Specify time-out settings for onboarding invitations, password resets, access tokens, and refresh tokens. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.

For more information on setting timeouts, see the following topics:

- [Configuring invitation timeouts](#)
- [Configuring the password-reset notification and timeout](#)
- [Configuring timeouts for access tokens and refresh tokens](#)

User Registries

Configure one or more user registries to authenticate users of Cloud Manager or API Manager. The user credentials for all users who login to each applications must be stored in the specified registries. For more information on configuring user registries, see [Selecting user registries for Cloud Manager and API Manager](#).

Roles

Create roles and assign them to members of the Admin organization to specify which tasks members are authorized to perform. For more information on assigning roles, see [Administering members and roles](#).

Role Defaults

The Role Defaults for the Admin organization are not configurable, but you can customize the base roles for provider organizations and consumer organizations. For more information on customizing base roles, see [Role Defaults overview](#).

Endpoints

View the list of endpoints configured for API Manager, provider APIs, and consumer APIs during the installation process.

Notifications

Select the email server for your on-premises cloud notifications, configure notification settings, and specify the sender name and email address to be included in the emails. You can also preview and customize email templates used for notifications. For more information on setting up notifications, see [Setting up notifications](#).

Note: Be sure to [configure the email server](#), because it is needed for sending invitations and other notifications to users.

Catalog Defaults

Specify one or more gateway services to be provided to every Catalog by default, so that Products (which contain APIs) can be made available to users. When a new Catalog is created in a provider organization, it is assigned to the default gateway service. Any changes you make to these settings do not affect existing Catalogs.

For more information on selecting gateway services, see [Configuring the default gateway services for Catalogs](#).

Audit Setting

Configure auditing settings to monitor API calls and log information about the calling users, the time of each call, and the activity involved in each event. The audit focuses on "who" did "what" and "when", including the request payload and the result of the operation. All create, update, and delete operations are audited.

Generally, read operations are only audited if the calling user logged in with an OIDC Provider user registry. For more information about configuring the use of auditing, see [Configuring audit logging to monitor user operations](#).

Use the following list to locate instructions for using specific cloud settings:

- [Change the name of your cloud](#)
You can change the name of your cloud.
- [Configuring an email server for notifications](#)
Connect to an email server in your API Connect on-premises cloud. The email server sends registration invitations and other event-driven emails. You must

configure the email server before you add any provider organizations or register a Portal service. Otherwise, the owner of the organization will not receive the email with the details that they require to access the API Manager.

- [Setting up notifications](#)
Select an email server and set up the "sent from" information for notifications.
- [Configuring invitation timeouts](#)
You can set the time period for when registration invitations for Cloud Settings access and the Admin organization expire.
- [Configuring API key settings](#)
You can set the time period for when an API key expires, and optionally authorize it to be used multiple times.
- [Using the CLI to modify cloud settings](#)
Use the toolkit CLI to edit the cloud settings.
- [Configuring Base64 encoding for temporary tokens](#)
How to enable and disable Base64 encoding for temporary tokens.
- [Configuring the password-reset notification and timeout](#)
Configure the time allowed for a user to reset a password, and customize the notification that the user receives.
- [Selecting user registries for Cloud Manager and API Manager](#)
Select the user registries to authenticate users for Cloud Manager and API Manager.
- [Configuring timeouts for access tokens and refresh tokens](#)
Configure timeout values for the access tokens and refresh tokens for user registries.
- [Viewing platform and UI endpoints](#)
A view-only list of platform and UI endpoints is provided.
- [Configuring the default gateway services for Catalogs](#)
Configure the list of default gateway services that are available to new Catalogs.
- [Managing the public/private key pairs for signing tokens](#)
Manage the public/private key pairs that are used for signing tokens in API Connects.

Change the name of your cloud

You can change the name of your cloud.

About this task

You can change the name of your cloud using the Overview page.

One of the following roles is required to change the name of your cloud:

- Administrator
- Owner
- A custom role with the `cloud settings:manage`

Procedure

Follow these steps to change the name of your cloud:

1. In the Cloud Manager, click  Settings.
2. Select Overview..
3. Click Edit to change the name of your cloud.
4. Enter a Title and the name is auto-generated. Enter a brief Summary and click Save.

Configuring an email server for notifications

Connect to an email server in your API Connect on-premises cloud. The email server sends registration invitations and other event-driven emails. You must configure the email server before you add any provider organizations or register a Portal service. Otherwise, the owner of the organization will not receive the email with the details that they require to access the API Manager.

Before you begin

You must complete the tasks in the following section:

1. [Defining your Cloud Manager topology](#).

About this task

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator
- Topology Administrator
- Custom role with `Settings:Manage` permission

The email server sends invitation emails with activation links and other system messages. More than one email server may be configured in Cloud Manager, but only one email server may be selected as the active server to send notifications at any one time. For instructions on how to select the active email server and to view a list of the email messages that are sent, see [Setting up notifications](#).

Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

Procedure

To configure one or more email servers to use for email notifications in Cloud Manager, complete the following steps:

1. In the Cloud Manager, click  Resources.
2. Choose Notifications.
3. Enter the values to configure the email server.

Field	Description
Title (required)	Enter a descriptive title for the email server. This title will display on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Address (required)	IP address for the email server
Port (required)	Port that the email server runs on
Authenticate User	Enter a user name to use for authorization with the SMTP server. The user name is required if the SMTP server requires authentication.
Authenticate Password	Enter the password for the Authenticate User. This password is used for authorization with the SMTP server. The password is required if the SMTP server requires authentication.
TLS Client Profile (optional)	Select an optional TLS Client Profile that will be used to communicate with the email server if the Secure Connection option is selected.
Secure Connection	Select this option to specify that TLS security is used. The following conditions apply: <ul style="list-style-type: none">• If this option is not selected then TLS security is not used even if the email server is configured to use the STARTTLS protocol.• If this option is selected and a TLS Client Profile is selected, that profile is used and the STARTTLS protocol configuration on the email server is honored.• If this option is selected and no TLS Client Profile is selected, the Default TLS client profile is used and the STARTTLS protocol configuration on the email server is honored.

4. You can send a test email to confirm that the email server is properly configured. Click Test email in the Test Connection panel to open a dialog window. Enter one or more valid email addresses in the Recipients field. Separate multiple recipients with commas. Click Send test email. Check that the test email was received by the recipients.
5. If the test email is successful, click Save to save the email server configuration. If the test is unsuccessful, check the configuration values and update as needed.
Note: In order to send emails, you must select an email server as your active server in Settings > Notifications.

Results

The email server is configured.

What to do next

You must now select the email server to use as your active email server in Cloud Settings > Notifications. You can enter the sender information, and customize the email templates. For more information, see [Setting up notifications](#).

Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

Setting up notifications

Select an email server and set up the "sent from" information for notifications.

Before you begin

You must configure an email server to use for your notifications in Resources > Notifications, before you can set up the notification configuration in Settings > Notifications. See [Configuring an email server for notifications](#) for more information.

About this task

In Settings > Notifications, you select the email server that you want to use as the active server to send notification emails. An active email server is required to send email notifications. More than one email server may be configured in Cloud Manager, but only one email server may be selected to send notifications at any one time. The email server must be configured and selected for notifications before adding a Portal Service to your cloud.

You also configure the sender information to be included on all the emails and optionally, edit the standard text for the email templates.

One of the following roles is required to add roles to select the email server, enter the sender information, and edit the email templates:

- Administrator
- Owner
- A custom role with the `Cloud settings:Manage` permission

Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

Procedure

1. In the Cloud Manager, click  Settings.
2. In the Settings navigation list, click Notifications.
3. To configure the active email server:
 - a. Click Edit in the Sender & Email Server section.
 - b. Select an email server in the list; a check mark is displayed next to the currently selected server.
 - c. Click Save.
4. To delete an email server from the list, click the options menu next to the server name and select Delete.
5. To change the sender name and email address for notifications:
 - a. Click Edit in the Sender & Email Server section.
 - b. Fill in the Name and Email address that notifications will be sent from.
 - c. Click Save.
6. To preview and edit the notification email templates, see [Customizing email notification templates](#)

What to do next

You can now [create a provider organization](#).

- [Customizing email notification templates](#)
API Connect includes a set of email templates for invitations and other notification emails. You can preview the templates and customize the text if required. You can also style the notifications to match your business theme.

Customizing email notification templates

API Connect includes a set of email templates for invitations and other notification emails. You can preview the templates and customize the text if required. You can also style the notifications to match your business theme.

About this task

The API Connect emails are sent automatically when certain system events occur. The email templates are organized by scope, as explained in Table 1.

Table 1. Notification scopes

Scope	Events that trigger the notification
admin	Admin organization activities such as invitations, portal sign up, and password reset.
catalog	Activities related to Catalogs; for example: such as application life cycle events, invitations to catalogs, product approvals, and subscription approvals.
consumer	Activities to consumer applications and subscription requests in the Developer Portal, invitations to Consumer organizations, and password reset requests for Developer Portal accounts.
provider	Invitations
space	Invitations

Email notifications contain a sender name and address that's based on a hierarchical search of the configured sender details in API Connect. Depending on the email template being sent, the search can start at the Space level, and then go through the Catalog, Provider Organization, and the Cloud Manager levels. The sender details that are used will be the first set of configured details found during this hierarchical search. To view which search path API Connect takes when looking for the sender details for each notification template, see [Configuring sender details for email notifications](#) in the Managing your APIs section.

One of the following roles is required to configure email notifications:

- Administrator
- Owner
- A custom role with the `Cloud settings:Manage` permission

Note: You can also customize notifications by using the developer toolkit CLI, or by using the API Connect REST APIs. See [Using the CLI to modify cloud settings](#), or [API Connect REST APIs](#), for more information.

If you want to configure the notifications at the Provider Organization level, see [Configuring notifications](#) in the Managing your APIs section.

Procedure

1. In the Cloud Manager, click  Settings.
2. In the Settings navigation list, click Notifications.
On the Notifications page, templates display in a list, sorted by scope. When selecting a template to modify, be sure to select the version that applies to the appropriate scope.
3. To preview the text for a template, select Preview from the actions menu next to the template name.
4. To edit the text for the template, either click the template name, or select Edit in the action menu.
When a template is opened, an attempt is made to get the language from the browser setting, but if this isn't possible the template defaults to English.

The text includes variables; for example, `{{ catalog }}`. The notification text is based on Handlebars syntax. Most variables are enclosed in double curly braces `{{ }}`, but can be enclosed in triple curly braces `{{{ }}` to disable HTML escaping, when the variable is a URL link for example. For more information on Handlebars, see <https://handlebarsjs.com/>.

To obtain the complete list of variables that are available for a particular notification template, complete the following steps:

- a. Log in to the management server from the command line as a member of the cloud administration organization; for details, see [Logging in to a management server](#). You can use the same management server URL, user name, and password in the login command that you use to log in to the Cloud Manager user interface.
- b. Enter the following command:

```
apic notification-templates:get template_name --server mgmt_endpoint_url --scope cloud --subcollection template_scope
--fields variables --output -
```

where:

- *template_name* is the name of the required notification template, as displayed in the Template column in the user interface.
- *template_scope* is the scope name displayed in the Scope column alongside that template.

For example:

```
apic notification-templates:get member-invitation --server https://myserver.com --scope cloud --subcollection catalog
--fields variables --output -
```

The variables that are available for the template are displayed, for example:

```
variables:
- org
- catalog
- activationLink
- expiresAt
- originator
- originatorFirstName
- originatorLastName
- originatorEmail
- username
- email
- firstName
- lastName
```

The `--output -` parameter causes the command output to be written to the command line. You can specify `--output filepath` to have the output written to a .yaml file at the specified location, or omit it altogether to have a file written to the current folder.

5. To view and edit the notification template in a different language, select one of the following supported languages from the View template in drop-down list:

- Chinese (Simplified)
- Chinese (Traditional)
- Czech
- Dutch
- English (US English)
- French
- German
- Italian
- Japanese
- Korean
- Polish
- Portuguese
- Russian
- Spanish
- Turkish

6. Edit the Subject as required.

7. Select the Content type that you want to use for the template, from HTML, PlainText, or Both. The default content type is PlainText.

An edit window for the selected content type is displayed, or both edit windows are displayed if Both is selected.

8. Edit the body of the template as required.

For HTML content, only the tags and their attributes that are shown in the following table are allowed.

Table 2. List of allowed HTML tags and their attributes

HTML tag	Attribute
<a>	"class", "href", "hreflang", "style"
	"class", "style"
	"class", "style"
<cite>	"class", "style"
<blockquote>	"class", "cite", "style"
<code>	"class", "style"
	"class", "type", "style"
	"class", "start", "type", "style"
	"class", "style"
<dl>	"class", "style"
<dt>	"class", "style"
<dd>	"class", "style"
<h1>	"class", "id", "style"
<h2>	"class", "id", "style"
<h3>	"class", "id", "style"
<h4>	"class", "id", "style"
<h5>	"class", "id", "style"
<h6>	"class", "id", "style"
<p>	"class", "style"
<div>	"class", "style"
 	"class", "style"
	"class", "style"
	"class", "src", "alt", "data-entity-type", "data-entity-uuid", "data-align", "data-caption", "width", "height", "style"
<table>	"class", "id", "style"
<tr>	"class", "id", "style"
<td>	"class", "id", "style"

If an HTML tag that is not allowed is used in a notification, the tag and its contents are displayed in the email as plain text.

Images can be used by adding a `<img`

`src="https://path/to/image.png"/>` tag in the template. The `src` attribute for the image must be a fully qualified web URL, and must be externally

accessible so that the email recipients can access the image. It's not possible to reference local images, they must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.

9. Click Save when done.

Note: Edits made to a template are saved only for the specific language version that is edited.

Related information

- [Configuring notifications](#)

Configuring invitation timeouts

You can set the time period for when registration invitations for Cloud Settings access and the Admin organization expire.

About this task

One of the following roles is required to change the name of your cloud:

- Administrator
- Owner
- A custom role with the `cloud_settings:manage` permission

Procedure

Follow these steps to set the invitation timeout:

1. In the Cloud Manager, click  Settings.
2. In the Settings navigation list, click Onboarding.
3. Click Edit next to the invitation timeout setting that you want to change:
 - Cloud Settings Invitation Timeout
 - Admin Organization Invitation Timeout
4. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
5. Click Save.

Results

Invitations contain a link, which expires after the specified the timeout. If the user does not register before the expiration, you can send a new invitation.

Configuring API key settings

You can set the time period for when an API key expires, and optionally authorize it to be used multiple times.

About this task

Applications exchange the API key exchange the API key for an access token.

Procedure

Follow these steps to set the API key timeout:

1. In the Cloud Manager, click  Settings.
2. In the Settings navigation list, click Onboarding.
3. Click Edit next to the API Key timeout setting.
4. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
5. Select Multiple use of apikey to allow applications to exchange the API key for an access token multiple times.
By default, the API key can be used only once.

To [enable this setting with the CLI](#), set the `api_key_multiple_uses` field to `true`.
6. Click Save.

Results

API Key times out based on the set timeout value.

Using the CLI to modify cloud settings

Use the toolkit CLI to edit the cloud settings.

About this task

Some cloud settings can be modified in the Cloud Manager UI, but all settings can be modified with the toolkit CLI. You can modify the cloud settings configuration file and upload the changes, or issue commands to modify individual settings directly. If multiple people modify the cloud settings, any newer settings overwrite older settings regardless of the method used to update the settings.

For more information about working with the toolkit CLI, see the following topics:

- For details on using `apic` to modify cloud settings, see [apic cloud-settings:update](#).
- For details on all the cloud settings commands, see [apic cloud-settings](#)

Procedure

1. Run the following command to log in to a management server as a member of the cloud administration organization:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

Cloud settings are stored on a management server and you must log in to the server before you can access the settings with the CLI.

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
- title: Cloud Manager User Registry
  realm: admin/default-idp-1
- title: Corporate LDAP user registry
  realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.

For more information on logging in, see [Logging in to a management server](#).

2. Optionally retrieve the current list of cloud settings with the following command:

```
apic cloud-settings:get --server mgmt_endpoint_url --output -
```

where `mgmt_endpoint_url` is the URL of the server where the cloud settings are stored.

3. Add or modify settings using one of the following methods:

- Issue each setting from the command line.
For simple changes, you can issue commands to modify settings without editing the configuration file.

- Issue the following command to start the update process:

```
apic cloud-settings:update --server mgmt_endpoint_url -
```

where `mgmt_endpoint_url` is the URL of the server where the cloud settings are stored. Include the hyphen at the end of the command to indicate that input follows on the next command line.

- Type the information for a single setting on one line, and press ENTER to submit it.
Specify each setting on a single line and use the following format to specify the setting's name and value:

```
setting_name: setting_value
```

For example, the following command updates a single setting:

```
apic cloud-settings:update --server mgmt_endpoint_url -
refresh_expires_in: expiration time
Ctrl+D
```

- Type Ctrl+D to indicate that the data entry is complete, as shown in the example.
- Upload a file containing the settings.
If you have multiple settings or lengthy values to add or modify, you might prefer to make all of the changes at once by creating or modifying the configuration file and then uploading it.

- Create a `.yaml` file with your settings.
You can choose the file name but must use YAML format. The file can contain as few or as many settings as needed.

Settings use the following format; notice that the setting's name must be enclosed in quotation marks as shown in the example. The last setting in the file does not end with a comma.

```
"setting_name": setting_value,
```

- Upload the file with the following command:

```
apic cloud-settings:update --server mgmt_endpoint_url my_cloud_settings.yaml
```

For information on using input files with the toolkit CLI, see [./com.ibm.apic.toolkit.doc/rapic_cli_command_line_input.html](#).

4. When you are ready to log out of the management server, use the following command:

```
apic logout --server mgmt_endpoint_url
```

Results

The settings are cached for a maximum of five minutes, so you might experience a delay before your changes take effect.

Configuring Base64 encoding for temporary tokens

How to enable and disable Base64 encoding for temporary tokens.

About this task

You can enable or disable Base64 encoding for temporary tokens. Temporary tokens are invitations, and password reset tokens. When Base64 encoding is enabled, the temporary token is encoded in Base64 format. When Base64 encoding is disabled, the temporary token remains in the JSON Web Token (JWT) format, and means that the length of the URL that the user receives is reduced.

Base64 encoding is enabled by default.

One of the following roles is required to configure Base64 encoding:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

Procedure

Follow these steps to configure Base64 encoding for temporary tokens:

1. In the Cloud Manager, click  Settings.
2. In the Settings navigation list, click Onboarding.
3. Click Edit next to the Base64 encoding setting.
4. Select Enable to enable Base64 encoding, or Disable to keep temporary tokens in the JSON Web Token (JWT) format.
5. Click Save.

Results

You have successfully enabled or disabled Base64 encoding for temporary tokens.

Configuring the password-reset notification and timeout

Configure the time allowed for a user to reset a password, and customize the notification that the user receives.

Before you begin

Configure an email server that can be used for mailing notifications to users. If you do not configure an email server, a link cannot be sent to a user who wants to reset a password. For information on configuring the email server, see [Setting up notifications](#).

About this task

When a user clicks Forgot Password? and provides an email address on the sign-in page, an email is generated with a link where the user can reset the password. When you deploy API Connect, the password-reset settings are configured with default values. You can optionally modify the time-out setting to set a new expiration for resets as well as the notification that is emailed to users.

Procedure

1. In the Cloud Manager, click  Settings.
2. In the Settings navigation list, click Onboarding.
3. Configure the password reset timeout:
 - a. In the Settings navigation list, click Onboarding.
 - b. Click Edit next to Reset Password Time to Live.
 - c. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
 - d. Click Save.
4. Customize the notification template for password resets:
 - a. In the Settings navigation list, click Notifications.
 - b. In the Notifications Templates list, select the appropriate version of the "password-reset" template by clicking the name.
You can create different versions of the template for different user roles.
 - c. Customize the template as explained in [Customizing email notification templates](#).
 - d. Click Save.

Results

Password reset notifications contain a link, which expires after the specified the timeout. If the user does not reset the password before the link expires, they can request a new link.

Selecting user registries for Cloud Manager and API Manager

Select the user registries to authenticate users for Cloud Manager and API Manager.

About this task

In Settings > User registries, you select one or more user registries to authenticate users of Cloud Manager and API Manager. The user credentials for all users who login to the applications must be stored in the selected registries.

One of the following roles is required to select the user registries for Cloud Manager and API Manager:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

For details on how to control which user registries can be used by provider organizations for authenticating Developer Portal users, or for securing APIs, see [Setting visibility for a user registry](#).

Procedure

To select the user registries for Cloud Manager and API Manager, follow these steps:

1. In the Cloud Manager, click  Settings.
2. In the Settings navigation list, click User Registries.
3. The current list of user registries is displayed for Cloud Manager and for API Manager. To add user registries, click Edit in either the Cloud Manager or API Manager panel.
Note: The list of user registries is derived from the user registries that were previously configured as a Resource in Resources > User Registries. For more information, see [User registries overview](#).
4. Select the user registry by placing a check mark next to the name in the list. Remove a user registry by removing the check mark.
5. Click Save.

Results

The user registry list is updated to reflect the selected user registries available for authenticating users.

What to do next

To set a user registry as the default, click the options menu next to the registry name in the list, and select Set as default.

- [Setting a default user registry for Cloud Manager and API Manager](#)
You can select a default user registry for Cloud Manager and and for API Manager.

Related tasks

- [Configuring an LDAP user registry in the Cloud Manager](#)

Setting a default user registry for Cloud Manager and API Manager

You can select a default user registry for Cloud Manager and and for API Manager.

About this task

In Settings > User registries, you can set a user registry as the default user registry.

One of the following roles is required to select the user registries for Cloud Manager and API Manager:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

Procedure

1. In the Cloud Manager, click  Settings.
2. In the Settings navigation list, click User Registries.
3. To set a user registry as the default, click the options menu next to the registry name in the list, and select Set as default.

Note: The list of user registries is derived from the user registries that were previously configured as resources in Resources > User Registries. For more information, see [User registries overview](#)

Results

The user registry list is updated to reflect the default user registry.

Related tasks

- [Configuring an LDAP user registry in the Cloud Manager](#)

- [Configuring a Local User Registry](#)

Configuring timeouts for access tokens and refresh tokens

Configure timeout values for the access tokens and refresh tokens for user registries.

About this task

IBM® API Connect supports the use of access tokens and refresh tokens for user registries that authenticate users of the Cloud Manager, the API Manager, and the Developer Portal.

Access tokens allow users to sign in and remain logged in for a specified amount of time (the timeout period). Refresh tokens allow the access token to be renewed automatically without requiring the user to sign in again. Access tokens are configured by default, and you can modify the timeout setting. Refresh tokens are disabled by default but are configured with a default timeout when you enable them.

Refresh tokens, when enabled, are generated every time an access token is created. Refresh tokens can be used to obtain a new access token without having to prompt a user to re-login. If you enable the use of refresh tokens, then when the token expires it is refreshed automatically in the background so that the user can continue working without interruption. When the user logs out, the refresh token is revoked and the application can no longer use it.

Note: If users log in with non-OIDC user registries, the use of refresh tokens is supported in API Manager, API Designer, the Developer Portal, and the CLI Toolkit. When the refresh token expires, the user is always redirected to the login page.

If users log in with OIDC user registries:

- The use of refresh tokens is supported only in the Developer Portal and the CLI Toolkit
- If the OIDC providers do not support refresh tokens, API Connect will not issue a `refresh_token`, regardless of the setting of `refresh_token_enabled` in the cloud settings.
- For more information about OIDC configuration, see [Configuring an OIDC user registry in Cloud Manager](#).

You can configure access tokens and refresh tokens using the [Cloud Manager UI](#), or the [Toolkit CLI](#).

Using the UI to configure tokens

Configure timeout settings for access tokens and refresh tokens in the Cloud Manager Settings pages.

Procedure

1. Click  in the navigation pane.
2. Configure the timeout for access tokens:
 - a. On the Onboarding page, click Edit next to Access Token Time to Live.
 - b. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
 - c. Click Save.
3. Configure the timeout for refresh tokens:
 - a. On the Onboarding page, click Edit next to Refresh Token Time to Live.
 - b. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
 - c. Click Save.

Using the CLI to configure tokens

Use the Toolkit CLI to configure timeout settings for access tokens and refresh tokens.

About this task

Use the following properties to specify refresh tokens for cloud settings:

- `access_token_expires_in`
Integer. Represents the expiration time, in seconds, for access tokens issued by API Connect.
- `refresh_expires_in`
Integer. Represents the expiration time, in seconds, for refresh tokens issued by API Connect. Must be greater than `access_token_expires_in`.
- `refresh_token_enabled`
Boolean. Disabled by default. To enable, set to `true`. When enabled, generates a `refresh_token` field in the response to the `/token` API call.

The following extract from a cloud settings file shows example settings for these properties:

```
"type": "cloud_setting",
"api_version": "2.0.0",
"name": "cloud-setting",
"access_token_expires_in": 28800,
.
.
"refresh_expires_in": 57600,
"refresh_token_enabled": false,
.
.
```

Use the toolkit CLI (`apic`) to update the cloud settings with new values for the properties. You can either specify values as command line arguments, or enter them manually in a configuration file as explained in [Using the CLI to modify cloud settings](#).

Viewing platform and UI endpoints

A view-only list of platform and UI endpoints is provided.

About this task

You can view the list of endpoints configured during the installation process. Included in this view-only list are the following endpoints:

- API Manager URL - the URL for opening the API Manager UI
- Platform REST API endpoint for the Admin and Provider REST APIs - this endpoint handles the REST APIs for Admin and Provider functions.
- Platform REST API endpoint for consumer REST APIs - this endpoint handles the REST APIs for consumer (Portal) functions.

One of the following roles is required to view endpoints:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` or `cloud-settings: view permissions`

Procedure

To view the endpoints, follow these steps:

1. In the Cloud Manager, click  Settings.
2. Select Endpoints.
3. View the list of endpoints.

Configuring the default gateway services for Catalogs

Configure the list of default gateway services that are available to new Catalogs.

About this task

One of the following roles is required to configure Catalog Defaults:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

You publish APIs by adding them to a Product and then publishing the Product to a Catalog. To be able to publish Products to a Catalog, the Catalog must be assigned at least one gateway service so that the APIs in the Product are available to be called at a gateway service endpoint. You can assign more than one gateway service to a Catalog, and they can be of mixed types: DataPower® API Gateway, DataPower Gateway (v5 compatible), and Event Gateway Service.

A Product is gateway type specific: DataPower API Gateway, DataPower Gateway (v5 compatible), or Event Gateway Service. By default, when you publish a Product to a Catalog, it is published to all the assigned gateway services of the same gateway type as the Product, but you can choose to publish the Product only to selected gateway services, of that type, at publish time; see [Publishing a draft Product](#) for more information. The APIs in the Product will be available to be called at all the specified gateway service endpoints.

The procedure described in this topic specifies the gateway services that are assigned by default to newly created Catalogs, but you can change the assigned gateway services for a specific Catalog; see [Creating and configuring Catalogs](#).

Procedure

To configure the gateway services that are assigned to new Catalogs by default, complete the following steps:

1. In the Cloud Manager, click  Settings.
2. In the Settings navigation list, click Catalog Defaults.
3. Click Edit to change the list of default gateway services.
4. Select the required gateway services, then click Save.

Results

When a new Catalog is created in a provider organization, the default gateway services are automatically assigned to it. Any changes you make to the list of default services affects only the Catalogs that are created after you save your changes. Existing Catalogs are not affected.

Managing the public/private key pairs for signing tokens

Manage the public/private key pairs that are used for signing tokens in API Connects.

API Connect uses public-key cryptography to secure tokens. By default, an API Connect deployment receives one public/private key pair, which is used for signing and verifying tokens. When a token is created, API Connect signs it with the deployment's private key. Any third-party can verify that digital signature with the deployment's public key.

The public/private key pair is generated for you by API Connect on the first start-up after installation, upgrade, or migration. The keys are stored in a keystore object.

Why do you need public/private key pairs?

API Connect uses a public/private key pair to sign and verify the following tokens:

- **access_token**: Verifies that the user has permission to access resources.
- **id_token**: Stored within the access token to specifies the user's ID. **Confirm?**
- **temporary_token**: Provides for short-lived access so that the user can log in and receive an access token. For example, when the user receives a link for resetting a password or to register for an account.

How does APIC use the public/private key pair?

Each API Connect deployment is assigned a public key, which is made openly available, plus a corresponding private key, which can only be accessed by that deployment. To verify a user's access to resources for a transaction, API Connect signs every token with the private key. Any other party can use the openly available public key to verify the signature. Because the private key is not shared, it can be used repeatedly instead of generating a new value for each signature.

When your app accesses an API endpoint, the access_token is in JWT format and includes a "kid" value that is the new key.

Note: The signature for public/private key schema is larger than for shared secrets, so the access_token that is returned will also be larger. If you encounter issues with headers becoming too large, refer to the following topic: [Resolving login problems by increasing HTTP header size](#).

How can you manage public/private key pairs?

By default, your deployment is assigned one key pair, which is stored in a keystore and never expires. The same key pair is used for signing and verify all tokens. The key pair consists of a public key and a private key:

- **key_signing**: The private key that API Connect uses for signing tokens
- **key_verify**: The public key that anyone can access and use for verifying token signatures

API Connect uses the following cloud settings to determine which public/private keystores are used for each type of token:

- **access_token_keystore_urls**: [keystore_url_0, keystore_url_n]
- **id_token_keystore_urls**: [keystore_url_0, keystore_url_n]
- **temporary_token_keystore_urls**: [keystore_url_0, keystore_url_n]

Each setting specifies an array of URLs where the keystores are hosted, with the keystore at position 0 representing the current key pair. You can optionally generate additional key pairs, store them in new keystores, and use them with the tokens to enhance security. Each key pair is stored in its own keystore and can be set to expire at a different time. Providing a different key pair for each type of token is a good practice because it limits the damage if a token is compromised.

If you specify one keystore for a token, that key pair is used for every new token of the same type, and it never expires. If you specify multiple keystores, you can assign a lifetime to each and when the keys in the first keystore expire, the keys are obtained from the next keystore in the list, and so on.

You can use the public/private key pairs and keystores to perform the following operations with tokens:

Sign a token

The first keystore in the array is the current keystore; use its key_signing key to sign tokens.

Verify a token's signature

To verify a token's signature, start with the current keystore (the first in the array). If the token doesn't match the key_verify key, move to the older keystores and compare the token with the key_verify value in each.

Add key pairs

When you create a new key pair, add the keys to a separate keystore, and then add that keystore's URL to the end of the token's keystore array. The first keystore in the array is the "current" keystore, and subsequent keystores in the array are used in turn.

Revoke key pairs

If you suspect that a token is compromised, you can revoke they keys for signing and verifying it. To revoke a key pair, delete the corresponding keystore from the token's keystore array. Removing a keystore removes the keys that were used for signing and verifying tokens, and invalidates all of the tokens that were issued with that key pair.

Attention: You must always retain at least one key pair for signing and verifying tokens.

Rotate through keystores to periodically change the key pairs in use

To rotate through key pairs for a token, configure at least two keystores for the token. Specify the “current” keystore first in the array, followed by the “next” keystores. Make sure that the each keystore’s lifetime overlaps that of the next keystore so that keys from the current keystore don’t expire before the new key pair takes effect.

Before you configure the lifetime for a keystore, you can refer to the Onboarding section of the Cloud Settings page to quickly see the lifetime that is configured for each type of token. Then make sure you specify enough keystores, with long enough lifetimes, to span each token’s lifetime. For example, if the temporary_token lives for 72 hours and the key used for signing it lives for 24 hours, you need to provide at least 3 sets of keys to span the token’s lifetime:

```
temporary_token: [keystore1, keystore2, keystore3]
```

- **Configuring public/private key pairs for tokens**

Configure public/private key pairs for signing and verifying tokens in your API Connect deployment.

Configuring public/private key pairs for tokens

Configure public/private key pairs for signing and verifying tokens in your API Connect deployment.

About this task

By default, an API Connect deployment receives one public/private key pair, which is used repeatedly. The public/private key pair is generated for you the first time you start API Connect after installing or upgrading it. The keys are stored in a keystore object. You can add and revoke keys, and configure a rotation through keys for enhanced security.

You can configure key pairs for tokens in the [Cloud Manager user interface](#), or by [using the Toolkit CLI](#).

Using the Cloud Manager UI to configure public/private key pairs

Use the Cloud Manager user interface to configure key pairs for signing and verifying tokens.

About this task

Manage Keystore assignment and Keystore history for tokens

Procedure

1. In the Cloud Manager, click .
2. In the Settings navigation list, click Signed Token.
The Signed Token page displays the list of supported tokens for signing.
3. Review the current token settings:
 - Click Payload to display the payload code for the set of tokens.
 - Click History log next to a token to view its previous keystore assignments (this history never includes the current keystore assignment). The most recent assignment displays at the top of the list. You can remove any keystore assignment from the history by clicking .
4. To add or change a keystore assignment for a token, complete the following steps:
 - a. On the Signed Token page, click Edit.
 - b. On the Edit signed token page, select a keystore for the token you want to modify.
 - c. Click Save to save your changes and update the keystore history.
Changes take effect immediately.

The previously selected keystore is added to the history for the token that you just updated. The history never includes the current keystore assignment.

Using the Toolkit CLI to configure public/private key pairs

Use the Toolkit CLI to configure key pairs for signing and verifying tokens.

About this task

Use the following properties to the keystore URLs that contain the public/private key pair for each type of token. For each setting, the list of keystores is an array of strings, with each string representing the complete URL of a keystore. The first keystore in the array (*keystore_url_0*) is the one that is currently in use.

- access_token:
`access_token_keystore_urls: [keystore_url_0, keystore_url_n]`
- id_token:
`id_token_keystore_urls: [keystore_url_0, keystore_url_n]`
- temporary_token:
`temporary_token_keystore_urls: [keystore_url_0, keystore_url_n]`

The keystore URLs can be lengthy. You can avoid errors by writing the settings in a file and uploading that file. Format the settings as a .yaml file (you can choose the file name) and upload the file using the toolkit CLI. The following example configures a different keystore for each type of token:

```
access_token_keystore_urls:
- >-
  https://mgmt_endpoint_url/api/orgs/1cdb71a1-b53c-4b66-b162-1b0f45ca8a54/keystores/de5298dd-a00b-45a0-9d08-96c5d93e1273
id_token_keystore_urls:
- >-
  https://mgmt_endpoint_url/api/orgs/1cdb71a1-b53c-4b66-b162-1b0f45ca8a54/keystores/85a21745-8ac3-499d-929a-2d017bade815
```

```
temporary_token_keystore_urls:
- >-
  https://mgmt_endpoint_url/api/orgs/1cdb71a1-b53c-4b66-b162-1b0f45ca8a54/keystores/63d6462f-c93d-439b-b422-0e604381e97a
```

Procedure

1. Create a YAML file with the keystore settings for each type of token as shown in the example.
For information on using input files with the toolkit CLI, see [Reading input from the command line](#).
2. Run the following command to log in to a management server as a member of the cloud administration organization:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

Cloud settings are stored on a management server and you must log in to the server before you can access the settings with the CLI.

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
- title: Cloud Manager User Registry
  realm: admin/default-idp-1
- title: Corporate LDAP user registry
  realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`. For more information on logging in, see [Logging in to a management server](#).

3. Upload the YAML file with the new settings by running the following command:

```
apic cloud-settings:update --server mgmt_endpoint_url my_token_keystore_settings.yaml
```

4. Run the following command to log out of the management server:

```
apic logout --server mgmt_endpoint_url
```

Administering provider organizations

Manage the provider organizations who have accounts to publish APIs in your API Connect cloud.

About this task

Perform these tasks to manage your provider organizations:

- [Creating a provider organization](#)
For developers to publish APIs, they must be a member of a provider organization. The first step is to create a provider organization and specify an organization owner. Then members can be added to the provider organization and can start publishing APIs.
- [Editing a provider organization](#)
You can edit the title of a provider organization, and also transfer ownership to a new organization owner.
- [Deleting a provider organization](#)
You can delete a provider organization. All Catalogs and Spaces are also removed.
- [Viewing current provider organizations](#)
View the list of current provider organizations for your cloud, including organization title, owner's name and email address, and status. From the list screen, you can add new provider organizations and owners, edit and delete provider organizations, send messages, and change owners.
- [Sending messages to provider organization owners](#)
You can send an email message to the owner of a provider organization. You can also style the email to match your business theme.

Related tasks

- [Creating a provider organization](#)
- [Editing a provider organization](#)
- [Deleting a provider organization](#)
- [Viewing current provider organizations](#)

Creating a provider organization

For developers to publish APIs, they must be a member of a provider organization. The first step is to create a provider organization and specify an organization owner. Then members can be added to the provider organization and can start publishing APIs.

Before you begin

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

You must also complete the following tasks before beginning:

- [Configuring an email server for notifications](#)
- [Setting up notifications](#)

About this task

Note that an email server must be configured and an active email server must be selected before a provider organization account can be created.

There are two options for creating a provider organization account, as follows:

- Option 1: Create a provider organization and send an email invitation to a new user to register and become the organization owner. Choose the Add > Invite organization owner option.
- Option 2: Create a provider organization and specify the user who will be the organization owner. Choose the Add > Create organization option.

Procedure

- **Option 1:** To create a provider organization and invite a new user to register as the owner, complete the following steps:

1. In the Cloud Manager, click  Provider Organizations.
2. Click Add > Invite organization owner
3. Enter a valid email address and click Invite. An email containing an activation link is sent to the email address inviting the person to register. The link opens the registration form. Alternately, you can copy and paste the activation link into an email; click Get Activation Link and click Copy in the pop up window. Note that the email server requires the Authenticate User and Authenticate Password values in order to send invitations. See [Configuring an email server for notifications](#).

The new provider organization is placed in Pending status, and is changed to Enabled status after the owner completes the registration form to activate their account. The owner can then log in to the API Manager user interface with the API Connect user name that they specified during account activation.

Note: If you use this option with a Local User Registry, and the user already exists in the registry, the user must re-activate their account by using the Sign In option, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail. This stipulation includes users that were previously provider organization owners but whose organization was deleted.

- **Option 2:** To create a provider organization and specify the user who will be the organization owner, complete the following steps:

1. In the Cloud Manager, click  Provider Organizations.
2. Click Add > Create organization.
3. In the Title field, enter a title for the provider organization. If desired, the title can be edited after the provider organization is created.
4. The internal Name is automatically generated for you by the system. The Name field contains the string that is included in the organization segment of the URL for API calls. For more information, see [Calling an API](#).

Tip: The Name field is auto-generated to ensure its validity in the URL.

The value in the Name field is also used to identify the provider organization in developer toolkit CLI commands. To view the CLI commands to manage provider organizations, see [apic orgs](#).

5. Select the user registry for the provider organization owner.

The remaining procedure varies according to the type of the selected user registry, as follows:

- Local User Registry
 - Select whether the user is an Existing user or a New User.
 - For an existing user, complete the following steps:
 - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
 - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.
 - For a new user, complete the following steps:
 - Enter a unique user name for the new user.
 - Supply an email address, name details, and a password.
 - Click Create. The user account is created, and the provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface with the specified user name and password; the user interface open in the new provider organization.
- LDAP
 - Enter the name of a user that exists in the selected user registry.
 - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface with their LDAP user name. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.
- Authentication URL and OIDC
 - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account. If the required organization owner has not previously been invited and activated their account, you must use the invitation mechanism described in [Option 1](#).
 - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.

What to do next

For details of how an invited organization owner activates their account see [Activating your API Manager user account](#). For details of how to log in to the API Manager user interface, see [Accessing the API Manager user interface](#).

Editing a provider organization

You can edit the title of a provider organization, and also transfer ownership to a new organization owner.

Before you begin

This task can be completed by users who are assigned the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

About this task

If you transfer ownership, the new organization owner can be an existing user, or you can create a new user. When the ownership changes, the new owner is assigned administration privileges for the organization, and the previous owner has their administration privileges removed. Optionally, you can also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner. If required, you can restore the privileges to the previous owner as described in [Administering members and roles](#).

Procedure

To update a provider organization, complete the following tasks:

1. In the Cloud Manager, click  Provider Organizations.
2. Click the name of the provider organization that you want to update.
3. To change the title, enter a new title in the Title field, then click Save.
4. To transfer ownership, select the user registry for the provider organization owner you want to transfer ownership to.
The remaining procedure varies according to the type of the selected user registry, as follows:
 - Local User Registry
 - Select whether the user is an Existing user or a New User.
 - For an existing user, complete the following steps:
 - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
 - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
 - Click Save.
 - For a new user, complete the following steps:
 - Enter a unique user name for the new user.
 - Supply an email address, name details, and a password.
 - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
 - Click Save.
 - LDAP
 - Enter the name of a user that exists in the selected user registry.
 - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
 - Click Save.
 - Authentication URL and OIDC
 - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account. If the required organization owner has not previously been invited and activated their account, you must ensure they have been invited to the organization first.
 - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
 - Click Save.

Deleting a provider organization

You can delete a provider organization. All Catalogs and Spaces are also removed.

Before you begin

This task can be completed by users who are assigned the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

About this task

The user account for the owner of the deleted provider organization remains in the associated API Connect user registry. The user can still log in to the API Manager user interface; if they are a member of one or more other provider organizations then those organizations are accessible, otherwise only information links are available, with no access to view or manage any resources.

The user can be added again as a provider organization owner at a later time; see [Creating a provider organization](#).

Procedure

To delete a provider organization, complete the following tasks:

1. In the Cloud Manager, click  Provider Organizations.
2. Navigate to the provider organization that you want to delete in the list and select Delete from the Actions menu.
3. Confirm that you want to delete the provider organization.
The provider organization is deleted and removed from the Provider Organizations list.

Results

The provider organization, and its Catalogs and Spaces, are deleted.

Viewing current provider organizations

View the list of current provider organizations for your cloud, including organization title, owner's name and email address, and status. From the list screen, you can add new provider organizations and owners, edit and delete provider organizations, send messages, and change owners.

Before you begin

You must also complete the following tasks before beginning:

- [Configuring an email server for notifications](#)
- [Setting up notifications](#)
- [Creating a provider organization](#)

This task can be completed by users who are assigned one of the following roles:

- All roles
- Custom role with the `Provider-org:Manage` or the `Provider-org:View` permissions

About this task

All roles can view the list of provider organizations. Use the provider organization list screen to manage your provider organizations.

Procedure

1. In the Cloud Manager, click  Provider Organizations.
2. View the list of provider organizations and their status. The statuses are as follows:
 - **Pending:** A provider organization is in `Pending` status until the invited owner successfully completes the registration form.
 - **Active:** A provider organization is in `Active` status if the owner is an existing user with an account in a user registry.
3. The Actions menu performs different functions depending on the organization's status. Use the Actions menu to edit or delete an Active organization. For Pending organizations, use the Actions menu to delete the organization and to resend the invitation to the owner
 - For an Enabled organization, you can Edit or Delete the organization.
 - For a Pending organization, you can Resend the Invitation, or Delete the request.
4. Add new provider organizations using the Add menu. See [Creating a provider organization](#)

Related tasks

- [Creating a provider organization](#)
- [Editing a provider organization](#)
- [Deleting a provider organization](#)

Sending messages to provider organization owners

You can send an email message to the owner of a provider organization. You can also style the email to match your business theme.

Before you begin

This task can be completed by users who are assigned the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

Note: You can also send email messages by using the developer toolkit CLI, or by using the API Connect REST APIs. See [Cloud administration commands](#), or [API Connect REST APIs](#), for more information.

Procedure

To send a message, complete the following steps:

1. In the Cloud Manager, click  Provider Organizations.
2. Click the options icon  alongside the provider organization that you want to work with, then click Message owner.
The Send message window opens, and the email address of the provider organization owner is displayed as the recipient.
3. Enter the subject of the message in the Subject field.
4. Select the Content type that you want to use for the entering the content of the message, from HTML, PlainText, or Both. The default content type is PlainText. An edit window for the selected content type is displayed, or both edit windows are displayed if Both is selected.
For HTML content, only the tags and their attributes that are shown in the following table are allowed.

Table 1. List of allowed HTML tags and their attributes

HTML tag	Attribute
<a>	"class", "href", "hreflang", "style"
	"class", "style"
	"class", "style"
<cite>	"class", "style"
<blockquote>	"class", "cite", "style"
<code>	"class", "style"
	"class", "type", "style"
	"class", "start", "type", "style"
	"class", "style"
<dl>	"class", "style"
<dt>	"class", "style"
<dd>	"class", "style"
<h1>	"class", "id", "style"
<h2>	"class", "id", "style"
<h3>	"class", "id", "style"
<h4>	"class", "id", "style"
<h5>	"class", "id", "style"
<h6>	"class", "id", "style"
<p>	"class", "style"
<div>	"class", "style"
 	"class", "style"
	"class", "style"
	"class", "src", "alt", "data-entity-type", "data-entity-uuid", "data-align", "data-caption", "width", "height", "style"
<table>	"class", "id", "style"
<tr>	"class", "id", "style"
<td>	"class", "id", "style"

If an HTML tag that is not allowed is used in a notification, the tag and its contents are displayed in the email as plain text.

Images can be used by adding a `<img`

`src="https://path/to/image.png"/>` tag in the template. The `src` attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images, they must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.

5. Enter the content of the message.
6. Click Send.

Administering members and roles

Cloud Administrators can add members and assign them roles to enable them to work in Cloud Manager. The Cloud and Topology Administrators can also create roles and role defaults. You can also delete users to prevent them from accessing Cloud Manager.

About this task

To manage roles, add members, and assign roles to member, perform the following tasks:

- [Creating roles in the admin organization](#)
Cloud Manager ships with a set of pre-configured roles. As the Cloud Manager administrator, you can create custom roles, add permissions, and assign the roles to members of the Admin organization.
- [Editing roles in the admin organization](#)
As the Cloud Manager administrator, you can edit the roles in the Admin Organization. Both pre-configured roles and custom roles may be edited, except for the Owner, Viewer, and Member roles. The Owner, Viewer, and Member roles may not be edited or deleted.
- [Configuring LDAP group mappings on Cloud Manager user roles](#)
As a Cloud Manager administrator, you can configure LDAP group mapping on API Connect roles in the Admin organization by using the developer toolkit CLI.
- [Deleting roles in the admin organization](#)
Roles can be deleted (except for the Owner, Viewer, and Member roles) from the Admin organization. If there are members assigned to a role that has been deleted, they will be assigned the Viewer role.
- [Viewing members and roles](#)
Use the Members page to view the current members of the Admin organization and manage the role assignments.

- [Adding members to the admin organization](#)
As the Cloud Manager administrator, you can add and remove members of the Admin organization and assign roles to them. Once removed, a user can no longer access the Cloud Manager.
- [Assigning roles to members](#)
As the Cloud Manager administrator, you manage the roles that are assigned to members. A member's role determines the tasks they are authorized to perform in Cloud Manager.
- [Deleting a member](#)
As the Cloud Manager administrator, you can delete members of the API Connect cloud administration organization. Once deleted, the user and associated roles are removed, however the user's account still remains in API Connect.
- [Role Defaults overview](#)
Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

Creating roles in the admin organization

Cloud Manager ships with a set of pre-configured roles. As the Cloud Manager administrator, you can create custom roles, add permissions, and assign the roles to members of the Admin organization.

About this task

If you are assigned a role that has the `Settings: manage` permission, you can create custom roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.

One of the following roles is required to add custom roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage permissions`

Procedure

Perform the following steps to add custom roles to the Admin Organization:

1. In the Cloud Manager, click  Settings.
2. Select Roles.
3. Click Add to add a new role.
4. Enter the Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see [User roles and permissions in the Cloud Manager UI](#).
6. Save the custom role.

Results

The custom role appears in the list of roles and can be assigned to members.

What to do next

Assign the role to a member in the Members list. See [Assigning roles to members](#)

Related tasks

- [Editing roles in the admin organization](#)

Editing roles in the admin organization

As the Cloud Manager administrator, you can edit the roles in the Admin Organization. Both pre-configured roles and custom roles may be edited, except for the Owner, Viewer, and Member roles. The Owner, Viewer, and Member roles may not be edited or deleted.

About this task

You can customize the per-configured roles (except for the Owner, Viewer, and Member roles) to reflect your business needs.

If you are assigned a role that has the `Settings: manage` permission, you can edit the roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.

One of the following roles is required to edit roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage permissions`

Following are the edits you can perform for a role:

- Change the title
- Add or delete permissions

Procedure

Perform the following steps to edit roles in the Admin organization:

1. In the Cloud Manager, click  Settings.
2. Select Roles.
3. Locate the Role you want to edit, and select Edit from the overflow menu.
4. Enter the desired Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see [User roles and permissions in the Cloud Manager UI](#).
6. Save the updated role.

Results

The Role will be updated with a new name and/or permissions. An updated role will affect the members who are assigned the role. If you change the name of a role, you will have to assign it to the members. If you change the permissions for a role, the way that members use the product may change.

Configuring LDAP group mappings on Cloud Manager user roles

As a Cloud Manager administrator, you can configure LDAP group mapping on API Connect roles in the Admin organization by using the developer toolkit CLI.

Before you begin

You must have an LDAP user registry resource in the Cloud Manager that has the `external_group_mapping_enabled` configuration set to `true`. See [Using the CLI to configure a shared LDAP user registry](#) for information.

One of the following roles is required to edit roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage permissions`

Note: The Admin organization roles apply only to Cloud Manager users. If you want to apply LDAP group mapping to API Manager users, see [Configuring LDAP group mapping on API Manager user roles](#). LDAP group mapping cannot be applied to Developer Portal users.

About this task

You can map external LDAP groups to the API Connect preconfigured user roles (except for the Owner and Member roles), as well as to any custom user roles, to reflect your business needs.

Notes:

- After LDAP group mapping is enabled on a role, user onboarding always honors the group mappings.
- Once on-boarded, user membership in API Connect is valid throughout the login period (`access_token_ttl`), irrespective of any changes in the external LDAP registry. Membership is updated only on the next login, when the LDAP information is fetched and refreshed.
- One or more API Connect roles can be mapped to one or more LDAP groups, and one or more LDAP groups can be mapped to a role.
- When multiple LDAP groups are mapped to a single role, it means that a user from any one of the LDAP groups can log in to API Connect.
- If a user is removed from the external LDAP user registry, then to ensure quick removal from API Connect you must also delete the user membership in API Connect.

You can configure LDAP group mappings using one of the following methods:

- [Using the UI to configure LDAP group mappings](#)
- [Using the CLI to configure LDAP group mappings](#)

Using the UI to configure LDAP group mappings

Use the Cloud Manager UI to configure LDAP group mappings.

Procedure

1. Login to the Cloud Manager UI as a user with the appropriate permissions.
2. Click Settings > Roles > Add a new Role or edit existing role .
3. Select the following settings:
 - Enable external group mapping - select to enable external group mapping for this role.
 - LDAP user Registry - LDAP user registry list which has external group mapping enabled. User must select one of the LDAP user registry from this list.
 - LDAP group names - add one or more LDAP group names that you want to map to the user role.
 - User group prefix - add the prefix for the LDAP user group.
 - User group suffix - add the suffix for the LDAP user group.
4. Save your changes.

Results

The role is updated with the LDAP group mapping information. Users can now log on to the Cloud Manager, and automatically be assigned the correct access permissions for their role.

Using the CLI to configure LDAP group mappings

Use the toolkit CLI to configure LDAP group mappings.

About this task

For detailed information about how to use the CLI, see [Installing the toolkit](#), and [Overview of the command-line tool](#).

Procedure

Perform the following steps to map external LDAP groups to Cloud Manager user roles.

1. Log in to the management server CLI.

Before you can update the role configuration, you must log in to your management server from the developer toolkit CLI as a member of the cloud administration organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

where `mgmt_endpoint_url` is the platform API endpoint URL.

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
- title: Cloud Manager User Registry
  realm: admin/default-idp-1
- title: Corporate LDAP user registry
  realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`. For full details of the login command, see [Logging in to a management server](#).

2. Run the following command to get the URL of the LDAP user registry resource in the Cloud Manager that you want to map the user roles to:

```
apic user-registries:get ldap_user_registry --org admin --server mgmt_endpoint_url --output -
```

where:

- `ldap_user_registry` is the name or ID of your LDAP user registry resource.
- `--org admin` means that the registry details are retrieved from the admin organization.
- `mgmt_endpoint_url` is the platform API endpoint URL.

This command outputs the configuration details of your LDAP user registry, and the `url` is shown at the end of the list, for example:

```
type: user_registry
api_version: 2.0.0
id: 35e75bad-1d89-4a65-a70f-xxxxxx
name: ldap
title: LDAP
integration_url: >-
  https://server.com/api/cloud/integrations/user-registry/147b5fb1-e88e-41e3-90e9-xxxxxx
registry_type: ldap
user_managed: false
user_registry_managed: false
external_group_mapping_enabled: true
...
url: >-
  https://server.com/api/user-registries/3d58ce7e-16a8-493b-9684-xxxxxx/35e75bad-1d89-4a65-a70f-xxxxxx
```

3. Create a role yaml file that contains the following LDAP group mapping configuration properties:

```
external_group_mapping:
  user_registry_url: https://server.com/api/user-registries/3d58ce7e-16a8-493b-9684-xxxxxx/35e75bad-1d89-4a65-a70f-xxxxxx
  ldap_groups:
    - 'cn=apic-administrators,ou=ibmggroups,o=ibm.com'
    - 'cn=apic-developers,ou=ibmggroups,o=ibm.com'
  user_group_filter_prefix: (&(uniquemember=
  user_group_filter_suffix: )(objectClass=groupOfUniqueNames))
```

Where:

- `user_registry_url` is the URL of your LDAP user registry resource from Step 2.
- `ldap_groups` is a list of the LDAP group names that you want to map to the user role.
- `user_group_filter_prefix` is the prefix for the LDAP user group.
- `user_group_filter_suffix` is the suffix for the LDAP user group.

4. Run the following command to update the user role with the `external_group_mapping` configuration properties:

```
apic roles:update role_name --scope org --org admin --server mgmt_endpoint_url mapping_properties_file
```

Where:

- `role_name` is the name of the user role that you want to add the LDAP group mapping to.

- `--scope` is the organization scope that you want the update to apply to. For this task, the value must be `org`.
- `--org admin` means that the user role is updated on the admin organization.
- `mgmt_endpoint_url` is the platform API endpoint URL.
- `mapping_properties_file` is the name of your mapping properties file from Step 3, for example `role_mapping_file.yaml`.

If you prefer to enter the configuration properties interactively on the command line, you can substitute the `mapping_properties_file` for a terminating hyphen character `-`, and enter the information manually, followed by pressing **CTRL** **D** to terminate the input.

If you want to create a custom role that includes LDAP group mapping, you can include the `external_group_mapping` configuration section in the `role_file`, and then create the new role by using the `apic roles:create` command.

For more information about the `apic roles` commands, see [apic roles](#) in the CLI reference section.

Results

The role is updated with the LDAP group mapping information. Users can now log on to the Cloud Manager, and automatically be assigned the correct access permissions for their role.

Deleting roles in the admin organization

Roles can be deleted (except for the Owner, Viewer, and Member roles) from the Admin organization. If there are members assigned to a role that has been deleted, they will be assigned the Viewer role.

About this task

All custom roles may be deleted. Pre-configured roles can also be deleted, except for the Owner, Viewer, and Member roles. Owner, viewer, and Member role cannot be deleted or edited. Members who are assigned a deleted role are given the most limited role, Viewer, with View-only privileges. These members will need to be assigned a new role if they require any other privileges.

If you are assigned a role that has the `Settings: manage` permission, you can delete roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.

One of the following roles is required to delete custom roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

Procedure

Perform the following steps to delete roles in the Admin organization:

1. In the Cloud Manager, click  Settings.
2. Select Roles.
3. Locate the Role you want to delete, and select Delete from the overflow menu.
4. Confirm that you want to proceed with deleting the role.

Results

The Role will be deleted. Members who had been assigned the role are given the Viewer role.

Viewing members and roles

Use the Members page to view the current members of the Admin organization and manage the role assignments.

Procedure

To view the members of the Admin organization and their roles in Cloud Manager, follow these steps:

1. In the Cloud Manager, click  Members.
2. From the Members list, you can scroll through the list of users to see their current roles and their status.
 - **Pending** - The invitation with the activation link has been sent to the user, but they have not yet completed the registration form.
 - **Enabled** - The user has completed the registration form and is now able to login and access the features associated with their role.

Note: If your role has the proper permissions, you can assign roles, add, and delete members from this list.

What to do next

- To add members, see [Adding members to the admin organization](#)
- To change the roles assigned to members see [Assigning roles to members](#)
- To delete a member, see [Deleting a member](#)

Adding members to the admin organization

As the Cloud Manager administrator, you can add and remove members of the Admin organization and assign roles to them. Once removed, a user can no longer access the Cloud Manager.

About this task

Membership in the Admin organization is required to use Cloud Manager to view and manage the topology of the API Connect cloud, to set up and manage provider organizations, and to manage other features of the cloud. There are two ways to add a member:

- Invite member - send an email invitation to a new user to register as a member of the Admin organization.
- Add member - specify the user and add them as a member of the Admin organization immediately.

One of the following roles is required to add members:

- Administrator
- Owner

Procedure

- To send an email invitation to a new user to register as a member of the Admin organization, complete the following steps:
 1. In the Cloud Manager, click  Members.
The list of current members for the Admin organization is displayed. You can view the owner of the Admin Organization by expanding View Owners.
 2. Click Add > Invite member.
 3. Enter a valid email address.
 4. Select the roles that you want to assign to the user.
 5. Click Invite. An email containing an activation link is sent to the email address inviting the person to register. The link opens the registration form. Alternately, you can copy and paste the activation link into an email; click Get Activation Link and click Copy in the pop up window.
Note that the email server requires the Authenticate User and Authenticate Password values in order to send invitations. See [Configuring an email server for notifications](#).

The user is placed in Pending status, and is changed to Enabled status after they complete the registration form to activate their account. They can then log in to the Cloud Manager user interface with the API Connect user name that they specified during account activation.

Note: If you use this option with a Local User Registry, and the user already exists in the registry, the user must re-activate their account by using the Sign In option, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail. This stipulation includes users that were previously members but were deleted from the admin organization.

- To specify the user and add them as a member of the Admin organization immediately, complete the following steps:
 1. In the Cloud Manager, click  Members.
The list of current members for the Admin organization is displayed. You can view the owner of the Admin Organization by expanding View Owners.
 2. Click Add > Add member.
 3. Select the required user registry
The remaining procedure varies according to the type of the selected user registry, as follows:
 - Local User Registry
 - Select whether the user is an Existing user or a New User.
 - For an existing user, complete the following steps:
 - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
 - Select the roles that you want to assign to the user, then click Add. The user is added and their membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.
 - For a new user, complete the following steps:
 - Enter a unique user name for the new user.
 - Supply an email address, name details, and a password.
 - Select the roles that you want to assign to the user, then click Add. The user account is created, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.
 - LDAP
 - Enter the name of a user that exists in the selected user registry.
 - Select the roles that you want to assign to the user, then click Add. The user is added, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface with their LDAP user name.
 - Authentication URL and OIDC
 - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
 - Select the roles that you want to assign to the user, then click Add. The user is added, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.

What to do next

The new member can log in and work in Cloud Manager. The member's authorization is defined by the roles assigned to them.

For instructions on assigning roles, see [Assigning roles to members](#). The list of roles and permissions can be viewed at [User roles and permissions in the Cloud Manager UI](#).

Assigning roles to members

As the Cloud Manager administrator, you manage the roles that are assigned to members. A member's role determines the tasks they are authorized to perform in Cloud Manager.

About this task

Members in the Admin organization use Cloud Manager to view and manage the topology of the Cloud, to set up and manage provider organizations, and to work with other features of the API Connect Cloud. The member's role determines what tasks they are authorized to perform. When assigning roles, you need to be aware that all members always have a basic set of permissions, which are contained in the **Member** role. The Member role is automatically granted to all members and cannot be removed. For this reason, you do not explicitly assign the Member role. You can grant additional permissions by selecting one or more roles. If additional roles are not assigned, then the user will have only the basic Member role.

One of the following roles is required to assign roles to members:

- Administrator
- Owner

Procedure

Perform the following steps to assign one or more roles to a member:

1. In the Cloud Manager, click  Members.
2. The list of current members for the Admin organization is displayed.
3. To change the roles assigned to a member, select the roles by marking the check boxes next to their name. The roles will be updated instantly. The list of roles and permissions can be viewed at [User roles and permissions in the Cloud Manager UI](#)

Results

The member will be assigned the permissions for the role(s).

What to do next

The new member can work in Cloud Manager. The member's authorization is defined by the roles assigned to them.

Deleting a member

As the Cloud Manager administrator, you can delete members of the API Connect cloud administration organization. Once deleted, the user and associated roles are removed, however the user's account still remains in API Connect.

About this task

One of the following roles is required to delete a member:

- Administrator
- Owner

Note: The user account of the deleted user remains in the associated API Connect user registry. The user can still log in to the Cloud Manager user interface but only information links are available; there is no access to view or manage any resources.

The user can be added again as a member at a later time; see [Adding members to the admin organization](#).

Procedure

To delete a member of the cloud administration organization, complete the following steps:

1. In the Cloud Manager, click  Members.
2. Choose Delete from the overflow menu that is adjacent to the member you want to delete.
3. Confirm the deletion.

Results

The member is deleted and removed from the Members list in Cloud Manager.

Role Defaults overview

Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

Role Defaults concepts

Role Defaults determine the base roles applied to either Provider or Consumer Organizations. The Role Defaults for the Admin organization are not configurable. Role Defaults help to standardize base roles for all organizations. Roles and permissions may be added or modified in the Role Defaults to customize the base roles as needed. Role Defaults are a "point-in-time" configuration, which effects only new organizations. You can add, delete, or modify roles (except for the Owner, Member, and Viewer roles) in the organization to customize the permissions for each organization.

Rules for editing Role Defaults:

- Edits to Role Defaults are not applied retroactively to existing organizations. Edits apply only to new organizations created after the changes are made.
- Role Defaults apply to all new organizations; roles can then be edited at the organization, catalog, and space level.
- Edits made to roles in an organization do not affect the Role Defaults. Role Defaults are the "parent" and organization roles are the "child". The child inherits from the parent, but changes do not filter up from the organization to the Role Default.
- **Managing role defaults for provider organizations**
Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.
- **Managing role defaults for consumer organizations**
Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

Related tasks

- [Managing role defaults for provider organizations](#)

- [Creating custom roles](#)

Managing role defaults for provider organizations

Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

About this task

If you are assigned a role that has permissions to manage Cloud Settings, you can create manage the Role Defaults for the provider organizations. One of the following roles is required to add roles to the role defaults:

- Administrator
- Topology Administrator
- Owner

Perform the following steps to add or edit roles to the Roles Defaults for provider organizations:

Procedure

1. In the Cloud Manager, click  Settings.
2. Select Role Defaults.
3. Click Add to add a new role.
 - a. To edit a role, select Edit from the overflow menu for the role.
 - b. To delete a role from the Role Default, select Delete from overflow menu and confirm the deletion. Owner, Member, and Viewer roles cannot be deleted.
Note: Role deletions apply to new members added after the deletion. If a current member is assigned the role, they will continue to have the permissions connected with the role. You need to manage the deletions for each member in the Members screen.
4. Enter the Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see [User roles and permissions in the Cloud Manager UI](#).
6. Save the role.

Results

The role appears in the list of roles for the provider organization Role Defaults. It will be included in the roles that can be assigned to members for all new provider organizations. The roles can be edited for individual organizations.

Related concepts

- [Role Defaults overview](#)

Related tasks

Managing role defaults for consumer organizations

Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

About this task

If you are assigned a role that has permissions to manage Cloud Settings, you can create and manage the Role Defaults for consumer organizations. One of the following roles is required to add roles to the role defaults:

- Administrator
- Topology Administrator
- Owner

Perform the following steps to add or edit roles to the roles defaults for consumer organization:

Procedure

1. In the Cloud Manager, click  Settings.
2. Select Role Defaults.
3. Click Add to add a new role.
 - a. To edit a role, select Edit from the overflow menu for the role.
 - b. To delete a role from the Role Default, select Delete from overflow menu and confirm the deletion. Owner, Member, and Viewer roles cannot be deleted.
Note: Role deletions apply to new members added after the deletion. If a current member is assigned the role, they will continue to have the permissions connected with the role. You need to manage the deletions for each member in the Members screen.
4. Enter the Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see [User roles and permissions in the Cloud Manager UI](#).
6. Save the role.

Results

The role appears in the list of roles for the consumer organization Role Defaults. It will be included in the roles that can be assigned to members for new consumer organizations. The roles can be edited for catalogs, but permissions inherited from the Role Default cannot be deleted. Permissions can be added at the catalog level, but not deleted.

Monitoring the cloud

API Connect generates events to monitor the status of your cloud.

About this task

You can monitor your API Connect cloud and configure destination targets for your analytics data by using the following tasks:

- [Accessing and configuring analytics](#)
Monitor the usage and performance of API calls by using the analytics feature to view, filter, sort, and aggregate your API event data.
- [Configuring audit logging to monitor user operations](#)
Configure auditing in IBM API Connect to monitor user operations such as who published which product and when.
- [Reviewing a gateway's processing status](#)
Review the processing status for the Gateway services that are enabled in your API Connect Catalogs and Spaces.

Accessing and configuring analytics

Monitor the usage and performance of API calls by using the analytics feature to view, filter, sort, and aggregate your API event data.

Use the API Connect Analytics service to monitor API usage and performance. API analytics provide data to help you manage service levels, set quotas, establish controls, set up security policies, manage communities, and analyze trends. The data for Analytics is collated from API events that are logged when API operations are invoked on your gateways. The captured event data can be viewed and exported from the Cloud Manager UI, API Manager UI, toolkit CLI or REST API. The API event data can also be offloaded to third-party systems as it is generated.

API event records

An API event is logged each time an API operation is invoked on the Gateway server. The API event record contains information about the API call. When an analytics service is associated with a gateway, all API invocations on that gateway are captured as API event records and sent to the analytics service. The content of the record depends on the logging policy that is set for the operation. For more information about the fields that are displayed in an API event record, see [API event record fields](#).

Analytics configuration options

API Connect offers several configuration options to customize data collection, storage, and retention. For example, you can define filters that refine data to add or remove fields before they are stored. You can choose to offload some, or all, of the data to a third-party storage system. You can choose whether to store any Analytics data in API Connect. Some options are configured during installation, while other options are easily changed after your Analytics subsystem is in service.

- [Counting total API calls for your Analytics service](#)
Count the API calls for the IBM® API Connect Analytics subsystem and see the total categorized by response status.
- [Viewing API event data in API Connect](#)
The gateway generates API event data for every API invocation and forwards this data to its associated analytics service. The captured event data can be viewed in the Cloud Manager UI, API Manager UI, from the toolkit CLI/REST API, or offloaded to third-party systems.
- [Including geoIP fields in analytics data](#)
Configure analytics settings to include geoIP fields in the data.
- [Configuring data retention and index rollover time periods](#)
You can set a time period for data retention and index rollover.
- [Configuring the Logstash persistent queue](#)
The Logstash persistent queue is embedded in the data ingestion pipeline. It ensures that data collection continues in the event of a failure.
- [Offloading analytics to third-party systems](#)
The event data that is generated and collected in your API Connect on-premises deployment can optionally be forwarded to external third-party systems for storage and analysis.
- [Applying filters to incoming analytics data](#)
Update your analytics configuration to apply filters to incoming data. You can add, modify, and remove API event record contents before they are saved.

Counting total API calls for your Analytics service

Count the API calls for the IBM® API Connect Analytics subsystem and see the total categorized by response status.

Note: If your IBM API Connect bases costs on usage, you can use the following methods to track this information so that you can accurately report it. If your organization did not deploy the Analytics subsystem, then this feature is not available. If you deployed Analytics but offload your data and do not store it in IBM API Connect, then you must capture usage information from the third-party application where you offload data.

You can see the total API calls over time for each analytics service in the consumption dashboard. To see the consumption dashboard, navigate to the Cloud Manager UI analytics view: [Cloud Manager analytics view](#).

Alternatively, the analytics CLI can be used to get your API count: [Using the Analytics CLI](#).

1. Use the following CLI command to retrieve a count of all Analytics events recorded by the Analytics service:

```
apic -m analytics events:cloudCount --server <management server platform api endpoint> --analytics-service <analytics service name> --format json
```

- *<management server platform api endpoint>* is the Management server platform api endpoint.
- *<analytics service name>* is the name of Analytics service as configured in the Cloud Manager.

2. If required, additional filters can be applied to the results. For example, `--timeframe last12hours`. See the `help` output from: `apic -m analytics events:cloudCount -h` for more details.

Viewing API event data in API Connect

The gateway generates API event data for every API invocation and forwards this data to its associated analytics service. The captured event data can be viewed in the Cloud Manager UI, API Manager UI, from the toolkit CLI/REST API, or offloaded to third-party systems.

You can view API event data within API Connect in the following ways:

- The Analytics view of the Cloud Manager UI, which is accessed by clicking  in the navigation pane. API event data across all organizations, catalogs, and spaces is presented on *dashboards*. Each dashboard contains a set of related *visualizations* that depict analytics data as a graphical or metric representation, see [Cloud Manager analytics view](#)
- The Analytics view of the API Manager UI, which is accessed by clicking `Manage > Catalog_name > Analytics`. Analytics data for each Catalog or Space is collected into *dashboards*. Each dashboard contains a set of related *visualizations* that depict analytics data as a graphical or metric representation. Dashboards are provided for viewing analytics data for APIs, Plans, Products, Catalogs and Spaces. For more information about accessing and working with the API event data shown in API, Plan, and Product dashboards, see [Managing your Products](#).
- By using the debug function for the integrated test tool that is provided in the API Manager user interface. The debug function is typically used to view information about the API configuration in order to identify possible causes for an API invocation failure.
- Using the toolkit CLI or REST API: [Using the analytics toolkit CLI](#)

API consumers who are members of a consumer organization can also view analytics data within dashboard views in the Developer Portal user interface. The dashboard views depict API invocation metrics about the APIs used either by a single application or within the entire consumer organization. For more information about accessing the analytics data for APIs that are invoked by developer applications, see [Analytics in the Developer Portal](#).

- [Cloud Manager analytics view](#)
How to view your analytics event data in the Cloud Manager user interface.

Cloud Manager analytics view

How to view your analytics event data in the Cloud Manager user interface.

API events from all catalogs, spaces, and organizations are captured and displayed together in the Cloud Manager analytics view. To view only analytics data for specific provider organizations, catalogs and spaces use the API Manager user interface [API Manager](#).

To access the analytics view click  in the navigation pane:

If you have multiple analytics services, use the drop-down at the upper right to select the analytics service whose API event data you want to view.

Discover view

By default the Dashboards tab is displayed. To view your API event data in tabular form, select Discover:

Analytics

The maximum number of API events that can be accessed from the UI is 10,000. The maximum number of event records that can be displayed per page on the Discover view is 200.

You can export the API event data from this view by clicking Actions at the upper right:

Note: When you export from the Discover view, only the data displayed on the current page of results is exported. If you want to export the data from all pages, you must export separately from each page. To export all your analytics data, do not use the UI, see [Exporting API event data](#).

Dashboards view

Seven dashboards are available:

- API Dashboard- contains charts that summarize total API calls, response codes, and response times.

- Product Dashboard - contains charts that show total API calls and application subscriptions per plan.
- Monitoring Latency Dashboard - contains charts that provide response time statistics and data usage.
- Monitoring Status Dashboard - contains charts that show the response codes and success/failure rates of API calls.
- Usage Dashboard - contains charts that show the main five APIs, products, and apps.
- Consumption Dashboard - contains charts that show total API consumption in your cloud.
- Gateway Operations Dashboard - contains charts that show API usage and latency by gateway.

Each chart in the dashboards can be exported as a PNG or JPG image. The source data for each chart can be exported as a JSON or CSV file. To export a chart, click Actions :

It is also possible to enlarge the chart to full-screen by clicking  . To see the source data in tabular form click  .

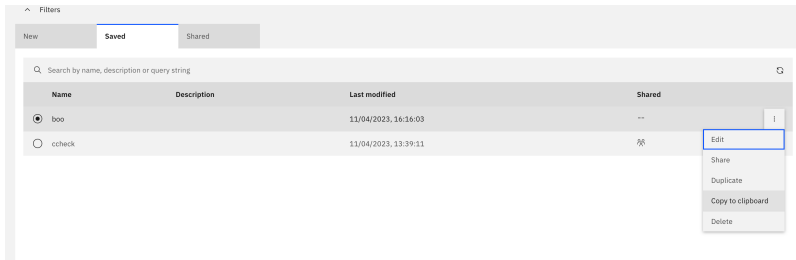

Filtering displayed data

You can filter the data that is displayed in the Dashboards and Discover view by defining queries. Expand the Filters section to view, define, and apply analytics queries to your displayed data:

You can save and share the queries that you define:

- Shared queries are visible to all users at the same scope. They are not visible to users in a different scope. For example, a query that is shared by a Cloud Manager UI user is not visible to an API Manager UI user. Within the API Manager UI, a query that is created at catalog scope is not visible to users viewing analytics data at provider organization scope.
- Other users cannot edit or delete queries that you share, but they can create a duplicate query, which they can edit and share.
- All queries have a name and an optional description. The name does not need to be unique.

Saved queries can be exported as strings for use in REST API and toolkit CLI queries, for example:

copies the following string to the clipboard:

```
api_name>equals:boo&timeframe=last30days
```

Including geoIP fields in analytics data

Configure analytics settings to include geoIP fields in the data.

About this task

By default, the `client_geoip` and `gateway_geoip` fields are not included in analytics data.

Configure the fields to include in your analytics data while deploying the analytics subsystem. For information on including the geoIP fields in analytics data, see the appropriate topic for your environment:

Note: The geoIP feature is useful with internet routable IP addresses only. For instance, `192.168.x.x` and `10.x.x.x` IP addresses, being internal private IP addresses, cannot be resolved to a geographical location.

- Kubernetes: [Configure analytics to include geoIP fields.](#)
- OpenShift: [Configure analytics to include geoIP fields.](#)
- VMware: [Configure analytics to include geoIP fields.](#)

Configuring data retention and index rollover time periods

You can set a time period for data retention and index rollover.

About this task

Each API event is recorded as a document in a shared index. When this index reaches a maximum size or age it is archived, and a new index is created for recording new API events. This is known as index rollover. When an archived index reaches a maximum age, which is known as the data retention maximum, it is deleted. You can specify index rollover and data retention settings that control how often new indexes are created, and how long archived indexes are stored.

The index rollover settings determine how long an index accumulates data before it "rolls over" and a new index is created. You can control the duration of an index two ways: by setting a maximum age for the index (default is 1 day), and by setting a maximum number of documents that can be recorded in the index (default is 25 million documents). When the rollover occurs, a new index is created and new API events are recorded there, while the previous index is archived and kept until its age exceeds the data retention settings. If you change the rollover settings, consider both the amount of data to be stored within each index and the total number of indexes. Allowing indexes to grow too large, or storing too many indexes, can cause performance problems.

The data retention setting determines how long the stored indexes are retained. When an index's creation date exceeds the retention period, that index and all its data is deleted, even if some of the data that is stored in that index is younger than the retention period.

The default retention period is 30 days for a one replica deployment, and 90 days for a three replica deployment. Reasons for changing this setting include storage constraints, and data retention requirements for your organization. You might want to set this value to be less than the default if many API events are stored, especially if payload logging is enabled on the APIs.

The most recently created index (the index that is currently being written to) is not deleted, even if you set the retention period as small as 1 hour. If you regularly need to delete data quickly, adjust the Index Rollover setting so that a new index is rolled over to sooner, and the old index can be deleted.

Note: The rollover and retention settings have a significant impact on the memory that is required by the analytics subsystem. If you have rollover set to one day (1d), then to maintain an acceptable level of performance the following retention settings are recommended for each deployment profile:

- **n1xc2.m16:** This profile provides 3 GB of heap memory for storage on one node. Recommended retention is four days or less.
- **n1xc4.m32:** This profile provides 11 GB of heap memory for storage on one node. Recommended retention is 15 days or less.
- **n1xc6.m48:** This profile provides 19 GB of heap memory for storage on one node. Recommended retention is 25 days or less.
- **n3xc4.m16:** This profile provides 3 GB of heap memory for storage on three nodes. Recommended retention is 12 days or less.
- **n3xc4.m32:** This profile provides 11 GB of heap memory for storage on three nodes. Recommended retention is 45 days or less.
- **n3xc6.m48:** This profile provides 19 GB of heap memory for storage on three nodes. Recommended retention is 76 days or less.
- **n3xc8.m64:** This profile provides 27 GB of heap memory for storage on three nodes. Recommended retention is 108 days or less.

If rollover is set to higher than one day, then more analytics data can be stored before a performance deterioration is observed. However, a higher rollover setting has the disadvantage that more data is deleted when an index reaches the retention age. For example, if you set your rollover period to seven days and you have the default 90-day retention period, then when your oldest index reaches the 90 days since it was created, it is deleted and you lose your first seven days of event data.

To view and update the rollover and retention settings, from v10.0.5.3 you can use the Cloud Manager UI. For previous releases, use the toolkit CLI.

Procedure

1. From the Cloud Manager UI, click  Topology.
2. Select the Analytics Service you want to view or edit.
3. Click Advanced settings.
4. Modify your rollover and retention settings as required and click Save.

v10.0.5.2 and previous releases: Use the toolkit CLI.

5. View the current retention and rollover settings by using the `clustermgmt:getStorageSettings` analytics CLI command:

```
apic -m analytics clustermgmt:getStorageSettings --server [SERVER] --analytics-service [ANALYTICS SERVICE] --format json
```

- `<management server platform api endpoint>` is the Management server platform api endpoint.
- `<analytics service name>` is the name of Analytics service as configured in the Cloud Manager.

Example output:

```
{
  "rollover": {
    "min_doc_count": 25000000,
    "min_index_age": "1d"
  },
  "retention": {
    "min_index_age": "30d"
  }
}
```

"min_" refers to the minimum age or number of documents that are reached before the action takes place.

6. To update the retention and rollover settings create a JSON file that is called `retention_and_rollover_settings.json`, paste in the output from step 5 and set the retention and rollover setting as required. Apply these new settings with: `clustermgmt:putStorageSettings`

```
apic -m analytics clustermgmt:putStorageSettings --server [SERVER] --analytics-service [ANALYTICS SERVICE]
retention_and_rollover_settings.json
```

- `<management server platform api endpoint>` is the Management server platform api endpoint.
- `<analytics service name>` is the name of Analytics service as configured in the Cloud Manager.

If the retention or rollover process fails, the Cloud Manager and API Manager UIs show the following error message:

Error: Analytics internal storage rollover might be experiencing problems. Contact your system administrator to investigate further. Rollover failure means that data retention is not correctly enforced and storage usage continues to grow which can eventually lead to service shutdown.

If you see this error, then open a support case.

Configuring the Logstash persistent queue

The Logstash persistent queue is embedded in the data ingestion pipeline. It ensures that data collection continues in the event of a failure.

To enable and configure the persistent queue, see:

- [Kubernetes - Analytics persistent queue](#)
- [OpenShift - Analytics persistent queue](#)

After making changes to these settings the ingestion pod will restart.

Offloading analytics to third-party systems

The event data that is generated and collected in your API Connect on-premises deployment can optionally be forwarded to external third-party systems for storage and analysis.

About this task

API Connect supports the offload of API analytics data to the following third-party systems: HTTP, Elasticsearch v7, Apache Kafka, OpenSearch, and Syslog. You can configure a custom certificate for connecting to the third-party target and define filters to refine data that will be stored.

You typically configure data offloading while deploying the Analytics subsystem, but this configuration can be changed after installation, and involves updating the analytics custom resource and a restart of the ingestion pod.

- [Kubernetes - Offloading data to a third-party system](#)
- [OpenShift - Offloading data to a third-party system](#)
- [VMware - Offloading data to a third-party system](#)
- [Troubleshooting your analytics offload](#)
Review information on common issues with offloading Analytics data.

Troubleshooting your analytics offload

Review information on common issues with offloading Analytics data.

If you determine that your third-party system is not receiving analytics data, you can complete some checks to help determine the cause and resolve the problem. For information on troubleshooting data offload, see the appropriate topic for your environment:

- Kubernetes, OpenShift, and Cloud Pak for Integration: [Troubleshooting your Analytics offload](#)

Applying filters to incoming analytics data

Update your analytics configuration to apply filters to incoming data. You can add, modify, and remove API event record contents before they are saved.

To create and update filters, see:

- [Kubernetes - Modifying incoming analytics data](#).
- [OpenShift - Modifying incoming analytics data](#).

If you want to modify the data for specific APIs rather than all incoming data, you can use gateway scripts or the `set-variable` policy, as described here: [Modifying analytics API event data](#).

Configuring audit logging to monitor user operations

Configure auditing in IBM® API Connect to monitor user operations such as who published which product and when.

Audit logging is useful when you want to monitor the create, read, update, delete, log-in, and log-out activity in your deployment; for example, who made changes, when, and what they changed.

Note: Actions performed by [Portal administrators](#) are not captured by the audit feature.

What events are audited?

All create, update, delete, log-in, and log-out operations that are performed by users in the Admin UI, Manager UI, Toolkit, and REST API are captured by this feature. For Portal users, all create, update, and delete operations involving applications are captured.

Beginning in API Connect 10.0.5.3, read operations can also be audited when the `audit_reads` setting is additionally enabled (using the toolkit CLI).

Attention: If you choose to enable auditing of read operations for an HTTP endpoint, be aware of that the response might return large payloads, and might contain sensitive information.

Internal calls and calls between system components are not audited because they are part of the product functionality and are not executed by users.

How are audit events logged?

Audit events are logged by sending the information about operations to one or more endpoints of the following types: HTTP, Syslog UDP, Syslog TCP, or Syslog TLS.

- HTTP endpoints:
Audit logging messages are sent as HTTP/HTTPS requests and use the payload format defined by the Cloud Auditing Data Federation (CADF). If the endpoint requires authentication, you can configure a header that will be included in the audit logging request. Audit logging requests are issued once only, on the assumption that every endpoint is available to receive the requests. There is no error checking to ensure that requests are received and stored by the endpoints, and failed requests are not re-sent. If you suspect that audit logging requests are not successfully reaching an endpoint, you can check the server logs on the console, where any error messages are recorded.

There are two modes that control how the auditing is sent to an endpoint: blocking and non-blocking. In non-blocking mode (the default), an audit event is sent to the endpoint and the system does not wait for a response from the endpoint. Non-blocking mode provides the best performance. Blocking mode should be used with caution: when an audit event is sent, the system pauses and waits for a response from the endpoint. Blocking mode has a negative impact on performance.

