
 username: preferred_username
 first_name: name
 last_name: name

```

- Standard

```

response_type: code
scope: openid
field_mapping:
 username: sub
 email: email
 last_name: family_name
 first_name: given_name
credential_location: auth_header

```

Although this is the default configuration for the `standard` provider type, you should contact your OIDC provider to obtain the details of the fields that you need to define.

## Creating your OIDC user registry

To create your OIDC user registry, use the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org admin oidc_config_file
```

where:

- `mgmt_endpoint_url` is the platform API endpoint URL.
- `organization_name` is the value of the `name` property of your provider organization.
- `oidc_config_file` is the name of the YAML file that defines the configuration of your OIDC user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

By default, the `registry_name` is derived from the `title` property in the configuration YAML file but you can override this by including a `name` property in the file. The `registry_url` is an internal URL that API Connect assigns to the registry.

After you have created your OIDC user registry, you must update your application registration with the third party OIDC provider to include the OIDC redirect URI; you can obtain this information by using the following command, which displays the details of the registry in the command window:

```
apic user-registries:get --server mgmt_endpoint_url --org organization_name registry_name --output -
```

The required `oidc_redirect_uri` value is in the `consumer:` section; for example:

```

consumer:
 oidc_redirect_uri: https://consumer.mycompany.com/consumer-api/oauth2/redirect

```

## Enabling your OIDC registry in a Catalog

If you want to make your OIDC registry available for onboarding and authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your OIDC user registry by using the following command:

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

2. Log in to the Management server as a member of a provider organization; enter the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

For full details of the `apic login` command, see [Logging in to a management server](#).

3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
```

where `catalog_name` is the value of the `name` property of the required Catalog. The command returns

```
Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
```

4. Enter the following data, followed by a new line:

```
user_registry_url: oidc_registry_url
```

where `oidc_registry_url` is the URL of your OIDC registry, obtained in step [1](#).

5. Press `CTRL D` to terminate the input.

For details of all the `apic user-registries` and `apic configured-catalog-user-registries` commands, see [apic user-registries](#) and [apic configured-catalog-user-registries](#).

You can also complete the operations described in this topic by using the API Connect REST APIs; see the [API Connect REST API documentation](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Setting visibility for a user registry

The visibility setting determines which provider organizations can access a resource, for example, user registries.

### Before you begin

---

You must complete the following tasks:

- [Creating an Availability Zone](#)
- [Registering a gateway service](#)

### About this task

---

The user registry visibility setting controls which provider organizations are able to use that registry for authenticating Developer Portal users, or for securing APIs. For details on how to specify the user registries that can be used for authenticating users of the Cloud Manager and API Manager user interfaces, see [Selecting user registries for Cloud Manager and API Manager](#).

### Procedure

---

Follow these steps to set the visibility for the resources (user registries) in your on-premises cloud:

1. In the Cloud Manager, click  Resources.
2. Select User Registries as the resource to view.
3. From the list of user registries, choose Edit visibility from the actions menu next to the name of the user registry you are working with.
4. Select the visibility setting for the user registry. The options are:
  - Private - the user registry is not visible and cannot be used by any provider organization
  - Public - the user registry is visible and can be used by all provider organizations
  - Custom - the user registry is visible only to the provider organizations designated by you
5. For Custom visibility, select the provider organizations that you want to have access to the user registry.
6. Click Make visible to complete the operation.

### Results

---

For Private, the user registry cannot be used by any provider organizations. For Public, the user registry can be used by all provider organizations. For Custom, the user registry can be used by the provider organizations that you designate.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Deleting a user registry

As the Cloud Manager administrator, you can delete user registries.

### About this task

---

Complete the following steps to delete a user registry. All users within the user registry will be deleted. The pre-configured user registries (API Manager Local User Registry and Cloud Manager Local User Registry) may not be deleted. Any user registry marked as the Default in Settings, > User Registries also may not be deleted.

One of the following roles is required to delete a user registry:

- Administrator
- Owner

### Procedure

---

1. In the Cloud Manager, click .
2. Select User Registries to see the list of current user registries in your cloud.
3. Choose Delete from the overflow menu that is adjacent to the user registry you want to delete.
4. Optionally, you can delete multiple user registries by marking the checkboxes and selecting Delete Selected User Registries from the overflow menu for the list.

5. Confirm the deletion.

## Results

---

The user registry is deleted and removed from the User Registries list in Cloud Manager. All user accounts contained in the user registry are deleted.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Removing a user from a user registry

As an API Connect user, you can remove yourself from an API Connect user registry. As an administrative user, you can remove other users from an API Connect user registry.

For details on how to remove a user from a user registry, see the following subtopics:

- [Removing yourself from a user registry](#)  
As an API Connect user, you can remove yourself from the API Connect user registry in which you were registered, by using the developer toolkit CLI.
- [Removing another user from a user registry](#)  
You can remove a user from an API Connect user registry by using the developer toolkit CLI.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Removing yourself from a user registry

As an API Connect user, you can remove yourself from the API Connect user registry in which you were registered, by using the developer toolkit CLI.

## Before you begin

---

You cannot remove yourself from a user registry if you are a member of a provider organization. Before removing yourself from a user registry, ensure that you have been deleted from any provider organizations. For more information, see [Removing a user from an organization](#).

## Procedure

---

1. Log in to the management server as the user that you want to remove.

The format of the login command depends on whether you are a user in the Cloud Manager admin organization, or you are a user in a provider organization.

If you are a Cloud Manager admin user, enter the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

If you are a provider organization user, enter the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

If you want to log in as a member of the cloud administration organization, or as a member of a provider organization, you can help determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope scope --server mgmt_endpoint_url --fields title,realm
```

where `scope` has the value `admin` or `provider` depending on whether you want to log in as a member of the cloud administration organization, or as a member of a provider organization. The output lists the names and titles of all identity providers, for example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
- title: Cloud Manager User Registry
 realm: admin/default-idp-1
- title: Corporate LDAP user registry
 realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`, and the default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.

For full details of the `apic login` command, see [Logging in to a management server](#).

Note: If the same user registry is used for both the Cloud Manager and API Manager user interfaces, and you have access to both, when you remove yourself from the user registry you will lose access to both user interfaces regardless of which organization you log in to.

2. Remove yourself from the user registry. Enter the following command:

```
apic me:delete --server mgmt_endpoint_url
```

For example:

```
apic me:delete --server platform-api.myserver.com.com
```

The command confirms successful removal by returning the details of the deleted user; for example:

```
user1 [state: enabled] https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Removing another user from a user registry

You can remove a user from an API Connect user registry by using the developer toolkit CLI.

### Before you begin

To complete this task, you must have Administrator access to your API Connect cloud, or be the owner of a provider organization, depending on the scope of the user registry.

You cannot remove a user from a user registry if that user is a member of the Cloud Manager admin organization, a provider organization, or a consumer organization, and that user registry is used for the associated login. Before removing a user from a user registry, ensure that they have been deleted from any organizations for which that user registry is used for login. For more information, see [Deleting a member](#) or [Removing a user from an organization](#).

### Procedure

1. Log in to the management server.
  - If the user registry is defined at the cloud administration level, and therefore available to all provider organizations, you must log in as a member of the Cloud Manager admin organization.
  - If the user registry is defined at a provider organization level, and therefore specific to that provider organization, you must log in as the organization owner.For full details of the `apic login` command, see [Logging in to a management server](#).

Note: If the same user registry is used for both the Cloud Manager and API Manager user interfaces, and the user has access to both, when you remove them from the user registry they will lose access to both even though you are logging in to the admin organization.

2. Identify the name of the user registry from which you want to remove the user. Enter the following command:

```
apic user-registries:list --server mgmt_endpoint_url --org organization_name
```

where `organization_name` has the value `admin` if you are logged in as a member of the Cloud Manager admin organization, or is the name of the provider organization if you are logged in as an organization owner.

For example:

```
apic user-registries:list --server platform-api.myserver.com.com --org admin
```

The command returns a list of all user registries, with the registry name displayed first; for example:

```
api-manager-lur https://platform-api.myserver.com.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245
cloud-manager-lur https://platform-api.myserver.com.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/3adbf524-cd74-4051-99c0-89ce5ffcc9c0
my-ldap https://platform-api.myserver.com.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/29eae413-cd74-4051-99c0-89ce5ffcc9c0
```

3. Identify the name of the user, from the required user registry, that you want to remove. Enter the following command:

```
apic users:list --server mgmt_endpoint_url --org organization_name --user-registry user_registry_name
```

For example:

```
apic users:list --server platform-api.myserver.com.com --org admin --user-registry my-ldap
```

The command returns a list of all users in the user registry, with the user name displayed first; for example:

```
user1 [state: enabled] https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
user2 [state: enabled] https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/12f1aa82-d9f0-4670-99f1-7500d1fb6583
```

4. Remove the required user from the user registry. Enter the following command:

```
apic users:delete user_name --server mgmt_endpoint_url --org organization_name --user-registry user_registry_name
```

For example:

```
apic users:delete user1 --server platform-api.myserver.com.com --org admin --user-registry my-ldap
```

The command confirms successful removal by returning the details of the deleted user; for example:

```
user1 [state: enabled] https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
```

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## TLS profiles overview

API Connect supports TLS Profiles for securing data transmission over HTTPS.

### Introduction to TLS profiles

---

Important: API Connect includes several default TLS profiles to help you get started working with the application. The default profiles should not be used in a production environment. It is important to create your own profiles to ensure a secure network.

API Connect may need to transmit data across an untrusted network, for example, when accessing the Gateway, email server, or LDAP server. TLS provides secure network layer transportation of data between two parties.

There are two types of TLS Profiles: a TLS Server Profile and a TLS Client Profile. A TLS Server Profile is used by the Gateway to configure its endpoint for use during API execution. A TLS Client profile is used whenever the system needs to communicate with another endpoint over TLS.

The components of a TLS Profile are:

- TLS Protocol version indicates the versions of the Transport Layer Security Protocol required for the profile. TLS Protocol versions 1.0, 1.1, and 1.2 are supported.
- Optional support for mutual authentication and renegotiation for Server Profiles.
- Optional support for weak server connections and Server Name Indication for Client Profiles.
- Cipher suites to secure HTTPs communication within the API Connect ecosystem.
- Keystores containing public and private key pairs.
- Truststores containing public keys for trusted third party services, such as Google, Facebook, or Verisign.
- [Viewing TLS Profiles, Keystores, and Truststores](#)  
The current list of TLS profiles, Keystores, and Truststores can be viewed on the main TLS screen.
- [Creating a TLS Server Profile](#)  
In Cloud Manager, you can configure the profile that is used on the gateway when it acts as a TLS server.
- [Creating a TLS Client Profile](#)  
In Cloud Manager, TLS profiles are configured as a Resource to provide secure transmission of data over HTTPs.
- [Creating a Keystore](#)  
Each keystore contain a matched pair of a public certificates and its private keys. These artifacts provide identity information during a TLS handshake.
- [Creating a Truststore](#)  
A truststore contains a list of certificates. The certificates are used to verify the peer during a TLS handshake.
- [Viewing certificate details and adding certificates to a keystore or truststore](#)  
You can view details for the certificates in an existing keystore or truststore and add additional certificates.
- [Generating a self-signed certificate using OpenSSL](#)  
OpenSSL is an open source implementation of the SSL and TLS protocols. It provides the transport layer security over the normal communications layer, allowing it to be intertwined with many network applications and services.
- [Generating a PKCS#12 file for Certificate Authority](#)  
PKCS#12 (P12) files define an archive file format for storing cryptographic objects as a single file. API Connect supports the P12 file format for uploading a keystore and truststore. The keystore should contain both a private and public key along with intermediate CA certificates.
- [Binding a TLS server profile to a gateway service](#)  
You can bind the SSL certificate of a TLS profile to a gateway service to establish an HTTPS binding. This enables you to access the service by using the HTTPS communication protocol.
- [Updating the PKCS#12 certificate for a TLS server profile](#)  
A server certificate bound to a gateway service can be invalidated if the host name in the digital certificate of the server does not match the URL specified by the client, or because it has expired. When this happens, you must update the TLS profile with a new CA certificate or PKCS#12 (P12) file.

### Related tasks

---

- [Creating a TLS Server Profile](#)
- [Creating a TLS Client Profile](#)
- [Creating a Keystore](#)

---

## Viewing TLS Profiles, Keystores, and Truststores

The current list of TLS profiles, Keystores, and Truststores can be viewed on the main TLS screen.

### Before you begin

---

Important: API Connect includes several default TLS profiles to help you get started working with the application. The default profiles should not be used in a production environment. It is important to create your own profiles to ensure a secure network. One of the following roles is required to view TLS Server Profiles:

- Administrator
- Owner
- Topology Administrator
- Viewer
- Custom role with the `Settings: Manage or Settings: view permissions`

## About this task

---

The TLS list screen provides a list of TLS Profiles, Keystores and Truststores configured for your cloud. Users with view permissions can use this screen as a reference for the TLS Profiles.

Users with manage permissions can create new Profiles, Keystores, and Truststores; edit existing ones; and delete items that are no longer needed. Users can view the Keystores and Truststores assigned to the profiles.

Users can view and set the visibility for Client Profiles. For more information on visibility, see [Setting visibility for a TLS Client Profile](#)

## Procedure

---

Following are the tasks you can perform using the list screen as a base:

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Complete your management task:
  - To create a new item, click Create next to the table for the type of item you want to create.
  - To edit an existing item, either click the Title of the item, or click the options menu  and then click Edit.
  - To set the visibility of a TLS Client Profile, click the options menu  for the profile, and then click Edit Visibility.
  - To delete an existing item, click the options menu  for the profile, and then click Delete.

## Related concepts

---

- [TLS profiles overview](#)

## Related tasks

---

- [Creating a TLS Server Profile](#)
- [Creating a TLS Client Profile](#)
- [Creating a Keystore](#)
- [Creating a Truststore](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details. For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

---

## Creating a TLS Server Profile

In Cloud Manager, you can configure the profile that is used on the gateway when it acts as a TLS server.

## Before you begin

---

Important: API Connect includes several default TLS profiles to help you get started. The default profiles should not be used in a production environment. It is important to create your own profiles to secure your network.

One of the following roles is required to configure TLS Server Profiles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage permissions`

## About this task

---

The Server profile is for the gateway when it is acting as the TLS server.

## Procedure

---

Perform the following steps to create a TLS Server profile:

1. In the Cloud Manager, click  Resources.

2. Select TLS.
3. Click Create in the TLS Server Profile table.
4. Enter the fields to configure the TLS Server Profile:

| Field                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)                 | Enter a Title for the profile. The title is displayed on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Name (required)                  | The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage TLS Server Profiles, see <a href="#">apic tls-server-profiles</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Version (required)               | Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, <i>MyProfile 1.0</i> and <i>MyProfile 1.1</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Summary (optional)               | Enter a description of the profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Protocols (required)             | Select one or more supported TLS protocol versions. The default is 1.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Mutual Authentication (required) | Determines the level of two-way authentication for the server profile. In two-way authentication, the server responds to a client by sending a request for the client certificate. <ul style="list-style-type: none"> <li>• None (default) No support for mutual authentication.</li> <li>• Request Enable this option to request client authentication during the TLS handshake. When the application sends the request, the gateway requests that the application sends the certificate. If the client does not send the certificate, the certificate is not checked on the gateway.</li> <li>• Require Enable this option to require client authentication during the TLS handshake. When the application sends the request, the gateway requests that the application sends the certificate. If the client does not send the certificate, the TLS handshake fails and the request is blocked.</li> </ul> |
| Limit Renegotiation (optional)   | Client-initiated renegotiation allows the connection to be retried. The default is to prevent renegotiation. Remove the checkmark to allow renegotiation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Keystore (required)              | A keystore is a repository containing a public and private key pair. The Server Profile requires a keystore in order to securely identify the system. When an application sends an API request, the keystore is used to verify a matching certificate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Truststore (optional)            | A truststore is a repository containing certificates. The certificates are used to verify the peer during a TLS handshake. If, in addition to a keystore, a truststore is specified, the certificate is further checked for validity by ensuring that is signed by the root certificate, which must be in the truststore.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Ciphers (required)               | Cipher suites are encryption/decryption algorithms used to secure HTTPs communication within the API Connect ecosystem. Select the ciphers that the profile supports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details. For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Creating a TLS Client Profile

In Cloud Manager, TLS profiles are configured as a Resource to provide secure transmission of data over HTTPs.

### Before you begin

One of the following roles is required to configure TLS Profiles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

### About this task

API Connect uses both TLS Server and TLS Client profiles. A TLS Server profile is presented when a communication request is received. The Server profile validates the request against the Keystore and protocol version to determine whether the connection is secure. The Client profile is presented to initiate communication with another system. Client Profiles may be made visible for use by provider organizations in policies in API Manager. See [Setting visibility for a TLS Client Profile](#).

### Procedure

Perform the following steps to create a TLS Client profile:

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Click Create in the TLS Client Profile table.
4. Enter the fields to configure the TLS Client Profile:

| Field                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)             | Enter a Title for the profile. The title is displayed on the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Name (required)              | The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage a TLS Client Profile, see <a href="#">apic tls-client-profiles</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Version (required)           | Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, <i>MyProfile 1.0</i> and <i>MyProfile 1.1</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Summary (optional)           | Enter a description of the profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Protocols (required)         | Select one or more supported TLS protocol versions. The default is 1.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Server Connection (optional) | Specify whether to support weak or insecure credentials. <ul style="list-style-type: none"> <li>• Allow insecure server connections - Insecure server connections may result from self-signed certificates, expired or corrupted certificates, or certificates from an unknown or untrusted source. Check this box to allow the connection to proceed with an insecure connection. The default is to not allow insecure server connections.</li> <li>• Support Server Name Indication (SNI) - Check this box to enable SNI. SNI allows support for multiple certificates presented on the same IP address using different host names. The client profile sends the name of a virtual domain as part of the TLS negotiation. The default is to enable SNI.</li> </ul> |
| Keystore (optional)          | A Keystore is a repository containing public and private key pairs. Select the keystore where you will store the certificates for the profile. Default keystores are provided, and you can also create your own.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Truststore (optional)        | A Truststore is a repository containing verified public keys, which are usually obtained from a third-party certificate authority. Truststores provide secure identification for peer systems. A truststore is usually used when mutual authentication is enabled. Select a truststore for the profile. Default truststores are provided, and you can also create your own.                                                                                                                                                                                                                                                                                                                                                                                          |
| Ciphers (required)           | Cipher suites are encryption/decryption algorithms used to secure HTTPs communication within the API Connect ecosystem. Select the ciphers that the profile supports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

5. Click Save.

## Setting visibility for a TLS Client Profile

The visibility setting determines which provider organizations can access a resource.

### Before you begin

You must complete the following task:

- [Creating a TLS Client Profile](#)

### About this task

The visibility setting gives you control over the resources that are available to provider organizations.

## Procedure

Follow these steps to set the visibility for the resources in your on-premises cloud:

1. In the Cloud Manager, click  Resources.
2. Select TLS as the resource to view.

3. From the table of TLS Client Profiles, choose Edit visibility from the  options menu next to the name of the profile you are managing.
4. Select the visibility setting for the profile. The options are:
  - Private - the profile is visible only in Cloud Manager and cannot be used by any provider organization
  - Public - the profile is visible and can be used by all provider organizations
  - Custom - the profile is visible only to the provider organizations designated by you
5. For Custom visibility, select the provider organizations that you want to have access to the profile.
6. Click Save to complete the operation.

## Results

For Private, the profile cannot be used by any provider organizations. For Public, the profile can be used by all provider organizations. For Custom, the profile can be used by the provider organizations that you designate. If visible, the profiles will be available in API Manager.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Defining elliptic curve cryptographic schemes for a TLS client profile

You define the elliptic curve cryptographic schemes for a TLS client profile by using the developer toolkit CLI.

### About this task

To define elliptic curve cryptographic schemes for a TLS client profile, you include `elliptic_curve_auto_negotiation` and `elliptic_curve` properties in a YAML file definition for the TLS client profile. The `elliptic_curve` property lists the required elliptic curve cryptographic schemes. For example:

```
elliptic_curve_auto_negotiation: false
elliptic_curve:
 - secp521r1
 - secp384r1
 - prime256v1
```

You then use the developer toolkit CLI to create the TLS client profile in API Connect.

When `elliptic_curve_auto_negotiation` is set to `true`, the system negotiates the Elliptic-curve Diffie-Hellman (ECDH) key agreement automatically with its peer, and any `elliptic_curve` property settings are ignored.

The following example shows a complete YAML file for a TLS client profile:

```
type: tls_client_profile
name: my-tls-client-profile
version: 1.0.0
title: My TLS client profile
protocols:
 - tls_v1.2
ciphers:
 - ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
elliptic_curve_auto_negotiation: false
elliptic_curve:
 - sect163k1
insecure_server_connections: false
server_name_indication: true
```

Note:

- The `elliptic_curve_auto_negotiation` option is not supported by any of the API Connect gateway types. If the TLS client profile is targeted for an API Connect gateway; this setting is ignored by the gateway.
- The elliptic curve cryptographic schemes shown in each row of the following table are equivalent. However, API Connect recognizes only one or the other depending on how the TLS profile is used, as indicated in the table.

Table 1.

| API enforcement on the gateway | API Connect server access security |
|--------------------------------|------------------------------------|
| secp192r1                      | prime192v1                         |
| secp256r1                      | prime256v1                         |

Therefore, if you want to use either of these schemes and are unsure whether you are targeting the TLS client profile to the API Connect gateway for API enforcement, whether you are using it to secure user access to the API Connect servers, or whether it will be used for both purposes, specify both equivalent schemes; API Connect will simply ignore the non-relevant scheme. For example:

```
elliptic_curve:
 .
 .
 .
 - secp256r1
 - prime256v1
 .
 .
 .
```

## Procedure

To create a TLS client profile with elliptic curve cryptographic schemes defined, complete the following steps:

1. Create a YAML file definition for your TLS client profile, with the required `elliptic_curve` property.
2. Log in to the management server from the developer toolkit CLI. Log in either as a member of the cloud administration organization or as a member of a provider organization, depending on where you want to create the TLS client profile. For details, see [Logging in to a management server](#).
3. Create the TLS client profile by using the following command:

```
apic tls-client-profiles:create --server mgmt_endpoint_url --org organization_name tls_client_profile_yaml_file
```

where:

- `mgmt_endpoint_url` is the platform API endpoint URL, and is the same as that which was used when you logged in at step 2.
- `organization_name` is either `admin`, for the cloud administration organization, or the name of your provider organization, and is the same as that which was used when you logged in at step 2.
- `tls_client_profile_yaml_file` is the name of the YAML file that contains the definition for your TLS client profile.

Note: When you install IBM® API Connect, the API Connect gateway has a pre-supplied default TLS client profile that is used for API enforcement if you do not configure a TLS client profile; you cannot configure this default TLS client profile on the gateway.

For reference details of all the `apic tls-client-profiles` commands, see [apic tls-client-profiles](#).

You can also complete the operations described in this topic by using the API Connect REST APIs; see the [API Connect REST API documentation](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Creating a Keystore

Each keystore contain a matched pair of a public certificates and its private keys. These artifacts provide identity information during a TLS handshake.

### Before you begin

Cloud Manager and API Manager both support and use TLS certificates, but they do not themselves produce strong encryption keys or manage your encryption keys. Encryption keys are generated and managed according to your own procedures. For more information, see [Generating a PKCS#12 file for Certificate Authority](#) and [Generating a self-signed certificate using OpenSSL](#).

One of the following roles is required to configure Keystores:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

### About this task

API Connect includes pre-configured Keystores which may be used for testing purposes. For production environments, we suggest creating a new, secure Keystore.

### Procedure

Perform the following steps to create a TLS Client profile:

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Click Create in the Keystore table.

| Field                                                   | Description                                                                                                                                                                                                                                                                                 |
|---------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)                                        | Enter a Title for the Keystore. The title is displayed on the screen.                                                                                                                                                                                                                       |
| Name (required)                                         | The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage keystores, see <a href="#">apic keystores</a> .                                                                           |
| Summary (optional)                                      | Enter a brief description.                                                                                                                                                                                                                                                                  |
| Private Key & Public Key:<br>Step 1: Upload private key | Upload the file containing the private key certificate. If necessary, you can click Browse to locate the file. If the file contains both the private and public keys, upload it in Step 1. Private and public keys are always uploaded in pairs, either in a single file or separate files. |
| Private key password (optional)                         | Enter the password for the private key if it has a password.                                                                                                                                                                                                                                |
| Private Key & Public Key:<br>Step 2: Upload public key  | If the public key is contained in a separate file, upload it in Step 2. Private and Public keys are always uploaded in pairs, either in a single file or separate files.                                                                                                                    |

4. Click Save.

Note: After they have been uploaded, private keys cannot be downloaded from API Connect.

## Creating a Truststore

A truststore contains a list of certificates. The certificates are used to verify the peer during a TLS handshake.

### Before you begin

One of the following roles is required to configure Truststores:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

### About this task

Cloud Manager and API Manager both support and use TLS certificates, but they do not themselves produce strong encryption keys or manage your encryption keys. Encryption keys are generated and managed according to your own procedures. For more information, see [Generating a PKCS#12 file for Certificate Authority](#) and [Generating a self-signed certificate using OpenSSL](#).

API Connect includes pre-configured Truststores which may be used for testing purposes. For production environments, we suggest creating a new, secure Truststore.

### Procedure

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Click Create in the Truststore table.

| Field              |                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title (required)   | Enter a Title for the Truststore. The title is displayed on the screen.                                                                                                                                               |
| Name (required)    | The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage truststores, see <a href="#">apic truststores</a> . |
| Summary (optional) | Enter a brief description.                                                                                                                                                                                            |
| Public Keys        | Upload the file containing the public key certificate. If necessary you can click Browse to locate the file.                                                                                                          |

4. Click Save.

## Viewing certificate details and adding certificates to a keystore or truststore

You can view details for the certificates in an existing keystore or truststore and add additional certificates.

### Before you begin

One of the following roles is required to edit Keystores and Truststores:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

## About this task

---

API Connect includes pre-configured Keystores and Truststores which you can use for testing purposes. For production environments, we suggest creating a new, secure Keystore or Truststore. From an existing Keystore or Truststore, you can edit the title, view the details of the certificates, and add new certificates.

## Procedure

---

To work with existing keystores and truststores:

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Click the name of the keystore or truststore.
4. Edit the name and summary if needed.
5. The Subject, Finger Print, and Expiration date is shown for each certificate in the keystore or truststore. Click > to view the certificate details.
6. Add additional private and/or public keys if needed.
7. Click Save.

Note: After they have been uploaded, private keys cannot be downloaded from API Connect.

---

---

## Generating a self-signed certificate using OpenSSL

OpenSSL is an open source implementation of the SSL and TLS protocols. It provides the transport layer security over the normal communications layer, allowing it to be intertwined with many network applications and services.

## Before you begin

---

One of the following roles is required to complete this task:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

## About this task

---

This topic tells you how to generate a self-signed SSL certificate request using the OpenSSL toolkit to enable HTTPS connections.

## Procedure

---

To generate a self-signed SSL certificate using the OpenSSL, complete the following steps:

1. Write down the Common Name (CN) for your SSL Certificate. The CN is the fully qualified name for the system that uses the certificate. For static DNS, use the hostname or IP address set in your Gateway Cluster (for example, `192.16.183.131` or `dp1.acme.com`).
2. Run the following OpenSSL command to generate your private key and public certificate. Answer the questions and enter the Common Name when prompted.

```
openssl req -newkey rsa:2048 -nodes -keyout key.pem -x509 -days 365 -out certificate.pem
```

3. Review the created certificate:

```
openssl x509 -text -noout -in certificate.pem
```

4. Combine your key and certificate in a PKCS#12 (P12) bundle:

```
openssl pkcs12 -inkey key.pem -in certificate.pem -export -out certificate.p12
```

5. Validate your P2 file.

```
openssl pkcs12 -in certificate.p12 -noout -info
```

Once the certificate file is created, it can be uploaded to a keystore.

6. In the Cloud Manager, click  Resources.

7. Select TLS.

8. Click Create in the Keystore table.

9. Create a Keystore and upload the certificate file following the instructions at [Creating a Keystore](#).

Note:

- API Connect supports only the P12 (PKCS12) format file for the present certificate.
- Your P12 file must contain the private key, the public certificate from the Certificate Authority, and all intermediate certificates used for signing.
- Your P12 file can contain a maximum of 10 intermediate certificates.

10. Click Save.

---

---

## Generating a PKCS#12 file for Certificate Authority

PKCS#12 (P12) files define an archive file format for storing cryptographic objects as a single file. API Connect supports the P12 file format for uploading a keystore and truststore. The keystore should contain both a private and public key along with intermediate CA certificates.

## Before you begin

---

One of the following roles is required to add a key to a keystore or truststore:

- Administrator
- Owner
- Topology Administrator
- Custom role with the *Settings*: Manage permissions

Before you can generate a P12 file, you must have a private key (for example: *key.pem*), a signed certificate by a Certificate Authority (for example *certificate.pem*) and one or more certificates from the CA authority.

Note: If your certificate file contains more than one certificate, you must manually split the file and create a single file for each entry. Each entry must be bound by the following markers:

```
-----BEGIN CERTIFICATE-----
```

```
-----END CERTIFICATE-----
```

## Procedure

---

1. If you have intermediate certificates from your CA, concatenate them into a single .pem file to build your `caChain`. Be sure to enter a new line following each certificate's data.

```
cat ca1.pem ca2.pem ca3.pem > caChain.pem
cat caChain.pem
-----BEGIN CERTIFICATE-----
MIIEpjCCA46gAwIBAgIQEod26KZabjd+BQMG1Dw16jANBgkqhkiG9w0BAQUFADC
...
lQX7CkTJn61AJUsyEa8H/gjVQnHp4VOLFR/dKgeVcCRvZF7Tt5AuiyHY
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
MIIEPDCCAySgAwIBAgIQSEus8arH1xND0aJ0NumXJTANBgkqhkiG9w0BAQUFADB
...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
MIIEENjCCAx6gAwIBAgIBATANBgkqhkiG9w0BAQUFADBvMQswCQYDVQGEWJTRTEU
...
-----END CERTIFICATE-----
```

2. Create the P12 file including the private key, the signed certificate and the CA file you created in step 1, if applicable. Omit the `-CAfile` option if you don't have CA certificates to include.

The following command uses OpenSSL, an open source implementation of the SSL and TLS protocols.