- Syslog endpoints:
Audit logging messages are sent as syslog messages. If the endpoint requires mutual TLS, you can configure a TLS profile to send the required client certificates. Audit logging requests are issued once only, on the assumption that every endpoint is available to receive the requests. There is no error checking to ensure that requests are received and stored by the endpoints, and failed requests are not re-sent. If you suspect that audit logging requests are not successfully reaching an endpoint, you can check the server logs on the console, where any error messages are recorded.

All syslog messages are sent as non-blocking regardless of the auditing mode, since syslog messages are designed to be fire and forget (syslog was originally a UDP protocol, which by its nature does not have any acknowledgment). Blocking is only used for HTTP endpoints.

Note: With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.

What's included in the audit logging request?

- HTTP endpoints:
The payload containing the audit logging record includes information about the user who executed the operation, the date and time of the call, the resource affected by the call, the operation performed, and the payload. If you enabled audit logging for read operations, the payload might also contain the properties from the response (based on your configuration settings).

To see the most recent set of fields that are included in the payload, refer to the OpenAPI schema for the audit logging request in the Provider API, which you can download at https://us-south.functions.cloud.ibm.com/api/v1/web/API%20Connect%20Native_apic-on-prem/default/v10-index.http.

HTTP Example 2: sample of the `responseData` part of the message payload for a read operation (`GET /orgs`) with `list_results_limit=3`:

```

responseData:
  results_read:6
  total_results:6
  results:
    [0]:{ summary: "Administers the admin organization", org_url: "https://localhost:3003/api/orgs/18361c4c-54a2-41b2-9ff1-79f72832d405", updated_at: "2023-04-03T10:03:53.000Z", scope: "org", name: "administrator", created_at: "2023-04-03T10:03:53.000Z", id: "e42e304e-a335-4df0-876d-682cd8a36725", type: "role", title: "Administrator", api_version: "2.0.0", url: "https://localhost:3003/api/orgs/18361c4c-54a2-41b2-9ff1-79f72832d405/roles/e42e304e-a335-4df0-876d-682cd8a36725", permission_urls: [<cut>] }
    [1]:{ summary: "Minimum role", org_url: "https://localhost:3003/api/orgs/18361c4c-54a2-41b2-9ff1-79f72832d405", updated_at: "2023-04-03T10:03:53.000Z", scope: "org", name: "member", created_at: "2023-04-03T10:03:53.000Z", id: "d415fcd9-7e22-4522-af15-c62d3094599a", type: "role", title: "Member", api_version: "2.0.0", url: "https://localhost:3003/api/orgs/18361c4c-54a2-41b2-9ff1-79f72832d405/roles/d415fcd9-7e22-4522-af15-c62d3094599a", permission_urls: [<cut>] }
    [2]:{ summary: "Manages API provider organizations", org_url: "https://localhost:3003/api/orgs/18361c4c-54a2-41b2-9ff1-79f72832d405", updated_at: "2023-04-03T10:03:53.000Z", scope: "org", name: "organization-manager", created_at: "2023-04-03T10:03:53.000Z", id: "4c51446d-417d-4c4a-albe-083ecc699c2c", type: "role", title: "Organization Manager", api_version: "2.0.0", url: "https://localhost:3003/api/orgs/18361c4c-54a2-41b2-9ff1-79f72832d405/roles/4c51446d-417d-4c4a-albe-083ecc699c2c", permission_urls: [<cut>] }

```

- Syslog endpoints:

The nature of syslog messaging means that the information logged is less structured and shorter than information logged using structured HTTP endpoints. With syslog, the information is more of a summary.

The following sample response shows payloads for an audit logging message directed to a syslog endpoint (IDs and users are not real):

```
The user admin:default-idp-1/admin has deleted the resource Org 'alpha (Alpha title)', id 19cf81c7-7cb3-43de-b5e5-d92cdfb26214 and url https://localhost:3003/api/orgs/19cf81c7-7cb3-43de-b5e5-d92cdfb26214
The user admin:default-idp-1/admin has deleted the resource Gateway Service 'webhook-gw-v5 (Webhook Gateway Service (v5) title)', id 08b87e25-616d-451e-8766-bad1c7b82a42 and url https://localhost:3003/api/orgs/69c878db-4f11-4c3e-9499-10daa25f04de/availability-zones/cb2caa3d-d619-4c2e-85f8-709956495a7b/gateway-services/08b87e25-616d-451e-8766-bad1c7b82a42
The user provider:default-idp-2/steve@example.com has created the resource Catalog 'climbon:1.0.1 (The climbon product description)', id 665036df-28ad-447e-b8de-fe9d6967b66d and url https://localhost:3003/api/catalogs/19cf81c7-7cb3-43de-b5e5-d92cdfb26214/8641fda7-43f8-4e59-b405-58a4844016c9/products/665036df-28ad-447e-b8de-fe9d6967b66d
The user admin:default-idp-1/admin has read the resource Cloud Setting 'cloud-setting', id settings and url https://localhost:3003/api/cloud/settings
```

Verifying that the endpoint is receiving audit logging messages

By default, auditing operates in `non_block` mode to ensure best performance. In `non_block` mode, each audit logging message is sent immediately without waiting to ensure that the previous message was received. If you suspect that audit logging messages are not being received by the endpoint, download the server logs from the Kubernetes console and examine the `apim` microservices file for messages related to the connection state. Review the messages to validate that the connection was successful or to further diagnose issues.

For HTTP endpoints (not available for Syslog endpoints), you can test the connection by issuing a "test-connection" call using either the toolkit or a REST API. A response status of `204` indicates that the call was successful and the endpoint is available. The following example contains the payload from a connection test (IDs and users are not real):

```
{
  "id": "8d8eaaa2-1b46-4dcb-cadf-639d7d1f7f20",
  "typeURI": "http://schemas.dmtf.org/cloud/audit/1.0/event",

      },
      "registration": {
        "url": "/api/cloud/registrations/734c04f7-0fe2-3ffa-b745-81027a3b8c76",
        "type": "toolkit"
      }
    }
  ]
}
```

Tip: To ensure that audit logging messages are not lost due to an unavailable endpoint, verify each endpoint periodically.

- [Configuring the audit settings](#)
Use the Cloud Manager UI or the toolkit CLI to enable auditing and configure settings.

Configuring the audit settings

Use the Cloud Manager UI or the toolkit CLI to enable auditing and configure settings.

About this task

The audit feature tracks platform-level changes in API Connect through the use of platform APIs, CLI, and Web UI. For information on tracking run-time API execution, see [API Analytics](#).

You can configure audit settings using either the Cloud Manager UI, or the [Toolkit CLI](#).

Using the Cloud Manager UI to configure audit settings

Use the Cloud Manager user interface to enable auditing of customer API calls.

Before you begin

Configure one or more audit endpoints where logging data can be directed, and validate that every endpoint is available by testing the connection as explained in [Configuring audit logging to monitor user operations](#).

About this task

By default, auditing is disabled. If you enable auditing, the API Connect management node emits audit events as messages and sends them to the endpoint for storage.

Note: Auditing for read operations can only be enabled and configured [using the CLI](#).

Procedure

1. In the Cloud Manager, click  Settings > Audit Setting > Edit.
2. Click Enable to enable the audit feature, or Disable to disable it.
3. Select an audit mode:
 - Non-blocking - Default value, offers the best performance. Each request is passed immediately without waiting for a response to the previous request. This is susceptible to errors if a request is dependent on the results of an earlier request whose response is not received before the new request is sent.
 - Blocking - If you select this mode, expect a degradation in performance. Each request is allowed to finish execution before the next request is sent. This mode results in fewer errors when requests are dependent on the responses of earlier operations, but the delayed requests slow the network.

Note: Blocking mode is only applied to HTTP endpoints and is ignored for Syslog endpoints.
4. Click Add and select the type of endpoint that you want to add (you must add at least one endpoint). Endpoints can be of the following types: HTTP, Syslog UDP, Syslog TCP, or Syslog TLS.
5. In the Endpoints section, fill in the fields to describe the new endpoint:

HTTP

- URL - Required, must not be empty. The URL of the server where audit logging messages will be sent. If you previously saved the audit settings with an empty URL and experienced problems, you can edit the URL to correct it.
- TLS client profile - Optional. The URL of the server where the endpoint's TLS client profile is stored.
- Header name and Header value - Optional. Multiple headers are allowed (click Add to add another header). For each header, specify the header name and the header value.

Syslog UDP

- Host name - Required, must not be empty. The host name of the server where audit logging messages will be sent; for example: www.example.com. Do not include the `syslog://` protocol with the host name. When audit logging messages are directed to the host server, the protocol is added to the host name programmatically.

- Port - Optional. The port number where audit logging messages should be directed.

Syslog TCP

- Host name - Required, must not be empty. The host name of the server where audit logging messages will be sent; for example: www.example.com. Do not include the `syslog://` protocol with the host name. When audit logging messages are directed to the host server, the protocol is added to the host name programmatically.

- Port - Optional. The port number where audit logging messages should be directed.

Syslog TLS

- Host name - Required, must not be empty. The host name of the server where audit logging messages will be sent; for example: www.example.com. Do not include the `syslog://` protocol with the host name. When audit logging messages are directed to the host server, the protocol is added to the host name programmatically.

- Port - Optional. The port number where audit logging messages should be directed.
- TLS client profile - Optional. The URL of the server where the endpoint's TLS client profile is stored.

6. Verify that you can reach the endpoint by clicking Test.
7. To specify another endpoint, click Add at the beginning of the "Endpoints" section.
8. When you finish adding endpoints, click Save to save your settings.

Results

With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.

What to do next

If you suspect that audit logging messages are not being received by the endpoint, see [Verifying that the endpoint is receiving audit logging messages](#) for information on validating the connection.

Using the CLI to configure audit settings

Use the IBM API Connect toolkit CLI to enable auditing of API calls.

Before you begin

Configure one or more audit endpoints where logging data can be directed, and validate that every endpoint is available by testing the connection as explained in [Configuring audit logging to monitor user operations](#).

About this task

By default, auditing is disabled. If you enable auditing, the API Connect management node emits audit events as messages and sends them to the endpoint for storage.

Use the following `audit_setting` options to enable auditing with the CLI toolkit:

- **enable** - Boolean, defaults to `false` (no audit). Set to `true` if you want to enable auditing.
- **mode** - Enumerated, defaults to `non_block`. The audit mode determines how audit requests are timed when they are sent to the endpoint:
 - `non_block` - Default value, offers the best performance. Each request is passed immediately without waiting for a response to the previous request. This is susceptible to errors if a request is dependent on the results of an earlier request whose response is not received before the new request is sent.
 - `block` - If you select this mode, expect a degradation in performance. Each request is allowed to finish execution before the next request is sent. This mode results in fewer errors when requests are dependent on the responses of earlier operations, but the delayed requests slow the network.
Note: Block mode is only applied to HTTP endpoints and is ignored for Syslog endpoints.
- **audit_reads** - Use this setting to enable auditing of read operations:
 - **enable** - Boolean, defaults to `false` and no audit events are sent to the endpoint for read operations. Set to `true` if you want to enable audit logging for read operations.
 - **response_data_to_http_endpoints** - Configure additional settings for HTTP endpoints only (the settings do not apply to Syslog endpoints).
 - **enable** - Boolean, defaults to `false` and audit events for GET operations are sent to the HTTP endpoint with no response data in the event. Set to `true` if you want to include the response data.
Attention: If you choose to include the response data, be aware that the response might return large payloads, and might contain sensitive information.
 - **list_results_limit** - Integer, must be 0 or larger. Use this setting to specify the maximum number of results of `GET list` operations to include in the audit message (default is 0 results).

If `audit_reads` is enabled, then the audit message for a `GET` of a *single object* (for example, `GET /orgs/admin`) always includes all of the properties of the response object.

If the `list_results_limit` is set to 0, then the audit message for a `GET` to *list objects* (for example, `GET /orgs`) does not include any objects from the GET response. If you set the `list_results_limit` to a value greater than 0, then the audit message includes all properties from the first `list_results_limit` number of objects from the `GET /orgs` response.
- **endpoints** - Array of strings. You must specify at least one endpoint where the audit logging messages are sent. Endpoints can be of the following types: HTTP, Syslog UDP, Syslog TCP, or Syslog TLS.
For HTTP and Syslog TLS endpoints, you can optionally include a TLS client profile URL. For HTTP endpoints, you can additionally include one or more optional headers. For example, if the endpoint requires an authorization header, you can include it in the endpoint setting.
 - **endpoint_type** - String. Required. Allowed values are: `http`, `syslog_udp`, `syslog_tcp` or `syslog_tls`.
 - **endpoint** - String. Required, must not be empty or blank. The URL of the server where audit logging messages will be sent. Include the protocol (`http://` or `syslog://`) and the port, if applicable. For example, `syslog://<hostname>:<port>`.
 - **tls_client_profile_url** - String. Optional; supported only for HTTP and Syslog TLS endpoints. The URL of the server where the endpoint's TLS client profile is stored.
 - **headers** - String. Optional; supported only for HTTP endpoints. Multiple headers are allowed. For each header, specify the header name and the header value using the format shown in the example.

The list of audit properties can be lengthy, so uploading the settings in a file helps to avoid errors. Format the settings as a `.yaml` file (you can choose the file name) and upload the file using the toolkit CLI. The following example enables auditing in non-blocking mode with multiple endpoints to demonstrate how the settings should be formatted.

```
audit_setting:
  enabled: true
  mode: non_block
  audit_reads:
    enabled: true
    response_data_to_http_endpoints:
      enabled: true
      list_results_limit: 0
  endpoints:
  - endpoint_type: syslog_udp
    endpoint:
      endpoint: syslog://syslog-audit-endpoint.example_1.com:514
  - endpoint_type: syslog_tls
    endpoint:
      endpoint: syslog://syslog-tls-audit-endpoint.example_1.com:1601
      tls_client_profile_url: https://security.tls_example.com/api/orgs/d8eac736-b4e2-3aa6-c7ff-978a4cd19d0b/tls-client-
profiles/19d0f087-b4e2-3aa6-926b-9f6d51d028c3
  - endpoint_type: http
    endpoint:
      endpoint: https://mutt-audit-endpoint.example_1.com/auditing
  - endpoint_type: http
    endpoint:
      endpoint: https://auditing-endpoint.example_1.com/inputs/64e38c02-acd9-6530-76f8-dd0f336d7b11
      tls_client_profile_url: https://security.tls_example.com/api/orgs/d8eac736-b4e2-3aa6-c7ff-978a4cd19d0b/tls-client-
profiles/19d0f087-b4e2-3aa6-926b-9f6d51d028c3
    headers:
      authorization: Basic c3Bvb246c2l1b25rYXRpZXVtYQ==
  - endpoint_type: http
    endpoint:
      endpoint: https://auditing-endpoint.example_2.com/inputs/64e38c02-acd9-6530-76f8-dd0f336d7b11
```

```
headers:
  authorization: Basic c3Bvb246c2ltb24=
  x-header: ForYourEyeOnly
```

Procedure

1. Create a YAML file with the audit settings as shown in the example.
For information on using input files with the toolkit CLI, see [Reading input from the command line](#).
2. Run the following command to log in to a management server as a member of the cloud administration organization:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

Cloud settings are stored on a management server and you must log in to the server before you can access the settings with the CLI.

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
- title: Cloud Manager User Registry
  realm: admin/default-idp-1
- title: Corporate LDAP user registry
  realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`. For more information on logging in, see [Logging in to a management server](#).

3. Upload the YAML file with the auditing settings by running the following command:

```
apic cloud-settings:update --server mgmt_endpoint_url my_audit_settings.yaml
```

4. Run the following command to log out of the management server:

```
apic logout --server mgmt_endpoint_url
```

Results

With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.

What to do next

If you suspect that audit logging messages are not being received by the endpoint, see [Verifying that the endpoint is receiving audit logging messages](#) for information on validating the connection.

Reviewing a gateway's processing status

Review the processing status for the Gateway services that are enabled in your API Connect Catalogs and Spaces.

About this task

Sometimes you might want to check the status of an API event that is being processed by the gateway. For example, you might want to ensure that a Product was published before and is available on the gateway before you invoke one of its APIs. Or perhaps it appears that API events are being processed too slowly and you want to see if all of the events for a particular gateway service are affected.

You can review a gateway's processing status in the API Manager user interface, or by [using the toolkit CLI](#) to retrieve the information.

Notes:

- You can only obtain processing status information for the DataPower® API Gateway. This feature is not supported for the DataPower Gateway (v5 compatible) service.
- Processing information is collected for each Catalog. If you view information for a particular Space, the display shows the results for the entire Catalog instead.

You can view the gateway processing status using the [UI](#) or the [CLI](#).

Using the UI to view the gateway processing status

About this task

Use the API Manager user interface to view the processing status for all of the gateway services associated with a particular Catalog or Space.

Procedure

1. Open the Gateway services page:
 - a. Log in to API Manager.

- b. In the navigation pane, click  Manage.
- c. Select a Catalog.
- d. Click the Catalog settings tab.
- e. On the Settings page, click Gateway services.

A list of all of the gateway services for the selected Catalog, including all of its Spaces, displays the gateway type and its endpoint URL. In addition, a status icon displays for each service name to provide a quick indication of that service's current status:

-  Normal: Between 0 and 10 events are waiting to be processed
-  Increased: Between 10 and 20 events are waiting to be processed
-  High: More than 20 events are waiting to be processed

You can view details about a service's status to gain insight into possible issues.

2. On the Gateway services page, click  next to a service and select View gateway processing status.

The Gateway processing status page displays a list of the events that were sent to the gateway. For each event, you can see the following information:

- Event type: The action performed by the event; for example, subscribing to a product, deleting an application, or creating a new consumer organization.
- Category: The feature area affected by the event; for example, subscriptions, applications, or consumer organizations.
- Time: The time when the event was processed by the gateway service.
- Status: The current event's processing status; for example, Queued (not yet sent for processing), Sent (but not processed yet), or Processed (complete).
The number of events in the Queued and Sent states determine the status level for the service.

The display includes events that were not processed yet, as well as the last event processed. If a particular event is not listed as Sent or Queued, then that event was already processed.

Using the CLI to obtain a gateway's processing status

About this task

You can use the developer toolkit CLI to obtain information about the processing status for the Gateway services that are enabled in your Catalogs and Spaces.

The processing status information is returned in the following fields:

Field	Description
<code>service_up_to_date</code>	If <code>true</code> then all outstanding events have been processed by the Gateway service.
<code>service_state</code>	An overall status summary of the various states of events and processing by the Gateway service: <ul style="list-style-type: none"> • green indicates normal status with between 0 and 10 events waiting to be processed • orange indicates that between 10 and 20 events are waiting to be processed • red indicates that more than 20 events are waiting to be processed
<code>last_processed_event</code>	Details of the last event that was processed by the Gateway service, helping to provide a timeline of when the last event was processed, and some statistics about how long ago it was and how long the processing took.
<code>last_sent_event</code>	Details of the last event that was sent to the gateway service
<code>number_of_outstanding_sent_events</code>	The number of events that have been sent but not yet processed by the Gateway service.
<code>number_of_outstanding_queued_events</code>	The number of events that have been queued but not yet sent to the Gateway service.

The following example shows a "green" response that includes the status information and the list of sent events:

```
gateway_processing_status:
  service_up_to_date: false
  service_state: green
  last_processed_event:
    event_id: 40e1a564-2aea-429b-9d35-f588218688a1

  processed_at: '2020-06-02 22:32:10.838+00'
  generated_at: '2020-06-02 22:31:43.38615+00'
  filter: product_del
  event_processing_time: 22597
  elapsed_time_since_last_processed_event: 18427
last_sent_event:
  event_id: 93d0bf8f-ebfb-4a8b-aa22-7f805719d5c8
  title: >-
    Update Product (name-version:lts-cat0-product-11:1.0.0, id:
    d0bf799f-7f3a-4546-b267-a85c6a7f4b10) by user shavon0
  sent_at: '2020-06-02 22:32:28.426+00'
  generated_at: '2020-06-02 22:32:25.505109+00'
  number_of_outstanding_sent_events: 37
  number_of_outstanding_queued_events: 1

```

The result includes events that were not processed yet, as well as the last event processed. If a particular event is not listed as Sent or Queued, then that event was already processed.

Procedure

To obtain processing status information for a Gateway service, complete the following steps:

1. Log in to your API Connect Management server as a provider organization member, by using the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

where:

- `mgmt_endpoint_url` is the platform API endpoint URL.
- `user_id` is the user ID of your provider organization account, and is the same as the user ID that you use to log in to the API Manager user interface.
- `password` is the password for your administrator account.
- `identity_provider` is the identity provider that is used to authenticate API Manager users.

For example:

```
apic login --server platform-api.myserver.com --username myuser --password password --realm provider/myldap
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```

apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
- title: API Manager Local User Registry
  realm: provider/default-idp-2
- title: Corporate LDAP user registry
  realm: provider/corporate-ldap

```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.

For full details on how to log in to your management server from the CLI, see [Logging in to the management server](#).

2. Obtain the Gateway processing status for a Gateway service that is enabled in a Catalog by running the following command:

```
apic configured-gateway-services:get --server mgmt_endpoint_url --scope catalog --org organization_name --catalog catalog_name gateway_service_name --fields "add(gateway_processing_status)" --output -
```

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.
- The `--scope scope` parameter specifies `catalog` as the scope of the request.
- *organization_name* is the name of the provider organization that contains the Catalog.
- *catalog_name* is the name of the Catalog in which the Gateway service is enabled.
- *gateway_service_name* is the name of the Gateway service whose processing status you want to obtain.
- The `--fields "add(arguments)"` parameter can include either, or both, of the following arguments (separated with a comma):
 - `gateway_processing_status`: returns the total number of sent events, queued events, and processed events
 - `events`: returns lists of sent events with details about each event

For example:

```
apic configured-gateway-services:get --server platform-api.myserver.com --scope catalog --org myorg --catalog sandbox my-gateway-service --fields "add(gateway_processing_status)" --output -
```

Changing your Cloud Manager password and profile information

You can change your Cloud Manager password and update your profile information.

Procedure

To change your password or profile information, follow these steps:

1. Log in to the Cloud Manager user interface.
2. Click the User icon , and then select My Account.
3. In the Profile section, enter a new email address and First Name and Last Name for the account owner.
4. Click Save.
5. In the Change password section, enter your current password and your new password, and confirm the new password.

The password must contain eight characters at a minimum. It must contain at least two of the following types of characters:

- Lowercase letters
- Uppercase letters
- Numbers
- Characters from the following list of allowed punctuation and special characters:

```
!
\"
#
$
%
&
\
(
)
*
+
, (comma)
- (dash/hyphen)
. (period)
/
: (colon)
; (semi-colon)
<
=
>
?
@
[
\\
]
^
_ (underscore)
` (back quote/grave accent)
{
| (pipe)
}
~ (tilde)
```

The password cannot contain more than two consecutive repeating characters.

6. Click Save.

Results

Your profile information and password are changed.

Resolving login problems by increasing HTTP header size

You can resolve login problems for the Cloud Manager UI by increasing the maximum HTTP client header size.

About this task

Login attempts to the user interface might fail with error **502 (Bad Gateway)**. This error can occur when logging in from a browser that has a large number of cookies. The error occurs because size of the login request exceeds the maximum HTTP client header size.

The maximum HTTP client header size is limited for security reasons. To workaround this issue, you can clear the browser cache and cookies, or open an incognito window from the browser, and then retry the login.

Alternatively, you can increase the maximum HTTP client header size. Use caution when increasing the maximum size because larger headers can raise a security risk to your system.

Procedure

1. SSH to your management system or appliance.
2. Enter the following commands:

```
kubectl get deployment -n namespace | grep apim-v2
kubectl edit deployment -n namespace apiconnect-apim-v2-deployment
```

3. In the `env` section of the deployment configuration, change `--max-http-header-size=12000` to a larger value that works for your environment. For example:

```
- name: NODE_OPTIONS
  value: --max-old-space-size=8094 --max-http-header-size=16000
```

4. Save the updated configuration.
5. Run `kubectl get pod -n namespace` a few times until the new `apiconnect-apim-v2` pod is up and running.

Onboarding a new admin for Cloud Pak for Integration

Use the API Connect toolkit CLI to create a new admin account for use with Cloud Pak for Integration.

About this task

If you changed the local admin account for Cloud Pak for Integration, you must create a new admin user in API Connect to ensure that the new Cloud Pak for Integration admin can log in to API Connect with the Common Services User Registry.

Procedure

1. Download and install the API Connect toolkit CLI and credentials file as explained in [Installing the toolkit](#).
2. Log in to the toolkit CLI.

Logging in to the toolkit CLI requires the endpoint URL for your API Connect management server. In Cloud Pak for Integration, the URL indicates the location of the management server within the Cloud Pak for Integration deployment.

- a. Determine the URL to the API Connect management server by running the following command:

```
oc -n APIC_namespace get mgmt APIC_instance -o jsonpath="{.status.zenRoute}" && echo ""
```

The response looks like the following example URL:

```
apic-mgmt-admin-apic.deve-cip-hlag-8e86d3798137c73f524cf9-0000.eu-de.containers.appdomain.cloud
```

- b. Log in to the API Connect toolkit CLI by running the following command:

```
apic -s API_Connect_URL login -u admin -p <password> -r admin/default-idp-1
```

where `API_Connect_URL` is the URL of the management server in your API Connect instance.

3. Create a new admin account by completing the following steps.

Use the toolkit CLI to create an admin account in the Common Services User Registry and then add the new admin to the API Connect `administrator` role.

- a. Create a YAML file called `newCp4iAdmin.yaml` with the following information for the new admin account.

```
username: <new_cp4i_admin_username>
first_name: CP4I
last_name: Administrator
```

- b. Create the CP4i admin account by running the following command:

```
apic -s API_Connect_URL users:create -o admin --user-registry common-services newCp4iAdmin.yaml
```

- c. Verify that the account was created by running the following command:

```
apic -s API_Connect_URL users:get -o admin --user-registry common-services <new_cp4i_admin_username> --output -
```

- d. Get the new admin account's URL by running the following command:

```
apic -s API_Connect_URL users:list -o admin --user-registry common-services | grep <new_cp4i_admin_username> | awk '{print $4}'
```

e. Get the URL of the API Connect `administrator` role by running the following command:

```
apic -s API_Connect_URL roles:list --scope org -o admin | grep -w administrator | grep -v topology | awk '{print $2}'
```

f. Create a YAML file called `newcp4iadminmember.yaml` with the following content:

```
name: <new_cp4i_admin_username>
user:
  url: <user_URL>
role_urls:
  - <role_URL>
```

g. Use the `newcp4iadminmember.yaml` file to add the new admin as a member of the API Connect instance's admin organization. Create the new member by running the following command:

```
apic -s API_Connect_URL members:create --scope org -o admin newcp4iadminmember.yaml
```

h. Verify that the new admin account works by using it to log in to the Cloud Manager interface in your API Connect instance.

4. Remove the old Cloud Pak for Integration admin user from API Connect.

After you verify that the new Cloud Pak for Integration admin can log into the API Connect Cloud Manager interface, delete the previous Cloud Pak for Integration admin account.

a. Remove the previous admin from the membership of the API Connect admin organization by running the following command:

```
apic -s API_Connect_URL members:delete --scope org -o admin cs-admin
```

When you initially deployed API Connect as a component of Cloud Pak for Integration, the admin username was `admin` and the member in the API Connect admin organization was `cs-admin`. If the `cs-admin` member does not exist in the admin organization, then the Cloud Pak for Integration admin user was changed after deployment. In this case, the member uses the same name as admin account's user name. Delete the member with that name:

```
apic -s API_Connect_URL members:delete --scope org -o admin <old_cp4i_admin_username>
```

b. Delete the previous Cloud Pak for Integration admin user account from the Common Services User Registry by running the following command:

```
apic -s API_Connect_URL users:delete -o admin --user-registry common-services <old_cp4i_admin_username>
```

Extending the Gateway server behavior

To support your enterprise requirements, you can extend the Gateway servers within IBM® API Connect to provide extra enforcement behavior.

Before you begin

Before you develop your extensions, consider the guidelines in the following topics depending on which type of gateway you are using:

- [Gateway extension guidelines - DataPower Gateway \(v5 compatible\)](#)
- [Gateway extension guidelines - DataPower API Gateway](#)

For information on the different types of gateway, see [API Connect gateway types](#).

About this task

API Connect Gateway servers uses a subset of DataPower® enforcement capabilities. You can supply DataPower Extensions to customize these enforcement capabilities further.

The DataPower extensibility function can be used to perform actions that include schema validation, antivirus scanning, message filtering, authentication, and authorization, token translation, message enrichment, encryption & decryption, digital signing, and validation and message transformation. For more information, see [IBM DataPower documentation](#).

Important: Gateway server extensions must not be used to modify objects that cause the `apic-gw-service` object to restart, such as TLS Profiles, and Gateway Peering. Extensions that cause the `apic-gw-service` object to restart, lead to unpredictable behavior in the Gateway service.

Procedure

To extend the default enforcement capabilities that are provided in API Connect for the Gateway server, complete the following steps.

1. In your IBM DataPower environment, develop the configuration that you want to add to your Gateway server.
2. Test your enforcement configuration before you add the configuration to the Gateway server.
3. When you complete the IBM DataPower configuration, save the enforcement objects and files as a DataPower exported .zip file. The package file is ready to be uploaded to the Gateway server.
4. Copy your exported configuration .zip file to a centralized file system ready for upload to the Gateway server.

What to do next

Upload your extension to the Gateway server; see [Configuring your Gateway server extensions](#).

- [Gateway extension guidelines - DataPower Gateway \(v5 compatible\)](#)
Before you develop your extensions to the DataPower Gateway (v5 compatible), consider these guidelines.

- [Gateway extension guidelines - DataPower API Gateway](#)

Before you develop your extensions to the DataPower API Gateway, consider these guidelines.

- [Configuring your Gateway server extensions](#)

You can add extra IBM DataPower enforcement capabilities to a Gateway service by uploading a .zip file that defines the required extension behavior, and then enabling the extension in IBM DataPower.

DataPower Gateway (v5 compatible)

Gateway extension guidelines - DataPower Gateway (v5 compatible)

Before you develop your extensions to the DataPower® Gateway (v5 compatible), consider these guidelines.

Note: These guidelines apply to the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see [Gateway extension guidelines - DataPower API Gateway](#).

For information on the different types of gateway, see [API Connect gateway types](#).

You can download sample gateway extensions from <https://github.com/ibm-apiconnect/dp-extensions>.

You can create DataPower Processing Rules that can extend the enforcement behavior of the IBM® API Connect Gateway server at the following locations:

- **pre-request** extension:
 - Before the Gateway server begins to use the policies in the assembly to process the request.
- **post-request** extension:
 - After the Gateway server processes all of the policies in the assembly up to the proxy policy, if a proxy policy is used.
 - After the Gateway server processes all policies in the assembly, but before any catch logic is processed, if a proxy policy is not used.
- **post-response** extension:
 - After the Gateway server processes all of the remaining policies in the assembly after the proxy policy (including catch logic), but before the response is returned to the client application, if a proxy policy is used.
 - After the Gateway server processes the catch logic, but before the response is returned to the client application, if a proxy policy is not used.
- **post-error** extension:
 - If an error occurs, then before the Gateway server returns the error response to the client application.

To configure the Gateway server to call your extension Processing Rule, you must create an XML file that indicates the extension location and Processing Rule name. For example,

```
<extensions>
<extension location="pre-request">CustomRule1</extension>
<extension location="post-request">CustomRule2</extension>
<extension location="post-response">CustomRule3</extension>
<extension location="post-error">CustomRule4</extension>
</extensions>
```

The **<extension>** element entries are optional for any of the locations. Refer to the Gateway server Extension schema for the XML file syntax.

An extension Processing Rule can be applied to a specific organization or to all of the organizations and Catalogs. If the **<extension>** element does not have a tenant attribute, then the **<extension>** element is applied to all of the organizations. The following example shows an **<extension>** element without a tenant attribute.

```
<extension location="post-error">gen_error_handling</extension>
```

To apply an extension Processing Rule to a specific organization, enter the organization name as the value for the tenant attribute in the **<extension>** element. The following example shows an **<extension>** element with a tenant attribute value of *organization1*.

```
<extension location="post-error" tenant="organization1">organization1_error_handling</extension>
```

If you want to exclude a specific organization in an extension Processing Rule, enter the organization name as the value for the tenant attribute in an empty **<extension>** element. Add the empty **<extension>** element immediately after the custom rule **<extension>** element that you want to exclude the organization from. The following example shows an empty **<extension>** element with a tenant attribute value of *organization1*.

```
<extension location="pre-request">a_specified_CustomRule</extension>
<extension location="pre-request" tenant="organization1"></extension>
```

Important: An extension Processing Rule with a specified tenant attribute takes precedence over an **<extension>** element that applies to all of the organizations. Also, only one extension Processing Rule is applied to each extension location.

This XML file must be saved to the following location and included in your DataPower exported configuration .zip file:

```
local:///ext/extensions.xml
```

There can be only one DataPower exported configuration .zip file added to a Gateway server in API Connect.

CAUTION:

- Do not modify these files directly in the DataPower API Gateway file system, use the gateway extension mechanism described on this page.
- Do not apply gateway extension modifications to configuration in the local:/config-sequence.cfg file.
- Do not use Gateway server extensions to modify objects that cause the **apic-gw-service** object to restart, such as TLS Profiles, and Gateway Peering. Extensions that cause the **apic-gw-service** object to restart, lead to unpredictable behavior in the Gateway service.

DataPower configuration restrictions

All Processing Rules have read access to the INPUT context.

Processing Rules must not rely on context variables that are created by the IBM Gateway server enforcement configuration, because those configuration variables might change in the future.

All Processing Rules except Before Request can transform or alter the message flowing through the Gateway server. Ensure that the Processing Rule returns the desired message output context back to the Gateway server at the end of processing.

To avoid name conflicts, all DataPower configuration object names prefixed with **webapi** are reserved for IBM use.

The following folders cannot be modified:

- `local:///isp/*`
- `local:///gwapi/*`

As a best practice, avoid adding asynchronous actions in your custom Processing Rules because they increase the use of memory per transaction.

Gateway extension guidelines - DataPower API Gateway

Before you develop your extensions to the DataPower® API Gateway, consider these guidelines.

Note: These guidelines apply to the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see [Gateway extension guidelines - DataPower Gateway \(v5 compatible\)](#).

For information on the different types of gateway, see [API Connect gateway types](#).

Introduction

You apply an extension to a DataPower API Gateway by uploading one or more `.cfg` files that define the required extension behavior. These `.cfg` files contain DataPower API Gateway CLI commands. For details of the full set of CLI commands that are available, see the [DataPower API Gateway CLI command documentation](#).

You package the `.cfg` files in a `.zip` file, together with any additional required files that are referenced from CLI commands; for example, a `.json` file that contains the OpenAPI definition for an API. The `.cfg` files are processed in alphanumeric order by file name.

Note:

- All the `.cfg` files must be at the root of the `.zip` file. If you are attempting to use an API Connect Version 2018 gateway extension that has files in sub-directories, see [Gateway extensions manifest](#) for information on how to deploy multiple extensions in a single package.
- On Mac OS X, run the `zip` command on the command line with the following flags:

```
-x ".DS_Store" -x "__MACOSX"
```

Including the flags prevents the auto-generated `.DS_Store` and `__MACOSX` files from being added to the zip.

You upload the extension `.zip` file to an API Connect Gateway service, and enable the extension, as described in [Configuring your Gateway server extensions](#). Gateway server extensions can be deployed without having to restart the DataPower API Gateway.

To control how gateway extensions are applied to the DataPower API Gateway, you can include a Gateway extensions manifest as a `manifest.json` file. The manifest allows you to deploy multiple extensions of different types in a single package. For more information, see [Gateway extensions manifest](#).

Using CLI commands in a Gateway extension

Although you can use any DataPower API Gateway CLI commands in your extension `.cfg` files, typically you use commands that modify API Connect objects that have previously been deployed to the DataPower API Gateway.

When API Connect objects are deployed to a DataPower API Gateway, `.cfg` are created on the Gateway that define the configuration of those objects. By examining those `.cfg` on the Gateway, you can determine the precise names of API Connect objects that you want to modify, and the current values of the properties of those objects. You can access these `.cfg` files by completing the following steps:

1. Log in to the DataPower administrative user interface; for the Graphical Interface, select WebGUI rather than Blueprint Console.
2. Switch to the DataPower application domain for API Connect if necessary.
3. Under Files and Administration, click File Management.
4. Expand the temporary: folder to locate the `.cfg` files. The files for API Connect objects are named according to their containing provider organization and Catalog, as follows:

```
20.provider-org-name_catalog-name_collection.cfg
```

The prefix `20` controls the position of the file in the overall processing sequence, which is in alphanumeric order by file name.

Restriction:

- Do not modify these files directly in the DataPower API Gateway file system. Instead, use the gateway extension mechanism described on this page.
- Do not apply gateway extension modifications to configuration in the `local:/config-sequence.cfg` file.
- Do not use Gateway server extensions to modify objects that cause the `apic-gw-service` object to restart, such as TLS Profiles, and Gateway Peering. Extensions that cause the `apic-gw-service` object to restart, lead to unpredictable behavior in the Gateway service.

Note: Modifying a `.cfg` file triggers the execution of all other `.cfg` files that run commands on the same object.

Config-Sequence tracks all of the objects that it manages through the `.cfg` files. Any change to a `.cfg` file that causes config-sequence to run commands on an object automatically executes all other `.cfg` files that run commands on the same object.

Example: If a new product is published to catalog A, then the `.cfg` file for that collection in `temporary://config` will be modified by the `apic-gw-service` to reflect the new product. Because that `.cfg` file was changed, config-sequence will execute every other `.cfg` file that also runs operations on catalog A, in the sequence of locations defined in the config-sequence object. If there are 2 `.cfg` files in the same location that run commands on catalog A, they run in alphabetical order.

Example 1 - change the scope of the rate limit for a Plan

Suppose the DataPower API Gateway configuration for a Plan has the following CLI command:

```
api-plan myorg_sandbox_financial-services_1.0.0_basic
```

The **api-plan** command has the following syntax:

```
api-plan plan_name
```

and creates a Plan of the specified name, or modifies a Plan of the same name if it already exists. By using the specified name, you can add **api-plan** commands in your Gateway extension .cfg files to modify the Plan.

Note: The names of API Connect objects in the DataPower API Gateway configuration are derived from their configuration in API Connect. For example, a Plan name has the following structure:

```
provider-org-name_catalog-name_product-name_product-version_plan-name
```

where:

- *provider-org-name* is the name of the provider organization.
- *catalog-name* is the name of the Catalog in that provider organization.
- *product-name* is the name of the Product that contains the Plan.
- *product-version* is the version of the Product.
- *plan-name* is the name of the Plan.

The default scope to which a Plan rate limit applies is per application. To change this setting on the Plan in this example, so that the rate limit scope is per client ID, add the following command to a .cfg in your Gateway extension:

```
api-plan myorg_sandbox_financial-services_1.0.0_basic
rate-limit-scope per-client-id
exit
```

For more information on configuring Plans by using DataPower API Gateway CLI commands, see [API Plan commands](#).

Example 2 - add a path to an API definition

The .cfg file in this example performs the following actions:

1. Uses the **top** and **configure terminal** commands to reset CLI processing.
2. Uses the **api-operation** command as follows:
 - a. Creates a new operation called **bank_branches_get_operation**.
 - b. Uses the **reset** command to set all properties to their default values.
 - c. Sets the operation method to **GET**.
3. Uses the **api-path** command as follows:
 - a. Creates a new path called **bank_branches_path**.
 - b. Uses the **reset** command to set all properties to their default values.
 - c. Sets the path URL segment to **/details**.
 - d. Adds the previously created operation **bank_branches_get_operation** to the path.
4. Uses the **api-definition** command as follows:
 - a. Modifies the existing API definition called **myorg_sandbox_myapi_1.0.0**.
Note: The name of the API definition was derived from its configuration in API Connect when it was published to the DataPower API Gateway, and has the following structure:

```
provider-org-name_catalog-name_api-name_api-version
```

where:

- *provider-org-name* is the name of the provider organization.
 - *catalog-name* is the name of the Catalog in that provider organization.
 - *api-name* is the name of the API definition in API Connect.
 - *api-version* is the version of the API.
- b. Adds the previously created path **bank_branches_path** to the API definition.
Note: The **reset** command is not used here because that would reset all the current settings on the **myorg_sandbox_myapi_1.0.0** API definition, whereas the requirement is to add a new path to the existing configuration of the API definition.

The .cfg file is as follows:

```
top; configure terminal

api-operation bank_branches_get_operation
reset
method GET
exit

api-path bank_branches_path
reset
path "/details"
operation bank_branches_get_operation
exit

api-definition myorg_sandbox_myapi_1.0.0
path bank_branches_path
exit
```

For more information on the DataPower API Gateway CLI commands used in this example, see the following pages:

- [Initial login and common commands](#)
- [API Operation commands](#)
- [API Path commands](#)
- [API Definition commands](#)

Gateway extension limitations

This section details the limitations of the extensions to the DataPower API Gateway.

- If you use an extension to create a user-defined policy and then delete the extension, the extension is removed from the filesystem, but the configuration sequence is not triggered to clean up related files. For the policy to be cleaned up, you must send a modified extension that explicitly removes the user-defined policy from `apic-gw-service`, as in the following example.

```
apic-gw-service
  no user-defined-policies udp-basic_1.0.0
exit
```

- `user-defined-policy-yaml` policies that use or reference another policy can be deployed only after the referenced policy has been advertised to API Manager. The deploy type must be set to `deferred` and the API Connect Gateway Service must be restarted.
- Deleting an extension that is used to create a user-defined policy using a `.cfg` file does not remove the policy reference in the `apic-gw-service` object. The policy is not removed from the assembly palette until a reboot or restart of the Gateway pod. To properly remove the policy, send an `apic extensions:update` command that explicitly removes the policy from the `apic-gw-service` prior to sending the `apic extensions:delete` command.
- v5 policies that contain files outside of the `/policy` directory are not supported. If multiple v5 policies reference the same file outside the `/policy` directory, the last applied policy will overwrite the file and will be used by all policies that reference it. Removing any policy that contains the file will cause the file to be deleted and may cause errors for the remaining policies that use it.
- If an extension contains or references objects and files that are also referenced by other objects outside of the extension, deleting the extension can cause errors that are difficult to troubleshoot.
- It is possible to delete an extension that is referenced by published APIs. This may cause those API requests to return errors.
- For an extension type of `user-defined-policy`, extra assembly functions may be present in the DataPower import `.zip` file, even if there is no `.yaml` file to indicate their presence. Using these functions without declaring them using a `.yaml` file is not supported. A policy `.yaml` file is required for each policy you want to advertise to API Manager.
- Extension type `user-defined-policy-yaml` may leak generated Gatewayscript `.js` files in temporary `/js/` or `.xslt` files when deleted.
- Extension types that use SOMA imports must use new objects with no overrides. If you override a singleton or shared object using an extension of this type, then the object will not be restored to its previous state when the extension is deleted, and those objects may be missing after the extension is deleted. You must then restore any needed objects.
- [Gateway extensions manifest](#)
The gateway extensions manifest controls how gateway extensions are applied to the DataPower API Gateway.
- [v5 policy emulation limitations](#)
This page details the limitations of v5 policy emulation for the current release.

Gateway extensions manifest

The gateway extensions manifest controls how gateway extensions are applied to the DataPower® API Gateway.

The gateway extensions manifest enables you to deploy multiple extension implementations in a single package. The manifest is a JSON file that lists the extensions `.zip` files to be applied and when they are to be deployed. You can also use the manifest to enable v5 policy emulation for the API Connect gateway service. V5 policy emulation enables you to deploy supported v5 built-in policies and custom policies, and manage them from API Manager without having to rewrite them for DataPower API Gateway. V5 policy emulation is supported only for policies that are applied to the Gateway service scope.

The `manifest.json` file must be at the root level of the extensions `.zip` file, along with the gateway extension files specified in the manifest. For example:

```
manifest.json
jws-sign-policy.zip
add_udp.zip
```

The `manifest.json` file contains the following sections.

properties section

The properties section determines whether to enable the v5 framework to deploy supported v5 built-in policies and custom policies and manage them from API Manager without having to rewrite them for DataPower API Gateway.

Table 1. `properties` section properties

Property	Description
<code>deploy-policy-emulator</code>	Determines whether to enable v5 framework emulation. Valid values are <code>true</code> and <code>false</code> . v5 framework emulation is enabled for the API Connect Gateway service if <code>deploy-policy-emulator</code> set to <code>true</code> , if a v5 policy is detected in the files list, or if a <code>deploy-policies</code> entry is specified.
<code>deploy-policies</code>	Contains a list of built-in policies to advertise for v5 emulation. The following policies are supported. <ul style="list-style-type: none">• <code>activity-log_1.5.0</code>• <code>gatewayscript_1.0.0</code>• <code>if_1.5.0</code>• <code>invoke_1.5.0</code>• <code>proxy_1.5.0</code>• <code>redact_1.5.0</code>• <code>switch_1.5.0</code>• <code>validate-usertoken_1.0.0</code>• <code>xslt_1.0.0</code>

Property	Description
<code>defer-all-override</code>	An override toggle to force the deployment property of all extension entries (including V5E) to be deferred. When enabled, the user must restart the <code>apic-gw-service</code> object to apply any extension events.

files section

The `files` section is an array of file entries that reference extension implementations. Each entry must reference a file that is in the `extension.zip` file (or the extension is rejected).

Table 2. `files` section properties

Property	Description
<code>filename</code>	The name of the file that contains the extension implementation. This property is required and cannot be changed while the extension is deployed as part of an update.
<code>type</code>	<p>The type of extension implementation to be deployed. This property is required.</p> <p>The following types are supported.</p> <p>dp-import A DataPower import used to add additional configuration and/or services to a gateway. Like the extension type, but <code>dp-import</code> persists the configuration on physical or virtual DataPowers.</p> <p>Note: A <code>dp-import</code> file cannot be used to change the <code>apic-gw-service</code> object. If it is configured for this purpose, the extension is rejected.</p> <p>extension A legacy API Gateway extension that can be used to add additional configuration to a gateway. <code>Extension</code> should not be used to modify objects created by the API Connect gateway service, see gwd_extension for that use case. For more information, see Gateway extension guidelines - DataPower API Gateway.</p> <p>gwd_extension A JSON file that allows users to customize objects created by the API Connect gateway service. Only one <code>gwd_extension</code> is allowed in the manifest and its deployment is always deferred. For more information about the <code>gwd_extension</code>, see GWD extension type.</p> <p>policy-v5 A complete, valid v5 policy implementation. For more information, see Authoring policies for the DataPower Gateway (v5 compatible).</p> <p>user-defined-policy A native API Gateway policy packaged in a DataPower import zip. Using a DataPower import to apply the policy implementations allows the configuration to persist through restarts and upgrades on virtual and physical forms. The import might contain one or more policy implementations. This policy type is always global scoped. For more information, see Defining, packaging, and publishing a global-scoped policy for the API Gateway.</p> <p>user-defined-policy-yaml A YAML file that includes an assembly. This policy type is always global scope. If the assembly references another user-defined policy, that policy must already be advertised to the API Manager before it can be deployed. For more information, see Working with global policies.</p> <p>v5_extension A migrated v5 extension that the migration utility generates. Only certain parts of v5 extensions are usable in API Gateway. For more information, see Migrating gateway extensions.</p> <p><code>v5_extension</code> is reserved for v5 extensions that the migration utility creates. Do not manually create this type of extension.</p> <p>Note: V5E is intended to allow users to migrate from V5 without editing their APIs. V5E type policies cause known performances degradations in the API gateway. To improve performance of V5E policies, it is recommended to convert them to native policies.</p>
<code>deploy</code>	<p>When to deploy the extension entry. If you are deploying extensions that might cause a temporary API Connect gateway service outage, it is recommended to use deferred.</p> <p>immediate Deploy the extension entry immediately when the API Connect gateway service receives it. All gateway nodes apply the extension in parallel. Warning: <code>immediate</code> can cause an outage across the cluster, dependent on what the extension does.</p> <p>deferred A managed deployment strategy that applies the extension entry after the API Connect gateway service is restarted. This value is the default. Using deferred allows the user to do a controlled roll out of the extension across the cluster. When a DRR occurs this property is ignored, and all entries are deployed immediately.</p>
<code>catalog</code>	Indicates that a v5 policy is to be used only by certain catalogs and should not be advertised as a gateway service-level user policy. This property is valid only if the file type is <code>policy-v5</code> . The <code>catalog</code> value must be in the format <code>orgname_catalogname</code> .

Example manifest.json

The following example `manifest.json` file enables v5 policy emulation and specifies two built-in v5 policies to deploy. The files section lists two v5 policy implementation files and two extension files.

```
{
  "extension": {
    "properties": {
      "deploy-policy-emulator": true,
      "deploy-policies": [
        "invoke_1.5.0"
      ]
    }
  },
  "files": [
    {
      "filename": "proxy_service.zip",
      "deploy": "immediate",
      "type": "dp-import"
    },
    {
      "filename": "add_udp.zip",
```

```

      "deploy": "deferred",
      "type": "extension"
    },
    {
      "filename": "override-parse-defaults.json",
      "type": "gwd_extension"
    },
    {
      "filename": "jws-sign-policy.zip",
      "deploy": "immediate",
      "type": "policy-v5"
    },
    {
      "filename": "jwe-decrypt-policy.zip",
      "deploy": "deferred",
      "type": "policy-v5",
      "catalog": "extension-org_ext-cat-2"
    },
    {
      "filename": "mypolicy.zip",
      "deploy": "immediate",
      "type": "user-defined-policy"
    },
    {
      "filename": "Invoke-Private-Backend-policy.yaml",
      "deploy": "immediate",
      "type": "user-defined-policy-yaml"
    }
  ]
}

```

GWD extension type

The `gwd_extension` type is a JSON map that is used to apply user customizations to objects generated by the API Connect gateway service.

The `gwd_extension` map contains an array of user-defined CLI commands to be run on one or more objects. Only one `gwd_extension` is allowed in the manifest and its deployment is always deferred. Restarting the API Connect gateway service object is required to apply, update, or remove the overrides.

Key features of the `gwd_extension` type:

- The `gwd_extension` type can be used to define overrides at various scope-levels, which means a single array of override commands can be applied to one or more objects of a particular type.
- With some object mappings, you can define instances within a scope so that you can apply the custom CLI commands to all objects in that scope that match a particular name or criteria. For example, you can apply overrides to all catalog instances with the name `MyCatalog` regardless of which organization it belongs to.
- By default, the overrides are applied in order of scope granularity (global → organization → catalog → product → instance).
- Add `"@exclusive": true` to the object at any scope level to signal not to apply the previous scopes. Similarly, using an empty override array in a scope is a signal to not apply all previous scope overrides for that mapping, see [tls-client](#) for an example.

The supported scopes are:

- `_global`: Applies customizations to all objects of a particular type. For example, add one or more custom `assembly-rate-limits` to all `api-collections`.
 - `_instance`: Applies customizations to all objects that match a name or criteria. For example, add one or more custom `assembly-rate-limits` to all `api-collections` with the name `my-restricted-catalog` regardless which organization it belongs to.
- `_organization`: Applies customizations to all objects used in an organization. For example, apply a customization to all TLS client profiles that are used in the organization called `provorg`.
 - `_instance`: Applies customizations to all objects that match a name or criteria. For example, applying a customization to all TLS client profiles with a particular name and version regardless of which catalog is using it.
- `_catalog`: Applies customizations to all objects used in a catalog. For example, apply a customization to all TLS client profiles used in the catalog `myCat` of organization `myOrg`.
 - `_instance`: Applies customizations to all objects that match a name or criteria. For example, applying a customization to all plans in a catalog with a particular name regardless of which product it comes from.
- `_product`: Applies customizations to all objects of a type used in a product. For example, apply a customization to all plans in `product my-prod:1.0.0` published in catalog `myCat` of organization `myOrg`. The product scope is only used by the api-plan `gwd_extension` extension type.
- `_instance`: Applies customizations to a single instance. For example, apply a customization to TLS client profile `my-profile:1.0.0` in catalog `myCat` of organization `myOrg`.

Example `gwd_extension` that shows multiple types of overrides:

```

{
  "parse-settings": {
    "_global": {
      "override": [
        "document-size 4194304"
      ]
    }
  },
  "apigw": {
    "_global": {
      "override": [
        "assembly-rate-limit ratelimit-reject-ALL 10000 5 second on on on off off off \"\" \"1\"",
        "assembly-rate-limit ratelimit-alert-ALL 7500 5 second off on on off off off \"\" \"1\""
      ]
    }
  }
}

```

The `gwd_extension` type supports the following objects:

- [config-sequence](#)
The config-sequence object created by `apic-gw-service`, which is used to create all API gateway objects.
- [parse-settings](#)
Parse settings used by the API Gateway.
- [analytics-endpoint](#)
- [front-side-handler](#)
FSH and associated SNI Server profiles and objects that are used by the API Gateway.
- [apigw](#)
API Gateway object.
- [tls-client](#)
- [api-collection](#)
Catalog objects.
- [api-plan](#)
API Plan objects that are created from published products.
- [registry](#)
Registry objects used in a catalog.
- [oauth-provider](#)
Oauth objects used in a catalog.
- [api-definition](#)
The API objects that are published to one or more catalogs.
- [assembly](#)
The assembly objects and their associated actions that are used by APIs and global policies.

config-sequence

The config-sequence object created by `apic-gw-service`, which is used to create all API gateway objects.

- Override Key: `override`
- Scopes:
 - `_global`
- Example:

```
{
  "config-sequence": {
    "_global": {
      "override": [
        "summary my-override"
      ]
    }
  }
}
```

parse-settings

Parse settings used by the API Gateway.

- Override Key: `override`
- Scopes:
 - `_global`
- Example:

```
{
  "parse-settings": {
    "_global": {
      "override": [
        "summary my-override"
      ]
    }
  }
}
```

analytics-endpoint

- Override Key: `override`
- Scopes:
 - `_global`
- Example:

```
{
  "analytics-endpoint": {
    "_global": {
      "override": [
        "summary my-override"
      ]
    }
  }
}
```

```
}  
}
```

front-side-handler

FSH and associated SNI Server profiles and objects that are used by the API Gateway.

- Override Key: `source-https`
- Child Objects:
 - `ssl-sni-server`
 - `ssl-sni-map`
 - `ssl-server`
 - Override Key: `profile`
 - `_instance`: SNI hostname key
 - Child Objects:
 - `valcred`
 - `idcred`
- Scopes:
 - `_global`
- Example:

```
{  
  "front-side-handler": {  
    "_global": {  
      "source-https": [  
        "summary global my-fsh-override"  
      ],  
      "ssl-sni-server": [  
        "summary global my-sni-server-override"  
      ],  
      "ssl-sni-map": [  
        "summary global my-sni-map-override"  
      ],  
      "ssl-server": {  
        "_instance": {  
          "*.myhost.com": {  
            "profile": [  
              "summary sni-host-instance-my-profile-override"  
            ],  
            "valcred": [  
              "summary sni-host-instance-my-valcred-override"  
            ],  
            "idcred": [  
              "summary sni-host-instance-my-idcred-override"  
            ]  
          }  
        },  
        "profile": [  
          "summary my-profile-override"  
        ],  
        "valcred": [  
          "summary my-valcred-override"  
        ],  
        "idcred": [  
          "summary my-idcred-override"  
        ]  
      }  
    }  
  }  
}
```

apigw

API Gateway object.

- Override Key: `override`
- Scopes:
 - `_global`
- Example:

```
{  
  "apigw": {  
    "_global": {  
      "override": [  
        "summary my-override"  
      ]  
    }  
  }  
}
```

tls-client

Profiles that are attached to catalogs.

- Override Key: profile
- Child Objects:
 - Valcred
 - Idcred
- Scopes:
 - _global
 - _instance: <profileName>V<profileVersion>
 - _organization
 - _instance: <profileName>V<profileVersion>
 - _catalog
 - _instance: <profileName>V<profileVersion>
- Example: In this example, an empty array for **valcred** in catalog scope is used. The use of any empty array means the **valcreds** for TLS profiles in that catalog do not get the global or organizational overrides.

```
{
  "tls-client": {
    "_global": {
      "_instance": {
        "my-profileV1.0.0": {
          "profile": [
            "summary global-instance-profile-override"
          ],
          "valcred": [
            "summary global-instance-valcred-override"
          ],
          "idcred": [
            "summary global-instance-idcred-override"
          ]
        }
      },
      "profile": [
        "summary global-profile-override"
      ],
      "valcred": [
        "summary global-valcred-override"
      ],
      "idcred": [
        "summary global-valcred-override"
      ]
    },
    "_organization": {
      "my-org": {
        "profile": [
          "summary org-profile-override"
        ]
      }
    },
    "_catalog": {
      "my-org": {
        "my-catalog": {
          "profile": [
            "summary cat-profile-override"
          ],
          "valcred": [
            "summary cat-valcred-override"
          ]
        }
      }
    },
    "_instance": {
      "my-org": {
        "my-catalog": {
          "my-tlsV1.0.0": {
            "profile": [
              "summary instance-profile-override"
            ],
            "valcred": [
              "summary instance-valcred-override"
            ]
          }
        }
      }
    }
  }
}
```

api-collection

Catalog objects.

- Override Key: collection
- Child Objects:
 - preflow-assembly-function
 - preflow-assembly-function-call
 - postflow-assembly-function
 - postflow-assembly-function-call

- global-assembly-rule
- global-assembly
- global-assembly-function
- global-assembly-function-call
- assembly-function-rule
- Scopes:
 - _global
 - _instance: <catalogName>
 - _organization
 - _catalog
- Example: In the example, global instance is used to apply override to all **api-collections** that have the name **my-catalog**, regardless of what organization they belong to.

```
{
  "api-collection": {
    "_global": {
      "_instance": {
        "my-catalog": {
          "collection": [
            "summary hello my-catalog"
          ]
        }
      },
      "preflow-assembly-function": [
        "summary hello preflow-assembly-function global scope"
      ],
      "preflow-assembly-function-call": [
        "summary hello preflow-assembly-function-call global scope"
      ],
      "postflow-assembly-function": [
        "summary hello postflow-assembly-function global scope"
      ],
      "postflow-assembly-function-call": [
        "summary hello postflow-assembly-function-call global scope"
      ],
      "global-assembly-rule": [
        "summary hello global-assembly-rule global scope"
      ],
      "global-assembly": [
        "summary hello global-assembly global scope"
      ],
      "global-assembly-function": [
        "summary hello global-assembly-function global scope"
      ],
      "global-assembly-function-call": [
        "summary hello global-assembly-function-call global scope"
      ],
      "assembly-function-rule": [
        "summary hello assembly-function-rule global scope"
      ],
      "collection": [
        "summary hello collection global scope"
      ]
    },
    "_organization": {
      "my-org": {
        "collection": [
          "summary hello collection org scope"
        ]
      }
    },
    "_catalog": {
      "my-org": {
        "my-catalog": {
          "collection": [
            "summary hello collection cat scope"
          ]
        }
      }
    }
  }
}
```

api-plan

API Plan objects that are created from published products.

- Override Key: override
- Child Objects:
 - **graphql-schema-options**
 - Override Key: override
 - Child Objects:
 - **visibility-list**
 - **rate-limit**
 - Child Object:
 - **rate-limit-definition**
 - Override Key: override

- **burst-limit**
 - Child Object:
 - **rate-limit-definition**
 - Override Key: `override`
 - **rate-limit-group**
 - Override Key: `override`
 - **api-operation-rate-limit**
 - Override Key: `override`
 - Child Objects:
 - **rate-limit-group**
 - **rate-limit-definition**
 - **assembly-limit**
 - Child Objects:
 - **rate-limit**
 - **burst-limit**
 - **count-limit**
- Scopes:
 - `global`
 - `_instance: <planName>`.
 - `organization`
 - `_instance: <planName>`.
 - `catalog`
 - `_instance: <planName>`.
 - `product: <name>:<version>`
 - `_instance: <planName>`.
 - Example:

```
{
  "api-plan": {
    "_global": {
      "graphql-schema-options": {
        "visibility-list": [
          "echo hello graphql-schema-options visibility_global"
        ],
        "override": [
          "echo hello graphql-schema-options_global"
        ]
      },
      "rate-limit": {
        "rate-limit-definition": {
          "override": [
            "echo hello rate-limit_global"
          ]
        }
      },
      "burst-limit": {
        "rate-limit-definition": {
          "override": [
            "echo hello burst-limit_global"
          ]
        }
      },
      "rate-limit-group": {
        "override": [
          "echo hello rate-limit-group_global"
        ]
      },
      "api-operation-rate-limit": {
        "rate-limit-definition": {
          "override": [
            "echo hello api-operation-rate-limit_global"
          ]
        },
        "rate-limit-group": {
          "override": [
            "echo hello api-operation-rate-limit-group_global"
          ]
        },
        "override": [
          "echo hello api-operation-rate-limit_global"
        ]
      },
      "assembly-limit": {
        "rate-limit": {
          "rate-limit-definition": {
            "override": [
              "echo hello assemby rate-limit_global"
            ]
          }
        },
        "burst-limit": {
          "rate-limit-definition": {
            "override": [
              "echo hello assebmly burst-limit_global"
            ]
          }
        },
        "count-limit": {
          "rate-limit-definition": {
            "override": [

```

```

    },
    "_organization":{
      "my-org":{
        "override":[
          ],
          "_instance":{
            "my-ldap-registry":{
              "override":[
                "ldap-version v3",
                "ldap-bind-password mypw",
                "ldap-search-param ldap-param",
                "summary override org instance"
              ]
            }
          }
        ]
      }
    },
    "_catalog":{
      "my-org":{
        "my-catalog":{
          "override":[
            "ldap-host 1.2.3.4",
            "ldap-bind-dn cn=root,dc=datapower,dc=com",
            "summary override catalog"
          ]
        }
      }
    },
    "_instance":{
      "my-org-3":{
        "my-catalog-3":{
          "my-ldap-reg":{
            "override":[
              ],
              "ldap-search-parameters":[
                ]
            ]
          }
        }
      }
    }
  },
  "authUrl":{
    "_global":{
      "override":[
        "summary override global"
      ],
      "_instance":{
        "httpbin":{
          "override":[
            "summary override global instance"
          ]
        }
      }
    }
  },
  "_organization":{
    "my-org":{
      "override":[
        ],
        "_instance":{
          "httpbin":{
            "override":[
              "summary override org instance"
            ]
          }
        }
      ]
    }
  },
  "_catalog":{
    "my-org":{
      "my-catalog":{
        "_instance":{
          "httpbin":{
            "override":[
              "summary override cat instance",
              "echo some other override"
            ]
          }
        }
      },
      "override":[
        "summary override cat"
      ]
    }
  },
  "_instance":{
    "my-org-3":{
      "my-catalog-3":{
        "my-authurl":{
          "override":[
            "summary override instance"
          ]
        }
      }
    }
  }
}

```

```
}
}
}
}
}
}
```

oauth-provider

Oauth objects used in a catalog.

- OAuth Types
 - Native
 - Override Key: override
 - Third-party
 - Override Key: override
- Scopes:
 - _global
 - _instance: APIM name
 - _organization
 - _instance: APIM name
 - _catalog
 - _instance: APIM name
- Example

```
{
  "oauth-provider": {
    "native": {
      "_global": {
        "override": [
          "apic-access-token-ttl 86400"
        ],
        "_instance": {
          "my-native-oauth": {
            "override": [
              "scopes-allowed cmcscope1",
              "enable-debug-mode on"
            ]
          }
        }
      },
      "organization": {
        "my-org-2": {
          "override": [
            ]
        }
      },
      "_instance": {
        "my-org": {
          "my-catalog": {
            "my-native-oauth-2": {
              "override": [
                "apic-enable-introspection on",
                "apic-auth-code-ttl 600",
                "apic-enable-refresh-token on "
              ]
            }
          }
        }
      },
      "third-party": {
        "organization": {
          "my-org": {
            "_instance": {
              "my-third-party-oauth": {
                "override": [
                  "third-party-introspect-url https://someaddress.com"
                ]
              }
            }
          }
        }
      }
    }
  }
}
```

api-definition

The API objects that are published to one or more catalogs.

- Override Key: api-definition
- Child Objects

- api-schema
- Security-definition
 - oauth2
 - api-sec-oauth
 - _instance: swagger name
 - apiKey
 - api-sec-apikey
 - _instance: swagger name
 - http
 - api-sec-http-scheme
 - _instance: swagger name
 - basic
 - x-ibm-authentication-url
 - api-sec-basic-auth
 - _instance: swagger name
- security-requirements
 - api-sec-oauth-req
 - Override Key: override
 - _instance: Datapower object name
 - api-sec-req
- api-path
 - Override Key: path
 - _instance: <Path URI>
 - Child Objects
 - api-operation
 - Override Key: operation
 - _instance: <Operation Method>
 - Child Objects
 - security-requirement
 - api-sec-oauth-req
 - Override Key: override
 - _instance: Datapower object name
 - api-sec-req
 - api-schema-request
 - api-schema-response
 - Override Key: override
 - _instance: Datapower object name
 - api-schema-request
- wsdl-validation-schema-location
- cors-policy
- cors-rule
 - Override Key: override
 - _instance: Datapower object name
- Scopes:
 - _global
 - _instance: name:version
 - _organization
 - _instance: name:version
 - _catalog
 - _instance: name:version
- Example: In this example, the **@exclusive** flag is used on the instance `nick-limits:1.0.0` in `my-catalog` of `my-organization`. The **@exclusive** flag means that only the CLI commands at the instance level are applied for that API while all other APIs in that catalog still have the `global`, `organization`, and `catalog` CLI commands applied to them.

```
{
  "api-definition": {
    "_global": {
      "api-schema": [
        "echo hello schema global scope"
      ],
      "security-definition": {
        "oauth2": {
          "api-sec-oauth": [
            "echo hello oauth def global scope"
          ]
        },
        "apiKey": {
          "api-sec-apikey": [
            "echo hello apikey global scope"
          ]
        },
        "http": {
          "api-sec-http-scheme": [

- Scopes:
 - _global
 - _instance: swagger name:version

- `_organization`
 - `_instance`: swagger name:version
- `_catalog`
- `_instance`: swagger name:version
- Example: In this example, 2 instances are included within the global scope mapping. First is, `my-global-policy:1.0.0`, which is a global-policy that is used in some catalogs. Since it is defined at the global scope, the overrides apply anytime an assembly is built from a swagger with the name and version of `my-global-policy:1.0.0`. Second is, `complex-switch:1.0.0`, which is an API that is published to various catalogs. Similarly, since it is defined as an instance with in the global scope the overrides apply anytime that the assembly is built from a swagger with the name and version of `complex-switch:1.0.0`. Also see the `set-var` example within global scope for an example of overriding assembly action instances based on the title that is given in APIM or the DataPower object name.

```

1. Log in to your API Connect Cloud Manager server as an administrator, using the following command:

```
apic login --server <cloud-manager_endpoint_url> --username <admin_user_ID> --password <admin_password> --realm admin/<identity_provider>
```

where:

- <cloud-manager_endpoint_url> is the Cloud Manager endpoint URL; for example: `mgmt-admin.<myserver>.com`.
- <admin_user_ID> is the user ID of your administrator account, and is the same as the user ID that you use to log in to the Cloud Manager user interface.
- <admin_password> is the password for your administrator account.
- <identity_provider> is the identity provider that is used to authenticate administrative users.

For example:

```
apic login --server mgmt-admin.myserver.com --username admin --password my-admin-password --realm admin/myldap
```

2. Upload the Gateway extension .zip file by using the following command:

```
apic gateway-extensions:create <extension_zip_file> --scope org --org admin --gateway-service <gateway_service> --availability-zone <availability-zone> --server <cloud-manager_endpoint_url>
```

where:

- <extension_zip_file> is the Gateway extension .zip file that you want to upload.
- <gateway_service> is the name of the Gateway service that you want add the extension to.
- <availability-zone> is the name of the availability zone that contains the Gateway service.
- <cloud-manager_endpoint_url> is the Cloud Manager endpoint URL.

For example:

```
apic gateway-extensions:create myextension.zip --scope org --org admin --gateway-service mygatewayservice --availability-zone availability-zone-default --server mgt-admin.myserver.com
```

This example uses the default supplied availability zone name of `availability-zone-default`, which will be the required value if you have not configured your own availability zones. To check the names of the currently configured availability zones, use the following command:

```
apic availability-zones:list --org admin --server <cloud-manager_endpoint_url>
```

For details on configuring availability zones, see [Creating an availability zone](#).

To check the names of the currently configured gateway services, use the following command:

```
apic gateway-services:list --org admin --availability-zone <availability-zone> --server <cloud-manager_endpoint_url>
```

You can confirm that the extension has been added to the Gateway service by using the `gateway-extensions:get` command; for example:

```
apic gateway-extensions:get --scope org --org admin --gateway-service mygatewayservice --availability-zone availability-zone-default --server mgt-admin.myserver.com --output -
```

(the parameter setting `--output -` writes the details of the Gateway extension object to the command window. You can specify the name of an existing folder to have the details written to a .yaml file in that folder.)

For reference details of the `apic gateway-extensions` commands, see [apic gateway-extensions](#).

Note: You cannot upload more than one Gateway extension .zip file to the same Gateway service. If you want add further extensions later, update the original .zip file, then use the `apic`

`gateway-extensions:update` command to replace the previous gateway extensions file with the revised one; for example:

```
apic gateway-extensions:update mynewextension.zip --scope org --org admin --gateway-service mygatewayservice --availability-zone myavailabilityzone --server mgt-admin.myserver.com
```

3. Apply the extension to each server by restarting the API Connect gateway service object; complete the following steps on **each** Gateway server in the Gateway service:

Note: In Kubernetes environments, the following steps can be accomplished by issuing `kubectl`

`delete pod` on **each** gateway pod. Be sure to wait until each pod gets back to the ready state before deleting the next gateway pod.

- Remove the Gateway server from the load balancing group.
- Disable, then enable the API Connect gateway service object. You can do this by using either the DataPower administrative user interface in a web browser, or by using the DataPower CLI.

- By using the administrative user interface:
 - Log in to the DataPower administrative user interface; for the Graphical Interface, select WebGUI rather than Blueprint Console.
 - Switch to the DataPower application domain for API Connect if necessary.
 - Search for API Connect Gateway Service.
 - Set the Administrative State to disabled.
 - Apply the changes.
 - Set the Administrative State to enabled.
 - Apply the changes.
- By using the CLI:
 - Enter configuration mode by entering the command `configure`.
 - Navigate to the DataPower application domain for API Connect by entering the command `switch api_connect_domain_name`, where `api_connect_domain_name` is the name of your API Connect application domain.
 - Disable the API Connect gateway service object by entering the following command:

```
apic-gw-service; admin-state disabled; exit
```

- Enable the API Connect gateway service object by entering the following command:

```
apic-gw-service; admin-state enabled; exit
```

c. Ensure that the gateway service object initialization has completed.

d. Re-add the Gateway server to the load balancing group.

4. Apply the extension to each server by restarting the API Connect gateway service object; complete the following steps on **each** Gateway server in the Gateway service:
Note: In Kubernetes environments, the following steps can be accomplished by issuing `kubectl delete pod` on **each** gateway pod. Be sure to wait until each pod gets back to the ready state before deleting the next gateway pod.

Results

The extension is uploaded and applied to each of the servers in the Gateway service, and the associated enforcement capabilities are applied to all incoming API resource requests.

Warning: DataPower Gateway (v5 compatible) only If you upload an extension to the DataPower Gateway (v5 compatible), a status file called `extension_import_response.xml` is written to the `local:/ext` folder in the gateway file system. Do not remove this file, otherwise if your gateway extension is subsequently removed then the referenced objects cannot be reverted to their original state automatically, and you will therefore have to either complete these clean up tasks manually, or re-add the gateway extension to regenerate the `extension_import_response.xml` file and then remove the gateway extension again. If the `extension_import_response.xml` exists and there is a cleanup failure for any object, a failure file is written to the `local:/ext` folder, with the failure details.

Cloud Manager Tutorials

Tutorials for using the Cloud Manager user interface in IBM® API Connect.

Prerequisites

To complete the following tutorials you must be the Cloud Administrator or Cloud Owner of an API Connect instance.

Overview

These tutorials guide you through common tasks performed to set up and maintain the configuration of a cloud.

- [Tutorial: Configuring the Cloud](#)
This tutorial shows you how to create a basic cloud configuration, with available gateway, analytics and developer portal services.
- [Tutorial: Creating a Provider Organization](#)
This tutorial shows you how to create a Provider Organization.

Tutorial: Configuring the Cloud

This tutorial shows you how to create a basic cloud configuration, with available gateway, analytics and developer portal services.

Before You Begin

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator

You will need the following information to complete this tutorial.

- The IP address or FQDN of the gateway, and the port assigned to accept API requests from clients.
- The IP address or FQDN of the gateway, and the port assigned to communicate with the API Management server. This cannot be the same as the port for API requests.
- The FQDN of the Developer Portal service to accept requests from clients.
- The FQDN of the Developer Portal to communicate with the API Management server.
- The FQDN of the Analytics service to accept requests from clients.
- The address, port and optional login credentials for an SMTP email server.

Note: The port for the `portal-www`, `portal-admin`, and `analytics-ingestion` services is **443**, and isn't configurable.

About this tutorial

In this tutorial you are going to complete the following lessons:

- [Initial Cloud Manager Console login](#)
- [Configure an Email Server](#)
- [Register a Gateway Service](#)
- [Register a Portal Service](#)
- [Register an Analytics Service](#)
- [Configure a Default Gateway Service](#)

Initial Cloud Manager Console login

Take the following steps to log in to the Cloud Manager user interface for the first time.

1. In a web browser, enter the management service URL. For example, `https://ManagementService.domain/admin` where `ManagementService.domain` is the fully qualified host name or IP address of the Management service.

Cloud Manager

Sign in using the Cloud Manager User Registry

Username

Password

Sign In

[Forgot Password?](#)

2. Enter the Cloud Administrator user name and password. The default values are `admin` for the user name and `7iron-hide` for the password.

OpenShift top-level CR install

If you installed API Connect on OpenShift using the top-level "API Connect Cluster" CR, the default user name is `admin`. If you are logging in for the first time, run the following commands to retrieve the initial password, which is generated automatically during deployment:

```
oc get secret -n <namespace> | grep mgmt-admin-pass
```

```
oc get secret -n <namespace> <secret_name_from_previous_command> -o jsonpath="{.data.password}" | base64 -d && echo "
```

3. You are immediately required to change the admin password, as well as provide an email address for the cloud administrator. Enter the necessary information. Note: If you forget your password and request a password reset, the notification email is sent to this email address. This action will use the email server set in the Notifications section of the cloud Settings. This tutorial shows you how to set this configuration.

Tutorial: Creating a Provider Organization

This tutorial shows you how to create a Provider Organization.

Before You Begin

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator

You must also complete the following tasks before beginning:

- [Configuring an email server for notifications](#)
- [Setting up notifications](#)

Note that an email server must be configured and an active email server must be selected before a provider organization account can be created.

About this tutorial

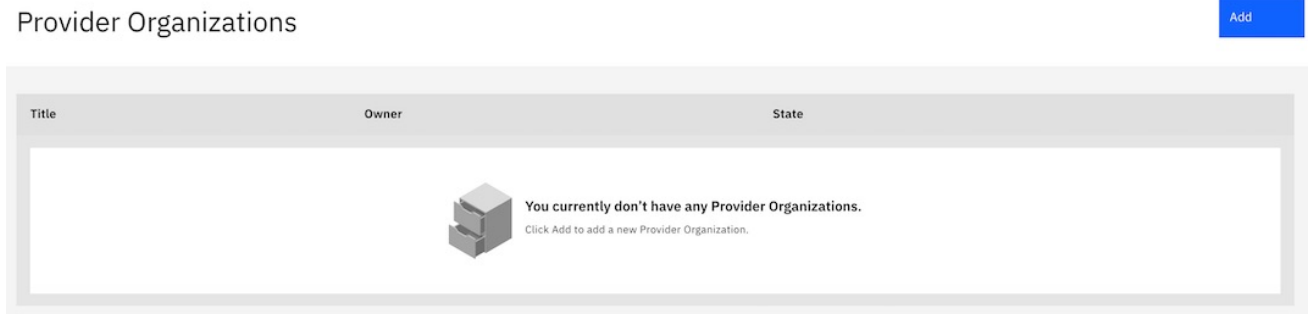

In this tutorial you are going to complete the following lessons:

- [Create a Provider Organization](#)

Create a Provider Organization

Take the following steps to create a new Provider Organization.

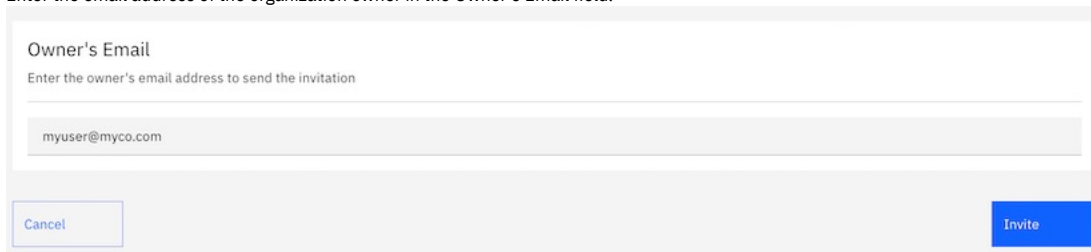

1. Log in to the Cloud Manager.
2. Click  Provider Organizations.

3. Click Add > Invite organization owner.

4. Enter the email address of the organization owner in the Owner's Email field.

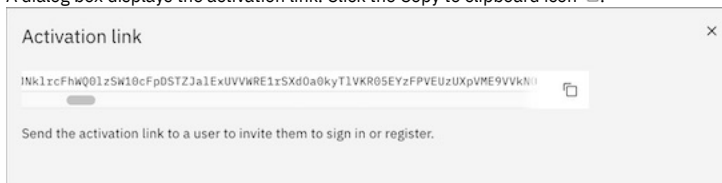

The screenshot shows the 'Owner's Email' form. The text 'Owner's Email' is at the top. Below it is a prompt: 'Enter the owner's email address to send the invitation'. A text input field contains the email address 'myuser@myco.com'. At the bottom left is a 'Cancel' button, and at the bottom right is a blue 'Invite' button.

5. Click Invite.
6. A notice appears when the activation email has been sent. Click Activation link..

7. A dialog box displays the activation link. Click the Copy to clipboard icon .

- Open a new window in your browser. Paste the copied activation link into the Location bar. Optionally, you can click the activation link in the invitation email to open the registration form.
- Complete fields shown in the form to sign up with the API Manager User Registry. Click Sign up.

Developing your APIs and applications

You develop APIs and LoopBack® applications by using the IBM® API Connect developer toolkit.

The API Connect developer toolkit provides both the API Designer user interface and a command line interface that you can use to develop APIs and LoopBack applications and publish them to API Connect.

You publish APIs by including them in a Product and then publishing the Product. You define your APIs and Products by creating and validating YAML definition files in your local file system. You can then interact with API Connect by using either the API Designer or the toolkit commands.

The developer toolkit is described in detail in the following subsections:

- [API development checklist](#)
A summary, with links, of the key tasks for developing APIs in IBM API Connect.
- [Working with the toolkit](#)
Install the developer toolkit by downloading an executable file. You can then use the toolkit commands to interact with IBM API Connect and publish APIs that you have defined in your file system.
- [Managing platform REST API keys](#)
Create API keys associated with your user account, and then use them to authenticate when you call the platform REST APIs provided by API Connect.
- [Searching for items in API Manager](#)
Use the search feature in IBM API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.
- [Working with API definitions](#)
An API definition specifies the complete configuration for an API. You can create and configure your APIs either by using either the API Designer UI application, or by using the browser based API Manager UI.
- [Working with Products](#)
In IBM API Connect, Plans and APIs are grouped together in Products, with which you can manage the availability and visibility of APIs and Plans.
- [Creating and validating API and Product definitions by using the CLI](#)
The developer toolkit of IBM API Connect provides a command line interface that you can use to create and publish API and Product definitions, and also to validate YAML or JSON definitions.
- [Working with global policies](#)
Use global policies to configure policy assemblies that are called just before, or just after, each of your API assemblies is called, or when an error is thrown. You can

upload global policies into each of the gateway services in your Catalogs, and then designate, for each gateway service, which global policy should be called before an API assembly is called, after an API assembly is called, or if an error occurs when an API assembly is called. The designated global policies are applied to all the APIs that are deployed to the associated gateway service.

- [Reference](#)

Reference information for developing your APIs in API Connect, including context variables, and template variables.

API development checklist

A summary, with links, of the key tasks for developing APIs in IBM® API Connect.

Task	Description
Activate your API Manager user account	For you to be able to connect to a Management server by using either the API Designer or API Manager user interfaces, one or other of the following prerequisites must be satisfied: <ul style="list-style-type: none">• Your administrator has created a provider organization, specifying you as the owner; see Creating a provider organization.• You have been added as a member of a provider organization; see Adding provider organization users and assigning roles.
Install the developer toolkit	The developer toolkit provides a command-line environment and an API Designer user interface, both of which enable you to develop and work with your APIs on your local machine; you publish your APIs to the Management server when ready. You can also develop your APIs directly on the Management server by using the API Manager user interface.
Log in to the user interface; see Logging in from API Designer , or Accessing the API Manager user interface , depending on which user interface you want to use.	After you have activated your account, you can log in to your Management server from either user interface. You can also use the API Designer in offline mode, but to be able to test and publish APIs you must be connected to a Management server.
Create your API definitions	You can create API definitions in the following ways: <ul style="list-style-type: none">• Create a REST API definition either by composing the API definition, and its operations, from scratch, creating a proxy API that calls an existing endpoint, or importing an OpenAPI definition.• Expose an existing SOAP service as an API.• Create a GraphQL API proxy definition that proxies a backend GraphQL server.
<ul style="list-style-type: none">• Secure your APIs (OpenAPI 2.0)• Secure your APIs (OpenAPI 3.0)	You configure security for an API by creating one or more security definitions that you then apply to your API, and to the operations in your API. Security mechanisms include basic authentication through a user registry, and token based authentication with OAuth.
Test your APIs	The user interfaces provide a test tool with which you can test your APIs through the gateway.
Productize and publish your APIs	To make your APIs available to application developers, you include them in a Product that you then publish to the gateway.
Apply visibility controls and rate limiting to your APIs	Visibility settings control which APIs the application developers can subscribe to. Rate limiting controls the usage of your APIs; for example, you can apply a rate limit of 100 calls per minute.
Develop your APIs by using the developer toolkit CLI	You can use the developer toolkit CLI to develop APIs based on OpenAPI definition files in YAML or JSON format.

Working with the toolkit

Install the developer toolkit by downloading an executable file. You can then use the toolkit commands to interact with IBM® API Connect and publish APIs that you have defined in your file system.

The following subsections describe how to install and use the toolkit:

- [Installing the toolkit](#)

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM API Connect.

- [Logging in from API Designer](#)

To log in from the API Designer user interface for IBM API Connect, you will need the host name of the management server and the user name and password associated with your API Manager account.

- [Using the developer toolkit command-line tool](#)

The IBM API Connect developer toolkit provides a command-line tool, `apic`, that you can use to perform all API Connect tasks. You can also use the command-line tool to script tasks such as continuous integration and delivery.

Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + LoopBack + Designer: provides a command line environment for working with IBM API Connect, including LoopBack® support, and the API Designer application.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + LoopBack + Designer option, an executable file for launching the API Designer application.

You can download the toolkit from one of the following locations:

- From IBM Fix Central.
- From the Cloud Manager or API Manager user interface.

Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.
 - To download the toolkit from IBM Fix Central, complete the following steps:
 - Open the [IBM Fix Central site](#) in your browser.
 - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
 - Select your Installed Version and click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
 - In the Text field, enter `toolkit`, then click Continue.
 - Select the toolkit file that you want to download.
 - Click Continue, then follow the instructions to complete the download operation.
 - To download the toolkit from Cloud Manager or API Manager user interface, complete the following steps:
 - Open the Cloud Manager or API Manager user interface.
 - On the welcome page, click the Download Toolkit tile. The two toolkit options are listed.
 - Click your platform alongside either the CLI option or the CLI + LoopBack + Designer option as required, then save the associated compressed file to your local file system.
 - To download the API Designer credentials (Client ID and Client Secret), click Download alongside API Designer Credentials, then save the `designer_credentials.json` file to your local file system. A command is provided for installing the credentials, as described in detail in [step 6](#).
 - To download the toolkit credentials (Client ID and Client Secret), click Download alongside Credential, then save the `credentials.json` file to your local file system. A command is provided for installing the credentials, as described in detail in [step 5](#).
 - Close the Install API Connect Toolkit window.

2. Extract the contents of the toolkit compressed file to a folder of your choice.

The contents of the file depend on the your chosen toolkit option and platform, as follows:

- The `apic-slim` or `apic-slim.exe` file is the CLI for IBM API Connect.
- The `apic` or `apic.exe` file is the CLI for IBM API Connect including LoopBack support.
Tip: If you are using the CLI option, then if you rename the `apic-slim` file to `apic`, or the `apic-slim.exe` file to `apic.exe`, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + LoopBack + Designer option.
- The `api_designer-platform` file is the API Designer user interface application for the specified platform.

3. Optional: Delete the `$HOME/.apiconnect/node_cli` directory.

You need to do this only if you replaced a version of `apic` or `apic.exe` and are using the `apic lb4` command. You need to delete the directory `get apic` to unpack the new loopback.

On Windows, `$HOME` is defined by environment `USERPROFILE`.

4. Run the CLI.

- For the Mac OSX or Linux® platforms, complete the following steps:
 - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
 - Make the CLI file an executable file by entering the following command:

```
chmod +x download_name
```

Where `download_name` is the name of the toolkit file that you downloaded, either `apic` or `apic-slim`.

- Run CLI commands as follows:

```
./apic command_name_and_parameters
```

or

```
./apic-slim command_name_and_parameters
```

For details of the CLI commands, see [apic](#).

- For the Windows platform, complete the following steps:
 - Open a command prompt and navigate to the folder where you extracted the contents of the toolkit compressed file.
 - Run CLI commands as follows:

```
apic command_name_and_parameters
```

or

```
apic-slim command_name_and_parameters
```

For details of the CLI commands, see [apic](#).

Tip: Add the folder location of your CLI file to your `PATH` variable so that you can run CLI commands from anywhere in your file system.

5. Install the toolkit credentials.

If you do not install the toolkit credentials that are provided for download, as detailed previously in the [toolkit credentials download instructions](#), API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the credentials into your local toolkit, run the following command:

```
apic client-creds: set toolkit_credentials_file_path/credentials.json
```

where `credentials_file_path` is the location to which you downloaded the toolkit credentials JSON file. After you have run this command, your toolkit uses these new credentials to authenticate with the management server.

Note: At any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.

To revert to the default toolkit credentials for all login operations from the toolkit CLI, use the following command:

```
apic client-creds:clear
```

For increased security, an administrator can remove the default credentials from the management server by completing the following steps:

- Log in to the management server as an administrator; see [Logging in to a management server](#).
- Delete the default credentials by running the following commands:

```
apic registrations:delete toolkit --server mgmt_endpoint_url
apic registrations:delete consumer-toolkit --server mgmt_endpoint_url
```

6. Install the API Designer credentials.

If you do not install the API Designer credentials that are provided for download, as detailed previously in the [API Designer credentials download instructions](#), API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the custom credentials into your local API Designer, set the `APIC_DESIGNER_CREDENTIALS` environment variable to the credentials download location, using the mechanism appropriate for your operating system.

After you have set the `APIC_DESIGNER_CREDENTIALS` environment variable, your API Designer uses the new credentials to authenticate with the management server.

• Windows:

If you are using Windows, create an environment variable using one of the following methods:

- Create a permanent environment variable so that you can start API Designer from any location on your computer:
 - Open the Environment Variables page: Click Start, Settings, System and in the "Related Settings" section of the page, click Advanced System Settings.
 - On the Advanced tab of the System Properties dialog box, click Environment Variables.
 - In the "User variables" section, click New and create an environment variable with the following settings:
 - Variable: `APIC_DESIGNER_CREDENTIALS`
 - Value: `<designer_credentials_file_path>\designer_credentials.json` where `<designer_credentials_file_path>` is the location where you stored the `designer_credentials.json` file.
 - Click OK to save the new environment variable, and then exit the dialog box.
- If you don't have the required permissions to create a permanent environment variable, you can create a temporary one that will only be used while you are running the API Designer application. The following steps must be performed every time you start API Designer:
 - Open the Windows command prompt.
 - Run the following command to set the temporary environment variable:

```
set APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>\designer_credentials.json
```

where `<designer_credentials_file_path>` is the location where you stored the `designer_credentials.json` file.

Note: Leave the command prompt open for the next step. You must set the temporary variable and start the API Designer within the same Windows command session.

- Now run the following command to start API Designer:

```
C:\>"Program Files\API Designer\API Designer.exe"
```

By default, API Designer is installed in the C:\Program Files\API Designer folder as shown in the example. If you installed it into a different location, use your own location in the command. Note that the path and file name are enclosed in quotation marks because they contain spaces.

• Mac:

If you are using Mac OS X, create an environment variable using one of the following methods:

- Run the following command to set the global environment variable:

```
launchctl setenv APIC_DESIGNER_CREDENTIALS <designer_credentials_file_path>/designer_credentials.json
```

where `<designer_credentials_file_path>` is the location where you stored the API Designer credentials JSON file.

- Pass in the environment variable while starting API Designer from the command line. With this method, you must run the following command every time you start API Designer:

```
APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>/designer_credentials.json open
<designer_application_file_path>/API Designer.app'
```

where:

- `<designer_credentials_file_path>` is the location to which you downloaded the API Designer credentials JSON file.
- `<designer_application_file_path>` is the location to which you downloaded and uncompressed the API Designer application.

7. Start the API Designer application from the location to where you stored the extracted file.

Note:

- To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
 - In Windows File Explorer, navigate to the USER_HOME\AppData\Local\Programs\api-designer folder.
 - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
- To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see [Developing your APIs and applications](#).

Logging in from API Designer

To log in from the API Designer user interface for IBM® API Connect, you will need the host name of the management server and the user name and password associated with your API Manager account.

About this task

API Designer provides a secure login to a management server for staging and publishing APIs and Products. You log in to the same host that was configured for API Manager and use your API Manager user name and password. You will need an account on API Manager and membership in a provider organization to access the API Designer.

You can also use the Explorer tab to see how your APIs look to a consumer in the Developer Portal. You can check the descriptions of the different artifacts, and refine any schemas or examples, and you can also use the Try it tool to test the behavior of the API.

Note:

- Configuration changes that are made in API Manager are not available in API Designer concurrently. You will need to log out of API Designer and log back in to access any updates.
- Set `SKIP_IBMID_LOGIN=true` as an environment variable to bypass the IBM ID login screen for API Designer. This applies to users who are working on an internal network, without access to external networks.

Procedure

To log in to API Designer, complete the following steps:

1. Download and extract API Designer, as described in [Installing the toolkit](#).
2. Start the API Designer user interface by running the application from the location where you extracted the contents of the toolkit compressed file.
Note: If you see a message stating that credentials cannot be found, download new credentials as explained in [Downloading the toolkit](#).
3. Optional: If you see the Accept License page, click the URL read the license agreement, then click the button to accept the license. This prompt appears only one time. It does not appear once you have accepted the license on the current system.
4. Optional: If you see the IBM ID login page, enter your IBM customer ID.
Note: You won't receive the IBM ID page if you are already authorized, or if you have set the `SKIP_IBMID_LOGIN` environment variable to `true`.
5. Open a directory on your local file system to store the API and Product specifications that you create in API Designer. The system defaults to a previously-accessed directory.
If you want to switch to a different directory after logging in, click Switch directory on the menu bar in the header.

Note: If you want to use an OpenAPI definition file from elsewhere, downloaded from an external website for example, rather than created by using API Connect, don't copy the file into your API Designer directory.

Such an API will **not** be visible in the API Designer user interface if it doesn't contain the API Connect specific sections that are required by API Designer.

Instead, copy the OpenAPI definition file to another folder, then import it into API Designer; the import operation adds the necessary API Connect specific sections; see [Adding a REST API by importing an OpenAPI definition file](#).

For more information on the API Connect specific sections in an OpenAPI definition file, see [IBM extensions to the OpenAPI specification](#).

6. If this is the first time you have logged in, establish a connection to API Connect by completing the following steps:
 - Contact your administrator and request the "management endpoint URL" for connecting to API Connect.
The management endpoint URL looks similar to the following example: `https://<host.domain>` and indicates the location where the API Manager is running.

Note: If you are using API Connect as a component of Cloud Pak for Integration, the management endpoint URL follows this format:
`https://cpd-your-company.domain/integration/apis/APIC_namespace/APIC_instance`

Example: `https://cpd-company.com/integration/apis/apic/production`

Do not add `/manager` to the URL. If you include `/manager` at the end of this URL, the connection with Cloud Pak for Integration will fail with a message stating that the host URL is invalid.
 - In the dialog window, enter the management endpoint URL as the Host URL and click Next.
 - Type the user name and password for your API Manager account.
 - Select a User Registry from the list.
 - Click Sign In.
7. For subsequent log ins, select the appropriate cloud where you will be working. You can select from any previous cloud connections.
8. When more than one cloud connection is configured, you can switch clouds when developing APIs and Products. See [Switching clouds from API Designer](#).
Note: If you are using an OIDC user registry that supports single sign-on (SSO), you cannot switch clouds to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then select the required cloud connection.
9. Click Add Another Cloud to add another cloud connection. Enter the URL, user name and password, and user registry to add the cloud connection.
Note: If you are using an OIDC user registry that supports single sign-on (SSO), and you are already logged in, you cannot add a new cloud connection to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then add the new cloud connection.
10. Delete a cloud connection by selecting the trash can icon.
11. API Designer will launch with the organization set to your provider organization in the selected cloud. If you have accounts for multiple provider organizations, it will default to the first organization in alphabetical order.
12. To choose another provider organization, select it from the drop-down list.

Setting the locale for API Designer

How to set one of the supported locales when you start the API Designer application.

About this task

If you want to use a different locale than your current operating system (OS) locale, you can set a locale code by using the `--lang` argument when you start the API Designer application. This locale is then effective for the duration that the application is open. If no `--lang` argument is set, then the current OS locale is used.

Procedure

To change the locale for API Designer, complete the following instructions.

From the command line, run the following command to start the API Designer application with the `--lang` argument:

Mac OS X Mac:

```
open "API Designer.app" --args --lang=locale_code
```

Windows Windows:

```
"API Designer".exe --args --lang=locale_code
```

Where *locale_code* is one of the following supported locale codes:

Table 1. List of supported locale codes and their associated language

Locale code	Language
cs	Czech
de	German (Standard)
en-US	English (United States)
es	Spanish
fr	French (Standard)
it	Italian (Standard)
ja	Japanese
ko	Korean
nl	Dutch (Standard)
pl	Polish
pt-br	Portuguese (Brazil)
ru	Russian
tr	Turkish
zh-cn	Chinese (PRC)
zh-tw	Chinese (Taiwan)

For example, running the following command on a Mac:

```
open "API Designer.app" --args --lang=es
```

sets the API Designer language to Spanish.

Switching clouds from API Designer

You can switch clouds to work in another cloud in API Designer.

About this task

API Designer allows the flexibility to connect to multiple clouds. For example, your organization may have separate clouds for testing, development, and demos. You select the cloud connection when you log in, but you can also switch clouds when you are developing APIs and Products. Multiple clouds must be configured in order to switch clouds. You must have a valid API Manager account to connect to a cloud.

Note: If you are using an OIDC user registry that supports single sign-on (SSO), you cannot switch clouds to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then select the required cloud connection.

Procedure

To switch clouds for working in API Designer, complete the following steps:

1. Log in to API Designer and select a cloud, or configure a new cloud connection.
2. From the Develop: APIs and Products screen, you can switch to another cloud by selecting it from the Switch Cloud Connection menu.
3. Delete a cloud connection by selecting the trash can icon.

Working offline with API Designer

You can work offline (without a connection to the cloud) with API Designer to create APIs. Some functionality is missing due to the lack of a cloud connection.

About this task

API Designer provides the capability to work in offline mode without a connection to a management server. You can work on APIs with no management server, but some functions will be changed or missing.

The preferred method for working in API Designer is with a Cloud Connection to the management server when logging into API Designer. Working while connected to a management server provides full functionality, with automatic field completion. When working offline, you will need to remember the values to complete the fields that are backfilled from the management server.

Following are the differences when working in offline mode:

- There is no connection to a management server.
- There is no Provider Organization selection.
- Only the Develop APIs and Products tile may be selected. The Learn more and Connect menu tiles are not available.
- When creating an API, the Gateway Type defaults to V5 Gateway and the default policies are loaded.
- Stage and Publish for APIs and Products functions are not available.
- The Sandbox catalog is not available.
- When configuring a Security Definition, there are no selection lists available for the User Registry for a Basic Auth security definition or for the OAuth Provider for an OAuth 2 security definition. You will need to enter the User Registry and OAuth Provider values correctly as text.
- When adding custom Visibility and custom Subscribability values for a product, there is no selection list for the Organization field. You will need to enter the organization name correctly as text.

Procedure

To work in offline mode in API Designer, complete the following steps:

1. Log in to API Designer and open a directory location.
2. To start offline mode, choose Work Offline from the selector in the upper right corner of the Connect to Cloud screen.
3. The Home page appears with the Develop APIs and Products tile. Select Develop APIs and Products to start working in offline mode.
4. To return to online mode, choose Connect to Cloud in the upper right hand corner and select the management server to log in to.

Gathering support information in API Designer

When you report an issue with the API Designer application, enable debug mode and provide as much information as possible.

To report an issue with API Designer, enable debug mode, collect the recommended information, and submit it with your report. Including the information will help IBM resolve the problem more quickly.

- [Enabling debug mode on Mac](#)
- [Enabling debug mode on Windows](#)
- [Enabling debug mode on Linux](#)
- [Information to gather for support](#)

Enabling debug mode on Mac

Start API Designer with debug mode enabled:

1. Start a terminal or command prompt.
2. Navigate to the directory where API Designer is installed.

3. Run the following command to start API Designer in debug mode:

```
DESIGNER_DEBUG=true open API/Designer.app/
```

If you add `DESIGNER_DEBUG=true` to your `.bash_profile`, then every time you start API Designer it will open in debug mode.

Enabling debug mode on Windows

Add a Windows environment variable that enables debug mode for API Designer:

1. Type "Environment" in the Windows search bar (on the task bar) and select Edit environment variables for your account.
2. In the Environment Variables dialog box, click New in the "User variables" section.
3. In the New User Variable dialog box, add the following variable settings and then click OK:
 - Variable name: `DESIGNER_DEBUG`
 - Variable value: `True`
4. Click OK to save your change.

Enabling debug mode on Linux

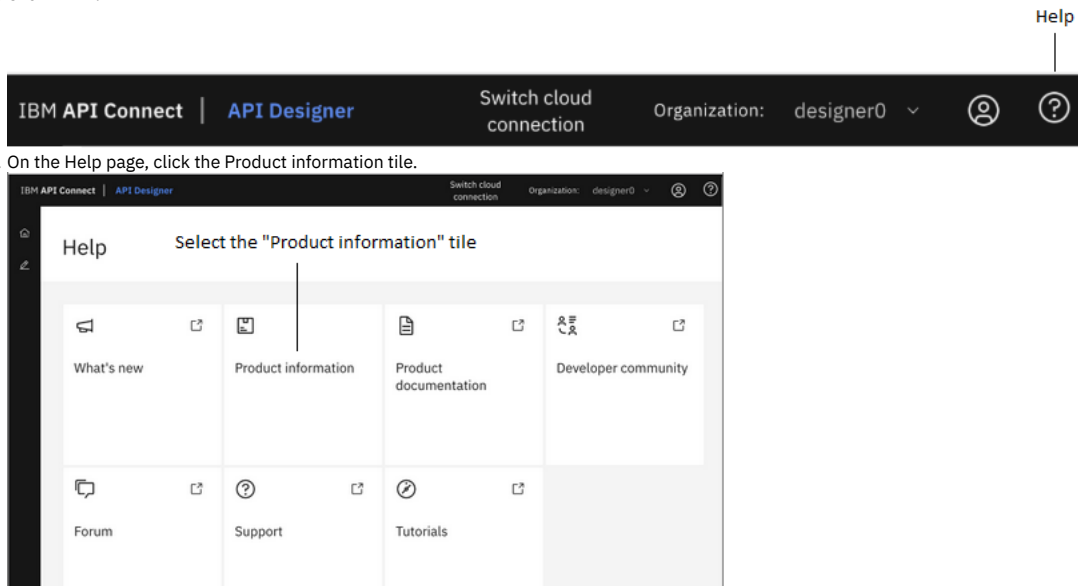

To start API Designer with debug mode enabled, add the following command to your `.bash_profile`:

```
EXPORT DESIGNER_DEBUG=true
```

Information to gather for support

Gather the following information about your problem and include it with your report.

- Operating system where you are running API Designer (Mac, Windows, or Linux)
- Product versions for API Designer and the API Manager that is connects to:
 1. Open API Designer.
 2. Click .

3. On the Help page, click the Product information tile.

4. On the Product information page, note down the following values for the following labels on the page:
 - Connected to API Manager Product version
 - Package

Product information	
API Manager version	Connected to API Manager Product version 10.0.3.0
Git information	
API Designer package version	Git 9affdfeeb3855c194edabdb933e1ee3c6f2afdbb
	Package 1.0.0
	api-client 0.2.3
	apim-sdk 5.0.31
	assembly-debugger 0.1.38
	async-api-editor 1.0.5
	doc-types 0.1.20

- HAR file
The HAR file contains the information about your browser's interaction with the web, and can be helpful in determining why your problem is happening. Complete the following steps to export the HAR file from the browser where you use API Designer:
 1. Open API Designer.
 2. Open the browser's developer console; for example in Google Chrome, click  More tools > Developer tools.
 3. In the developer console, click the Network tab.
 4. Click  to download the HAR file.
- Are you using API Designer in Online mode or Offline mode?
If you're using Online mode, are you connecting to a local test environment, or to an API Manager server?
- When does the problem happen?
Provide reproducible steps with optional screen captures or video so the support team can recreate the problem.
- Supporting data.
Provide any related data that would be useful while examining the problem; for example, a copy of the API or Product that you were using.
- How often does the problem happen?
Is the problem intermittent? Does it happen constantly? Does it only happen with certain artifacts (for example, only with a particular API)? If the problem is associated with an artifact, try to include it with your report.

Using the developer toolkit command-line tool

The IBM® API Connect developer toolkit provides a command-line tool, `apic`, that you can use to perform all API Connect tasks. You can also use the command-line tool to script tasks such as continuous integration and delivery.

The command line tool is described in detail in the following subtopics. For summary reference material for each of the available commands for the developer toolkit, see [Command-line tool reference for the developer toolkit](#).

- [Overview of the command-line tool](#)
The IBM API Connect developer toolkit provides commands for cloud administration and API development and management.
- [Logging in to a management server](#)
You log in to a management server from the command line by using the `apic login` command. The parameters that you supply determine the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in.
- [Logging in to a management server with an OIDC registry](#)
Logging in with an OIDC registry involves several steps, in which you obtain a temporary token and pass it to the toolkit to ensure it can communicate securely with the management server.
- [Cloud administration commands](#)
A summary of the cloud administration commands in the IBM API Connect developer toolkit.
- [API development and management commands](#)
A summary of the core commands in the IBM API Connect developer toolkit.
- [Creating APIs and applications](#)
You can develop API proxies and API implementations by using the developer toolkit. In the documentation, *API* refers to the API proxy and *application* refers to the API implementation.
- [Publishing APIs and applications](#)
To publish APIs and applications by using the developer toolkit of IBM API Connect, you set configuration variables to define where you want to publish, log in to the target cloud platform, and then use the appropriate publishing commands.
- [Managing API Products](#)
Use the `apic products` and `apic apis` commands to manage Products and APIs that have been published to IBM API Connect Catalogs. Use the `--scope space` option to manage Products and APIs that have been published to Spaces within Catalogs.

- [Working with Drafts](#)
Co-locate your APIs and applications in your local source code control systems to support typical development activities such as commits, branching, merges, continuous integration, and so on. The developer toolkit provides the bridge from the developer's environment to the IBM API Connect runtime services.
- [Reading input from the command line](#)
If a developer toolkit command takes a file as an input parameter, you can direct the command to read the input directly from the command line rather than supplying a separate file; this can be useful when writing scripts to automate command line operations, for example.
- [Scripting with the toolkit commands](#)
The IBM API Connect developer toolkit provides commands for cloud administration and API development and management.
- [Working with OpenAPI extensions](#)
Use the developer toolkit CLI **extensions** commands to manage OpenAPI extensions in your Catalogs or Spaces.

Overview of the command-line tool

The IBM® API Connect developer toolkit provides commands for cloud administration and API development and management.

Command syntax

In general, commands have the following syntax:

```
apic command:sub-command [argument] [options]
```

where

- *command* is the command, usually the thing on which you are acting (for example, product, app, API, Catalogs, and so on).
- *sub-command* is the action to perform.
- *argument* is the argument, where applicable (for example, `catalog`).
- *options* are any number of command-line options, which have the form `--option [value]`. Options also have a short form with a single dash instead of a double dash.

For example, `apic apps:publish --server mgmthost.com`.

For some commands, either the command or sub-command portion is optional. For example:

- `apic products:publish` is equivalent to `apic publish`.
- `apic products:list` is equivalent to `apic products`.

The `create` command has a slightly different syntax:

```
apic create:type [options]
```

Use the `-h` or `--help` option to view command help.

Note: The language in which the CLI help text, and other command response text, is displayed is determined by the locale setting on your local machine.

Viewing command line tool help

Display general command-line help information by entering the following command: `apic --help` or `apic -h`. Display help information for a specific `apic` command by entering the following command: `apic command_name --help` or `apic command_name -h`.

Viewing version information

Display the version of the command-line tool by entering the command: `apic --version`.

Setting the mode

The API Connect toolkit CLI runs commands on either the provider organization or on the consumer organization. When you run the command, you use the different mode options to identify the instance on which you want to run the command. The following list provides a summary of the modes that are available:

apim

This mode applies to the administrative instances of the CLI. When you run commands in this mode, it uses the overall API Manager as its scope. This mode is the default mode.

An example of running a command in the apim mode:

```
apic extensions:list-all --mode apim --scope catalog --server server1 --catalog catalog1 --org myOrg --configured-gateway-service service1
```

portaladmin

This mode applies to the developer portal instances of the CLI. This mode supports commands that you can use to replicate all or part of your Developer Portal environment.

An example of running a command in the portaladmin mode:

```
apic --mode portaladmin custom-theme:create-export --catalog catalog1 --org myOrg --server server1 --format json
```

consumer

This mode applies to the consumer instances of the CLI. This command uses the consumer organizations that you have permission to access as its scope. You must specify this mode or set it as the default value for the command to use it.

An example of running a command in the consumer mode:

```
apic catalogs:list --mode consumer --scope catalog --server server1 --catalog catalog1 --org myOrg
```

To avoid having to supply the parameter on every consumer CLI command, you can set the `mode` configuration variable, as described in the next section.

Using configuration variables

You can set the values of commonly-used properties in configuration variables. In general, it's easier and more consistent to set configuration variables instead of specifying them using command-line options.

Note:

You can set a configuration variable locally (the default) to affect only the current LoopBack project, or globally (with command-line option `-g`), to affect all projects. The local value supersedes the global value. You can set local configuration variables only for LoopBack projects. When you set configuration variables for OpenAPI projects, they are always global.

The values of local configuration variables are stored in the `project-root/.apiconnect/config` file, where `project-root` is the project root directory. The values of global configuration variables are stored in the `user-home-dir/.apiconnect/config` file, where `user-home-dir` is the user's home directory.

Use the following commands to work with configuration variables:

- `apic config:get varname` - Get a configuration variable. Use `apic config` to display the values of all local configuration variables or `apic config -g` to display the values of all global configuration variables.
- `apic config:set varname` - Set or update the specified configuration variable.
- `apic config:delete varname` - Delete the specified configuration variable.
- `apic config:clear` - Delete all configuration variables.

You set configuration property values by using the `apic config:set` command. By setting configuration properties (for example `catalog` and `app`), you do not need to supply values for these options when you enter a command.

Additionally, you can use `apic properties` commands to work with configuration properties:

- `apic properties:clear` - Clear the configuration properties.
- `apic properties:create` - Augment the configuration properties with additional name/value pairs.
- `apic properties:delete` - Delete the configuration property.
- `apic properties:get` - Get the configuration property.
- `apic properties:list` - List the configuration properties.
- `apic properties:update` - Update the configuration property.

Note:

If you have an environment variable of the same name as a CLI configuration property then, by default, its value will override the value of the corresponding CLI configuration property for any CLI command at that scope.

For example, if you have defined an environment variable called `SPACE` then, by default, that value will be assumed for the value of the `--space` parameter in the following command, regardless of any `space` configuration property setting:

```
apic products:publish my_product.yaml --scope space
```

To prevent environment variables overriding CLI configuration properties, define an environment variable called `APIC_LOAD_FROM_ENV`, set to the value `false`.

The following table describes the configuration variables:

Table 1. Configuration variables

Variable name	Description	Use instead of (or override with) these flags...
catalog	Default Catalog URI for all commands that manage aspects of a Catalog. Form: <code>mgmt-server/api/catalogs/org-name/catalog-name</code> , where <code>mgmt-server</code> is the management server, <code>org-name</code> is the organization name, and <code>catalog-name</code> is the Catalog name. Note: The Catalog name <code>apic-dev</code> is reserved for local testing.	--catalog, --organization, --server
cloud	Default management server host name for cloud administration commands. Form: <code>mgmt-server/api/</code> .	--server
consumer	Default URI of an API consumer. Form: <code>mgmt-server/api/consumer-orgs/org-name/catalog-name/consumer-org-name</code> , where <code>mgmt-server</code> is the management server, <code>org-name</code> is the organization name, <code>catalog-name</code> is the Catalog name, and <code>consumer-org-name</code> is the consumer organization name.	--server, --organization, --catalog, --consumer
mode	The default value of the <code>--mode</code> parameter for CLI commands. Set the value to <code>apim</code> or <code>consumer</code> depending on whether you want to run commands on a provider organization or a consumer organization. If you do not set this variable, and do not supply a <code>--mode</code> parameter on a command, the value <code>apim</code> is assumed.	--mode
org	Default org URI for all commands that manage organizations. Form: <code>mgmt-server/api/orgs/org-name</code> , where <code>mgmt-server</code> is the management server, <code>org-name</code> is the organization name. The <code>mgmt-server</code> portion sets the default value of the <code>--server</code> option. You can append the port number to the server name if it is not the default value of 443.	--organization, --server
space	Default Space URI for all commands that manage aspects of a Space. Form: <code>mgmt-server/api/spaces/org-name/catalog-name/space-name</code> , where <code>mgmt-server</code> is the management server, <code>org-name</code> is the organization name, <code>catalog-name</code> is the Catalog name, and <code>space-name</code> is the Space name. You can append the port number to the server name if it is not the default value of 443.	--server, --organization, --catalog, --space

To set configuration properties, enter the following command:

```
apic config:set name=value
```

where `name` is the name of the configuration property and `value` the value to assign to it.

For example:

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
```

Scripting commands

It's often helpful to automate a series of `apic` commands in a shell script. Since the `apic` tool first requires you to interactively accept the license, you must first use the following command:

```
apic --accept-license
```

Once you do that, your scripts can run non-interactively.

To disable collection of usage analytics, enter this command:

```
apic --live-help
```

Related information

- [Command-line tool reference for the developer toolkit](#)

Logging in to a management server

You log in to a management server from the command line by using the `apic`

`login` command. The parameters that you supply determine the identity provider that is used to authenticate the supplied user ID, and the scope of the tasks that can be performed after successful log in.

Attention: If you want to log in with an OIDC user registry or if you are an IBM Cloud Pak for Integration (CP4I) user, see [Logging in to a management server with an OIDC registry](#).

1. Clear the credentials from any previous login by running the following command:

```
apic client-creds:clear
```

Clearing the credentials ensures that you do not inadvertently log in with the wrong set of credentials (for example, from a different product release or environment).

2. Set the credentials that you want to use now by running the following command:

```
apic client-creds:set path_to_credentials/credential.json
```

where `path_to_credentials` is the location of the `credential.json` file that you want to use. For example:

```
apic client-creds:set /Users/local_user/credential.json
```

3. Log in by running the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm realm
```

The parameters for the `apic login` command are as follows:

mgmt_endpoint_url

The URL depends on the type of organization that you are logging in with:

- Cloud admin organization or Provider organization: Use one of the following URLs:
 - platform API endpoint URL
 - management API manager URL
- Consumer organization: Use the consumer API endpoint URL

These endpoint URLs are configured during the installation of API Connect. If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in [Viewing platform and UI endpoints](#), ignoring any segments at the end of the displayed URLs. If you are not sure of the endpoint URL, ask your administrator.

user_id

The user ID you want to log in with. Depending on the tasks that you want to perform, this user ID might be any of the following:

- A user ID that is a member of the cloud administration organization. This is an ID that you could also use to log in to the Cloud Manager user interface.
- A user ID that is a member of a provider organization. This is an ID that you could also use to log in to the API Manager user interface.
- A user ID that is a member of a consumer organization. This is an ID that you could also use to log in to the Developer Portal.

password

The password associated with the supplied user ID.

realm

The `realm` parameter specifies the identity provider that is used to authenticate the supplied user ID, and the scope of the tasks that can be performed after successful log in.

The format of the `realm` depends on the type of user, as follows:

- Member of the cloud administration organization:

```
admin/identity_provider
```

To determine the identity provider, see [How to determine the identity provider](#).

- Member of a provider organization:

```
provider/identity_provider
```

To determine the identity provider, see [How to determine the identity provider](#).

- Member of a consumer organization:

```
consumer:provider_org:catalog/identity_provider
```

where *provider_org* is the name of your provider organization, and *catalog* is the name of the Catalog in that provider organization. To determine the identity provider, see [How to determine the identity provider](#).

Important:

- If you have installed toolkit credentials, as detailed in [Installing the toolkit](#), then at any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.

To revert to the default pre-supplied toolkit credentials for all login operations from the toolkit CLI, use the following command:

```
apic client-creds:clear
```

- If you log in to the CLI as a member of a consumer organization, you must supply the `--mode=consumer` parameter to the `apic login` command, and to all consumer commands. To avoid having to type the parameter every time, you can set the `mode` configuration variable, by entering the following command:

```
apic config:set mode=consumer
```

You can also use the command interactively; enter `apic login` and you will be prompted for the values. For example:

```
apic login
Enter your API Connect credentials
Server? platform-api.myserver.com
Realm? provider/default-idp-2
Username? myuser
Password?
Logged into myserver.com successfully
```

Note: If you see a message stating that credentials cannot be found, download new credentials as explained in [Downloading the toolkit](#).

How to determine the identity provider

If you want to log in as a member of the cloud administration organization, or as a member of a provider organization, you can help determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope scope --server mgmt_endpoint_url --fields title,realm
```

where *scope* has the value `admin` or `provider` depending on whether you want to log in as a member of the cloud administration organization, or as a member of a provider organization. The output lists the names and titles of all identity providers, for example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
- title: Cloud Manager User Registry
  realm: admin/default-idp-1
- title: Corporate LDAP user registry
  realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`, and the default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.

By default, API Connect creates a local user registry for user login for every context. The identity providers associated with these default registries are as follows:

Registry	Identity provider name
Cloud Manager Local User Registry (for login as a member of the cloud administration organization)	default-idp-1
API Manager Local User Registry (for login as a member of a provider organization)	default-idp-2
Sandbox Catalog User Registry (for login as a member of a consumer organization)	sandbox-idp

If you want to log in as a member of a consumer organization, see [Logging in as a consumer to the Developer Portal by using the CLI](#) for full details.

Logging out

To log out of a management server, use the following command:

```
apic logout --server mgmt_endpoint_url
```

Logging in to a management server with an OIDC registry

Logging in with an OIDC registry involves several steps, in which you obtain a temporary API token and pass it to the toolkit to ensure it can communicate securely with the management server.

Attention: Logging in with an OIDC registry is supported for the developer toolkit (used with API Manager) and the Developer Portal admin toolkit, but is not supported for members of consumer organizations. If you are using IBM Cloud Pak for Integration (CP4I), review this topic for login instructions. If you want to log in using a non-OIDC registry, see [Logging in to a management server](#).

To log in, complete the following steps:

1. Clear the credentials from any previous login by running the following command:

```
apic client-creds:clear
```

Clearing the credentials ensures that you do not inadvertently log in with the wrong set of credentials (for example, from a different product release or environment).

2. Set the credentials that you want to use now by running the following command:

```
apic client-creds:set path_to_credentials/credential.json
```

where `path_to_credentials` is the location of the `credential.json` file that you want to use. For example:

```
apic client-creds:set /Users/local_user/credential.json
```

3. Log in by running the following command:

```
apic login --server mgmt_endpoint_url --sso
```

where `mgmt_endpoint_url` is the endpoint URL. When you log in with a Cloud admin or Provider organization, specify one of the following URLs:

- platform API endpoint URL
- management API manager URL

These endpoint URLs are configured during the installation of API Connect. If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in [Viewing platform and UI endpoints](#), ignoring any segments at the end of the displayed URLs. If you are not sure of the endpoint URL, ask your administrator.

CP4I: If you are using API Connect as a component of IBM Cloud Pak for Integration (CP4I), your administrator can provide the correct URL.

4. When the toolkit prompts for the context, type **admin** API Connect (administrators) or **provider** (everyone else):

```
Context? provider
```

5. The server responds with the following message:

```
Please copy and paste the url https://mgmt_endpoint_url/auth/manager/sign-in/?from=TOOLKIT to a browser to start the authentication process.
Do you want to open the url in default browser? [y/n]: y
```

Take one of the following actions:

- If you want to use your default browser to log in to API Manager, type **y** and press Enter. The API Manager sign-in page opens in a new browser tab.
- If you don't use to use your default browser, type **n** and press Enter.
 - Copy the URL from the command window.
 - Open a browser, paste the URL, and press Enter. The API Manager sign-in page displays.

6. On the API Manager sign-in page, select the OIDC registry and then log in to API Connect.

CP4I: Select the Common Services User Registry.

After you log in, API Connect displays the "You are authenticated!" message and provides a temporary token. Copy the token.

7. Return to the command window. Paste the token at the **API Key?** prompt and press Enter.

When the token is validated and you are successfully logged in to the toolkit, the following message displays:

```
Warning: Using default toolkit credentials.
Logged into mgmt_endpoint_url successfully
```

Note: If you see a message stating that credentials cannot be found, download new credentials as explained in [Downloading the toolkit](#).

Logging out

To log out of a management server, use the following command:

```
apic logout --server mgmt_endpoint_url
```

Cloud administration commands

A summary of the cloud administration commands in the IBM® API Connect developer toolkit.

Authenticating

Use the `apic login` command to authenticate to an API Manager service, and the `apic logout` command to remove your local authentication credentials.

Note: When you authenticate successfully, your credentials are stored, in plain text, in the file `Linux .netrc` or `Windows _netrc`. You should therefore set the file permissions in such a way that your credentials are not accessible by others.

For full details on how to log in to your management server from the CLI, see [Logging in to the management server](#).

Configuring the command-line tool to use TLS certificates

API Manager uses TLS profiles to secure data transmission. For information on how to create a TLS profile in API Manager, see [TLS profiles](#).

To configure the toolkit command-line tool to use certificates to communicate with an API Manager that has TLS profiles enabled, follow these steps:

For more information about the `NODE_EXTRA_CA_CERTS` environment variable, see [Node.js documentation](#).

Note: When using any CLI command that applies directly to the configuration of your IBM API Connect cloud, you must supply the parameter setting `--org admin` for a command that requires an organization name as a parameter.

Command summary

The following tables summarize **apic** commands for cloud administration.

Table 1. Summary commands for cloud administrators

Command	Description	Sub-commands
apic analytics-services	Analytics Service commands	<ul style="list-style-type: none"> • apic analytics-services - Analytics Service collection operations. • apic analytics-services:clear - Clear the Analytics Services. • apic analytics-services:create - Create a Analytics Service. • apic analytics-services:delete - Delete the Analytics Service by name or ID. • apic analytics-services:get - Get the Analytics Service by name or ID. • apic analytics-services:list - List the Analytics Services. • apic analytics-services:update - Update the Analytics Service by name or ID.
apic associates	Associates commands	<ul style="list-style-type: none"> • apic associates - Associate collection operations. • apic associates:get - Get the Associate by name or ID. • apic associates:list - List the Associates.
apic availability-zones	Availability Zone commands	<ul style="list-style-type: none"> • apic availability-zones - Availability Zone collection operations. • apic availability-zones:clear - Clear the Availability Zones. • apic availability-zones:create - Create a Availability Zone. • apic availability-zones:delete - Delete the Availability Zone by name or ID. • apic availability-zones:get - Get the Availability Zone by name or ID. • apic availability-zones:list - List the Availability Zones. • apic availability-zones:update - Update the Availability Zone by name or ID.
apic cloud-settings	Cloud settings commands	<ul style="list-style-type: none"> • apic cloud-settings:get - Get the Cloud Setting. • apic cloud-settings:mail-server-configured - indicates whether a mail server has been configured. • apic cloud-settings:topology - Returns summary details of the configuration of your cloud topology. • apic cloud-settings:update - Update the Cloud Setting.
apic configured-gateway-services	Commands for Configured Gateway Services in a Catalog or Space.	<ul style="list-style-type: none"> • apic configured-gateway-services - Configured Gateway Services operations. • apic configured-gateway-services:clear - Delete all Configured Gateway Services from a Catalog or Space. • apic configured-gateway-services:create - Configure a Gateway Service in a Catalog or Space. • apic configured-gateway-services:delete - Delete a Configured Gateway Service from a Catalog or Space. • apic configured-gateway-services:get - Obtain the details of a Configured Gateway Service in a Catalog or Space. • apic configured-gateway-services:list - List the Configured Gateway Services in a Catalog or Space.
apic credentials	Credential commands	<ul style="list-style-type: none"> • apic credentials - Application Credential collection operations. • apic credentials:clear - Clear the Application Credentials. • apic credentials:create - Create a Application Credential. • apic credentials:delete - Delete the Application Credential by name or ID. • apic credentials:get - Get the Application Credential by name or ID. • apic credentials:list - List the Application Credentials. • apic credentials:reset - Reset the client id and client secret. • apic credentials:reset-client-secret - Reset the client secret. • apic credentials:update - Update the Application Credential by name or ID. • apic credentials:verify-client-secret - Verify the client secret.
apic extensions	Extension commands	<ul style="list-style-type: none"> • apic extensions - Extension collection operations. • apic extensions:document - Get the document for an extension by id, or by name and version. • apic extensions:get - Get an extension by id, or by name and version. • apic extensions:list - List all versions of an extension given the name. • apic extensions:list-all - List all versions of all extensions.
apic gateway-services	Gateway service commands	<ul style="list-style-type: none"> • apic gateway-services - Gateway Service collection operations. • apic gateway-services:clear - Clear the Gateway Services. • apic gateway-services:create - Create a Gateway Service. • apic gateway-services:delete - Delete the Gateway Service by name or ID. • apic gateway-services:get - Get the Gateway Service by name or ID. • apic gateway-services:list - List the Gateway Services. • apic gateway-services:reset-oauth-secret - Reset the OAuth cryptographic • apic gateway-services:update - Update the Gateway Service by name or ID.

Command	Description	Sub-commands
apic integrations	Integrations commands	<ul style="list-style-type: none"> • apic integrations - Integration collection operations. • apic integrations:clear - Clear the Integrations. • apic integrations:clear-all - Clear all of the Integrations in all of the collections. • apic integrations:create - Create a Integration. • apic integrations:delete - Delete the Integration by name or ID. • apic integrations:get - Get the Integration by name or ID. • apic integrations:list - List the Integrations. • apic integrations:list-all - List all Integrations in all collections. • apic integrations:update - Update the Integration by name or ID.
apic keystores	Keystores commands	<ul style="list-style-type: none"> • apic keystores - Keystore collection operations. • apic keystores:clear - Clear the Keystores. • apic keystores:create - Create a Keystore. • apic keystores:delete - Delete the Keystore by name or ID. • apic keystores:get - Get the Keystore by name or ID. • apic keystores:list - List the Keystores. • apic keystores:update - Update the Keystore by name or ID.
apic mail-servers	Mail server commands	<ul style="list-style-type: none"> • apic mail-servers - Mail Server collection operations. • apic mail-servers:clear - Clear the Mail Servers. • apic mail-servers:create - Create a Mail Server. • apic mail-servers:delete - Delete the Mail Server by name or ID. • apic mail-servers:get - Get the Mail Server by name or ID. • apic mail-servers:list - List the Mail Servers. • apic mail-servers:test-connection - Test a mail server connection. • apic mail-servers:update - Update the Mail Server by name or ID.
apic notification-templates	Notification template commands	<ul style="list-style-type: none"> • apic notification-templates - Notification Template collection operations. • apic notification-templates:get - Get the Notification Template by name or ID. • apic notification-templates:list - List the Notification Templates. • apic notification-templates:list-all - List all Notification Templates in all collections. • apic notification-templates:update - Update the Notification Template by name or ID.
apic permissions	Permissions commands	<ul style="list-style-type: none"> • apic permissions - Permission collection operations. • apic permissions:get - Get the Permission by name or ID. • apic permissions:list - List the Permissions. • apic permissions:list-all - List all Permissions in all collections.
apic portal-services	Portal services commands	<ul style="list-style-type: none"> • apic portal-services - Portal Service collection operations. • apic portal-services:clear - Clear the Portal Services. • apic portal-services:create - Create a Portal Service. • apic portal-services:delete - Delete the Portal Service by name or ID. • apic portal-services:get - Get the Portal Service by name or ID. • apic portal-services:list - List the Portal Services. • apic portal-services:update - Update the Portal Service by name or ID.
apic services	Services commands	<ul style="list-style-type: none"> • apic services - Service collection operations. • apic services:clear - Clear the Services. • apic services:clear-all - Clear all Services in all collections. • apic services:create - Create a Service. • apic services:delete - Delete a Service. • apic services:get - Get the Service by name and version. • apic services:list - List the Services. • apic services:list-all - List all Services in all collections. • apic services:update - Update the Service by name and version.
apic space-settings	Space settings commands	<ul style="list-style-type: none"> • apic space-settings:get - Get the Space Setting. • apic space-settings:update - Update the Space Setting.
apic spaces	Space commands	<ul style="list-style-type: none"> • apic spaces - Space collection operations. • apic spaces:clear - Clear the Spaces. • apic spaces:create - Create a Space. • apic spaces:delete - Delete the Space by name or ID. • apic spaces:get - Get the Space by name or ID. • apic spaces:list - List the Spaces. • apic spaces:transfer-owner - Transfer owner to a new member. • apic spaces:update - Update the Space by name or ID.

Command	Description	Sub-commands
<code>apic tls-client-profiles</code>	TLS client profile commands	<ul style="list-style-type: none"> • <code>apic tls-client-profiles</code> - TLS Client Profile collection operations. • <code>apic tls-client-profiles:clear</code> - Clear the TLS Client Profiles. • <code>apic tls-client-profiles:clear-all</code> - Clear all of the TLS Client Profiles in the collection. • <code>apic tls-client-profiles:create</code> - Create a TLS Client Profile. • <code>apic tls-client-profiles:delete</code> - Delete the TLS Client Profile by name or ID. • <code>apic tls-client-profiles:get</code> - Get the TLS Client Profile by name or ID. • <code>apic tls-client-profiles:list</code> - List the TLS Client Profiles. • <code>apic tls-client-profiles:list-all</code> - Lists all of the TLS Client Profiles in a collection. • <code>apic tls-client-profiles:update</code> - Update the TLS Client Profile by name or ID.
<code>apic tls-server-profiles</code>	TLS server profile commands	<ul style="list-style-type: none"> • <code>apic tls-server-profiles</code> - TLS Server Profile collection operations. • <code>apic tls-server-profiles:clear</code> - Clear the TLS Server Profiles. • <code>apic tls-server-profiles:clear-all</code> - Clear all of the TLS Server Profiles in the collection. • <code>apic tls-server-profiles:create</code> - Create a TLS Server Profile. • <code>apic tls-server-profiles:delete</code> - Delete the TLS Server Profile by name or ID. • <code>apic tls-server-profiles:get</code> - Get the TLS Server Profile by name or ID. • <code>apic tls-server-profiles:list</code> - List the TLS Server Profiles. • <code>apic tls-server-profiles:list-all</code> - List all of the TLS Server Profiles in the collection. • <code>apic tls-server-profiles:update</code> - Update the TLS Server Profile by name or ID.
<code>apic truststores</code>	Truststore commands	<ul style="list-style-type: none"> • <code>apic truststores</code> - Truststore collection operations. • <code>apic truststores:clear</code> - Clear the Truststores. • <code>apic truststores:create</code> - Create a Truststore. • <code>apic truststores:delete</code> - Delete the Truststore by name or ID. • <code>apic truststores:get</code> - Get the Truststore by name or ID. • <code>apic truststores:list</code> - List the Truststores. • <code>apic truststores:update</code> - Update the Truststore by name or ID.
<code>apic user-registries</code>	User registry commands	<ul style="list-style-type: none"> • <code>apic user-registries</code> - User Registry collection operations. • <code>apic user-registries:clear</code> - Clear the User Registries. • <code>apic user-registries:create</code> - Create a User Registry. • <code>apic user-registries:delete</code> - Delete the User Registry by name or ID. • <code>apic user-registries:execute</code> - Execute a User Registry operation. • <code>apic user-registries:get</code> - Get the User Registry by name or ID. • <code>apic user-registries:list</code> - List the User Registries. • <code>apic user-registries:search</code> - search for users in a user registry. • <code>apic user-registries:test-connection</code> - Test a User Registry connection. • <code>apic user-registries:update</code> - Update the User Registry by name or ID.
<code>apic user-registry-settings</code>	User registry settings commands	<ul style="list-style-type: none"> • <code>apic user-registry-settings:get</code> - Get the User Registry Setting. • <code>apic user-registry-settings:update</code> - Update the User Registry Setting.
<code>apic users</code>	Users commands	<ul style="list-style-type: none"> • <code>apic users</code> - User collection operations. • <code>apic users:clear</code> - Clear the Users. • <code>apic users:create</code> - Create a User. • <code>apic users:delete</code> - Delete the User by name or ID. • <code>apic users:get</code> - Get the User by name or ID. • <code>apic users:list</code> - List the Users. • <code>apic users:request-password-reset</code> - send a password reset link. • <code>apic users:search-provider</code> - Search for provider users from an organization. • <code>apic users:update</code> - Update the User by name or ID.
<code>apic webhooks</code>	Webhooks commands	<ul style="list-style-type: none"> • <code>apic webhooks</code> - Webhooks collection operations. • <code>apic webhooks:get</code> - Get the Webhooks by name or ID. • <code>apic webhooks:list</code> - List the Webhooks. • <code>apic webhooks:update</code> - Update the Webhooks by name or ID.

API development and management commands

A summary of the core commands in the IBM® API Connect developer toolkit.

Authenticating

Use the `apic login` command to authenticate to an API Manager service, and the `apic logout` command to remove your local authentication credentials.

Note: When you authenticate successfully, your credentials are stored, in plain text, in the file `Linux` `.netrc` or `Windows` `_netrc`. Therefore, you should set the file permissions in such a way that your credentials are not accessible by others.

For full details on how to log in to your management server from the CLI, see [Logging in to the management server](#).

Configuring the command-line tool to use TLS certificates

API Manager uses TLS profiles to secure data transmission. For information on how to create a TLS profile in API Manager, see [TLS profiles](#).

To configure the toolkit command-line tool to use certificates to communicate with an API Manager that has TLS profiles that are enabled, follow these steps:

For more information about the `NODE_EXTRA_CA_CERTS` environment variable, see [Node.js documentation](#).

Creating and managing local files

You create and work with API and Product definition YAML files locally before you stage them to API Manager.

To create a local API definition file, use the `apic create:api` command. To create a local Product definition file, use the `apic create:product` command.

Use the `apic apis` and `apic products` commands to list API Manager artifacts of the specified type.

To validate the syntactical correctness of a local API or Product definition file, use the `apic validate` command.

To create a draft API in API Manager from a local API or Product definition file, use the `apic draft-apis:create` and `apic draft-products:create` commands, respectively.

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before an API is validated, created in draft, staged, or published. For more information, see [Using \\$ref to reuse code fragments in your OpenAPI files](#).

Working with Catalogs and Spaces

To create a Catalog, use the `apic catalog:create` command. To view information on a Catalog, use the `apic catalog:get` command; to list all Catalogs that are contained in organizations that the currently authenticated user is a member of, use the `apic catalogs` command.

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a subcatalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see [Using syndication in IBM API Connect](#).

To enable Spaces for a Catalog, use the following command:

```
apic catalogs:set catalog_name --spaces enabled
```

Use the toolkit `apic spaces` commands to create and manage Spaces:

- `apic spaces` - List Spaces contained in a Catalog.
- `apic:spaces create` - Create a Space in a Catalog.
- `apic:spaces get` - Get information on a Space in a Catalog.
- `apic:spaces set` - Set information on a Space in a Catalog.
- `apic:spaces delete` - Delete a Space in a Catalog.

Command summary

The following tables summarize `apic` commands for API development and management.

Table 1. Summary of general-purpose commands

Command	Description	Subcommands
<code>apic config</code>	List and manage configuration variables. For more information, see Using configuration variables . With no subcommand, lists values of defined configuration variables.	<ul style="list-style-type: none">• <code>apic config</code> - Manage configuration variables• <code>apic config:clear</code> - Delete all configuration variables• <code>apic config:delete</code> - Delete a configuration variable• <code>apic config:get</code> - Get a configuration variable• <code>apic config:list</code> - List the application and global configuration variables• <code>apic config:set</code> - Set or update configuration variables
<code>apic create</code>	Create a draft API or Product definition YAML file.	<ul style="list-style-type: none">• <code>create:api</code> - Create a draft API OpenAPI definition YAML file• <code>create:product</code> - Create a Product definition YAML file

Command	Description	Subcommands
<code>apic extensions</code>	Manage OpenAPI extensions in a Catalog. With no subcommand, lists the extensions in the production Catalog.	<ul style="list-style-type: none"> • <code>apic extensions</code> - Extension collection operations. • <code>apic extensions:clear</code> - Delete all versions of an extension given the name. • <code>apic extensions:clear-all</code> - Delete all versions of all extensions. • <code>apic extensions:clone</code> - Download all versions of all extensions to your local drive. • <code>apic extensions:create</code> - Create an extension. • <code>apic extensions:delete</code> - Delete an extension by ID, or by name and version. • <code>apic extensions:document</code> - Get the document for an extension by ID, or by name and version. • <code>apic extensions:get</code> - Get an extension by ID, or by name and version. • <code>apic extensions:list</code> - List all versions of an extension given the name. • <code>apic extensions:list-all</code> - List all versions of all extensions. • <code>apic extensions:update</code> - Update an extension by ID, or by name and version.
<code>apic lb4</code>	<p>Create LoopBack® project and project artifacts. With no subcommand, creates a new LoopBack project.</p> <p>Note: To use the <code>apic lb4</code> command, you need to add a double dash, <code>--</code>, after the <code>lb4</code> subcommand to tell <code>apic</code> that the options behind the <code>--</code> are for the subcommand belonging to <code>lb4</code>. The second <code>--</code> is to signify the end of the options. For example,</p> <pre>\$ apic lb4 controller -- --help</pre> <p>Note: You can use</p> <pre>\$ apic lb4 --help</pre> <p>to show a list of commands that are available, and you can use</p> <pre>\$ apic lb4 subcommand -- --help</pre> <p>to show the usage of a subcommand.</p>	<ul style="list-style-type: none"> • <code>app</code> - Create a new LoopBack project (default) • <code>controller</code> - Add a controller to a LoopBack 4 application • <code>datasource</code> - Add a datasource to a LoopBack 4 application • <code>discover</code> - Discover models from relational databases • <code>example</code> - Download one of LoopBack 4 example projects • <code>extension</code> - Create a LoopBack 4 extension • <code>import-lb3-models</code> - Import one or more LoopBack 3 models to a LoopBack 4 application • <code>interceptor</code> - Generate interceptors • <code>model</code> - Add a new model to a LoopBack 4 application • <code>observer</code> - Generate life cycle observers for application start and stop • <code>openapi</code> - Generate controllers and models from OpenAPI specs • <code>relation</code> - Add a relation between two models in a LoopBack 4 application • <code>repository</code> - Add a new repository for a selected model to a LoopBack 4 application • <code>rest-crud</code> - Generate rest configs for model endpoints • <code>service</code> - Add a new remote or local service to a LoopBack 4 application • <code>update</code> - Check or update project dependencies of LoopBack modules
<code>apic login</code>	Log in to API Manager.	<p>None. Specify server and credentials with the required flags:</p> <ul style="list-style-type: none"> • <code>-p, --password password</code> • <code>-r, --realm realm</code>. Determines the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in. • <code>-s, --server mgmt_endpoint_url</code>. Use the value of the platform API endpoint URL for this entry. • <code>-u, --username user_name</code> <p>For full details on how to log in to your management server from the CLI, see Logging in to the management server.</p>
<code>apic logout</code>	Log out from API Manager.	<p>None. Specify server with the required flag:</p> <ul style="list-style-type: none"> • <code>-s, --server mgmt_service</code>. <p>You can append the port number to the server name if it is not the default value of 443.</p>
<code>apic validate</code>	Validate API or Product definition YAML file.	None

Table 2. Summary of commands to manage APIs, Products, and Catalogs

Command	Description	Subcommands
<code>apic apis</code>	List and manage APIs that are staged or published to Catalog or Space. Default subcommand is <code>list-all</code> .	<ul style="list-style-type: none"> • <code>apic apis</code> - API collection operations • <code>apic apis:get</code> - Get the OpenAPI definition YAML file for an API by name and version, or by ID • <code>apic apis:list</code> - List an API by name • <code>apic apis:list-all</code> - List all APIs in a Catalog or Space • <code>apic apis:update</code> - Update an API by name

Command	Description	Subcommands
apic apps	List and manage developer applications that are registered in a consumer organization. Default subcommand is list .	<ul style="list-style-type: none"> • apic apps - Application collection operations • apic apps:clear - Clear all applications • apic apps:create - Create an application • apic apps:delete - Delete an application by name or ID • apic apps:get - Get an application object by name • apic apps:list - List all the applications in a consumer organization • apic apps:update - Update an application by name or ID
apic catalogs	List and manage Catalogs in a provider organization. Default subcommand is list .	<ul style="list-style-type: none"> • apic catalogs:clear - Clear all Catalogs from provider organization • apic catalogs:create - Create a Catalog • apic catalogs:delete - Delete a Catalog by name or ID • apic catalogs:get - Get a Catalog object by name or ID • apic catalogs:list - List all the Catalogs in a provider organization • apic catalogs:transfer-owner - Transfer the ownership of a Catalog to another user • apic catalogs:update - Update a Catalog by name or ID
apic catalog-settings	Manage the configuration settings for a Catalog	<ul style="list-style-type: none"> • apic catalog-settings:get - Get the Catalog settings. • apic catalog-settings:update - Update the Catalog settings.
apic drafts	List and manage the draft API and Product definitions in a provider organization. Default subcommand is list .	<ul style="list-style-type: none"> • apic drafts - Draft collection operations • apic drafts:clear - Delete all draft APIs and Products in a provider organization • apic drafts:list - List the draft APIs and Products in a provider organization
apic draft-apis	List and manage the draft API definitions in a provider organization. Default subcommand is list-all .	<ul style="list-style-type: none"> • apic draft-apis - Draft API collection operations • apic draft-apis:clear - Delete all versions of a draft API by name • apic draft-apis:clear-all - Delete all draft APIs in a provider organization • apic draft-apis:clone - Clone all draft APIs in a provider organization • apic draft-apis:create - Create a draft API • apic draft-apis:delete - Delete a Draft API by name and version • apic draft-apis:document - Get the Draft API document by name and version • apic draft-apis:get - Get the OpenAPI definition YAML file for an API by name and version • apic draft-apis:list - List all versions of a draft API by name • apic draft-apis:list-all - List all draft APIs in a provider organization • apic draft-apis:update - Update a draft API by name and version, supplying the revised OpenAPI definition file • apic draft-apis:update-wsdl - Update a draft SOAP API by name and version, supplying the revised WSDL definition file in a .wsdl or .zip format Note: There must be a match of the service names in the existing WSDL with the revised WSDL. If a match is found, the WSDL service is converted into a YAML file that is used to update the API. If no match is found, an error message is displayed. • apic draft-apis:validate - Validates a draft API • apic draft-apis:wsdl - Get the Draft API WSDL document by name and version
apic draft-products	List and manage the draft Product definitions in a provider organization. Default subcommand is list-all .	<ul style="list-style-type: none"> • apic draft-products - Draft Product collection operations • apic draft-products:clear - Delete all versions of a draft Product by name • apic draft-products:clear-all - Delete all draft Products in a provider organization • apic draft-products:create - Create a draft Product • apic draft-products:delete - Delete a draft Product by name and version • apic draft-products:get - Get the Draft Product by name and version • apic draft-products:list - List the Draft Products • apic draft-products:list-all - List all draft Products in a provider organization • apic draft-products:publish-all - Publishes the Draft Product • apic draft-products:update - Update a draft Product by name and version, supplying the revised definition file • apic draft-products:validate - Validates a draft Product
apic members	List and manage the members of a provider organization, consumer organization, Catalog, or Space. Default subcommand is list .	<ul style="list-style-type: none"> • apic members - Member operations • apic members:clear - Delete all members • apic members:create - Create a member • apic members:delete - Delete a member by name or ID • apic members:get - Get a member object by name or ID • apic members:list - List all members • apic members:update - Update the member by name or ID
apic member-invitations	List and manage member invitations. A member invitation is created when a user is invited to be a member of a provider organization, consumer organization, Catalog, or Space. Default subcommand is list .	<ul style="list-style-type: none"> • apic member-invitations - Member invitation collection operations. • apic member-invitations:clear - Delete all member invitations. • apic member-invitations:create - Create a member invitation. • apic member-invitations:delete - Delete a member invitation by name or ID. • apic member-invitations:get - Get a member invitation object by name or ID. • apic member-invitations:list - List all member invitations. • apic member-invitations:update - Update a member invitation by name or ID.

Command	Description	Subcommands
apic orgs	List and manage provider organizations, and the admin organization. Default subcommand is list .	<ul style="list-style-type: none"> • apic orgs - Organization collection operations • apic orgs:clear - Delete all organizations • apic orgs:create - Create an organization • apic orgs:delete - Delete an organization by name or ID • apic orgs:get - Get an organization object by name or ID • apic orgs:list - List all organizations • apic orgs:transfer-owner - Transfer ownership of an organization • apic orgs:update - Update an organization by name or ID
apic org-settings	Manage settings for provider organizations, and the admin organization.	<ul style="list-style-type: none"> • apic org-settings:get - Get the settings object for an organization • apic org-settings:update - Update the settings for an organization
apic policies	List and manage policies in a Catalog. Default subcommand is list .	<ul style="list-style-type: none"> • apic policies - Policy collection operations • apic policies:clear - Clear the Policies • apic policies:clear-all - Clear all Policies in all collections • apic policies:create - Create a Policy • apic policies:delete - Delete a Policy • apic policies:get - Get the Policy by name and version • apic policies:list - List the Policies • apic policies:list-all - List all Policies in all collections • apic policies:update - Update the Policy by name and version
apic products	List and manage Products that are staged or published to Catalog or Space. Default subcommand is list-all .	<ul style="list-style-type: none"> • apic products - Product collection operations • apic products:clear - Delete all versions of a Product by name • apic products:clear-all - Delete all Products • apic products:delete - Delete a Product by name and version • apic products:execute-migration-target - Products execute migration target operations • apic products:get - Get a Product object by name and version • apic products:list - List all versions of a Product by name • apic products:list-all - List all Products • apic products:publish - Publish a Product to a Catalog or Space, supplying the Product definition YAML file • apic products:replace - Replace a Product with another Product • apic products:set-migration-target - Set the target Product for migrating subscriptions from a Product • apic products:supersede - Supersede a Product with another Product • apic products:update - Update a Product by name and version, supplying the revised Product definition YAML file
apic identity-providers	View information about identity providers.	<ul style="list-style-type: none"> • apic identity-providers - Identity provider operations • apic identity-providers:list - List the identity providers.
apic spaces	List and manage Spaces contained in a Catalog. Default subcommand is list .	<ul style="list-style-type: none"> • apic spaces - Space collection operations • apic spaces:clear - Delete all Spaces from a Catalog • apic spaces:create - Create a Space in a Catalog • apic spaces:delete - Delete a Space from a Catalog, by name or ID • apic spaces:get - Get a Space object by name or ID • apic spaces:list - List all the Spaces in a Catalog • apic spaces:transfer-owner - Transfer the ownership of a Space to another user • apic spaces:update - Update a Space by name or ID
apic subscriptions	List and manage subscriptions in a Product or a Catalog. Default subcommand is list .	<ul style="list-style-type: none"> • apic subscriptions - Subscription collection operations • apic subscriptions:clear - Clear the Subscriptions • apic subscriptions:create - Create a Subscription • apic subscriptions:delete - Delete the Subscription by name or ID • apic subscriptions:get - Get the Subscription by name or ID • apic subscriptions:list - List the Subscriptions • apic subscriptions:update - Update the Subscription by name or ID

Table 3. Summary of other commands for API developers and managers

Command	Description	Subcommands
apic consumer-orgs	Manage consumer organizations	<ul style="list-style-type: none"> • apic consumer-orgs - Consumer Organization collection operations. • apic consumer-orgs:clear - Clear the Consumer Organizations. • apic consumer-orgs:create - Create a Consumer Organization. • apic consumer-orgs:delete - Delete the Consumer Organization by name or ID. • apic consumer-orgs:get - Get the Consumer Organization by name or ID. • apic consumer-orgs:list - List the Consumer Organizations. • apic consumer-orgs:transfer-owner - Transfer owner to a new member. • apic consumer-orgs:update - Update the Consumer Organization by name or ID.

Command	Description	Subcommands
apic consumer-org-settings	Manage consumer organization settings	<ul style="list-style-type: none"> • apic consumer-org-settings:delete - Delete the Consumer Organization Setting. • apic consumer-org-settings:get - Get the Consumer Organization Setting. • apic consumer-org-settings:update - Update the Consumer Organization Setting.
apic groups	Manage groups	<ul style="list-style-type: none"> • apic groups - Group collection operations. • apic groups:clear - Clear the Groups. • apic groups:create - Create a Group. • apic groups:delete - Delete the Group by name or ID. • apic groups:get - Get the Group by name or ID. • apic groups:list - List the Groups. • apic groups:update - Update the Group by name or ID.
apic invitations	Manage invitations. An invitation is created when a user is invited to be the owner of a provider organization, consumer organization, Catalog, or Space.	<ul style="list-style-type: none"> • apic invitations - Invitation collection operations. • apic invitations:clear - Delete all invitations. • apic invitations:create - Create an invitation. • apic invitations:delete - Delete an invitation by name or ID. • apic invitations:get - Get the details of an invitation by name or ID. • apic invitations:list - List all invitations. • apic invitations:update - Update an invitation by name or ID.
apic member-invitations	Manage member invitations. A member invitation is created when a user is invited to be a member of a provider organization, consumer organization, Catalog, or Space.	<ul style="list-style-type: none"> • apic member-invitations - Member invitation collection operations. • apic member-invitations:clear - Delete all member invitations. • apic member-invitations:create - Create a member invitation. • apic member-invitations:delete - Delete a member invitation by name or ID. • apic member-invitations:get - Get the details of a member invitation by name or ID. • apic member-invitations:list - List all member invitations. • apic member-invitations:update - Update a member invitation by name or ID.
apic members		<ul style="list-style-type: none"> • apic members - Member collection operations. • apic members:clear - Clear the Members. • apic members:create - Create a Member. • apic members:delete - Delete the Member by name or ID. • apic members:get - Get the Member by name or ID. • apic members:list - List the Members. • apic members:update - Update the Member by name or ID.
apic registrations		<ul style="list-style-type: none"> • apic registrations - Registration collection operations. • apic registrations:clear - Clear the Registrations. • apic registrations:create - Create a Registration. • apic registrations:delete - Delete the Registration by name or ID. • apic registrations:get - Get the Registration by name or ID. • apic registrations:list - List the Registrations. • apic registrations:update - Update the Registration by name or ID.

Command	Description	Subcommands
apic role-defaults		<ul style="list-style-type: none"> • apic role-defaults - Role Default collection operations. • apic role-defaults:clear - Clear the Role Defaults. • apic role-defaults:create - Create a Role Default. • apic role-defaults:delete - Delete the Role Default by name or ID. • apic role-defaults:get - Get the Role Default by name or ID. • apic role-defaults:list - List the Role Defaults. • apic role-defaults:list-all - List all Role Defaults in all collections. • apic role-defaults:update - Update the Role Default by name or ID.
apic roles		<ul style="list-style-type: none"> • apic roles - Role collection operations. • apic roles:clear - Clear the Roles. • apic roles:create - Create a Role. • apic roles:delete - Delete the Role by name or ID. • apic roles:get - Get the Role by name or ID. • apic roles:list - List the Roles. • apic roles:update - Update the Role by name or ID.
apic tasks		<ul style="list-style-type: none"> • apic tasks - Task collection operations. • apic tasks:clear - Clear the Tasks. • apic tasks:create - Create a Task. • apic tasks:delete - Delete the Task by name or ID. • apic tasks:get - Get the Task by name or ID. • apic tasks:list - List the Tasks. • apic tasks:update - Update the Task by name or ID.
apic user-registries		<ul style="list-style-type: none"> • apic user-registries - User Registry collection operations. • apic user-registries:clear - Clear the User Registries. • apic user-registries:create - Create a User Registry. • apic user-registries:delete - Delete the User Registry by name or ID. • apic user-registries:execute - Execute a User Registry operation. • apic user-registries:get - Get the User Registry by name or ID. • apic user-registries:list - List the User Registries. • apic user-registries:search - search for users in a user registry. • apic user-registries:test-connection - Test a User Registry connection. • apic user-registries:update - Update the User Registry by name or ID.
apic user-registry-settings		<ul style="list-style-type: none"> • apic user-registry-settings:delete - Delete the User Registry Setting. • apic user-registry-settings:get - Get the User Registry Setting. • apic user-registry-settings:update - Update the User Registry Setting.
apic users		<ul style="list-style-type: none"> • apic users - User collection operations. • apic users:clear - Clear the Users. • apic users:create - Create a User. • apic users:delete - Delete the User by name or ID. • apic users:get - Get the User by name or ID. • apic users:list - List the Users. • apic users:request-password-reset - send a password reset link. • apic users:search-provider - Search for provider users from an organization. • apic users:update - Update the User by name or ID.

Creating APIs and applications

You can develop API proxies and API implementations by using the developer toolkit. In the documentation, *API* refers to the API proxy and *application* refers to the API implementation.

LoopBack® is a high-performance Node.js interaction-tier framework for APIs and micro-services. The [LoopBack framework](#) can be downloaded and installed using the **CLI + LoopBack + Designer** option for downloading the toolkit. See [Installing the toolkit](#). To create a new LoopBack project, use the command `apic lb4`.

Note: IBM® API Connect is packaged with, and supports, LoopBack version 4. For more information on how to migrate your LoopBack 3 applications to LoopBack 4, see [LoopBack 4 Migration Guide](#).

You can use the developer toolkit or LoopBack to create language-independent APIs by using [OpenAPI](#) to proxy to an existing backend implementation or to augment applications that are developed in other languages or frameworks such as [Express®](#), Java™, [Swift](#), Go, and others.

Creating development artifact definitions

Use the `apic create` command to create development artifacts, by using the following commands:

Command	Description
<code>apic create:api</code>	Create an OpenAPI definition.
<code>apic create:api --wsdl filename</code>	Create a SOAP API definition from a WSDL definition file, or a .zip file that contains the WSDL definition files for a service. The name and version of the generated API are obtained from the WSDL file. If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service .
<code>apic create:product</code>	Create an API Product definition.

Note: You can create an API or Product from an OpenAPI template file by using the `--template template-name` option.

You can also create Product and API definitions non-interactively by providing the `--title` option. This option sets several values that you can also customize with additional options; for example:

```
apic create:api --title Routes
apic create:product --title "Climb On"
```

You can also create the API and Product definitions at the same time:

```
apic create:api --title Routes --product "Climb On"
apic create:api --wsdl globalweather.wsdl --product "Weather Forecasting"
```

Alternatively, you can create APIs and then reference them when you create a new Product; for example:

```
apic create:api --title Routes
apic create:api --title Ascents
apic create:product --title "Climb On" --apis "routes.yaml ascents.yaml"
```

Validating development artifact definitions

After you edit development artifacts or before you publish artifacts, best practice is to validate them; for example:

```
apic validate routes.yaml # Validate an API
apic validate climb-on.yaml # Validate the Product and its APIs
apic validate climb-on.yaml --product-only # Validate the Product only (do not validate the referenced APIs)
```

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the draft API is created with the `apic drafts:validate` command. For more information, see [Using \\$ref to reuse code fragments in your OpenAPI files](#).

Developing LoopBack applications

After you've created a LoopBack application with the `apic lb4 app` command, you can add additional functionality to the application with the commands listed in the following table. Run these commands from the project root directory of the application. APIs created with LoopBack can be imported into API Manager.

Command	Description	Subcommands
---------	-------------	-------------

Command	Description	Subcommands
<code>apic lb4</code>	<p>Create LoopBack project and project artifacts. With no subcommand, creates a new LoopBack project.</p> <p>Note: To use the <code>apic lb4</code> command, you need to add a double dash, <code>--</code>, after the <code>lb4</code> subcommand to tell <code>apic</code> that the options behind the <code>--</code> are for the subcommand belonging to <code>lb4</code>. The second <code>--</code> is to signify the end of the options. For example,</p> <pre>\$ apic lb4 controller -- --help</pre>	<ul style="list-style-type: none"> • <code>app</code> - Create a new LoopBack project (default) • <code>controller</code> - Add a controller to a LoopBack 4 application • <code>datasource</code> - Add a datasource to a LoopBack 4 application • <code>discover</code> - Discover models from relational databases • <code>example</code> - Download one of LoopBack 4 example projects • <code>extension</code> - Create a LoopBack 4 extension • <code>import-lb3-models</code> - Import one or more LoopBack 3 models to a LoopBack 4 application • <code>interceptor</code> - Generate interceptors • <code>model</code> - Add a new model to a LoopBack 4 application • <code>observer</code> - Generate life cycle observers for application start and stop • <code>openapi</code> - Generate controllers and models from OpenAPI specs • <code>relation</code> - Add a relation between two models in a LoopBack 4 application • <code>repository</code> - Add a new repository for a selected model to a LoopBack 4 application • <code>rest-crud</code> - Generate rest configs for model endpoints • <code>service</code> - Add a new remote or local service to a LoopBack 4 application • <code>update</code> - Check or update project dependencies of LoopBack modules

Publishing APIs and applications

To publish APIs and applications by using the developer toolkit of IBM® API Connect, you set configuration variables to define where you want to publish, log in to the target cloud platform, and then use the appropriate publishing commands.

See the following sections for more information:

- [Setting configuration variables](#)
- [Logging in to API Connect](#)
- [Publishing APIs](#)

Setting configuration variables

The `apic config` command provides global and project-based configuration variables that specify the target Catalog for publishing APIs and applications. The values of these variables are stored in `~/ .apiconnect/config` (for global variables) and `project-dir/ .apiconnect` (for project variables). For a full list of configuration variables, see [Overview of the command-line tool](#).

Set the `catalog` configuration variable to the URI of an API Connect Catalog to define a default Catalog target for all commands managing Catalogs. The `catalog` URI has the form:

```
https://mgmt_endpoint_url/api/catalogs/org_name/catalog_name
```

where `mgmt_endpoint_url` is the platform API endpoint URL, `org_name` is the provider organization name, and `catalog_name` is the Catalog name. The `mgmt_endpoint_url` portion sets the default value of the `--server` option, the `org_name` portion sets the default value of the `--org` option, and the `catalog_name` portion sets the default value of the `--catalog` option; you can override any of these values by including the corresponding option in a command.

Set the `space` configuration variable to the URI of an API Connect Space, to define a default Space target for all commands that manage Spaces. The `space` URI has the form:

```
https://mgmt_endpoint_url/api/spaces/org_name/catalog_name/space_name
```

where `mgmt_endpoint_url` is the platform API endpoint URL, `org_name` is the provider organization name, `catalog_name` is the Catalog name, and `space_name` is the name of the Space. The `mgmt_endpoint_url` portion sets the default value of the `--server` option, the `org_name` portion sets the default value of the `--org` option, the `catalog_name` portion sets the default value of the `--catalog` option, and the `space_name` sets the default value of the `--space` option; you can override any of these values by including the corresponding option in a command.

Although setting these configuration variables is not required, doing so simplifies commands that interact with API Connect clouds by providing default values for frequently used command-line options.

Here is an example of publishing with and without the `catalog` configuration variable set.

Without the configuration variable set:

```
apic products publish climb-on.yaml --server mgmthost.com --org climbon --catalog sandbox
```

With the configuration variable set:

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
catalog: https://platform-api.myserver.com/api/catalogs/climbon/sandbox
apic products publish climb-on.yaml
```

You can override default values provided by the `catalog` configuration variable by providing one of the standard options with a different value. For example, use the `--catalog` option with the `apic products publish` command to specify the `qa` Catalog:

```
apic products publish climb-on.yaml --catalog qa
```

Don't forget about global configuration variables. If you use the same Catalog as the default target for multiple projects, set the value globally:

```
apic config:set --global catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
```

Note:

If you have an environment variable of the same name as a CLI configuration property then, by default, its value will override the value of the corresponding CLI configuration property for any CLI command at that scope.

For example, if you have defined an environment variable called `SPACE` then, by default, that value will be assumed for the value of the `--space` parameter in the following command, regardless of any `space` configuration property setting:

```
apic products:publish my_product.yaml --scope space
```

To prevent environment variables overriding CLI configuration properties, define an environment variable called `APIC_LOAD_FROM_ENV`, set to the value `false`.

Logging in to API Connect

Use the `apic login` and `apic logout` commands to manage your authentication. For details, see [Logging in to a management server](#).

Publishing APIs

Publishing APIs to API Catalogs in API Connect clouds enables you to socialize the APIs by using the developer portal and secure them by using the Gateway.

An *API Product* (or simply *Product*) is used to compose APIs for publishing. API Product managers can use it to bundle one or more APIs together, control the visibility of the Product in the developer portal (for example, only allow partners `x`, `y`, and `z` to view and subscribe to the Product), and define Plans to provide consumption options. The Products that reference the APIs and define the consumption Plans are also the primary unit of lifecycle management for APIs.

Use the `apic products publish` command (equivalent to `apic products:publish`) to publish API Products to an API Connect cloud. The following example demonstrates how to create APIs composed by a Product, and publishing the Product and its APIs to a Catalog:

```
apic create:api --title Routes
apic create:api --title Ascents
apic create:product --title "Climb On" --apis "routes.yaml ascents.yaml"
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/default-idp-2
apic products publish climb-on.yaml
```

For full details on how to log in to your management server from the CLI, see [Logging in to a management server](#).

Add the `--stage` option to `apic publish` to stage the Product into a Catalog instead of publishing it. Products in a Catalog can be in the following states: staged, published, deprecated, or retired. For example:

```
apic products publish --stage climb-on.yaml
```

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a subcatalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see [Using syndication in IBM API Connect](#).

If default configuration values have been set for the Space, Catalog, organization and management server, the following publish command could be used:

```
apic products publish --scope space product.yaml
```

where *product* is the name of the product that you want to publish.

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the Product that contains the API is staged or published with the `apic publish` command. For more information, see [Using \\$ref to reuse code fragments in your OpenAPI files](#).

Managing API Products

Use the `apic products` and `apic apis` commands to manage Products and APIs that have been published to IBM® API Connect Catalogs. Use the `--scope space` option to manage Products and APIs that have been published to Spaces within Catalogs.

Product management command summary

The following table summarizes the commands available for managing API Products. Usage examples follow.

Example command	Description
<code>apic config:set catalog=https://platform-api.myserver.com/api/catalogs/myorg/sandbox</code>	Set the default Catalog.
<code>apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/my-identity-provider</code>	Login into the management server. For full details on how to log in to your management server from the CLI, see Logging in to the management server .
<code>apic create:api --title Routes --product "ClimbOn"</code>	Create the Product and API.
<code>apic products:publish climbon.yaml</code>	Publish the Product to the default catalog. Add <code>--stage</code> argument to stage the Product.
<code>apic products:list-all --scope catalog</code>	List the Products in the default catalog.
<code>apic products:get climbon:1.0.0 --output -</code>	Display the Product's properties. Omit the output argument to download to a file.
<code>apic apis:list-all --scope catalog</code>	List the APIs in the Catalog.
<code>apic apis:get routes:1.0.0 --output -</code>	Get the API properties. Omit the output argument to download to a file.
<code>apic products:replace climbon:1.0.0 mapfile.txt</code>	Replace the Product indicated on the command line with the staged or published Product designated in the mapfile. This retires the replaced Product.
<code>apic products:supersede climbon:1.0.0 mapfile.txt</code>	Supersede the Product indicated on the command line with the staged or published Product designated in the mapfile. This deprecates the superseded Product.
<code>apic products:delete climbon:1.0.0</code>	Delete the Product from the Catalog. The Product must be either retired or deprecated.

Using the `products` and `apis` commands through a full lifecycle

This example shows a complex lifecycle where a new version of a Product and API replaces the original version at run time.

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the Product that contains the API is staged or published with the `apic publish` command. For more information, see [Using \\$ref to reuse code fragments in your OpenAPI files](#).

Set the default Catalog and login to the mgmthost.com API Connect cloud

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
apic login --username some-user --password some-password --server platform-api.myserver.com --realm my-identity-provider
```

For full details on how to log in to your management server from the CLI, see [Logging in to the management server](#).

Create and publish an initial version

```
apic create:api --title Routes --version 1.0.0 --filename routes100.yaml
apic create:product --title "Climb On" --version 1.0.0 --apis routes100.yaml --filename climbon100.yaml
apic products:publish climbon100.yaml
```

Create a new version to fix a bug in the API, stage it to the Catalog

```
apic create:api --title Routes --version 1.0.1 --filename routes101.yaml
apic create:product --title "Climb On" --version 1.0.1 --apis routes101.yaml --filename climbon101.yaml
apic products:publish --stage climbon101.yaml
```

Inspect the Catalog

```
apic products:list-all --scope catalog
```

This produces a list of all Products in the catalog. Copy the ID of the `climbon:1.0.1` Product. The ID resembles the following example.

```
https://server/api/catalogs/3eca6046-3c27-4ad/ab8772bf-0f65-45/products/8f854623-bda1-4f9
```

Create a mapping file

For example, if you are replacing a Product, the mapping file specifies the Product that you want to replace, and the mapping of the Plans from the source Product to the target Product. For example, if you are replacing `climbon:1.0.0` with `climbon:1.0.1` then `product_url` property specifies the URL of `climbon:1.0.0`. This file takes the following form:

```
product_url: https://server/api/catalogs/{id}/products/{id}
plans:
- source: {source_plan_name_1}
  target: {target_plan_name_1}
- source: {source_plan_name_2}
  target: {target_plan_name_2}
  .
  .
```

Note:

- The source and target Plan names can be the same or different.
- Every Plan in the Product you are replacing must be mapped to a Plan in the replacement Product.

"Hot-replace" version 1.0.0 with 1.0.1

```
apic products:replace climbon:1.0.1 PRODUCT_PLAN_MAPPING_FILE
```

After it is replaced in this way, a Product is retired. It is no longer active.

Note: The Product specified on the command line is the replacement Product. For example, if you are replacing `climbon:1.0.0` with `climbon:1.0.1` then the Product specified on the command line is `climbon:1.0.1`.

Supersede version 1.0.0 with 1.0.1

Rather than hot-replacing an existing Product with a new one (usually an updated version), you can supersede the existing Product with a new one. When you replace a Product, all external application subscriptions to that Product are automatically moved to the new Product. When you supersede a Product, the subscriptions are not automatically moved to the new Product, some action must be taken to subscribe external applications to the superseding Product. The command to supersede a Product uses the same mapping file as the command to replace a Product. The name of the superseding Product is given on the command line.