```
openssl pkcs12 -inkey key.pem -in certificate.pem -export -out certificate.p12 -CAfile caChain.pem -chain
```

Once the certificate file is created, it can be uploaded to a keystore.

3. In the Cloud Manager, click  Resources.
  4. Select TLS.
  5. Click Create in the Keystore table.
  6. Create a Keystore and upload the certificate file following the instructions at [Creating a Keystore](#).
- Note:
- API Connect supports only the P12 (PKCS12) format file for the present certificate.
  - Your P12 file must contain the private key, the public certificate from the Certificate Authority, and all intermediate certificates used for signing.
  - Your P12 file can contain a maximum of 10 intermediate certificates.
7. Click Save.

## Binding a TLS server profile to a gateway service

You can bind the SSL certificate of a TLS profile to a gateway service to establish an HTTPS binding. This enables you to access the service by using the HTTPS communication protocol.

---

## Before you begin

One of the following roles is required:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Topology: Manage permissions`

For more information on which user roles have access, see [Adding members to the admin organization](#).

---

## About this task

Perform the following steps to bind a TLS profile to a gateway service.

---

## Procedure

1. In the Cloud Manager user interface, click  Topology, then select the gateway service that you want to work with.
2. Scroll down to the API Invocation Endpoint section, and under Server Name Indication (SNI) select the required TLS server profile.  
You can also bind a TLS server profile during the initial registration of a gateway service; see [Registering a gateway service](#).
3. Click Save when done.

---

## Results

The TLS profile binds to the gateway service.

---

## Related tasks

- [Creating a TLS Server Profile](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

---

---

## Updating the PKCS#12 certificate for a TLS server profile

A server certificate bound to a gateway service can be invalidated if the host name in the digital certificate of the server does not match the URL specified by the client, or because it has expired. When this happens, you must update the TLS profile with a new CA certificate or PKCS#12 (P12) file.

## Before you begin

---

One of the following roles is required:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

## About this task

---

If the expiration date of a certificate or a P12 file is approaching, or if a certificate is invalidated, use the steps in this topic to update a TLS profile bound to a gateway service. CA certificate and P12 file expiration dates are displayed in the details of the containing keystore; see step 3.

You update the certificate for a TLS server profile by replacing the certificate in the keystore that is associated with the TLS server profile.

Complete the following steps to update a TLS profile that has an invalidated or expired certificate or P12 file.

## Procedure

---

1. In the Cloud Manager user interface, click  Resources, then click TLS.
2. To identify the keystore that is associated with the TLS server profile, complete the following steps:
  - a. In the TLS Server Profile section, select the required profile.
  - b. In the Keystore/Truststore section, note the selected keystore, then click Cancel to close the TLS server profile details page.
3. In the Keystore section, select the required keystore.

The Certificates section displays the expiration date of a certificate. You can expand a certificate to see further details.
4. Click Browse and select the required P12 file.

Note:

  - API Connect supports only the P12 (PKCS12) format file for the present certificate.
  - Your P12 file must contain the private key, the public certificate from the Certificate Authority, and all intermediate certificates used for signing.
  - Your P12 file can contain a maximum of 10 intermediate certificates.
5. Click Save when done.

## Related tasks

---

## OAuth Provider overview

---

API Connect supports OAuth Specification 2.0, for both Native and Third party implementations.

## Introduction to OAuth

---

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information. In API Connect, you can secure an API with OAuth.

In Cloud Manager, you configure both Native and Third party OAuth providers that can be made visible to selected Provider organizations. The OAuth Provider configuration is based on the OAuth 2.0 Specification, which is available at <https://tools.ietf.org/html/rfc6749>. Knowledge of the OAuth 2.0 specification is required to implement an OAuth Provider in API Connect.

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

Note: In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- [Configuring a native OAuth provider](#)  
Native OAuth providers are configured and managed by you within your cloud.
- [Configuring a third-party OAuth provider](#)  
Enter the secure endpoints to provide OAuth authentication from a third party.
- [Setting the visibility for OAuth providers](#)  
The visibility setting determines which provider organizations can use an OAuth provider to secure APIs.

- [OAuth concepts for API Connect](#)

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Configuring a native OAuth provider

Native OAuth providers are configured and managed by you within your cloud.

### About this task

A native OAuth provider object provides settings for OAuth processing operations such as generating and validating OAuth tokens. An OAuth provider object is referenced by an OAuth security definition to protect an API. When a native OAuth provider is used, the OAuth operations are performed natively by API Connect.

Every OAuth provider object has a backing API. Your configuration here automatically updates the OpenAPI document of the API. You can edit the OpenAPI document directly by navigating to the  Resources > OAuth Providers page, selecting your OAuth provider, then clicking API Editor.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example:

- If you change the name of auto generated assembly actions in the source code, the assembly will be prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the `oauth-provider-settings-ref` field in each OAuth assembly action.

When a published API references an OAuth provider object, the backing API is automatically made available in the gateway.

Token requests and client\_id checks:

If you are calling an OAuth endpoint, the sequence of `client_id` checks in the token request is as follows:

1. Check both body and query.
  - If found in only the body, validate and return a **200** or appropriate return code.
  - If found in only the query, return a **wrong location** error.
  - If found in both the body and the query, return a **more than one location** error.
2. When not found in the body or the query, check the `Authorization` header.
  - If found in this header, validate and return a **200** or appropriate return code.
3. Not found, return the appropriate error and code.

The best location for the `client_id` is in the request body.

One of the following roles is required to configure a native OAuth provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note:

- The OAuth provider logs Analytics data for failure cases, but does not log successful cases. Activity log policies that call for logging of Analytics data upon success do not apply for the OAuth provider.
- You must ensure the OAuth Provider is configured in the Sandbox Catalog before using the OAuth Provider in a non-Sandbox Catalog.

### Procedure

OAuth provider configuration uses a series of screens. The first set of screens controls a basic OAuth provider configuration. Perform the following steps to configure a native OAuth Provider for your cloud:

1. In the Cloud Manager, click  Resources.
2. Click OAuth Providers > Add > Native OAuth provider.
  - a. Complete the following parameters for the first screen, then click Next.

| Field                  | Description                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title                  | Enter a title for the native OAuth provider.                                                                                                                                                                                                                                                                                                        |
| Name                   | This field is auto-populated by the system.                                                                                                                                                                                                                                                                                                         |
| Description (optional) | Enter a brief description.                                                                                                                                                                                                                                                                                                                          |
| Base path (optional)   | The base path is the URL segment of the API that is shared by all operations in the API. It does not include the host name or any additional segments for paths or operations. The base path must be unique for a given catalog. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty. |
| Gateway Type           | Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway.<br>For information about types of gateways, see <a href="#">API Connect gateway types</a> .<br>OAuth Providers apply to one gateway type.                                                                                                              |

- b. In the next screen, enter the following additional configuration parameters, then click Next.

| Field          | Description                                                                                   |
|----------------|-----------------------------------------------------------------------------------------------|
| Authorize Path | <code>/oauth2/authorize/</code> is the standard OAuth endpoint to login to account            |
| Token Path     | <code>/oauth2/token/</code> is the standard OAuth endpoint to exchange code for access token. |

| Field                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Supported grant types  | <ul style="list-style-type: none"> <li>Implicit - An access token is returned immediately without an extra authorization code exchange step.</li> <li>Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." Does not require User Security.</li> <li>Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code."</li> <li>Resource owner - Password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients.</li> <li><b>API Gateway only</b> Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token.</li> </ul> |
| Supported client types | <ul style="list-style-type: none"> <li>Confidential - Client can maintain secure credentials on a secure server</li> <li>Public - Client credentials are not secure.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

c. Enter the scopes in the next screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

| Field             | Description     |
|-------------------|-----------------|
| sample_scope_1    | Scope for token |
| additional scopes | Scope for token |

d. Enter the parameters for User Security in the next screen. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User Security is not required for the Application grant type. Click Next when done.

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Identity Extraction | <p>Determines how the user credential is extracted:</p> <ul style="list-style-type: none"> <li>Basic Authentication - HTTP basic authentication (requires no additional configuration)</li> <li>Default HTML Form - Use default login form for user name and password</li> <li><b>API Gateway only</b> Context variable - Specify which variable contains the user name and password. API Connect OAuth context variables as listed here <a href="#">API Connect context variables</a><br/>Note: DataPower API Gateway only. Not available for DataPower Gateway (v5 compatible).</li> <li>Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see <a href="#">Creating a custom HTML login form for user security</a>.</li> <li>Redirect - Enter an endpoint to redirect to a third-party identity provider. For more information, see <a href="#">Authenticating and authorizing through a redirect URL</a>.</li> <li><b>API Gateway only</b> Disabled - do not collect the user credential</li> </ul> <p>Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint <b>must</b> maintain the order of the query parameters before the <code>state_nonce</code> query parameter, otherwise the authorization fails.</p> |
| Authentication      | Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL User Registry. For a DataPower API Gateway, you have the option to disable authentication with a user registry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Authorization       | <p>The following methods for extracting the user credential are available:</p> <ul style="list-style-type: none"> <li>Authenticated - Authorize authenticated users automatically.</li> <li>Default HTML Form - Use default HTML form to authorize.</li> <li>Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see <a href="#">Creating a custom HTML authorization form for user security</a>.</li> <li><b>API Gateway only</b> Disabled - Disable authorization.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

3. Review the Summary for the native OAuth provider configuration.

4. Click Back to make changes.

5. Click Finish to save the basic configurations and to proceed to the Advanced Parameters for a native OAuth Provider.

## Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

- [Configuring basic settings for a native OAuth provider](#)  
You can update the identification details and basic configuration settings for a native OAuth provider.
- [Configuring scopes for a native OAuth provider](#)  
Access tokens contain authorization for specific scopes.
- [Configuring user security for a native OAuth provider](#)  
Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.
- [Configuring tokens for a native OAuth provider](#)  
Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.
- [Configuring token management and revocation for a native OAuth provider](#)  
Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.
- [Configuring introspection for a native OAuth provider](#)  
Define an introspection path to allow the metadata for an access token to be examined.
- [Configuring metadata for a native OAuth provider](#)  
Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- [Configuring the OIDC parameters for a native OAuth provider](#)  
Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.
- [Editing a native OAuth provider by using the API Editor](#)  
You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

# Configuring basic settings for a native OAuth provider

You can update the identification details and basic configuration settings for a native OAuth provider.

## About this task

One of the following roles is required to configure the basic settings for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the basis settings pages for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the basic settings for an existing native OAuth provider. If you want to update the basic settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

1. To modify the identification details, click Info in the sidebar menu, then update the following fields as required:

| Field                  | Description                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Title                  | Enter a title for the native OAuth provider.                                                                                                                                                                                                                                                                                                        |
| Name                   | This field is auto-populated by the system.                                                                                                                                                                                                                                                                                                         |
| Description (optional) | Enter a brief description.                                                                                                                                                                                                                                                                                                                          |
| Base path (optional)   | The base path is the URL segment of the API that is shared by all operations in the API. It does not include the host name or any additional segments for paths or operations. The base path must be unique for a given catalog. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty. |

2. To modify the basic configuration settings, click Configuration in the sidebar menu, then update the following fields as required:

| Field                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Authorize Path         | <code>/oauth2/authorize/</code> is the standard OAuth endpoint to login to account                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Token Path             | <code>/oauth2/token/</code> is the standard OAuth endpoint to exchange code for access token.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Supported grant types  | <ul style="list-style-type: none"><li>• Implicit - An access token is returned immediately without an extra authorization code exchange step.</li><li>• Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." Does not require User Security.</li><li>• Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code."</li><li>• Resource owner - Password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients.</li><li>• <span style="border: 1px solid green; padding: 2px;">API Gateway only</span> Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token.</li></ul> <p>Tip: Selecting only the Resource owner - JWT grant type when defining a native OAuth provider in the user interface is not supported and results in an invalid configuration. To avoid this problem, additionally select either the Access code or the Resource owner - Password grant type.</p> <p>Note: If you plan to configure OpenID Connect (OIDC) for a native OAuth provider, you must include at least one of the following grant types: Implicit, Access code.</p> |
| Supported client types | <ul style="list-style-type: none"><li>• Confidential - Client can maintain secure credentials on a secure server</li><li>• Public - Client credentials are not secure.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

DataPower Gateway (v5 compatible) only Note: If the gateway type is DataPower® Gateway (v5 compatible) and, when the native OAuth provider was created, only the Application grant type was selected, you cannot add further grant types until you configure the user security settings. In particular, you must specify the user registry for authenticating application users. To configure the user security settings, complete the following steps:

- a. Click User Security in the sidebar menu, then click Edit.
  - b. Update the user security settings as required; for more details, see [Configuring user security for a native OAuth provider](#).
  - c. Click Save when done.
3. Click Save when done.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

# Configuring scopes for a native OAuth provider

Access tokens contain authorization for specific scopes.