```
apic products:supersede climbon:1.0.1 PRODUCT_PLAN_MAPPING_FILE
```

Once superseded, a Product is marked deprecated, meaning that no further subscriptions to the Product are allowed, although it is still active and existing subscriptions still work.

Note: The Product specified on the command line is the superseding Product. For example, if you are replacing `climbon:1.0.0` with `climbon:1.0.1` then the Product specified on the command line is `climbon:1.0.1`. The mapping file specifies the URL of the Product you are superseding.

Set a migration target

It is possible to set a migration target for the existing Product. This helps migration.

Use a command like the following to set the migration target.

```
apic products:set-migration-target climbon:1.0.0 PRODUCT_PLAN_MAPPING_FILE
```

Note: The Product specified on the command line is the Product from which you want to migrate subscriptions. The mapping file specifies the target Product for the subscriptions.

Once a migration target is set, external application developers will be able to migrate their application subscriptions through the Developer Portal with ease. It is also possible to execute a subscription migration using the following command.

```
apic products:execute-migration-target climbon:1.0.0
```

Delete a Product

When the replaced or superseded Product is no longer needed, it can be deleted.

```
apic products:delete climbon:1.0.0
```

Additional Product and API operations

In addition to the lifecycle management capabilities, you can download Products and APIs in a catalog or space using the `clone` sub-command:

Command	Description
<code>apic products:clone</code>	Download all Products and their APIs from the catalog or space.
<code>apic apis:clone</code>	Download all APIs from the catalog or space.

It can also be useful to clear all Products and their APIs from a Catalog, particularly for a development Catalog (you must provide the name of the Catalog as the value of the `--confirm` parameter):

```
apic products:clear --confirm catalog_name
```

where `catalog_name` is the name of the Catalog.

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a subcatalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see [Using syndication in IBM API Connect](#).

To manage the Products and APIs that have been published to a Space, include the `--scope space` option with the `apic products` and `apic apis` commands. For example, to list the Products that are contained in a Space called `flights`, use the following command:

```
apic products --scope space --space flights --catalog production --org climbonorg --server platform-api.myserver.com
```

Changing the lifecycle state of a Product in a Catalog or Space

To directly change the lifecycle state of a Product that has previously been staged or published to a Catalog or Space, complete the following steps:

- Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic products:update product_name:version --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [-space space] -
```

where:

- `product_name` is the name of the Product whose lifecycle state you want to change.
- `version` is the version of that Product.
- `mgmt_endpoint_url` is the platform API endpoint URL.
- `organization` is the name of the provider organization in which the Product was previously staged or published.
- `scope` has one of the following values:
 - `catalog` if the Catalog does not have Spaces enabled.
 - `space` if the Catalog has Spaces enabled. If you specify `space` for the `--scope` parameter you must also supply the `--space` parameter.
- `catalog` is the name of the Catalog in which the Product was previously staged or published.
- (optional) `space` is the name of the Space. The `--space` parameter is required if the Catalog has Spaces enabled, in which case you must also include `--scope space` in the command.

The command returns:

```
Reading PRODUCT_FILE arg from stdin
```

- Enter the following data, followed by a new line:

```
state: new_state
```

where `new_state` is the state that you want to change the Product to, and must have one of the following values.

- staged
- published
- deprecated
- retired

- archived
- Press **CTRL D** to terminate the input. If the command is successful, the lifecycle state change is confirmed.

For example:

```
apic products:update finance:1.0.0 --server https://myserver.com --org development --scope catalog --catalog sandbox -
Reading PRODUCT_FILE arg from stdin
state: published
finance:1.0.0 [state: published] https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-
9e82-427a-abe6-be5b126210f7/products/0f0af980-f505-4f36-b09c-d7b1c9c1a2f2
```

Note:

The command will not succeed if the lifecycle state change you are attempting is not permitted.

For example, the following lifecycle state changes are permitted:

- staged to published
- deprecated to retired

The following lifecycle state changes are not permitted:

- published to staged
- retired to published

For full details, see [The Product lifecycle](#).

To list all Products in a Catalog or Space, together with their lifecycle states, use the following command:

```
apic products:list-all --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [--space space]
```

For example:

```
apic products:list-all --server https://myserver.com --org development --scope catalog --catalog sandbox
graphql-services:1.0.0 [state: staged] https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-
9e82-427a-abe6-be5b126210f7/products/7652d568-b396-4bfa-bf71-2f18cea63737
finance:1.0.0 [state: published] https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-
9e82-427a-abe6-be5b126210f7/products/0f0af980-f505-4f36-b09c-d7b1c9c1a2f2
```

To find out the lifecycle state of a specific Product, use the following command:

```
apic products:get product_name:version --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [--space
space] --fields state --output -
```

For example:

```
apic products:get finance:1.0.0 --server https://myserver.com --org development --scope catalog --catalog sandbox --fields
state --output -
state: published
```

Example scripts

A set of example toolkit scripts that demonstrate how to create and manage organizations, users, apps, Products and APIs are available at <https://github.com/ibm-apiconnect/example-toolkit-scripts>.

Working with Drafts

Co-locate your APIs and applications in your local source code control systems to support typical development activities such as commits, branching, merges, continuous integration, and so on. The developer toolkit provides the bridge from the developer's environment to the IBM® API Connect runtime services.

API Connect provides an online development capability called *Drafts* where you can define API and Product definitions. The **apic drafts** commands enable synchronization of Product and API artifacts between local source code control systems and drafts.

You can use **drafts** to clear and list your drafts. For example:

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox # set the default Catalog
apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/myldap # login
into the management server
```

```
apic create:api --title routes --product ClimbOn
apic drafts # list what is in drafts
apic drafts:clear --confirm drafts # clear drafts collection
apic drafts:list # list the available drafts
```

For full details on how to log in to your management server from the CLI, see [Logging in to the management server](#).

Reading input from the command line

If a developer toolkit command takes a file as an input parameter, you can direct the command to read the input directly from the command line rather than supplying a separate file; this can be useful when writing scripts to automate command line operations, for example.

Reading input from a file

Many developer toolkit commands that create or update new objects in API Connect take a file as an input parameter. For example:

- Register a new gateway service:

```
apic gateway-services:create [flags] GATEWAY_SERVICE_FILE
```

- Update a provider organization:

```
apic orgs:update [flags] ORG_FILE
```

- Create a new Catalog:

```
apic catalogs:create [flags] CATALOG_FILE
```

- Create a new consumer organization:

```
apic consumer-orgs:create [flags] CONSUMER_ORG_FILE
```

- Register a new developer application:

```
apic apps:create [flags] APP_FILE
```

- Create a new email server:

```
apic mail-servers:create [flags] MAIL_SERVER_FILE
```

- Update the list of applications that subscribe to a Product:

```
apic subscriptions:update [flags] SUBSCRIPTION_FILE
```

You can format the input file as a YAML file (the default) or as a JSON file. To use a JSON file as input, include the `--format json` parameter.

Reading input from the command line

As an alternative to supplying an explicit file name to the command, you can supply a hyphen (-) in place of the file name parameter; the command will then read the file content directly from the command line as shown in the following examples.

- Register a new DataPower® Gateway (v5 compatible) gateway service:

```
apic gateway-services:create --server platform-api.myserver.com --org admin --availability-zone availability-zone-default -
Reading GATEWAY_SERVICE_FILE arg from stdin
name: dpgw-service
title: DataPower gateway service, compatible with v5
gateway_service_type: datapower-gateway
endpoint: 'https://mygwhost.com:3000'
api_endpoint_base: 'https://mygwhost.com:9443'
sni:
  - host: '*'
    tls_server_profile_url: https://platform-api.myserver.com/api/orgs/75203636-f038-4287-a732-24af4bf7059d/tls-server-
profiles/3c0a0e93-6aa4-4288-b09c-eccf4901b104
visibility:
  type: public
```

Note: You can obtain the `tls_server_profile_url` property value for a TLS server profile by using the following command, which lists the URLs for all TLS server profiles:

```
apic tls-server-profiles --org organization_name --server mgmt_endpoint_url
```

- Create a new provider organization:

```
apic orgs:create --server platform-api.myserver.com -
Reading ORG_FILE arg from stdin
name: development
title: Development organization
owner_url: https://platform-api.myserver.com/api/user-registries/1bbbd414-22f1-47cf-8eac-2050530d29a7/c082d755-866e-4394-
959f-fbb264c6c3a1/users/2db491c7-2d0f-4f60-a8ae-f38d07481f21
```

Note: You can obtain the `owner_url` property value by using the following command, which returns the `url` property for a specific user:

```
apic users:get username --user-registry user_registry_name --server mgmt_endpoint_url --org organization_name --fields url
--output -
```

- Create a new Catalog:

```
apic catalogs:create --server platform-api.myserver.com --org myorg -
Reading CATALOG_FILE arg from stdin
name: production
title: Production Catalog
summary: Catalog containing APIs in production use
```

- Create a new consumer organization:

```
apic consumer-orgs:create --server platform-api.myserver.com --catalog sandbox --org myorg -
Reading CONSUMER_ORG_FILE arg from stdin
name: finance-apps
title: Developers of finance applications
owner_url: https://platform-api.myserver.com/api/user-registries/a1fb8159-fda1-410f-93ab-a0ea5fd04535/70ce7ec3-e83f-4c87-
9f3c-4662ad108bbc/users/fddd5df5-c178-4a34-ab92-0a48344d5c9b
```

Note: You can obtain the `owner_url` property value by using the following command, which returns the `url` property for a specific user:

```
apic users:get username --user-registry user_registry_name --server mgmt_endpoint_url --org organization_name --fields url
--output -
```

- Register a new developer application:

```
apic apps:create --server consumer-api.myserver.com --org my-consumer-org --mode consumer -
Reading APP_FILE arg from stdin
name: finance
title: Finance application
summary: Mobile app for personal finance management
```

- Create a new email server:

```
apic mail-servers:create --org admin --server platform-api.myserver.com -
Reading MAIL_SERVER_FILE arg from stdin
title: My email server
name: my-email-server
host: smtp.myemail.com
port: 20
credentials:
  username: me@myemail.com
  password: password
```

- Create a new subscription to subscribe an application to a Product:

```
apic subscriptions:create --app myapp --catalog sandbox --org myorg --server platform-api.myserver.com --consumer-org my-
consumer-org -
Reading SUBSCRIPTION_FILE arg from stdin
product_url: https://platform-api.myserver.com/api/catalogs/960733c1-d7f7-4b90-9bc7-69dbf4ce31/ca34537d-adf4-4320-8495-
a7feaa62d679/products/638015c6-a8b0-452e-841f-2ac441ab6962
plan: default-plan
```

Note: You can obtain the `product_url` property value for a Product by using the following command, which lists the URLs for all versions of a Product given the Product name:

```
apic products:list product_name --scope catalog --catalog catalog_name --org provider_org_name --server mgmt_endpoint_url
```

Scripting with the toolkit commands

The IBM® API Connect developer toolkit provides commands for cloud administration and API development and management.

Scripting commands

It's often helpful to automate a series of `apic` commands in a shell script. Since the `apic` tool first requires you to interactively accept the license, you must first use the following command:

```
apic --accept-license
```

Once you do that, your scripts can run non-interactively.

Toolkit command scripts allow you to automate many of the tasks required to set up and maintain your API products. A set of example scripts are available at <https://github.com/ibm-apiconnect/example-toolkit-scripts>.

These scripts demonstrate how to perform the following tasks.

- Create a Provider Organization
- Configure a catalog to use one or more gateways
- Create draft APIs and Products
- Publish Products
- Replace an existing published product with a new version
- Delete a product
- Create a Consumer Organization
- Create a new consumer app
- Subscribe the new app to an existing published product
- Stage a new product version
- Supersede the existing published product with the new one
- Migrate existing subscriptions from the old product to the new product

Working with OpenAPI extensions

Use the developer toolkit CLI **extensions** commands to manage OpenAPI extensions in your Catalogs or Spaces.

You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API, depending on the version of IBM® API Connect you are using. An extension is imported into a Catalog, or as Space ion a Catalog, then added to the API schema.

The commands described here are for importing OpenAPI extensions into a Catalog or Space, and viewing and managing them. After you have imported an OpenAPI extension, you can reference it in your API definitions; for details, see [Referring to an extension in an API definition](#).

Note: If Spaces are enabled in a Catalog, an OpenAPI extension that you import into one Space is imported into **all** Spaces; you cannot import an OpenAPI extension into an individual Space in the Catalog. Any subsequent updates are also applied to all Spaces.

Command name	Action	Syntax
extensions clear	<p>The extensions:clear command deletes all versions of an extension given the extension name.</p> <p>The parameters are as follows:</p> <p>--scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available:</p> <p>catalog The command is to be applied to Catalog</p> <p>space The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to space and supply the --space parameter.</p> <p>--catalog or -c <catalog_name> Specifies a single Catalog with the Catalog name.</p> <p>--space Specifies the name of a Space in a Catalog. The --space parameter is required if the Catalog has Spaces enabled, in which case you must also include --scope space in the command.</p> <p>--configured-gateway-service <service_name> Specifies the name of the gateway service.</p> <p>--confirm <catalog_name> Confirms the clear of the extension.</p> <p><extension_name> Specifies the name of the existing extension. Note: This is the extension name, not the file name.</p> <p>--org or -o <organization_name> Specifies a single organization with the organization name.</p> <p>--server or -s <management_server_endpoint> Specifies the server endpoint.</p>	<pre>apic extensions:clear --scope catalog space --catalog -c catalog_name extension_name --server -s management_server_endpoint --configured-gateway-service gw_service_name --confirm catalog_name --org -o org_name [--space space]</pre> <p>Example:</p> <pre>apic extensions:clear --scope catalog --catalog catalog1 extension1 --server endpoint1 --configured-gateway-service gw_service1 --confirm catalog1 --org my_org</pre> <p>This example deletes all versions of the extension1 extension that are in catalog1 of the my_org organization, and are paired with endpoint1.</p>
extensions clear-all	<p>The extensions:clear-all command deletes all of the extensions in the specified Catalog or Space.</p> <p>The parameters are as follows:</p> <p>--scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available:</p> <p>catalog The command is to be applied to Catalog</p> <p>space The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to space and supply the --space parameter.</p> <p>--catalog or -c <catalog_name> Specifies a single Catalog with the Catalog name.</p> <p>--space Specifies the name of a Space in a Catalog. The --space parameter is required if the Catalog has Spaces enabled, in which case you must also include --scope space in the command.</p> <p>--configured-gateway-service <service_name> Specifies the name of the gateway service.</p> <p>--confirm <catalog_name> Confirms the clear of the extension.</p> <p>--org or -o <organization_name> Specifies a single organization with the organization name.</p> <p>--server or -s <management_server_endpoint> Specifies the server endpoint.</p>	<pre>apic extensions:clear-all --scope catalog space --catalog -c catalog_name --server -s mgt_server_endpoint --configured-gateway-service gw_service_name --confirm catalog_name --org -o org_name [--space space]</pre> <p>Example:</p> <pre>apic extensions:clear-all --scope catalog --catalog catalog1 --server endpoint1 --configured-gateway-service gw_service1 --confirm catalog1 --org my_org</pre> <p>This example deletes all the extensions that are in catalog1 of the my_org organization, and are paired with endpoint1.</p>

Command name	Action	Syntax
extensions clone	<p>The extensions:clone command creates a local definition file for each extension.</p> <p>The parameters are as follows:</p> <p>--scope</p> <p>Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available:</p> <p>catalog</p> <p>The command is to be applied to Catalog</p> <p>org</p> <p>Sets the scope to the organization.</p> <p>space</p> <p>The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to space and supply the --space parameter.</p> <p>--catalog or -c <catalog_name></p> <p>Specifies a single Catalog with the Catalog name.</p> <p>--space</p> <p>Specifies the name of a Space in a Catalog. The --space parameter is required if the Catalog has Spaces enabled, in which case you must also include --scope space in the command.</p> <p>--org or -o <organization_name></p> <p>Specifies a single organization with the organization name.</p> <p>--server or -s <management_server_endpoint></p> <p>Specifies the server endpoint.</p> <p>--configured-gateway-service <service_name></p> <p>Specifies the name of the gateway service.</p>	<pre>apic extensions:clone --scope catalog space --catalog -c catalog_name --org -o org_name [--space space] --server -s mgt_server_endpoint --configured-gateway-service gw_service_name</pre> <p>Example:</p> <pre>apic extensions:clone --scope catalog --catalog catalog1 --org my_org --server endpoint1 --configured-gateway-service gw_service_1</pre> <p>This example clones the extensions that are in catalog1 of the my_org organization, and are paired with endpoint1.</p>
extensions create	<p>The extensions:create command creates an extension in a Catalog or Space, given an extension definition file.</p> <p>The parameters are as follows:</p> <p>--scope</p> <p>Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available:</p> <p>catalog</p> <p>The command is to be applied to Catalog</p> <p>space</p> <p>The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to space and supply the --space parameter.</p> <p><extension_file></p> <p>Specifies the name of the extension file that contains the new information for your extension.</p> <p>Note: This is the OpenAPI file name, not the name of the extension.</p> <p>--server or -s <management_server_endpoint></p> <p>Specifies the server endpoint.</p> <p>--catalog or -c <catalog_name></p> <p>Specifies a single Catalog with the Catalog name.</p> <p>--space</p> <p>Specifies the name of a Space in a Catalog. The --space parameter is required if the Catalog has Spaces enabled, in which case you must also include --scope space in the command.</p> <p>--org or -o <organization_name></p> <p>Specifies a single organization with the organization name.</p> <p>--configured-gateway-service <service_name></p> <p>Specifies the name of the gateway service.</p>	<pre>apic extensions:create --scope catalog space extension_file --server -s mgt_server_endpoint --catalog -c catalog_name [--space space] --org -o org_name --configured-gateway-service gw_service_name</pre> <p>Example:</p> <pre>apic extensions:create --scope catalog filename.yaml --server endpoint1 --catalog catalog1 --org my_org --configured-gateway-service gw_service_1</pre> <p>This example creates an extension in catalog1 of the my_org organization, paired with endpoint1, using the filename.yaml OpenAPI extension definition file.</p>

Command name	Action	Syntax
extensions delete	<p>The extensions:delete command deletes a specific version of an extension.</p> <p>The parameters are as follows:</p> <p>--scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available:</p> <p>catalog The command is to be applied to Catalog</p> <p>space The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to space and supply the --space parameter.</p> <p>--server or -s <management_server_endpoint> Specifies the server endpoint.</p> <p>--catalog or -c <catalog_name> Specifies a single Catalog with the Catalog name.</p> <p>--space Specifies the name of a Space in a Catalog. The --space parameter is required if the Catalog has Spaces enabled, in which case you must also include --scope space in the command.</p> <p><extension_name>:<version_number> Specifies the name and version number of the extension. Note: <i>extension_name</i> is the extension name, not the file name.</p> <p>--org or -o <organization_name> Specifies a single organization with the organization name.</p> <p>--configured-gateway-service <service_name> Specifies the name of the gateway service.</p>	<pre>apic extensions:delete --scope catalog space extension_name:version_number --catalog -c catalog_name --org -o org_name [--space space] --server -s mgt_server_endpoint --configured-gateway-service gw_service_name</pre> <p>Example:</p> <pre>apic extensions:delete --scope catalog myextension:1.0.0 --catalog catalog1 --org orgmain --server endpoint1 --configured-gateway-service gw_service_1</pre> <p>This example deletes myextension version 1.0.0 that is in catalog1 of the orgmain organization, and is paired with endpoint1.</p>
extensions get	<p>The extensions:get command retrieves the definition file for a specific version of an extension.</p> <p>The parameters are as follows:</p> <p>--scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available:</p> <p>catalog The command is to be applied to Catalog</p> <p>org Sets the scope to the organization.</p> <p>space The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to space and supply the --space parameter.</p> <p>--server or -s <management_server_endpoint> Specifies the server endpoint.</p> <p>--catalog or -c <catalog_name> Specifies a single Catalog with the Catalog name.</p> <p>--space Specifies the name of a Space in a Catalog. The --space parameter is required if the Catalog has Spaces enabled, in which case you must also include --scope space in the command.</p> <p><extension_name>:<version_number> Specifies the name and version number of the extension. Note: <i>extension_name</i> is the extension name, not the file name.</p> <p>--org or -o <organization_name> Specifies a single organization with the organization name.</p> <p>--configured-gateway-service <service_name> Specifies the name of the gateway service.</p>	<pre>apic extensions:get --scope catalog space extension_name:version_number --catalog -c catalog_name --org -o org_name [--space space] --server -s mgt_server_endpoint --configured-gateway-service gw_service_name</pre> <p>Example:</p> <pre>apic extensions:get --scope catalog myextension:1.0.0 --catalog catalog1 --org orgmain --server endpoint1 --configured-gateway-service gw_service_1</pre> <p>This example gets myextension version 1.0.0 that is in catalog1 of the orgmain organization, and is paired with endpoint1.</p>

Command name	Action	Syntax
extensions list	<p>The extensions:list command lists all versions of an extension given the extension name.</p> <p>The parameters are as follows:</p> <p>--scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available:</p> <p>catalog The command is to be applied to Catalog</p> <p>org Sets the scope to the organization.</p> <p>space The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to space and supply the --space parameter.</p> <p>--server or -s <management_server_endpoint> Specifies the server endpoint.</p> <p>--catalog or -c <catalog_name> Specifies a single Catalog with the Catalog name.</p> <p>--space Specifies the name of a Space in a Catalog. The --space parameter is required if the Catalog has Spaces enabled, in which case you must also include --scope space in the command.</p> <p><extension_name> Specifies the name of the existing extension. Note: This is the extension name, not the file name.</p> <p>--org or -o <organization_name> Specifies a single organization with the organization name.</p> <p>--configured-gateway-service <service_name> Specifies the name of the gateway service.</p>	<pre>apic extensions:list --scope catalog space extension_name --catalog -c catalog_name --org -o org_name [--space space] --server -s mgt_server_endpoint --configured-gateway-service gw_service_name</pre> <p>Example:</p> <pre>apic extensions:list --scope catalog my_extension --catalog catalog1 --org my_org --server endpoint1 --configured-gateway-service gw_service_1</pre> <p>This example lists all versions of the extension my_extension that are paired with endpoint1, are in catalog1, and in the my_org organization.</p>
extensions list-all	<p>The extensions:list-all command lists all of the extensions that are available in a Catalog or Space. This is the default command if you enter only apic extensions.</p> <p>The parameters are as follows:</p> <p>--scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available:</p> <p>catalog The command is to be applied to Catalog</p> <p>org Sets the scope to the organization.</p> <p>space The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to space and supply the --space parameter.</p> <p>--server or -s <management_server_endpoint> Specifies the server endpoint.</p> <p>--catalog or -c <catalog_name> Specifies a single Catalog with the Catalog name.</p> <p>--space Specifies the name of a Space in a Catalog. The --space parameter is required if the Catalog has Spaces enabled, in which case you must also include --scope space in the command.</p> <p>--org or -o <organization_name> Specifies a single organization with the organization name.</p> <p>--configured-gateway-service <service_name> Specifies the name of the gateway service.</p>	<pre>apic extensions:list-all --scope catalog space --catalog -c catalog_name --org -o org_name [--space space] --server -s mgt_server_endpoint --configured-gateway-service gw_service_name</pre> <p>Example:</p> <pre>apic extensions:list-all --scope catalog --catalog catalog1 --org my_org --server endpoint1 --configured-gateway-service gw_service1</pre> <p>This example lists the extensions that are paired with endpoint1, are in catalog1, and in the my_org organization.</p>

Command name	Action	Syntax
extensions update	<p>The extensions:update command replaces the information of an existing version of an extension with the information in an external file.</p> <p>The parameters are as follows:</p> <p>--scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available:</p> <p>catalog The command is to be applied to Catalog</p> <p>space The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to space and supply the --space parameter.</p> <p>--server or -s <management_server_endpoint> Specifies the server endpoint.</p> <p>--catalog or -c <catalog_name> Specifies a single Catalog with the Catalog name.</p> <p>--space Specifies the name of a Space in a Catalog. The --space parameter is required if the Catalog has Spaces enabled, in which case you must also include --scope space in the command.</p> <p>--org or -o <organization_name> Specifies a single organization with the organization name.</p> <p>--configured-gateway-service <service_name> Specifies the name of the gateway service.</p> <p><extension_name>:<version_number> Specifies the name and version number of the extension. Note: <i>extension_name</i> is the extension name, not the file name.</p> <p><extension_file> Specifies the name of the extension file that contains the new information for your extension. Note: This is the OpenAPI file name, not the name of the extension.</p>	<pre> apic extensions:update --scope catalog space extension_name:version_number extension_file --catalog -c catalog_name --org -o org_name [--space space] --server -s mgt_server_endpoint --configured-gateway-service gw_service_name </pre> <p>Example:</p> <pre> apic extensions:update --scope catalog extension1:1.0.0 extension2.yaml --catalog catalog1 --org my_org --server endpoint1 --configured-gateway-service gw_service1 </pre> <p>This example updates extension1 version 1.0.0 that is paired with endpoint1, in catalog1, and in the my_org organization, from the file extension2.yaml.</p>

Managing platform REST API keys

Create API keys associated with your user account, and then use them to authenticate when you call the platform REST APIs provided by API Connect.

About this task

The [API Connect platform REST APIs](#) require authentication for use. To call an API interactively, you can log into the toolkit CLI with an option to generate the API key. To call an API programmatically, you can generate an API key and then exchange it for an API Connect access token. This requirement applies only to the APIs that are provided by API Connect. You do not need the API key for calling APIs that you imported or created. The API key is intended for use with the IBMid and might not work with other user registries.

Procedure

1. Create an API key:
 - a. Log in to API Connect.
 - b. On the address bar, add **/apikey** to the end of the URL (after the organization name).
For example:

```
https://manager.example.com/manager/myorg/apikeys
```
 - c. On the API Keys page, click Add.
 - d. In the "Create API Connect API Key" box, provide a title for the key (unique within your user account) and an optional description; then click Create.
2. Manage API Keys:
 - a. Log in to API Connect.
 - b. On the address bar, add **/apikey** to the end of the URL.

Searching for items in API Manager

Use the search feature in IBM® API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.

Search is available from any page in API Manager and can be accessed by typing in the search field in the page banner, or by clicking  Search in the navigation list.

Using Search

The Search feature is available on all pages of the API Manager. To start searching, just type a string into the Search field and press Enter. Whenever you press Enter in the Search field, the Search page displays with results and additional options. If you press Enter in an empty Search field, or click  Search in the navigation list, then the Search page displays a list all items. If you type a string before pressing Enter, the page displays the results from the corresponding search.

Search results include all items that contain the search string in a text field. For example, suppose you searched for "Crafted". The results might look like the following image, with items that don't match the search string exactly, but do include the string in a text field such as a title or a name.

By default, the search returns all types of items that contain the string. Sort results on a particular column by clicking the column header.

When you find an item you want to work with, click the . . . actions menu next to the item's "Modified" date to see what you can do. The list of possible actions depends on the item's type.

You can limit the search results by selecting an item type from the list that displays before the results. Click More to view additional types. If you select a type from the More menu, it replaces a type in the list.

If you want to refine the search further, click Options. On the Options panel, click Catalogs to Search and select which catalogs to search (the default is all catalogs). You can select up to 5 catalogs for a limited search.

You can also choose whether only exact matches (the complete string) are included in results, or items containing similar strings are also included.

Working with API definitions

An API definition specifies the complete configuration for an API. You can create and configure your APIs either by using either the API Designer UI application, or by using the browser based API Manager UI.

If you are working with APIs that conform to the OpenAPI Specification, note that API Connect uses the following terms:

- **OpenAPI Specification:**
The OpenAPI Specification defines a standard, language-agnostic interface to RESTful APIs. API Connect supports version 2 and version 3 of the OpenAPI Specification.
- **OpenAPI document:**
One or more files that describe an API conforming to the OpenAPI Specification.
- **OpenAPI definition:**
The description of an API that conforms to the OpenAPI Specification. In API Connect, you can create the API definition by filling in settings and properties, or by importing an OpenAPI document that contains an API definition that you want to work with.

The following topics provide full details for creating and configuring your APIs.

- **[Creating an API definition](#)**
You can create API definitions by using the API Designer or the command line interface in IBM® API Connect.
- **[Editing an OpenAPI 2.0 API definition](#)**
IBM API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 2.0 specification.
- **[Editing an OpenAPI 3.0 API definition](#)**
IBM API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 3.0 specification.
- **[LDAP authentication](#)**
The Lightweight Directory Access Protocol (LDAP) is an internet protocol for accessing and maintaining distributed directory information services over a network. If you rely on LDAP to authenticate users for web applications, take a minute to review the contents of this topic before beginning.
- **[Authentication URL user registry](#)**
You can use an Authentication URL user registry to specify a REST authentication service to manage user authentication, and to optionally provide additional metadata to be embedded in the token.
- **[Activating an API](#)**
After you have created an API definition you can activate it to make it available for testing.
- **[Testing an API](#)**
Select a test tool and verify that your API works as you intended.
- **[Staging an API](#)**
The graphical wizard provides an option that adds the API to a Product and stages the Product in a Catalog. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.
- **[Publishing an API](#)**
The user interface provides an option that adds an API to a Product and publishes the Product in a Catalog. Publishing a draft Product makes the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.
- **[Creating a new version of an API definition](#)**
You can create multiple versions of an API definition and edit the versions independently by using IBM API Connect.
- **[Updating an API definition from a file](#)**
You can update an API by uploading a .yaml or .json file that contains the OpenAPI definition for the revised API.
- **[Updating a SOAP API](#)**
You can update the configuration of an existing SOAP API either by uploading a WSDL file, or by uploading a .zip archive that contains a primary WSDL file together with other WSDL or XSD files that it references.
- **[Renaming an API definition](#)**
By renaming an API definition, you change the **name** property that, together with the version, is used to uniquely identify the API definition in API Connect. The **name** property is initially generated automatically when you first create the API definition, based on the title, but you can later change it if desired.
- **[Changing an API rate limit](#)**
When you activate an API to make it available for testing, as described in [Activating an API](#), no rate limit is applied to restrict calls to the API. However, if desired, you can apply a rate limit to the API, or modify a previously applied rate limit. The rate limit defines the maximum number of calls allowed in a specified time period.

- [Adding an OpenAPI extension to an API](#)
You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An OpenAPI extension is imported into a Catalog, or to a Space within a Catalog, then added to the API schema.
- [Downloading an API definition](#)
You can download the details of your API definitions so that you can store them for later recovery.
- [Deleting an API definition](#)
You can delete an API definition that is no longer required.
- [Using an options file when importing a WSDL service](#)
When you create an API definition, or add a target WSDL service to an API definition, by importing a .zip file, you can specify additional directives by including an options file in the .zip file.
- [Variable references in API Connect](#)
In API Connect you can reference different variables in your API definition.
- [API properties](#)
Properties are used by the gateway to control behavior of certain policies. Typically, you provide properties, but the policy can also provide properties settings.
- [API policies and logic constructs](#)
Policies and logic constructs are pieces of configuration that control a specific aspect of processing in the Gateway server during the handling of an API invocation at run time.
- [Tags in API Connect](#)
There are a number of forms of tagging in IBM API Connect.

Creating an API definition

You can create API definitions by using the API Designer or the command line interface in IBM® API Connect.

Before you begin

An API is a set of functions that provide some business or technical capability and can be called by applications by using a defined protocol. Applications are typically mobile or web applications, and they use the HTTP protocol. An API definition is composed of paths, and can be one of the following types:

REST API definition

A REST API is a defined set of interactions that uses the HTTP protocol, typically by using JSON or XML as the data format that is exchanged. For example, a data request might use an HTTP GET method, and a data record might use an HTTP POST method. The choice of data format depends on the type of application that is calling the API. JSON is commonly used for web pages or mobile applications that present a user interface (by using JavaScript or HTML), whereas XML is often used for machine-to-machine scenarios.

You can create REST APIs by using LoopBack® functions to create models and data sources. These are then used by your REST API definition and exposed to your users.

Alternatively, you can expose and secure your existing APIs by using a [Proxy](#) or [Invoke](#) policy.

In either case, you can configure your API definition either by using the API Designer, or by writing an OpenAPI definition file and publishing it using either API Designer or the command line interface.

SOAP API

You can create SOAP API definitions that are based on an existing Web Services Description Language (WSDL) file. You can use this facility to benefit from the capabilities that are provided by API Connect, which include analytics and mapping between variables. You can also expose the API by using the Developer Portal for any existing SOAP services in your organization, including any SOAP services that are part of a service-oriented architecture (SOA) or Enterprise Service Bus (ESB) infrastructure.

You can create SOAP API definitions through either the command line interface, or through API Designer.

About this task

You can create definitions for REST APIs or SOAP APIs.

- In the API Designer, you can add a REST API definition either by composing the API definition, and its operations, from scratch, or by importing an OpenAPI definition file. You can also use the tooling to quickly create a proxy API that calls an existing endpoint.
- If you have an existing SOAP service that you want to expose more widely, you can add a SOAP API to IBM® API Connect. You can use the Developer Portal to publicize the SOAP service to the developers. If a developer wants to use the SOAP API, you can use API Connect to manage their sign-up and access to the service, and track the usage of that API.

Procedure

1. Quickly create an API definition by using one of the following wizards:
 - [Creating a REST proxy API from a target service](#)
 - [Creating a REST proxy API from an existing OpenAPI service](#)
 - [Creating a new REST OpenAPI definition](#)
 - [Creating a REST proxy API from an existing WSDL service](#)
 - [Adding a REST API by importing an OpenAPI definition file](#)
 - [Creating a SOAP proxy API from an existing WSDL service](#)
 2. After you create your API definition, you can define it in more detail by following the instructions in [Editing an OpenAPI 2.0 API definition](#).
- [Creating a REST proxy API from a target service](#)
If you have an existing REST service that you want to expose through an IBM API Connect API definition, you can create a proxy API and specify the target endpoint by using the API Designer.
 - [Creating a REST proxy API from an existing OpenAPI service](#)
If you have an existing OpenAPI described target service that you want to expose through an IBM API Connect API definition, you can create a proxy API and

specify the target endpoint.

- [Creating a REST proxy API from an existing WSDL service](#)

If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect REST proxy API that calls that SOAP service.

- [Creating a SOAP proxy API from an existing WSDL service](#)

If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect SOAP proxy API that calls that SOAP service.

- [Creating a new REST OpenAPI definition](#)

You can create and edit draft REST API definitions by using the API Designer or the API Designer user interface in IBM API Connect.

- [Adding a REST API by importing an OpenAPI definition file](#)

You can use an OpenAPI definition file to import a REST API into IBM API Connect.

- [Adding a SOAP API by importing a zip file](#)

You can use an OpenAPI definition file to import a SOAP API into IBM API Connect.

- [Creating a GraphQL proxy API](#)

GraphQL is a query language for APIs that gives an application client greater control over what data it retrieves in an API request when compared with a REST API request. IBM API Connect enables you to create a GraphQL API proxy definition that proxies a backend GraphQL server, and to define rate limiting controls that reflect the amount of data that is returned from the server by a request to the GraphQL API.

- [Importing an API from the CP4I asset repository](#)

If you are using IBM API Connect with IBM Cloud Pak for Integration (CP4I), you can import an API definition from the CP4I asset repository.

- [Using the developer toolkit command-line tool](#)

Creating a REST proxy API from a target service

If you have an existing REST service that you want to expose through an IBM® API Connect API definition, you can create a proxy API and specify the target endpoint by using the API Designer.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **Api-Drafts:Edit**, **Settings:View**, and **App:View** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).

Create proxy REST APIs in minutes by using the API Designer tool to create an API from target service. This procedure creates a REST proxy that routes all traffic to a target REST API or service endpoint.

Procedure

To compose a proxy API from a target service, complete the following steps.

1. In the navigation pane, click  Develop, select the APIs tab, then click Add API (from REST, GraphQL or SOAP). The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. Select From target service.
4. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
 - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
 - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see [apic draft-apis](#).
 - The Version corresponds to the value of the `info.version` property of the API's OpenAPI definition. The `version.release.modification` version numbering scheme is recommended; for example `1.0.0`.
 - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
 - The optional Description helps to identify the API.
5. Specify the existing REST API endpoint that you want to call in the Target Service URL field.
6. Click Next. In the Secure section, configure the API security that you require.
 - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the `X-IBM-Client-Id` parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
 - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.For information about security options in IBM API Connect, see [Configuring API security](#).
 - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.

Note:

 - CORS support is available only on the DataPower® API Gateway.
 - When CORS is enabled, the API Gateway runs the `cors` preflight policy to handle all CORS requests that are made to the API.
 - When CORS is enabled and a preflight request is received, only the following API actions are performed:
 - The `cors` preflight policy configures the appropriate response headers.
 - The response headers are set.
 - When a preflight request is received, the `request.attributes.isCORSPreflight` flag is set to `true`.
 - For all preflight requests, the `security` and `client-identification` preflight policies are always skipped, whether CORS is enabled or not enabled.
7. Click Next to create your API definition.

The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.
8. Select one of the following options:

- To further configure your API, click Edit API. For details, see [Editing an API definition](#).
- If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see [Editing an API definition](#).

Results

You created a proxy API from an existing target service.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see [Working with Products](#) and [Working with Catalogs](#).

Creating a REST proxy API from an existing OpenAPI service

If you have an existing OpenAPI described target service that you want to expose through an IBM® API Connect API definition, you can create a proxy API and specify the target endpoint.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **Api-Drafts:Edit**, **Settings:View**, and **App:View** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).

Create proxy REST APIs in minutes by using the API Designer tool to create an API from existing OpenAPI service. This procedure creates a REST proxy that routes all traffic to a target REST API or service endpoint.

Procedure

To compose a proxy API from an existing OpenAPI service, complete the following steps.

1. In the navigation pane, click  Develop, select the APIs tab, then click Add API (from REST, GraphQL or SOAP).
The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. Select From existing OpenAPI service, and click Next.
4. To upload the service information from an OpenAPI file, you can either drag and drop your file, or browse and select the file that you want to use. Valid file types are YAML, YML, etc.
 - Click Browse and browse for the OpenAPI file.
 - Drag and drop the file into the active area.After you upload the file, the OpenAPI specification is evaluated and a message displays whether it is valid.
5. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
 - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
 - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see [apic draft-apis](#).
 - The Version corresponds to the value of the `info.version` property of the API's OpenAPI definition. The `version.release.modification` version numbering scheme is recommended; for example `1.0.0`.
 - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
 - The optional Description helps to identify the API.
6. Click Next. In the Secure section, configure the API security that you require.
 - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the `X-IBM-Client-Id` parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
 - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.For information about security options in IBM API Connect, see [Configuring API security](#).
 - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
Note:
 - CORS support is available only on the DataPower® API Gateway.
 - When CORS is enabled, the API Gateway runs the `cors` preflight policy to handle all CORS requests that are made to the API.
 - When CORS is enabled and a preflight request is received, only the following API actions are performed:
 - The `cors` preflight policy configures the appropriate response headers.
 - The response headers are set.
 - When a preflight request is received, the `request.attributes.isCORSPreflight` flag is set to `true`.

- For all preflight requests, the **security** and **client-identification** preflow policies are always skipped, whether CORS is enabled or not enabled.
7. Optional: Select Activate API if you want to immediately use the API for further development and testing.
- Note:
- When you select the Activate API option, API Connect automatically completes the following actions:
 - Creates a draft Product, adds the API to the Product, and publishes the Product to the Sandbox Catalog so that the API is available to be called. The Product has the title *api_title* auto product. This Product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft Product is deleted together with the API; see [Deleting an API definition](#). The Product is visible in any Catalogs to which it is published. If you want to remove the Product from a Catalog, you must do this separately; see [Removing a Product from a Catalog](#)
 - Subscribes the Sandbox test application to the Product so that you can immediately test the API in the test environment. For information on testing an API, see [Testing an API](#).
 - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox Catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see [Creating and configuring Catalogs](#).
 - To use the Activate API option, you must be assigned a role that has the **Product:Manage** and **Subscription:Manage** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).
8. Click Next to create your API definition.
The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.
- If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.
9. Select one of the following options:
- To further configure your API, click Edit API. For details, see [Editing an API definition](#).
 - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see [Editing an API definition](#).

Results

You created a proxy API from an existing OpenAPI service.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see [Working with Products](#) and [Working with Catalogs](#).

Creating a REST proxy API from an existing WSDL service

If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect REST proxy API that calls that SOAP service.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **Api-Drafts:Edit**, **Settings:View**, and **App:View** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).

If the WSDL file is a stand-alone file with no external dependencies, you can load the .wsdl file from a directory to create the REST API definition.

If the WSDL file references other WSDL files or references XSD files containing XML schema definitions, you must create a .zip archive of the WSDL file and its dependent documents, and then load the .zip file from a directory to add the REST API definition.

Procedure

To add a REST API definition by loading a WSDL file, complete the following steps:

1. In the navigation pane, click  Develop, select the APIs tab, then click Add API (from REST, GraphQL or SOAP).
The Select API type screen is displayed.
2. Select OpenAPI 2.0; this API type does not support OpenAPI 3.0.
3. On the Add API pane, select From existing WSDL service (REST Proxy). Click Next.
The Create API from Existing WSDL Service (REST Proxy) window opens.
4. To upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, you can either drag and drop your file, or browse and select the file that you want to use.
After you upload the file, the WSDL is evaluated and a message displays whether the WSDL is valid.

If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see [Using an options file when importing a WSDL service](#).

5. Click Next. At the Select Service panel, select a WSDL service from the imported file.
6. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
 - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
 - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see [apic draft-apis](#).
 - The Version corresponds to the value of the `info.version` property of the API's OpenAPI definition. The `version.release.modification` version numbering scheme is recommended; for example `1.0.0`.
 - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
 - The optional Description helps to identify the API.
7. Click Next. In the Secure section, configure the API security that you require.
 - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the `x-IBM-Client-Id` parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
 - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.For information about security options in IBM® API Connect, see [Configuring API security](#).
 - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain. Note:
 - CORS support is available only on the DataPower® API Gateway.
 - When CORS is enabled, the API Gateway runs the `cors` preflight policy to handle all CORS requests that are made to the API.
 - When CORS is enabled and a preflight request is received, only the following API actions are performed:
 - The `cors` preflight policy configures the appropriate response headers.
 - The response headers are set.
 - When a preflight request is received, the `request.attributes.isCORSPreflight` flag is set to `true`.
 - For all preflight requests, the `security` and `client-identification` preflight policies are always skipped, whether CORS is enabled or not enabled.
8. Optional: Select Activate API if you want to immediately use the API for further development and testing. Note:
 - When you select the Activate API option, API Connect automatically completes the following actions:
 - Creates a draft Product, adds the API to the Product, and publishes the Product to the Sandbox Catalog so that the API is available to be called. The Product has the title `api_title` auto product. This Product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft Product is deleted together with the API; see [Deleting an API definition](#). The Product is visible in any Catalogs to which it is published. If you want to remove the Product from a Catalog, you must do this separately; see [Removing a Product from a Catalog](#)
 - Subscribes the Sandbox test application to the Product so that you can immediately test the API in the test environment. For information on testing an API, see [Testing an API](#).
 - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox Catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see [Creating and configuring Catalogs](#).
 - To use the Activate API option, you must be assigned a role that has the `Product:Manage` and `Subscription:Manage` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).
9. Click Next to create your API definition.

The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.

If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.
10. Select one of the following options:
 - To further configure your API, click Edit API. For details, see [Editing an API definition](#).
 - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see [Editing an API definition](#).

Results

You created a REST API definition by using an existing WSDL file.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see [Working with Products](#) and [Working with Catalogs](#).

You can also manage the Product lifecycle, and control who can see and subscribe to your Product, by opening the Sandbox Catalog associated with your API in the  Manage page of the API Designer UI.

Creating a SOAP proxy API from an existing WSDL service

If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect SOAP proxy API that calls that SOAP service.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **Api-Drafts:Edit**, **Settings:View**, and **App:View** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).

Note: By default, the SOAP proxy API that is created will have the basepath set to the WSDL service name. You can edit the SOAP proxy API to change this basepath. You can add a SOAP API to expose an existing SOAP service by supplying the WSDL file that defines that existing service in one of the following ways:

- If the WSDL file is a stand-alone file with no external dependencies, you can load the .wsdl file from a directory to create the SOAP API definition.
- You can provide one or more WSDL files in a single .zip file that contains the WSDL files and any necessary schemas. If the WSDL file references other WSDL files or references XSD files containing XML schema definitions, you must create a .zip archive of the WSDL file and its dependent documents, and then load the .zip file from a directory to add the SOAP API definition.
- If you are using API Designer with existing APIs that were created from a WSDL or WSDL.zip file in Version 5 API Designer, make sure that the following requirements are met:
 - The WSDL or WSDL.zip file must be stored in the same directory as the API's YAML file.
 - In the API's YAML file, the **x-ibm-configuration --> wsdl-definition --> wsdl** property must point directly to the WSDL or WSDL.zip file with no path specified (the files are located in the same directory).

The service must support Web Services Basic Profile Version 1.1 - Second Edition.

Procedure

To add a SOAP API definition by loading a WSDL file, complete the following steps:

1. In the navigation pane, click  Develop, select the APIs tab, then click Add API (from REST, GraphQL or SOAP). The Select API type screen is displayed.
2. Select OpenAPI 2.0; this API type does not support OpenAPI 3.0.
3. Select From existing WSDL service (SOAP Proxy). Click Next. The Create API from Existing WSDL Service (SOAP Proxy) window opens.
4. To upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, you can either drag and drop your file, or browse and select the file that you want to use. After you upload the file, the WSDL is evaluated and a message displays whether the WSDL is valid. If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see [Using an options file when importing a WSDL service](#).
5. Click Next. At the Select Service panel, select a WSDL service from the imported file.
6. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
 - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
 - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see [apic draft-apis](#).
 - The Version corresponds to the value of the **info.version** property of the API's OpenAPI definition. The **version.release.modification** version numbering scheme is recommended; for example 1.0.0.
 - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
 - The optional Description helps to identify the API.
7. Click Next. In the Secure section, configure the API security that you require.
 - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **x-IBM-Client-Id** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
 - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.For information about security options in IBM® API Connect, see [Configuring API security](#).
 - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain. Note:
 - CORS support is available only on the DataPower® API Gateway.
 - When CORS is enabled, the API Gateway runs the **cors** preflow policy to handle all CORS requests that are made to the API.
 - When CORS is enabled and a preflight request is received, only the following API actions are performed:
 - The **cors** preflow policy configures the appropriate response headers.
 - The response headers are set.
 - When a preflight request is received, the **request.attributes.isCORSPreflight** flag is set to **true**.
 - For all preflight requests, the **security** and **client-identification** preflow policies are always skipped, whether CORS is enabled or not enabled.
8. Optional: Select Activate API if you want to immediately use the API for further development and testing. Note:
 - When you select the Activate API option, API Connect automatically completes the following actions:
 - Creates a draft Product, adds the API to the Product, and publishes the Product to the Sandbox Catalog so that the API is available to be called. The Product has the title *api_title* auto product. This Product is not visible in the Develop view and you cannot delete it directly. However, if you delete the

- API the draft Product is deleted together with the API; see [Deleting an API definition](#). The Product is visible in any Catalogs to which it is published. If you want to remove the Product from a Catalog, you must do this separately; see [Removing a Product from a Catalog](#).
- Subscribes the Sandbox test application to the Product so that you can immediately test the API in the test environment. For information on testing an API, see [Testing an API](#).
 - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox Catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see [Creating and configuring Catalogs](#).
 - To use the Activate API option, you must be assigned a role that has the `Product:Manage` and `Subscription:Manage` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).
9. Click Next to create your API definition.
The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.
- If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.
10. Select one of the following options:
- To further configure your API, click Edit API. For details, see [Editing an API definition](#).
 - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see [Editing an API definition](#).

Results

You created a SOAP API definition by using an existing WSDL file.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see [Working with Products](#) and [Working with Catalogs](#).

You can also manage the Product lifecycle, and control who can see and subscribe to your Product, by opening the Sandbox Catalog associated with your API in the  Manage page of the API Designer UI.

Creating a new REST OpenAPI definition

You can create and edit draft REST API definitions by using the API Designer or the API Designer user interface in IBM® API Connect.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task you must be assigned a role that has the `Api-Drafts:Edit` permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see [Creating custom roles](#).

Procedure

To create a new REST OpenAPI definition, complete the following steps.

1. In the navigation pane, click  Develop, select the APIs tab, then click Add API (from REST, GraphQL or SOAP).
The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. Select New OpenAPI.
4. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
 - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
 - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see [apic draft-apis](#).
 - The Version corresponds to the value of the `info.version` property of the API's OpenAPI definition. The `version.release.modification` version numbering scheme is recommended; for example `1.0.0`.
 - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
 - The optional Description helps to identify the API.

5. Click Next. In the Secure section, configure the API security that you require.
 - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the `x-IBM-Client-Id` parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
 - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.
 - For information about security options in IBM API Connect, see [Configuring API security](#).
 - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain. Note:
 - CORS support is available only on the DataPower® API Gateway.
 - When CORS is enabled, the API Gateway runs the `cors` preflow policy to handle all CORS requests that are made to the API.
 - When CORS is enabled and a preflight request is received, only the following API actions are performed:
 - The `cors` preflow policy configures the appropriate response headers.
 - The response headers are set.
 - When a preflight request is received, the `request.attributes.isCORSPreflight` flag is set to `true`.
 - For all preflight requests, the `security` and `client-identification` preflow policies are always skipped, whether CORS is enabled or not enabled.
6. Click Next to create your API definition.

The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.
7. Select one of the following options:
 - To further configure your API, click Edit API. For details, see [Editing an API definition](#).
 - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see [Editing an API definition](#).

Results

You successfully created a REST API definition. For API Designer, the specifications for the APIs and Products are stored in the directory that you specified when you logged in. For API Manager, the specifications for the APIs and Products are stored on the management server.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see [Working with Products](#) and [Working with Catalogs](#).

Adding a REST API by importing an OpenAPI definition file

You can use an OpenAPI definition file to import a REST API into IBM® API Connect.

Before you begin

Your file must conform to version 2.0 or version 3.0 of the OpenAPI specification. The format of the file can be JSON or YAML.

Note: Products that contain an API with a Swagger property using `regex` that include lookahead assertions, such as `"(?"` cannot be validated or published. An error message is returned. For example:

```
Product has not been published!  
The multipart 'openapi' field contains an OpenAPI definition with validation errors.  
definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:  
0)  
400
```

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the `Api-Drafts:Edit`, `Settings:View`, and `App:View` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).

If you are using the API Designer UI and you want to use an OpenAPI definition file from elsewhere, downloaded from an external website for example, rather than created by using API Connect, use the import mechanism described here rather than copying the file into your local API Designer directory; the import operation adds API Connect specific sections that are required by API Designer.

Procedure

To add a REST API by importing an OpenAPI file, complete the following steps:

1. In the navigation pane, click  Develop, select the APIs tab, then click Add API (from REST, GraphQL or SOAP).
The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. In the Import section, select Existing OpenAPI, then click Next.
4. Choose one of the following methods for importing the file:
 - Drag and drop a file
Open another window, select a file. Drag the file to the Select a file box, and release the file.
 - Browse for a file
Click the Select a file box. Locate the file and select it.
 - Specify the URL of a file
In the Or specify a file URL field, type or paste a URL for the file. Optionally add a User name and Password if they are required for accessing the file.

The following file types are supported if they contain a valid OpenAPI definition: .json, .yaml, and .yml.

5. Click Next to import the selected file.
The wizard checks the validity of the YAML, and displays a message indicating successful validation.

Notes:

- If you are using the API Manager UI, the import operation fails if the file defines an API that has the same name and version as an existing API definition. However, if you are using the API Designer UI, API definitions are uniquely identified by the file name in your local file system; therefore, if you import two different files that define the same API name and version, two API definitions with the same name and version are created in API Connect, with no error.
 - Any validation error messages are displayed in English only, and are not translated.
6. Optional: Select Activate API if you want to immediately use the API for further development and testing.
Note:
 - When you select the Activate API option, API Connect automatically completes the following actions:
 - Creates a draft Product, adds the API to the Product, and publishes the Product to the Sandbox Catalog so that the API is available to be called. The Product has the title *api_title* auto product. This Product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft Product is deleted together with the API; see [Deleting an API definition](#). The Product is visible in any Catalogs to which it is published. If you want to remove the Product from a Catalog, you must do this separately; see [Removing a Product from a Catalog](#)
 - Subscribes the Sandbox test application to the Product so that you can immediately test the API in the test environment. For information on testing an API, see [Testing an API](#).
 - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox Catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see [Creating and configuring Catalogs](#).
 - To use the Activate API option, you must be assigned a role that has the **Product:Manage** and **Subscription:Manage** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).
 7. Click Next. The Import API Summary panel indicates that the YAML file is loaded and valid.
If you selected Activate API, the wizard populates an API Endpoint URL, and displays a Client ID and Client Secret that you can use.
 8. Select one of the following options:
 - To further configure your API, click Edit API. For details, see [Editing an API definition](#).
 - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see [Editing an API definition](#).

Results

When the API definition has been imported, it is shown in the list of API definitions in the Develop page. For API Designer, the specifications for the APIs and Products are stored in the directory that you specified when you logged in. For API Manager, the specifications for the APIs and Products are stored on the management server.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see [Working with Products](#) and [Working with Catalogs](#).

Adding a SOAP API by importing a zip file

You can use an OpenAPI definition file to import a SOAP API into IBM® API Connect.

Before you begin

The format of the file must be .zip, and the file must contain the WSDL definition and the YAML file that defines the API. The YAML file must conform to version 2.0 of the OpenAPI specification.

Note: Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "(?" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!  
The multipart 'openapi' field contains an OpenAPI definition with validation errors.  
definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:  
0)  
400
```

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **Api-Drafts:Edit**, **Settings:View**, and **App:View** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).

If you are using the API Designer UI and you want to use an OpenAPI definition file from elsewhere, downloaded from an external website for example, rather than created by using API Connect, use the import mechanism that is described here rather than copying the file into your local API Designer directory; the import operation adds API Connect specific sections that are required by API Designer.

For more information on how to create a .zip file, see [Downloading an API definition](#).

Procedure

To add a SOAP API by importing a .zip file, complete the following steps:

1. In the navigation pane, click  Develop, select the APIs tab, then click Add > API (from REST, GraphQL or SOAP). The Select API type screen is displayed.
2. Select OpenAPI 2.0; this API type does not support OpenAPI 3.0.
3. In the Import section, select Existing OpenAPI, then click Next.
4. To import a file from your local file system, you can either drag and drop the file or click the link to select the file from your local file system. The wizard checks the validity of the WSDL and YAML, and displays a message that indicates a successful validation.
Note:
 - If you are using the API Manager UI, the import operation fails if the file defines an API that has the same name and version as an existing API definition. However, if you are using the API Designer UI, API definitions are uniquely identified by the file name in your local file system; therefore, if you import two different files that define the same API name and version, two API definitions with the same name and version are created in API Connect, with no error.
 - Any validation error messages are displayed in English only, and are not translated.
5. Click Next.
6. Optional: Select Activate API if you want to immediately use the API for further development and testing.
Note:
 - When you select the Activate API option, API Connect automatically completes the following actions:
 - Creates a draft Product, adds the API to the Product, and publishes the Product to the Sandbox Catalog so that the API is available to be called. The Product has the title *api_title* auto product. This Product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft Product is deleted together with the API; see [Deleting an API definition](#). The Product is visible in any Catalogs to which it is published. If you want to remove the Product from a Catalog, you must do this separately; see [Removing a Product from a Catalog](#)
 - Subscribes the Sandbox test application to the Product so that you can immediately test the API in the test environment. For information on testing an API, see [Testing an API](#).
 - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox Catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see [Creating and configuring Catalogs](#).
 - To use the Activate API option, you must be assigned a role that has the **Product:Manage** and **Subscription:Manage** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).
7. Click Next. The Import API Summary panel indicates that the file is loaded and valid.
If you selected Activate API, the wizard populates an API Endpoint URL, and displays a Client ID and Client Secret that you can use.
8. Select one of the following options:
 - To further configure your API, click Edit API. For details, see [Editing an API definition](#).
 - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see [Editing an API definition](#).

Results

When the API definition has been imported, it is shown in the list of API definitions in the Develop page. For API Designer, the specifications for the APIs and Products are stored in the directory that you specified when you logged in. For API Manager, the specifications for the APIs and Products are stored on the management server.

Creating a GraphQL proxy API

GraphQL is a query language for APIs that gives an application client greater control over what data it retrieves in an API request when compared with a REST API request. IBM® API Connect enables you to create a GraphQL API proxy definition that proxies a backend GraphQL server, and to define rate limiting controls that reflect the amount of data that is returned from the server by a request to the GraphQL API.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **Api-Drafts:Edit**, **Settings:View**, and **App:View** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).

GraphQL provides the following particular advantages over REST APIs:

- The application client can request only the data that it needs. For example, when retrieving bank account records, request only the account number and current balance for each account, but not the customer name and address details. With a REST API request, either the backend REST service must provide separate endpoints for different data subsets, or the application client must retrieve the complete records and then discard the unwanted data.
- The application client can retrieve multiple related resources in a single request. For example, a customer's bank account record might include an array that references other finance products that the customer holds. If an application client wants to retrieve the bank account details for a specific customer, and details of the other finance products for that customer, then with a REST API the client would first retrieve the bank account details, then make separate requests for each of the other products. A GraphQL API can be designed to allow the client to retrieve all this information in a single request.

However, this flexibility presents rate limiting challenges, because two seemingly very similar requests might return vastly different amounts of data, and what might have required multiple REST API requests, each counting towards the rate limit, might require only a single GraphQL API request. It is important therefore that rate limiting controls are imposed that reflect the amount of data that is retrieved. API Connect extends the GraphQL standard by providing, in a GraphQL API definition, the ability to configure a range of settings that are used to calculate the complexity of a GraphQL request and an associated cost that counts towards the rate limit.

Procedure

To create a GraphQL API proxy definition, complete the following steps:

1. In the navigation pane, click  Develop, select the APIs tab, then click Add API (from REST, GraphQL or SOAP). The Select API type screen is displayed.
2. Select OpenAPI 2.0; this API type does not support OpenAPI 3.0.
3. Select From existing GraphQL service (GraphQL proxy).
4. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
 - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
 - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see [apic draft-apis](#).
 - The Version corresponds to the value of the `info.version` property of the API's OpenAPI definition. The `version.release.modification` version numbering scheme is recommended; for example `1.0.0`.
 - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
 - The optional Description helps to identify the API.
5. In the GraphQL Server section, specify the following values:
 - GraphQL server URL: this is the URL that is used for requests to the backend GraphQL API. The GraphQL schema is imported automatically from the specified URL.
 - Schema name: the name that you enter here is used to identify the schema definition that is created from the imported GraphQL schema. The field is pre-populated with host name segment of the value entered in the GraphQL server URL field, but you can change it.
6. Click Next. If there are any warnings indicated relating to the imported schema, you can review them now by clicking View. You can deal with these warnings as appropriate after you have created your GraphQL proxy API.
7. In the Operations and Paths section, select the operations and paths that you want to include. The operation path of `/graphql` is already selected and you cannot change this setting; this is the path for application client requests to API Connect that invoke the GraphQL API.

For details of the mechanisms supported for sending a request to the `/graphql/cost` endpoint, see [Request mechanisms supported by GraphQL endpoints](#).

You can also select the operation path of `graphql/cost`; this path enables application clients to obtain details of the cost of a request to the GraphQL API before making the actual request. In a production environment, in particular, you should consider carefully the resource implications of making this path available. For full details regarding the enablement of the cost endpoint, see [Enabling the cost endpoint for a GraphQL API](#).

To form the full API paths, these path segments are appended to the `basepath` that you specified in step 4.

To allow application clients to send introspection requests for this GraphQL proxy API, select Support default introspection. For full details, see [Supporting introspection for a GraphQL API](#).

To allow users to test the GraphQL proxy API from a GraphQL editor, select Enable GraphQL editor. For full details, see [Enabling the GraphQL editor for a GraphQL API](#).

Note: The `graphql/cost`, Support default introspection, and Enable GraphQL editor options each automatically generate policy configuration in your API assembly that would have to be created manually if you disable this option and later decide that it is required.

8. Optionally, you can replace the GraphQL schema that was imported from the GraphQL server URL by uploading a schema from your local file system. Click Replace; you can then either drag and drop your file, or click where indicated to select the file from your local file system. Click Upload when done.

Note:

- The schema must be written in the GraphQL Schema Definition Language (SDL). For more information, see [Type language](#) in the GraphQL documentation at <https://graphql.org/>.
 - If you upload a schema from a local file having previously uploaded a schema from a URL, the schema URL setting that is stored in the OpenAPI source for the API, and subsequently displayed in the user interface, retains the previously specified URL value rather than indicating a file location.
9. Click Next. In the Secure section, configure the API security that you require.
- Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the `X-IBM-Client-Id` parameter to be included in the request header for the API. For information about security options in IBM API Connect, see [Configuring API security](#).
 - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
Note:
 - CORS support is available only on the DataPower® API Gateway.
 - When CORS is enabled, the API Gateway runs the `cors` preflight policy to handle all CORS requests that are made to the API.
 - When CORS is enabled and a preflight request is received, only the following API actions are performed:
 - The `cors` preflight policy configures the appropriate response headers.
 - The response headers are set.
 - When a preflight request is received, the `request.attributes.isCORSPreflight` flag is set to `true`.
 - For all preflight requests, the `security` and `client-identification` preflight policies are always skipped, whether CORS is enabled or not enabled.
10. Optional: Select Activate API if you want to immediately use the API for further development and testing.
Note:
- When you select the Activate API option, API Connect automatically completes the following actions:
 - Creates a draft Product, adds the API to the Product, and publishes the Product to the Sandbox Catalog so that the API is available to be called. The Product has the title `api_title` auto product. This Product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft Product is deleted together with the API; see [Deleting an API definition](#). The Product is visible in any Catalogs to which it is published. If you want to remove the Product from a Catalog, you must do this separately; see [Removing a Product from a Catalog](#)
 - Subscribes the Sandbox test application to the Product so that you can immediately test the API in the test environment. For information on testing an API, see [Testing an API](#).
 - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox Catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see [Creating and configuring Catalogs](#).
 - To use the Activate API option, you must be assigned a role that has the `Product:Manage` and `Subscription:Manage` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).
11. Click Next to create your API definition.
The Summary panel displays messages as the definition is created, and the selected security options are enforced.
- If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.
12. Click Next to create your API definition.
The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.
13. Select one of the following options:
- To further configure your API, click Edit API. For details, see [Editing an API definition](#).
 - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see [Editing an API definition](#).

What to do next

Use the GraphQL schema editor to review, and deal with, any warnings associated with the schema, and to configure a range of settings that are used to calculate the complexity of a GraphQL request, and an associated cost that counts towards the rate limit; for details, see [Using the GraphQL schema editor](#).

- [Using the GraphQL schema editor](#)
The GraphQL schema editor allows you to configure a range of settings that are used to calculate the complexity of a GraphQL request, and an associated cost that counts towards the rate limit.

API Gateway only

Using the GraphQL schema editor

The GraphQL schema editor allows you to configure a range of settings that are used to calculate the complexity of a GraphQL request, and an associated cost that counts towards the rate limit.

Introduction

When the GraphQL schema editor opens, all the types defined in the GraphQL schema are listed. You can expand a type to display all the fields that are defined for that type.

For each type, you can specify the following setting:

Type weight

The weighting factor that you want to apply to the type for use when calculating the type cost for a request to the GraphQL API. In general, the weighting factor for a type will reflect the resource implications for a request that retrieves values of that type; for example:

- A complex object might be weighted more heavily than a String.
- Values of one type might be retrieved from a different backend database to values of another type, and accessing one database requires more CPU resource, so types associated with this database are weighted more heavily.

For each field, you can specify the following settings:

Field weight

The weighting factor that you want to apply to the field for use when calculating the field cost of a request to the GraphQL API.

Assumed size

The size limit that the backend server imposes on the number of values of this field that are returned, in a list, for each separate retrieval of the field in an API request. If an assumed size has been defined for this field in the imported GraphQL schema, its value is displayed. You can enter a value, or change the current value, and the schema definition stored in API Connect is updated accordingly. You must ensure that the specified value corresponds with the implementation or configuration on the backend server so that API Connect can apply rate limiting correctly. The assumed size is intended to be configured for fields that return lists of values, to tell the cost analysis how many values to expect.

Slicing arguments

A comma separated list of the arguments that are used by the backend server to limit the number of values of this field that are returned, in a list, for each separate retrieval of the field in an API request. These must correspond with the implementation or configuration on the backend server. For example, there might be slicing arguments of `first` and `last` that are used to specify a range of objects to be returned by an API request.

Sized fields

In some cases, a field with a configured Assumed size or Slicing arguments setting returns an object, a field of which returns the values whose number is to be sized. This is common in the [connections pattern for pagination](#), where fields with slicing arguments `first` or `last` return a `connections` object, that contains the sized list in an `edges` field. The Sized fields option allows the cost analysis to consider these indirect relationships between assumed sizes or slicing arguments and the sized list of values. Supply a comma separated list of field names.

You access the GraphQL schema editor in either of the following ways:

- Immediately after creating a new GraphQL proxy API, by clicking Edit API, then clicking the GraphQL Schema tab. For GraphQL proxy API creation details, see [Creating a GraphQL proxy API](#).
- By modifying the configuration of an existing API; complete the following steps:
 1. In the navigation pane, click  Develop, then select the APIs tab.
 2. Alongside the GraphQL API definition that you want to work with, click the options icon  and then click Edit API.
 3. Click the GraphQL Schema tab.

Modifying a setting for a single type or field

For a numerical setting, click the setting alongside the required type or field, then enter the required value, or use the stepper control. For a setting that has a textual value, enter the value directly. You might first want to filter the display to show only a relevant subset of types and fields; see [Filtering the display](#).

Modifying settings for multiple types and fields

To modify settings for multiple types and fields in a single operation, complete the following steps:

1. Select the check boxes alongside the types and fields whose settings you want to modify.
2. Click Apply analysis configuration.
3. On the Type tab, specify the settings that you want to apply to the selected types.
4. On the Field tab, specify the settings that you want to apply to the selected fields.
5. Click Apply to apply the settings to the selected types and fields.
6. When you have made all the required modifications to the selected types and fields, click Done; this action clears all check box settings.

To restore any type or field settings to the initial default settings after having applied an analysis configuration, select the check boxes alongside the required types and fields, then click Remove analysis configuration.

You might first want to filter the display to show only a relevant subset of types and fields; see [Filtering the display](#).

Filtering the display

To display only those type and fields that contain a specified string, enter the required filter string in the Search schema field, then press Enter.

If a type matches the filter, the type and all its fields are displayed. If a field matches the filter but not its parent type, the parent type is displayed together with all matching fields. You can enter multiple filter strings; the items displayed are those that contain all strings.

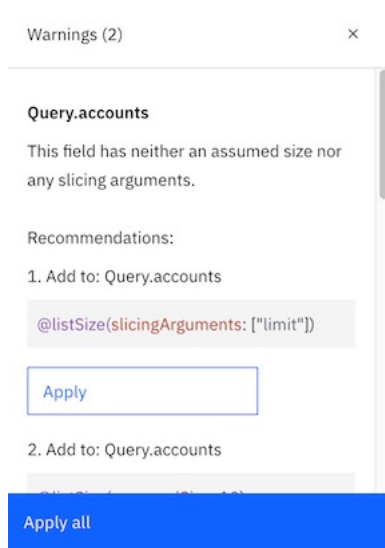

You can now use the operations described in [Modifying a setting for a single type or field](#) and [Modifying settings for multiple types and fields](#) to update the settings for the displayed types and fields.

To remove a specific filter string from the search, click the Close icon  for that filter string. To restore the full type and field display by removing all filter strings, click the Clear icon  at the end of the search field.

GraphQL schema warnings

Where applicable, API Connect will recommend updates to the analysis configuration to protect the backend server from excessive resource utilization, and to ensure correct cost estimation for requests. These recommendations are displayed as warnings in the GraphQL schema editor.

If a type contains one or more fields with warnings, this is indicated by a warning count icon  2 alongside the type. You can click the warning count icon to see the warnings for that type; the Warnings window opens at the relevant warnings, for example:

To see the fields that have warnings, expand the type; a warning icon  is displayed alongside fields with warnings. To see the details of a warning for a field, click the warning icon  alongside the field

If you click Accept under any warning in the Warnings window, the recommended update is applied to the schema automatically.

To apply the suggested updates for all warnings in a single operation, click Apply all in the Warnings window, then click Apply to confirm.

You can filter the display to include only items with warnings; click the Menu icon , then select Show warnings only.

Applying @remove directives to types and fields in the GraphQL schema

The `@remove` GraphQL schema directive specifies conditions for removing items from validation or introspection for each transaction based on values in the API context. For example, you can prevent specific Plans from using certain types or fields.

For more details on the `@remove` directive, including examples, see [rapic_graphql_extensions.html#reference_wrt_bk1_5mb_at_remove](https://www.ibm.com/docs/apiconnect/10.0.5.x?topic=rapic_graphql_extensions.html#reference_wrt_bk1_5mb_at_remove).

To apply an `@remove` directive to an item in your GraphQL schema, complete the following steps:

1. Click the settings icon  in the Show/hide column alongside the required item. The Show/hide settings window opens.
2. To remove the item depending on a boolean condition, enter the boolean expression in the Custom expression field; the following directive will be added to the item in the schema:

```
@remove(if: [expression])
```

To remove the item unconditionally, change the Show in schema slider control to Hide in schema; the following directive will be added to the item in the schema:

```
@remove(if: [\"true\"])
```

3. Click Next. A summary window opens. If the removal is permitted, any related items that will also have the `@remove` directive applied are listed; for example, if you apply an `@remove` directive to a type, and that type is referenced as the data type of a field on another type, the `@remove` directive is also applied to that field. If the removal is not permitted, an explanation is displayed.
4. If the removal is permitted, click Done to apply the `@remove` directive. If the removal is not permitted, either click Cancel to close the window or click Back and amend your settings.
5. To see the updates to the GraphQL JSON schema, click View source.

You can use the settings icon  to modify or delete previously applied `@remove` directives. To remove a conditional `@remove` directive, delete the expression from the Custom expression field. To remove an unconditional `@remove` directive, change the Hide in schema slider control to Show in schema.

Viewing the GraphQL schema

To view the GraphQL JSON schema that was previously uploaded, click View source. Note that the schema includes `directive` statements and attribute values, added by API Connect, that reflect the configuration settings.

Replacing the GraphQL schema

To replace the GraphQL schema, complete the following steps:

1. Click Replace.
2. Specify the replacement schema:
 - To replace the schema by introspecting a URL, complete the following steps:

- Select Introspect from URL.
- Enter the URL in the GraphQL server URL field, then click Introspect.

Note: If you replace the schema from a URL that is different to the one specified as the backend GraphQL server, in the GraphQL server URL field, when the GraphQL proxy API was created, the schema itself is replaced but the backend URL remains unchanged. You must correspondingly modify the URL setting on the **invoke** policy in the API assembly of your GraphQL proxy API.

- To replace the schema by uploading a file, complete the following steps:
 - Select Upload schema definition language (SDL) file.
 - Either drag and drop the file or click the link to select the file from your local file system.

Note:

- The schema must be written in the GraphQL Schema Definition Language (SDL). For more information, see [Type language](#) in the GraphQL documentation at <https://graphql.org/>.
- If you upload a schema from a local file having previously uploaded a schema from a URL, the schema URL setting that is stored in the OpenAPI source for the API, and subsequently displayed in the user interface, retains the previously specified URL value rather than indicating a file location.

All the changes between the replacement schema and the current schema are listed.

3. Update the schema as required:

- To have all new types and fields shown by default, select New schema for the Update schema defaults giving preference to setting. You can then choose to hide specific items by selecting Hide in the Action column alongside an item. Hiding an item causes an **@remove** directive to be added to the item in the schema source, as detailed in [Applying @remove directives to types and fields in the GraphQL schema](#).
- To have all new types and fields hidden by default, select Old schema for the Update schema defaults giving preference to setting. You can then choose to show specific items by selecting Show in the Action column alongside an item.

Note: If the current schema contains items that are not in the replacement schema, these items are deleted. Such deletions are shown in the change listing with the Accept setting displayed in the Action column; you cannot change this setting.

4. Click Next. A change summary page is displayed. If any removals are not permitted, an explanation is displayed, and you cannot complete the schema replacement; either click Cancel to close the window or click Back and amend your settings..
5. Click Submit to complete the schema replacement.

Downloading the GraphQL schema

To download the GraphQL schema to a local file, click the Download. Note that the downloaded schema includes all additional settings that reflect your configuration updates.

Supporting introspection for a GraphQL API

If you select the Support default introspection option when creating a GraphQL proxy API, client applications can send GraphQL introspection requests to the API.

Introspection allows client applications to request details of all the types and fields that are defined in a GraphQL schema. When you create a GraphQL proxy API, introspection requests sent to that API from client applications are handled by the gateway. The response reflects any modifications you have made to the schema by using the [GraphQL schema editor](#).

When you select the Support default introspection option, API Connect creates the introspection endpoint. A GraphQL editor always attempts to introspect a GraphQL endpoint, so disabling this option significantly reduces the test capability for GraphQL editor users. This option also automatically generates policy configuration in your API assembly that would have to be created manually if you disable this option and later decide that it is required; see the [API assembly policies for introspection support](#) section for details. Disabling this option also limits the capability of the Developer Portal to test the GraphQL proxy API.

On the other hand, providing introspection support can have resource implications, and you might choose to communicate the schema information in another way. However, note that the GraphQL editor does not allow custom introspection queries to populate the document explorer. For more information on introspection, see [Introspection](#) in the GraphQL documentation at <https://graphql.org/>.

API assembly policies for introspection support

This section details the API assembly policy configuration that is generated automatically if the Support default introspection option is selected when a GraphQL proxy API is created. If the option is not selected at creation time, and you later decide that you want to enable it, you must add it manually to the API assembly.

A **case** is added to a **switch** policy with the following condition:

```
(${operationPath()} = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'standard-introspection')
```

If the condition is true, the following policies are executed in sequence, with property settings as indicated:

Rate limit

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume

GraphQL introspect

Property	Value
Input	message
Output	No value, defaults to input

The automatically generated configuration, as it appears in the assembly UI, is as follows:

Enabling the GraphiQL editor for a GraphQL API

If you select the Enable GraphiQL editor option when creating a GraphQL proxy API, users can test the API by using a GraphiQL editor in a web browser; API Connect responds to the initial GraphiQL editor request with an HTML page that enables testing from the GraphiQL editor.

Disabling the Enable GraphiQL editor option reduces gateway traffic and latency and, furthermore, the Developer Portal provides equivalent test capability regardless of whether or not you enable the option.

This option automatically adds the following property setting to the OpenAPI source for the GraphQL proxy API:

html-page: 'store:///graphiql.html'

If you disable the Enable GraphiQL editor during API creation and later decide that it is required, you can either manually add this property setting, or you can select Enable GraphiQL editor on the API Setup page of the Design tab of the API..

Note:

- The **html-page** property should be used **only** with a GraphQL proxy API.
- **store:///graphiql.html** is the only value allowed for the **html-page** property.
- If you add the **html-page** property but the Support standard introspection property was not enabled during API creation, the GraphiQL HTML page will not show any documentation regarding the GraphQL backend server, perform query validation, or perform smart lookup. For details on how to manually create the required assembly policy configuration, see [Supporting introspection for a GraphQL API](#).

Enabling the cost endpoint for a GraphQL API

If you enable the `/graphql/cost` endpoint when creating a GraphQL proxy API, a calling application can obtain details of the cost of executing a request on the backend GraphQL server before making the actual backend request.

The "cost" does not relate purely to monetary cost but can take into account factors such as computational time, memory consumption, and other such factors, in addition to the actual financial costs associated with, say, using third-party systems to retrieve data.

In a production environment, in particular, you should consider carefully the resource implications of making this path available. Note, however, that enabling the `/graphql/cost` endpoint automatically generates policy configuration in your API assembly that would have to be created manually if you disable this option and later decide that it is required; see the [API assembly policies for the cost endpoint](#) section for details.

API assembly policies for the cost endpoint

This section details the API assembly policy configuration that is generated automatically if the `/graphql/cost` operation path is selected when a GraphQL proxy API is created. If the path is not selected at creation time, and you later decide that you want to enable it, you must add it manually to the API assembly.

A **case** is added to a **switch** policy with the following condition:

```
($operationPath() = '/graphql/cost' and message.attributes.parse.GraphQLIntrospection = 'not-introspection')
```

If the condition is true, the following policies are executed in sequence, with property settings as indicated:

Rate limit

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume

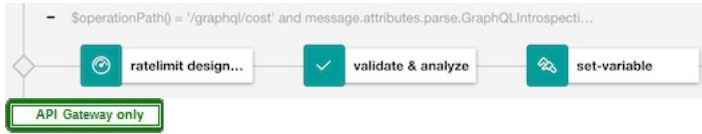

Validate

Property	Value
Input	message
Output	No value, defaults to input
Validate against	GraphQL

Set Variable

Property	Value
Action	Set
Set	message.body
Type	any
Value	\$(message.attributes.graphql)

The automatically generated configuration, as it appears in the assembly UI, is as follows:

Securing a GraphQL API by using a client ID

If you select the Secure using Client ID option when creating a GraphQL proxy API, API Connect automatically adds Rate limit policies to the API assembly.

This section details the Rate limit policy configuration that is generated automatically. If the Secure using Client ID option is not selected at creation time, and you later decide that you want to enable it, you must add the appropriate Rate limit policies manually to the API assembly.

The automatically generated Rate limit policies are added to the `switch` cases in the assembly as follows:

- **switch case:**

```
($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'not-introspection' and message.attributes.graphql.operationType = 'subscription')
```

A single Rate limit policy with the following property settings:

Property	Value
Source	Plan by Name
Count Limit Name	graphql-subscription-type-cost
Operation	Increment
Count Limit Name	graphql-subscription-field-cost
Operation	Increment

The policy as it appears in the assembly UI is as follows:

This Rate limit policy limits the number of HTML web browser requests for a GraphQL editor sent to the `/graphql` endpoint.

- **switch case:**

```
($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'not-introspection' and message.attributes.graphql.operationType != 'subscription')
```

Two Rate limit policies with the following property settings:

- Policy 1:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-type-cost
Operation	Consume
Rate Limit Name	graphql-field-cost
Operation	Consume
Rate Limit Name	graphql-input-type-cost
Operation	Consume

This Rate limit policy limits calls to the GraphQL proxy API by calculating the expected cost of the query, and then correspondingly reducing the available cost balance that remains of the total configured cost limit. The expected cost is calculated by applying the weighting factors that have been attached to the types and fields in the GraphQL schema; for more information, see [Using the GraphQL schema editor](#).

The expected cost is calculated by the Validate policy that precedes the Rate limit policy and placed in the API context to be made available to the Rate limit policy. For details on the Validate policy, see [Validate](#).

The details of the cost calculations to which the referenced rate limits are applied are as follows:

- **graphql-field-cost:** The weighted sum of fields being selected in a query. Fields that return values of scalar or enum types have a weight of 0.0 and therefore don't affect field cost. For example, consider the following query, where it is assumed that the value `max` in the `filter` argument of field `Query.offices` constrains the number of `Office` objects being returned:

```
query {
  offices (filter: {location: "NY", max: 3}) {
    address {
      street
    }
  }
}
```

The `Address.street` field is of type `String` and therefore has a weight of 0.0. Non scalar and non enum field weights that are not changed in the GraphQL schema editor assume a default value of 1.0. If the `Office.address` field weight has been set to 3.0, the total field cost is 10.0, calculated as follows:

Field	Weight	Field cost
<code>Query.offices</code>	1.0	$1 \times 1.0 = 1.0$

Field	Weight	Field cost
Office.address	2.0	3 x 3.0 = 9.0
Address.street	0.0	0.0
	Total cost:	1.0 + 9.0 + 0.0 = 10.0

- **graphql-type-cost:**
The weighted sum of types being returned by a query. Scalar or enum types have a weight of 0.0 and therefore don't affect type cost.

Considering the previous example, and assuming that all types have a default weight of 1.0, the total type cost is 7 (1 x **Query** type + 3 x **Office** types + 3 x **Address** types).

- **graphql-input-type-cost:**
The weighted sum of input types being sent in a query. Scalar or enum input types have a weight of 0.0 and therefore don't affect input type cost.

Considering the previous example, the input type cost is 1.0, because one **FilterInput** type is sent in the **filter** argument. **FilterInput.location** is a **String** type and **FilterInput.max** is an **Int** type, so they are not included as they are scalars.

o Policy 2:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-type-cost
Operation	Replenish
Rate Limit Name	graphql-field-cost
Operation	Replenish

This Rate limit policy limits calls to the GraphQL proxy API by calculating the actual cost of the query, and then correspondingly reducing the available cost balance that remains of the total configured cost limit. The actual cost is calculated by applying the weighting factors that have been attached to the types and fields in the GraphQL schema; for more information, see [Using the GraphQL schema editor](#).

Note that if the actual cost is less than the expected cost, this Rate limit policy will appropriately restore some of the available cost balance that had been removed by Policy 1, thereby overriding the original actual cost limitation. The actual cost might be less than the expected cost if, for example, the query requested more data than was available in a backend database. You can delete one or other of these Rate limit policies from the assembly if desired.

Note: Such unused cost is **not** restored if there are GraphQL response errors. The purpose of this restriction is to prevent malicious requests that cause large amounts of erroneous backend processing while only using a small amount of cost.

The actual cost is calculated by the Validate policy that precedes the Rate limit policy and placed in the API context to be made available to the Rate limit policy. For details on the Validate policy, see [Validate](#).

The policies as they appear in the assembly UI are as follows:

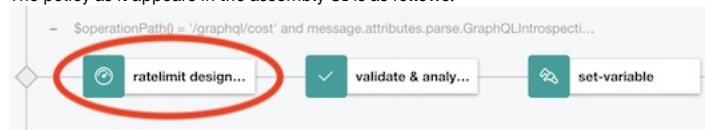

• **switch case:**

```
($operationPath() = '/graphql/cost' and message.attributes.parse.GraphQLIntrospection = 'not-introspection')
```

A single Rate limit policy with the following property settings:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume

The policy as it appears in the assembly UI is as follows:

This Rate limit policy limits the requests sent to the **/graphql/cost** endpoint for retrieving the cost of a GraphQL query.

• **switch case:**

```
($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'standard-introspection')
```

A single Rate limit policy with the following property settings:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume

The policy as it appears in the assembly UI is as follows:

This Rate limit policy limits standard introspection requests sent to the **/graphql** endpoint.

The rate limits that are referred to by the Rate Limit Name settings in these policies are predefined in Plans that are created in Products that contain one or more GraphQL proxy APIs. You can configure the actual rate limiting values there; for more information, see [Editing a draft Product](#).

For more information on the Rate Limit policy, see [Rate Limit](#).

Request mechanisms supported by GraphQL endpoints

API Connect supports various mechanisms for sending requests to GraphQL proxy API endpoints.

You can use any of the following mechanisms for sending requests to the `/graphql` and `/graphql/cost` endpoints on a GraphQL proxy API:

- **GET**: the GraphQL query must be specified in a URL query parameter called `query`.
For example:

```
https://hostname/basepath/graphql?query={accounts(limit:100){name{first,last}}}
```

The following example includes the `variables` and `operationName` properties, with URL encoding:

```
https://hostname/basepath/graphql?query=query%20fetchAccounts%20($limit:%20Int)%20{accounts(limit:%20$limit)%20{name{first,last}}&variables={"limit":100}&operationName=fetchAccounts
```

- **POST** with a JSON-encoded body: the `Content-Type` header must be set to `application/json`, and the GraphQL query must be sent in the `query` key of the JSON object.
For example:

```
{  "query": "query fetchAccounts ($limit: Int) {accounts(limit: $limit) {name{first,last}}}",  "variables": {"limit": 100},  "operationName": "fetchAccounts"}
```

The `variables` and `operationName` are optional. For more information, see [POST request](#) in the GraphQL documentation at <https://graphql.org/>.

- **POST** with `graphql` content: the `Content-Type` header must be set to `application/graphql`; the entire body of the **POST** is treated as the GraphQL query

Note: For a request sent to the `/graphql` endpoint, the GraphQL proxy API always sends the request to the backend GraphQL server as a **POST** with a JSON-encoded body, so the backend GraphQL server must support this mechanism otherwise the call fails.

GraphQL custom schema directives and scalar types

The API Connect DataPower® API Gateway extends the GraphQL specification by providing additional schema directives and custom scalar types.

Custom schema directives

`@cost`

The `@cost` directive associates weight values with types or fields. Types are used to calculate type cost of a request to the GraphQL API. Fields are used to calculate field cost of a request to the GraphQL API. For more information, see [The Cost Directive](#).

`@listSize`

The `@listSize` directive applies slicing arguments to fields. For more information, see [The List Size directive](#).

`@remove`

The `@remove` GraphQL schema directive specifies conditions for removing types and fields from validation or introspection for each transaction based on values in the API context. For more information, see [@remove directive](#)

`@scalarParam`

The `@scalarParam` directive allows further customization of custom scalar types. For more information, see [@scalarParam directive](#).

Custom scalar types

`Date`

The `Date` custom scalar type is used to define custom scalars that specify dates. For more information, see [Date Custom Scalar](#).

`DateTime`

The `DateTime` custom scalar type is used to define custom scalars that specify date and time. For more information, see [DateTime Custom Scalar](#).

`JSON`

The `JSON` custom scalar type is used to specify JSON payloads. For more information, see [JSON Custom Scalar](#).

`Long`

The `Long` custom scalar type enables the use of integers larger than those allowed by `Int`. For more information, see [Long Custom Scalar](#).

Related reference

- [Using the GraphQL schema editor](#)

`@remove` directive

The `@remove` GraphQL schema directive specifies conditions for removing types and fields from validation or introspection for each transaction based on values in the API context.

For example, you can prevent specific Plans from using certain types or fields. For more information on the API context, see [API Connect context variables](#).

Note: The `@remove` directive dynamically modifies the schema so that queries that do not conform to the schema, after any `@remove` directives have been evaluated, would be rejected by a `validate` policy.

Syntax

```
@remove(if: [String]) on SCALAR | OBJECT | FIELD_DEFINITION | ARGUMENT_DEFINITION | INTERFACE | UNION | ENUM | ENUM_VALUE | IN
```

Arguments

Argument name	Type	Description
<code>if</code>	List of strings	JSONata condition that specifies the criteria for removal of a type or field from validation or introspection.

Limitations and propagation rules

For limitations and propagation rules, see [Limitations and propagation rules for the GraphQL @remove directive](#).

Example 1

Remove the `creditCard` type if the current API plan is `bronze`.

```
type creditCard @remove(if: ["plan.name in [\\"bronze\\""]])
```

Example 2

Remove the `creditCard` type if the current API plan is not `gold`, and remove the field `card1` if the API plan is `bronze`.

```
type creditCard @remove(if: ["$not(plan.name = \\"gold\\")"]){
  field1: String
}
type User {
  card1: creditCard @remove(if: ["plan.name = 'bronze'", "$not(plan.name = \\"gold\\")"])
}
```

GraphQL limitations

This page details the limitations in the API Connect GraphQL implementation for the current release.

- Specialized handling of custom scalars is not supported, except for validation of the `Long` custom scalar type. Input values provided for all other custom scalar types are passed through.
 - The following actions and functions cannot read or write to parsed GraphQL queries. Some of these policies might read and write a serialized form of the GraphQL query.
 - Assembly GatewayScript policy
 - Assembly Map policy
 - Assembly Redaction policy
 - Assembly Set Variable policy
 - Assembly XSLT policy
 - `setVar ()` function
 - When reading parsed GraphQL queries, the Assembly Switch policy cannot use wildcards or read arguments.
 - GraphQL schemas cannot be serialized.
 - GraphQL messages received with `Content-Type: application/graphql` or `Content-Type: application/json` will send that same content type to the backend. This behavior cannot be overridden.
 - All GraphQL schemas are checked for unbounded lists, including those that are not referenced in the assembly. This behavior can cause validation errors that prevent the GraphQL API from being published.
 - The GraphQL schema editor generates warnings for fields that contain unbound lists of values if either of the following conditions is true.
 - The values in the list are of composite type. However, the warning is not valid if the composite type in the list has a defined type weight of 0.0 and all its sub-fields also have weights of 0.0 (both the fields and the types of the values they return).
 - The values in the list are of scalar type, for which a weight other than 0.0 was defined.
 - Extending schemas is not supported.
 - GraphQL APIs can be tested from the Developer Portal user interface. However, not all authentication methods are supported. You must use one of the following authentication methods:
 - Unsecured
 - Client ID, passed in the header
 - Client ID and secret, passed in the header
- Also, `cost` metrics are not supported, and rate limits specific to GraphQL are not listed in Product plans.

Importing an API from the CP4I asset repository

If you are using IBM® API Connect with IBM Cloud Pak for Integration (CP4I), you can import an API definition from the CP4I asset repository.

About this task

To complete this task you must be assigned a role that has the `Api-Drafts:Edit` permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see [Creating custom roles](#).

Procedure

1. In the navigation pane, click  Develop, select the APIs tab, then click Add API (from REST, GraphQL or SOAP).
The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. In the Import section, select From asset repository, then click Next.
4. Click Launch the asset repository.
5. From the asset repository listing, click the name of the API that you want to import.
An API explorer window opens, enabling you to examine the details of the API.
6. Click Create from asset.
The validity of the API definition is checked, and a message is displayed indicating successful validation.
7. Click Next.
8. Optional: Select Activate API if you want to immediately use the API for further development and testing.
Note:
 - When you select the Activate API option, API Connect automatically completes the following actions:
 - Creates a draft Product, adds the API to the Product, and publishes the Product to the Sandbox Catalog so that the API is available to be called. The Product has the title *api_title* auto product. This Product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft Product is deleted together with the API; see [Deleting an API definition](#). The Product is visible in any Catalogs to which it is published. If you want to remove the Product from a Catalog, you must do this separately; see [Removing a Product from a Catalog](#)
 - Subscribes the Sandbox test application to the Product so that you can immediately test the API in the test environment. For information on testing an API, see [Testing an API](#).
 - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox Catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see [Creating and configuring Catalogs](#).
 - To use the Activate API option, you must be assigned a role that has the **Product:Manage** and **Subscription:Manage** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).
9. Click Next.
The Summary panel displays messages as the API definition is created.
10. Select one of the following options:
 - To further configure your API, click Edit API. For details, see [Editing an API definition](#).
 - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see [Editing an API definition](#).

Editing an OpenAPI 2.0 API definition

IBM® API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 2.0 specification.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

You can open an API for editing in either of the following ways:

- During the initial creation of an API, the API wizard guides you to enter the minimum configuration settings; on completion of the initial configuration, click Edit API.
- To open an existing API for editing, complete the following steps:
 1. In the navigation pane, click  Develop, then select the APIs tab.
 2. Click the title of the API version that you want to work with.
- [Specifying API metadata](#)
API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.
- [Specifying the host for an API](#)
You specify a host for an API if you want external developers on the portal to access your APIs by using a host address that is not the same as the API endpoints that are defined for the gateway services where your API will run.
- [Specifying the basepath for an API](#)
The base path is the initial URL segment of the API, and does not include the host name or any additional segments for paths or operations. It is shared by all operations in the API.
- [Specifying the schemes for an API](#)
Schemes define which transfer protocols you want your API to use. If your API is enforced by an API Connect gateway, only the HTTPS protocol is supported.
- [Specifying the MIME types that an API consumes](#)
You can specify which types of media your API will accept when calls are made to it. The API Connect gateway supports XML and JSON.
- [Specifying the MIME types that an API produces](#)
You can specify which types of media your API will return when calls are made to it. The API Connect gateway supports XML and JSON.
- [Enforcing security requirements on an API](#)
To enforce security requirements on an API, you apply previously created security schemes that specify various aspects of API security configuration.
- [Specifying external documentation for an API](#)
You can reference an external resource for extended documentation for an API.
- [Adding tags to an API](#)
You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.
- [Defining Paths for an API](#)
A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.

- **Defining schemas for an API**
Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.
- **Defining parameters for an API**
Parameters can specify variable elements of a URL path, query parameters, headers, or a request body.
- **Defining responses for an API**
Responses define the HTTP status code and data returned in a response body and headers. Responses defined for an API can be used across operations.
- **Specifying gateway and portal settings**
Define general configuration settings for your API.
- **Defining target services for an API**
A target service defines a web service that you want to use in your API definition.
- **Setting API properties**
In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.
- **Configuring application authentication for an API**
Application authentication settings allow you to protect your API with a certificate, for example, by using TLS mutual authentication. You can select whether a client certificate is sent as a TLS client certificate or in an HTTP header.
- **Configuring activity logging**
You can configure your logging preferences for the API activity that is stored in Analytics, overriding the default activity logging behavior.
- **Configuring v5 compatibility options**
You can configure settings to ensure compatibility with API Connect Version 5.0 compatible APIs that are converted for use with the DataPower® API Gateway.
- **Including elements in your API assembly**
An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.
- **Specifying the gateway type for an API definition**
An API definition is specific to one or other of the gateway types, DataPower API Gateway or DataPower Gateway (v5 compatible). A default gateway type is set when you create an API definition, but you can edit the API configuration to specify a different gateway type.
- **Converting an API definition for deployment to the DataPower API Gateway**
IBM API Connect provides two gateway types, DataPower Gateway (v5 compatible) and DataPower API Gateway. If you have an API definition that was developed for the DataPower Gateway (v5 compatible) and you want to port it to the DataPower API Gateway, you must make changes to convert it before deployment.
- **Modifying a GraphQL schema**
For a GraphQL API, an editor is provided for modifying the associated GraphQL schema.
- **Validating the OpenAPI YAML source**
How to validate the OpenAPI YAML source when you're editing an API.

Specifying API metadata

API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand the General section, then click Info.
3. Provide the following information:
 - Title (required): The title of the API.
 - Name: The name was generated automatically when the API was created and cannot be changed. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see [apic draft-apis](#).
 - Version: The API version is specified when the API is initially created and cannot be changed thereafter. You can, however, create a new version of an existing API; see [Creating a new version of an API definition](#).
 - Description: An optional description of the API. You can use [CommonMark syntax](#) for rich text representation.
 - Terms of Service: A URL to the Terms of Service for the API.
 - Contact Name: The identifying name of the contact person/organization.
 - Contact Url: A URL pointing to the contact information.
 - Contact Email: The email address of the contact person/organization.
 - License Name: The license name used for the API.
 - License Url: A URL to the license used for the API.
4. Click Save when done.

Specifying the host for an API

You specify a host for an API if you want external developers on the portal to access your APIs by using a host address that is not the same as the API endpoints that are defined for the gateway services where your API will run.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand the General section, then click Host.
3. Enter the required host name.

Note: To enable this capability, you must additionally configure API vanity endpoints in the Catalog Settings for the Catalog to which the API is published. For information on configuring vanity endpoints, see [Creating and configuring Catalogs](#)

4. Click Save when done.

Specifying the basepath for an API

The base path is the initial URL segment of the API, and does not include the host name or any additional segments for paths or operations. It is shared by all operations in the API.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand the General section, then click Base Path.
3. Enter the required base path, preceded by a forward slash character (/).
4. Click Save when done.

Specifying the schemes for an API

Schemes define which transfer protocols you want your API to use. If your API is enforced by an API Connect gateway, only the HTTPS protocol is supported.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand the General section then, if there are already one or more schemes defined, expand Schemes List.
3. To specify a new scheme, click the add icon  alongside Schemes List. To modify an existing scheme, click the scheme entry in the navigation pane.
4. Select the required scheme from the list provided, then click Create.
5. Click Save when done.

Specifying the MIME types that an API consumes

You can specify which types of media your API will accept when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand the General section then, if there are already one or more consumes MIME types defined, expand Consumes.
3. To specify a new MIME type, click the add icon  alongside Consumes. To modify an existing MIME type, click the MIME type entry in the navigation pane.
4. Enter the required value in the Mime Type field; for example, `application/json` or `application/xml`. Then click Create.
5. Click Save when done.

Specifying the MIME types that an API produces

You can specify which types of media your API will return when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand the General section then, if there are already one or more produces MIME types defined, expand Produces.
3. To specify a new MIME type, click the add icon  alongside Produces. To modify an existing MIME type, click the MIME type entry in the navigation pane.
4. Enter the required value in the Mime Type field; for example, `application/json` or `application/xml`. Then click Create.
5. Click Save when done.

Enforcing security requirements on an API

To enforce security requirements on an API, you apply previously created security schemes that specify various aspects of API security configuration.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security scheme definitions, see [Defining security schemes](#).

The following restrictions exist when you apply security schemes to an API:

- You cannot apply more than two API key security schemes to an API.
- If you apply an API key security scheme for client secret, you must also apply an API key security scheme for client ID.
- If you require the application developer to supply both client ID and client secret, you must apply two separate API key security schemes.
- You can have at most one API key scheme of type client ID, regardless of whether the client ID is sent in the request header or as a query parameter.
- You can have at most one API key scheme of type client secret, regardless of whether the client secret is sent in the request header or as a query parameter.
- You cannot apply more than one basic security scheme to an API. If you apply a basic security scheme, you cannot also apply an OAuth security scheme.
- You can apply at most one OAuth security scheme to an API.

A security requirement specifies one or more security schemes whose conditions must all be satisfied for the API to be called successfully. You can define multiple security requirements; in this case, an application can call your API if it satisfies any of the security requirements you have defined.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand General.
3. To create a new security requirement for the API, complete the following steps:
 - a. Click the add icon  alongside Security in the navigation pane.
 - b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have been defined; see [Defining security schemes](#).

If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme; for more information, see [Defining OAuth2 security schemes](#).

If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower® API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see [Configuring scopes for a native OAuth provider](#).

Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the `x-IBM-Client-Id` or `client_id` must be included in the security credentials so that the correct Plan configuration settings can be enforced.

- c. Click Create. The security scheme selections are shown; you can change them again before saving.
- d. Click Submit when done.

4. To modify an existing security requirement, complete the following steps:

- a. Click Security in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
- b. To change the security schemes for a security requirement, click the edit icon  alongside the required security requirement, then change your security requirement selections as required.
- c. Click Submit when done, then click Save.
- d. To delete a security requirement, click the appropriate delete icon , click Delete to confirm, then click Save.
- e. To disable security for the API, clear the Require one of the following Security Requirements check box, then click Save.

- [Defining security schemes](#)

A security scheme specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

- [Enabling CORS support for an API](#)

You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Defining security schemes

A security scheme specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can create security definitions of the following types:

Type	Description
Basic authentication	Use a basic authentication security definition to specify a user registry or an authentication URL to be used to authenticate access to the API.
API key	Use an API key security definition to specify what application credentials are required to call an API.
OAuth2	Use an OAuth2 security definition to specify settings for OAuth token based authentication for your API.

- [Defining basic authentication security schemes](#)

A basic authentication security scheme is used when an application that calls the API is required to authenticate through a user registry.

- [Defining API key security schemes](#)

An API key security scheme is used to specify the credentials that an application must provide to identify itself when calling the API operations.

- [Defining OAuth2 security schemes](#)

An OAuth2 security scheme defines the settings for controlling access to the API operations through the OAuth authorization standard.

Defining basic authentication security schemes

A basic authentication security scheme is used when an application that calls the API is required to authenticate through a user registry.

Before you begin

For authenticating access to the operations of APIs that are enforced on the API Connect gateway, the following user registry types are supported:

- Authentication URL
- LDAP

The following user registry types are **not** supported:

- OpenID Connect (OIDC)
- Local User Registry (LUR)
- A custom user registry

Before you can create a basic authentication security definition in an API, the user registry must exist. To create a user registry, you can use either API Manager or Cloud Manager. When you create a registry in API Manager, it is visible only to your provider organization. When you create a registry in Cloud Manager, you can make it visible to multiple provider organizations.

To create a user registry with API Manager, see [Working with user registries](#).

To create a user registry with Cloud Manager, see [User registries overview](#).

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you use basic authentication, you require API users to provide a valid user name and password to access selected operations. The application developer must also provide an HTTP authorization header in requests that are sent to operations that require basic authentication.

When you use an authentication URL, the user credentials that are provided in the authorization header are validated by the endpoint specified in the URL. If the user is authenticated, IBM® API Connect expects an authentication URL to return an HTTP 200 OK response status code. All other HTTP response status codes result in an authentication failure and access is denied.

For more information about using an LDAP user registry for authentication, see [LDAP authentication](#).

For information about using an Authentication URL, see [Authentication URL user registry](#).

To make use of a basic authentication security scheme, you must reference it from elsewhere in your API definition. For more information, see [Enforcing security requirements on an API](#) and [Enforcing security requirements on an operation](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. If there are already one or more security schemes defined, expand Security Schemes.
3. To create a basic authentication security scheme, click the add icon  alongside Security Schemes, then select basic for the Security Definition Type. To edit an existing basic authentication security scheme, click the security scheme name in the navigation pane.
4. Enter an identifying name of your choice in the Name field.
5. Select the user registry from the Authenticate using User Registry list.
The user registries in the list are those that have been enabled in the Sandbox Catalog; for details, see [Creating and configuring Catalogs](#).
6. Optionally, provide a Description for the security scheme. You can use [CommonMark syntax](#) for rich text representation.
7. If you are creating a new basic authentication security scheme, click Create.
The security scheme details are displayed for further editing.
8. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see [Enforcing security requirements on an API](#) and [Enforcing security requirements on an operation](#).

For more information on LDAP and Authentication URL, see [LDAP authentication](#) and [Authentication URL user registry](#).

Defining API key security schemes

An API key security scheme is used to specify the credentials that an application must provide to identify itself when calling the API operations.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can require that, when calling an API operation, an application must provide either a client ID, or a client ID and client secret; you create an API key security scheme to specify a credentials requirement. If you require that an application must provide both a client ID and client secret, you must create two API key security schemes, one for each type of credentials.

To make use of an API key security scheme, you must reference it from elsewhere in your API definition. For more information, see [Enforcing security requirements on an API](#) and [Enforcing security requirements on an operation](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. If there are already one or more security schemes defined, expand Security Schemes.
3. To create an API key security scheme, click the add icon  alongside Security Schemes, then select apiKey for the Security Definition Type. To edit an API key existing security scheme, click the security scheme name in the navigation pane.
4. Enter an identifying name of your choice in the Security Scheme Name field.
5. Specify the parameter name in the Name field.

If your API is not enforced by the API Connect gateway, enter the parameter name required by your gateway.

If your API is enforced by the IBM® API Connect gateway, the required value depends on the gateway type setting for the API, as follows:

- DataPower® API Gateway: For a key of type client secret, you must include the string "secret", ignoring case, in the value you specify in the Name field; if the value does not contain the string "secret" then the key is assumed to be of type client ID.
- DataPower Gateway (v5 compatible): the value must be as specified in the following table, depending on where the client credentials are located, and the type of credentials.

Table 1. Client ID and Client secret parameter name values for the DataPower Gateway (v5 compatible)

Location of credentials	Type of credentials	Parameter name
Header	Client ID	X-IBM-Client-Id
Header	Client secret	X-IBM-Client-Secret
Query	Client ID	client_id

Location of credentials	Type of credentials	Parameter name
Query	Client secret	client_secret

When you first create an API, a default API key security definition, of type client ID, is provided.

For information about including API key parameters in an API call, see [Calling an API](#).

Note:

- You cannot apply more than two API key security definitions to an API.
- If you apply an API key security definition for client secret, you must also apply an API key security definition for client ID.
- If you require the application developer to supply both client ID and client secret, you must apply two separate API key security definitions.
- You can have at most one API key definition of type client ID, regardless of whether the client ID is sent in the request header or as a query parameter.
- You can have at most one API key definition of type client secret, regardless of whether the client secret is sent in the request header or as a query parameter.
- The client ID and client secret headers that are specified in the request when the API is called are **not** added automatically to the message context. If you need these headers in the message context for subsequent processing, include a **set-variable** policy in your API assembly that adds the headers to the message content, taking the values specified in the request; you can do this in either of the following ways:
 - In the Assemble tab, add a Set Variable policy to your API assembly that defines the appropriate actions; for example:

Table 2.

Action	Set	Type	Value
Set	message.headers.X-IBM-Client-Id	string	\$(request.headers.X-IBM-Client-Id)
Set	message.headers.X-IBM-Client-Secret	string	\$(request.headers.X-IBM-Client-Secret)

For more information on configuring a Set Variable policy, see [Set Variable](#).

- In the Source tab, add a **set-variable** policy directly to the assembly section in your OpenAPI source; for example:

```
assembly:
  execute:
    - set-variable:
      version: 2.0.0
      title: set-variable
      actions:
        - set: message.headers.X-IBM-Client-Id
          value: $(request.headers.X-IBM-Client-Id)
          type: string
        - set: message.headers.X-IBM-Client-Secret
          value: $(request.headers.X-IBM-Client-Secret)
          type: string
```

For more information on defining a **set-variable** policy in your OpenAPI source, see [set-variable](#).

You should position the **set-variable** before any policy that needs to access the API key headers; for example, an invoke policy that calls a back-end service that is required to identify the application that made the initial request.

- Select the Key Type: client_id or client_secret.

Important: The client_id is not confidential and functions as a "SecurityScheme" only in the meaning of the OpenAPI specification.

If you use only the client_id (without the client_secret) as your API Key, be aware that the client_id is not considered a confidential value in the API Manager UI; for example, it might be displayed to other authenticated members of the provider organization. The client_id is treated as a public identifier for apps and cannot be kept private.

If authentication of the identity of the app calling an API is needed, then the API Key should use both a client_id to identify the app, plus a client_secret to authenticate it. The client_secret is designed to be known only to the app and the authorization server, and it should be protected. IBM API Connect protects the client_secret: it is only available when first generated, it can be stored as a one-way hash to prevent retrieval or leaks, and it can be changed and reset without changing the corresponding client_id. When an API Key is not marked as a client_secret, it will not be protected in the API Manager UI.

- Specify whether the credentials are sent in the request header, or as query parameters, by selecting one of the following Located In options:

header

The credentials are sent in the request header. This is the default setting.

query

The credentials are sent as query parameters. This method is less secure because the client secret could be exposed in a log file.

The selected option is enforced, and API calls fail if the credentials are included in the wrong location by the caller.

Note:

- You must specify the same location for the client ID and client secret, either header or query.
- If you migrated from API Connect V5, API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. For information about the differences, see [Client ID behavior in API key security definitions](#).

- Optionally, provide a Description for the security scheme. You can use [CommonMark syntax](#) for rich text representation.

- If you are creating a new API key security scheme, click Create.

The security scheme details are displayed for further editing.

- Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see [Enforcing security requirements on an API](#) and [Enforcing security requirements on an operation](#).

- [Client ID behavior in API key security definitions](#)
How the Client ID behaves in API key security definitions in IBM API Connect 10 compared to Version 5.

Client ID behavior in API key security definitions

How the Client ID behaves in API key security definitions in IBM® API Connect 10 compared to Version 5.

API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. Refer to the following table to understand the differences in Client ID behavior for different use cases.

Note: Although a client_id in the request body is supported, this data is not used during security requirement processing.

Table 1. Client ID behavior in V5 and V10

Use case	Description of security requirement	V5 behavior	V10 behavior
1	Allows client_id in the query, and the request contains multiple client_ids in the query.	Uses the first client ID in the request.	401 invalid client ID or secret.
2	Allows client_id in the header, and the request contains multiple client_ids in the header.	401 invalid client ID or secret.	401 invalid client ID or secret.
3	Allows client_id in the header, and the request contains multiple client_ids in the query and the header (1 in the query, 1 in the header).	401 client ID in wrong location.	Client ID in query is ignored.
4	Allows client_id in the query, and the request contains multiple client_ids in the query and the header.	Client ID in header is ignored.	Client ID in header is ignored.
5	Allows client_id in the query or header, and both the query and header contain multiple client_ids.	Header returns 401 client ID in wrong location. Query uses the first client ID in the request.	401 invalid client ID or secret.
6	Allows client_id in the header, and the request contains a valid client_id in the query, and an invalid client_id in the header.	401 client ID in wrong location.	401 invalid client ID or secret.
7	Allows client_id in the query, and the request contains a valid client_id in the header, and an invalid client_id in the query.	401 invalid client ID or secret.	401 invalid client ID or secret.
8	Allows client_id in the query or header, and both the query and header contain valid client_ids.	200 OK.	403 multiple client IDs.
9	Allows client_id in the query or header, and both the query and header contain invalid client_ids.	401 client ID in wrong location.	401 invalid client ID or secret.
10	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the query is valid.	200 OK.	Uses the valid one 200 OK.
11	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the header is valid.	401 client ID in wrong location.	Uses the valid one 200 OK.
12	Allows client_id in the query or header, and both the query and client_id is missing in the request (no security requirement, but client security is defined in the assembly).	401 invalid client ID or secret.	<ul style="list-style-type: none"> When Return V5 Responses compatibility option is off: 401 client ID is missing. When Return V5 Responses compatibility option is on: 401 invalid client ID or secret. <p>For information about setting compatibility options, see Configuring v5 compatibility options.</p>

Defining OAuth2 security schemes

An OAuth2 security scheme defines the settings for controlling access to the API operations through the OAuth authorization standard.

Before you begin

Before you can create an OAuth2 security scheme, you must:

1. Create an OAuth provider.
 - To use Cloud Manager, see [Configuring a native OAuth provider](#) or [Configuring a third-party OAuth provider](#).
 - To use API Manager, see [Configuring a native OAuth provider](#) or [Configuring a third-party OAuth provider](#).
2. Add the OAuth provider to a catalog. If you have not created any catalogs, use the Sandbox Catalog. See the [OAuth instructions step](#) in [Creating and configuring Catalogs](#).

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of an OAuth2 security scheme, you must reference it from elsewhere in your API definition. For more information, see [Enforcing security requirements on an API](#) and [Enforcing security requirements on an operation](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. If there are already one or more security schemes defined, expand Security Schemes.
3. To create an OAuth2 security scheme, click the add icon  alongside Security Schemes, then select oauth2. To edit an existing OAuth2 security scheme, click the security scheme name in the navigation pane.
4. Enter an identifying name of your choice in the Security Scheme Name field.
5. Provide the following information:
 - Security Scheme Name: An identifying name of your choice.

- OAuth Provider: Select the OAuth provider to be used.
 - Flow: Select one of the following options:
 - Implicit
 - Resource Owner
 - Application
 - Access Code
- Note: The flow options that are available for selection depend on which options are supported by the selected OAuth provider.
- Description: An optional description of the OAuth2 security scheme. You can use [CommonMark syntax](#) for rich text representation.
 - The URL endpoints (the applicable endpoints depend on the flow type):
 - Authorization Url
 - Token Url
- Note: The URL endpoint values supplied here are maintained only for informative purposes, no validation or other action is applied to them by API Connect. The OAuth security that is applied depends on the specified OAuth provider.
- Scopes (available if you are editing an existing OAuth2 security scheme):
 - To add a new scope, click Add. To edit an existing scope, click the options icon  alongside the required scope, then click Edit.
 - Provide the following information:
 - Scope: The scope identifier.
 - Description: An optional description of the scope. You can use [CommonMark syntax](#) for rich text representation.
 - If you are creating a new scope, click Create.
6. If you are creating a new OAuth2 security scheme, click Create.
The security scheme details are displayed for further editing.
7. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see [Enforcing security requirements on an API](#) and [Enforcing security requirements on an operation](#).

Enabling CORS support for an API

You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Before you begin

This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

About this task

Note:

- CORS support is available only on the DataPower® API Gateway.
- When CORS is enabled, the API Gateway runs the `cors` preflow policy to handle all CORS requests that are made to the API.
- When CORS is enabled and a preflight request is received, only the following API actions are performed:
 - The `cors` preflow policy configures the appropriate response headers.
 - The response headers are set.
- When a preflight request is received, the `request.attributes.isCORSPreflight` flag is set to `true`.
- For all preflight requests, the `security` and `client-identification` preflow policies are always skipped, whether CORS is enabled or not enabled.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

To enable CORS support for an API, complete the following steps:

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Select the Gateway tab, expand Gateway and portal settings, then click CORS.
The CORS page opens.
3. Select Enabled.
4. Optional: Configure a CORS policy.
Should you create a CORS policy? Review the following considerations:
 - A CORS policy is an optional part of an API definition. If an API definition has no CORS policy but CORS is enabled, then CORS requests will be accepted from all Origins.
If you want to accept CORS requests from all Origins, then enable CORS but do not add a CORS policy to the API definition.
 - If you create a CORS policy, then CORS requests will only be accepted from Origins that are explicitly listed in the CORS rules contained in the CORS policy. CORS requests from any other Origins will be rejected.
If you want to accept CORS requests from only a limited number of Origins (and might also want to configure the Access-Control-Allow-Credentials and Access-Control-Expose-Headers response headers), then you should enable CORS and create a CORS policy. Only those Origins explicitly listed in the allow-origin field of the CORS rules in the CORS policy will be accepted; CORS requests from any Origins not listed will be rejected.
 - To configure a new CORS policy, complete the following steps:
 - Alongside Policy, click Add.

- To include the header `Access-Control-Allow-Credentials: true` in a response, select Allow Credentials. The `Access-Control-Allow-Credentials` response header tells browsers whether to expose the response to front-end JavaScript code when the request's credentials mode (`Request.credentials`) is set to `include`.
- To append one or more of the following values to the `Access-Control-Expose-Headers` response header, select Expose headers, and select from the following options:
 - Predefined - The predefined value of the Gateway. This option is selected by default.
 - Backend - The value of `Access-Control-Expose-Headers` from the backend response.
 - Custom - A custom string.
- Click Create.
- Alongside Allowed Origins click Add.
- Enter the origin URL, then click Create. This setting indicates that the response can be shared with requesting code from the specified origin.
- To modify an existing CORS policy, click its entry on the CORS page. You can then modify individual origin URLs, add further origins, and change the Allow Credentials setting.

Example

The following example has three rules:

- Accept an Origin header of `https://example.com`, and return `Access-Control-Allow-Credentials: true` in the CORS response.
- Accept an Origin header of `http://domain.com`. No `Access-Control-Allow-Credentials` header will be returned in the response.
- Accept any of the following Origin headers:
 - `http://example2.com`
 - `http://example3.com`
 - `http://example4.com`

No `Access-Control-Allow-Credentials` header will be returned in the response.

```
cors:
  enabled: true
  policy:
    -
      allow-origin:
        - 'https://example.com'
      allow-credentials: true
    -
      allow-origin:
        - 'http://domain.com'
    -
      allow-origin:
        - 'http://example2.com'
        - 'http://example3.com'
        - 'http://example4.com'
```

5. Click Save to save your changes.
6. Optional: To implement your own CORS solution using custom OPTIONS operations, complete the following steps:
 - a. Add the following headers to your HTTP responses:

```
Access-Control-Allow-Origin: https://<portalhostname>
Access-Control-Allow-Headers: Origin, X-Requested-With, Content-Type, Accept
```

Where `<portalhostname>` is your Developer Portal host name.

- b. Optional: You can proxy your API through API Connect as an enforced invoke API so that CORS is handled automatically.

Important:

- If you implement your own CORS solution, you **must** disable the CORS option described in step 3
- CORS preflight requests are sent by using the HTTP `OPTIONS` method. Therefore, if you require these requests to be handled by the API Connect gateway then you must enable the `OPTIONS` method for all APIs that will handle preflight requests; see [Defining Paths for a REST API](#).
- `OPTIONS` requests are counted as API calls against any configured rate limit. Note that you can apply rate limits to individual operations; see [Defining rate limits for an API operation](#).

Specifying external documentation for an API

You can reference an external resource for extended documentation for an API.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand the General section, then click External Documentation.
3. Provide the following information:
 - URL (required): The URL for the target documentation.
 - Description: An optional description of the target documentation. You can use [CommonMark syntax](#) for rich text representation.
4. Click Save when done.

Adding tags to an API

You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand the General then, if there already one or more tags defined, expand Tags.
3. To add a new tag, click the add icon  alongside Tags in the navigation pane. To edit an existing tag, click the tag name in the navigation pane.
4. Provide the following information:
 - Name (required): The name of the tag.
 - Description: An optional description of the tag. You can use [CommonMark syntax](#) for rich text representation.
 - External Documentation URL (available when editing an existing tag): The URL for target documentation that describes this tag.
 - External Documentation Description (available when editing an existing tag): An optional description of the target documentation.
5. If you are creating a new tag, click Create.
6. Click Save when done.

Defining Paths for an API

A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. If there are already one or more Paths defined, expand Paths.
3. To create a new Path, click the add icon  alongside Paths in the navigation pane. To edit an existing Path, click the Path in the navigation pane.
4. Provide the following information:
 - Path: A relative path to an individual endpoint.
The path is appended to the base path to construct the full URI to access the APIs. The path must start, but not end, with the / character. A parameter at the end of the path can contain a qualifier to match one or more path levels.

If you specify just the name of the parameter, then one level of that path is matched. If you want to allow for multiple levels of the path, you can prefix the parameter with one of the following qualifiers:

- * to indicate 0 or more occurrences
- + to indicate 1 or more occurrences

The + and * qualifiers can only be used at the end of the path.

For example, the path:

```
/petstore/{type}/{*category}
```

matches the following paths, where only one type value is matched, but all (0 or more) categories are matched:

```
/petstore/cats  
/petstore/cats/supplies  
/petstore/cats/supplies/health  
/petstore/cats/supplies/health/medicines  
/petstore/cats/supplies/health/medicines/a/b/c
```

- \$ref (available when editing an existing Path): A reference to a Path that is defined elsewhere, either in this OpenAPI definition, or in an external file. A reference enables reuse of a set of operations already defined for a Path in this API, or in a file that is either a complete API definition or an OpenAPI fragment.

The reference uses JSON pointer notation. For example, a reference to a Path called `/mypath` in this API would have the following format:

```
#/paths/~1mypath
```

The `~1` characters are used to escape the / character, which is being used literally in the path name rather than as a special character.

A reference to a path in an external file called `path_fragments.yaml` would have the following format:

```
file://path_fragments.yaml/paths/~1mypath
```

5. If you are creating a new Path, click Create.

The Path details are displayed for further editing as described in step 4.
6. Click Save when done.

- **Defining parameters for a path**

Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.

- **Defining operations for a path**

Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

Defining parameters for a path

Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand Paths.
3. Expand the required Path, then, if there already one or more parameters defined, expand Path Parameters.
4. You can either create a new parameter, or edit any existing parameter.
 - To create a parameter, click the add icon  alongside Path Parameters, then refer to [Creating a parameter](#).
 - To edit an existing parameter, click the parameter name in the navigation pane, then refer to [Editing a parameter](#).

Defining operations for a path

Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand Paths, then expand the required path.
3. Click the add icon  alongside Operations under the Path in the navigation pane.
4. Provide the following information:
 - Verb: Select the operation type from the following options:
 - get
 - post
 - put
 - delete
 - options
 - head
 - patch
 - trace
 - Summary: A summary of what the operation does.
 - Description: A description of the operation behavior.
 - Operation: Unique string used to identify the operation. The id must be unique among all operations described in the API.
 - Deprecated: Declares this operation to be deprecated. Consumers should refrain from using the declared operation.
5. Click Create.
6. Click Save when done.

- **Adding tags to an operation**

You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

- **Specifying external documentation for an operation**

You can referencing an external resource for extended documentation for an API operation.

- [Specifying the MIME types that an API operation produces](#)
You can specify which types of media your API operation will return when calls are made to it. The API Connect gateway supports XML and JSON.
- [Specifying the MIME types that an API operation consumes](#)
You can specify which types of media your API operation will accept when calls are made to it. The API Connect gateway supports XML and JSON.
- [Defining parameters for an operation](#)
Responses define the HTTP status code and data returned in a response body and headers.
- [Defining responses for an operation](#)
Responses define the HTTP status code and data returned in a response body and headers. A response defined for an operation is one that can be returned by executing the operation.
- [Specifying schemes for an operation](#)
The schemes settings define which transfer protocols you want your API operation to use.
- [Enforcing security requirements on an operation](#)
To enforce security requirements on an API operation, you apply previously created security schemes that specify various aspects of API security configuration.

Adding tags to an operation

You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To add a new operation tag, click the add icon  alongside the Tags entry for the operation in the navigation pane. To edit an existing tag, expand Tags then click the tag name in the navigation pane.
5. Provide the following information:
 - Name (required): The name of the tag.
6. If you are creating a new operation tag, click Create.
7. Click Save when done.

Specifying external documentation for an operation

You can refer to an external resource for extended documentation for an API operation.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then click External Documentation.
4. Provide the following information:
 - URL (required): The URL for the target documentation.
 - Description: An optional description of the target documentation. You can use [CommonMark syntax](#) for rich text representation.
5. Click Save when done.

Specifying the MIME types that an API operation produces

You can specify which types of media your API operation will return when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To specify a new MIME type, click the add icon  alongside Produces. To modify an existing MIME type, click the MIME type entry in the navigation pane.
5. Enter the required value in the Mime Type field; for example `application/json` or `application/xml`. Then click Create.
6. Click Save when done.

Specifying the MIME types that an API operation consumes

You can specify which types of media your API operation will accept when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To specify a new MIME type, click the add icon  alongside Consumes. To modify an existing MIME type, click the MIME type entry in the navigation pane.
5. Enter the required value in the Mime Type field; for example, `application/json` or `application/xml`. Then click Create.
6. Click Save when done.

Defining parameters for an operation

Responses define the HTTP status code and data returned in a response body and headers.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. You can either create a new operation parameter, or edit any existing parameter.
 - To create an operation parameter, click the add icon  alongside Path Parameters, then refer to [Creating a parameter](#).
 - To edit an existing operation parameter, click the parameter name in the navigation pane, then refer to [Editing a parameter](#).

Defining responses for an operation

Responses define the HTTP status code and data returned in a response body and headers. A response defined for an operation is one that can returned by executing the operation.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there are any existing responses, expand Responses.
4. You can either create a new response, or edit any existing response.
 - To create a response, click the add icon  alongside Responses, then refer to [Creating a response](#).
 - To edit an existing response, click the response name in the navigation pane, then refer to [Editing a response](#).

Specifying schemes for an operation

The schemes settings define which transfer protocols you want your API operation to use.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there are any existing schemes, expand Schemes List.
4. You can either add a new scheme, or edit any existing scheme.
 - To add a scheme, click the add icon  alongside Schemes List, select the required transfer protocol, then click Create.
Note: If your API is enforced by an API Connect gateway, only the HTTPS protocol is supported.
 - To edit an existing scheme, click the scheme in the navigation pane, then change the transfer protocol as required.
5. Click Save when done.

Enforcing security requirements on an operation

To enforce security requirements on an API operation, you apply previously created security schemes that specify various aspects of API security configuration.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security schemes, see [Defining security schemes](#).

A security requirement specifies one or more security scheme definitions whose conditions must all be satisfied for the API operation to be called successfully. You can define multiple security requirements; in this case, an application can call your API operation if it satisfies any of the security requirements you have defined.

Any security requirements that you define for an operation completely override any security requirements defined on the parent API. If you do not define any security requirements for an operation, or you delete all security requirements from an operation, the operation inherits the security requirements defined on the parent API. For more information, see [Enforcing security requirements on an API](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To create a new security requirement for the operation, complete the following steps:
 - a. Click the add icon  alongside the Security entry for the operation in the navigation pane.
 - b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have previously been defined; see [Defining security schemes](#).
If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme; for more information, see [Defining OAuth2 security schemes](#).

If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower® API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see [Configuring scopes for a native OAuth provider](#).

Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the `X-IBM-Client-Id` or `client_id` must be included in the

- security credentials so that the correct Plan configuration settings can be enforced.
- c. Click Create. The security scheme selections are shown; you can change them again before saving.
 - d. Click Save when done.
5. To modify an existing security requirement, complete the following steps:
- a. Click the Security entry for the operation in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
 - b. To change the security schemes for a security requirement, click the edit icon  alongside the required security requirement, then change your security requirement selections as required.
 - c. Click Submit when done, then click Save.
 - d. To delete a security requirement, click the appropriate delete icon , click Delete to confirm, then click Save.
 - e. To disable security for the operation, clear the Require one of the following Security Requirements check box, then click Save.
- Note: These settings completely override any security requirements defined on the parent API; see [Enforcing security requirements on an API](#).

Defining schemas for an API

Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
 2. If there are already one or more schemas defined, expand Definitions.
 3. You can create a new schema, or edit any existing schema.
 - To create a schema, click the add icon  alongside Definitions, then refer to [Creating a schema](#).
 - To edit an existing schema, click the schema component name in the navigation pane, then refer to [Editing a schema](#).
- **Creating a schema**
Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.
 - **Editing a schema**
Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Creating a schema

Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.

Launch the schema creation window. For details of the areas in your API definition from where you can create a schema, see the following topics:

- [Defining schemas for an API](#)
- [Editing a response](#)

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
 - Schema Name: This name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

`#/definitions/Name`

- Title: The schema title.
 - Type: The schema data type; select one of the following:
 - array
 - boolean
 - integer
 - number
 - object
 - string
 - Description: An optional description of the schema. You can use [CommonMark syntax](#) for rich text representation.
 - Select the following options as required:
 - Read Only: A property associated with this schema can be sent in a response but should not be sent in a request.
 - Write Only: A property associated with this schema can be sent in a request but should not be sent in a response.
 - Deprecated: The schema is deprecated and should be transitioned out of usage.
2. Click Create.
- The schema details are displayed for further editing; see [Editing a schema](#).

Editing a schema

Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.

Open the details form for a schema. For details of the areas in your API definition from where you can edit a schema, see the following topics:

- [Defining schemas for an API](#)
- [Editing a response](#)

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

You can configure the following schema settings:

- Schema Name: This name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

`#/definitions/Name`

To change the name, click Update, change the value in the field, then click Save.

- Title: The schema title.
- Type: The schema data type; select one of the following:
 - - array
 - boolean
 - integer
 - number
 - object
 - string

Note: If you change the type of an existing schema, any existing settings that are not relevant to the new type are still retained in the OpenAPI source even though they are no longer displayed in the user interface. You should therefore avoid porting a schema from one type to another but instead either create a new schema or modify the OpenAPI source directly; to open the source editor, click the Source icon .

- Additional schema settings dependent on the selected Type, as follows:
 - array:
 - Max Items: The maximum allowed number of items in an array instance.
 - Min Items: The minimum allowed number of items in an array instance.
 - Unique Items: If selected, all items in an array instance must be unique.
 - boolean: no type specific settings.
 - integer:
 - Format: An optional data type modifier. For more information, see [Data Types](#) in the [OpenAPI Specification](#).
 - Multiple Of: Division of an integer instance by this value must result in an integer.
 - Maximum: An integer instance must be less than or equal to this value.
 - Exclusive Maximum: An integer instance must be strictly less than this value.
 - Minimum: An integer instance must be greater than or equal to this value.
 - Exclusive Minimum: An integer instance must be strictly greater than this value.
 - number:
 - Format: An optional data type modifier. For more information, see [Data Types](#) in the [OpenAPI Specification](#).
 - Multiple Of: Division of a number instance by this value must result in an integer.

- Maximum: A number instance must be less than or equal to this value.
- Exclusive Maximum: A number instance must be strictly less than this value.
- Minimum: A number instance must be greater than or equal to this value.
- Exclusive Minimum: A number instance must be strictly greater than this value.
- object
 - Properties: To add properties to the schema, click Add alongside the Properties section heading. You configure a property by defining its schema with the schema editor.
To create the property, refer to [Creating a schema](#).

To further configure the property, follow the steps on this page.

By defining properties, you can create more complex data structures. For example, you could define an "Address" schema that has the following properties:

PROPERTY NAME	PROPERTY TYPE
street1	string
street2	string
city	string
state	string
zip_code	string

and then define a "BankBranch" schema that has the following properties, one of which is a reference to the Address schema:

PROPERTY NAME	PROPERTY TYPE
address	address
type	string
id	string

- Max Properties: The number of properties in an object instance must be less than or equal to this value.
- Min Properties: The number of properties in an object instance must be greater than or equal to this value.
- Required Properties: An array of property names; every property name in the array must be the name of a property in an object instance. To add a required property name, click Add alongside the Required Properties section heading, enter the name, then click Create.
- string:
 - Format: An optional data type modifier. For more information, see [Data Types](#) in the [OpenAPI Specification](#).
 - Pattern: A regular expression; a string instance must successfully match the expression.
 - Max Length: The maximum allowed number of characters in a string instance.
 - Min Length: The minimum allowed number of characters in a string instance.
 - Enum: An array of string values; a string instance must match one of the array values. To add an enum value, click Add, enter the value, then click Create.
- Description: An optional description of the schema. You can use [CommonMark syntax](#) for rich text representation.
- General settings; select the required options:
 - Read Only: A property associated with this schema can be returned in a response but should not be included in a request. For example, properties whose values are system generated identifiers will be defined as Read Only because application clients wouldn't be able to set these.
 - Write Only: A property associated with this schema can be included in a request but should not be returned in a response. For example, password properties are usually defined as Write Only because application clients would supply these when creating a user object but shouldn't be able see them when retrieving the object.
 - Deprecated: The schema is deprecated and should be transitioned out of usage.
- Example Value: An example value. Whatever you enter here is displayed as-is in the Developer Portal.
- External Documentation: An external resource for extended documentation; provide the following information:
 - URL (required): The URL for the target documentation.
 - Description: An optional description of the target documentation. You can use [CommonMark syntax](#) for rich text representation.
- Xml: Metadata that allows for more fine-tuned XML model definitions; provide the following information:
 - Name: Replaces the name of the element or attribute used for the described schema property.
 - Namespace: The URL of the namespace definition.
 - Prefix: The prefix to be used for the Name.
 - Attribute: Specifies whether the property definition translates to an attribute instead of an element.
 - Wrapped: For an array definition, Specifies whether the array is wrapped (for example, `<books><book/></books>`) or unwrapped (`<book/></book/>`).
- Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining parameters for an API

Parameters can specify variable elements of a URL path, query parameters, headers, or a request body.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).

2. If there already one or more parameters defined, expand Parameter Definitions.
3. You can either create a new parameter, or edit any existing parameter.
 - To create a parameter, click the add icon  alongside Parameters, then refer to [Creating a parameter](#).
 - To edit an existing parameter, click the parameter name in the navigation pane, then refer to [Editing a parameter](#).

• [Creating a parameter](#)

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.

• [Editing a parameter](#)

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for the API, or for Paths and Path operations in your API definition.

Creating a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.

Before you begin

Launch the parameter creation window. For details of the areas in your API definition from where you can create a parameter, see the following topics:

- [Defining parameters for a path](#)
- [Defining parameters for an operation](#)
- [Defining parameters for an API](#)

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **header**.
- A parameter can have various format styles, the style of a header is always **simple**.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
 - Parameter Name: The name of the parameter.
 - Located In: The location of the parameter. Select one of the following options:
 - query: Parameters that are appended to the URL. For example, `url_path?myparam=myvalue`.
 - header: Custom headers that are expected as part of the request.
 - path: The parameter value is part of the operation's URL, enclosed in {}.
 - body: Parameters that describe the body of POST, PUT and PATCH requests.
 - Description: A description of the parameter.
 - Type: The data type of the parameter.
 - Format: Select the data format; the available options depend on the selected Type.
 - Select the following option as required:
 - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
 - Allow Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
2. Click Create.

The parameter details are displayed for further editing; see [Editing a parameter](#).

Editing a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for the API, or for Paths and Path operations in your API definition.

Before you begin

Open the details form for a parameter. For details of the areas in your API definition from where you can edit a parameter, see the following topics:

- [Defining parameters for a path](#)
- [Defining parameters for an operation](#)
- [Defining parameters for an API](#)

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **header**.
- A parameter can have various format styles, the style of a header is always **simple**.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
 - Description: A description of the parameter. You can use [CommonMark syntax](#) for rich text representation.
 - Type: The data type of the parameter.
 - Format: Select the data format; the available options depend on the selected Type.
 - Select the following options as required:
 - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
 - Allow Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining responses for an API

Responses define the HTTP status code and data returned in a response body and headers. Responses defined for an API can be used across operations.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
 2. If there already one or more responses defined, expand Response Definitions.
 3. You can either create a new response, or edit any existing response.
 - To create a response, click the add icon  alongside Response Definitions, then refer to [Creating a response](#).
 - To edit an existing response, click the response name in the navigation pane, then refer to [Editing a response](#).
- [Creating a response](#)
Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.
 - [Editing a response](#)
Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.

Creating a response

Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.

Before you begin

Launch the response creation window. For details of the areas in your API definition from where you can create a response, see the following topics:

- [Defining responses for an API](#)
- [Defining responses for an operation](#)

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
 - Name: The HTTP status code.
 - Description (required): A description of the response.
2. Click Create.
The response details are displayed for further editing; see [Editing a response](#).

Editing a response

Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.

Before you begin

Open the details form for a response. For details of the areas in your API definition from where you can edit a response, see the following topics:

- [Defining responses for an API](#)
- [Defining responses for an operation](#)

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
 - Name: The HTTP status code.
 - Description (required): A description of the response.
 - Schema: The schema defines the response structure.
To define a schema for the response, click Create, then refer to [Creating a schema](#).

If the response already has a schema defined, click View to edit the schema.

For full details on editing a schema, see [Editing a schema](#).
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Specifying gateway and portal settings

Define general configuration settings for your API.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Select the Gateway tab, then click Gateway and portal settings.
3. Provide the following information:
 - Target Services: Define web services that you want to use in your API definition. For details, see [Defining target services for an API](#).
 - Enforced: Select this option to enforce the API by using the DataPower® API Gateway. Clear this option if you are managing the API on a gateway other than the DataPower API Gateway. Although not published to a gateway by API Connect, an unenforced API is still available in the Developer Portal for subscription by application developers.
 - Phase: The phase of the lifecycle that your API is in; select one of the following options:
 - Realized (default) - The API is in the implementation phase.
 - Identified - The API is in the early conceptual phase and is neither fully designed nor implemented.
 - Specified - The API has been fully designed and passed an internal milestone but has not yet been implemented.

- Testable: Select this option to allow the API's operations to be tested using the test tool in the Developer Portal.
Note: For the test tool to work, an API must be included in a Plan in a Product that is staged in a Catalog.
- CORS: Enable and configure cross-origin resource sharing (CORS) support for your API. For details, see [Enabling CORS support for an API](#).
- Properties: Add properties that can be referenced in your API definition. For details, see [Setting API properties](#).
- Catalog Properties: Define property values that are specific to a particular Catalog. For details, see [Defining Catalog specific property values](#).
- Gateway: For details, see [Specifying the gateway type for an API definition](#).
- Application Authentication: Enable application authentication to protect your API with a certificate. For details, see [Configuring application authentication for an API](#).
- Application Authentication Source: If application authentication is enabled, specify how the client certificate is sent to the gateway. For details, see [Configuring application authentication for an API](#).
- Activity Log: Configure your logging preferences for the API activity that is stored in Analytics. For details, see [Configuring activity logging](#).
- Compatibility: For details, see [Configuring v5 compatibility options](#).
- HTML Page: For a GraphQL API, the HTML page with which the API responds to an initial GraphQL editor request. Currently, the only option is `store:///graphql.html`. For more information, see [Enabling the GraphQL editor for a GraphQL API](#).
- GraphQL Schema: For a GraphQL API, the name of the schema definition that references the imported GraphQL schema. For information on uploading a schema during GraphQL API creation, see [Creating a GraphQL proxy API](#). For information on replacing the schema for an existing GraphQL API, see [Using the GraphQL schema editor](#).
- Extensions: Extensions added to the API to extend the OpenAPI specification. For details, see [Adding an OpenAPI extension to an API](#).

Defining target services for an API

A target service defines a web service that you want to use in your API definition.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more target services defined, expand Target Services.
3. To define a new API target service, complete the following steps:
 - a. Click the add icon  alongside Target Services in the navigation pane.
 - b. Upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, by either dragging and dropping your file, or browsing and selecting the file that you want to use.
If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see [Using an options file when importing a WSDL service](#).

The target services that you add are now available in the palette on the Policies view for you to add to your API assembly flow; for more information, see [Including elements in your API assembly](#).

4. Select the service that you want to add.
5. Click Save to save your changes.
6. To view the source for an existing target service, click the target service name in the navigation pane.

Results

The target services that you add are now available in the palette on the Policies view for you to add to your API assembly flow; for more information, see [Including elements in your API assembly](#).

Setting API properties

In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API properties include property name, value, and, optionally a specific Catalog to which a property value applies. For a list of pre-supplied API properties relating to various policies, see [API properties](#).

Note: Once defined, an API property is read only.

For information on how to reference a property in an API definition, see [Variable references in API Connect](#).

It is also possible to define properties that are specific to a Catalog and can be referenced by any of the APIs in that Catalog; for more information, see [Creating and configuring Catalogs](#). Note that if you define a Catalog property of the same name as an API property, the API property takes precedence over the Catalog property.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
 2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more API properties defined, expand Properties.
 3. Configure an API property.
 - To define a new API property, complete the following steps:
 - Click the add icon  alongside Properties in the navigation pane.
 - Provide the following information:
 - Property Name: Enter a name for the property; this name is used to reference the property. The following character set is supported for the name of an API property: `[A-Za-z0-9_-]+`. Spaces are allowed.
 - Property Value: A default value for the property. Leave blank if the property is to have a null value by default.
 - Description: An optional description of the property. You can use [CommonMark syntax](#) for rich text representation.
 - Select Property Value is Base64 Encoded if you want to hide the property values, or protect user passwords from casual observance.
Note: If you encode a property value, it is saved in Base64 encoded form; it is **not** encrypted. If you subsequently clear the Encoded check box, the original property value is restored in its unencoded form.
 - Click Create.
 - To modify an existing API property, click the property name in the navigation pane. You can then change any of the configuration settings.
 4. Click Save to save your changes.
- [Defining Catalog specific property values](#)
For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Defining Catalog specific property values

For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Before you begin

You must have previously created the API property that you now want to define a Catalog specific value for; see [Setting API properties](#).

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more Catalog specific property values defined, expand Catalog Properties.
3. Configure a Catalog specific property value.
 - To define a new Catalog specific property value, complete the following steps:
 - Click the add icon  alongside Catalog Properties in the navigation pane.
 - Type the Catalog Name exactly as it displays in the **name** field for the selected Catalog.
Tip: For the best result, manually type the catalog's name instead of selecting its title. Using the catalog name is safer than using its title, because the title might not be unique within the provider organization and might be modified later (which breaks the association between the property and the catalog). The catalog's name is always unique within the provider organization and cannot be changed.
 - Click Create. The Catalog properties details for the specified catalog are displayed for further editing.
 - Alongside Property Overrides, click Add.
 - Provide the following information:
 - Property Name to Override: Enter the name of the API property that you want to define a Catalog specific value for. The name **must** match the name of a previously defined API property; see [Setting API properties](#).
 - Property Value: The Catalog specific property value. Leave blank if the property is to have a null value by default.
 - Click Create.
 - To modify an existing Catalog specific property value, click the Catalog name in the navigation pane. You can then change the Catalog name, and add, modify, or delete property override settings.
4. Click Save to save your changes.

Configuring application authentication for an API

Application authentication settings allow you to protect your API with a certificate, for example, by using TLS mutual authentication. You can select whether a client certificate is sent as a TLS client certificate or in an HTTP header.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Enable application authentication, as follows:
 - a. Select the Gateway tab, expand Gateway and portal settings, then click Application Authentication.
 - b. Select Certificate.
3. Specify how the client certificate is sent to the gateway, as follows:
 - a. In the navigation pane, click Application Authentication Source.
Any existing application authentication source definitions are listed.
 - b. Alongside Application Authentication Source, click Add.
 - c. Select the required option, header or tls-cert.
You can separately add one or both of the options.
When the API is called, an X509 client certificate must be supplied, either in the specified HTTP header, or as a TLS client certificate from TLS mutual authentication. For any Developer Portal application that calls the API, the certificate must be entered in the Developer Portal user interface; for details, see [Registering an application](#).

The Gateway service to which the API is published can be configured to use TLS mutual authentication to secure API calls made to that Gateway service; for details, see [Configuring the initial Gateway service](#). If you select this option, continue to sub-step d.

If you are using a load balancer, you must configure the load balancer to use the specified HTTP header to relay the appropriate client certificate to the Gateway service after the load balancer terminates the TLS communication.

- d. If you select the tls-cert option, enable mTLS at the Gateway level.
This can be done by enabling "Mutual authentication: Required" in the TLS Server Profile configured in the Gateway Service in the Cloud Manager Topology (requires cloud administrator permissions). For information, see [Registering a gateway service](#).

You can create a Truststore (with the root or intermediate CA certificate) for use with the TLS Server Profile.

The following example cURL command uses a client-cert during SSL:

```
**curl -X GET 'https://GW-Server:9443/test/sandbox/mtls-testing/callmtls-call' -H 'X-IBM-Client-Id: 1872xxxxxxxxxxxx' --cert my-leaf-cert.pem --key my-leaf-cert.key -k -v**
```

Note: This feature is intended for the scenario where different applications will be registered with different end certificates in the Developer Portal, which will have the same intermediate or root CA issuer. The certificate will pass Gateway-level mTLS if it matches the issuer available in the Truststore, but will only allow access to the API that matches the correct end certificate.

4. Click Create.
5. Click Save to save your changes.

Configuring activity logging

You can configure your logging preferences for the API activity that is stored in Analytics, overriding the default activity logging behavior.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

An API event record exists for each API execution event in the Gateway server. By default, the content type for a successful API execution is activity, and payload for an API call the results in an error code. When you compose your API definition, you can change the type of content to log in these API event records. During API execution, the activity data is stored in the `log` context variable, which populates the API event record on completion of the API execution; for more information, see [API activity logging context variables](#).

Note:

Activity logging that calls for logging of Analytics data upon success doesn't apply for the OAuth provider. The OAuth provider logs Analytics data for failure cases, but doesn't log successful cases.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Select the Gateway tab, expand Gateway and portal settings, then click Activity Log.
3. Select Enabled, then select options for the Success Content and Error Content fields as follows:

Field label	Description
-------------	-------------

Field label	Description
Success Content	<p>Defines the type of content to be logged when the operation is successful.</p> <ul style="list-style-type: none"> • none: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • activity: Logs invocation only; only the resource URI is recorded. • header: Logs activity and header; the HTTP headers, in addition to the resource URI are recorded. • payload: Logs activity, header, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. <p>The default value is activity.</p>
Error Content	<p>Indicates what content to log when an error occurs.</p> <ul style="list-style-type: none"> • none: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • activity: Logs invocation only; only the resource URI is recorded. • header: Logs activity and header; the HTTP headers, in addition to the resource URI are recorded. • payload: Logs activity, header, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. <p>The default value is payload.</p>
Preserved request header	Click Add to specify customized request headers to preserve for logging to analytics.
Preserved response header	Click Add to specify customized response headers to preserve for logging to analytics.

4. Click Save to save your changes.

Configuring v5 compatibility options

You can configure settings to ensure compatibility with API Connect Version 5.0 compatible APIs that are converted for use with the DataPower® API Gateway.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Select the Gateway tab, expand Gateway and portal settings, then click Compatibility.
3. Select from the following options as required:
 - Return V5 Responses: Return v5-compatible responses, such as OAuth and client security error responses.
 - Copy Id Headers to Message: Copy security headers to the message context for retrieval by the invoke back-end service.
 - Enforce Required Params: Check the request for required parameters during API routing. When enabled, a request that does not provide a required parameter is rejected.
 - Allow Chunked Uploads: Allow the assembly `invoke` policy to send documents to the server with `Transfer-Encoding: chunked`. This setting applies only to the `invoke 1.5.0` wrapper policy deployed from API Connect using the migration utility. It does not apply to the native API Gateway assembly `invoke` policy.
4. Use the YAML source to set the following options as required:

Option	Valid values	Description
<code>allow-trailing-slash</code>	<code>true / false</code>	Specify whether to allow the request URL to end with a / character. The default value is <code>false</code> .
<code>get-raw-body-value</code>	<code>true / false</code>	Specify whether the GatewayScript <code>apim.getvariable()</code> API returns the raw body instead of parsing. This setting applies only when the context is other than <code>message</code> . The default value is <code>false</code> .
<code>request-headers</code>	<code>true / false</code>	Specify whether to populate v5-compatible headers such as <code>X-Client-IP</code> and <code>X-Global-Transaction-ID</code> in the <code>request.headers</code> context variable. The default value is <code>false</code> .

5. Click Save to save your changes.

Including elements in your API assembly

An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

In the Policies view of IBM® API Connect, you can add and configure elements in your assembly. You can also directly add elements to the OpenAPI definition of your API.

- **The assembly editor**
The API Designer of IBM API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.

- [Adding elements to your assembly](#)
Create your API assembly by using the Assemble view in the API Designer.
- [Handling errors in the assembly](#)
Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

The assembly editor

The API Designer of IBM® API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can access the Assemble view by clicking the Gateway tab in the API editor, and then click Policies. This tab includes a palette, which lists the available elements, a property sheet, which is used to configure an element, and a canvas, which is used to arrange and visualize the assembly's elements.

The palette

The palette is a list of different elements that you can include in your assembly. The palette can be hidden by clicking the Show/hide policy palette icon .

The canvas

You can use the canvas to create a graphical representation of the assembly flow. You can drag various elements from the palette to the appropriate location on the canvas. When you drag an element, valid positions are shown by dashed boxes.

Note: You must click Save in the Assemble view to save your assembly updates, and to make them appear in the Source view.

API calls are made at the initial, unfilled, circle, and returned at the final, filled, circle. You can insert elements between the two circles to modify the data received from the call, or returned by the response. To add an element, select it in the palette and drag it across to one of the dashed boxes that appear when you move the element over the canvas.

You can use the Show catches toggle to show and hide error catches in the palette. A catch is a section of the assembly that is applied when an API call results in the corresponding HTTP status code being returned. Click the catch section to open the property sheet for all your catches.

You can zoom the view of your canvas in and out by clicking the + and - icons. To fit the canvas to the screen size, click the Fit to screen icon .

You can filter the canvas to show only the parts of it that will apply to a specific operation by clicking the Filter by operation icon  and then selecting the operation from the drop-down list. Click the Clear operation filter icon  to remove the filter.

The property sheet

When you select an element that is in the assembly by clicking it, details about the element are displayed in the property sheet. In this pane, you can configure the element's properties. The options available to you in the property sheet are specific to the type of element you are working with. For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down menu.

You can release the property sheet by clicking the Close icon .

The behavior of an assembly

The assembly runs policies in order and acts on different contexts of the API call. When an API call is made, security and rate limits are enforced before the assembly is executed. During the assembly, the flow can branch or be thrown and caught, according to the policies contained in it. The message context can be thought to flow through the assembly, being used and altered by various policies. In addition to the message, other contexts can be accessed and created.

Security and rate limiting

Before the assembly is executed, security and then rate limits are enforced.

First, security definitions and CORS access control are used to authenticate an API call. Any API Key security definitions are used to identify applications that have subscriptions to a Product containing the API. If a security definition does not allow access, the API call is rejected.

If an application is identified by its client ID or client secret, a rate limit can be enforced based on the Plan or operation called.

The assembly execution sequence

The assembly is executed in order from the initial, filled, circle to the final, unfilled, circle. However, there is room for branching, when if and operation-switch logic constructs are used, or for the remaining assembly to be ignored when a throw policy is executed.

The message is the context that is acted upon by any policy that isn't otherwise configured. At the beginning of the API call, the message is empty and, at the end of the API call, the message is used as the response.

The request context contains the information that is sent by the API caller and varies with the type of operation called and the configuration of that operation. For example, a GET operation can never have a populated `request.body`, and you can configure an operation to have `request.parameters` (query parameters).

The first policy in an assembly acts on the request and produces the first instance of the message. If there are no policies, the request is returned to the caller.

Managing contexts

Because the message can be overwritten, it can be useful to create and reference new contexts where possible so that they are saved and reusable during the API call.

- Use the map policy to overwrite the message context when you need to execute a policy that only acts on the message.
- Use the request context when you want to use the original request made to the API.
- Use the map, invoke, and proxy policies to create new contexts when you want to save your message.

Note: When you create a new context, unless you are also mapping to the message, the message is overwritten with an empty object.

For example, an invoke policy is the first policy in the assembly and its response overwrites the request as the message. The message is then acted upon by a validate policy, and a map policy then saves the message as a new context, ready for a second invoke policy to overwrite the message without losing the first invoke policy's output.

You can also access contexts outside of the message or your custom contexts, but these cannot be written to. For a list of contexts, see [API Connect context variables](#).

Branches and catches

Using logic constructs, such as operation-switch or if, you can execute different sections of the assembly when certain conditions are fulfilled. When the assembly branches, the subsection of the assembly contained by the construct is executed in the same manner as a complete assembly. However, contexts are shared with the complete assembly.

When a catch is triggered, either by an error occurring during the execution of a policy, or because a throw policy is encountered, the rest of the assembly flow is ignored. All contexts are shared by the catch being executed and when the end of the catch is reached, the API call is completed. There is no way to return from a catch to the rest of the assembly.

Adding elements to your assembly

Create your API assembly by using the Assemble view in the API Designer.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can use the assembly tool in the UI to create assemblies that are used to manipulate requests made to or responses made by any of your API's operations.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

If you want to use the Source view to edit the source of your API definition, see [execute OpenAPI extension](#) for more information about how to configure the OpenAPI YAML.

For more information about the use of the assembly tool, see [The assembly editor](#).

Procedure

To add elements to your assembly using the assembly tool, complete the following steps:

1. In the navigation pane, click  Develop, then select the APIs tab.
The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Use the Policies view to add an element.

Note: You must specify a version for the policy. To prevent errors due to incompatible versions of a policy between the API and the gateway, API Connect will only publish an API to the gateway if the policy version in the API exactly matches the version that is present on the gateway.

- a. Select the Gateway tab, then click Policies in the navigation pane.
- b. Find the element that you want to add in the palette.
- c. Drag the element onto the canvas; dashed boxes are displayed. Drop the element in a dashed box to insert it into that position in the assembly.

Note:

- Elements are applied in order from the initial, unfilled, circle to the final, filled, circle.
 - Unless an Operation Switch element is used, the whole assembly applies to every operation in the API.
- d. Add and edit properties of the element by clicking the element and using the property sheet.
For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down list. For information about the properties of policy elements, see [API policies and logic constructs](#). For information about the properties of logic constructs, see [Logic Constructs](#).
 - e. Specify a version for the policy.
To add a version, click the Source icon , and complete the `version` section of the policy YAML. For example:

```
execute:
- invoke:
  version: 2.2.0
  title: invoke
...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions. For more information about how to configure the policy OpenAPI YAML, see

[execute OpenAPI extension.](#)

- Optional: Repeat Steps 3.b to 3.e for any additional elements that you want to add.
- Click Save to save your changes.

Results

You have added one or more elements to your assembly.

Handling errors in the assembly

Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see [Editing an OpenAPI 3.0 API definition](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The catch section of the assembly is used to implement an assembly in the instance that an error is thrown during the assembly execution. For example, the assembly could contain a throw element, the API caller could fail to authenticate, or a policy could fail to execute correctly. Each error can be handled with a different catch and each catch can handle multiple status errors.

Procedure

To create a catch and include elements in it, complete the following steps:

- In the navigation pane, click  Develop, then select the APIs tab.
The Develop page opens.
- Click the title of the API definition that you want to apply a catch to.
- Select the Gateway tab, then click Policies in the navigation pane.
- Set the Show catches toggle in the menu bar of the canvas to the Show position.
- Click Catches in the canvas, or a Catch icon  if one is displayed.
The property sheet for the API's catches opens.
- To add a default catch that is executed when an otherwise uncaught error is thrown, click Add default catch.
Note: If you have a default catch before another catch in precedence, the default catch will activate even when the other catch's error is thrown.
- To add a new catch, click Add catch.
- To specify which errors the catch applies to, type the name of a custom error and press Enter, or use the Search errors field to search for the appropriate error.
- Optional: To remove an error case from a catch, click the corresponding cross.
- Optional: To change the precedence of your catches, use the Move up  or Move down  icons.
If an error case is handled by multiple catches, the catch at the beginning of the list is applied.
- To add an element to a catch, drag the element over the dashed, gray box that appears in the flow from the Catch icon  for the catch that you want to apply the element to.
- Click Save to save your changes.

What to do next

If you added a catch for ConnectionError, SOAPError, or OperationError, you must add the same error to the Stop on error setting for the Invoke policy in your assembly. Otherwise if the error occurs during the execution of the Invoke policy, it is not caught, the policy execution is allowed to complete, and the assembly flow continues. For details on configuring an Invoke policy, see [Invoke](#).

For details of all the errors that can be returned by the assembly and are available to the catch function, see [Error cases supported by assembly catches](#).

Specifying the gateway type for an API definition

An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). A default gateway type is set when you create an API definition, but you can edit the API configuration to specify a different gateway type.

About this task

Note: This task relates only to an OpenAPI 2.0 API definition. An OpenAPI 3.0 API is supported only on the DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM® API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see [API Connect gateway types](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You must specify which type of gateway each API uses. APIs can use only one type of gateway.

When you create a new API definition, or import an API definition that has no gateway type configured, the gateway type defaults according to the gateway types of the gateway services that are enabled in your Sandbox Catalog, as indicated in the following table.

Table 1. Default gateway type for a new API definition

Gateway Service enablement in Sandbox Catalog	Default gateway type for new API definition
No gateway services enabled	DataPower API Gateway
At least one gateway service of each type enabled	DataPower API Gateway
One or more gateway services only of type DataPower API Gateway enabled	DataPower API Gateway
One or more gateway services only of type DataPower Gateway (v5 compatible) enabled	DataPower Gateway (v5 compatible)

If you import an API definition that already has a gateway type configured, that gateway type is retained.

Note that when you modify your API definitions to use a specific gateway type, you must ensure that each policy and policy version in the API are supported by the gateway type. DataPower Gateway (v5 compatible) and DataPower API Gateway each support policies that the other gateway type does not. In some cases, the same policy is supported by both gateway types, but with a different version number.

For example, DataPower Gateway (v5 compatible) supports version **1.0.0** of the **invoke** policy, but DataPower API Gateway requires version **2.0.0**.

For information on policies, see [execute](#).

For information on policy versions, see the documentation for each individual policy. For example, to review the **invoke** policy, see [invoke](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Click the title of the API you want to update.
3. Select the Gateway tab, then click Gateway and portal settings.
4. Select the type:
 - datapower-gateway for the DataPower Gateway (v5 compatible)
 - datapower-api-gateway for the DataPower API Gateway.

Note: The Gateway Type selection is not applicable if the Enforced option is disabled, because an unenforced API is not managed on an API Connect gateway.

5. Click Save to retain the changes.
6. In the navigation pane, select Policies to ensure that your API uses policies that are supported by the gateway type you selected.

Policies in an existing API that are not supported by the new gateway type are grayed out and flagged with a red exclamation point: .

Some policies are supported by only one gateway type. Some policies are supported by both gateway types, but require a different version of the policy for each gateway type.

Related tasks

- [Converting an API definition for deployment to the DataPower API Gateway](#)

Converting an API definition for deployment to the DataPower API Gateway

IBM® API Connect provides two gateway types, DataPower® Gateway (v5 compatible) and DataPower API Gateway. If you have an API definition that was developed for the DataPower Gateway (v5 compatible) and you want to port it to the DataPower API Gateway, you must make changes to convert it before deployment.

About this task

Note: This task relates only to an OpenAPI 2.0 API definition. An OpenAPI 3.0 API is supported only on the DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

To convert an API for deployment to the DataPower API Gateway, you must, as a minimum, change the gateway type setting on the API definition, and ensure that each policy and policy version in the API are supported by the DataPower API Gateway; DataPower Gateway (v5 compatible) and DataPower API Gateway each support policies that the other gateway type does not. In some cases, the same policy is supported by both gateway types, but with a different version number.

In addition, depending on the specific policies in your API assembly, some policies might require modification to adapt them for use with the DataPower API Gateway.

The following procedure provides instructions for converting your API definition:

Procedure

1. Set the gateway type for the API to DataPower API Gateway, and ensure policy type and version compatibility. For details, see [Specifying the gateway type for an API definition](#).
2. Refer to the [DataPower API Gateway porting notes](#) for detailed instructions on how to convert your API definition.

Modifying a GraphQL schema

For a GraphQL API, an editor is provided for modifying the associated GraphQL schema.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

To open the GraphQL schema editor for a GraphQL API, complete the following steps:

1. Open the API for editing, as described in [Editing an OpenAPI 2.0 API definition](#).
2. Select the GraphQL Schema tab.

What to do next

For full details on how to use the editor, see [Using the GraphQL schema editor](#).

Validating the OpenAPI YAML source

How to validate the OpenAPI YAML source when you're editing an API.

About this task

When you're configuring an API in the API editor, you can validate the OpenAPI YAML source by clicking Validate. If any swagger parser validation errors are found, an error icon is displayed that you can then click to see the individual errors, and where they occur in the YAML. You can then fix the errors, save the updates, and continue to validate the OpenAPI YAML throughout the API configuration process.

Note: OpenAPI validation does not show gateway or policy errors that will stop your API from being staged or published. This type of validation occurs only when you try to stage or publish your API. For more information, see [Staging an API](#) or [Publishing an API](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

To validate the OpenAPI YAML source, complete the following steps.

1. Open the required API for editing, as described in [Editing an OpenAPI 2.0 API definition](#) or [Editing an OpenAPI 3.0 API definition](#).
2. Click Validate from the menu bar in the header.

3. If any swagger parser validation errors are found, an error icon is displayed on the header menu bar, with the number of OpenAPI errors found displayed next to the icon.

For example,  .

4. You can then click the error icon to see a detailed list of the errors, and their location in the YAML. If you're in Form  view, you can click an individual error to navigate directly to the relevant API section in the form.
5. After you fix the error, click Save to save your updates, and then click Validate again.
6. When all of the errors are fixed, the validation returns a success message.

For example,  API has been validated

Editing an OpenAPI 3.0 API definition

IBM® API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 3.0 specification.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

You can open an API for editing in either of the following ways:

- During the initial creation of an API, the API wizard guides you to enter the minimum configuration settings; on completion of the initial configuration, click Edit API.
- To open an existing API for editing, complete the following steps:
 1. In the navigation pane, click  Develop, then select the APIs tab.
 2. Click the title of the API version that you want to work with.
- [OpenAPI 3.0 support in IBM API Connect](#)
IBM API Connect supports the OpenAPI 3.0 specification, with some limitations. The current implementation includes complete support for the Berlin Group NextGen PSD2 requirements.
- [Specifying API metadata](#)
API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.
- [Defining servers for an API](#)
Server definitions in an API provide information for connecting to target servers.
- [Enforcing security requirements on an API](#)
To enforce security requirements on an API, you apply previously created security scheme components that define various aspects of API security configuration.
- [Specifying external documentation for an API](#)
You can reference an external resource for extended documentation for an API.
- [Adding tags to an API](#)
You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.
- [Defining Paths for an API](#)
A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.
- [Defining components for an API](#)
Components are reusable objects relating to various aspects of your API definition. A component has no effect on the API unless it is explicitly referenced from elsewhere in your API definition.
- [Specifying gateway and portal settings](#)
Define general configuration settings for your API.
- [Defining target services for an API](#)
A target service defines a web service that you want to use in your API definition.
- [Setting API properties](#)
In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.
- [Configuring activity logging](#)
You can configure your logging preferences for the API activity that is stored in Analytics, overriding the default activity logging behavior.
- [Including elements in your API assembly](#)
An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.
- [Validating the OpenAPI YAML source](#)
How to validate the OpenAPI YAML source when you're editing an API.

OpenAPI 3.0 support in IBM API Connect

IBM® API Connect supports the OpenAPI 3.0 specification, with some limitations. The current implementation includes complete support for the Berlin Group NextGen PSD2 requirements.

Overview

A Product can contain any combination of OpenAPI 2.0 and OpenAPI 3.0 APIs. When you publish a Product that contains an OpenAPI 3.0 API, that API is validated to ensure that it is syntactically correct, and that references to configuration resources and policies resolve correctly, in the same way that OpenAPI 2.0 APIs are validated.

You can also validate OpenAPI 3.0 APIs in your local file system by using the `apic validate` command provided by the developer toolkit CLI; for details, see [Validating the YAML or JSON definition of an API or Product](#).

If you retrieve an API object by using the developer toolkit CLI or the API Connect REST APIs, there is an `oai_version` property that defines which OpenAPI version the API represents.

There is no OpenAPI 3.0 API support with the DataPower® Gateway (v5 compatible); OpenAPI 3.0 API support is provided by the DataPower API Gateway **only**.

Limitations

The limitations to the OpenAPI 3.0 support in IBM API Connect are as follows:

User interface limitations

- Some aspects of the OpenAPI 3.0 specification are not currently supported by the user interface. In such circumstances, use the OpenAPI source directly.
- Validation errors that are identified locally are reflected in the API editor header almost immediately. However, some validation errors can be identified only by the API Manager backend and are not reflected until the API is saved; this means that, on saving an API, some validation errors might appear or disappear.
- The user interface does not currently support referencing a request body component from the request body of an operation. If you want to reference a request body component, add the reference to the request body of the operation directly in the OpenAPI source:

```
requestBody:  
  $ref: '#/components/requestBodies/request_body_component_name'
```

The reference is confirmed on the details page for the request body in the user interface however.

- If, in the API Designer user interface, you create and activate an API of the same name and version as one that has already been activated from the API Manager user interface, the Edit Rate Limit operation fails.

Limitations for APIs that are enforced by the DataPower API Gateway

To suppress the error message for the following limitations and publish the API, set the `x-ibm-configuration.compatibility.suppress-limitation-errors` property to `true` as shown in the following example:

```
compatibility:
  suppress-limitation-errors: true
```

Attention: Enabling `suppress-limitation-errors` merely disables the error messages so that the API can be published.

- General limitations.
 - The `servers` array cannot contain more than one server.
 - The `url` entry in the `servers` array cannot contain `variables`.
 - `path` objects cannot contain server object overrides.
 - Using wild cards in response objects is not supported for error codes or success codes.
 - There is no support for converting a WSDL defined SOAP service into an OpenAPI 3.0 API.
 - There is no support for callbacks or webhooks, and APIs containing them will not be published.
 - Assembly policies.
 - All policies are supported.
 - JSON schema support is limited to Draft 4 and earlier. Therefore, the following policies are limited to those drafts:
 - `gatewayscript`
 - `set-variable`
 - `switch`
 - `json-to-xml`
 - `xml-to-json`
 - `parse`
 - `xslt`
 - `map`
 - `validate`
- For detailed information about the Draft 4 and earlier specifications, see <https://json-schema.org/specification-links.html#draft-4>.
- Security.
 - The OpenID Connect (OIDC) security scheme is not supported.
 - The use of cookies in an API key is not supported.

Specifying API metadata

API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand the General section, then click Info.
3. Provide the following information:
 - Title (required): The title of the API.
 - Name: The name was generated automatically when the API was created and cannot be changed. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see [apic draft-apis](#).
 - Version: The API version is specified when the API is initially created and cannot be changed thereafter. You can, however, create a new version of an existing API; see [Creating a new version of an API definition](#).
 - Description: An optional description of the API. You can use [CommonMark syntax](#) for rich text representation.
 - Terms of Service: A URL to the Terms of Service for the API.
 - Contact Name: The identifying name of the contact person/organization.
 - Contact URL: A URL pointing to the contact information.
 - Contact Email: The email address of the contact person/organization.
 - License Name: The license name used for the API.
 - License URL: A URL to the license used for the API.
4. Click Save when done.

Defining servers for an API

Server definitions in an API provide information for connecting to target servers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can define more than one server but only the first is used by API Connect.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand General then, if there are already one or more servers defined, expand Servers.
3. To create a new server definition, click the add icon  alongside Servers in the navigation pane. To edit an existing server definition, click the server URL in the navigation pane.
4. Provide the following information:
 - Server URL (required): The specified URL is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the Catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, the value entered here is interpreted as the basepath so you would typically provide only the basepath value; for example:
`/my_basepath`
For full details on how the server URL is used to determine the full URL endpoint, see [Configuring vanity endpoints for a Catalog](#).
 - Server Description: An optional description of the host designated by the URL. You can use [CommonMark syntax](#) for rich text representation.
 - Server Variables (available when editing an existing server definition): A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
 - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
 - Provide the following information:
 - Server Variable Name (required).
 - Default value (required).
 - An optional rich text description. You can use [CommonMark syntax](#) for rich text representation.
 - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add a new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
 - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
 - If required, use the breadcrumb trail to return to your server definition for further editing.
5. If you are creating a new server definition, click Create.
The server definition details are displayed for further editing as described in step 4.
6. Click Save when done.

Enforcing security requirements on an API

To enforce security requirements on an API, you apply previously created security scheme components that define various aspects of API security configuration.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security scheme components, see [Defining security scheme components](#).

The following restrictions exist when you apply security schemes to an API:

- You cannot apply more than two API key security schemes to an API.
- If you apply an API key security scheme for client secret, you must also apply an API key security scheme for client ID.
- If you require the application developer to supply both client ID and client secret, you must apply two separate API key security schemes.
- You can have at most one API key scheme of type client ID, regardless of whether the client ID is sent in the request header or as a query parameter.
- You can have at most one API key scheme of type client secret, regardless of whether the client secret is sent in the request header or as a query parameter.
- You cannot apply more than one basic security scheme to an API. If you apply a basic security scheme, you cannot also apply an OAuth security scheme.
- You can apply at most one OAuth security scheme to an API.

A security requirement specifies one or more security scheme components whose conditions must all be satisfied for the API to be called successfully. You can define multiple security requirements; in this case, an application can call your API if it satisfies any of the security requirements you have defined.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand General.
3. To create a new security requirement for the API, complete the following steps:
 - a. Click the add icon  alongside Security in the navigation pane.
 - b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have been defined in security scheme components; see [Defining security scheme components](#).

If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme component; for more information, see [Defining OAuth2 security scheme components](#).

If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see [Configuring scopes for a native OAuth provider](#).

Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the `x-IBM-Client-Id` or `client_id` must be included in the security credentials so that the correct Plan configuration settings can be enforced.

- c. Click Create. The security scheme selections are shown; you can change them again before saving.
 - d. Click Submit when done.
4. To modify an existing security requirement, complete the following steps:
 - a. Click Security in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
 - b. To change the security schemes for a security requirement, click the edit icon  alongside the required security requirement, then change your security requirement selections as required.
 - c. Click Submit when done, then click Save.
 - d. To delete a security requirement, click the appropriate delete icon , click Delete to confirm, then click Save.
 - e. To disable security for the API, clear the Require one of the following Security Requirements check box, then click Save.

What to do next

For more information on LDAP and Authentication URL, see [LDAP authentication](#) and [Authentication URL user registry](#).

- [Enabling CORS support for an API](#)
You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Enabling CORS support for an API

You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Before you begin

This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).

About this task

Note:

- CORS support is available only on the DataPower® API Gateway.
- When CORS is enabled, the API Gateway runs the `cors` preflow policy to handle all CORS requests that are made to the API.
- When CORS is enabled and a preflight request is received, only the following API actions are performed:
 - The `cors` preflow policy configures the appropriate response headers.
 - The response headers are set.
- When a preflight request is received, the `request.attributes.isCORSPreflight` flag is set to `true`.
- For all preflight requests, the `security` and `client-identification` preflow policies are always skipped, whether CORS is enabled or not enabled.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

To enable CORS support for an API, complete the following steps:

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Select the Gateway tab, expand Gateway and portal settings, then click CORS.
The CORS page opens.
3. Select Enable CORS.
4. Optional: Configure a CORS policy.
Should you create a CORS policy? Review the following considerations:
 - A CORS policy is an optional part of an API definition. If an API definition has no CORS policy but CORS is enabled, then CORS requests will be accepted from all Origins.
If you want to accept CORS requests from all Origins, then enable CORS but do not add a CORS policy to the API definition.

- If you create a CORS policy, then CORS requests will only be accepted from Origins that are explicitly listed in the CORS rules contained in the CORS policy. CORS requests from any other Origins will be rejected.
If you want to accept CORS requests from only a limited number of Origins (and might also want to configure the Access-Control-Allow-Credentials and Access-Control-Expose-Headers response headers), then you should enable CORS and create a CORS policy. Only those Origins explicitly listed in the allow-origin field of the CORS rules in the CORS policy will be accepted; CORS requests from any Origins not listed will be rejected.
- To configure a new CORS policy, complete the following steps:
 - Alongside CORS Policy, click Add.
 - To include the header `Access-Control-Allow-Credentials: true` in a response, select Allow Credentials. The `Access-Control-Allow-Credentials` response header tells browsers whether to expose the response to frontend JavaScript code when the request's credentials mode (`Request.credentials`) is set to `include`.
 - To append one or more of the following values to the `Access-Control-Expose-Headers` response header, select Expose headers, and select from the following options:
 - Predefined - The predefined value of the Gateway. This option is selected by default.
 - Backend - The value of `Access-Control-Expose-Headers` from the backend response.
 - Custom - A custom string.
 - Click Create.
 - Alongside Allowed Origins click Add.
 - Enter the origin URL, then click Create. This setting indicates that the response can be shared with requesting code from the specified origin.
- To modify an existing CORS policy, click its Allowed Origins entry on the CORS page. You can then modify individual origin URLs, add further origins, and change the Allow Credentials setting.

Example

The following example has three rules:

- Accept an Origin header of `https://example.com`, and return `Access-Control-Allow-Credentials: true` in the CORS response.
- Accept an Origin header of `http://domain.com`. No `Access-Control-Allow-Credentials` header will be returned in the response.
- Accept any of the following Origin headers:
 - `http://example2.com`
 - `http://example3.com`
 - `http://example4.com`

No `Access-Control-Allow-Credentials` header will be returned in the response.