## About this task

Client applications can request only the scopes or a subset of the scopes that you define here. The scopes are included in the access tokens that are generated from the provider. When an OAuth protected API is invoked, the gateway checks the scopes carried in the access tokens against the list of allowed scopes in the security definition

for the API to determine whether to grant access.

In addition, you can enforce advanced scope checks. The advanced scope check URLs are invoked after application authentication or after user authentication based on which URLs are configured. The final scope permission that is granted by the access token is the result of all scope checks.

Per IETF RFC 6749, the value of the scope parameter is a list of space-delimited, case-sensitive strings. For more information, see [The OAuth 2.0 Authorization Framework](#).

One of the following roles is required to configure scopes for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the scope settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the scope settings for an existing native OAuth provider. If you want to update the scope settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources > OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

Perform the following steps to configure the scopes for the access token:

1. Click Scopes in the sidebar menu. The currently configured scopes are listed. Review and update the scopes as required.

| Field             | Description     |
|-------------------|-----------------|
| sample_scope_1    | Scope for token |
| additional scopes | Scope for token |

In the Default scopes section, select the default scopes to be used if the API request doesn't contain any scopes.

If the user authorization method is set to Default HTML Form in the User Security settings, all scopes specified here are added automatically to the authorization consent form.

2. Advanced scope check before token generation. This setting specifies the scope check endpoint where additional scope verification is performed in addition to the basic scopes. The advanced scope check URLs are invoked after application authentication or after owner authentication based on which URLs are configured. The scopes are included in the token and will overwrite any previous scopes.

| Field                   | Description                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application scope check | Allow extra verification by running a scope check from an endpoint. Enter the endpoint and an optional TLS Profile to use for an application scope check. |
| Owner scope check       | Further refine the scope with an additional check. Enter the endpoint and an optional TLS Profile to use for an owner scope check.                        |

For more information about scope, see [Scope](#).

3. Advanced scope check after token generation. This setting specifies an additional scope check at the API consumer level to verify compliance with the scope requirements of the API.

| Field                 | Description                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------|
| Enabled               | Select the check box to enable the advanced scope check after token validation. Enter an optional default validator endpoint. |
| Use endpoint from API | Select the check box to use the endpoint from the API, or clear the check box to override the endpoint from the API.          |

For more information about scope, see [Scope](#).

4. Click Save when done.

## Results

Depending upon the visibility setting, the OAuth Provider with the specified scopes can be used to secure the APIs in catalog.

## Configuring user security for a native OAuth provider

Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.

### About this task

User security authenticates the user. It is required for the Implicit, Access code, and Resource owner - Password grant types. It is not used for the Application or Resource owner - JWT grant types.

One of the following roles is required to configure user security for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the user security settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the user security settings for an existing native OAuth provider. If you want to update the user security settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

Perform the following steps to configure the user security settings for the OAuth Provider:

1. Click User Security in the sidebar menu.
2. Specify the following parameters for User Security. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User Security is not required for the Application or Resource owner - JWT grant types. Click Next when done.

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Identity Extraction | <p>Determines how the user credential is extracted:</p> <ul style="list-style-type: none"> <li>• Basic Authentication - HTTP basic authentication (requires no additional configuration)</li> <li>• Default HTML Form - Use default login form for user name and password</li> <li>•  Context variable - Specify which variable contains the user name and password. API Connect OAuth context variables as listed here <a href="#">API Connect context variables</a></li> <li>• Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see <a href="#">Creating a custom HTML login form for user security</a>.</li> <li>• Redirect - Enter an endpoint to redirect to a third-party identity provider. For more information, see <a href="#">Authenticating and authorizing through a redirect URL</a>.</li> <li>•  Disabled - do not collect the user credential</li> </ul> <p>Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint <b>must</b> maintain the order of the query parameters before the <code>state_nonce</code> query parameter, otherwise the authorization fails.</p> |
| Authentication      | <p>Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL User Registry.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Authorization       | <p>Various methods may be used to authorize application users. For a DataPower® API Gateway, the following methods for extracting the user credential are available:</p> <ul style="list-style-type: none"> <li>• Authenticated - Authorize authenticated users automatically.</li> <li>• Default HTML Form - Use default HTML form to authorize.<br/>If you select the Default HTML Form method, all scopes that are specified in the Scopes settings are added automatically to the authorization consent form.</li> <li>• Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form.</li> <li>•  Disabled - Disable authorization.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

3. Click Save when done.

## Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

## Configuring tokens for a native OAuth provider

Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.

## About this task

Access tokens are granted to the client application to allow the application to access resources on behalf of the application user. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or more narrow scope. You can also specify how long the consent given by the combination of any number of access and refresh token remains valid.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Administrator

- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the token settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the token settings for an existing native OAuth provider. If you want to update the token settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, > OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

Perform the following steps to configure tokens for the native OAuth provider:

1. Click Tokens in the sidebar menu.
2. Define the settings to configure tokens.

| Field                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Access tokens time to live                                               | Enter the expiration time period in seconds for access tokens.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <input type="checkbox"/> API Gateway only<br>One time use access token   | Click the check box to enable one time use for the access token. Access tokens are multiple use by default which allows them to be used for multiple requests. When one time use is enabled, the access token will be consumed after one use. The OAuth flow will need to be repeated to obtain another access token.<br>Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: <ul style="list-style-type: none"> <li>• <a href="#">Configuring token management and revocation for a native OAuth provider</a> (Cloud Manager)</li> <li>• <a href="#">Configuring token management and revocation for a native OAuth provider</a> (API Manager)</li> </ul>                                                                                                                                                                                                      |
| Refresh tokens                                                           | Click the check box to enable Refresh tokens. Set the Count to limit the number of times a refresh token can be issued. Set the Refresh Token Time to Live value to determine the time to live, or expiration time period, for each refresh token in seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| One time use refresh token                                               | Clear the check box to disable one time use for the refresh tokens. Refresh tokens are one time use by default which allows them to be used one time only to generate an access token and a new refresh token. When refresh token one time use is disabled then the refresh token count is limited to one and the refresh token can be used multiple times to generate new access tokens, however, another refresh token will not be generated unless the initial OAuth flow (Authorization Code or Password) is repeated.<br>Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: <ul style="list-style-type: none"> <li>• <a href="#">Configuring token management and revocation for a native OAuth provider</a> (Cloud Manager)</li> <li>• <a href="#">Configuring token management and revocation for a native OAuth provider</a> (API Manager)</li> </ul> |
| Maximum consent                                                          | Click the check box to enable Maximum consent and enter the Maximum Consent Time to Live value in seconds. This is the time to live, or expiration time period, for all tokens, both access and refresh.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <input type="checkbox"/> API Gateway only<br>Token secret                | Click the check box to select the Shared Secret which was configured for the gateway. If no Shared Secret was entered in the Gateway Configuration, then enter an key name and key value to use as the token secret.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <input type="checkbox"/> API Gateway only<br>Proof Key for Code Exchange | Proof Key for Code Exchange (PKCE) is a method to protect OAuth 2.0 public clients from an authorization code interception attack when they use Authorization Code grant requests. ## Configuring token management and revocation for a native OAuth provider

Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.

## About this task

---

Token management enables you to prevent replay attacks by configuring token revocation. API Connect supports token revocation using a native gateway (DataPower) or a third party endpoint. For a native gateway, quota enforcement is used to manage tokens. For a third party endpoint, a URL to an external service is used to manage tokens.

For more information, see the IETF RFC 7009 [OAuth 2.0 Token Revocation](#).

One of the following roles is required to configure token management and revocation for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the token management settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the token management settings for an existing native OAuth provider. If you want to update the token management settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, > OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

---

Perform the following steps to configure revocation settings for tokens:

1. Select Token Management in the sidebar menu.
2. Enable token management by selecting the check box.
3. From the Type list, select either Native or External. Native points to DataPower as the token storage location; External points to a revocation URL for token storage.  
Note: If you are using the API Manager user interface then, for the External option to be available, you must be using DataPower® API Gateway Version 10.0.1.0 or later, and the gateway service must be enabled in the Sandbox Catalog; for details on how to enable a gateway service in a Catalog, see [Creating and configuring Catalogs](#).
4. For Native, select one or both of the Resource owner revocation path and Client revocation path.
  - Resource owner revocation path - Uses the standard OAuth revocation path to allow the resource owner (end user) to revoke the application permission.
  - Client revocation path - Uses the standard OAuth revocation path to allow the client (application) to revoke a single token when the application closes.For more information about managing tokens with the Native DataPower Gateway, see [Token management with the native DataPower Gateway](#).
5. For External, the settings depend on the gateway type, as follows:  
DataPower API Gateway:
  - Endpoint - the URL of the external management endpoint.
  - TLS Client Profile (optional) - the TLS client profile to secure connections.
  - Security - how to secure connections. The only supported method is basic authentication.
  - Basic authentication username (optional) - the user name for authentication.
  - Basic authentication password (optional) - the password for authentication.
  - Basic authentication request header name (optional) - the request header that contains the authentication string; if you supply both a request header name and user name/password, the request header authentication method is used.
  - Custom header pattern (optional) - the name pattern of the headers to use for sending additional information to the external management service.
  - Cache type - the cache type to control whether and how to cache positive responses. If you select Time to live, specify how long to keep responses in the cache; the default value is 900 seconds.
  - Fail on error - if selected, processing is stopped if the connection to the external management service fails.Note: For details of the JSON format that is required when exchanging messages with the external management service, see [JSON format to exchange messages with the external management service](#).  
DataPower Gateway (v5 compatible):
  - Endpoint - Enter the URL to an external web server that contains information about access or refresh tokens. API Connect calls the URL to determine if the associated token can be trusted. The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing. For more information see [Token revocation](#).
  - TLS Client Profile - Select a TLS profile to verify the external endpoint.
6. Click Save when done.

## Results

---

Depending on the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Configuring introspection for a native OAuth provider

Define an introspection path to allow the metadata for an access token to be examined.

## About this task

---

Token introspection allows an authorized holder of an access token to examine the contents of tokens using an introspection path. The access token to introspect must be obtained through the native OAuth provider. Introspection provides context for the token by allowing an authorized protected resource to query the authorization server to determine the set of metadata for a given token. The metadata includes whether or not the token is currently active, the scopes assigned to the token, and the

authorization context in which the token was granted (including who authorized the token and which client it was issued to). API Connect token introspection conforms to IETF RFC 7662. See [OAuth 2.0 Token Introspection](#).

One of the following roles is required to enable introspection for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the introspection settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the introspection settings for an existing native OAuth provider. If you want to update the introspection settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

---

Perform the following steps to enable introspection:

1. Click Introspection in the sidebar menu.
2. Select the check box to enable Introspection. The OAuth standard path for introspection, `/oauth2/introspect` is automatically entered. This path will be used when another entity inspects the token contents.
3. Click Save when done.

## Results

---

Tokens will be queried using the `/oauth2/introspect` path. Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Configuring metadata for a native OAuth provider

---

Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

### About this task

---

Configure an Authentication URL or an External URL from which custom metadata is collected for inclusion in the token. The metadata is either stored inside the access token or it is sent along with the access token to the client application. For more information about how the metadata is collected, see [OAuth external URL and authentication URL](#).

Following are examples of metadata that can be included with the access token:

- Metadata about the authenticated resource owner
- Grant type that was used to obtain the token
- A confirmation code to be provided to the client application

One of the following roles is required to configure metadata collection for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the metadata settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the metadata settings for an existing native OAuth provider. If you want to update the metadata settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

---

Perform the following steps to configure metadata collection:

1. Click Metadata in the sidebar menu.
2. Select Collect metadata to enable metadata collection.
3. The Authentication URL user registry is selected by default and is required. For more information about the Authentication URL, see [Authentication URL user registry](#).
4. Select the External URL to collect metadata from an external URL. Enter the endpoint and an option TLS Client Profile.

5. API Gateway only If required, override the default Header name token value. The value of this header, if returned in the response from the OAuth endpoint, is placed in the response payload and indicated as **metadata**.
6. API Gateway only If required, override the default Header name payload value. The value of this header, if returned in the response from the OAuth endpoint, is placed within the access token and indicated as **miscinfo**.
7. Save the OAuth Provider.
8. Click Save when done.

## Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Configuring the OIDC parameters for a native OAuth provider

Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.

### About this task

When you enable OpenID connect, a template is provided for generating ID tokens along with access tokens and the required assembly policies are automatically created. You can customize the policies to suit your needs in the API Editor. The sample key provided is for test purposes only and is used to sign the JWT token.

One of the following roles is required to configure an OIDC template for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note: You can configure OIDC parameters only if the selected grant types for the native OAuth provider include at least one of the Implicit or Access code grant types; see [Configuring basic settings for a native OAuth provider](#).

You can select the OIDC settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the OIDC settings for an existing native OAuth provider. If you want to update the OIDC settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources > OAuth Providers.