```
cors:
  enabled: true
  policy:
  -
    allow-origin:
      - 'https://example.com'
    allow-credentials: true
  -
    allow-origin:
      - 'http://domain.com'
  -
    allow-origin:
      - 'http://example2.com'
      - 'http://example3.com'
      - 'http://example4.com'
```

5. Click Save to save your changes.
6. Optional: To implement your own CORS solution using custom OPTIONS operations, complete the following steps:
 - a. Add the following headers to your HTTP responses:

```
Access-Control-Allow-Origin: https://<portalhostname>
Access-Control-Allow-Headers: Origin, X-Requested-With, Content-Type, Accept
```

Where `<portalhostname>` is your Developer Portal host name.

- b. Optional: You can proxy your API through API Connect as an enforced invoke API so that CORS is handled automatically.

Important:

- If you implement your own CORS solution, you **must** disable the CORS option described in step 3
- CORS preflight requests are sent by using the HTTP `OPTIONS` method. Therefore, if you require these requests to be handled by the API Connect gateway then you must enable the `OPTIONS` method for all APIs that will handle preflight requests; see [Defining Paths for a REST API](#).
- `OPTIONS` requests are counted as API calls against any configured rate limit. Note that you can apply rate limits to individual operations; see [Defining rate limits for an API operation](#).

Specifying external documentation for an API

You can reference an external resource for extended documentation for an API.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand the General section, then click External Documentation.
3. Provide the following information:
 - URL (required): The URL for the target documentation.
 - Description: An optional description of the target documentation. You can use [CommonMark syntax](#) for rich text representation.
4. Click Save when done.

Adding tags to an API

You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand the General then, if there already one or more tags defined, expand Tags.
3. To add a new tag, click the add icon  alongside Tags in the navigation pane. To edit an existing tag, click the tag name in the navigation pane.
4. Provide the following information:
 - Name (required): The name of the tag.
 - Description: An optional description of the tag. You can use [CommonMark syntax](#) for rich text representation.
 - External Documentation_>_URL (available when editing an existing tag): The URL for target documentation that describes this tag.
 - External Documentation_>_Description (available when editing an existing tag): An optional description of the target documentation.
5. If you are creating a new tag, click Create.
The tag details are displayed for further editing as described in step 4.
6. Click Save when done.

Defining Paths for an API

A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The Path is appended to the server URL to form the full URL. For details on configuring servers, see [Defining servers for an API](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. If there are already one or more Paths defined, expand Paths.
3. To create a new Path, click the add icon  alongside Paths in the navigation pane. To edit an existing Path, click the Path in the navigation pane.
4. Provide the following information:
 - Path: A relative path to an individual endpoint.
The path is appended to the base path to construct the full URI to access the APIs. The path must start, but not end, with the / character. A parameter at the end of the path can contain a qualifier to match one or more path levels.

If you specify just the name of the parameter, then one level of that path is matched. If you want to allow for multiple levels of the path, you can prefix the parameter with one of the following qualifiers:

- * to indicate 0 or more occurrences
- + to indicate 1 or more occurrences

The + and * qualifiers can only be used at the end of the path.

For example, the path:

```
/petstore/{type}/{*category}
```

matches the following paths, where only one type value is matched, but all (0 or more) categories are matched:

```
/petstore/cats
/petstore/cats/supplies
/petstore/cats/supplies/health
/petstore/cats/supplies/health/medicines
/petstore/cats/supplies/health/medicines/a/b/c
```

- Ref (available when editing an existing Path): A reference to a Path that is defined elsewhere, either in this OpenAPI definition, or in an external file. A reference enables reuse of a set of operations already defined for a Path in this API, or in a file that is either a complete API definition or an OpenAPI fragment.

The reference uses JSON pointer notation. For example, a reference to a Path called `/mypath` in this API would have the following format:

```
#/paths/~1mypath
```

The `~1` characters are used to escape the `/` character, which is being used literally in the path name rather than as a special character.

A reference to a path in an external file called `path_fragments.yaml` would have the following format:

```
file://path_fragments.yaml/paths/~1mypath
```

- Summary: An optional summary, intended to apply to all operations in this path.
- Description: An optional description, intended to apply to all operations in this path. You can use [CommonMark syntax](#) for rich text representation.

5. If you are creating a new Path, click Create.

The Path details are displayed for further editing as described in step 4.

6. Click Save when done.

- [Defining servers for a Path](#)

Server definitions for a Path provide alternative target servers when calling the API at that Path.

- [Defining parameters for a Path](#)

Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.

- [Defining operations for a Path](#)

Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

Defining servers for a Path

Server definitions for a Path provide alternative target servers when calling the API at that Path.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note: It is unlikely that you will need to define servers for a Path because it applies only if the API operations are distributed across different gateway endpoints, and such a configuration is possible only if you are hosting your API operations on your own runtime endpoints outside of API Connect. For an API that is published to the DataPower API Gateway, all API operations are invoked on the same gateway service.

A server defined for a Path overrides any server defined for the parent API. You can define more than one server but only the first is used by API Connect.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand Paths.
3. Expand the required Path, then, if there already one or more servers defined for the Path, expand Servers.
4. To create a new server definition for the Path, click the add icon  alongside Servers under the Path in the navigation pane. To edit an existing server definition, click the server URL under the Path in the navigation pane.
5. Provide the following information:
 - Server URL (required): The specified URL is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the Catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, the value entered here is interpreted as the basepath so you would typically provide only the basepath value; for example:

```
/my_basepath
```

For full details on how the server URL is used to determine the full URL endpoint, see [Configuring vanity endpoints for a Catalog](#).

- Server Description: An optional description of the host designated by the URL. You can use [CommonMark syntax](#) for rich text representation.

- Server Variables (available when editing an existing server definition): A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
 - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
 - Provide the following information:
 - Server Variable Name (required).
 - Default value (required).
 - An optional rich text description. You can use [CommonMark syntax](#) for rich text representation.
 - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add a new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
 - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
 - If required, use the breadcrumb trail to return to your server definition for further editing.
6. If you are creating a new server definition, click Create.
The path details are displayed for further editing as described in [5](#).
7. Click Save when done.

Defining parameters for a Path

Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **header**.
- A parameter can have various format styles, the style of a header is always **simple**.

For more information on headers, see [Creating a header](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand Paths.
3. Expand the required Path, then, if there already one or more parameters defined, expand Parameters.
4. You can either create a new parameter, or edit any existing parameter.
 - To create a parameter, click the add icon  alongside Parameters, then refer to [Creating a parameter](#).
 - To edit an existing parameter, click the parameter name in the navigation pane, then refer to [Editing a parameter](#).

Defining operations for a Path

Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand Paths.
3. Expand the required Path, then, if there are one or more operations, expand Operations.

- To create an operation, click the add icon  alongside Operations under the Path in the navigation pane. To edit an existing operation, click the operation name under the Path in the navigation pane.
- Provide the following information:
 - Verb: Select the operation type from the following options:
 - get
 - post
 - put
 - delete
 - options
 - head
 - patch
 - trace
 - Summary: A summary of what the operation does.
 - Description: A description of the operation behavior. You can use [CommonMark syntax](#) for rich text representation.
 - Operation ID: Unique string used to identify the operation. The id must be unique among all operations described in the API.
 - Deprecated: Declares this operation to be deprecated. Consumers should refrain from using the declared operation.
- If you are creating a Path operation, click Create.
- Click Save when done.

- [Adding tags to an operation](#)**

You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

- [Specifying external documentation for an operation](#)**

You can referencing an external resource for extended documentation for an API operation.

- [Defining parameters for an operation](#)**

Operation parameters can, for the URL path associated with that specific operation, define variable elements of the URL path, query parameters, headers, or body parameters.

- [Defining the request body for an operation](#)**

A request body defines the structure of the body of an API request.

- [Defining responses for an operation](#)**

Responses define the HTTP status code and data returned in a response body and headers.

- [Enforcing security requirements on an operation](#)**

To enforce security requirements on an API operation, you apply previously created security scheme components that define various aspects of API security configuration.

- [Defining servers for an operation](#)**

Server definitions for an API operation provide alternative target servers when calling that operation.

Adding tags to an operation

You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

- Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
- Expand Paths, then expand the required Path.
- Expand Operations, then expand the required operation.
- To add a new operation tag, click the add icon  alongside the Tags entry for the operation in the navigation pane. To edit an existing tag, expand Tags then click the tag name in the navigation pane.
- Provide the following information:
 - Name (required): The name of the tag.
- If you are creating a new operation tag, click Create.
The tag details are displayed for further editing as described in step [5](#).
- Click Save when done.

Specifying external documentation for an operation

You can referencing an external resource for extended documentation for an API operation.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then click External Documentation.
4. Provide the following information:
 - URL (required): The URL for the target documentation.
 - Description: An optional description of the target documentation. You can use [CommonMark syntax](#) for rich text representation.
5. Click Save when done.

Defining parameters for an operation

Operation parameters can, for the URL path associated with that specific operation, define variable elements of the URL path, query parameters, headers, or body parameters.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

An operation parameter overrides a parameter of the same name defined on the parent Path; see [Defining parameters for a Path](#).

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **header**.
- A parameter can have various format styles, the style of a header is always **simple**.

For more information on headers, see [Creating a header](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. You can either create a new operation parameter, or edit any existing parameter:
 - To create an operation parameter, click the add icon  alongside Parameter, then refer to [Creating a parameter](#).
 - To edit an existing operation parameter, click the parameter name in the navigation pane, then refer to [Editing a parameter](#).

Defining the request body for an operation

A request body defines the structure of the body of an API request.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Note: The user interface doesn't currently support referencing a request body component from an operation. However, you can add the reference directly to the OpenAPI YAML source for your API definition, for example:

```
paths:
  /mypath:
    get:
      .
      .
      .
      requestBody:
        $ref: '#/components/requestBodies/my_requestbody_component'
```

For information on request body components, see [Defining request body components](#).

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then click requestBody.
4. Provide the following information:
 - Description: An optional description of the request body. This could contain examples of use. You can use [CommonMark syntax](#) for rich text representation.
 - Content: A content definition describes the content of the request body.
To define a new content definition for the request body, click Add, then refer to [Creating a content definition](#).

To edit an existing content definition, click the content definition name, then refer to [Editing a content definition](#).
 - Required: Determines if the request body is required in the request.
5. Click Save when done.

Defining responses for an operation

Responses define the HTTP status code and data returned in a response body and headers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there are any existing responses, expand Responses.
4. You can either create a new response, or edit any existing response.
 - To create a response, click the add icon  alongside Responses, then refer to [Creating a response](#).
 - To edit an existing response, click the response name in the navigation pane, then refer to [Editing a response](#).

Enforcing security requirements on an operation

To enforce security requirements on an API operation, you apply previously created security scheme components that define various aspects of API security configuration.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security scheme components, see [Defining security scheme components](#).

A security requirement specifies one or more security scheme components whose conditions must all be satisfied for the API operation to be called successfully. You can define multiple security requirements; in this case, an application can call your API operation if it satisfies any of the security requirements you have defined.

Any security requirements that you define for an operation completely override any security requirements defined on the parent API. If you do not define any security requirements for an operation, or you delete all security requirements from an operation, the operation inherits the security requirements defined on the parent API. For more information, see [Enforcing security requirements on an API](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To create a new security requirement for the operation, complete the following steps:
 - a. Click the add icon  alongside the Security Requirements entry for the operation in the navigation pane.
 - b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have been defined in security scheme components; see [Defining security scheme components](#).

If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme component; for more information, see [Defining OAuth2 security scheme components](#).

If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see [Configuring scopes for a native OAuth provider](#).

Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the `X-IBM-Client-Id` or `client_id` must be included in the security credentials so that the correct Plan configuration settings can be enforced.

- c. Click Create. The security scheme selections are shown; you can change them again before saving.
 - d. Click Submit when done.
5. To modify an existing security requirement, complete the following steps:
 - a. Click the Security entry for the operation in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
 - b. To change the security schemes for a security requirement, click the edit icon  alongside the required security requirement, then change your security requirement selections as required.
 - c. Click Submit when done, then click Save.
 - d. To delete a security requirement, click the appropriate delete icon , click Delete to confirm, then click Save.
 - e. To disable security for the operation, clear the Require one of the following Security Requirements check box, then click Save.

Note: These settings completely override any security requirements defined on the parent API; see [Enforcing security requirements on an API](#).

Defining servers for an operation

Server definitions for an API operation provide alternative target servers when calling that operation.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A server defined for an operation overrides any server defined for the parent API or Path. You can define more than one server but only the first is used by API Connect.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there already one or more servers defined for the operation, expand Servers.
4. To create a new server definition for the operation, click the add icon  alongside Servers under the operation in the navigation pane. To edit an existing server definition, click the server URL under the operation in the navigation pane.
5. Provide the following information:

- Server URL (required): The specified URL is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the Catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, the value entered here is interpreted as the basepath so you would typically provide only the basepath value; for example:

```
/my_basepath
```

For full details on how the server URL is used to determine the full URL endpoint, see [Configuring vanity endpoints for a Catalog](#).

- Server Description: An optional description of the host designated by the URL. You can use [CommonMark syntax](#) for rich text representation.
- Server Variables (available when editing an existing server definition): A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
 - To add a new server variable, click Add. To edit an existing server variable, click the variable name.

- Provide the following information:
 - Server Variable Name (required).
 - Default value (required).
 - An optional rich text description. You can use [CommonMark syntax](#) for rich text representation.
 - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add a new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
 - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
 - If required, use the breadcrumb trail to return to your server definition for further editing.
6. If you are creating a new server definition, click Create.
The path details are displayed for further editing as described in [5](#).
7. Click Save when done.

Defining components for an API

Components are reusable objects relating to various aspects of your API definition. A component has no effect on the API unless it is explicitly referenced from elsewhere in your API definition.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The following subtopics detail the various types of API component:

- [Defining schema components](#)
Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.
- [Defining response components](#)
Response components define reusable response objects that specify the HTTP status code and data returned in a response body and headers.
- [Defining parameter components](#)
Parameter components define reusable parameters that can specify variable elements of a URL path, query parameters, headers, or a request body.
- [Defining example components](#)
An example component is a reusable example that you can add to an API to make the specification of your API clearer.
- [Defining request body components](#)
A request body component is a reusable definition of the structure of the body of an API request.
- [Defining header components](#)
A header component defines a reusable custom header that can be sent in an API request or returned in an API response.
- [Defining security scheme components](#)
A security scheme component specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.
- [Defining link components](#)
A link component is a reusable link definition that can be used to describe how various values returned by one operation can be used as input for other operations. In this way, links provide a known relationship and traversal mechanism between the operations.

Defining schema components

Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a schema component, you reference it from elsewhere in your API definition. You can reference a schema from the following locations:

- An API Path parameter; see [Defining parameters for a Path](#).
- An API operation parameter; see [Defining parameters for an operation](#).
- The request body of an API operation; see [Defining the request body for an operation](#).
- An API operation response; see [Defining responses for an operation](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
 2. Expand Components then, if there are already one or more schemas components defined, expand Schemas.
 3. You can create a new schema component, or edit any existing schema component.
 - To create a schema component, click the add icon  alongside Schemas, then refer to [Creating a schema](#).
 - To edit an existing schema component, click the schema component name in the navigation pane, then refer to [Editing a schema](#).
- **Creating a schema**
Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.
 - **Editing a schema**
Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Creating a schema

Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.

Launch the schema creation window. For details of the areas in your API definition from where you can create a schema, see the following topics:

- [Editing a content definition](#)
- [Editing a header](#)
- [Editing a parameter](#)
- [Defining schema components](#)

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Create the schema; you can either create a schema from scratch, or you can reference a schema that is defined in a schema component.
 - To create the schema from scratch, provide the following information on the Definition tab:
 - Schema Name: If you are creating a schema component, this name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:
`#/components/schemas/Name`
 - Title: The schema title.
 - Type: The schema data type; select one of the following:
 - array
 - boolean
 - integer
 - number
 - object
 - string
 - Description: An optional description of the schema. You can use [CommonMark syntax](#) for rich text representation.
 - Select the following options as required:
 - Read Only: A property associated with this schema can be sent in a response but should not be sent in a request.
 - Write Only: A property associated with this schema can be sent in a request but should not be sent in a response.
 - Deprecated: The schema is deprecated and should be transitioned out of usage.
 - To reference a schema that is defined in another schema component, provide the following information on the Reference tab:
 - Schema Name: If you are creating a schema component, this name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:
`#/components/schemas/Name`
 - Reference from: Select a reference to a schema component.
2. Click Create.
The schema details are displayed for further editing; see [Editing a schema](#).

Editing a schema

Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.

Open the details form for a schema. For details of the areas in your API definition from where you can edit a schema, see the following topics:

- [Editing a content definition](#)
- [Editing a header](#)
- [Editing a parameter](#)
- [Defining schema components](#)

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

You can configure the following schema settings:

- Schema Name: Available if you are editing a schema component, this name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

`#/components/schemas/Name`

To change the name, click Update, change the value in the field, then click Save.

- Title: The schema title.
- Type: The schema data type; select one of the following:

- - array
 - boolean
 - integer
 - number
 - object
 - string

Note: If you change the type of an existing schema, any existing settings that are not relevant to the new type are still retained in the OpenAPI source even though they are no longer displayed in the user interface. You should therefore avoid porting a schema from one type to another but instead either create a new schema or modify the OpenAPI source directly; to open the source editor, click the Source icon .

- Additional schema settings dependent on the selected Type, as follows:
 - array:
 - Max Items: The maximum allowed number of items in an array instance.
 - Min Items: The minimum allowed number of items in an array instance.
 - Unique Items: If selected, all items in an array instance must be unique.
 - boolean: no type specific settings.
 - integer:
 - Format: An optional data type modifier. For more information, see [Data Types](#) in the [OpenAPI Specification](#).
 - Multiple Of: Division of an integer instance by this value must result in an integer.
 - Maximum: An integer instance must be less than or equal to this value.
 - Exclusive Maximum: An integer instance must be strictly less than this value.
 - Minimum: An integer instance must be greater than or equal to this value.
 - Exclusive Minimum: An integer instance must be strictly greater than this value.
 - number:
 - Format: An optional data type modifier. For more information, see [Data Types](#) in the [OpenAPI Specification](#).
 - Multiple Of: Division of a number instance by this value must result in an integer.
 - Maximum: A number instance must be less than or equal to this value.
 - Exclusive Maximum: A number instance must be strictly less than this value.
 - Minimum: A number instance must be greater than or equal to this value.
 - Exclusive Minimum: A number instance must be strictly greater than this value.
 - object
 - Properties: To add properties to the schema, click Add alongside the Properties section heading. You configure a property by defining its schema with the schema editor.
To create the property, refer to [Creating a schema](#).

To further configure the property, follow the steps on this page.

By defining properties, you can create more complex data structures. For example, you could define an "Address" schema that has the following properties:

PROPERTY NAME	PROPERTY TYPE
street1	string
street2	string
city	string
state	string
zip_code	string

and then define a "BankBranch" schema that has the following properties, one of which is a reference to the Address schema:

PROPERTY NAME	PROPERTY TYPE
address	address
type	string
id	string

- Max Properties: The number of properties in an object instance must be less than or equal to this value.
- Min Properties: The number of properties in an object instance must be greater than or equal to this value.
- Required Properties: An array of property names; every property name in the array must be the name of a property in an object instance. To add a required property name, click Add alongside the Required Properties section heading, enter the name, then click Create.
- string:
 - Format: An optional data type modifier. For more information, see [Data Types](#) in the [OpenAPI Specification](#).
 - Pattern: A regular expression; a string instance must successfully match the expression.
 - Max Length: The maximum allowed number of characters in a string instance.
 - Min Length: The minimum allowed number of characters in a string instance.
 - Enum: An array of string values; a string instance must match one of the array values. To add an enum value, click Add, enter the value, then click Create.
- Description: An optional description of the schema. You can use [CommonMark syntax](#) for rich text representation.
- General settings; select the required options:
 - Read Only: A property associated with this schema can be returned in a response but should not be included in a request. For example, properties whose values are system generated identifiers will be defined as Read Only because application clients wouldn't be able to set these.
 - Write Only: A property associated with this schema can be included in a request but should not be returned in a response. For example, password properties are usually defined as Write Only because application clients would supply these when creating a user object but shouldn't be able see them when retrieving the object.
 - Deprecated: The schema is deprecated and should be transitioned out of usage.
- Example Value: An example value. Whatever you enter here is displayed as-is in the Developer Portal.
- External Documentation: An external resource for extended documentation; provide the following information:
 - URL (required): The URL for the target documentation.
 - Description: An optional description of the target documentation. You can use [CommonMark syntax](#) for rich text representation.
- Xml: Metadata that allows for more fine-tuned XML model definitions; provide the following information:
 - Name: Replaces the name of the element or attribute used for the described schema property.
 - Namespace: The URL of the namespace definition.
 - Prefix: The prefix to be used for the Name.
 - Attribute: Specifies whether the property definition translates to an attribute instead of an element.
 - Wrapped: For an array definition, Specifies whether the array is wrapped (for example, `<books><book/></books>`) or unwrapped (`<book/></book/>`).
- Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining response components

Response components define reusable response objects that specify the HTTP status code and data returned in a response body and headers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a response component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand Components then, if there are already one or more response components defined, expand Responses.
3. You can create a new response component, or edit any existing response component.

- To create a response component, click the add icon  alongside Responses, then refer to [Creating a response](#).
 - To edit an existing response component, click the response component name in the navigation pane, then refer to [Editing a response](#).
- **Creating a response**
Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.
 - **Editing a response**
Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.
 - **Creating a content definition**
A content definition describes the content of an API request, response, or parameter. You can create content definitions in various places in your API definition.
 - **Editing a content definition**
A content definition describes the content of an API request, response, or parameter. You can edit content definitions that have been previously created in various places in your API definition.
 - **Creating an encoding definition**
An encoding definition defines a map between a specific schema property and its encoding information.
 - **Editing an encoding definition**
An encoding definition defines a map between a specific schema property and its encoding information

Creating a response

Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.

Before you begin

Launch the response creation window. For details of the areas in your API definition from where you can create a response, see the following topics:

- [Defining responses for an operation](#)
- [Defining response components](#)

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Create the response; you can either create a response from scratch, or you can reference a response that is defined in a response component.
 - To create the response from scratch, provide the following information on the Definition tab:
 - Response name: A name for the response.
If you are creating an operation response, this name is the HTTP status code.

If you are creating a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

`#/components/responses/Name`
 - Description (required): A description of the response. You can use [CommonMark syntax](#) for rich text representation.
 - To reference a response that is defined in a response component, provide the following information on the Reference tab:
 - Response name: A name for the response.
If you are creating an operation response, this name is the HTTP status code.

If you are creating a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

`#/components/responses/Name`
 - Reference from: Select a reference to a response component.
2. Click Create.
The response details are displayed for further editing; see [Editing a response](#).

Editing a response

Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.

Before you begin

Open the details form for a response. For details of the areas in your API definition from where you can edit a response, see the following topics:

- [Defining responses for an operation](#)
- [Defining response components](#)

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:

- Response name: A name for the response.
If you are editing an operation response, this name is the HTTP status code.

If you are editing a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

#/components/responses/Name

To change the name, click Update, then click Save when done.

- Description: A description of the response. You can use [CommonMark syntax](#) for rich text representation.
- Headers: Headers define information that can be returned in the response.
To define a new header for the response, click Add, then refer to [Creating a header](#).

To edit an existing header, click the header name, then refer to [Editing a header](#).
- Content: A content definition describes the content of the response.
To define a new content definition for the response, click Add, then refer to [Creating a content definition](#).

To edit an existing content definition, click the content definition name, then refer to [Editing a content definition](#).
- Links: Links describe how various values returned by one operation can be used as input for other operations.
To define a new link for the response, click Add, then refer to [Creating a link](#).

To edit an existing link, click the link name, then refer to [Editing a link](#).

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Creating a content definition

A content definition describes the content of an API request, response, or parameter. You can create content definitions in various places in your API definition.

Before you begin

Launch the content definition creation window. For details of the areas in your API definition from where you can create a content definition, see the following topics:

- [Editing a header](#)
- [Editing a request body](#)
- [Defining the request body for an operation](#)
- [Editing a response](#)

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:

- Content Type: Select the content type; for example, application/json.

Note: While the Content Type field in the editor provides a selection list of media types, by editing the OpenAPI source for the API directly you can specify a [media type range](#); for example, `text/*, */json`, or `*/*`. For requests or responses that match multiple types, only the most specific type is applicable; for example, `text/plain` overrides `text/*`.

2. Click Create.

The content definition details are displayed for further editing; see [Editing a content definition](#).

Editing a content definition

A content definition describes the content of an API request, response, or parameter. You can edit content definitions that have been previously created in various places in your API definition.

Before you begin

Open the details form for a content definition. For details of the areas in your API definition from where you can edit a content definition, see the following topics:

- [Editing a header](#)
- [Editing a request body](#)
- [Defining the request body for an operation](#)
- [Editing a response](#)

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:

- Content Type: Select the content type; for example, application/json.

Note: While the Content Type field in the editor provides a selection list of media types, by editing the OpenAPI source for the API directly you can specify a [media type range](#); for example, `text/*, */json`, or `*/*`. For requests or responses that match multiple types, only the most specific type is applicable; for example, `text/plain` overrides `text/*`.

- Schema:

To define a schema for the content definition, click Create, then refer to [Creating a schema](#).

If the content definition already has a schema defined, click View to edit the schema.

For full details on editing a schema, see [Editing a schema](#).

Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see [Defining schema components](#). You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.

- Example Value: An example of a parameter value. Whatever you enter here is displayed as-is in the Developer Portal.

- Examples:

To add an example of the content, click Add, then refer to [Creating an example](#).

To edit an existing example, click the example name, then refer to [Editing an example](#).

- Encoding: An encoding definition describes how a specific schema property is encoded.

To add an encoding definition, click Add, then refer to [Creating an encoding definition](#).

To edit an existing encoding definition, click the name, then refer to [Editing an encoding definition](#).

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Creating an encoding definition

An encoding definition defines a map between a specific schema property and its encoding information.

Before you begin

Launch the encoding definition creation window when configuring a content definition; see [Editing a content definition](#).

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:

- Name: The name of the schema property.
- Content Type: The Content-Type for encoding the property; for example, `application/xml; charset=utf-8, image/png, image/jpeg`.
- Style: Describes how the property value will be serialized depending on the type of the property value. Select one of the following options:
 - form: Form style properties defined by [RFC6570](#).
 - spaceDelimited: Space separated array values.
 - pipeDelimited: Pipe separated array values.
 - deepObject: Provides a simple way of rendering nested objects using form properties.
- Explode: When selected, property values of type `array` or `object` generate separate properties for each value of the array or key-value pair of the map.
- Allow Reserved: Determines whether the property value should allow reserved characters, as defined by [RFC3986](#) (`:/?#[]@!$&'()*+,-=`) to be included without percent-encoding.

2. Click Create.

The encoding definition details are displayed for further editing; see [Editing an encoding definition](#).

Editing an encoding definition

An encoding definition defines a map between a specific schema property and its encoding information

Before you begin

Open the details form for an encoding definition when configuring a content definition; see [Editing a content definition](#).

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:

- Name: The name of the schema property. To change the name, click Update, then click Save when done.
- Content Type: The Content-Type for encoding the property; for example:
 - `application/xml; charset=utf-8`
 - `image/png, image/jpeg`.
- Headers: A map allowing additional information to be provided as headers.
To add a new header, click Add, then refer to [Creating a header](#).

To edit an existing header, click the header name, then refer to [Editing a header](#).
- Style: Describes how the property value will be serialized depending on the type of the property value. Select one of the following options:
 - form: Form style properties defined by [RFC6570](#).
 - spaceDelimited: Space separated array values.
 - pipeDelimited: Pipe separated array values.
 - deepObject: Provides a simple way of rendering nested objects using form properties.
- Explode: When selected, property values of type `array` or `object` generate separate properties for each value of the array or key-value pair of the map.
- Allow Reserved: Determines whether the property value should allow reserved characters, as defined by [RFC3986](#) (`:/?#[]@!$&'()*+,-=`) to be included without percent-encoding.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining parameter components

Parameter components define reusable parameters that can specify variable elements of a URL path, query parameters, headers, or a request body.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a parameter component, you must reference it from elsewhere in your API definition.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **header**.
- A parameter can have various format styles, the style of a header is always **simple**.

For more information on headers, see [Creating a header](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
 2. Expand Components then, if there are already one or more parameter components defined, expand Parameters.
 3. You can create a new parameter component, or edit any existing parameter component.
 - To create a parameter component, click the add icon  alongside Parameters, then refer to [Creating a parameter](#).
 - To edit an existing parameter component, click the parameter component name in the navigation pane, then refer to [Editing a parameter](#).
- [Creating a parameter](#)
Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.
 - [Editing a parameter](#)
Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for Paths and Path operations in your API definition.

Creating a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.

Before you begin

Launch the parameter creation window. For details of the areas in your API definition from where you can create a parameter, see the following topics:

- [Defining parameters for a Path](#)
- [Defining parameters for an operation](#)
- [Defining parameter components](#)

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **header**.
- A parameter can have various format styles, the style of a header is always **simple**.

For more information on headers, see [Creating a header](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Create the parameter; you can either create a parameter from scratch, or you can reference a parameter that is defined in a parameter component.

- To create the parameter from scratch, provide the following information on the Definition tab:
 - Name: Available if you are creating a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/parameters/Name
```

- Parameter name (required): The name of the parameter.
- Located In (required): The location of the parameter. Select one of the following options:
 - query: Parameters that are appended to the URL. For example, `url_path?myparam=myvalue`.
 - header: Custom headers that are expected as part of the request.
 - path: The parameter value is part of the operation's URL, enclosed in {}.
 - cookie: Used to pass a specific cookie value to the API.
- Description: A description of the parameter. You can use [CommonMark syntax](#) for rich text representation.
- Style: Describes how the parameter value will be serialized depending on the type of the parameter value. Select one of the following options:
 - matrix: Path-style parameters defined by [RFC6570](#).
 - label: Label style parameters defined by [RFC6570](#).
 - simple: Simple style parameters defined by [RFC6570](#).
 - form: Form style parameters defined by [RFC6570](#).
 - spaceDelimited: Space separated array values.
 - pipeDelimited: Pipe separated array values.
 - deepObject: Provides a simple way of rendering nested objects using form parameters.
- Select the following options as required:
 - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
 - Deprecated: Specifies that a parameter is deprecated and should be transitioned out of usage.
 - Allows Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
 - Explode: When selected, parameter values of type **array** or **object** generate separate parameters for each value of the array or key-value pair of the map.
 - Allow Reserved: Determines whether the parameter value should allow reserved characters, as defined by [RFC3986](#) (`:/?#[]@!$&'()*+,-;=`) to be included without percent-encoding. This property applies only if the Located In property is set to query.
- To reference a parameter that is defined in a parameter component, provide the following information on the Reference tab:
 - Name: Available if you are creating a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/parameters/Name
```

- Parameter name (required, available if you are creating a path or operation parameter): The name of the parameter.
- Reference from: Select a reference to a parameter component.

2. Click Create.

The parameter details are displayed for further editing; see [Editing a parameter](#).

Editing a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for Paths and Path operations in your API definition.

Before you begin

Open the details form for a parameter. For details of the areas in your API definition from where you can edit a parameter, see the following topics:

- [Defining parameters for a Path](#)
- [Defining parameters for an operation](#)
- [Defining parameter components](#)

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **header**.
- A parameter can have various format styles, the style of a header is always **simple**.

For more information on headers, see [Creating a header](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:

- Name: Available if you are editing a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

`#/components/parameters/Name`

To change the name, click Update, then click Save when done.

- Parameter name (required): The name of the parameter.
- Located In (required): The location of the parameter. Select one of the following options:
 - query: Parameters that are appended to the URL. For example, `url_path?myparam=myvalue`.
 - header: Custom headers that are expected as part of the request.
 - path: The parameter value is part of the operation's URL, enclosed in {}.
 - cookie: Used to pass a specific cookie value to the API.
- Description: A description of the parameter. You can use [CommonMark syntax](#) for rich text representation.
- Style: Describes how the parameter value will be serialized depending on the type of the parameter value. Select one of the following options:
 - matrix: Path-style parameters defined by [RFC6570](#).
 - label: Label style parameters defined by [RFC6570](#).
 - simple: Simple style parameters defined by [RFC6570](#).
 - form: Form style parameters defined by [RFC6570](#).
 - spaceDelimited: Space separated array values.
 - pipeDelimited: Pipe separated array values.
 - deepObject: Provides a simple way of rendering nested objects using form parameters.
- Select the following options as required:
 - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
 - Deprecated: Specifies that a parameter is deprecated and should be transitioned out of usage.
 - Allows Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
 - Explode: When selected, parameter values of type `array` or `object` generate separate parameters for each value of the array or key-value pair of the map.
 - Allow Reserved: Determines whether the parameter value should allow reserved characters, as defined by [RFC3986](#) (`:/?#[]@!$%&'()*+,-=`) to be included without percent-encoding. This property applies only if the Located In property is set to query.
- Schema:
 - To define a schema for the parameter, click Create, then refer to [Creating a schema](#).

If the parameter already has a schema defined, click View to edit the schema.

For full details on editing a schema, see [Editing a schema](#).

Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see [Defining schema components](#). You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.

- Example Value: An example of a parameter value. Whatever you enter here is displayed as-is in the Developer Portal.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining example components

An example component is a reusable example that you can add to an API to make the specification of your API clearer.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of an example component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand Components then, if there are already one or more example components defined, expand Examples.
3. You can create a new example component, or edit any existing example component.
 - To create an example component, click the add icon  alongside Examples, then refer to [Creating an example](#).
 - To edit an existing example component, click the example component name in the navigation pane, then refer to [Editing an example](#).

- [Creating an example](#)
You add examples to an API to make the specification of your API clearer.
- [Editing an example](#)
You add examples to an API to make the specification of your API clearer.

Creating an example

You add examples to an API to make the specification of your API clearer.

Before you begin

Launch the example creation window. For details of the areas in your API definition from where you can create an example, see the following topics:

- [Editing a content definition](#)
- [Defining example components](#)

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Create the example; you can either create an example from scratch, or you can reference an example that is defined in an example component.
 - To create the example from scratch, provide the following information on the Definition tab:
 - Example Name: If you are creating an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/examples/Name
```
 - Summary: A summary description of the example.
 - Description: A full description of the example. You can use [CommonMark syntax](#) for rich text representation.
 - External Value: A URL that points to a literal example. This provides the capability to reference examples that cannot easily be included in JSON or YAML documents. This could be a PDF, for example.
 - To reference an example that is defined in an example component, provide the following information on the Reference tab:
 - Example Name: If you are creating an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/examples/Name
```
 - Reference from: Select a reference to an example component.
2. Click Create.
The example details are displayed for further editing; see [Editing an example](#).

Editing an example

You add examples to an API to make the specification of your API clearer.

Before you begin

Open the details form for an example. For details of the areas in your API definition from where you can edit an example, see the following topics:

- [Editing a content definition](#)
- [Defining example components](#)

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:

- Example Name: If you are editing an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

`#/components/examples/Name`

To change the name, click Update, then click Save when done.

- Summary: A summary description of the example.
- Description: A full description of the example. You can use [CommonMark syntax](#) for rich text representation.
- Example Value: A literal example.
- External Value: A URL that points to a literal example. This provides the capability to reference examples that cannot easily be included in JSON or YAML documents. This could be a PDF, for example.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining request body components

A request body component is a reusable definition of the structure of the body of an API request.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
 2. Expand Components then, if there are already one or more request body components defined, expand Request Bodies.
 3. You can create a new request body component, or edit any existing request body component.
 - To create a request body component, click the add icon  alongside Request Bodies, then refer to [Creating a request body](#).
 - To edit an existing request body component, click the request body component name in the navigation pane, then refer to [Editing a request body](#).
- [Creating a request body](#)
A request body defines the structure of the body of an API request.
 - [Editing a request body](#)
A request body defines the structure of the body of an API request.

Creating a request body

A request body defines the structure of the body of an API request.

Before you begin

Launch the request body creation window; see [Defining request body components](#).

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Create the request body; you can either create a request body from scratch, or you can reference a request body that is defined in a request body component.
 - To create the request body from scratch, provide the following information on the Definition tab:
 - Name: A name for the request body.
If you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/requestBodies/Name
```
 - Description: A description of the request body. You can use [CommonMark syntax](#) for rich text representation.
 - Required: Determines if the request body is required in the request.
 - To reference a request body that is defined in a request body component, provide the following information on the Reference tab:
 - Name: A name for the request body.
If you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/requestBodies/Name
```
 - Reference from: Select a reference to a request body component.
2. Click Create.
The request body details are displayed for further editing; see [Editing a request body](#).

Editing a request body

A request body defines the structure of the body of an API request.

Before you begin

Open the details form for a request body; see [Defining request body components](#).

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
 - Name: A name for the request body.
Available if you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/requestBodies/Name
```
 - Description: A description of the request body. You can use [CommonMark syntax](#) for rich text representation.
 - Content: A content definition describes the content of the request body.
To define a new content definition for the request body, click Add, then refer to [Creating a content definition](#).

To edit an existing content definition, click the content definition name, then refer to [Editing a content definition](#).
 - Required: Determines if the request body is required in the request.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining header components

A header component defines a reusable custom header that can be sent in an API request or returned in an API response.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a header component, you must reference it from elsewhere in your API definition.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **header**.
- A parameter can have various format styles, the style of a header is always **simple**.

For more information on parameters, see [Creating a parameter](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
 2. Expand Components then, if there are already one or more header components defined, expand Headers.
 3. You can create a new header component, or edit any existing header component.
 - To create a header component, click the add icon  alongside Headers, then refer to [Creating a header](#).
 - To edit an existing header component, click the header component name in the navigation pane, then refer to [Editing a header](#).
- [Creating a header](#)
A header defines information that can be sent in an API request or returned in an API response. You can create headers in various places in your API definition.
 - [Editing a header](#)
A header defines information that can be sent in an API request or returned in an API response. You can edit headers that have been previously created in various places in your API definition.

Creating a header

A header defines information that can be sent in an API request or returned in an API response. You can create headers in various places in your API definition.

Before you begin

Launch the header creation window. For details of the areas in your API definition from where you can create a header, see the following topics:

- [Editing a response](#)
- [Editing an encoding definition](#)
- [Defining header components](#)

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **header**.
- A parameter can have various format styles, the style of a header is always **simple**.

For more information on parameters, see [Creating a parameter](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Create the header; you can either create a header from scratch, or you can reference a header that is defined in a header component.
 - To create the header from scratch, provide the following information on the Definition tab:
 - Header name: If you are creating a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:
`#/components/headers/Name`
 - Description: A description of the header. You can use [CommonMark syntax](#) for rich text representation.
 - Required: Determines whether this header is mandatory.
 - Deprecated: Specifies that this header is deprecated and should be transitioned out of usage.

- Allow Empty Value: The header can be sent with an empty value.
- Explode: When selected, header values of type **array** or **object** generate separate headers for each value of the array or key-value pair of the map.
- Allow Reserved: Determines whether the header value should allow reserved characters, as defined by [RFC3986](#) (:/?#[]@!\$&'()*+,-;=) to be included without percent-encoding.
- To reference a header that is defined in a header component, provide the following information on the Reference tab:
 - Header name: If you are creating a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:

#/components/headers/Name

- Reference from: Select a reference to a header component.

2. Click Create.

The header details are displayed for further editing; see [Editing a header](#).

Editing a header

A header defines information that can be sent in an API request or returned in an API response. You can edit headers that have been previously created in various places in your API definition.

Before you begin

Open the details form for a header. For details of the areas in your API definition from where you can edit a header, see the following topics:

- [Editing a response](#)
- [Editing an encoding definition](#)
- [Defining header components](#)

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **header**.
- A parameter can have various format styles, the style of a header is always **simple**.

For more information on parameters, see [Creating a parameter](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:

- Header name: If you are editing a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:

#/components/headers/Name

To change the name, click Update, then click Save when done.

- Description: A description of the header. You can use [CommonMark syntax](#) for rich text representation.
- Required: Determines whether this header is mandatory.
- Deprecated: Specifies that this header is deprecated and should be transitioned out of usage.
- Allow Empty Value: The header can be sent with an empty value.
- Explode: When selected, header values of type **array** or **object** generate separate headers for each value of the array or key-value pair of the map.
- Allow Reserved: Determines whether the header value should allow reserved characters, as defined by [RFC3986](#) (:/?#[]@!\$&'()*+,-;=) to be included without percent-encoding.
- Schema:
 - To define a schema for the header, click Create, then refer to [Creating a schema](#).

If the header already has a schema defined, click View to edit the schema.

For full details on editing a schema, see [Editing a schema](#).

Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see [Defining schema components](#). You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.

- Content: A content definition describes the content of the header.

To define a new content definition for the header, click Add, then refer to [Creating a content definition](#).

To edit an existing content definition, click the content definition name, then refer to [Editing a content definition](#).

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining security scheme components

A security scheme component specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can create security definitions of the following types:

Type	Description
Basic authentication	Use a basic authentication security definition to specify a user registry or an authentication URL to be used to authenticate access to the API.
API key	Use an API key security definition to specify what application credentials are required to call an API.
OAuth2	Use an OAuth2 security definition to specify settings for OAuth token based authentication for your API.
HTTP Bearer	Use an HTTP Bearer definition to specify how to validate the Bearer token that is required to call an API.

- [Defining basic authentication security scheme components](#)
A basic authentication security scheme component is used when an application that calls the API is required to authenticate through a user registry.
- [Defining API key security scheme components](#)
An API key security component is used to specify the credentials that an application must provide to identify itself when calling the API operations.
- [Defining OAuth2 security scheme components](#)
An OAuth2 security scheme component defines the settings for controlling access to the API operations through the OAuth authorization standard.
- [Defining an HTTP bearer security scheme](#)
An HTTP bearer security scheme is used to generate access tokens that are exchanged between the server and the client when calling the API operations.

Defining basic authentication security scheme components

A basic authentication security scheme component is used when an application that calls the API is required to authenticate through a user registry.

Before you begin

For authenticating access to the operations of APIs that are enforced on the API Connect gateway, the following user registry types are supported:

- Authentication URL
- LDAP

The following user registry types are **not** supported:

- OpenID Connect (OIDC)
- Local User Registry (LUR)
- A custom user registry

Before you can create a basic authentication security definition in an API, the user registry must exist. To create a user registry, you can use either API Manager or Cloud Manager. When you create a registry in API Manager, it is visible only to your provider organization. When you create a registry in Cloud Manager, you can make it visible to multiple provider organizations.

To create a user registry with API Manager, see [Working with user registries](#).

To create a user registry with Cloud Manager, see [User registries overview](#).

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you use basic authentication, you require API users to provide a valid user name and password to access selected operations. The application developer must also provide an HTTP authorization header in requests that are sent to operations that require basic authentication.

When you use an authentication URL, the user credentials that are provided in the authorization header are validated by the endpoint specified in the URL. If the user is authenticated, IBM API Connect expects an authentication URL to return an HTTP 200 OK response status code. All other HTTP response status codes result in an authentication failure and access is denied.

For more information about using an LDAP user registry for authentication, see [LDAP authentication](#).

For information about using an Authentication URL, see [Authentication URL user registry](#).

To make use of a basic authentication security scheme component, you must reference it from elsewhere in your API definition. For more information, see [Enforcing security requirements on an API](#) and [Enforcing security requirements on an operation](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.
3. To create a basic authentication security scheme component, click the add icon  alongside Security Schemes. To edit an existing basic authentication security scheme component, click the component name in the navigation pane.
4. If you are creating a new basic authentication security scheme component, you can either create it from scratch or you can reference another basic authentication security scheme component.

To create a basic authentication security scheme component from scratch, provide the following information on the Definition tab:

- Security Scheme Name (required): A key that enables this basic authentication security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/securitySchemes/Security_Scheme_Name
```

- Security Scheme Type (required): Select http.
- Scheme (required): The name of the HTTP Authorization scheme to be used in the Authorization header as defined in [RFC7235](#).
- Authenticate using User Registry: The name of the user registry to be used for authentication. This is the value of the `name` field that was auto-generated when the user registry was created.
- Bearer format: A hint to the client to identify how the bearer token is formatted. Bearer tokens are usually generated by an authorization server, so this information is primarily for documentation purposes.
- Description: An optional description of the basic authentication security scheme. You can use [CommonMark syntax](#) for rich text representation.

To reference another basic authentication security scheme component, provide the following information on the Reference tab:

- Security Scheme Name (required): A key that enables this basic authentication security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/securitySchemes/Security_Scheme_Name
```

- Reference from: Select a reference to another basic authentication security scheme component.

5. If you are creating a new basic authentication security scheme component, click Create.
The security scheme component details are displayed for further editing.
6. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see [Enforcing security requirements on an API](#) and [Enforcing security requirements on an operation](#).

For more information on LDAP and Authentication URL, see [LDAP authentication](#) and [Authentication URL user registry](#).

Defining API key security scheme components

An API key security component is used to specify the credentials that an application must provide to identify itself when calling the API operations.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can require that, when calling an API operation, an application must provide either a client ID, or a client ID and client secret; you create an API key security scheme component to specify a credentials requirement. If you require that an application must provide both a client ID and client secret, you must create two API key security scheme components, one for each type of credentials.

To make use of an API key security scheme component, you must reference it from elsewhere in your API definition. For more information, see [Enforcing security requirements on an API](#) and [Enforcing security requirements on an operation](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.

- To create an API key security scheme component, click the add icon  alongside Security Schemes. To edit an API key existing security scheme component, click the component name in the navigation pane.
- If you are creating a new API key security scheme component, you can either create it from scratch or you can reference another API key security scheme component.

To create an API key security scheme component from scratch, provide the following information on the Definition tab:

- Security Scheme Name: A key that enables this API key security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/securitySchemes/Security_Scheme_Name
```

- Security Scheme Type: Select apiKey.
- Name: The name of the header, query or cookie parameter to be used. For a key of type client secret you must include the string "secret", ignoring case, in the value you specify in the Name field; if the value does not contain the string "secret" then the key is assumed to be of type client ID.
Note: The client ID and client secret headers that are specified in the request when the API is called are **not** added automatically to the message context. If you need these headers in the message context for subsequent processing, include a **set-variable** policy in your API assembly that adds the headers to the message content, taking the values specified in the request; you can do this in either of the following ways:

- In the Assemble tab, add a Set Variable policy to your API assembly that defines the appropriate actions; for example:

Table 1.

Action	Set	Type	Value
Set	message.headers.X-IBM-Client-Id	string	\$(request.headers.X-IBM-Client-Id)
Set	message.headers.X-IBM-Client-Secret	string	\$(request.headers.X-IBM-Client-Secret)

For more information on configuring a Set Variable policy, see [Set Variable](#).

- In the Source tab, add a **set-variable** policy directly to the assembly section in your OpenAPI source; for example:

```
assembly:
  execute:
    - set-variable:
      version: 2.0.0
      title: set-variable
      actions:
        - set: message.headers.X-IBM-Client-Id
          value: $(request.headers.X-IBM-Client-Id)
          type: string
        - set: message.headers.X-IBM-Client-Secret
          value: $(request.headers.X-IBM-Client-Secret)
          type: string
```

For more information on defining a **set-variable** policy in your OpenAPI source, see [set-variable](#).

You should position the **set-variable** before any policy that needs to access the API key headers; for example, an invoke policy that calls a back-end service that is required to identify the application that made the initial request.

- Key Type: Select client_id or client_secret.

Important: The client_id is not confidential and functions as a "SecurityScheme" only in the meaning of the OpenAPI specification.

If you use only the client_id (without the client_secret) as your API Key, be aware that the client_id is not considered a confidential value in the API Manager UI; for example, it might be displayed to other authenticated members of the provider organization. The client_id is treated as a public identifier for apps and cannot be kept private.

If authentication of the identity of the app calling an API is needed, then the API Key should use both a client_id to identify the app, plus a client_secret to authenticate it. The client_secret is designed to be known only to the app and the authorization server, and it should be protected. IBM API Connect protects the client_secret: it is only available when first generated, it can be stored as a one-way hash to prevent retrieval or leaks, and it can be changed and reset without changing the corresponding client_id. When an API Key is not marked as a client_secret, it will not be protected in the API Manager UI.

- Located In: Select one of the following options, to specify how the credentials are sent:
 - header: The credentials are sent in the request header.
 - query: The credentials are sent as query parameters. This method is less secure because the client secret could be exposed in a log file.

Note: If you migrated from API Connect V5, API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. For information about the differences, see [Client ID behavior in API key security definitions](#).

- Description: An optional description of the API key security scheme. You can use [CommonMark syntax](#) for rich text representation.

- To reference another API key security scheme component, provide the following information on the Reference tab:

- Security Scheme Name: A key that enables this API key security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/securitySchemes/Security_Scheme_Name
```

- Reference from: Select a reference to another API key security scheme component.

- If you are creating a new API key security scheme component, click Create.

The security scheme component details are displayed for further editing.

- Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see [Enforcing security requirements on an API](#) and [Enforcing security requirements on an operation](#).

- [Client ID behavior in API key security definitions](#)

How the Client ID behaves in API key security definitions in IBM API Connect 10 compared to Version 5.

Client ID behavior in API key security definitions

How the Client ID behaves in API key security definitions in IBM® API Connect 10 compared to Version 5.

API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. Refer to the following table to understand the differences in Client ID behavior for different use cases.

Note: Although a client_id in the request body is supported, this data is not used during security requirement processing.

Table 1. Client ID behavior in V5 and V10

Use case	Description of security requirement	V5 behavior	V10 behavior
1	Allows client_id in the query, and the request contains multiple client_ids in the query.	Uses the first client ID in the request.	401 invalid client ID or secret.
2	Allows client_id in the header, and the request contains multiple client_ids in the header.	401 invalid client ID or secret.	401 invalid client ID or secret.
3	Allows client_id in the header, and the request contains multiple client_ids in the query and the header (1 in the query, 1 in the header).	401 client ID in wrong location.	Client ID in query is ignored.
4	Allows client_id in the query, and the request contains multiple client_ids in the query and the header.	Client ID in header is ignored.	Client ID in header is ignored.
5	Allows client_id in the query or header, and both the query and header contain multiple client_ids.	Header returns 401 client ID in wrong location. Query uses the first client ID in the request.	401 invalid client ID or secret.
6	Allows client_id in the header, and the request contains a valid client_id in the query, and an invalid client_id in the header.	401 client ID in wrong location.	401 invalid client ID or secret.
7	Allows client_id in the query, and the request contains a valid client_id in the header, and an invalid client_id in the query.	401 invalid client ID or secret.	401 invalid client ID or secret.
8	Allows client_id in the query or header, and both the query and header contain valid client_ids.	200 OK.	403 multiple client IDs.
9	Allows client_id in the query or header, and both the query and header contain invalid client_ids.	401 client ID in wrong location.	401 invalid client ID or secret.
10	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the query is valid.	200 OK.	Uses the valid one 200 OK.
11	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the header is valid.	401 client ID in wrong location.	Uses the valid one 200 OK.
12	Allows client_id in the query or header, and both the query and client_id is missing in the request (no security requirement, but client security is defined in the assembly).	401 invalid client ID or secret.	<ul style="list-style-type: none"> When Return V5 Responses compatibility option is off: 401 client ID is missing. When Return V5 Responses compatibility option is on: 401 invalid client ID or secret. <p>For information about setting compatibility options, see Configuring v5 compatibility options.</p>

Defining OAuth2 security scheme components

An OAuth2 security scheme component defines the settings for controlling access to the API operations through the OAuth authorization standard.

Before you begin

Before you can create an OAuth2 security scheme component, you must:

1. Create an OAuth provider.
 - To use Cloud Manager, see [Configuring a native OAuth provider](#) or [Configuring a third-party OAuth provider](#).
 - To use API Manager, see [Configuring a native OAuth provider](#) or [Configuring a third-party OAuth provider](#).
2. Add the OAuth provider to a catalog. If you have not created any catalogs, use the Sandbox Catalog. See the [OAuth instructions step](#) in [Creating and configuring Catalogs](#).

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of an OAuth2 security scheme component, you must reference it from elsewhere in your API definition. For more information, see [Enforcing security requirements on an API](#) and [Enforcing security requirements on an operation](#).

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.

- To create an OAuth2 security scheme component, click the add icon  alongside Security Schemes. To edit an existing OAuth2 security scheme component, click the component name in the navigation pane.
- If you are creating a new OAuth2 security scheme component, you can either create it from scratch or you can reference another OAuth2 security scheme component.

To create an OAuth2 security scheme component from scratch, provide the following information on the Definition tab:

- Security Scheme Name: A key that enables this OAuth2 security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/securitySchemes/Security_Scheme_Name
```

- Security Scheme Type: Select oauth2.
- Flow Type: Select one or more of the following options:
 - implicit
 - password
 - clientCredentials
 - authorizationCode
- OAuth Provider: The name of the OAuth provider to be used. This is the value of the **name** field that was auto-generated when the OAuth provider was created.
- Description: An optional description of the OAuth2 security scheme. You can use [CommonMark syntax](#) for rich text representation.

To reference another OAuth2 security scheme component, provide the following information on the Reference tab:

- Security Scheme Name: A key that enables this OAuth2 security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/securitySchemes/Security_Scheme_Name
```

- Reference from: Select a reference to another OAuth2 security scheme component.
- If you are editing an existing OAuth2 security scheme component, provide the following information:
 - The URL endpoints (the applicable endpoints depend on the flow type):
 - Authorization URL
 - Refresh URL
 - Token URL

Note: The URL endpoint values supplied here are maintained only for informative purposes, no validation or other action is applied to them by API Connect. The OAuth security that is applied depends on the specified OAuth provider.

- Scopes:
 - To add a new scope, click Add. To edit an existing scope, click the options icon  alongside the required scope, then click Edit.
 - Provide the following information:
 - Scope: The scope identifier.
 - Description: An optional description of the scope. You can use [CommonMark syntax](#) for rich text representation.

- If you are creating a new OAuth2 security scheme component, click Create.

The security scheme component details are displayed for further editing.

- Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see [Enforcing security requirements on an API](#) and [Enforcing security requirements on an operation](#).

Defining an HTTP bearer security scheme

An HTTP bearer security scheme is used to generate access tokens that are exchanged between the server and the client when calling the API operations.

About this task

For information on the use of bearer tokens with OpenAPI 3 APIs, see [Bearer Authentication](#) in the OpenAPI 3 specification.

If an HTTP bearer token is found in the request, its value is stored within the context as `api->security->bearer_token`. If an external URL validation is invoked, any response with a status code of 200 is stored within the context as `api->security->bearer_validation_response`.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

- Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
- Expand Components, , Security Schemes.
- Click Add.
- In the Add Object dialog box, provide the following information:
 - Security Scheme Name (Key) - Provide a descriptive name for the new scheme.

- Security Scheme Type - Select http.
 - Scheme - Select Bearer.
 - Bearer Format - Select JWT.
 - Validation Method - Select a method. If you select external-url, provide the following additional information:
 - Validation Endpoint - Provide the URL of the server used for validation. To ensure a secure connect, the URL should use the **https** protocol.
 - TLS Profile name - If the validation endpoint uses the **https** protocol, select the name of the TLS client profile to use for a secure connection.
 - Description - Provide a description of the JWT scheme.
5. Click Create to create the new scheme.
 6. Click Save in the page header.

Defining link components

A link component is a reusable link definition that can be used to describe how various values returned by one operation can be used as input for other operations. In this way, links provide a known relationship and traversal mechanism between the operations.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a link component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
 2. Expand Components then, if there are already one or more link components defined, expand Links.
 3. You can create a new link component, or edit any existing link component.
 - To create a link component, click the add icon  alongside Links, then refer to [Creating a link](#).
 - To edit an existing link component, click the link component name in the navigation pane, then refer to [Editing a link](#).
- [Creating a link](#)
Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.
 - [Editing a link](#)
Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Creating a link

Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Before you begin

Launch the link creation window. For details of the areas in your API definition from where you can create a link, see the following topics:

- [Editing a response](#)
- [Defining link components](#)

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Create the link; you can either create a link from scratch, or you can reference a link that is defined in a link component.

- To create the link from scratch, provide the following information on the Definition tab:
 - Name: If you are creating a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/links/Name
```
 - Operation ID: The ID of an existing operation; this field is mutually exclusive of the Operation Ref field. For details on defining operations, see [Defining operations for a Path](#).
 - Operation Ref: A relative or absolute URI reference to an existing operation; this field is mutually exclusive of the Operation ID field. For details on defining operations, see [Defining operations for a Path](#).
 - Description: A description of the link. You can use [CommonMark syntax](#) for rich text representation.
- To reference a link that is defined in a link component, provide the following information on the Reference tab:
 - Name: If you are creating a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/links/Name
```
 - Reference from: Select a reference to a link component.

2. Click Create.

The link details are displayed for further editing; see [Editing a link](#).

Editing a link

Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Before you begin

Open the details form for a link. For details of the areas in your API definition from where you can edit a link, see the following topics:

- [Editing a response](#)
- [Defining link components](#)

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:

- Name: If you are editing a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

```
#/components/links/Name
```

To change the name, click Update, then click Save when done.

- Operation ID: The ID of an existing operation; this field is mutually exclusive of the Operation Ref field. For details on defining operations, see [Defining operations for a Path](#).
- Operation Ref: A relative or absolute URI reference to an existing operation; this field is mutually exclusive of the Operation ID field. For details on defining operations, see [Defining operations for a Path](#).
- Parameters: A map representing parameters to pass to an operation as specified with Operation ID or identified via Operation Ref. The key is the parameter name to be used, whereas the value can be a constant or an expression to be evaluated and passed to the linked operation.
- Request Body: The request body to use when calling the target operation.
- Description: A description of the link. You can use [CommonMark syntax](#) for rich text representation.
- Server: A server to be used by the target operation. Provide the following information:
 - Server URL The specified URL is used to determine the full URL endpoint for the calling the API, according to any vanity endpoint configuration in the Catalog in which the API is published. For full details, see [Configuring vanity endpoints for a Catalog](#).
 - Server Description: An optional description of the host designated by the URL. You can use [CommonMark syntax](#) for rich text representation.
 - Server Variables A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
 - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
 - Provide the following information:
 - Server Variable Name (required).
 - Default value (required).
 - An optional rich text description. You can use [CommonMark syntax](#) for rich text representation.
 - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add a new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
 - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Specifying gateway and portal settings

Define general configuration settings for your API.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Select the Gateway tab, then click Gateway and portal settings.
3. Provide the following information:
 - Phase: The phase of the lifecycle that your API is in; select one of the following options:
 - Realized (default) - The API is in the implementation phase.
 - Identified - The API is in the early conceptual phase and is neither fully designed nor implemented.
 - Specified - The API has been fully designed and passed an internal milestone but has not yet been implemented.
 - Testable: Select this option to allow the API's operations to be tested using the test tool in the Developer Portal.
Note: For the test tool to work, an API must be included in a Plan in a Product that is staged in a Catalog.
 - CORS: Enable and configure cross-origin resource sharing (CORS) support for your API. For details, see [Enabling CORS support for an API](#).
 - Target Services: Define web services that you want to use in your API definition. For details, see [Defining target services for an API](#).
 - Enforced: Select this option to enforce the API by using the DataPower API Gateway. Clear this option if you are managing the API on a gateway other than the DataPower API Gateway. Although not published to a gateway by API Connect, an unenforced API is still available in the Developer Portal for subscription by application developers.
 - Properties: Add properties that can be referenced in your API definition. For details, see [Setting API properties](#).
 - Catalog Properties: Define property values that are specific to a particular Catalog. For details, see [Defining Catalog specific property values](#).
 - Activity Log: Configure your logging preferences for the API activity that is stored in Analytics. For details, see [Configuring activity logging](#).
 - Extensions: Extensions added to the API to extend the OpenAPI specification. For details, see [Adding an OpenAPI extension to an API](#).

Defining target services for an API

A target service defines a web service that you want to use in your API definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more target services defined, expand Target Services.
3. To define a new API target service, complete the following steps:
 - a. Click the add icon  alongside Target Services in the navigation pane.
 - b. Upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, by either dragging and dropping your file, or browsing and selecting the file that you want to use.
If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see [Using an options file when importing a WSDL service](#).

4. Select the service that you want to add.
5. Click Save to save your changes.
6. To view the source for an existing target service, click the target service name in the navigation pane.

Results

The target services that you add are now available in the palette on the Policies view for you to add to your API assembly flow; for more information, see [Including elements in your API assembly](#).

Setting API properties

In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API properties include property name, value, and, optionally a specific Catalog to which a property value applies. For a list of pre-supplied API properties relating to various policies, see [API properties](#).

Note: Once defined, an API property is read only.

For information on how to reference a property in an API definition, see [Variable references in API Connect](#).

It is also possible to define properties that are specific to a Catalog and can be referenced by any of the APIs in that Catalog; for more information, see [Creating and configuring Catalogs](#). Note that if you define a Catalog property of the same name as an API property, the API property takes precedence over the Catalog property.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more API properties defined, expand Properties.
3. Configure an API property.
 - To define a new API property, complete the following steps:
 - Click the add icon  alongside Properties in the navigation pane.
 - Provide the following information:
 - Property Name: Enter a name for the property; this name is used to reference the property. The following character set is supported for the Name of an API property: `[A-Za-z0-9_-]+`. Spaces are allowed.
 - Value: A default value for the property. Leave blank if the property is to have a null value by default.
 - Description: An optional description of the property. You can use [CommonMark syntax](#) for rich text representation.
 - Select Encoded if you want to hide the property values, or protect user passwords from casual observance.
Note: If you encode a property value, it is saved in Base64 encoded form; it is **not** encrypted. If you subsequently clear the Encoded check box, the original property value is restored in its unencoded form.
 - Click Create.
 - To modify an existing API property, click the property name in the navigation pane. You can then change any of the configuration settings.
4. Click Save to save your changes.

What to do next

Optionally, define a value for the property that is specific to a particular Catalog; see [Defining Catalog specific property values](#).

- [Defining Catalog specific property values](#)
For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Defining Catalog specific property values

For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Before you begin

You must have previously created the API property that you now want to define a Catalog specific value for; see [Setting API properties](#).

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more Catalog specific property values defined, expand Catalog Properties.
3. Configure a Catalog specific property value.
 - To define a new Catalog specific property value, complete the following steps:
 - Click the add icon  alongside Catalog Properties in the navigation pane.
 - Type the Catalog Name exactly as it displays in the **name** field for the selected Catalog.
Tip: For the best result, manually type the catalog's name instead of selecting its title. Using the catalog name is safer than using its title, because the title might not be unique within the provider organization and might be modified later (which breaks the association between the property and the catalog). The catalog's name is always unique within the provider organization and cannot be changed.
 - Click Create. The Catalog properties details for the specified catalog are displayed for further editing.
 - Alongside Property Overrides, click Add.
 - Provide the following information:
 - Property Name: Enter the name of the API property that you want to define a Catalog specific value for. The name **must** match the name of a previously defined API property; see [Setting API properties](#).
 - Property Value: The Catalog specific property value. Leave blank if the property is to have a null value by default.
 - Click Create.
 - To modify an existing Catalog specific property value, click the Catalog name in the navigation pane. You can then change the Catalog name, and add, modify, or delete property override settings.
4. Click Save to save your changes.

Configuring activity logging

You can configure your logging preferences for the API activity that is stored in Analytics, overriding the default activity logging behavior.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

An API event record exists for each API execution event in the Gateway server. By default, the content type for a successful API execution is activity, and payload for an API call the results in an error code. When you compose your API definition, you can change the type of content to log in these API event records. During API execution, the activity data is stored in the `log` context variable, which populates the API event record on completion of the API execution; for more information, see [API activity logging context variables](#).

Note:

Activity logging that calls for logging of Analytics data upon success doesn't apply for the OAuth provider. The OAuth provider logs Analytics data for failure cases, but doesn't log successful cases.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in [Editing an OpenAPI 3.0 API definition](#).
2. Select the Gateway tab, expand Gateway and portal settings, then click Activity Log.
3. Select Enabled, then select options for the Success Content and Error Content fields as follows:

Field label	Description
-------------	-------------

Field label	Description
Success Content	<p>Defines the type of content to be logged when the operation is successful.</p> <ul style="list-style-type: none"> • none: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • activity: Logs invocation only; only the resource URI is recorded. • header: Logs activity and header; the HTTP headers, in addition to the resource URI are recorded. • payload: Logs activity, header, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. <p>The default value is activity.</p>
Error Content	<p>Indicates what content to log when an error occurs.</p> <ul style="list-style-type: none"> • none: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • activity: Logs invocation only; only the resource URI is recorded. • header: Logs activity and header; the HTTP headers, in addition to the resource URI are recorded. • payload: Logs activity, header, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. <p>The default value is payload.</p>

4. Click Save to save your changes.

Including elements in your API assembly

An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

In the Policies view of IBM API Connect, you can add and configure elements in your assembly. You can also directly add elements to the OpenAPI definition of your API.

- [The assembly editor](#)
The API Designer of IBM API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.
- [Adding elements to your assembly](#)
Create your API assembly by using the Assemble view in the API Designer.
- [Handling errors in the assembly](#)
Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

The assembly editor

The API Designer of IBM® API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM API Connect](#).

You can access the Assemble view by clicking the Gateway tab in the API editor, and then click Policies. This view includes a palette, which lists the available elements, a property sheet, which is used to configure an element, and a canvas, which is used to arrange and visualize the assembly's elements.

The palette

The palette is a list of different elements that you can include in your assembly. The palette can be hidden by clicking the Show/hide policy palette icon .

The canvas

You can use the canvas to create a graphical representation of the assembly flow. You can drag various elements from the palette to the appropriate location on the canvas. When you drag an element, valid positions are shown by dashed boxes.

Note: You must click Save in the Assemble view to save your assembly updates, and to make them appear in the Source view.

API calls are made at the initial, unfilled, circle, and returned at the final, filled, circle. You can insert elements between the two circles to modify the data received from the call, or returned by the response. To add an element, select it in the palette and drag it across to one of the dashed boxes that appear when you move the element over the canvas.

You can use the Show catches toggle to show and hide error catches in the palette. A catch is a section of the assembly that is applied when an API call results in the corresponding HTTP status code being returned. Click the catch section to open the property sheet for all your catches.

You can zoom the view of your canvas in and out by clicking the + and - icons. To fit the canvas to the screen size, click the Fit to screen icon .

You can filter the canvas to show only the parts of it that will apply to a specific operation by clicking the Filter by operation icon  and then selecting the operation from the drop-down list. Click the Clear operation filter icon  to remove the filter.

The property sheet

When you select an element that is in the assembly by clicking it, details about the element are displayed in the property sheet. In this pane, you can configure the element's properties. The options available to you in the property sheet are specific to the type of element you are working with. For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down menu.

You can release the property sheet by clicking the Close icon .

The behavior of an assembly

The assembly runs policies in order and acts on different contexts of the API call. When an API call is made, security and rate limits are enforced before the assembly is executed. During the assembly, the flow can branch or be thrown and caught, according to the policies contained in it. The message context can be thought to flow through the assembly, being used and altered by various policies. In addition to the message, other contexts can be accessed and created.

Security and rate limiting

Before the assembly is executed, security and then rate limits are enforced.

First, security definitions and CORS access control are used to authenticate an API call. Any API Key security definitions are used to identify applications that have subscriptions to a Product containing the API. If a security definition does not allow access, the API call is rejected.

If an application is identified by its client ID or client secret, a rate limit can be enforced based on the Plan or operation called.

The assembly execution sequence

The assembly is executed in order from the initial, filled, circle to the final, unfilled, circle. However, there is room for branching, when if and operation-switch logic constructs are used, or for the remaining assembly to be ignored when a throw policy is executed.

The message is the context that is acted upon by any policy that isn't otherwise configured. At the beginning of the API call, the message is empty and, at the end of the API call, the message is used as the response.

The request context contains the information that is sent by the API caller and varies with the type of operation called and the configuration of that operation. For example, a GET operation can never have a populated `request.body`, and you can configure an operation to have `request.parameters` (query parameters). The first policy in an assembly acts on the request and produces the first instance of the message. If there are no policies, the request is returned to the caller.

Managing contexts

Because the message can be overwritten, it can be useful to create and reference new contexts where possible so that they are saved and reusable during the API call.

- Use the map policy to overwrite the message context when you need to execute a policy that only acts on the message.
- Use the request context when you want to use the original request made to the API.
- Use the map, invoke, and proxy policies to create new contexts when you want to save your message.

Note: When you create a new context, unless you are also mapping to the message, the message is overwritten with an empty object.

For example, an invoke policy is the first policy in the assembly and its response overwrites the request as the message. The message is then acted upon by a validate policy, and a map policy then saves the message as a new context, ready for a second invoke policy to overwrite the message without losing the first invoke policy's output.

You can also access contexts outside of the message or your custom contexts, but these cannot be written to. For a list of contexts, see [API Connect context variables](#).

Branches and catches

Using logic constructs, such as operation-switch or if, you can execute different sections of the assembly when certain conditions are fulfilled. When the assembly branches, the subsection of the assembly contained by the construct is executed in the same manner as a complete assembly. However, contexts are shared with the complete assembly.

When a catch is triggered, either by an error occurring during the execution of a policy, or because a throw policy is encountered, the rest of the assembly flow is ignored. All contexts are shared by the catch being executed and when the end of the catch is reached, the API call is completed. There is no way to return from a catch to the rest of the assembly.

Adding elements to your assembly

Create your API assembly by using the Assemble view in the API Designer.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can use the assembly tool in the UI to create assemblies that are used to manipulate requests made to or responses made by any of your API's operations.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

If you want to use the Source view to edit the source of your API definition, see [execute OpenAPI extension](#) for more information about how to configure the OpenAPI YAML.

For more information about the use of the assembly tool, see [The assembly editor](#).

Procedure

To add elements to your assembly using the assembly tool, complete the following steps:

1. In the navigation pane, click  Develop, then select the APIs tab.
The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Use the Policies view to add an element.

Note: You must specify a version for the policy. To prevent errors due to incompatible versions of a policy between the API and the gateway, API Connect will only publish an API to the gateway if the policy version in the API exactly matches the version that is present on the gateway.

- a. Select the Gateway tab, then click Policies in the navigation pane.
- b. Find the element that you want to add in the palette.
- c. Drag the element onto the canvas; dashed boxes are displayed. Drop the element in a dashed box to insert it into that position in the assembly.

Note:

- Elements are applied in order from the initial, unfilled, circle to the final, filled, circle.
 - Unless an Operation Switch element is used, the whole assembly applies to every operation in the API.
- d. Add and edit properties of the element by clicking the element and using the property sheet.

For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down list. For information about the properties of policy elements, see [API policies and logic constructs](#). For information about the properties of logic constructs, see [Logic Constructs](#).

- e. Specify a version for the policy.

To add a version, click the Source icon , and complete the **version** section of the policy YAML. For example:

```
execute:
- invoke:
  version: 2.2.0
  title: invoke
...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions. For more information about how to configure the policy OpenAPI YAML, see [execute OpenAPI extension](#).

4. Optional: Repeat Steps [3.b](#) to [3.e](#) for any additional elements that you want to add.
5. Click Save to save your changes.

Results

You have added one or more elements to your assembly.

Handling errors in the assembly

Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see [Editing an OpenAPI 2.0 API definition](#).
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see [OpenAPI 3.0 support in IBM® API Connect](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The catch section of the assembly is used to implement an assembly in the instance that an error is thrown during the assembly execution. For example, the assembly could contain a throw element, the API caller could fail to authenticate, or a policy could fail to execute correctly. Each error can be handled with a different catch and each catch can handle multiple status errors.

Procedure

To create a catch and include elements in it, complete the following steps:

1. In the navigation pane, click  Develop, then select the APIs tab. The Develop page opens.
2. Click the title of the API definition that you want to apply a catch to.
3. Select the Gateway tab, then click Policies in the navigation pane.
4. Set the Show catches toggle in the menu bar of the canvas to the Show position.
5. Click Catches in the canvas, or a Catch icon  if one is displayed. The property sheet for the API's catches opens.
6. To add a default catch that is executed when an otherwise uncaught error is thrown, click Add default catch. Note: If you have a default catch before another catch in precedence, the default catch will activate even when the other catch's error is thrown.
7. To add a new catch, click Add catch.
8. To specify which errors the catch applies to, type the name of a custom error and press Enter, or use the Search errors field to search for the appropriate error.
9. Optional: To remove an error case from a catch, click the corresponding cross.
10. Optional: To change the precedence of your catches, use the Move up  or Move down  icons. If an error case is handled by multiple catches, the catch at the beginning of the list is applied.
11. To add an element to a catch, drag the element over the dashed, gray box that appears in the flow from the Catch icon  for the catch that you want to apply the element to.
12. Click Save to save your changes.

What to do next

If you added a catch for `ConnectionError`, `SOAPError`, or `OperationError`, you must add the same error to the Stop on error setting for the Invoke policy in your assembly. Otherwise if the error occurs during the execution of the Invoke policy, it is not caught, the policy execution is allowed to complete, and the assembly flow continues. For details on configuring an Invoke policy, see [Invoke](#).

For details of all the errors that can be returned by the assembly and are available to the catch function, see [Error cases supported by assembly catches](#).

Validating the OpenAPI YAML source

How to validate the OpenAPI YAML source when you're editing an API.

About this task

When you're configuring an API in the API editor, you can validate the OpenAPI YAML source by clicking Validate. If any swagger parser validation errors are found, an error icon is displayed that you can then click to see the individual errors, and where they occur in the YAML. You can then fix the errors, save the updates, and continue to validate the OpenAPI YAML throughout the API configuration process.

Note: OpenAPI validation does not show gateway or policy errors that will stop your API from being staged or published. This type of validation occurs only when you try to stage or publish your API. For more information, see [Staging an API](#) or [Publishing an API](#).

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

To validate the OpenAPI YAML source, complete the following steps.

1. Open the required API for editing, as described in [Editing an OpenAPI 2.0 API definition](#) or [Editing an OpenAPI 3.0 API definition](#).
2. Click Validate from the menu bar in the header.

3. If any swagger parser validation errors are found, an error icon is displayed on the header menu bar, with the number of OpenAPI errors found displayed next to the icon.

For example, .

4. You can then click the error icon to see a detailed list of the errors, and their location in the YAML. If you're in Form  view, you can click an individual error to navigate directly to the relevant API section in the form.
5. After you fix the error, click Save to save your updates, and then click Validate again.
6. When all of the errors are fixed, the validation returns a success message.

For example, .

LDAP authentication

The Lightweight Directory Access Protocol (LDAP) is an internet protocol for accessing and maintaining distributed directory information services over a network. If you rely on LDAP to authenticate users for web applications, take a minute to review the contents of this topic before beginning.

Programming guidelines

When authenticating with LDAP, observe the following guidelines:

- Use only a LDAP interface -- Users can only be authenticated via a connection to an LDAP server.
- Active Directory -- Use of an Active Directory interface is prohibited, however, LDAP authentication with Active Directory is supported.
- Administrator properties -- The LDAP administrator must have access to all user's LDAP properties.

LDAP attributes read by IBM® API Connect are as follows:

Attribute	Definition
mail	User's SMTP email address.
cn	Used internally to determine user's common name.
sn	Used internally to determine user's last name or surname.
givenname	Used internally to determine user's first name.
Prefix from Search dn	Used as username.

Using an LDAP Server for User Authentication

Every entry in an LDAP directory server has a distinguished name (DN). The DN is the name that uniquely identifies an entry in the directory. A DN is made up of **attribute=value** pairs, separated by commas. For example:

```
cn=Ben Gray,ou=editing,o=New York Times,c=US
cn=Lucille White,ou=editing,o=New York Times,c=US
cn=Tom Brown,ou=reporting,o=New York Times,c=US
```

Any of the attributes defined in the directory schema can be used to make up a DN. The order of the component attribute value pairs is important. The DN contains one component for each level of the directory hierarchy from the root down to the level where the entry resides. LDAP DNs begin with the most specific attribute (usually some sort of name) and continue with progressively broader attributes, often ending with a country attribute. The first component of the DN is referred to as the Relative Distinguished Name (RDN). It identifies an entry distinctly from any other entries that have the same parent. In the previous examples, the RDN "cn=Ben Gray" separates the first entry from the second entry, (with RDN "cn=Lucille White"). These two example DNs are otherwise equivalent. The attribute=value pair making up the RDN for an entry must also be present in the entry. (This is not true of the other components of the DN.)

Examples

In the following examples, a user search is performed from Base DN. The search is done anonymously, or if authenticated bind is used, an authenticated user is used. Search DN appends the prefix, the given user name, and the suffix. If the prefix used is **{uid=}** and the suffix used is **"**", **uid** becomes the user name attribute. The default search filter used is: **(| (cn={filter}*) (sn={filter}*) (mail={filter}*) (givenName={filter}))** and attributes used for prefix are also added to the search filter. In this case, where **{uid=}** is the prefix, when searching for users, the search filter becomes:

```
(| (cn={filter}*) (sn={filter}*) (mail={filter}*) (givenName={filter}*) (uid={filter}*))
```

where **{filter}** is replaced by actual text.

The authenticated bind DN is a user on the external LDAP server permitted to get base DNs and search the LDAP directory within the defined search base. It should also be able to read other user properties and be used if anonymous access to LDAP to get base DNs and to search and get access to user attributes is not allowed. When a search is performed for **Steve**, the LDAP query filter shown in the following example is used and search is done from base DN specified in UI. When the user's DN is returned, the DN and password are used to authenticate the user:

```
(| (cn=Steve*) (sn=Steve*) (mail=Steve*) (givenName=Steve*) (uid=Steve*)).
```

For bind during login calls, the search string used is the prefix. For example, if the prefix is **{uid=}**, the search string used to search for a user during log in becomes: **{uid=Steve}**.

Using the mail attribute as the user name

When you want to use an email address as the user name, (for example **steve@company.com**), you typically use the mail attribute as the prefix **{mail=}**. In this case, use the following search string to perform the search internally (assuming **{mail=}** as prefix):

```
(| (cn=steve@company.com*) (sn=steve@company.com*) (mail=steve@company.com*) (givenName=steve@company.com*) (mail=steve@company.com*))
```

In the previous example, if DN is found, the password is used with the DN to perform a bind. The first result is taken, so be sure to use a unique attribute for username. Next, the LDAP properties for the user are read (**cn**, **sn**, **mail**, **givenName**). If LDAP properties cannot be read using the logged-in user, they are read from the user's DN using authenticated bind credentials. If the user name attribute differs, it is also queried for. For example, if the prefix is **{uid=}**, the **uid** attribute is also read from the user's DN object:

```
(| (cn={filter}*) (sn={filter}*) (mail={filter}*) (givenName={filter}*))
```

Note: The prefix and suffix cannot be used to get a user's DN directly. For example, the following attempt to directly get a user's DN fails:

```
Prefix: "uid=_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_con_ldap_requirements_
Suffix: ",ou=users,dc=company,dc=com"
```

LDAP referrals

LDAP referrals allow a directory tree to be partitioned and distributed between multiple LDAP servers. An LDAP referral is a domain controller's way of indicating to a client application that it does not have a copy of a requested object, while giving the client a location that is more likely to hold the object. The client then uses the object as the basis for a DNS search for a domain controller.

API Connect support for LDAP referral includes:

- Searching for users that are part of multiple Active Directory trees and forests.
- Authenticating users in the Cloud Manager, API Manager and the Developer Portal.

Note: API Connect LDAP referral support is dependent on the following conditions:

- A single LDAP host/port is configured with administrator credentials and all users are referred to from the tree/server's base DN.
- As part of the user search following the LDAP referral, the same administrator credentials are used in the downstream trees/forests.
- LDAP API authentication does not support external LDAP referral. Internal LDAP referral is supported.

Authentication URL user registry

You can use an Authentication URL user registry to specify a REST authentication service to manage user authentication, and to optionally provide additional metadata to be embedded in the token.

This support can optionally enable any of the following:

- Providing the authenticated credential to IBM® API Connect. For example, the user logs-in with user name: `spoon`, and password: `fork`. When the user is authenticated, the credential becomes `cn=spoon,o=eatery`. The credential is kept in the OAuth `access_token` to represent the user.
- Providing metadata support. Allow extra metadata to be stored in the `access_token`.
- Overriding the `scope` that the application receives after a successful OAuth protocol processing. By responding with a specific header, the Authentication URL endpoint can replace the `scope` value that the application receives. For example, you can provide a specific resource owner an account number within the `scope` header response for use in future processing steps.

When you call the Authentication URL user registry, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.

The following response from the REST authentication service indicates that user authentication is successful and that API Connect will use `cn=spoon,o=eatery` as the user identity.

```
HTTP/1.1 200 OK
Server: example.org
X-API-Authenticated-Credential: cn=spoon,o=eatery
```

For information on how to configure a User Security policy in an API assembly for use with an Authentication URL user registry, see [User Security policy](#).

For an example of an OAuth provider configuration that uses an Authentication URL user registry, see [Example - using multiple OAuth policies in an OAuth provider assembly](#).

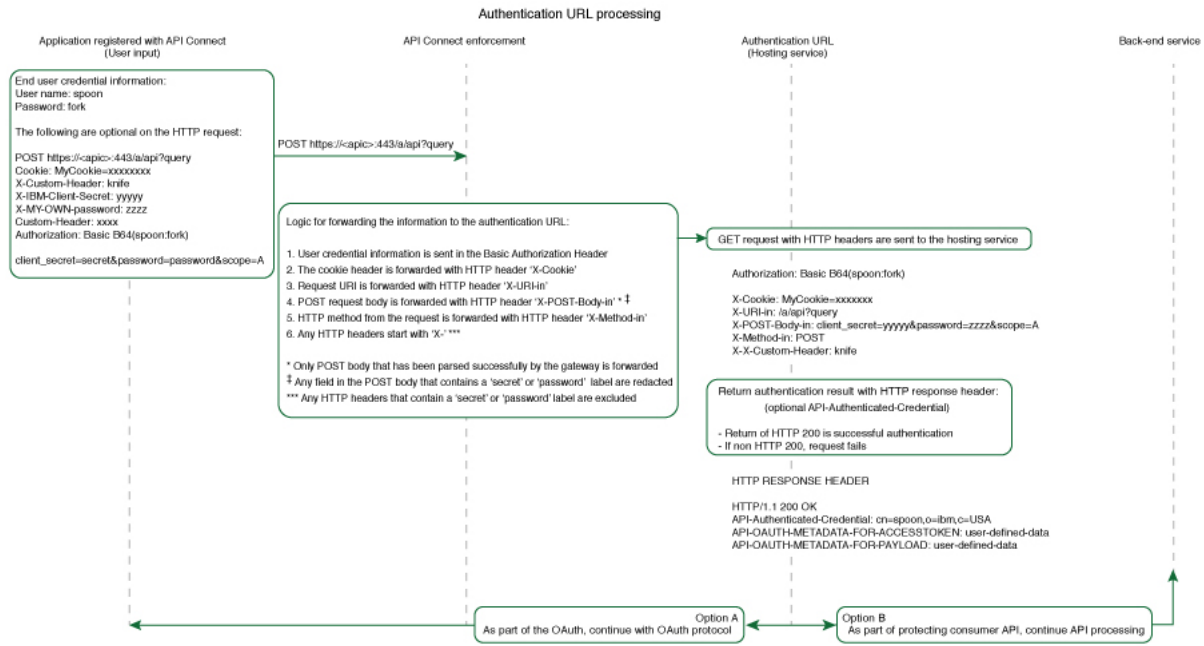

API Connect considers any non-200 HTTP response code a failed user authentication attempt.

When an Authentication URL user registry is invoked, two HTTP response headers are available that include metadata in the access token or the response payload that contains the access token. For more information, see [OAuth external URL and authentication URL](#). The two metadata response headers are:

```
API-OAUTH-METADATA-FOR-ACCESSTOKEN
API-OAUTH-METADATA-FOR-PAYLOAD
```

When an Authentication URL is invoked, an HTTP response header is available to override the requested `scope` from the application. For more information, see [Scope](#). The response header is:

```
x-selected-scope
```

If you are using the DataPower® API Gateway rather than the DataPower Gateway (v5 compatible), this diagram is provided for guidance only and is not fully accurate for this release.

Activating an API

After you have created an API definition you can activate it to make it available for testing.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you activate an API, API Connect automatically completes the following actions:

- Creates a draft Product, adds the API to the Product, and publishes the Product to the Sandbox Catalog so that the API is available to be called. The Product has the title *api_title* auto product. Note that if you later want to delete the draft Product, you cannot delete it directly; instead, delete the API and the draft Product is deleted together with the API; see [Deleting an API definition](#). If you want to remove the Product from any Catalogs to which it is published, you must do this separately; see [Removing a Product from a Catalog](#)
- Subscribes the Sandbox test application to the Product so that you can immediately test the API in the test environment. For information on testing an API, see [Testing an API](#).

To activate an API, you must be assigned a role that has the **Product:Manage** and **Subscription:Manage** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see [Creating custom roles](#).

Note:

- The API activation will not complete successfully if lifecycle approval is enabled in the Sandbox Catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to activate an API they must be disabled; for information on lifecycle approval settings, see [Creating and configuring Catalogs](#).
- To activate an API from the API Designer user interface, you must be connected to a Management server; API activation is not available with API Designer in offline mode. For more information, see [Logging in from API Designer](#).
- Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "(?)" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0,
col: 0)
400
```

Procedure

To activate an API, complete the following steps:

1. In the navigation pane, click  Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Move the activation slider control to the on position:

Results

On successful completion, the API is shown as Online:

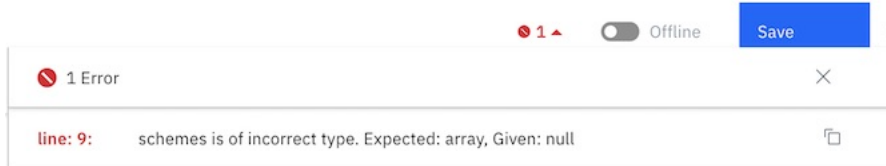

You can stop the API by moving the activation slider control to the off position:

If you stop an API, the application subscription is deleted, and the auto Product is removed from the Sandbox Catalog.

If you make a change to the API, it is republished automatically. You can also republish a running API manually by stopping it and then re-activating it.

The error indicator shows whether there are validation errors in the OpenAPI source for the API definition. If there are errors, click the icon for more details:

You can also activate an API during the creation process, and on the API test page; see [Creating an API definition](#) and [Testing an API](#).

Note: If an OpenAPI 3 API contains a response wildcard (which is not supported), publishing is disabled for that API. You must correct the problem before you can publish the API.

Testing an API

Select a test tool and verify that your API works as you intended.

Before you publish an API where customers can access it, you need to test it and ensure that it is defined and implemented correctly. API Connect offers tools for running both simple and complex tests, in different environments. Use the following list of options to choose the test tool that best meets your needs:

- Execute and debug the API in the [Test tab](#)
On the Test tab, you can quickly invoke your API from the API Connect UI with minimal preparation. The Test tab offers full control over the API call through a simple set of fields where you can define your request. The response includes both a visual flow diagram and a code trace that shows how the API's process flow is executed. Note: the Test tab tool is only available to APIs that use the DataPower API Gateway.
- Call the API externally from the Automated API behavior testing application as explained in [Testing an API with Automated API behavior testing](#)
Automated API behavior testing provides a simple set of fields where you can quickly invoke your API. You can automate tests and define schedules for running them. You can even set up API monitoring and receive alerts on your API health before issues occur.
- Call the API from a [local test environment](#)
The Local Test Environment is a lightweight API Manager, running on your computer, that allows you to rapidly test APIs without connecting to an API Connect management server.
- Run a simple test in the [Policies editor](#)
Note: The Test panel is deprecated and might be removed without warning.
- Use the Try it tool in the [Explorer tab](#) to run simple tests
You can use the Explorer tab in the API editor to see how your APIs look to a consumer in the Developer Portal. You can check the descriptions of the different artifacts, and review any schemas or examples, and you can also use the Try it tool to test the behavior of the API.
- [Locating API information on the Endpoints tab](#)
The assembly tool's Endpoints tab opens a page that displays information for use when you call APIs externally. This tab displays only when an API's status is Online (the API was activated).
- [Using the Test tab to debug your API](#)
Use the Test tab to execute calls and trace the API's actions in API Connect.
- [Testing an API with Automated API behavior testing](#)
Use the IBM Automated API behavior testing application to invoke an API from outside of the API Connect Assembly page so that you can verify that it executes properly.
- [Testing an API with the Policies editor](#)
IBM API Connect provides a basic test environment in the Policies editor so that you can ensure that your APIs are defined and implemented correctly.
- [Testing an API with the Local Test Environment](#)
Use the Local Test Environment to test APIs on your local machine, without the need to connect to an API Connect management server. The Local Test Environment is a lightweight API Manager running on your local machine. It allows you to rapidly test APIs locally.
- [Testing an API with the Explorer tab](#)
Use the Explorer tab in the API editor to see how your APIs look to a consumer in the Developer Portal. You can also use the Try it tool to test the behavior of the API.

Locating API information on the Endpoints tab

The assembly tool's Endpoints tab opens a page that displays information for use when you call APIs externally. This tab displays only when an API's status is Online (the API was activated).

Use the Endpoints tab to retrieve information that you can use when you call the API from an application.

Note: The fields in the Sandbox Sample Application Credentials section apply to the assembly tool's built-in client application and not to any application that you created. The credentials that display here are the default credentials that display in the assembly tool Test panel's "Identification" section.

To copy information from the Endpoints tab, click  next to a field.

The following values for the API are displayed in the Endpoints tab so that you can copy them and paste them into calls:

Base API Endpoint

The URL representing the endpoint of the API that you are editing and testing. To invoke the API, append one of its supported queries (path and parameters) to this URL.

Client ID and Client Secret

The values of the built-in test application's client ID and client secret. You can invoke APIs externally by providing the application's credentials in the request header.

OAuth Token URL

If you specified an OAuth provider in the API's security definition, then this field displays the URL where you can obtain an access token for calling the API.

OAuth Auth URL

If you specified an OAuth provider in the API's security definition, then this field displays the URL where you can submit an access token and receive an authorization token in exchange. You then use the authorization token when calling the API.

Rate Limit

If you specified a rate limit on the Security panel when you created the API, the limit is displayed here for reference. If you did not specify a rate limit, the default rate limit displays.

Using the Test tab to debug your API

Use the Test tab to execute calls and trace the API's actions in API Connect.

The Test tab not only lets you quickly invoke an API with any needed headers and parameters, but lets you view the content of the response in both parsed and raw format. Additionally, you can view a trace of the actions execute as the API's process flow operates to complete the call. Viewing the trace can help you debug problems with the API's execution.

Note: The Test tab tool is only available to APIs that use the DataPower API Gateway.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Complete the following tasks to prepare your API for testing, execute requests, and debug responses.

1. [Preparing an API for debugging with the Test tab](#)

Ensure that your API's definition meets the requirements for debugging it in the API Connect Test tab.

2. [Specifying the testing preferences for an API](#)

By default, when you test an API with the Test tab, a range of test parameters are preconfigured. For example, a default Product is automatically generated, to which the API is added, and that Product is published to the Sandbox Catalog. However, you can configure testing preferences for each of your APIs, including the required Product and target Catalog.

3. [Sending the API request](#)

Fill in fields to set up the request for an API that you want to debug on the Test tab.

4. [Reviewing the API response and trace](#)

Review the response to an API that was invoked in the API Connect Test tab. You can use the included trace information to debug the API's execution.

5. [Testing a GraphQL API with the Test tab](#)

For a GraphQL API definition, the Test tab contains a GraphiQL editor. You can use the GraphiQL editor to help construct a GraphQL query. When you test your GraphQL API, the response is displayed in the GraphiQL editor.

Preparing an API for debugging with the Test tab

Ensure that your API's definition meets the requirements for debugging it in the API Connect Test tab.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To invoke your API in the Test tab, the following requirements must be satisfied:

The DataPower API Gateway is configured to support the API probe

To enable the Test tab's trace feature, the DataPower API Gateway must be configured to support gateway peering and the gateway probe. In a gateway service running in Kubernetes, the API probe is automatically enabled. In a gateway service running external to Kubernetes, the DataPower configuration must be added to the application domain supporting API Connect. Check with your administrator to confirm that gateway peering and the gateway probe are enabled as explained in [Configuring DataPower API Gateway](#).

The API uses the DataPower API Gateway

A gateway exposes APIs to calling applications, and provides processing actions that enable the APIs to integrate with various endpoints. API Connect supports two versions of the DataPower Gateway, but you can only debug APIs that use the DataPower API Gateway. The V5-compatible gateway is not supported. If your API definition has CORS enabled but you cannot see the Test tab, the API is probably configured to use the wrong version of the gateway.

You can determine which gateway your API uses by completing the following steps:

1. Log in to API Manager.
2. In the navigation list, click  Develop, then select the APIs tab.
3. Click the title of the API you want to test.
4. On the API's Design page, locate the Gateway field and note which option is selected.

You can change the gateway selection for an API on the Design page, but you must ensure that the policies used in the API's process flow are compatible with the new selection. For information on changing the gateway for an API, see [Specifying the gateway type for an API definition](#).

CORS is enabled in the API definition

Cross-Origin Resource Sharing support ensures that the API can be accessed from another domain. CORS support must be enabled for your API to be properly invoked and traced. If your API uses the API Gateway but you cannot open the Test tab, it's possible that CORS was not enabled in the API definition. You can enable CORS for you API by completing the following steps:

1. Log in to API Manager.
2. In the navigation list, click  Develop.
3. On the Develop page, click the name of the API you want to test.
4. On the API's Design page, locate the CORS field and select it to enable support.
5. Click Save in the page header.

The API is published in the Sandbox catalog with the default Product/Plan, or a specified catalog and Product/Plan

By default, when you test an API with the Test tab, a default Product/Plan is generated for the API and published to the built-in Sandbox Catalog. However, you can optionally specify a range of API testing preferences including an alternative Product/Plan, and target Catalog; for more information, see [Specifying the testing preferences for an API](#). When you publish (activate) an API, the API is enabled online and becomes available for use. You cannot execute an offline API, even for testing purposes. You can set an API online by completing the following steps:

1. Log in to API Manager.
2. In the navigation list, click  Develop.
3. On the Develop page, click the name of the API you want to test.
4. In the Design page header, click Offline to toggle the API to its Online state.

Next topic: [Specifying the testing preferences for an API](#)

Specifying the testing preferences for an API

By default, when you test an API with the Test tab, a range of test parameters are preconfigured. For example, a default Product is automatically generated, to which the API is added, and that Product is published to the Sandbox Catalog. However, you can configure testing preferences for each of your APIs, including the required Product and target Catalog.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note: This feature is not available if you are using the [Local Test Environment](#).

Procedure

1. Open the required API for editing, in either of the following ways:
 - During the initial creation of an API, the API wizard guides you to enter the minimum configuration settings; on completion of the initial configuration, click Edit API.
 - To open an existing API for editing, complete the following steps:
 - In the navigation pane, click  Develop, then select the APIs tab.
 - Click the title of the API version that you want to work with.

2. Click the settings icon
The Preferences page opens.
3. Use the Edit links to configure the following testing preferences, as required:

Target catalog

The Catalog to which you want to publish the Product that contains the API. The selected Catalog is used as the scope for the other preference settings. You can select a Catalog of your choice, or you can opt to use the Sandbox Catalog by selecting Use the default built-in Sandbox Catalog.

Target Gateway service

The gateway service to which you want to publish the Product that contains the API.

Target product

The Product that will contain the API; you can select any of the Products from the selected Target catalog, or you can opt to use an automatically generated Product by selecting Generate Product on Save. The auto-generated Product has the title *api_title* auto product.

Target product rate limit

If you opted to use an automatically generated Product, you can configure a rate limit to control calls to the API. If you selected your own Product, the Target product rate limit option is not available; instead, the rate limits that are configured in the selected Product and Plan are applied.

Target Plan

The Plan in the selected Product that you want the test application to subscribe to. If you opted to use an automatically generated Product, the Target Plan option is not available; instead, the application is subscribed to the Default Plan in the automatically generated Product.

Test application

The application that you want to subscribe to the selected Plan. You can select an application of your choice or, if you opted to use the Sandbox Catalog, you can instead use the pre-supplied test application by selecting Use the built-in Test Application.

Test Consumer Org

The consumer organization that you want to subscribe to the selected Plan. If you selected your own application, the consumer organization is preset to that which contains the application, and cannot be changed. If you opted to use the pre-supplied test application you can, if required, select a consumer organization of your choice.

4. Click Save Preferences when done.

Results

The next time you bring the API online, the API is published as specified by the preference settings, ready for testing.

Note: These settings are stored in your browser's local storage and will be used for your API testing in subsequent sessions. The following settings are specific to each individual API:

- Target product
- Target product rate limit
- Target Plan

The remaining settings will be applied to all your APIs.

Previous topic: [Preparing an API for debugging with the Test tab](#)

Next topic: [Sending the API request](#)

Sending the API request

Fill in fields to set up the request for an API that you want to debug on the Test tab.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Open the Test tab

1. Log in to API Manager or API Designer.
2. In the navigation list, click  Develop, then select the APIs tab.
3. Click the title of the API you want to test.
4. On the API Design page, click the Test tab in the page header.

Fill in the "Request" section

Use the Request section of the page to set up the request URL, the authentication mechanism, and the request parameters. Complete the following steps to fill in the fields needed for configuring the request.

1. Select an operation and request URL from the list provided.
2. On the Parameters tab, define header, query and path parameters.
An empty row is provided for you to define parameters; enter the parameter name in the Key field, select query, header, or path in the Located in field as appropriate, and supply a string value in the Value field. As you begin to define a new parameter, a further empty row is added automatically.

Default header parameters and values are provided. For example, if the API has client ID or client secret definitions applied, the corresponding keys are added as header parameters, with the values preset; for details on configuring client ID and client secret definitions, see [Creating an API key security definition](#).

The following table lists some common header definitions that are used in a request:

Table 1. Common request headers

Key	Value	Comments
Accepts	<i>media_type/sub type</i>	Specify the type of content that the response headers should use. The default is application/json .
X-IBM-Client-Id	<i>client_ID_val</i>	If you are using the built-in test application in the Sandbox catalog, the value is pre-populated automatically. If you are using your own client application, replace the value with the client ID of your application.
X-IBM-Client-Secret	<i>client_secret_val ue</i>	If you are using the built-in test application in the Sandbox catalog, the value is pre-populated automatically. If you are using your own client application, replace the value with the client secret of your application..
Authorization	Bearer <i>access_token</i>	Encode the token in base64. API Connect cannot encode the token for you.
Content-Type	<i>media_type/sub type</i>	Specify the type of content that the response body should use; for example, application/json or image/png .

If the API has path or query parameters defined, these are added to the parameters list, ready for you to supply values; for details on configuring path and query parameters, see [Defining Paths for a REST API](#) and [Configuring an operation](#).

3. If your API definition uses Basic authorization for the security setting, click the Authentication tab and provide the User name and Password needed for authenticating with the user registry.
When you invoke the API, API Connect populates a header using the provided information.
If your API definition does not use Basic authorization, the Authentication tab is not available.
4. If the operation is POST or PUT, set up the request body.
 - a. Click the Body tab.
 - b. Type the information for the body of the request.

Send the request

When your API request is configured, click Send to execute the call.

If a message displays indicating "No Response", the API call cannot be completed. Possible causes of this problem are as follows::

- CORS is not enabled in the API's definition
Edit the API's definition and enable CORS. Then, save the change and publish the API. If you are using your own client app, remember to subscribe it to the API again after publishing.
- The gateway service URL has an invalid certificate

Follow the instructions to accept the certificate and continue testing.

- The browser cannot connect to the gateway service

Previous topic: [Specifying the testing preferences for an API](#)

Next topic: [Reviewing the API response and trace](#)

Reviewing the API response and trace

Review the response to an API that was invoked in the API Connect Test tab. You can use the included trace information to debug the API's execution.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When the API request is invoked, the response displays in the "Response" section of the Test tab. The response always includes the HTTP status code the amount of time it took to receive a response. If the call completes (even if it returns an error), the response also includes headers and a body.

Click the Body tab to see the body of the response. When you review the body of the response, click the Parsed tab to view the response using the format that you specified in the "Accepts" request header. Click the Raw tab to view the unformatted response body.

Click the Headers tab to see the content of request headers and response headers.

Attention: If the assembly or back-end API returns a Cache-Control header, add the **Cache-Control: no-store** request header to prevent the browser from caching the request. Depending on your server, you might want to use the **Cache-Control: no-cache** header instead.

Click the Trace tab to display a record of the API execution so you can see what actions were triggered and the code that we executed for each action.

Examine the trace

Use the Trace tab to see exactly how the API call was executed. This is helpful when the call returned an error and you don't know why. You can debug the API by reviewing the trace to see each step of the API's execution.

Note: The Trace works only with the default Gateway's URL. You cannot select a different Gateway for the trace.

The Trace tab contains the following components to help you debug the API:

Process flow diagram

In the diagram, the policies (actions) that were executed during the call are highlighted while the rest of the process flow is dimmed. The highlights make it easy to see where the executed actions occurred in the overall flow while clarifying the actual flow of execution for the call. For example, if the process flow includes a switch with three options, only the option that was selected during the call is highlighted.

Policies list

A list of the highlighted policies lets you select a policy to examine its trace.

Advanced toggle

The Advanced toggle that lets you control the level of detail in the trace. A basic trace shows the code for the input and output of the selected policy. An advanced trace shows the full code for the policy's execution.

Code box

The selected level of code for the current policy displays in the code box, where you can review it in detail to see exactly how that policy was executed. By default, a minimal version of the response displays (the endpoint, the request, and the response, and the status message), with sections collapsed. You can expand individual sections by clicking the expand icon next to each. To see the complete response, click the Advanced toggle.

Previous topic: [Sending the API request](#)

Next topic: [Testing a GraphQL API with the Test tab](#)

Testing a GraphQL API with the Test tab

For a GraphQL API definition, the Test tab contains a GraphQL editor. You can use the GraphQL editor to help construct a GraphQL query. When you test your GraphQL API, the response is displayed in the GraphQL editor.

You can test a GraphQL query in either of the following ways:

- Use a **POST** operation, in which case the query is sent in the body of the operation request.
- Use a **GET** operation, in which case the query is sent as a query parameter.

For each operation type, you can test the query against either the GraphQL API endpoint itself, or against the cost endpoint that returns details of the cost of a request to the GraphQL API endpoint.

Whichever method and endpoint you use, you can either supply the query directly, or you can use the GraphQL editor to help construct the query; the editor provides type ahead assistance based on the schema that is defined for the API, and highlights errors along with correction suggestions. The schema was initially uploaded when the GraphQL API definition was created, but might have been modified subsequently. For details on creating a GraphQL API definition, see [Creating a GraphQL proxy API](#). For details on modifying the schema, see [Using the GraphQL schema editor](#).

Before you begin

See [Preparing an API for debugging with the Test tab](#) for the requirements that your API definition must meet for you to test it with the Test tab.

Procedure

1. In the Request section, select the required operation type and endpoint; for example:
 - **POST** `https://myserver.com/myorg/sandbox/mybasepath/graphql`

- GET <https://myserver.com/myorg/sandbox/mybasepath/graphql/cost>
2. On the GraphQL tab, in the left hand pane of the editor, supply the query; for example:

```
{
  accounts(limit: 100) {
    name {
      first
      last
    }
  }
}
```

3. If required, you can supply additional request headers on the Parameters tab.
4. If your query includes variables, you can supply values for the variables in the Query Variables pane. For example, if the query is as follows:

```
query MyQuery($Query__accounts__limit: Int)
{
  accounts(limit: $Query__accounts__limit) {
    name {
      first
      last
    }
  }
}
```

you can set a value for the `Query__accounts__limit` by entering the following in the Query Variables pane:

```
{
  "Query__accounts__limit": variable_value
}
```

where `variable_value` is the required value.

5. Click either Send, or the Execute Query icon  in the editor. The response is displayed in the GraphQL editor, and the Trace section shows you how the API call was executed. For details on the trace information, see [Examine the trace](#).

Previous topic: [Reviewing the API response and trace](#)

Testing an API with Automated API behavior testing

Use the IBM® Automated API behavior testing application to invoke an API from outside of the API Connect Assembly page so that you can verify that it executes properly.

Automated API behavior testing provides a simple set of fields where you can quickly invoke your API. You can automate tests and define schedules for running them.

Automated API behavior testing is an optional add-on to API Connect, and must be deployed by your administrator. If Automated API behavior testing is available in your deployment, a Test API displays on the Home page in API Manager.

Known limitations:

- AutoTest Assist is only available in Cloud Pak for Integration 2022.2.1 and later.
- Insights-Driven Test Generation is only available in Cloud Pak for Integration 2021.2.1 and later.

The following OpenAPI 3.0 features are not currently supported in Automated API behavior testing, but their usage doesn't impact on any other supported features:

- The `links` object; allows developers to describe how various values returned by one operation can be used as input for other operations.
- The `callbacks` object; enables asynchronous, out-of-band requests that your service sends to some other service in response to certain events.
- The `oneOf` keyword for defining complex schemas; allows developers to define more sophisticated validation rules. Automated API behavior testing doesn't generate a valid test for this keyword.

Note that you can add checks for missing assertions manually by using the **Add Request/Assertions** option.

If you want to use Automated API behavior testing for validating an API, complete the following steps to get started.

1. Log in to API Manager.
2. Publish your API to make sure that it's available online.
3. Create a client application and copy its client ID and client secret.
4. Subscribe the client app to the API.
5. Open the Test application.
 - Cloud Pak for Integration only: Click Design in the page header, and then click Test APIs; or
 - All users: Click API Manager in the banner to return to the Home page, and then click the Test API tile.

Getting started

The Automated API behavior testing interface provides collaborative and powerful API testing capabilities.

- **Create automated and simple to use API tests quickly and easily.**
 - Produce high quality APIs consistently, with automated and simple to use API testing that you can rely on.
- **Intelligent validation of API payload accuracy.**
 - Add more intelligence to your tests to verify the accuracy of the payload. You can easily make logical assertions to create flexible and powerful conditions for validation, with no code necessary.
- **Collaborative testing.**
 - Accelerate your API development and testing, by sharing your tests and results through the intuitive visual composer.

- **Easily integrate into your CI/CD pipeline to execute tests as part of your deployment.**
 - Create [API Hooks](#) to allow your tests to be run via the command line and become part of your automated build processes.
- **No code necessary.**

How to get started

- [Creating a test](#)
- [Modifying a test](#)
- [Running a test](#)
- [Publishing a test](#)
- [Variables](#)

Creating a test

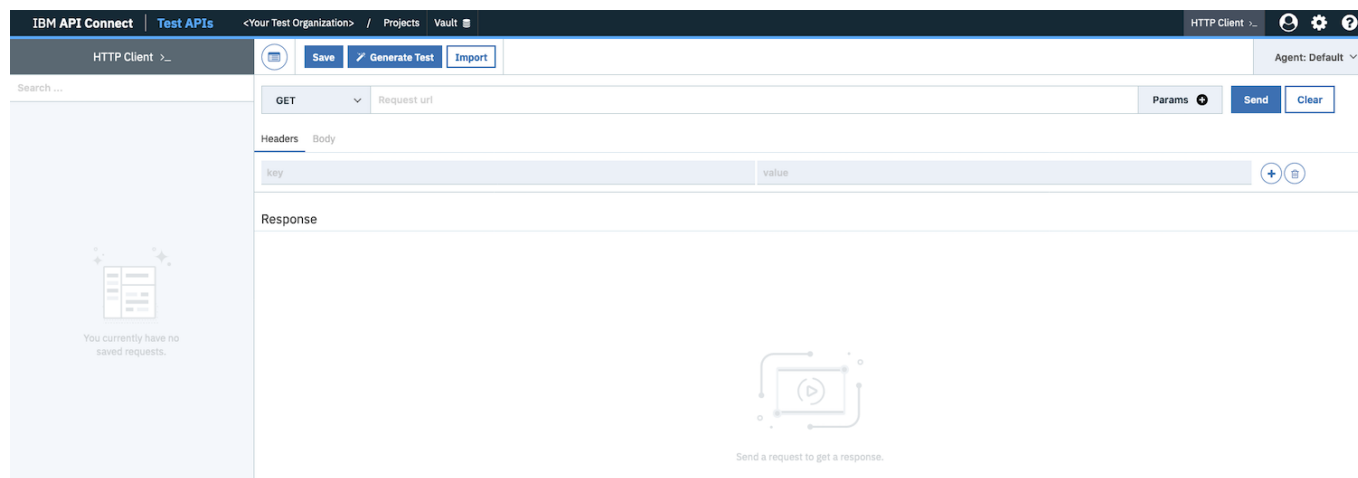

Creating an API test involves the following three steps:

1. Creating a request.
2. Sending the request to an API endpoint.
3. Generating a test from the response that's returned from the endpoint.

The following instructions show you how to create a test by using the **HTTP Client**.

What is the HTTP client?

After you log in to IBM API Connect Test APIs, you land on the HTTP Client.

To reach the HTTP Client from any other page, click **HTTP Client** in the menu bar.

Step 1: Creating a request

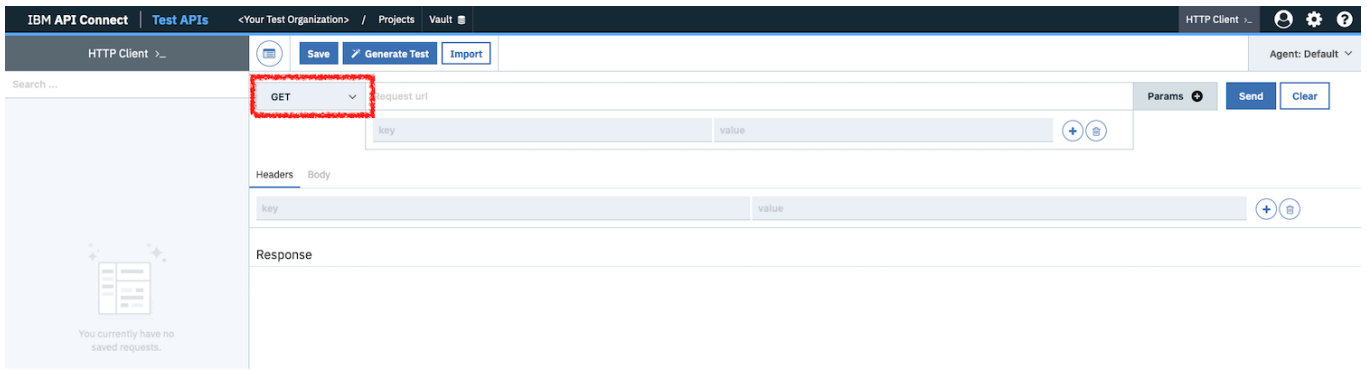

The HTTP Client page contains the following three sections:

1. The initial section is where you specify the request type, the URL, and any other parameters that are needed. It's also where the **Send** and **Clear** buttons are located.
2. The central Headers and Body section is where you define the request headers and body.
3. The Response section is where the headers and body of the response appear after you've sent the request. You don't need to do anything in this section.

The following instructions use `GET https://us-east.apitest.apiconnect.ibmcloud.com/app/api/examples/retail/products` for illustration purposes, which is a built-in API endpoint example. This example requires no parameters to be added to the URL, and requires no request headers or body to be supplied.

Set the request type

In the initial section of the HTTP Client, select the type of request that you want from the drop-down menu alongside the **Request url** field.

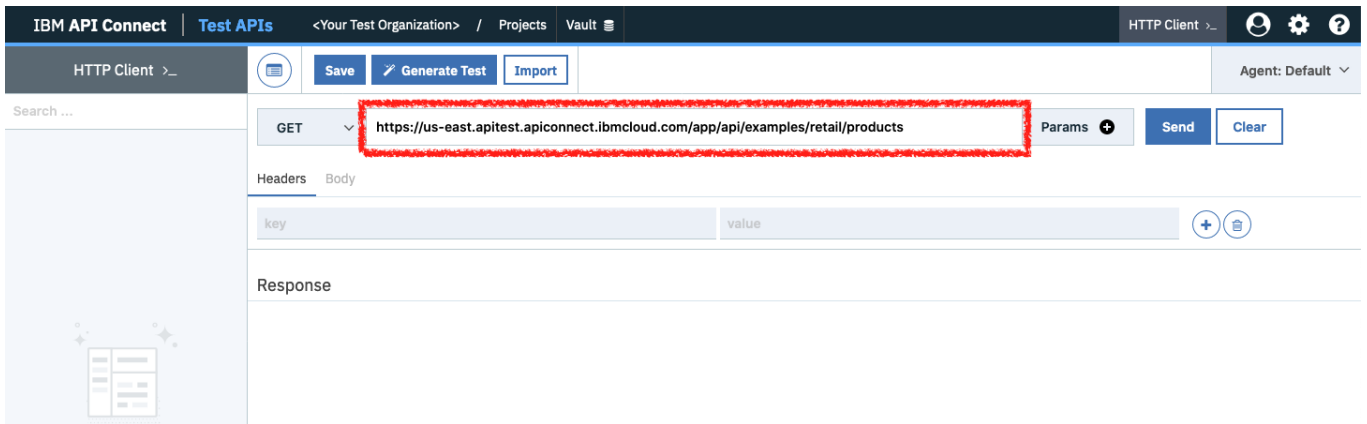

The following options are available:

- **GET**
- **POST**
- **PUT**
- **PATCH**
- **DELETE**

For our example, select **GET**.

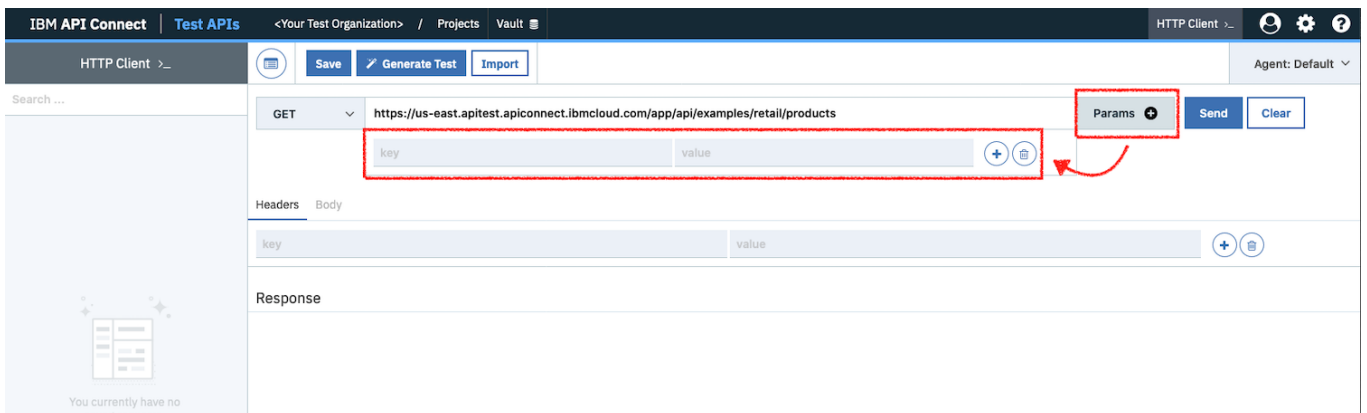

Set the API endpoint URL

In the initial section, complete the **Request url** field with the API endpoint URL. For our example, enter: **https://us-east.apitest.apiconnect.ibmcloud.com/app/api/examples/retail/products**.

Add parameters to the URL

If you are using a different API endpoint from our example, and it requires one or more parameters, click **Params +** next to the **Request url** field. A parameter line is added after the URL, which you can edit.

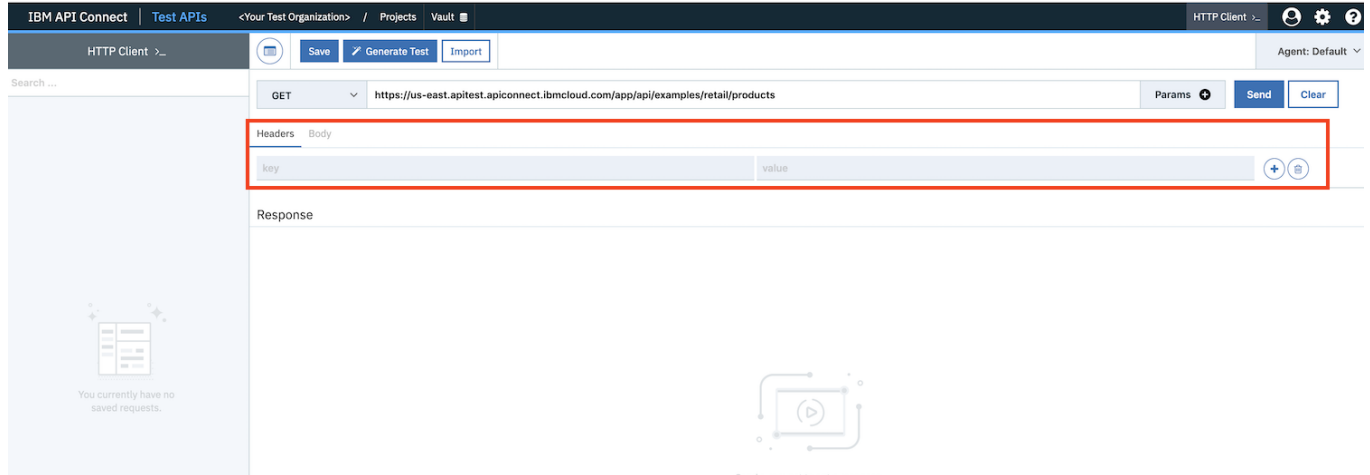

Enter a parameter as a key-value pair.

To add more parameters, click the **add** icon  next to any defined parameter.

To remove a parameter, click the **delete** icon  next to the parameter.

Configure the request headers

In the central Headers and Body section of the HTTP Client, select the **Headers** tab. If you're using our example, you don't need to supply any headers.

Define a header as key-value pair.

To add more headers, click the **add** icon  next to any defined header.

To remove a header, click the **delete** icon  next to the header.

Configure the request body

In the central Headers and Body section of the HTTP Client, select the **Body** tab. This tab is not available if the request type is **GET**, so you don't need to complete this section if you're following our example.

Set the body type to either **URL Encoded** or **Raw**.

If you set the body type to **URL Encoded**, you must provide one or more key-value pairs.

- To add more key-value pairs to the body, click the **add** icon  next to any defined key-value pair.
- To remove a key-value pair, click the **delete** icon  next to the key-value pair.

If you set the body type to **Raw**, you must complete the following actions:

- Select the content type from the content type drop-down menu. The following options are available:
 - `application/x-www-form-urlencoded`
 - `application/json`
 - `text/xml`
 - `text/plain`
- Complete the request body in the text box under the body type selection.

Step 2: Sending the request

Click **Send** in the initial section of the HTTP Client.

The response from the endpoint is displayed in the Response section of the page. You can examine the returned headers and body by clicking the **Headers** and **Body** tabs in the response section.

Step 3: Generating a test

Now that you've sent a request and received the response, you can generate the test.

Click **Generate Test** in the initial section of the HTTP Client.

Enter a test name.

Generate Test ✖ ✓

Name

Save to Project

From the **Save to Test Suite** drop-down menu, select a test suite name, or select **Create new test suite** to create your own test suite.

Generate Test ✖ ✓

Name

Save to Project

Create new project
project-1

If you selected **Create new test suite**, enter a name for the test suite.

Generate Test ✖ ✓

Name

Save to Project

Click the **confirm** icon  to save the test and start the test generation.

Generate Test ✖ ✓

Name

Save to Project

After generation is complete, the **All set!** page is displayed. This page confirms the creation of your generated test.

Click **Close** to continue.

All set!

Input/Globals

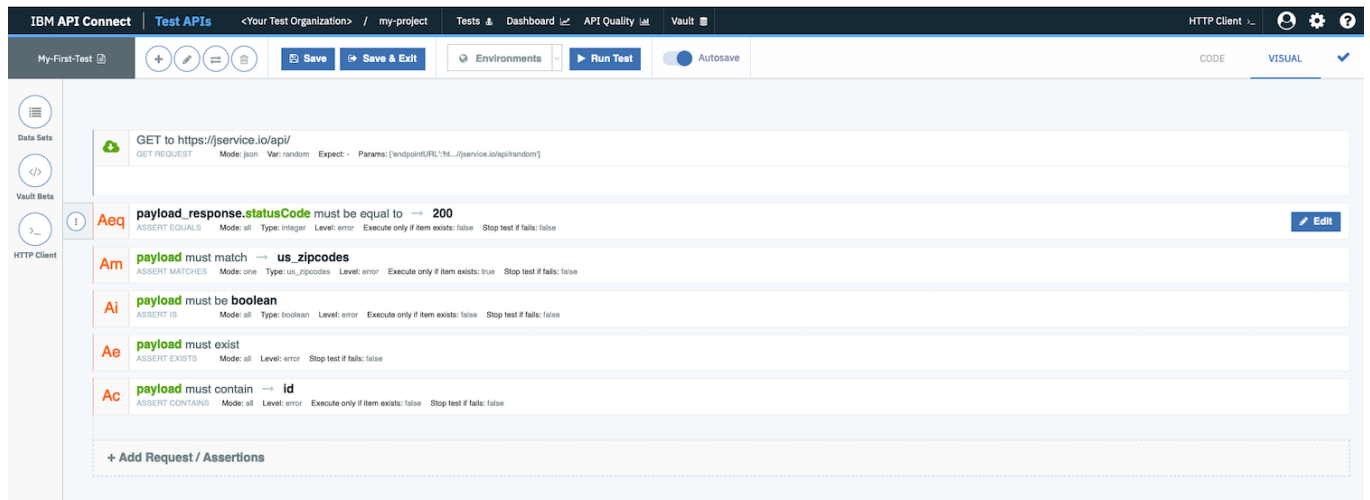

- ✓ Global params added successfully.
- ✓ Input-set added successfully.

Assertions

- ✓ Request added successfully.
- ✓ Assertions added successfully.

You are now in the test editor, called the Composer. In the Composer you can edit and run the test.

What to do next

- Next topic: [Modifying a test](#)

Modifying a test

Use the Composer to update and modify your test. The following sections provide information about the Composer, and how to use it.

- [About the Composer](#)
- [Using the editor](#)
- [Adding a component](#)
- [Editing a component](#)
- [Moving components](#)
- [Transforming a component](#)
- [Deleting a component](#)

About the Composer

If you are not on the Composer page, or you want to modify a different test, follow the instructions in [Opening a test in the Editor](#) to find the test that you want to modify, and open it in the Composer.

The Composer shows all of the components that make up the test. In our getting started example, the first component is the request to the API endpoint - which in this case is a **GET** to `https://service.io/api/`. When the test was generated, it extracted the URL that you provided into a variable. To see any variables that were generated, click

the **Data Sets** icon in the navigation pane.

After the request line, you will see the assertions and other components, for example **Aeq**, **Ai**, **Ae**, **for each in** and so on. For more information about assertion components, see [Assertion components](#).

Using the editor

The test can be edited by using either the code (text) editor, or the visual (graphical) editor. Toggle between these two editors by clicking the **CODE** and **VISUAL** tabs. The visual editor is the default editor.

The following instructions describe how to make changes by using the visual editor.

Adding a component

You can add a component by using one of the following options:

- By clicking the **add component** icon .
- By clicking a component at the location where you want to add a new component, then clicking the **menu** icon , and selecting **Add component before** or **Add component after**, depending on where you want the new component to be positioned.

A list of component types is displayed.

After you've chosen your component type, carry out the following steps to add the component to your test. Note that you can hover over each component to see a description of what that component does.

1. Click the component type that you want to add.
2. Configure the new component's parameters in the component dialogue box.
3. Click the **Confirm changes** icon  to apply the changes.
4. If your new component is in the wrong location, you can drag it to the correct location. Note that you can drag any component in your test.
5. Click **Save** to save your changes.

Editing a component

You can edit a component in any one of the following ways:

1. Double-click the component to be edited.
2. Click the component, and then click the **Edit component** icon .
3. Click the component, then click the **menu** icon  and select **Edit component**.
4. Click the component, then click **Edit**.

The edit dialogue box is displayed. Each component dialogue box will look different, as they all have different sets of parameters.

In the edit dialogue box, you can make the following changes:

- Modify any of the component's parameters.
- Clone the component by clicking the **Clone component** icon .
- Delete the component by clicking the **Remove component** icon .
- Cancel changes by clicking the **Cancel changes** icon .
- Apply changes by clicking the **Confirm changes** icon .

Click **Save** to save your changes.

Moving components

Simply drag-and-drop any component from one position within the test to another position in the visual editor.

Remember to click **Save** to save your changes.

Transforming a component

You can transform a request component to be a different type of request, and an assertion component to be a different type of assertion.

1. Click the request or assertion component to be transformed, then click the **Transform component** icon .
2. Select the type of request or assertion that you require.
3. Complete the edit dialogue box for the new type of component.
4. Apply the changes by clicking the **Confirm changes** icon .
5. Click **Save** to save your changes.

Deleting a component

You can delete a component in any one of the following ways:

- Click the component to be deleted, and click the **Remove selected component** icon 
 - This technique can also be used to delete a block of components. Click the first component in the block, and press the shift key while clicking the last component in the block. Then click the **Remove selected component** icon .
- Click the component to be deleted, then click the **menu** icon , and select **Remove component**.
- Click the component to be deleted, then click **Edit** alongside the component pane, and then click the **Remove component** icon .

Remember to click **Save** to save your changes.

What to do next

- Next topic: [Running a test](#)
- Previous topic: [Creating a test](#)

Running a test

Tests are run from the Composer page of IBM API Connect Test APIs.

If you are not on the Composer page, or you want to run a different test, see [Opening a test in the Editor](#) for instructions.

Before you begin

Ensure that your browser is set to allow pop-ups for this application.

Running the test

1. From the Composer page for the test that you want to run, click **Run Test**.

2. Select a downloader from the drop-down list in the "Run Test" dialog box.
3. Click **Run Test**.
4. Your test results are displayed in a Test Report on a separate tab in your browser.

<Test Organization Name>

[See Request](#)

Troubleshooting

If an Internal Server Error message is displayed during the test, follow the instructions in [Opening a test in the Editor](#) to return to the Editor page, and run the test again.

What to do next

- Next: [Publishing a test](#)
- Previous: [Modifying a test](#)

Publishing a test

After you have completed the configuration of your test, and run it manually to confirm that it works correctly, you can publish the test.

Following on from publishing a test, you can continue to work on the test in the Composer without affecting the published test, and then publish the test again later to update the published test.

To publish a test, complete the following steps:

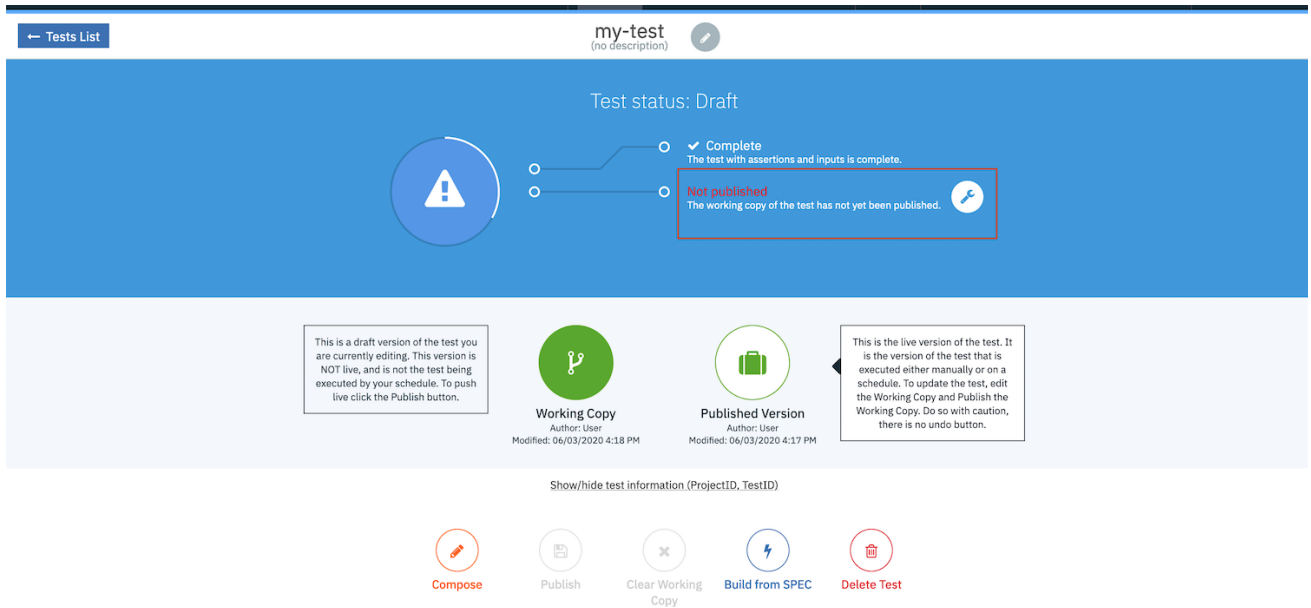

1. Click your test suite name in the menu bar to get to the "Test Suites" page.

2. On the "Test Suites" page, click the **Tests** icon  for the test suite that contains the test that you want to publish. The list of tests is displayed.

3. From the list of tests double-click the test that you want to publish, or click the **edit** icon  for the test.

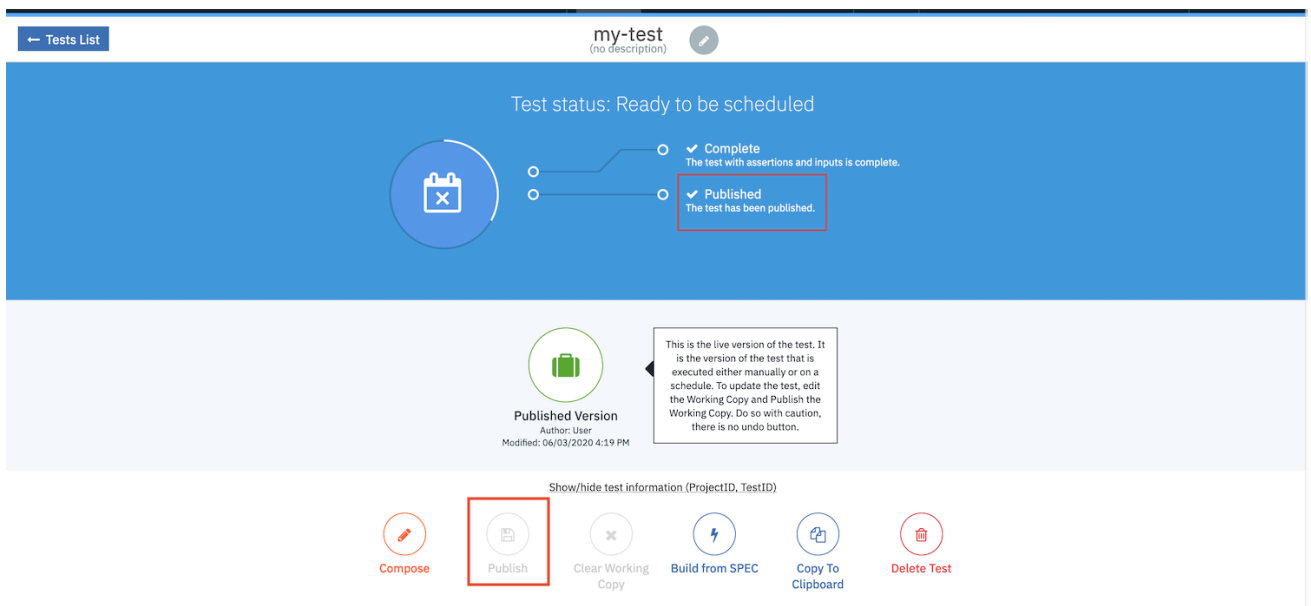

4. The status page for your test is displayed. If your test has not been published before, the status will show as **Not published**.

5. Click the **Publish** icon  to publish your test.

6. The test status page is updated with the following changes:

- The status of the test now shows as **Published**.
- The **Publish** icon is disabled.

What to do next

- Next topic: [Tagging a test](#)
- Previous topic: [Running a test](#)

Tagging a Test

Adding tags to your tests is an easy way to keep them organized in your Test Suite. Furthermore, tags can be used as a way to selectively execute certain tests in your test suite when running them via an [API Hook](#) (see [Run Published Tests by Tag](#) for more information).

Note: To tag a test, you must have first [created a test](#).

Adding a Tag to a Test

1. Click your test suite name in the menu bar to get to the "Test Suites" page.

2. On the "Test Suites" page, click the **Tests** icon  for the test suite that contains the test that you want to tag. The list of tests is displayed.

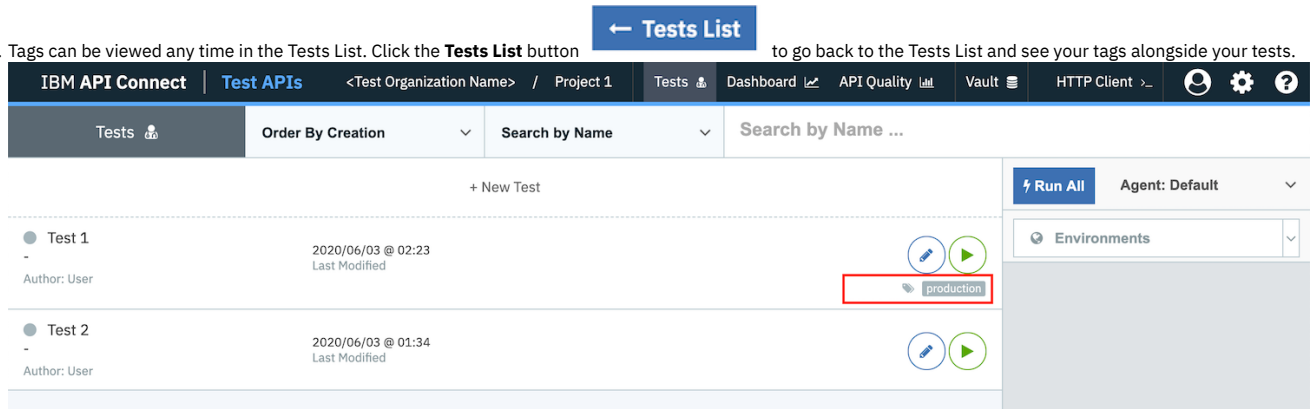

3. From the list of tests double-click the test that you want to tag, or click the **edit** icon  for the test.

4. The status page for your test is displayed. Click on the **edit** icon  alongside your test name.

5. The Edit Details dialog box will open, allowing you to edit information about your test. To add Tags to your test, simply begin typing a name for a Tag into the Tags box within this dialog. You can assign multiple Tags to a test separating each Tag with a space. To remove a Tag from a test, click the **x** button alongside the Tag.

6. Click the **confirm** icon  to confirm and save your edits.

7. Tags can be viewed any time in the Tests List. Click the **Tests List** button to go back to the Tests List and see your tags alongside your tests.

What to do next

- Next topic: [Create an API Hook](#)
- Previous topic: [Publishing a test](#)

Variables

Within API Testing there are multiple ways to define variables to address different requirements

Defining variables

Global Variables

Global variables are ones that are common across the whole test and typically does not change between runs based on Input sets

Add a Global variable

To add a Global Variable within the Test Editor Select Data Sets Click **Add Global Variable** Provide Variable Name and value Click 

Edit A Global Variable

To edit an existing variable to change either the name or value For the given variable click 

Input Set Variables

The input set, is a group of input variables representing a scenario (e.g product id). Where the number of input sets determines how many times the test will be executed using those values.

If 3 input sets are defined, the test will run 3 times using the inputs defined within each of those sets on each run.

Vault Variables

Variables can be defined within the vault which provides Test Suite scoped variables that can be used in all tests within that suite.

Vault variables can be defined as

- Variable - Visible
- Password - Hidden

Hook Variables

When [Using API Hooks](#) it is possible to override Global defined variables within the request payload when running tests.

```
curl -X POST \  
-H X-API-Key:{API-Key} \  
-H X-API-Secret:{API-Secret} \  
-H Content-Type:application/json \  
-d "  
  {  
    "options": {  
      "allAssertions": boolean,  
      "JUnitFormat": boolean  
    },  
    "variables": {  
      "url": "https://www.ibm.com",  
      "username": "test",  
      "password": "passw0rd"  
    }  
  }  
"
```

```
}  
  }  
  "  
  \
```

```
<API-Hook-URL>/tests/{Test-ID}/run
```

Variable Hierarchy

- If a variable is defined in Vault and either in Global or Input sets, Global or Input will take precedence
- If a variable is defined in both Global or Input set, Input set takes precedence
- If a variable is supplied as part of a Hook request and is defined in Vault, Global or Input set, the Hook will take precedence

Referencing variables within a request

For setting variables during a test refer to [Set](#)

Insights-Driven Test Generation

Available only as part of Cloud Pak for Integration 2021.2.1

Insights-driven test generation takes the OpenTelemetry data from a source deployment and compares the observed behaviors to your current set of API Management test cases to find untested and non-obvious behaviors inherent within API calls in a specific environment.

- [Enabling Insights for Test Suites](#)
- [Generating Test Cases from Insights](#)
- [Watson Insights](#)
- [Troubleshooting](#)

The insight generation process is made up of the following stages:

1. Training and testing
2. Scoring
3. New behaviour generation
4. Test template generation

During insight generation you'll be able to see the current stage of the generation process on the insights panel:

Tests	0	
Events	0	
Failures	0	
Insights  Processing	?	

Dashboard

Tests

API Quality

Settings

Restart analysis 
×

Analyzing Data...

You can still create tests however their data might not contribute to insight generation.

- Training & testing
- Scoring
- Getting new behaviours
- Generating test template

Known limitations

- API Management Spaces are not currently supported.
- The user currently has to manually refresh the tests page in order to obtain the most up-to-date insights status.

Enabling Insights for Test Suites

The following details are required in order to enable insights-driven test generation for a new or existing test suite:

Jaeger

To configure the Jaeger connection details the following values are required:

To obtain the service names used to identify the Jaeger traces from the API Gateway, review the options under the service dropdown on the Jaeger UI; the service name will be **apiconnect** by default.

The test service name is for the Jaeger instance deployed in the same environment as test APIs; source is the remote Jaeger instance.

- **Service in test:** Test API Gateway Jaeger service name for the local system defined Jaeger instance
- **Service in production:** Source API Gateway Jaeger service name for the remote system defined in the Data service section
- **Time range:** Select the date range from which to obtain OpenTelemetry traces
- **Results limit:** Sets the number of OpenTelemetry traces that are to be retrieved from the source environment for use to build the training model

Data Service Connection Details

Define the connection details of the remote data service to enable connection to the source environment to retrieve OpenTelemetry and analytics data:

- **Endpoint:** The route created for the insights data service
- **API key:** The key can be found in the **ai-data-service-api-key** secret mounted to the data service, this may need to be retrieved by your administrator
- **TLS certificate:** The certificate presented on the endpoint - if signed by an internal certificate authority or uses a self-signed certificate then please provide the full certificate

API Management Connection Details

Provide the definitions for the source API Management deployment to enable the retrieval of analytics data.

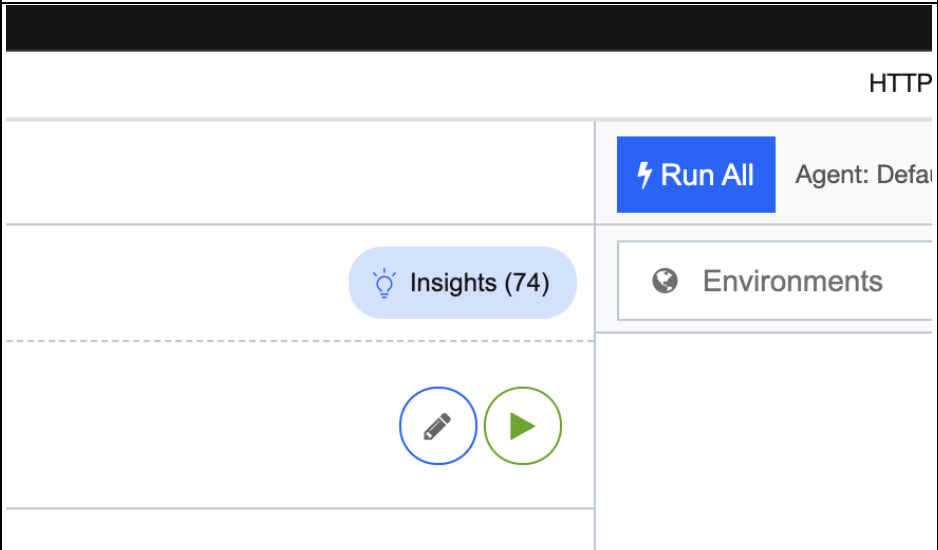

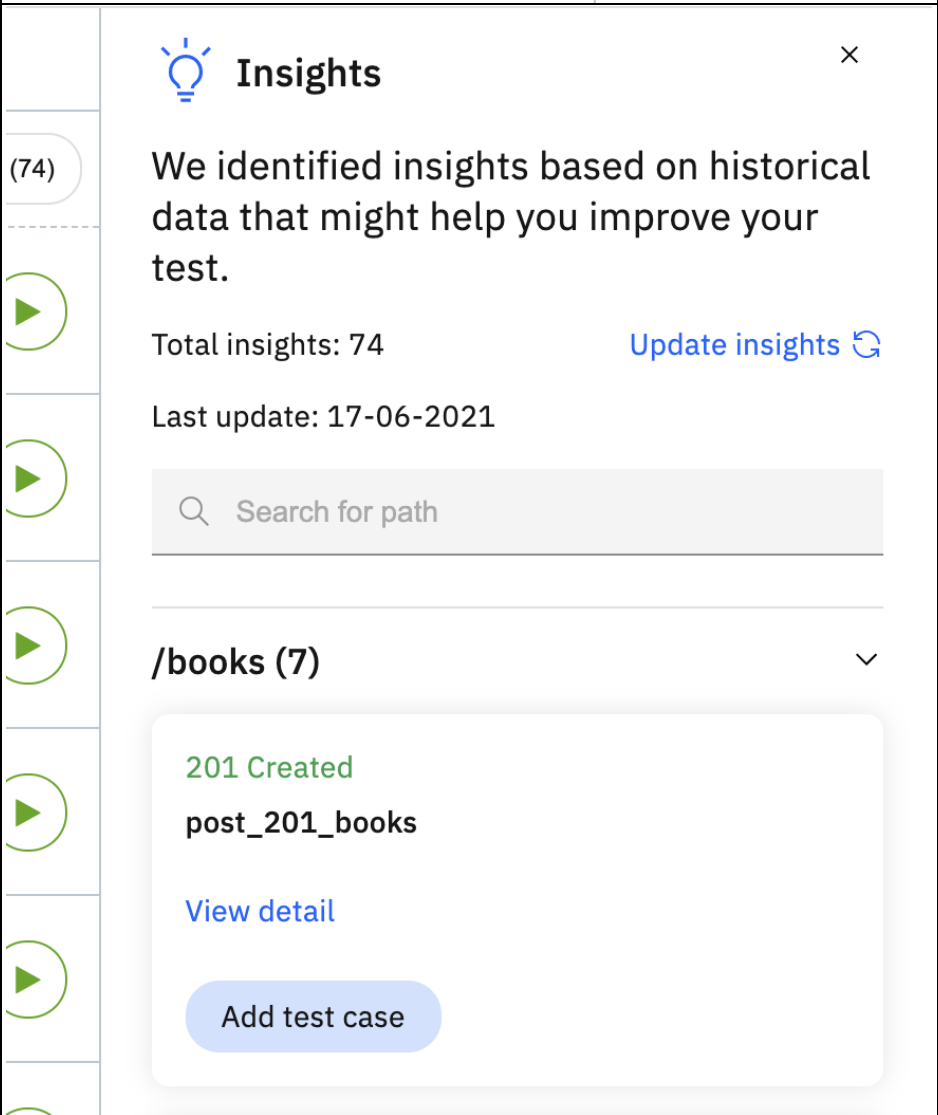

- **Provider organization:** The name of your API Management organization
- **Catalog:** Name of the catalog in the above organization that you wish to use
- **Analytics service:** The name of the deployed analytics service that you wish to use
- **Username:** The username of the user created to retrieve analytics data from the source API Management instance
- **Password:** Password for the above user
- **Realm:** The user realm which the user authenticates against, should be in this format: **provider/idp**
- **OpenAPI document:** The OpenAPI spec document describing the set of APIs to be used for insights generation
- **Client ID:** The id of the application registered for use with the API Management REST API - No longer required as of CP4I 2021.3.1
- **Client secret:** The secret of the application registered for use with the API Management REST API - No longer required as of CP4I 2021.3.1

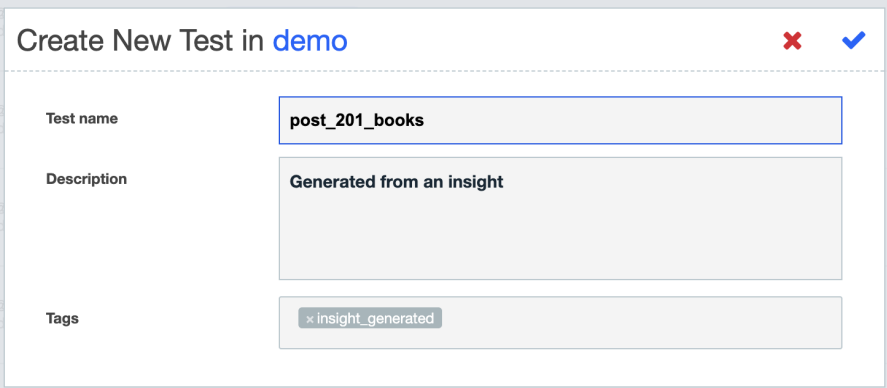

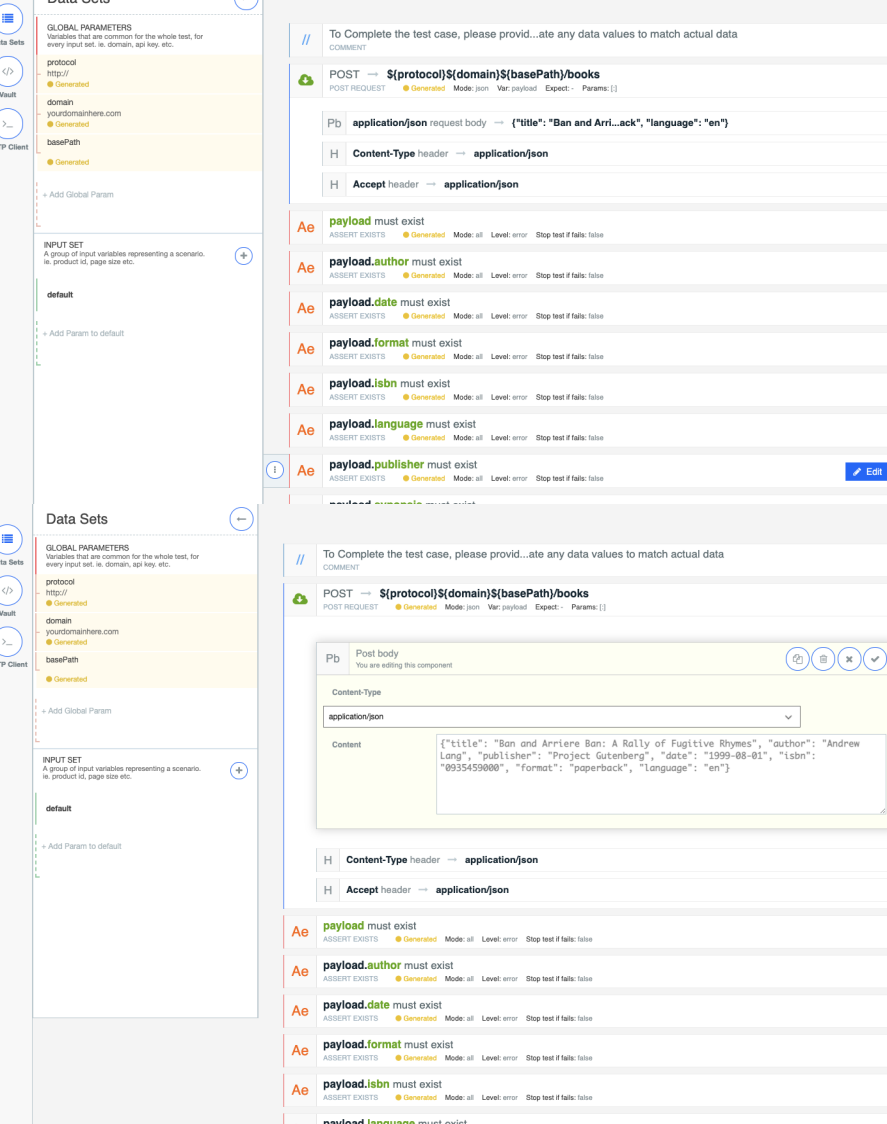

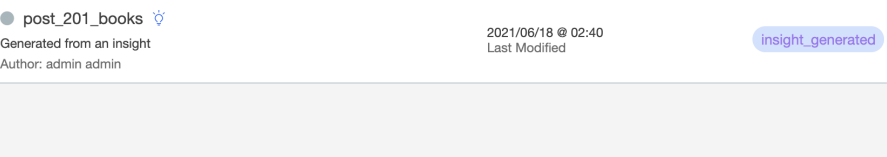

If a client application has not been created, then you may use a local user registry and create a new user for analytics.

Generating Test Cases from Insights

To make use of the Insights feature, create a new Test Suite with the details described in [Enabling Insights for Test Suites](#), and follow the steps below once the insights generation process has successfully completed:

Step	Screenshot	Instruction
1		Click on the "Tests" button of the insights-enabled Test Suite to navigate to the tests dashboard

Step	Screenshot	Instruction
2	 <p>The screenshot shows a top navigation bar with a dark background. Below it, the word 'HTTP' is visible. A blue button labeled 'Run All' with a lightning bolt icon is next to the text 'Agent: Defa'. Below this, there is a light blue button labeled 'Insights (74)' with a lightbulb icon. To its right is a button labeled 'Environments' with a globe icon. At the bottom, there are two circular icons: a blue one with a pencil and a green one with a play button.</p>	<p>Click on the "Insights" button next to the "Create Test" button to bring the insights panel up</p>
3	 <p>The screenshot shows the 'Insights' panel. At the top, it says 'Insights' with a lightbulb icon and a close button. Below this, it says 'We identified insights based on historical data that might help you improve your test.' It also shows 'Total insights: 74' and 'Last update: 17-06-2021'. There is a search bar with the placeholder 'Search for path'. Below the search bar, there is a section for '/books (7)' with a dropdown arrow. Underneath, there is a card for '201 Created post_201_books' with a 'View detail' link and an 'Add test case' button. On the left side of the panel, there is a vertical list of green play button icons.</p>	<p>Click on the "Add test case" button on the desired insight</p>

Step	Screenshot	Instruction
4		Name the test case to be generated (and update its description and tags if desired) and click on the green tick to create the test case
5		You should then edit the test case so that the protocol , domain , and basePath data set parameters match those of your deployment's
6		The insight-generated test case should now show up on the tests dashboard (with the insights icon next to the test name)

Watson Insights

Available as of APIC release 10.0.4

As an enhancement to the AI Test Generation feature introduced in the 2021.2.1 release of CP4I, AI generated insights now take the form of *Watson Insights*. Up to three test cases with an impact score of at least 70% can be recommended, as denoted by the **Impact score nn%** annotation on each tile.

Panel breakdown:

1 - Test coverage improvement

- By analyzing the amount of occurrences covered by each of the highlighted test cases we can calculate a number for the total potential coverage improvement for your API provided by utilising all of the recommended cases.

2 - Impact score

- An impact score should be seen as a quick "overview" of how impactful a test case would be to add. The score is calculated by comparing the overall usefulness of all cases and calculating a relative score expressed as a percentage. These values are shown in the tooltip seen in point 3.

3 - Impact score tooltip

- The values used to calculate the impact score are shown here. *Data completeness* describes how *complete* the test case is based on the values that are pre-populated for you. *Occurrences covered* describes how many traces from this set of results were covered by this single test case. The final *Impact Score* is calculated by taking these two values, comparing them with the other generated insights, normalising the data and combining them to calculate a geometric mean between the two values which creates our final score*.

**This value may change in future updates as more data is used to further enhance AI Test Generation.*

AutoTest Assist

The AutoTest assistant (or, simply, the *auto-tester*) exercises your API by sending it a series of randomly-generated requests, guided by the API definition and any custom rules that you provide, and alerts you about any conformance errors and server-side errors that it observes.

You control the auto-tester by creating and running an AutoTest *profile*, and you can create multiple profiles against the same API to cover different use-cases. A profile specifies how the auto-tester should run, which endpoints it should test, and what kind of data it should send. A default profile is constructed so that you can get immediate feedback by providing no more than a target URL and credentials.

The AutoTest assistant is especially useful while an API is under development as it can quickly identify errors in an implementation without you having to write test cases. It is also valuable later in the cycle for spotting regressions, as the random nature of its requests can provide coverage that your existing test cases do not match. However, it is not meant as a replacement for other testing tools in API Connect, but is rather complementary, and the information it provides when it identifies an error is often a good starting point for creating a test case.

Follow these steps to create and run your first profile:

- [Creating a profile](#)
- [Running a profile](#)
- [Viewing the report](#)

Consult these additional guides for detailed instructions on how to configure the auto-tester to support your use case:

- [Profile Configuration](#)
- [Profile Security](#)
- [API Extensions](#)
- [Data Generation Rules](#)

Known limitations

- The API definition must conform to OpenAPI 2.0 (Swagger 2.0)
- The API definition document must have a `.json` or `.yaml` extension (you cannot select a document with another extension)
- If there are errors in the API definition then you will see only a blank screen, and the errors are not reported
- You must provide either a username and password, or a bearer token, to authenticate against the target API; other authentication methods are not supported
- You can run only one profile at a time

Creating an AutoTest profile

An AutoTest profile exists within a test suite, alongside your test cases.

To add an AutoTest profile to a test suite: open the suite, select the **Tests** tab, and click on **AutoTest** profiles.

The screenshot shows the 'Tests' tab in the API Management console. The 'AutoTest profiles' section is highlighted with a red box. Below it, a table with columns 'Name', 'Tags', 'Status', and 'Modified' is shown. The table is empty, and a message states 'No recent items found' with a question mark icon and the text 'When you have resources of this type, they will show up here.' An 'Add +' button is visible in the top right corner of the table area.

Click **Add**, and select the API you wish to target: choose either an existing API from the dropdown (from a definition you have uploaded previously) or upload a new definition by dragging and dropping an OpenAPI document in either JSON or YAML format. It doesn't matter if you upload the same document more than once as it will be recognized.

Known limitations

- The API definition must conform to OpenAPI 2.0 (Swagger 2.0)
- The API definition document must have a `.json` or `.yaml` extension

The screenshot shows the 'Select API' dialog box. It has two main sections: 'Add by existing API document' with a dropdown menu currently showing 'None selected', and 'Add API document by drag and drop' with the text 'Supported file types are yaml and json.' Below this is a dashed box for file upload. A file named 'movies-v0.1.yaml' is shown in a preview area at the bottom, highlighted with a red box. At the bottom of the dialog are 'Cancel' and 'Next' buttons.

Click **Next** and provide at least a name for your new profile. You can also add comments and tags.

[AutoTest profiles](#) /

Profile info

Info

Name

Description

Tags

This is a list of comma separated values

[Cancel](#) [Back](#) [Next](#)

Click **Next** and AutoTest scans the API document and extracts semantic information that will inform its generation of requests. You get a chance to review the information here, but if you need to change anything you must wait until the profile is complete. If this is your first time with AutoTest you can take the content on trust and move on, but read through [API Extensions](#) if you want to understand the detail.

Known limitations

- If you see a blank screen at this point then there is most likely an error in your API definition, and you should validate it in the Swagger editor

[AutoTest profiles](#) /

Review API Extension

Info: AutoTest has generated these extensions for the API you selected. You can edit the extensions once you have completed the profile.

```

1 properties:
2   - items:
3     - name: order_id
4       semantic: id
5       json_ptr: '#/definitions/Order'
6   - items:
7     - name: customer_id
8       semantic: id
9       json_ptr: '#/definitions/Customer'
10  - items:
11    - name: name
12      semantic: name
13      json_ptr: '#/definitions/ErrorTarget'
14  - items:
15    - name: message
16      semantic: sentence
17      json_ptr: '#/definitions/ErrorItem'
18  - items:
19    - name: phone
20      semantic: phone_number
21    - name: last_name
22      semantic: last_name
23    - name: first_name
24      semantic: first_name
25    - name: email
26      semantic: email
27    - name: username
28      semantic: username
    
```

Click **Create** and AutoTest will have created a profile with the default configuration.

[AutoTest profiles](#) /

Summary

- ✔ Created AutoTest profile: movies - default.
- ✔ Generated associated API Extension.

Click **Close** and it takes you back to the starting page, but now showing your new profile.

Test cases **AutoTest profiles** [View API Extensions](#)

Find

Name	Tags	Status	Modified
movies - default	dev	Never run	3 minutes ago

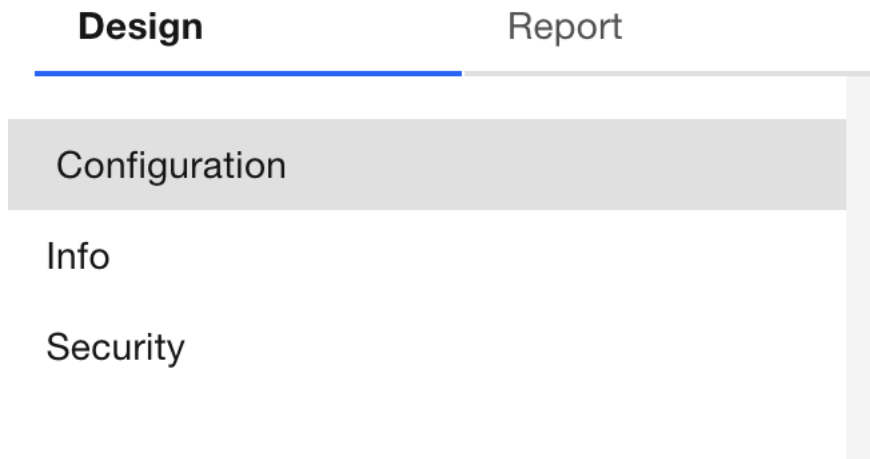

Items per page: 10 | 1-1 of 1 items | 1 of 1 page

Alternatively, click **Edit** and it takes you straight on to the next step, which is [Running a profile](#).

Running an AutoTest profile

To be able to run an AutoTest profile you will need to configure it first. Make sure to set the ServerURL parameter correctly otherwise all the generated API calls will fail. For more information please refer to [AutoTest Profile Configuration](#). At any point during this process you can click on the save button to maintain your progress.