2. Select the required native OAuth provider.

### Procedure

Perform the following steps to configure an OIDC template:

1. Click OpenID Connect in the sidebar menu.
2. Select the initial check box to configure an OIDC Template. Enter the following parameters:

| Field                                                                                                                        | Description                                                                                                                                                                                      |
|------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <span style="border: 1px solid green; padding: 2px;">API Gateway only</span> Support hybrid response types (optional)        | Select the response types for the OpenID Connect hybrid flow to be supported by this OAuth provider.                                                                                             |
| <span style="border: 1px solid green; padding: 2px;">API Gateway only</span> Auto Generate OIDC API Assembly                 | Select this option to generate the full OIDC assembly. Leave this option unselected to simply enable OIDC support in the OAuth provider and allow the developer to implement their own assembly. |
| <span style="border: 1px solid blue; padding: 2px;">DataPower Gateway (v5 compatible) only</span> ID token issuer            | Descriptive text to indicate the source of the key.                                                                                                                                              |
| <span style="border: 1px solid blue; padding: 2px;">DataPower Gateway (v5 compatible) only</span> ID token signing key       | Specify the JSON Web Key (JWK) to be used to sign the ID token.                                                                                                                                  |
| <span style="border: 1px solid blue; padding: 2px;">DataPower Gateway (v5 compatible) only</span> ID token signing algorithm | Select the algorithm used to sign the token.                                                                                                                                                     |

3. Click Save when done. You can edit the policies by using the API Editor.

## Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

# Editing a native OAuth provider by using the API Editor

You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

## About this task

If you have configured an OIDC template, you can customize it in API Editor. In the API Editor, the Source tab allows you to edit the code for the configuration using a text editor. The API Assemble tab provides a graphical drag-and-drop editor (identical to the one in API Manager) that allows you to add additional elements to the assembly for the OAuth Provider.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example:

- If you change the name of auto generated assembly actions in the source code, the assembly will be prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the `oauth-provider-settings-ref` field in each OAuth assembly action.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can modify the native OAuth provider configuration by selecting the API Editor page immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the configuration for an existing native OAuth provider. If you want to update the configuration for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, > OAuth Providers.
2. Select the required native OAuth provider.

## Procedure

Perform the following steps to edit the OAuth configuration:

1. Click API Editor in the sidebar menu.
2. In the Source tab, view and edit the policies to customize the behavior for the OAuth provider.
3. In the API Assemble tab, use the drag and drop editor to add additional policies to the OIDC behavior.  
Note: If you add a policy that references a TLS profile, an `invoke` policy for example, then when you publish an API that uses this OAuth provider, you must ensure that the TLS profile is enabled for the Catalog to which you publish the API. For details on how to enable a TLS profile in a Catalog, see [Creating and configuring Catalogs](#).
4. Click Save when done.

## Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

# Configuring a third-party OAuth provider

Enter the secure endpoints to provide OAuth authentication from a third party.

## About this task

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

## Procedure

Complete the following steps to configure a third party OAuth provider:

1. In the Cloud Manager, click  Resources.
2. Select OAuth Providers, > Add, > Third party OAuth Provider.
  - a. Complete the following parameters for the first screen and click Next.

| Field | Description                                                                                    |
|-------|------------------------------------------------------------------------------------------------|
| Title | Enter a descriptive title for the gateway service. This title will be displayed on the screen. |

| Field                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name                  | This field is auto-populated by the system and used as the internal field name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Supported grant types | Select from the following options: <ul style="list-style-type: none"> <li>• Implicit: An access token is returned immediately without an extra authorization code exchange step.</li> <li>• Application: Application to application. Corresponds to the OAuth grant type Client Credentials. Does not require User Security.</li> <li>• Access code: An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type Authorization Code.</li> <li>• Resource owner - Password: The user's username and password are exchanged directly for an access token, so can only be used by first-party clients.</li> <li>• <b>API Gateway only</b> Resource owner - JWT: a JSON Web Token (JWT) Bearer Token is used as a means for requesting an OAuth 2.0 access token, and for client authentication, as defined by the <a href="#">JSON Web Token (JWT) Profile for OAuth 2.0 Client Authentication and Authorization Grants</a>.</li> </ul> |
| Gateway type          | Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For information about types of gateways, see <a href="#">API Connect gateway types</a> .<br>OAuth Providers apply to one gateway type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

b. Specify configuration settings for the endpoints.

| Field                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Authorization URL                                                | An authorization URL where the resource owner grants authorization to the client application to access a protected resource. Example:<br><b>https://example.com/oauth2/authorize</b>                                                                                                                                                                                                                                                                                                                       |
| Token URL                                                        | A token request URL where the client application exchanges an authorization grant for an access token. Example:<br><b>https://example.com/oauth2/token</b>                                                                                                                                                                                                                                                                                                                                                 |
| Introspect URL                                                   | The introspection URL is where the API gateway validates the access tokens that are issued by the third party provider. Example:<br><b>https://example.com/oauth2/introspect</b><br>For more information on integrating third party OAuth providers for introspection, see <a href="#">OAuth introspection for third-party OAuth providers</a> .                                                                                                                                                           |
| <b>API Gateway only</b> Introspect cache type                    | The cache type determines how long responses from the third party provider are cached, if at all. Select one of the following options: <ul style="list-style-type: none"> <li>• No cache (default): Responses are not cached.</li> <li>• Protocol: Defined by the <b>cache-control</b> header in the provider response.</li> <li>• Time to live: Defined by the provider.</li> </ul>                                                                                                                       |
| <b>API Gateway only</b> Cache Time to Live                       | The length of time, in seconds, for which provider responses are cached, if the Introspect cache type is set to Time to live. The default value is 900.                                                                                                                                                                                                                                                                                                                                                    |
| TLS Profile (optional)                                           | Select an optional TLS profile for communicating with the third party provider.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Security                                                         | Default is Basic Authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Basic authentication request header name                         | The <b>x-introspect-basic-authorization-header</b> is available to provide a user-configured HTTP Basic authentication header.                                                                                                                                                                                                                                                                                                                                                                             |
| <b>API Gateway only</b> Basic authentication username (optional) | The default user name for HTTP Basic authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>API Gateway only</b> Basic authentication password (optional) | The default password for HTTP Basic authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>API Gateway only</b> Token validation                         | Specifies the method used to determine the success of the introspection request that is sent to the third party service to validate the provided token. Select one of the following options: <ul style="list-style-type: none"> <li>• Connected: The query is successful if the status return code is <b>200</b>.</li> <li>• Active (default): The query is successful if the status return code is <b>200</b> and the response JSON body includes the property <b>active</b>:<br/><b>true</b>.</li> </ul> |
| <b>API Gateway only</b> Custom header pattern (optional)         | A regular expression for request headers that are to be passed to the third-party provider; for example, <b>x-Introspect-*</b> .                                                                                                                                                                                                                                                                                                                                                                           |
| <b>API Gateway only</b> Authorization header pass through        | Select this check box if you want to retain the <b>Authorization</b> header for a bearer token. The default behavior is to remove this header.                                                                                                                                                                                                                                                                                                                                                             |

c. Enter the scopes in the third screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

| Field             | Description     |
|-------------------|-----------------|
| sample_scope_1    | Scope for token |
| sample_scope_2    | Scope for token |
| additional scopes | Scope for token |

d. Review the settings on the Summary panel.

3. Click Save and Edit to complete the configuration.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## Setting the visibility for OAuth providers

The visibility setting determines which provider organizations can use an OAuth provider to secure APIs.

### About this task

---

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

### Procedure

---

Follow these steps to set the visibility for the OAuth providers in your on-premises cloud:

1. In the Cloud Manager, click  Resources.
2. Select OAuth Providers.
3. Choose Edit visibility from the actions menu next to the name of the OAuth Provider that requires a visibility setting.
4. Select the visibility setting for the OAuth provider. The options are:
  - Private - the OAuth provider is not visible and cannot be used by any provider organization. It is accessible only to the admin organization in Cloud Manager.
  - Public - the OAuth provider is visible and can be used by all provider organizations
  - Custom - the OAuth provider is visible only to the provider organizations that you designate
5. For Custom visibility, select the provider organizations that you want to have access to the OAuth provider.
6. Click Save to complete the operation.

### Results

---

For Private, the OAuth provider is not visible and cannot be used by any provider organizations. For Public, the OAuth provider is visible and can be used by all provider organizations. For Custom, the OAuth provider is visible only to the provider organizations designated by you.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## OAuth concepts for API Connect

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information.

Note: In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- [OAuth user scenario](#)  
Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.
- [OAuth introspection for third-party OAuth providers](#)  
OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by IBM API Connect. IBM API Connect can use this feature along with the mentioned provider to protect access to the API.
- [OAuth external URL and authentication URL](#)  
You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- [Scope](#)  
Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.
- [Tokens](#)  
Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.
- [Authentication URL user registry](#)  
You can use an Authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides additional metadata to be embedded in the token.
- [Custom forms for user security](#)  
You can create custom forms for the authorization and identity extraction phase of OAuth.
- [Securing an API with a JSON Web Token](#)  
There are two methods to secure your API with a JSON Web Token. You can use the `jwt-generate` command, or you can use a token that has been generated external to IBM API Connect.
- [Troubleshooting OAuth](#)  
You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

## OAuth user scenario

Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.

### Scenario overview

---

In this scenario, Alice is a user of an application. Alice can grant permission for an application to access specific information about Alice in a third-party system that is using OAuth. Depending on the type of OAuth that is supported by the target service, Alice does not enter her user name and password into the application. Instead, the application receives an access token that represents her credentials (user name and password). The application can now access the information about Alice in the target system.

For example, Alice maintains a list of books that she reads on a service that is provided by mybooks.com. Following the purchase of a smartphone, Alice installs an application on her new phone to display the book details. The phone application wants to call an API provided by mybooks.com, which can access the information. The mybooks.com API is secured by using the OAuth protocol.

To access the book details, the application must complete a two-step process:

1. The application must first obtain permission from Alice.
2. The application then uses that permission to call the target service and obtain the list of books.

In the first step, the application typically directs Alice to the provider of the target service, mybooks.com. Alice provides her user name and password, and gives permission for the application to access her information. It is important that Alice trusts that she is providing her credentials to the provider of the target service and not to an untrusted proxy application. For example, by checking that the security certificate of the website where Alice enters her credentials matches what Alice expects from the provider of the target service.

The result of this step is the access token that the application can use to call the API. The application then generates the appropriately formatted OAuth request. For example, the Authorization header, or HTTP query parameters, which includes the access token, consumer key, and signature method that are required by OAuth. This OAuth request is used to invoke the API proxy operation.

### Scenario within API Connect

---

No changes to the definition of your API operation are required to support this scenario.

1. Alice grants permission for the application to access her information *before* the invocation of the API.
2. When the application provides the Authorization header, or query parameters, containing the OAuth details about the call to the operation endpoint, the header is automatically passed through to the target service without any additional configuration.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.  
For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## OAuth introspection for third-party OAuth providers

OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by IBM API Connect. IBM® API Connect can use this feature along with the mentioned provider to protect access to the API.

You can use API Connect to protect an API that is secured by using the third-party OAuth access token in accordance with Introspection specification as defined in [RFC 7662](#). In addition to the specification, the **x-Introspect-** header is provided to pass other content to the third party as you require.

Authentication information can be carried in the request by configuring a basic authentication request header.

The following sequence diagram depicts the overall flow of request and response. The purpose of this diagram is only to provide a general visualization of the nature of the flow; for the precise details, refer to the explanatory information after the diagram.

The Introspect URL is configured in the Third Party OAuth provider configuration. See [Configuring a third-party OAuth provider](#).

When an API is protected by a third-party OAuth provider, API Connect will extract the bearer token and issue an HTTP POST request to the endpoint specified in the Introspect URL field.

The GET request is protected by API Connect with this feature.

You can use a header prefix to pass information to the third-party provider. The header prefix can include a regular expression and specifies the name pattern of the headers to use for sending additional information, such as `x-introspect-*`.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
Authorization: Bearer tGzv3JOkF0XG5Qx2TlKWIA
x-IBM-Client-Id: xxx-xxx
```

However, if you want to use a different header prefix, specify the required value in the Custom header pattern field in the third party OAuth provider configuration. For third-party OAuth provider configuration details, see [Configuring a third-party OAuth provider](#). The Custom header pattern feature is available only with the DataPower® API Gateway, if you are using the DataPower Gateway (v5 compatible) the header prefix must be `x-Introspect-`.

API Connect will issue this POST request to the introspection endpoint specified in `x-tokenIntrospect`, as illustrated in the code sample:

```
POST /oauth/introspectURL HTTP/1.1
Host: apiconnect.ibm.com
Content-Type: application/x-www-form-urlencoded
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
token_type_hint=access_token&token=tGzv3JOkF0XG5Qx2TlKWIA
```

The third party OAuth/OIDC provider will respond with HTTP 200 indicating the request was successful and that payload contains the token information. API Connect honors the active claim as defined in the RFC specification.

If the value of the active claim is `true`, the token is treated as valid.

```
HTTP/1.1 200 OK
Content-Type: application/json; charset=UTF-8
Cache-Control: no-store
Pragma: no-cache

{
 "active": true,
 "token_type": "bearer",
 "client_id": "xxx-xxx",
 "username": "John Smith",
 ...
}
```

If the value of the active claim is `false`, the token is treated as invalid.

```
HTTP/1.1 200 OK
Content-Type: application/json; charset=UTF-8
Cache-Control: no-store
Pragma: no-cache

{
 "active": false
}
```

A response code other than **HTTP 200** indicates failure to process the request.

When the OAuth token is valid and active, context variables are populated with information from the introspect JSON response. For more information, see [API Connect context variables](#).

When contacting the introspection endpoint, API Connect uses `client_id/appId` and `client_secret/appSecret` to construct the HTTP Basic authorization header.

By default, if `x-introspect-basic-authorization-header` exists in the request, the value is used for the HTTP Basic authentication header when the introspection endpoint is contacted. API Connect verifies that the HTTP Basic authentication header value is Base64 encoded before it is sent, and encodes it if necessary as shown in the following example. If the header is already encoded, it is sent without modification.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-introspect-basic-authorization-header: user:password
```

API Connect issues the following:

```
POST ..
Authorization: Basic M3JkLXBhcncR5LWNsaWVudF9pZDozcmQtcGFydH1fY2xpZW50X3N1Y3JldA==token_type_hint=access_token&token= ..
```

If you are using the DataPower API Gateway, you can specify your own value for the HTTP Basic authentication header by providing the required value in the Basic authentication request header name field in the third party OAuth provider configuration. The following rules determine what authentication data is passed to the introspection endpoint:

- If there is a basic authentication header in the request, the specified credentials are used. The value must be either a string in the format `user:password`, or the Base64 encoded equivalent; API Connect will Base64 encode the value if necessary before sending the request to the introspection endpoint.
- If there is no basic authentication header in the request but there are values specified in the Basic authentication username and Basic authentication password fields in the third party OAuth provider configuration, those values are used.
- If there is no basic authentication header in the request, and user name and password details are not supplied in the third party OAuth provider configuration, but `client_id` and `client_secret` values are supplied in the body of the request, these are used.
- Otherwise, an error is returned.

For third-party OAuth provider configuration details, see [Configuring a third-party OAuth provider](#).

If either, or both, of `scope` and `scope validate url` are configured, and if the response is an active token with a scope claim from the third-party OAuth Provider introspection endpoint, API Connect will further enforce the scope validation in the following order:

1. If `scope` is configured for the OAuth API protection, verify the third-party scope against the scope that is configured.
2. If `scope validation url` is configured, verify the third-party scope against the scope validation URL.
3. If the third-party OAuth provider introspection endpoint does not return a scope, the Gateway will not check the scope defined in the security definition of the API where the third-party OAuth provider resource is used. For details on configuring an OAuth security definition in an API, see [Creating an OAuth security definition](#).

For more information, see [Scope](#).

DataPower Gateway (v5 compatible) only By default the API Connect client ID and scope are sent to the third party OAuth provider. You can suppress this behavior in either of the following ways:

- Supply a `suppress-parameters` header as follows:  

```
suppress-parameters: client_id
suppress-parameters: scope
```

or  

```
suppress-parameters: client_id scope
```

depending on which parameters you want to suppress.
- Define an API property called `suppress-parameters` in the API definition itself, with one of the following string values:

```
client_id
scope
or
client_id scope
```

depending on which parameters you want to suppress. For information on how to define API properties, see [Setting API properties](#).

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

---

## OAuth external URL and authentication URL

You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

---

## Including custom metadata in a token

In many scenarios, custom metadata needs to be included during the access token generation process. The metadata is either stored inside the access token or it is sent along with the access token to the client application. The client application can then send that access token, or the metadata in the payload, in a subsequent request to IBM® API Connect where the metadata is retrieved, validated, or sent to the downstream systems as required.

Examples include, but are not limited to:

- When resource owners are authenticated, metadata about the authenticated resource owner needs to be stored within the access token.
- The grant type that was used to obtain the token is another example of metadata stored within the access token.
- A confirmation code that needs to be sent to the client application along with access token is stored as metadata within the access token.

## Configuring External URL or Authentication URL in API Connect to obtain metadata

Metadata can be set by using either or both of the following URLs:

- External URL - When you call the External URL, an HTTP GET request is sent and API Connect expects an HTTP 200 OK along with an optional set of the specified response headers.
- Authentication URL - When you call the Authentication URL, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.  
See: [Authentication URL](#).

The External URL endpoint is entered in the Metadata section when you configure an OAuth Provider in the Cloud Manager or API Manager UI.

Use the following HTTP headers in the response, depending on the type of gateway you are using:

- DataPower® API Gateway:

**X-API-OAUTH-METADATA-FOR-PAYLOAD**

**X-API-OAUTH-METADATA-FOR-ACCESSTOKEN**

Note: These are the default header names for the DataPower API Gateway but you can override them; see [Configuring metadata for a native OAuth provider](#).

- DataPower Gateway (v5 compatible):

**API-OAUTH-METADATA-FOR-PAYLOAD**

**API-OAUTH-METADATA-FOR-ACCESSTOKEN**

The response header value from **X-API-OAUTH-METADATA-FOR-PAYLOAD** or **API-OAUTH-METADATA-FOR-PAYLOAD** is placed in the response payload and indicated as **metadata**.

The response header value from **X-API-OAUTH-METADATA-FOR-ACCESSTOKEN** or **API-OAUTH-METADATA-FOR-ACCESSTOKEN** is placed within the access token and indicated as **miscinfo**.

The two metadata response headers are case insensitive and you must escape any special characters in the string value content.

An example response payload that contains metadata along with the access token:

```
{
 "token_type": "bearer",
 "access_token": "AAEkNzhjDHYyyYy...cL0Mv6ct137w7ZU",
 "metadata": "m:metadata-for-payload_content"
 "expires_in": 3600,
 "scope": "read",
 "refresh_token": "AAEnj5SynCMYbF...oEZ6JjxYax_HdNg",
}
```

This example output from the token introspection endpoint shows the contents of the access token with **miscinfo** containing the metadata information.

```
{
 "active": true,
 "token_type": "bearer",
 "client_id": "78c2f10f-799a-4e1f-8e0a-098634997a35",
 "username": "Fred Smith",
 "sub": "fred",
 "exp": 1479850049,
 "expstr": "2016-11-22T21:27:29Z",
 "iat": 1479846449,
 "nbf": 1479846449,
 "nbfstr": "2016-11-22T20:27:29Z",
 "scope": "read",
 "miscinfo": "m:metadata-for-accesstoken_content",
 "client_name": "MobileApp"
}
```

## Input to the External URL

The following request headers are sent to the External URL.

Note: Any existing metadata values that were previously sent from the Authentication URL are also sent in the two request headers **x-existing-metadata-for-payload** and **x-existing-metadata-for-access-token**. The Metadata URL can make use of this information to create a new set of metadata values.

The two request headers that are sent to the Metadata URL are displayed in bold text.

```
X-existing-metadata-for-payload payload-from-auth-url
X-existing-metadata-for-access-token token-from-auth-url
X-URI-in /org/env/miscinfo/oauth2/token (the URL that was sent to APIConnect for this particular token request)
X-METHOD-in POST
X-POST-Body-in client_id=client_id&grant_type=password&scope=read&username=name&password=password
X-X-Client-IP IP_address
X-X-Global-Transaction-ID ID_number
...
```

Note: If you are using the DataPower API Gateway rather than the DataPower Gateway (v5 compatible), the **X-POST-Body-in** header is not supported.

## Retrieving Metadata in API Connect

As described in the previous example scenarios, the metadata can be retrieved from the access token in the Application API and sent to the downstream systems. Retrieval can be done in the API assembly, which is secured to accept tokens in the security definitions.

In the resource API that accepts an access token, the `miscinfo` field can be accessed in the Assembly with the `oauth.miscinfo` context variable, as in the example.

```
apim.setvariable('message.body', apim.getvariable('oauth.miscinfo'));
```

You can also use token introspection to look at the contents of the access token.

## Refresh tokens and metadata

The Authentication URL (if configured for authentication) is invoked first, during authentication of the resource owner. The External URL is invoked as the last step, just before the generation of the access token. The only exception is when access tokens are generated from a refresh token. In cases where refresh tokens are used to generate new access tokens, the External URL is not invoked. The metadata from the refresh token is retained and then copied into the newly generated access token.

## Identifying the source of the metadata

The metadata is prefixed with keywords to indicate whether it originated from the External URL or the Authentication URL.

- Metadata from the External URL is prefixed with `m`:
- Metadata from the Authentication URL is prefixed with `a`:

Note: When revocation is enabled, some internal details are also stored in the `miscinfo` field, in brackets within the access token as shown in the following example:

```
"miscinfo": "[tlsprofile@https://api-revoke-url:443/server/revocation-url]m:metadata-for-accesstoken_content"
```

## Maximum size of the metadata

Metadata for the access token cannot exceed 512 bytes.

Metadata for the payload does not have a specific size restriction, except for when you use the Authorization code grant type. These restrictions are described in following sections.

## Characters are not allowed in metadata in certain scenarios

When you use the Authorization code grant type, or when a consent form is used for implicit grant type, there is a temporary state or code where the metadata from the authentication URL is stored. API Connect internally uses two prefixes - `!ma` and `!mp` to differentiate between payload and token metadata received from the Authentication URL and store them internally in the temporary state/code. Hence these specific character sequences - `!ma` and `!mp` should not be used as the metadata itself.

## Grant types and metadata

The OAuth grant types described in the following sections include `authorization code` (access code), `implicit`, and `client credentials` (application).

Authorization code grant type

- When metadata is included from an Authentication URL for an Authorization code grant type, as it is a three legged flow, both the content and the payload are stored within the `dp-state` and carried on to the authorization code and to the access token. Note that around 10 characters are used internally to differentiate between the metadata for payload and metadata for the access token when stored in the `dp-state`. In addition, if revocation is enabled, that will also be part of the token metadata. Hence the combined size of the token metadata, the payload metadata (including the 10 characters of internal data), and internal revocation details, cannot exceed 512 bytes in total.

If the overall size of the metadata exceeds 512 bytes, then the access token generation succeeds, but the metadata fields contain an error message of "metadata too large" as shown in the example.

```
"metadata": "m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-payload]"
"miscinfo": "[r:gateway]m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-token]"
```

This size restriction can be overcome when the metadata is sent from the Metadata URL and not from the Authentication URL, because the metadata is not stored in `dp-state` or in the authorization code.

Example of the `authorization code` (access code) grant type:

```
$ curl -k -d
"grant_type=authorization_code&code=$mycode&client_id=$myid&scope=scope_introspect&redirect_uri="
https://9.70.153.90/fei/sb/introspectpl/oauth2/token
{ "token_type": "bearer",
"access_token": "AAEkOTh1ZDhhNjYtYTQ1ZS00YTMzLWE0N2QtZmE2OGZkMzQ0NzQ0Zn5Tl_TqYFeIfB7Bff6HFgibEoOjWXXEA84oFsWuE4NY-
RRZVdnGSaXAIYJz7s5vczfk5EV-BIb_6P_lYKm3ahrfrhR5kI3sPO0uADEoseIP5-09anUpEM5yhsayXvZbJ_6VDYz-hyXSJHTNqVj-
PHBialoRkBD5qca6k00fV2M", "metadata": "a:[Authorization Code-Test-auth-url-payload]", "expires_in": 3600,
"scope": "scope_introspect", "refresh_token": "AAFAG1EVmbwicr_L0FTZ4q6HZ-
RcQygniXFC9zbSKO4wd3hcniC4KQX21X0fL2c8cnmzCZgws8xxLzNyfjQhUJNG15C1GbIe3dwhXJdiWA0Go-

#### Client credentials grant type

Authentication URL will not be invoked when using client credentials grant type, as there is no resource owner. The metadata from Authentication URL is not available for this grant type. However, content returned from Metadata URL will be included as metadata.

## Behavior when retrieving metadata with both an External URL and an Authentication URL

If an External URL is configured and a connection to the external server is successful, the response headers overwrite any existing metadata obtained from the Authentication URL to become the final value. Therefore, you must carefully examine the incoming request headers and create appropriate response headers from the External URL.

If an External URL is configured, but the connection to the External URL fails, then a failure message of "error on metadata url" is written for metadata in both the payload and the access token.

If an External URL is configured and the connection is successful, but the remote server does not send any of the specified HTTP response headers, a blank value is written for metadata in both the payload and the access token.

Attention: An External URL overwrites existing values from Authentication URL. This includes blank values.

If no External URL is configured, the metadata that is obtained from the Authorization URL is retained as the final value.

**Note:** IBM API Connect 10.0.1.x is EOS after 30 September 2023. See [support policy](#) for details.

For a more recent version of LTS documentation, see the [IBM API Connect 10.0.5.x product documentation](#).

## Scope

Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.

In IBM® API Connect, scopes have no inherent meaning. Instead, scopes are defined in the OAuth Provider so that an application can request an access token that is valid for one or more of the scopes. In the secured API, scopes are listed as requirements for an access token to be considered valid. All scopes that are listed by the security definition for the API must be granted by the access token.

## OAuth provider

To provide more refined support for the OAuth scope handling, API Connect allows the [Authentication URL user registry](#) extension to modify the scope value.

When you define an [OAuth provider](#), the Advanced scope check extensions provide the flexibility to check and override allowed scopes. The optional extensions are Application scope check and Owner scope check.

The scope that is eventually received by the application is determined by the interactions that are described in the three following paragraphs. Scope processing follows the sequence of items 1, 2, and 3 in the following list, offering three opportunities to override the scope value. Figure 1 provides an overview of the process.

- After the application successfully authenticates, and if OAuth Native provider `>Advanced scope check` `>Application scope check` is configured, API Connect makes a call to allow extra verification and uses the contents of `x-selected-scope` to override the scope value that was initially requested by the application. When Application scope check is enabled, the HTTP response header `x-selected-scope` must be present, or the call fails.
- If OAuth Native provider `>User Security` `>Authentication` is configured to authenticate application users using an Authentication URL, then API Connect makes a call, as documented in [Authentication URL user registry](#). When the response code is HTTP 200, and the response header `x-selected-scope` is present, the value that is configured in `x-selected-scope` is used as the new scope value, overriding both what the application already requested and what was provided in the Application scope check described in paragraph 1. In the response header, `x-selected-scope` is an optional element.
- After the user successfully authenticates, and if OAuth Native provider `>Advanced scope check` `>Owner scope check` is enabled and configured with a valid URL, API Connect makes a call to allow the content of `x-selected-scope` to refine the scope value. When Owner scope check is enabled, the HTTP response header `x-selected-scope` must be present, or the call fails.

Figure 1. OAuth advanced scope overview

The final scope permission that is granted by the access token is the result of the flow described in items 1, 2, and 3. [Figure 2](#) shows a more detailed view of the transaction flow with examples that show when `x-selected-scope` provides a new scope value.

Figure 2. OAuth advanced scope detail

For the above example, `x-extra-data` is accessible at `oauth.advanced-consent.x-extra-data`.  
 If other than `HTTP 200` is returned, it has the same effect as if the access token does not contain necessary permissions to access the resource.

## Consumer API enforcement

Standard scope validation

To access the API `/getaccount` the application must send a `GET` request with an access token that contains the scope, or scopes, defined in the OAuth provider.

```
GET /getaccount
HTTP/1.1
Host: server.example.com
X-IBM-Client-Id: 8888-8888-8888
Authorization: Bearer AAEkNjVkwOWIyYjgtOWY5ZS00YWQwLWIyYzktZ
```

The following application OpenAPI file `secure-banking.yaml` defines the scope, or scopes, that must exist in the token to be granted access to the API `/getaccount`.

```
secure-banking.yaml

securityDefinitions:
 scope-only:
 type: oauth2
 description: ''
 flow: implicit
 authorizationUrl: ''
 scopes:
 checking: 'Checking Account'
 saving: 'Saving Account'
 mutual: 'Mutual Fund Account'
 security:
 - scope-only:
 - checking
 - scope-only:
 - saving
 - mutual
```

In the examples, the access token `AAEkNjVkwOWIyYjgtOWY5ZS00YWQwLWIyYzktZ` is able to access the API because it contains one, or a combination of `scope-only` that is defined in `secure-banking.yaml` such as:

- `checking`
- `saving mutual`
- `checking saving mutual`

Advanced Scope Check

Administrators can enable an additional scope check by configuring the consumer API property Advanced Scope Check URL that becomes `x-scopeValidate` as shown in the following OpenAPI file example.

```
securityDefinitions:
 advanced-scope-only:
 type: oauth2
 description: ''
 flow: implicit
 authorizationUrl: ''
 scopes:
 checking: 'Checking Account'
 saving: 'Saving Account'
 mutual: 'Mutual Fund Account'
 x-scopeValidate:
 url: 'https://advanced-scope-check.bk.com/validate-scope'
 tls-profile: 'ssl-client'
```

After API Connect successfully verifies the access token against any scope requirement, API Connect will make an `HTTP POST` request to the `x-scopeValidate` endpoint similar to the following example. Response code `HTTP 200` from the endpoint indicates a success. Any other response code, or a connection error, is treated as a permission error for the token.

```
POST /validate-scope?app-name=..&appid=..&org=..&orgid=..&catalog=..&catalogid=..&transid=..
HTTP/1.1
Host: advanced-scope-check.bk.com
Content-Type: application/json
```

```
{
 "context-root" : checking,
 "resource" : accountinfo,
 "method" : GET,
 "api-scope-required" : [jointaccount],
 "access_token" : {
 "client_id" : "2cd71759-1003-4a1e-becb-0474d73455f3",
 "not_after" : 174364070,
 "not_after_text" : "2017-07-11T02:27:50Z",
 "not_before" : 174360470,
 "not_before_text" : "2017-07-11T01:27:50Z",
 "grant_type" : "code",
 "consented_on" : 1499736470,
 "consented_on_text" : "2017-07-11T01:27:50Z",
 "resource_owner" : "cn=spoon,email=spoon@poon.com",
 "scope" : "jointaccount mutual",
 "miscinfo" : "[r:gateway]"
 }
}
```

An example of successful response follows.

```
HTTP/1.1 200 OK
Cache-Control: no-store
Pragma: no-cache
X-Custom-For-Assemble-Process: audit
```

Any HTTP response header that begins with "x-" is kept as the context variable `oauth.advanced-consent`. Based on the example successful response, `X-Custom-For-Assemble-Process: audit` becomes `oauth.advanced-consent.x-custom-for-assemble-process`, and can be accessed in the assemble step.

Additional validation options

You can optionally use additional fields for validation:

Request Header

Defines the regular expression to match against **request** headers. Matching headers are included in the request to the advanced scope validation endpoint.

Response Context Variable

Defines the regular expression to match against **response** headers. Matching headers are saved as context variables in the format `oauth.advanced-consent.*`.

## Tokens

Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.

This section contains information regarding token management, including refreshing and revoking tokens, redirecting, and managing tokens with the DataPower Gateway.

- [Refresh tokens](#)  
If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.
- [Token revocation](#)  
In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.
- [Authenticating and authorizing through a redirect URL](#)  
You can use a service that is hosted externally from IBM API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.
- [Token management with the DataPower Gateway \(v5 compatible\)](#)  
API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.
- [Token management with the DataPower API Gateway](#)  
API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.