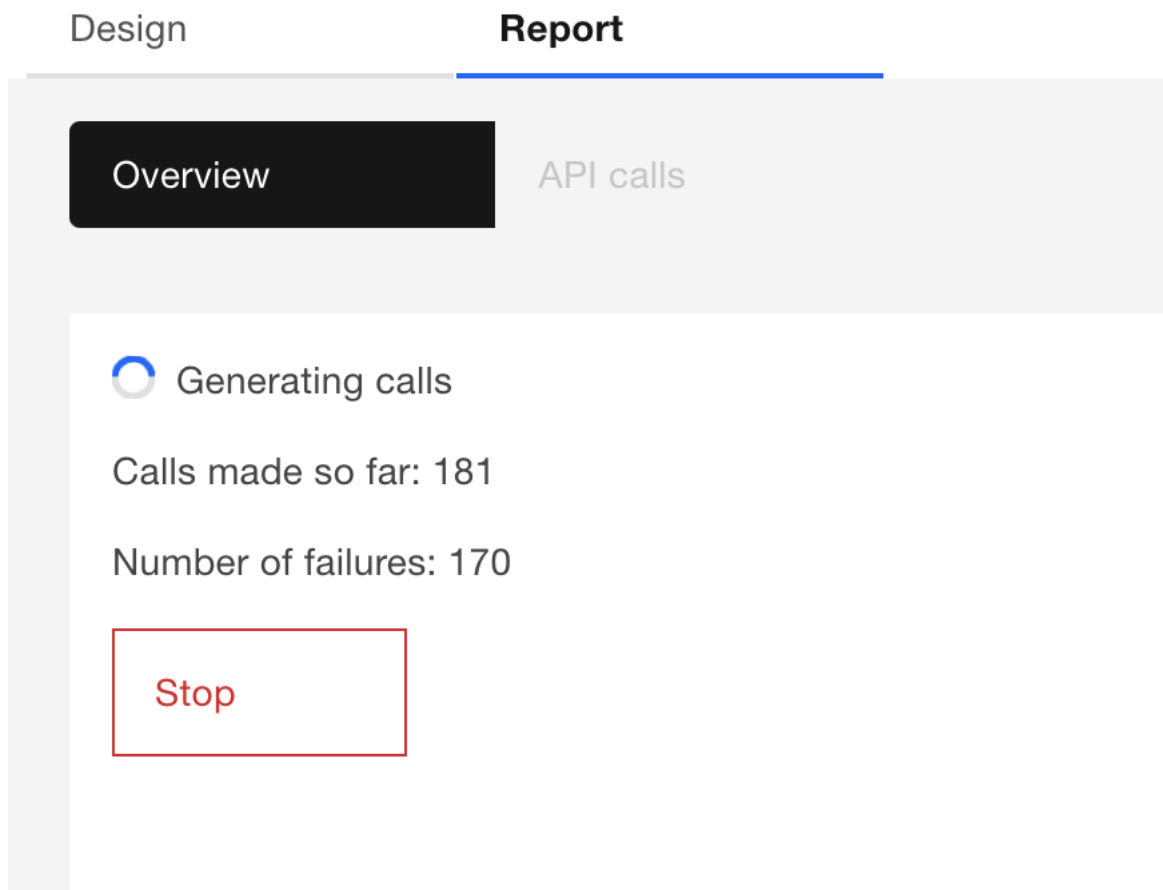

Once you have made your changes in the configuration panel, go to the security panel to set your authentication.

For more information read through [AutoTest Profile Security](#).

Once you have made all your changes to the configuration and security. You can either save, or click on the run button.

This will take you to the report page where the exerciser will generate calls to test the API.

Once the generation has finished, it will take you to the next step [AutoTest Report](#).

Viewing the AutoTest report

Once the AutoTest run has completed (either stopped manually or the configured time to run threshold has been reached) you will be presented with the **Report** section, where you will be able to view the results of the run.

First up is the **Overview** tab, which contains a table displaying all the paths defined in the AutoTest profile's API specification, alongside their associated HTTP methods (verbs), and followed by the number of each class of responses received throughout the course of the AutoTest profile run.

The screenshot shows the 'ACME Bookshop' report in the 'Report' section. It features a navigation bar with 'Design' and 'Report' tabs, and a sub-navigation bar with 'Overview' and 'API calls' tabs. A search bar is located above the table. The table displays the following data:

Path	Verb	2xx successes	4xx successes	2xx errors	4xx errors	5xx errors	Total
/books	POST	0	0	0	307	0	307
/customers	POST	0	0	0	312	0	312
/services/author	POST	0	0	0	911	0	911
/services/category	POST	0	0	0	886	0	886
/services/usage	POST	0	0	0	955	0	955

At the bottom of the table, there is a pagination control showing 'Items per page: 10' and '1-5 of 5 items'. The right side of the report indicates 'Last ran - a few seconds ago' and 'Error only' is turned off.

The **API calls** tab contains a more detailed view of every API call made by the run. The left side contains the list of the calls and their respective response statuses; the search bar lets you filter on the HTTP method, the path, and the response code; this should make it relatively easy to find specific requests amongst the potentially large number of API calls.

You can also get to the details view by clicking on any of the non-zero numbers in the overview table; this will automatically filter the list of API calls by the appropriate class of responses (or just the path and verb if the total tally is clicked on), as shown below.

No call selected
First select a call from the left side navigation and its content will show up here.

Either of the two views lets you apply a global **Errors only** filter by interacting with the toggle in the top right corner, under the **Save** and **Run** buttons. This will apply a filter to both the overview table and the detailed API calls list so that they will either display only errored or all requests.

Selecting one of the calls from the list will render the details of that call on the right hand side. As seen below information such as headers and bodies for both the request and response is shown. This lets you closely examine precisely how a specific API endpoint had been called and the response the request received.

The screenshot shows the API Management Test APIs interface. The top navigation bar includes 'API Management Test APIs', 'API Test Generation Provider Organization', 'Docs', 'Tests', 'Dashboard', 'API Quality', 'Vault', 'HTTP Client', and 'admin'. The main content area is titled 'POST/books 404' and displays an error message: 'Illegal returnStatus code 404'. Below this, the 'Request' section shows the URL 'https://ademo-gw-gateway-atm.apps.fermi-gyges.cp.fyre.ibm.com/books', the verb 'POST', and headers including 'Authorization: Bearer *****' and 'Content-Type: application/json'. The request body is a JSON object with fields like 'author', 'date', 'format', 'isbn', 'language', 'publisher', and 'title'. The 'Response' section shows the status code '404' and a list of headers including 'Content-Type: application/json', 'Date: Tue, 28 Jun 2022 13:06:55 GMT', and various Uberctx headers. The response body is a JSON object with fields like 'httpCode', 'httpMessage', and 'moreInformation'.

Profile Configuration

The configuration controls the execution of your profile; it determines for how long the test should run, and what kinds of requests it should generate. A newly-created profile includes a default configuration that you can run immediately to check that the auto-tester works with your API. The one thing you may have to set or change before you can run is the target [Server URL](#) which must point to your test deployment; the default value is copied from the API definition, where one is provided. You must also specify appropriate authentication settings on the separate **Security** tab (see [Profile Security](#)).

The configuration is in YAML format. The editor highlights syntactic errors as you type, and verifies the content for consistency with the API definition each time you press **Save**. If there is an error in the configuration, then the profile cannot run.

```

Sections in the configuration:

- [The API](#)
- [Stopping Criteria](#)
- [Execution Control](#)
- [Resources](#)
- [Operations](#)
- [Datatypes](#)

The API

ServerURL

The server URL is the single endpoint to which all requests are sent. It must be a valid URL, reachable from your namespace, and include at least a scheme and a server address; it may also include a port number and a path prefix. It must not include a trailing slash. The server URL is prefixed to an operation path from the API definition to create the target of a request. For example, given this URL definition from the configuration:

ServerURL: `https://api-host:8000/apis`

And this operation path from the API definition:

```
paths:
  /movies:
    post:
```

The auto-tester will send `POST` requests to this target URL:

`https://api-host:8000/apis/movies`

Stopping Criteria

The profile stops running as soon as any of these criteria are met.

TimeToRun

The maximum length of time to run, in minutes: the auto-tester stops sending requests once this time period has elapsed. The overall running time will be longer because it includes additional time for setup and teardown.

For example, to set a maximum running time of ten minutes:

TimeToRun: `10`

MaxRequests

The maximum number of requests to send: the auto-tester stops issuing requests once this number has been reached. The final total of requests may be greater if additional requests are needed for setup and teardown.

Set this to zero to disable the request limit, and then the auto-tester will issue as many requests as fit into the allotted time period.

For example, to set a maximum of two thousand requests:

```
MaxRequests: 2000
```

MaxErrors

The maximum number of error responses to allow: the auto-tester stops issuing requests once this number has been reached.

An error in this context is not an API error indicated by a **4xx** (or even, sometimes, a **5xx**) response, which is to be expected if the profile exercises all execution paths through the implementation. An error here is one where the response to a request is inconsistent with the API definition, which is a defect. Common cases include:

- the status code is not documented
- the payload does not conform to the schema
- any 500 error

There should be no such errors in a mature implementation so the limit is typically set low, so that the profile can terminate early if they occur. You can set the limit to zero and disable this stopping condition, which might be appropriate for a development environment where you know that some operations have defects (or you can disable those operations from ever being called as described under [Operations](#)).

For example, to set the error limit to three:

```
MaxErrors: 3
```

Execution Control

ParallelRequests

If this is **true** then the auto-tester spawns threads to issue multiple requests concurrently, otherwise it issues just one request at a time. The concurrent option increases throughput and can be helpful in exposing synchronization issues in the API.

The number of concurrent threads is fixed and cannot be changed.

For example, to disable concurrent requests:

```
ParallelRequests: false
```

ErrorInjection

If this is **true** then the auto-tester issues a certain percentage of malformed requests to further exercise the validation logic of the API, otherwise it only issues requests that are well-formed according to the API definition.

The percentage of requests is specified as **ErrorPercent**.

For example, to enable malformed requests:

```
ErrorInjection: true
```

ErrorPercent

The percentage of malformed requests, when **ErrorInjection** is **true**.

For example, to include 2% of malformed requests:

```
ErrorPercent: 2.0
```

Resources

The AutoTest execution model is based around the notion of "resources", where a resource has a schema (of object type) and a set of operations (or methods). Resources are defined in the [API extensions](#).

The auto-tester only exercises operations that belong to resources. To decide which operation to execute next, the auto-tester first picks a resource type at random, and then an operation from that type (again, at random).

You control the frequency with which resources are selected by assigning them weights. The selection frequency for a given resource is computed as the weight for that resource divided by the sum of all the weights.

A zero weight means that the resource will never be selected, and you can use this to exclude certain resources from testing; for example, when you know that they are not yet fully implemented. It is an error for all weights to be zero which would leave nothing to test.

Use the **Resources** key to assign weights to specific resources, and **ResourceDefault** to set the default weight for any resources not specified.

Resources

The weights assigned to specific resource types. The value is an object, where the keys are resource names, and the values are non-negative integer weights. Resource names must be declared in the API extensions.

For example, to increase the test focus on **Customer** operations, and exclude **Order** operations entirely:

```
Resources:  
  Customer: 2  
  Order: 0
```

ResourceDefault

The default weight for any resource type not mentioned explicitly under **Resources**. The weight can be any non-negative integer value, but there are two common use cases:

- if the weight is 1 then all resources are selected with equal frequency, except where specified otherwise under **Resources**
- if the weight is 0 then all resources are disabled, except for those specified otherwise under **Resources**

For example, to disable all resources by default:

```
ResourceDefault: 0
```

In this case there must be at least one non-zero weight under **Resources**.

Instances

Upper and lower bounds on the number of resource instances that should exist at any time. The value is an object, where the keys are resource names, and the values specify lower and upper bounds for those resource types. Resource names must be declared in the API extensions, and the bounds must be non-negative integers that together define a non-empty range. The upper bound may also be **unlimited** in which case the number of instances depends upon the balance of create and delete requests issued for that type.

The auto-tester keeps track of the instances it creates for each resource type, in order to provide valid references and avoid too many 404 responses, and makes best efforts to keep the number of instances within any specified bounds.

For example, to place an upper bound on the number of **Customer** instances that should exist at any time:

```
Instances:
  Customer:
    maximum: 25
```

InstanceDefault

The default instance bounds for any resource type not mentioned explicitly under **Instances**.

For example, to make the default unlimited:

```
InstanceDefault:
  minimum: 1
  maximum: unlimited
```

Operations

Once the auto-tester has selected a resource type, it uses a similar weighting strategy to choose an operation from that type.

You control the frequency with which operations are selected by assigning them weights. Use the **Operations** key to assign weights to specific operations, and **OperationDefault** to set the default weight for any operations not specified.

A zero weight disables an operation entirely, and if all the operations are disabled for a resource then the resource itself is also disabled.

Operations

The weights assigned to specific operations. The value is an object whose schema follows the pattern established by the **Paths** object in OpenAPI, but the values assigned to each operation are non-negative integer weights.

For example, to increase test focus on the **put_customer** operation, and avoid **patch_customer** completely:

```
Operations:
  /customers/{customer_id}:
    put: 10
    patch: 0
```

The special key **_** can be used to match all methods defined on a path that are not called out explicitly. For example, to disable all but the **put_customer** operation:

```
Operations:
  /customers/{customer_id}:
    put: 10
    _: 0
```

Remember that the weights are interpreted only across operations within the same resource type, and not across all operations in the API, so the overall distribution is determined by both the weight on the resource and the weight on the operation.

OperationDefault

The default weight for any operations not mentioned explicitly under **Operations**. The value is an object where the keys are method names and the values are the default weights for those methods where they occur under any path. The special key **_** matches all method names that are not listed separately.

For example, to disable all operations by default:

```
OperationDefault:
  _: 0
```

In this case there must be at least one non-zero weight under **Operations**.

Datatypes

Place here any custom rules that guide the auto-tester in generating values for operation parameters and payloads. These rules override the default rules derived from the API definition and any semantic annotations in the API extensions.

Rule syntax is described in [Data Generation Rules](#).

Schemas

Data generation rules for named schemas found under **definitions** (OpenAPI 2.0) or **components/schemas** (OpenAPI 3.0).

For example, given the schema definition:

```
Movie:
  type: object
  properties:
    title:
      type: string
    release_date:
      type: string
    format: date
    language:
      description: Two-letter ISO 639-1 language code
      type: string
      pattern: '[a-z]{2}'
```

The default generation rule for the **language** property, derived from this schema, will produce random string values that match the specified pattern (two lower-case alphabetic characters) but many of these will not be valid language codes, potentially giving rise to an excessive number of 400 responses.

To override the default generation rule and specify instead some particular language codes sufficient for testing:

```
Datatypes:
  schemas:
    Movie:
      properties:
        language:
          enum:
            - en
            - fr
            - de
```

To inject a small percentage of invalid values:

```
Datatypes:
  schemas:
    Movie:
      properties:
        language:
          choice:
            - enum:
                - en
                - fr
                - de
              weight: 98
            - const: xx
              weight: 2
```

Operations

Data generation rules for operation parameters and payloads described by inline (or unnamed) schemas and types. The value is an object whose schema follows the pattern established by the **Paths** object in OpenAPI.

Note that the auto-tester only supports **path** and **query** parameters at present, and other parameter types are ignored.

For example, given these (abbreviated) operation definitions:

```
paths:
  /movies:
    get:
      parameters:
        - name: limit
          in: query
          description: Sets an upper bound on the number of movies returned
          schema:
            type: integer
    post:
      requestBody:
        content:
          application/json:
            schema:
              type: object
              allOf:
                - $ref: '#/definitions/Movie'
                - properties:
                    keywords:
                      type: array
                      items:
                        type: string
```

To set values for the **limit** query parameter, and the **keywords** property of the payload to **post**:

```
Datatypes:
  operations:
    /movies:
      get:
        parameters:
          - name: limit
            in: query
            data:
              # pick a random value between 0 and 500 (inclusive)
              minimum: 0
              maximum: 500
```

```

post:
  requestBody:
    content:
      application/json:
        data:
          properties:
            keywords:

              maxItems: 3

```

Profile Security

Security is where you set credentials for the API under test. The auto-tester supports only **Basic** authentication (username and password) and **Bearer** (or **Token**) authentication; it does not support other authentication methods such as **OAuth**, or the use of custom headers.

Select your security type from the dropdown and enter the required information:

Security Type	Description	Credentials
None	Unsecured endpoint	n/a
Basic	Basic HTTP authentication	Username/Password
Basic-url	Same as Basic but omits the word Basic from the Authorization header	Username/Password
Bearer	Bearer (or Token) authentication	Token

If you provide incorrect credentials then they will not prevent the profile from running, but you can expect to see all requests fail, typically with the response **401 Unauthorized** or **403 Forbidden**.

If you provide a bearer token then be sure that it has a sufficient lifetime to cover the full period of the test, which is determined by the [stopping criteria](#) in the profile configuration. Otherwise, once the token expires, you can expect to see authentication failures as described earlier.

Custom headers

You can also configure custom security headers should your APIs require them for authentication/authorization. Simply add the required header(s) and the appropriate value(s) under the custom headers section like so:

Custom headers

Name	Value	
X-IBM-Client-Id 👁	🗑

Add new header

API Extensions

An **API Extension** augments an OpenAPI definition with semantic information designed to improve the automatic generation of test cases. Extensions are used primarily by the AutoTest assistant to refine its randomly-generated test cases, but have wider applicability.

An extension comes in two parts:

- [Resources](#) identify the key resource types managed by the API, and their methods
- [Properties](#) attach semantic categories to schema properties, to constrain the format of values suggested for those fields

An extension is associated with a specific OpenAPI document and uses [JSON Pointer](#) notation to locate terms in that document.

Resources

The **resources** section contains a set of resource definitions, where each definition contains at least the following:

- a name for the resource
- a pointer to a schema of type **object** that models the resource
- a collection of methods that operate on the resource

Typically, a resource definition also identifies a field within the schema that stores a unique identifier for instances of that type.

For example, consider this extract from an API extension:

```
resources:
  Book:
    schemas:
      primary:
        json_ptr: '#/definitions/Book'
    properties:
      id_name: '$.book_id'
    operations:
      create:
        - json_ptr: '#/paths/~1books/post'
      retrieve:
        - json_ptr: '#/paths/~1books~1{book_id}/get'
        - json_ptr: '#/paths/~1books/get'
      update:
        - json_ptr: '#/paths/~1books~1{book_id}/put'
      delete:
        - json_ptr: '#/paths/~1books~1{book_id}/delete'
```

The **resources** section contains a single resource definition with the following properties:

- it defines a resource named **Book**
- a book is modeled by a schema of the same name located in the OpenAPI document under **definitions**
- each book has a property **book_id** that holds its unique ID
- there are operations defined in the OpenAPI document under **paths** that create, retrieve, update and delete books

The correspondence between the resource name and the schema name is common but not required: a resource name can be anything, as long as it is unique within the API.

The unique ID field for a book is identified by a simplified form of JSON Path expression that locates a property (**book_id**) within the primary schema.

Operations (or methods) on a resource are grouped by category:

- Create
- Retrieve
- Update
- Delete

There can be multiple operations in each. In this example there are two operations that retrieve books: one that returns a single book by ID, and another that returns a list of books, and this is common. A different definition might have **patch** as well as (or instead of) **put** under **update**.

JSON Pointer expressions in a resource definition all refer implicitly to the associated OpenAPI document, so the prefix **#** introduces a relative location within that document. JSON Pointer syntax uses the string **~1** to stand for a forward slash character (**/**) to prevent confusion with the same character used as a separator, so the operation defined in the OpenAPI document by the term:

```
paths:
  /books/{book_id}:
    get:
```

is identified here by the JSON Pointer:

```
#/paths/~1books~1{book_id}/get
```

Dependencies

A resource definition may also describe a dependency from one resource type to another.

For example:

```
Order:
  schemas:
    primary:
      json_ptr: '#/definitions/Order'
  properties:
    id_name: '$.order_id'
  dependencies:
    - name: Book
      required: true
      references:
        - name: $.book_id
          in: body
      dependee_deletion: disabled
    - name: Customer
      required: true
      references:
        - name: customer_id
          in: path
      dependee_deletion: mutual
  operations:
    create:
```

```
- json_ptr: '#/paths/~1customers~1{customer_id}~1orders~1{order_id}/post'
# rest omitted for brevity
```

This definition says that the resource **Order** has dependencies on two other resources **Customer** and **Book** (which must be defined in the same extension).

Both dependencies are **required** in the sense that an order cannot exist unless there is a customer (to place the order) and at least one book (to buy).

An order refers to an existing book through the property **book_id** in the primary schema, and to a customer through the path parameter **customer_id**, as in the **create** method shown (and in other methods omitted).

A customer *owns* a set of orders; this is a hierarchical relationship implicit in the path:

```
/customer/{customer_id}/orders/{order_id}
```

When a customer is deleted, all their orders are also deleted, and this behavior is indicated by the **mutual** value of the deletion property.

A different relationship applies to books: a book cannot be deleted until all the orders which refer to it have been deleted, so deletion is indicated as **disabled** in that case.

There are three possible values for the **dependee_deletion** property:

- **enabled**: a referenced resource can be deleted even while dependent resources that refer to it still exist
- **disabled**: a referenced resource cannot be deleted until all dependent resources that refer to it have been deleted
- **mutual**: deleting a referenced resource deletes all the dependent resources that refer to it: this is typical where the dependent is owned by or contained in the referent

Pure resources

A pure resource is one that has no instances, or at least no instances that can be tracked with unique IDs, and is used as a placeholder for operations that do not behave as resource methods.

A pure resource differs from a standard resource in the following ways:

- it has no ID field (because there are no instances)
- dependencies have no **dependee_deletion** (for the same reason)
- all operations are grouped under a single **pure** category

For example:

```
ServiceAvailability:
  schemas:
    primary:
      json_ptr: '#/definitions/ServiceAvailability'
  operations:
    pure:
      - json_ptr: '#/paths/~1service~1status/get'
```

ServiceAvailability is a type that is returned as the result of a service status request but has no unique, persistent state.

Properties

The **properties** section assigns semantic categories to schema properties occurring in operation payloads, to constrain the range of values interpolated into generated request bodies.

For example:

```
properties:
- json_ptr: '#/definitions/CardPayment'
  items:
    - name: card_number
      semantic: credit_card_number
    - name: expiry_date
      semantic: expiry
    - name: security_code
      semantic: cvv
```

The JSON Pointer expression locates a schema named **CardPayment** in the API document under **definitions**; the schema must have **object** type with at least the properties **card_number**, **expiry_date** and **security_code** which are specified here to have particular semantics that will guide the auto-generation of appropriate values wherever a **CardPayment** occurs in a request payload.

Semantic categories must be drawn from the following set:

address	cvv	latitude	state_code
age	date	longitude	street
area_code	domain	minutes	temperature
birthday	email	month	time
certificate	expiry	name	timestamp
charset	first_name	number	token
cidr	gender	paragraph	twitter
city	geo_location	percentage	url
color	hours	phone	user_agent
content_encoding	humidity	phone_number	username
content_type	iban	prefix	uuid
coordinates	id	pressure	version
country	identity_provider	price	year
country_code	ip_address	revision	zip_code
credit_card_number	language	sentence	
currency	language_code	social_security_number	
currency_code	last_name	state	

Data Generation Rules

Data generation rules guide the auto-tester in choosing values to populate the parameters and payloads of its requests.

There are default rules derived from the API definition and extensions, but sometimes you want to override these, either to improve the general accuracy of the auto-tester or to tailor its requests to a specific use case, and you do that by adding custom rules to the [Datatypes](#) section of the profile configuration.

A data generation rule binds a **data generator** to a schema or type in the API definition such that, when the auto-tester assembles the data for a request and encounters that schema or type, it uses the generator to provide an appropriate value at that point.

Data generators

A **data generator** describes a never-ending sequence of values, and whenever the auto-tester calls on a generator it takes the next value from the sequence.

The syntax for generation rules reuses terms from JSON Schema where the implied constraints on a schema are sufficient to guide the auto-tester in generating conformant values. Such constraints occurring in the API definition help inform the default rules.

Constant

The **constant** generator always returns the same value, which can be of any simple type.

```
const: 0
```

```
# ==> 0, 0, 0, ...
```

```
const: Thursday
```

```
# ==> "Thursday", "Thursday", "Thursday", ...
```

Enumeration

The **enumeration** generator returns values selected at random from a given list, which can be of any simple type.

```
enum:
```

```
- 0  
- 1  
- 2
```

```
# ==> 1, 0, 2, 0, ...
```

```
enum:
```

```
- Thursday  
- Friday  
- Saturday
```

```
# ==> "Friday", "Saturday", "Saturday", ...
```

Pattern

The **pattern** generator returns string values that match a given regular expression.

```
pattern: '[0-9]{3}'
```

```
# ==> "884", "924", "121", ...
```

```
pattern: '[a-z][a-z_]{0,15}'
```

```
# ==> "dbe", "kg_cfsv", "dhhfgbjxavmsaxq", ...
```

Range

The **range** generator returns numeric values uniformly distributed over a given range (inclusive).

```
minimum: 0
```

```
maximum: 10
```

```
# ==> 10, 6, 8, ...
```

If either endpoint is omitted then it defaults to the most negative or most positive value of the type:

```
minimum: 0
```

```
# ==> 10029625, 3162517758, 841054690, ...
```

Semantic

The **semantic** generator returns values that conform to some pre-defined semantic category, covering names, addresses, credit card numbers, etc. The set of categories is the same as that allowed in the [API extensions](#).

```
semantic: email
```

```
# ==> "herbertschaden@fahey.net", "emmyfarrell@cruickshank.com", "vilmaprohaska@zboncak.org", ...
```

```
semantic: first_name
```

```
# ==> "Antwan", "Connie", "Modesto", ...
```

Resource

The **resource** generator returns values that are unique identifiers of resource instances of a given type, selected at random from the pool of existing instances. The identifier of an instance is taken from the `id_name` property of the resource type defined in the [API extensions](#) and its type and format will vary accordingly.

```
resource: Customer
```

```
# ==> "e5537298-9041-47fc-b97e-c910d8f9d971", "f60521c8-2ccb-4036-a742-9f350271675f", "e5537298-9041-47fc-b97e-c910d8f9d971", ...
```

Array

The **array** generator returns array values whose contents are populated from a data generator defined recursively. The length of the array is chosen at random between `minItems` and `maxItems` inclusive.

```
items:
  pattern: '[0-9]{3}'
minItems: 3
maxItems: 3
```

```
# ==> ["770", "496", "219"], ["431", "895", "331"], ["864", "130", "204"], ...
```

```
items:
  enum:
    - 0
    - 1
minItems: 0
maxItems: 5
```

```
# ==> [], [1, 0, 1, 1], [0], ...
```

Object

The **object** generator returns object values whose properties are populated from named data generators, defined recursively.

```
properties:
  x:
    minimum: 0
    maximum: 100
  y:
    minimum: 0
    maximum: 100
```

```
# ==> {"x": 59, "y": 63}, {"x": 22, "y": 8}, {"x": 95, "y": 57}, ...
```

```
properties:
  code:
    pattern: '[0-9]{3}'
  language:
    enum:
      - en
      - fr
      - de
```

```
# ==> {"code": "452", "language": "fr"}, {"code": "504", "language": "en"}, {"code": "846", "language": "fr"}, ...
```

If a property is not required by the target schema then it may be marked with an **optional** attribute which specifies a frequency (between 0.0 and 1.0) that determines how often the property is included in the generated object (where 0 means never, and 1 means always).

```
properties:
  code:
    pattern: '[0-9]{3}'
  language:
    optional: 0.5
    enum:
      - en
      - fr
      - de
  tag:
    optional: 0.0
```

```
# ==> {"code": "452", "language": "fr"}, {"code": "504", "language": "en"}, {"code": "846"}, ...
```

Choice

The **choice** generator returns values selected at random from a given list of data generators, using optional weights to bias the outcome. The alternatives must be simple generators, which excludes **array** and **object** generators.

```
choice:
  # bias the selection towards English
  - const: en
    weight: 5
  - const: fr
  - const: de
```

```
# ==> "en", "en", "en", ..., "de", "en", ...
```

```
choice:
  # normal values in the range 1-10
  - minimum: 1
    maximum: 10
    weight: 98
  # with a small percentage of outliers
  - const: 999
    weight: 2
```

```
# ==> 6, 3, 9, 1, ..., 999, 6, ...
```

Data generation rules

A **data generation rule** binds a data generator to a schema occurring in the API definition so that the auto-tester knows how to generate values for that schema in an API call. Rules are specified in the [Datatypes](#) section of the profile configuration, and override the default rules derived from the API definition and extensions.

Schemas occur widely in the OpenAPI specification, but there are three key locations which have most relevance to the auto-tester where the profile allows override rules:

- Named schemas
- Parameters
- Inline request bodies

Named schemas

A schema rule assigns a data generator to a named schema from the API definition, found either under **definitions** (OpenAPI 2.0) or **components/schema** (OpenAPI 3.0). The auto-tester will use the specified generator wherever the named schema occurs in a request.

Schema rules appear in the [schemas](#) section of the profile configuration, under **Datatypes**.

Because this is an *override*, the generator may be incomplete for the original schema, and the auto-tester will fall back to using the default rules to cover any gaps. In particular, if the schema describes an object type then the generator need only name a subset of the object properties, and the auto-tester will apply the override for those properties but use default rules for the rest.

For example, given this named schema in the API definition:

```
Movie:
  type: object
  properties:
    title:
      type: string
    release_date:
      type: string
      format: date
    language:
      description: Two-letter ISO 639-1 language code
      type: string
      pattern: '[a-z]{2}'
```

The default rule derived from the schema returns values such as:

```
{
  "title": "mkLHM22Ohabb6YG4-wdZFUwxQa7dn",
  "release_date": "2018-09-14",
  "language": "jq"
}
```

You can refine this by overriding the default rules for the **title** and **language** properties:

```
Datatypes:
  schemas:
    Movie:
      properties:
        title:
          semantic: sentence
        language:
          enum:
            - en
            - fr
            - de
```

This rule binds an object generator (introduced by the keyword **properties**) to the schema named **Movie** which -- combined with the default rule for **release_date** -- returns values such as:

```
{
  "title": "What dog everybody am myself hourly meeting how group over example her",
  "release_date": "2094-06-31",
  "language": "de"
}
```

Parameters

A parameter rule binds a data generator to a named parameter within an operation found under **paths** in the API definition.

Parameter rules appear in the [operations](#) section of the profile configuration, under **Datatypes**.

For example, given this parameter definition on **GET /movies** in the API definition that restricts the number of movies returned in a single call:

```
paths:
  /movies:
    get:
      parameters:
        - name: limit
          in: query
          description: Sets an upper bound on the number of movies returned
          schema:
            type: integer
```

The default rule derived from this definition will return values from the full integer range, but you can override this with a rule in the profile configuration that specifies a more realistic range, with occasional outliers to check the validation logic:

```
Datatypes:
  operations:
    /movies:
```

```

get:
  parameters:
    - name: limit
      data:
        choice:
          - minimum: 1
            maximum: 500
            weight: 95
          - const: 0
            weight: 3
          - const: 8000000
            weight: 2

```

The format of the rule follows the format of the original definition but with the keyword **data** in place of **schema** to introduce the data generator.

In OpenAPI, a parameter is uniquely identified by a name *and a location* (so the same name could be used in, say, both query and header) so the parameter rules allow the **in** property as optional where needed to disambiguate. It's not used in this example because the query parameter is the only one named **limit**.

The auto-tester only supports parameters of type **query** and **path** at present (and **body** in OpenAPI 2.0). Rules bound to other parameter types are ignored.

Request body

A request body rule binds a data generator to the body of a request where the corresponding schema is specified directly as part of the operation in the API definition, rather than via a reference to a named schema.

Request body rules appear in the [operations](#) section of the profile configuration, under **Datatypes**.

For example, given this definition of the payload to a **POST** request:

```

paths:
  /movies:
    post:
      requestBody:
        content:
          application/json:
            schema:
              type: object
              allOf:
                - $ref: '#/components/schemas/Movie'
                - properties:
                    keywords:
                      type: array
                      items:
                        type: string

```

The following rule generates some appropriate keywords to attach to a new movie (where the movie itself is covered by the rules discussed earlier):

```

Datatypes:
  operations:
    /movies:
      post:
        requestBody:
          content:
            application/json:
              data:
                properties:
                  keywords:
                    # pick up to 3 items from the following list
                    items:
                      enum:
                        - avant-garde
                        - dystopia
                        - epic
                        - postmodern
                        - remake
                        - shootout
                    minItems: 0
                    maxItems: 3

```

As with the parameter rules, the format follows that of the original definition but with **data** in place of **schema**. The definition is in the style of OpenAPI 3.0, but the rule can work for OpenAPI 2.0 as well as long as the content type is consistent; alternatively, starting from an OpenAPI 2.0 definition, you can use a **body** parameter rule to specify the payload, but that does not work for 3.0.

Assertion components

IBM API Connect Test APIs supports the following assertion types:

- [Assert Compares](#)
Asserts that two elements are equivalent in some way.
- [Assert Contains](#)
Asserts that the value of the element identified by a given expression contains a specific substring.
- [Assert Equals](#)
Asserts that the value of the element identified by a given expression is equal to a specific value.
- [Assert Exists](#)
Asserts that the value of the element identified by a given expression exists.

- [Assert Greater](#)
Asserts that the value of the element identified by a given expression is greater than a specific value.
- [Assert In](#)
Asserts that the element identified by a given expression matches at least one item from a given list.
- [Assert Is](#)
Asserts that the value of the element identified by a given expression is of a specific type.
- [Assert Less](#)
Asserts that the value of the element identified by a given expression is less than a specific value.
- [Assert Matches](#)
Asserts that the value of the element identified by a given expression matches a knowledge base of some kind.
- [Set](#) Set a variable during test executions

Assert Compares

Asserts that two elements are equivalent in some way.

Parameters

Name	Type	Required?	Description	Default value
Expression 1	Expression	Yes	Path to the first element for comparison; for example, <code>payload1.productId</code> .	
Expression 2	Expression	Yes	Path to the second element for comparison; for example, <code>payload2.productId</code> .	
Mode	Selection list	Yes	Select one of the following values: <ul style="list-style-type: none"> • text: compare the text of the two elements as plain text. • values: compare the two elements regardless of their text layout. • structure: compare only the structure of the two elements. 	text
Level	Selection list	No	Select error or warning . Specifies whether, if the assertion fails, it should be considered an 'error' or just a 'warning.' A warning does not trigger alerts, such as email or text messages.	error
Stop test if fails	Selection list	No	Select true or false . If true , the test is immediately stopped if the assertion fails.	false
Assertion comment	String	No	An optional comment for information.	

Assert Contains

Asserts that the value of the element identified by a given expression contains a specific substring.

Parameters

Name	Type	Required?	Description	Default value
Expression	Expression	Yes	Path to the element to be searched; for example, <code>payload.productId</code> .	
Value	String	Yes	Path to the second element for comparison; for example, <code>payload2.productId</code> .	
Mode	Selection list	No	Select one of the following values: <ul style="list-style-type: none"> • all: If the path expression matches multiple elements in the payload then they must all match the assertion. • one: Only one of the matching elements in the payload needs to match the assertion. 	all
Level	Selection list	No	Select error or warning . Specifies whether, if the assertion fails, it should be considered an 'error' or just a 'warning.' A warning does not trigger alerts, such as email or text messages.	error
Modifier	Selection list	No	Select not to negate the assertion; the assertion is considered verified if it does not pass.	None
Execute if item exists	Selection list	No	Select true or false . If true , the assertion is evaluated only if the element exists. This is useful when the element does not always exist.	false
Stop test if fails	Selection list	No	Select true or false . If true , the test is immediately stopped if the assertion fails.	false
Assertion comment	String	No	An optional comment for information.	

Assert Equals

Asserts that the value of the element identified by a given expression is equal to a specific value.

Parameters

Name	Type	Required?	Description	Default value
Expression	Expression	Yes	Path to the element to be compared with the specified value; for example, <code>payload.productId</code> .	
Value	String	Yes	The value that the element is to be compared with.	
Type	Selection list	No	The data type of the value. If you do not specify a data type, the values are compared as strings. Select one of the following values: <ul style="list-style-type: none"> integer: the values are evaluated as whole numbers. float: the values are evaluated as decimal numbers. 	
Mode	Selection list	No	Select one of the following values: <ul style="list-style-type: none"> all: If the path expression matches multiple elements in the payload then they must all match the assertion. one: Only one of the matching elements in the payload needs to match the assertion. 	all
Level	Selection list	No	Select error or warning . Specifies whether, if the assertion fails, it should be considered an 'error' or just a 'warning.' A warning does not trigger alerts, such as email or text messages.	error
Modifier	Selection list	No	Select not to negate the assertion; the assertion is considered verified if it does not pass.	None
Execute if item exists	Selection list	No	Select true or false . If true , the assertion is evaluated only if the element exists. This is useful when the element does not always exist.	false
Stop test if fails	Selection list	No	Select true or false . If true , the test is immediately stopped if the assertion fails.	false
Assertion comment	String	No	An optional comment for information.	

Assert Exists

Asserts that the value of the element identified by a given expression exists. The presence of the element, even if it is empty, is enough to consider it a valid assertion.

Parameters

Name	Type	Required?	Description	Default value
Expression	Expression	Yes	Path to the element to be checked for existence; for example, <code>payload.productId</code> .	
Mode	Selection list	No	Select one of the following values: <ul style="list-style-type: none"> all: If the path expression matches multiple elements in the payload then they must all match the assertion. one: Only one of the matching elements in the payload needs to match the assertion. 	all
Level	Selection list	No	Select error or warning . Specifies whether, if the assertion fails, it should be considered an 'error' or just a 'warning.' A warning does not trigger alerts, such as email or text messages.	error
Modifier	Selection list	No	Select not to negate the assertion; the assertion is considered verified if it does not pass.	None
Stop test if fails	Selection list	No	Select true or false . If true , the test is immediately stopped if the assertion fails.	false
Assertion comment	String	No	An optional comment for information.	

Assert Greater

Asserts that the value of the element identified by a given expression is greater than a specific value.

Parameters

Name	Type	Required?	Description	Default value
Expression	Expression	Yes	Path to the element to be compared with the specified value; for example, <code>payload.productId</code> .	
Value	String	Yes	The value that the element is to be compared with.	
Type	Selection list	No	The data type of the value. If you do not specify a data type, the values are compared as strings. Select one of the following values: <ul style="list-style-type: none"> integer: the values are evaluated as whole numbers. float: the values are evaluated as decimal numbers. 	

Name	Type	Required?	Description	Default value
Mode	Selection list	No	Select one of the following values: <ul style="list-style-type: none"> all: If the path expression matches multiple elements in the payload then they must all match the assertion. one: Only one of the matching elements in the payload needs to match the assertion. 	all
Level	Selection list	No	Select error or warning . Specifies whether, if the assertion fails, it should be considered an 'error' or just a 'warning.' A warning does not trigger alerts, such as email or text messages.	error
Modifier	Selection list	No	Select not to negate the assertion; the assertion is considered verified if it does not pass.	None
Execute if item exists	Selection list	No	Select true or false . If true , the assertion is evaluated only if the element exists. This is useful when the element does not always exist.	false
Stop test if fails	Selection list	No	Select true or false . If true , the test is immediately stopped if the assertion fails.	false
Assertion comment	String	No	An optional comment for information.	

Assert In

Asserts that the element identified by a given expression matches at least one item from a given list.

Parameters

Name	Type	Required?	Description	Default value
Expression	Expression	Yes	Path to the element to be compared with the items in the list; for example payload.productId .	
Value	String	Yes	The items that the specified element is to be compared with. Click anywhere in the field, enter the first item, then click the + icon to add further items. Alternatively, you can enter the items as a comma separated list.	
Type	Selection list	No	The data type of the value. If you do not specify a data type, the values are compared as strings. Select one of the following values: <ul style="list-style-type: none"> integer: the values are evaluated as whole numbers. float: the values are evaluated as decimal numbers. 	
Mode	Selection list	No	Select one of the following values: <ul style="list-style-type: none"> all: If the path expression matches multiple elements in the payload then they must all match the assertion. one: Only one of the matching elements in the payload needs to match the assertion. 	all
Level	Selection list	No	Select error or warning . Specifies whether, if the assertion fails, it should be considered an 'error' or just a 'warning.' A warning does not trigger alerts, such as email or text messages.	error
Modifier	Selection list	No	Select not to negate the assertion; the assertion is considered verified if it does not pass.	None
Execute if item exists	Selection list	No	Select true or false . If true , the assertion is evaluated only if the element exists. This is useful when the element does not always exist.	false
Stop test if fails	Selection list	No	Select true or false . If true , the test is immediately stopped if the assertion fails.	false
Assertion comment	String	No	An optional comment for information.	

Assert Is

Asserts that the value of the element identified by a given expression is of a specific type.

Parameters

Name	Type	Required?	Description	Default value
Expression	Expression	Yes	Path to the element whose type is to be examined; for example, payload.productId .	
Type	Selection list	Yes	Select one of the following values: <ul style="list-style-type: none"> integer: Checks if the element is an integer value. float: Checks if the element is a decimal value. url: Checks if the element is a well-formatted URL. boolean: Checks if the element is a boolean value. phone: Checks if the element is a valid phone number format. email: checks if the element is a valid email format. map: Checks if the element is a map type. array: Checks if the element is an array. 	

Name	Type	Required?	Description	Default value
Mode	Selection list	No	Select one of the following values: <ul style="list-style-type: none"> all: If the path expression matches multiple elements in the payload then they must all match the assertion. one: Only one of the matching elements in the payload needs to match the assertion. 	all
Level	Selection list	No	Select error or warning . Specifies whether, if the assertion fails, it should be considered an 'error' or just a 'warning.' A warning does not trigger alerts, such as email or text messages.	error
Modifier	Selection list	No	Select not to negate the assertion; the assertion is considered verified if it does not pass.	None
Execute if item exists	Selection list	No	Select true or false . If true , the assertion is evaluated only if the element exists. This is useful when the element does not always exist.	false
Stop test if fails	Selection list	No	Select true or false . If true , the test is immediately stopped if the assertion fails.	false
Assertion comment	String	No	An optional comment for information.	

Assert Less

Asserts that the value of the element identified by a given expression is less than a specific value.

Parameters

Name	Type	Required?	Description	Default value
Expression	Expression	Yes	Path to the element to be compared with the specified value; for example, <code>payload.productId</code> .	
Value	String	Yes	The value that the element is to be compared with.	
Type	Selection list	No	The data type of the value. If you do not specify a data type, the values are compared as strings. Select one of the following values: <ul style="list-style-type: none"> integer: the values are evaluated as whole numbers. float: the values are evaluated as decimal numbers. 	
Mode	Selection list	No	Select one of the following values: <ul style="list-style-type: none"> all: If the path expression matches multiple elements in the payload then they must all match the assertion. one: Only one of the matching elements in the payload needs to match the assertion. 	all
Level	Selection list	No	Select error or warning . Specifies whether, if the assertion fails, it should be considered an 'error' or just a 'warning.' A warning does not trigger alerts, such as email or text messages.	error
Modifier	Selection list	No	Select not to negate the assertion; the assertion is considered verified if it does not pass.	None
Execute if item exists	Selection list	No	Select true or false . If true , the assertion is evaluated only if the element exists. This is useful when the element does not always exist.	false
Stop test if fails	Selection list	No	Select true or false . If true , the test is immediately stopped if the assertion fails.	false
Assertion comment	String	No	An optional comment for information.	

Assert Matches

Asserts that the value of the element identified by a given expression matches a specified format.

Parameters

Name	Type	Required?	Description	Default value
Expression	Expression	Yes	Path to the element that you want to examine; for example, <code>payload.productId</code> .	
Type	Selection list	Yes	<ul style="list-style-type: none"> regex: Evaluate the element value as a regular expression, as specified in the Regex value parameter. US states: Check if the element value is a valid US State; for example, 'NY'. US zipcodes: Check if the element value is a valid US Zipcode. credit card: Check if the element value contains a valid credit card number from the most popular credit cards. country codes: Checks if the element value contains a valid country code. currency codes: Checks if the element value is a valid currency code. 	
Mode	Selection list	No	Select one of the following values: <ul style="list-style-type: none"> all: If the path expression matches multiple elements in the payload then they must all match the assertion. one: Only one of the matching elements in the payload needs to match the assertion. 	all

Name	Type	Required?	Description	Default value
Level	Selection list	No	Select error or warning . Specifies whether, if the assertion fails, it should be considered an 'error' or just a 'warning.' A warning does not trigger alerts, such as email or text messages.	error
Modifier	Selection list	No	Select not to negate the assertion; the assertion is considered verified if it does not pass.	None
Execute if item exists	Selection list	No	Select true or false . If true , the assertion is evaluated only if the element exists. This is useful when the element does not always exist.	false
Stop test if fails	Selection list	No	Select true or false . If true , the test is immediately stopped if the assertion fails.	false
Assertion comment	String	No	An optional comment for information.	

Set Variable

Set Variable is a component that can be added to the test to capture a particular value for later use or to perform computations to arrive at a given result.

Parameters

Name	Type	Required?	Description	Default value
Variable Name	String	Yes	Name of variable to be used in subsequent components	
Mode	Selection List	Yes	Select one of the following values: <ul style="list-style-type: none"> String: Provide a string for the value of the variable, this can be referencing a payload property Object: Interrogate the object being processed Language: Using Groovy script provide logic to determine a value for the variable 	String
Value	String	No	Provide the Value of the variable if String was selected for Mode	
Object	String	No	Provide the logic for use when Mode is set to Object	
Language	Selection List	No	The language you wish to script in, Groovy is the only option available	Groovy
Content	String	No	Your Groovy script logic	

String

To set a variable from a requests response if one is given.

for example to set a variable to the **name** property Add **Set Variable Component from list** Provide the name of the variable Set the value to `${<request variable name>.name}`

If the variable being referenced is within a loop the variable name will be `_1`

Setting a Variable using Groovy script

To set variable to a value that requires a bit of additional logic, you can write a segment of groovy script to process inputs and provide an single output.

To write script, within **Set Variable** change the **Variable Mode** to **Language**

As an example if given a temperature I want to check if where it falls on a set of parameters using the tempature from a prior request

```
def temperature="Just Right"

if(payload.temperature>22){
    temperature='Its Warm'
} else if(payload.temperature<16){
    temperature='Its Cold'
}

return temperature
```

You much return a inner variable at the end to set the value of variable to be used later

NOTE: within Groovy script you do not need to wrap existing variables within `{ }`

Object Mode

Object allows you to inspect the a larger object to find particular parts of a varialbe

```
payload.findAll {it.name == 'Douglas Adams'}
```

Security

It is important to be aware of potential security implications when using IBM API Connect Test APIs.

- [Storing sensitive data](#)

Storing sensitive data

When using IBM API Connect Test APIs, it is always helpful to remember:

- Before making a request to any endpoint, it is important to pause and think about the data supplied in the request and the data expected in the response. If the data contains sensitive data such as authentication credentials or any form of personal data, then we **strongly** discourage you from making that request.
- Try to always use test accounts when monitoring production services.

Additional tasks

Additional tasks with Test APIs.

- [Deleting a test suite](#)
- [Deleting a test](#)
- [Opening a test in the Editor](#)

Template Test from Specification Document

As an alternative to making requests against an existing API deployment to create a test, instead you can create a test template from a document that specifies the APIs behavior, or use a Postman Collection.

The template will include parameterized requests with payloads if they can be determined and assertions based on the API document.

Once the template has been generated, you may need to make changes to the datasets to use the correct endpoint and complete any request payloads that have been partially generated.

Supported document types

Test Templating supports generating test cases from the following document types

- Swagger 2.0 JSON
- Swagger 2.0 YAML
- SOAP WSDL (single wsdl file)
- Postman Collection

Templating Options

Once the document has been uploaded, you will be presented with a list of requests based on Path and expected status code

From Scratch

Generates a single request and any assertions that can be determined about that request

This replaces an existing test definition

Merge

Generate additional request and adds to the end of the existing test case

Note: This does not include any assertions, it is recommended the core request to be tested is generated from scratch and then additional requests merged into it

Smart Generation

Restrictions:

- OpenAPI 2.0/Swagger 2.0 only
- Enterprise as a Service and Cloud Pak for Integration only

Once you've enabled the insights-driven test generation feature you will be able to generate a test template which can contain multiple related requests that include setup and teardown operations for the targeted operation.

Smart Generation uses static analysis and natural language processing of the API document to determine links between API requests and data that can be shared between the requests

Deleting a test suite

To delete a test suite, complete the following steps:

1. Click your test organization name in the menu bar to open your test organization test suite page.

2. On the test suites page, locate the test suite you want to delete and determine whether it contains any tests by observing the displayed **Tests** count.

Note: You can't delete a test suite that contains tests, so if your test suite does contain any tests you must delete them first; see [Deleting a test](#).

3. To delete the test suite, click its **Settings** icon **Settings**, then click **Remove Test Suite**

Note: If the test suite contains tests, you will get an error when you click the **Settings** icon.

!Image of delete error(./dist/images/cant-delete-test suite.png)

If your test suite is deleted successfully, you are returned to your test organization test suite page, and your deleted test suite is no longer displayed.

Deleting a test

To delete a test, complete the following steps:

1. Click your test organization name in the menu bar to open your test organization test suite page.

2. On the test suites page, locate the test suite you want to work with and ensure that it contains tests by confirming that the displayed **Tests** count is not zero.

3. Click the test suite's **Tests** icon **Tests**. A list of the tests that have been created in the test suite are displayed.

4. Double-click the test you want to work with, or click its edit icon .

5. On the test details page, click the **Delete Test** icon **Delete Test**, then click the tick icon to confirm. You are returned to the tests list and your deleted test is no longer displayed.

Opening a test in the Editor

To open a test in the Editor, complete the following steps:

1. Click your test organization name in the menu bar to open your test organization test suite page.

2. On the test suites page, locate the test suite you want to work with and ensure that it contains tests by confirming that the displayed **Tests** count is not zero.

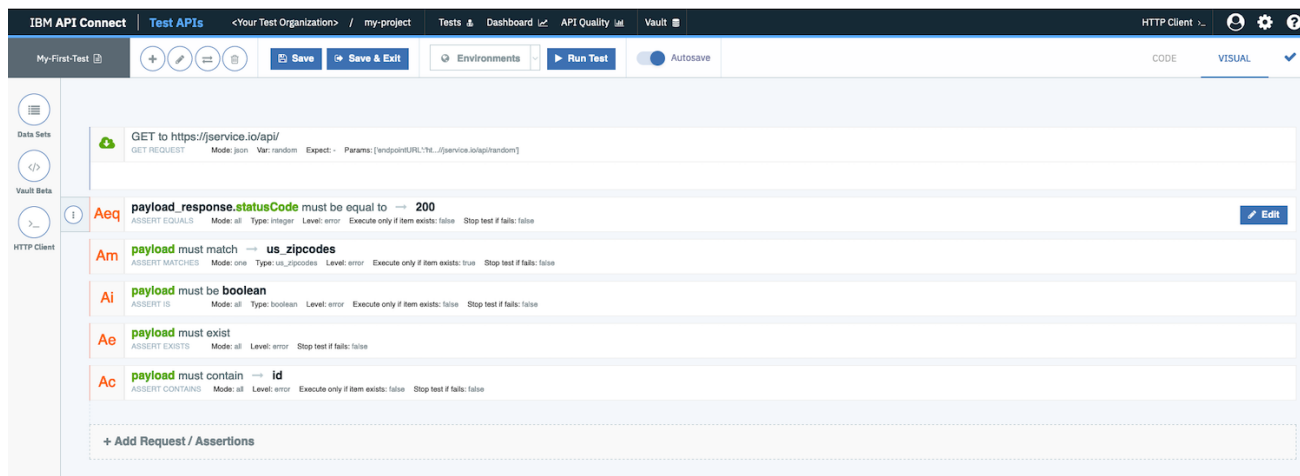

3. Click the test suite's **Tests** icon **Tests**. A list of the tests that have been created in the test suite are displayed.

4. Double-click the test you want to work with, or click its edit icon .

5. On the test details page, click the **Compose** icon . The Editor page opens for the selected test; for example:

API Hooks

In addition to viewing and executing tests within the IBM API Connect Test interface, you may also perform these actions via an API. This allows tests to be executed via the command line, through third-party applications, or as part of a CI/CD pipeline. API hooks form the basis of this API, providing a base URL on which subsequent API operations can be performed. To start using an API Hook, see:

- [Creating An API Hook](#).

API Hooks require authentication to use in the form of an API Key and Secret. Once you have created your API Hook, view the following page to learn how to create an API Key and Secret for your Test Organization:

- [Creating API Keys and Secrets](#)

Once you've set up your API Hook, Key and Secret, see:

- [Using API Hooks](#)

Creating an API Hook

You can generate an API hook for each of the Test Suites within your Test Organization. API hooks are scoped to only one test suite and thus will only have access to operate on the data within that test suite; that is, if an API Hook is generated for **Test Suite 1**, it may only access the tests and test results associated with **Test Suite 1**. If you wish to interact with tests in multiple test suites, you will need to generate an API hook for each Test Suite.

API Hooks are protected and require an API Key and Secret to be used. You can find out how to create a API Key and Secret [here](#).

Prerequisites

1. Your account must have administrators or Test Organization manager privileges.
2. You must have at least one Test Suite in your Test Organization.

To see a list of all the Test Suites in your Test Organization, navigate to the Main Dashboard by clicking on your Test Organization Name in the menu bar.

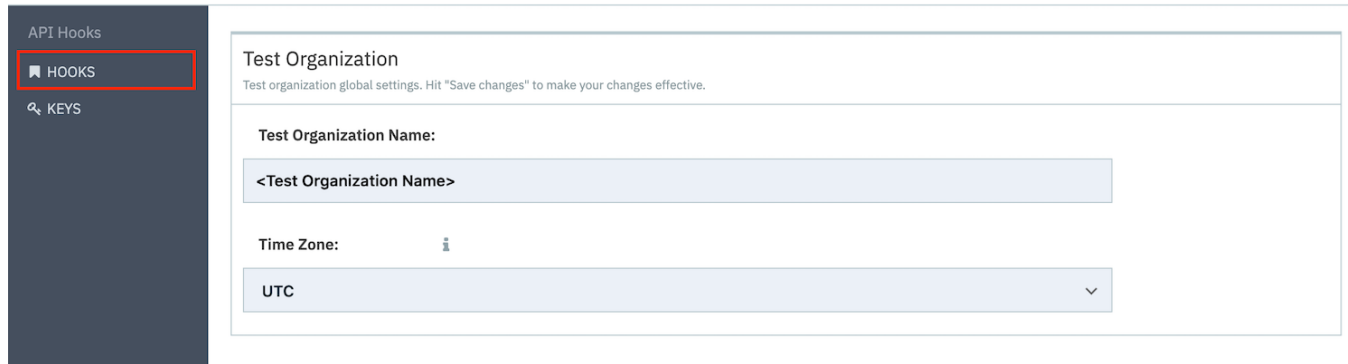

If there are no Test Suites here, you can create one by clicking the **Create Test Suite** button after the Test Status chart.

How to create an API Hook

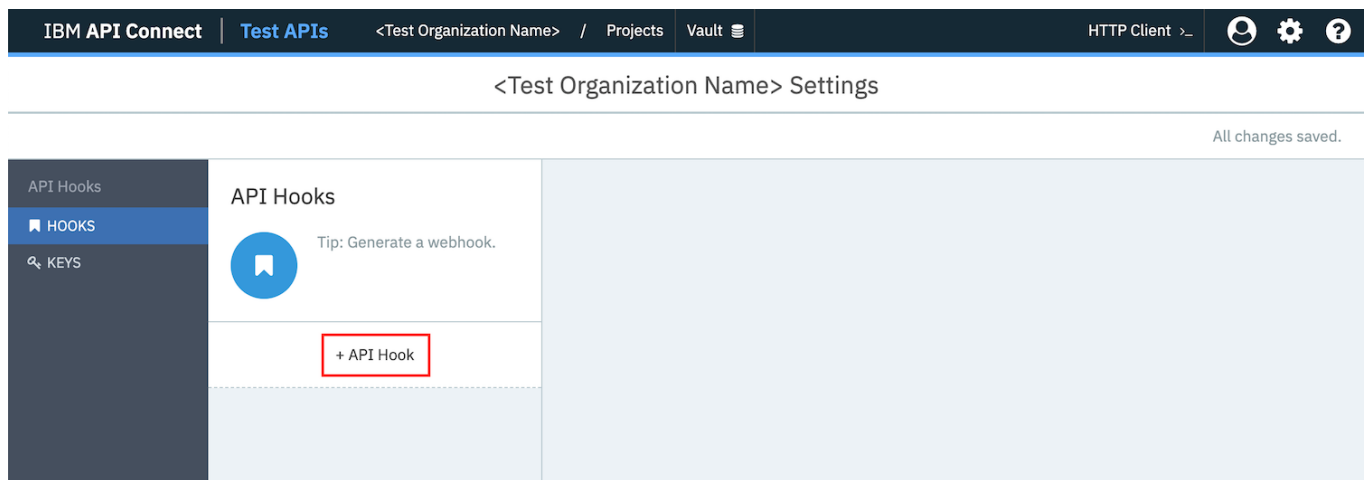

First navigate to the Test Organization settings page by clicking the **Cog** icon in the menu bar.

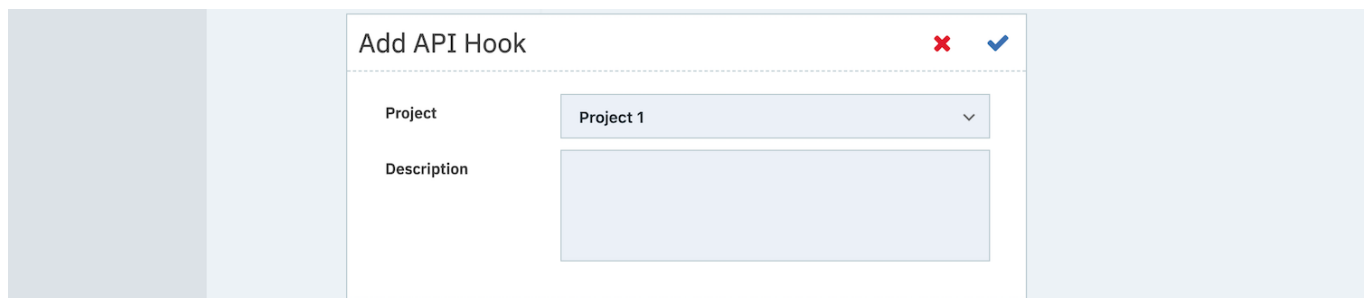

Within the Test Organization settings page, click the **Hooks** option under the API Hooks heading in the navigation menu.

Now click on the **+ API Hook** button to begin creating a new API Hook.

As API Hooks are scoped at a Test Suite level, you will need to select the test suite you wish to generate the hook for. Choose the appropriate test suite from the Test Suite dropdown and optionally add a description for the API Hook. Click the **confirm**  icon to generate and save the API Hook.

You've now created the API Hook URL for your Test Suite. Make a note of this this URL as this will form the base path of all future API requests you make to this test suite.

Close the Hook URL dialog box. You can see that your new API Hook is now in the list of API Hooks. You can click on this at anytime to view the URL again in the future should you need. Note that this URL will remain active until it is deleted. To delete the API Hook, simply click on the **Delete** icon next to the API Hook you want to remove.

<Test Organization Name> Settings

All changes saved.

The screenshot displays the 'API Hooks' configuration page. On the left, a navigation menu includes 'API Hooks' and 'KEYS'. The main content area is titled 'API Hooks' and features a tip: 'Tip: Generate a webhook.' Below this, there is a '+ API Hook' button and a list of hooks. One hook, 'Project 1', is highlighted with a red rectangular box. To the right, the 'API Hook details' panel shows the 'Automation hook URL' as 'https://localhost:8443/app/api/rest/v1/a5d655a2-b966-4a59-ba04-a1197b90d89a303' with a 'Copy' button.

In order to use your new API Hook, you need to ensure you have an API Key and Secret for your Test Organization. Steps do do this can be found [here](#). Alternatively, if your Key and Secret is set up, see [Using API Hooks](#) for more information on how to use the API Hook.

What to do next

- Next Topic: [Creating API Keys and Secrets](#)

Creating API Keys and Secrets

API Keys and Secrets are the credentials required to use an [API Hook](#). For a request to an API Hook to be authorised, both the **X-API-Key** and **X-API-Secret** headers must be provided. The values of the API Key and Secret represent the values of these headers respectively.

Unlike API Hooks which are scoped to a single Test Suite, API Keys and Secrets are scoped to a Test Organization. Therefore, any API Key and Secret pair which is generated within a Test Organization will have permission to authorise requests to all API Hooks within the same organization, regardless of the Test Suite the API Hook is associated with. API Keys and Secrets can only be generated by system administrators or test organization managers.

Creating an API Key and Secret

First navigate to the Test Organization settings page by clicking the **Cog** icon in the menu bar. Note that you will only see this icon if you are a administrator or a test organization manager.

Within the Test Organization settings page, click the **KEYS** option under the API Hooks heading in the navigation menu.

API Keys

Tip: Generate an API Key.

+ API Key

You will then be shown the generated **Key** and **Secret**. Make a note of both of these, especially the **Secret** as this will be the only time this is visible. Give your new API Key a name and then click the **confirm** icon to save it.

Add API Key

Name: My API Key

Key: 30eb22de-03db-40d3-8b50-d218ef449f24

Secret: ad9f94ce7b20b7a6f305df5e723b80d9c064f7f0c7cb

Your new API Key is now active and will now appear in the list of API Keys in the navigation menu. Clicking on the key will show you the API Key's value should you need to reference this again in the future. If you want to remove the API Key at any point, simply click on the **Delete** icon next to the API Key you want to remove. This will invalidate all future requests to API Hooks within you Test Organization using this Key and Secret combination.

What to do next

- Next Topic: [Using API Hooks](#)

Using API Hooks

[API Hooks](#) provide a mechanism to interact with tests within a Test Suite via an API. Whilst the API Hook itself defines the basepath of this API, it also exposes a series of endpoints which, when appended onto this basepath, allow you to list and execute published tests within the API Hook's scope. The following pages detail these endpoints and subsequent parameters you can provide to either list, execute all, or execute only specific tests within a test suite.

Endpoints

- [List All Tests](#)
Lists all of the published tests within an API Hook's scope.
- [Run All Published Tests](#)
Runs all of the published tests within an API Hook's scope.
- [Run Published Tests By Tag](#)
Runs the published tests within an API Hook's scope that match the tags specified in the request body.
- [Run Published Test By ID](#)
Run a specified test within an API Hook's scope.

List All Tests

Description

The List All Tests endpoint lists all of the published tests within an API Hook's scope.

HTTP Request

```
GET <API-Hook-URL>/tests
```

Sample Method Invocation

```
curl -X GET \  
-H X-API-Key: {API-Key} \  
-H X-API-Secret: {API-Secret} \  
-H X-API-URL: {API-URL}
```

<API-Hook-URL>/tests

Parameters	Header Parameters API-Key: A valid API Key for the Test Organization this API Hook belongs to. API-Secret: A valid API Secret for the Test Organization this API Hook belongs to.
Response Content	MIME type: application/json <pre>[{ testId: string, testName: string, testDescription: string, lastModified: string, authorName: string, tags: array[string] }]</pre> Response Description <ul style="list-style-type: none">• testId<ul style="list-style-type: none">◦ ID of the test.• testName<ul style="list-style-type: none">◦ Name of the test.• testDescription<ul style="list-style-type: none">◦ Description of the test.• lastModified<ul style="list-style-type: none">◦ Date and time the test was last modified.• authorName<ul style="list-style-type: none">◦ User who composed the test.• tags<ul style="list-style-type: none">◦ Array of tags associated with the test.
Status Codes	200: Success 400: Missing Authorization Headers 401: Invalid Authorization Headers

Run All Published Tests

Description

The Run All Tests endpoint executes all of the published tests within an API Hook's scope.

HTTP Request

POST <API-Hook-URL>/tests/run

Sample Method Invocation

```
curl -X POST \  
-H X-API-Key:{API-Key} \  
-H X-API-Secret:{API-Secret} \  
-H Content-Type:application/json \  
-d "  
  {

<API-Hook-URL>/tests/run
```

Parameters	<p>Header Parameters</p> <p>API-Key: A valid API Key, for the Test Organization this API Hook belongs to. API-Secret: A valid API Secret for the Test Organization this API Hook belongs to.</p>
Request Body	<p>MIME type: application/json</p> <pre>{ options: { allAssertions: boolean, JUnitFormat: boolean }, variables: { string: string, } }</pre> <p>Body Parameters</p> <ul style="list-style-type: none"> • options (Only required if providing a child element) <ul style="list-style-type: none"> ◦ A wrapper object for the containing options on how what data should be returned in the response, or how the response should be formatted. ◦ Child Elements: <ul style="list-style-type: none"> ▪ allAssertions (Optional) <ul style="list-style-type: none"> ▪ When false, only the results of failing assertions in the test are returned. When true, all assertions in the test are returned. allAssertions is false by default. ▪ JUnitFormat (Optional) <ul style="list-style-type: none"> ▪ When false, application/json format is returned for the test results. When true, text/xml JUnit format is used for the test results (see text/xml response). JUnitFormat is false by default. • variables (Optional) <ul style="list-style-type: none"> ◦ The variables section is used to pass a list of named variables and their values into the tests being run. It is only used by tests that have been written to make use of variables, and have values stored alongside them. Declaring the variable name as the object key, and its new value as the key's value (as type string), will overwrite the current value of the variable in the test which shares its name with the object key.
Response Content	<p>MIME type: application/json</p> <p>application/json is the default response from the endpoint.</p> <pre>[{ testRunId: string, testId: string, testName: string, location: string, initiated: string, duration: integer, status: enum['passed' or 'failed'], reportUrl: string, results: { warningsCount: integer, failureCount: integer, httpFailures: array[object], criticalFailures: array[object], assertions: array[object] } }]</pre> <p>Response Description</p> <ul style="list-style-type: none"> • testRunID <ul style="list-style-type: none"> ◦ ID of the test run. • testId <ul style="list-style-type: none"> ◦ ID of the test which was executed. • testName <ul style="list-style-type: none"> ◦ Name of the test. • location <ul style="list-style-type: none"> ◦ Location of the agent which executed the test. • initiated <ul style="list-style-type: none"> ◦ Date and time when the test was initiated. • duration <ul style="list-style-type: none"> ◦ Total duration of the test run in seconds. • status <ul style="list-style-type: none"> ◦ Overall result of the test. • reportUrl

- URL to the test run report.
- **results**
 - A wrapper object containing the results of the test run.
 - Child Elements:
 - **warningsCount**
 - Count of the HTTP warnings returned by the test assertions.
 - **failureCount**
 - Count of the HTTP status code responses that are greater than 400.
 - **httpFailures**
 - Description of failures whose HTTP Status response code is greater than or equal to 400.
 - **criticalFailures**
 - Description of failures whose HTTP Status response code is greater than or equal to 500.
 - **assertions**
 - A description of the assertions executed in the test. By default, only failing assertions will be listed.

MIME type: text/xml

To receive a **text/xml** response, the optional **JUnitFormat** variable in the request body must be set to **true**. JUnit responses can be useful when you wish to incorporate your test results with a build pipeline such as Jenkins, via the [JUnit plugin](#).

```
<?xml version="1.0" encoding="UTF-8"?>
<testSuite name="" tests="" disabled="" errors="" failures="" timestamp="" time="">
<testcase name="" classname="" time="">
  <failure message="" type="" />
</testcase>
</testSuite>
```

Response Description

- **<testSuite>**
 - Child Elements: **<testCase>**
 - Attributes:
 - **name**
 - Test Suite name.
 - **tests**
 - Number of published tests ran.
 - **disabled**
 - Number of disabled tests.
 - **errors**
 - Number of errors.
 - **failures**
 - Number of tests within the test suite that failed.
 - **timestamp**
 - Date and time the tests were ran.
 - **time**
 - Total duration of all test runs in seconds.
- **<testCase>**
 - Child Elements: **<failure>**
 - Attributes:
 - **name**
 - Test name.
 - **classname**
 - ID of the test which was executed.
 - **time**
 - Total duration of the test run in seconds.
- **<failure>**
 - Attributes:
 - **message**
 - Failure message containing the expected and actual response.
 - **type**
 - Type of failure.

Run Published Tests By Tag

Description

The Run Published Test By Tag endpoint executes all of the published tests within an API Hook's scope that match the tags specified in the request body. See [Tagging a Test](#) for more information on how to tag a test.

HTTP Request

```
POST <API-Hook-URL>/tests/run/tag
```

Sample Method Invocation

```
curl -X POST \  
-H X-API-Key:{API-Key} \  
-H X-API-Secret:{API-Secret} \  
-H Content-Type:application/json \  
-d "  
  {  
    "options": {  
      "allAssertions": boolean,  
      "JUnitFormat": boolean  
    },  
    "variables": {  
      string: string,  
    },  
    "tags": {  
      "tagList": array[string],  
      "operator": enum['not' or 'and' or 'or']  
    }  
  }  
" \  
<API-Hook-URL>/tests/run/tag
```

Parameters	Header Parameters API-Key: A valid API Key for the Test Organization this API Hook belongs to. API-Secret: A valid API Secret for the Test Organization this API Hook belongs to.
Request Body	MIME type: application/json <pre>{ options: { allAssertions: boolean, JUnitFormat: boolean }, variables: { string: string, }, tags: { tagList: array[string], operator: enum['not' or 'and' or 'or'] } }</pre> Body Parameters <ul style="list-style-type: none">• options (Only required if providing a child element)<ul style="list-style-type: none">◦ A wrapper object for the containing options on how what data should be returned in the response, or how the response should be formatted.◦ Child Elements:<ul style="list-style-type: none">▪ allAssertions (Optional)<ul style="list-style-type: none">▪ When false, only the results of failing assertions in the test are returned. When true, all assertions in the test are returned. allAssertions is false by default.▪ JUnitFormat (Optional)<ul style="list-style-type: none">▪ When false, application/json format is returned for the test results. When true, text/xml JUnit format is used for the test results (see text/xml response). JUnitFormat is false by default.• variables (Optional)<ul style="list-style-type: none">◦ The variables section is used to pass a list of named variables and their values into the tests being run. It is only used by tests that have been written to make use of variables, and have values stored alongside them. Declaring the variable name as the object key, and its new value as the key's value (as type string), will overwrite the current value of the variable in the test which shares its name with the object key.• tags (Required)<ul style="list-style-type: none">◦ A wrapper object containing both the list of tags and the operator to use on them.◦ Child Elements:

- **tagList** (Required)
 - The list of tags which correspond to the tests you want to execute or ignore (see **operator** element).
- **operator** (Required)
 - The operator indicates how to treat the list of tags and can be either one of three values: **not**, **and**, **or**.
 - The **not** operator will omit executing any test within the API Hook's scope that has been tagged with a tag listed in the **tagList**.
 - The **and** operator will include any test within the API Hook's scope that has been tagged with all the tags provided in the **tagList**.
 - The **or** operator will include any test within the API Hook's scope that has been tagged with at least one of the tags provided in the **tagList**.

Response Content

MIME type: application/json

`application/json` is the default response from the endpoint.

```
[
  {
    testRunId: string,
    testId: string,
    testName: string,
    location: string,
    initiated: string,
    duration: integer,
    status: enum['passed' or 'failed'],
    reportUrl: string,
    results: {
      warningsCount: integer,
      failureCount: integer,
      httpFailures: array[object],
      criticalFailures: array[object],
      assertions: array[object]
    }
  }
]
```

Response Description

- **testRunID**
 - ID of the test run.
- **testId**
 - ID of the test which was executed.
- **testName**
 - Name of the test.
- **location**
 - Location of the agent which executed the test.
- **initiated**
 - Date and time when the test was initiated.
- **duration**
 - Total duration of the test run in seconds.
- **status**
 - Overall result of the test.
- **reportUrl**
 - URL to the test run report.
- **results**
 - A wrapper object containing the results of the test run.
 - Child Elements:
 - **warningsCount**
 - Count of the HTTP warnings returned by the test assertions.
 - **failureCount**
 - Count of the HTTP status code responses that are greater than 400.
 - **httpFailures**
 - Description of failures whose HTTP Status response code is greater than or equal to 400.
 - **criticalFailures**
 - Description of failures whose HTTP Status response code is greater than or equal to 500.
 - **assertions**
 - A description of the assertions executed in the test. By default, only failing assertions will be listed.

MIME type: text/xml

To receive a `text/xml` response, the optional `JUnitFormat` variable in the request body must be set to `true`. JUnit responses can be useful when you wish to incorporate your test results with a build pipeline such as Jenkins, via the [JUnit plugin](#).

```
<?xml version="1.0" encoding="UTF-8"?>
<testSuite name="" tests="" disabled="" errors="" failures="" timestamp="" time="">
<testcase name="" classname="" time="">
  <failure message="" type="" />
</testcase>
</testSuite>
```

```
</testcase>
</testSuite>
```

Response Description

- **<testSuite>**
 - Child Elements: **<testCase>**
 - Attributes:
 - **name**
 - Test Suite name.
 - **tests**
 - Number of published tests ran.
 - **disabled**
 - Number of disabled tests.
 - **errors**
 - Number of errors.
 - **failures**
 - Number of tests within the test suite that failed.
 - **timestamp**
 - Date and time the tests were ran.
 - **time**
 - Total duration of all test runs in seconds.
- **<testCase>**
 - Child Elements: **<failure>**
 - Attributes:
 - **name**
 - Test name.
 - **classname**
 - ID of the test which was executed.
 - **time**
 - Total duration of the test run in seconds.
- **<failure>**
 - Attributes:
 - **message**
 - Failure message containing the expected and actual response.
 - **type**
 - Type of failure.

Status Codes 200: Success
400: Missing Authorization Headers
401: Invalid Authorization Headers

Run Published Test By ID

Description

The Run Published Test By ID endpoint executes a single specified test within an API Hook's scope.

HTTP Request

```
POST <API-Hook-URL>/tests/{Test-ID}/run
```

Sample Method Invocation

```
curl -X POST \  
-H X-API-Key:{API-Key} \  
-H X-API-Secret:{API-Secret} \  
-H Content-Type:application/json \  
-d "  
  {  
    "options": {  
      "allAssertions": boolean,  
      "JUnitFormat": boolean  
    },  
    "variables": {  
      string: string,  
    }  
  }  
"
```

```
" \
<API-Hook-URL>/tests/{Test-ID}/run
```

Parameters	Path Parameters Test-ID: The ID of the Test to execute. Header Parameters API-Key: A valid API Key , for the Test Organization this API Hook belongs to. API-Secret: A valid API Secret for the Test Organization this API Hook belongs to.
Request Body	MIME type: application/json <pre>{ options: { allAssertions: boolean, JUnitFormat: boolean }, variables: { string: string, } }</pre> Body Parameters <ul style="list-style-type: none">• options (Only required if providing a child element)<ul style="list-style-type: none">◦ A wrapper object for the containing options on how what data should be returned in the response, or how the response should be formatted.◦ Child Elements:<ul style="list-style-type: none">▪ allAssertions (Optional)<ul style="list-style-type: none">▪ When false, only the results of failing assertions in the test are returned. When true, all assertions in the test are returned. allAssertions is false by default.▪ JUnitFormat (Optional)<ul style="list-style-type: none">▪ When false, application/json format is returned for the test results.  - **failureCount**
 - Count of the HTTP status code responses that are greater than 400.
 - **httpFailures**
 - Description of failures whose HTTP Status response code is greater than or equal to 400.
 - **criticalFailures**
 - Description of failures whose HTTP Status response code is greater than or equal to 500.
 - **assertions**
 - A description of the assertions executed in the test. By default, only failing assertions will be listed.

MIME type: text/xml

To receive a `text/xml` response, the optional `JUnitFormat` variable in the request body must be set to `true`. JUnit responses can be useful when you wish to incorporate your test results with a build pipeline such as Jenkins, via the [JUnit plugin](#).

```
<?xml version="1.0" encoding="UTF-8"?>
<testSuite name="" tests="" disabled="" errors="" failures="" timestamp="" time="">
<testcase name="" classname="" time="">
  <failure message="" type="" />
</testcase>
</testSuite>
```

Response Description

- **<testSuite>**
 - Child Elements: **<testCase>**
 - Attributes:
 - **name**
 - Test Suite name.
 - **tests**
 - Number of published tests ran.
 - **disabled**
 - Number of disabled tests.
 - **errors**
 - Number of errors.
 - **failures**
 - Number of tests within the test suite that failed.
 - **timestamp**
 - Date and time the tests were ran.
 - **time**
 - Total duration of all test runs in seconds.
- **<testCase>**
 - Child Elements: **<failure>**
 - Attributes:
 - **name**
 - Test name.
 - **classname**
 - ID of the test which was executed.
 - **time**
 - Total duration of the test run in seconds.
- **<failure>**
 - Attributes:
 - **message**
 - Failure message containing the expected and actual response.
 - **type**
 - Type of failure.

Status Codes 200: Success

- [Tutorial: Linking requests using variables](#)

Tutorial: Invoking test cases from Jenkins with JUnit result format

Before you begin

You must have the Automated API behavior testing application enabled and have created and published at least one test. You must have a Jenkins instance that you can create a new build in with the [JUnit Plugin](#) installed

About this tutorial

In this tutorial, you invoke a test case using injected variables from a Jenkins pipeline

This tutorial takes you through the following steps

1. Creating an API Hook
2. Creating an API Key and Secret
3. Creating a Jenkins build that invokes the API Hook
4. Executing the build and reviewing the test results

Creating an API Hook

You can generate an API hook for each of the Test Suites within your Test Organization. API hooks are scoped to only one test suite and thus will only have access to operate on the data within that test suite; that is, if an API Hook is generated for **Test Suite 1**, it grants access only to the tests within **Test Suite 1**. If you wish to interact with tests in multiple test suites, you will need to generate an API hook for each Test Suite.

How to create an API Hook

1. Navigate to the Test Organization settings page by clicking the **Cog** icon in the menu bar.

2. Within the Test Organization settings page, click the **Hooks** option under the API Hooks heading in the navigation menu.

<Test Organization Name> Settings

All changes saved.

API Hooks

- HOOKS
- KEYS

Test Organization

Test organization global settings. Hit "Save changes" to make your changes effective.

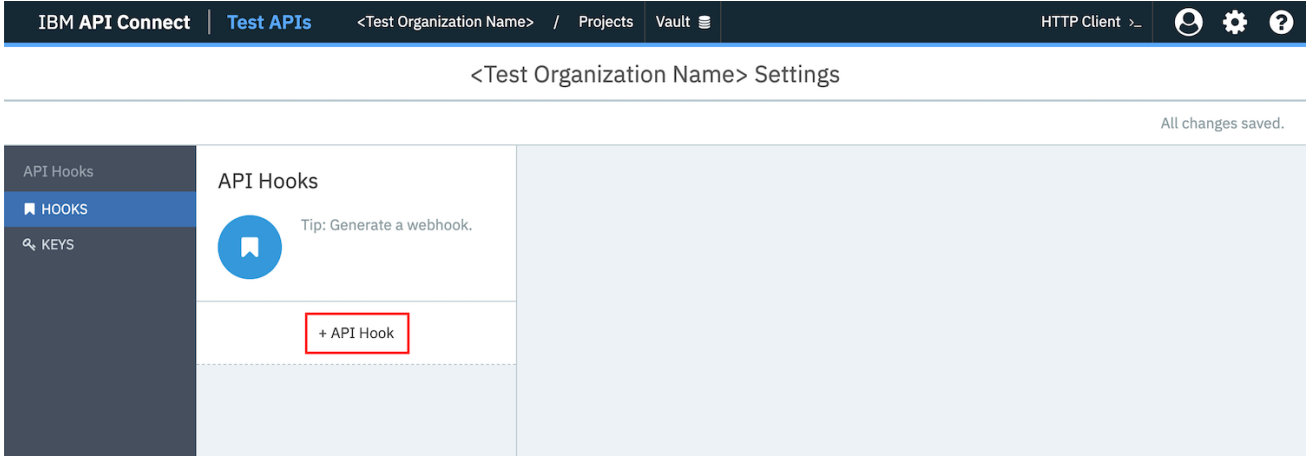

Test Organization Name:

<Test Organization Name>

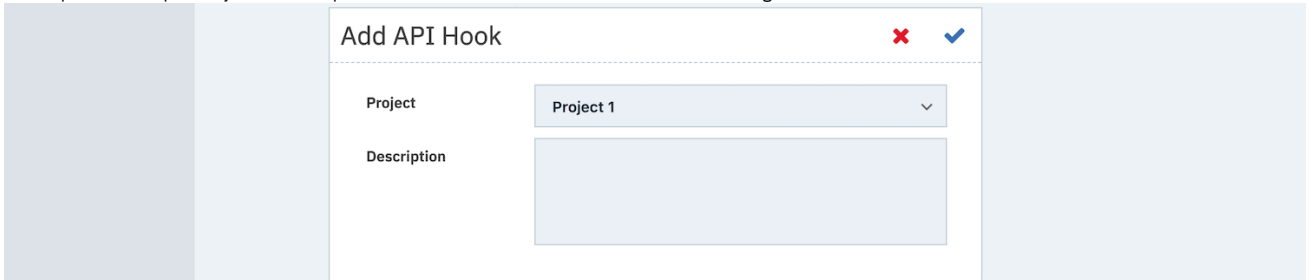

Time Zone: ?

UTC

3. Now click on the **+ API Hook** button to begin creating a new API Hook.

4. Because API Hooks are scoped at a Test Suite level, you will need to select the test suite you wish to generate the hook for. Choose the appropriate test suite from the dropdown and optionally add a description for the API Hook. Click the **confirm**  icon to generate and save the API Hook.

5. The API Hook URL has been created for your Test Suite. Make a note of this URL as this will form the base path of all future API requests you make for the test suite.

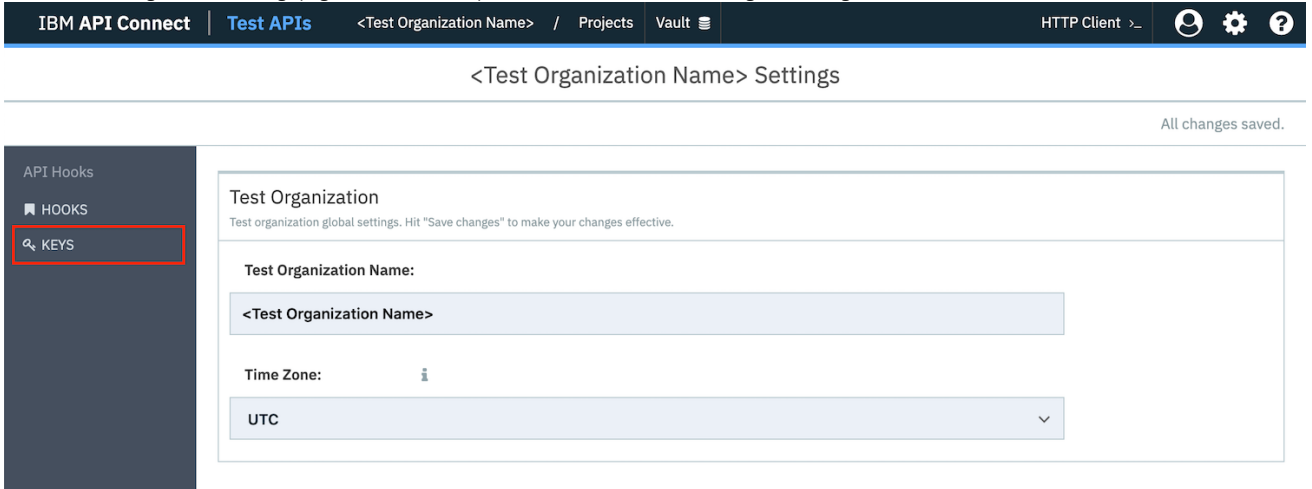

Creating an API Key and Secret

API Keys and Secrets are the credentials required to use an [API Hook](#). For a request to an API Hook to be authorised, both the **X-API-Key** and **X-API-Secret** headers must be provided. The values of the API Key and Secret represent the values of these headers respectively.

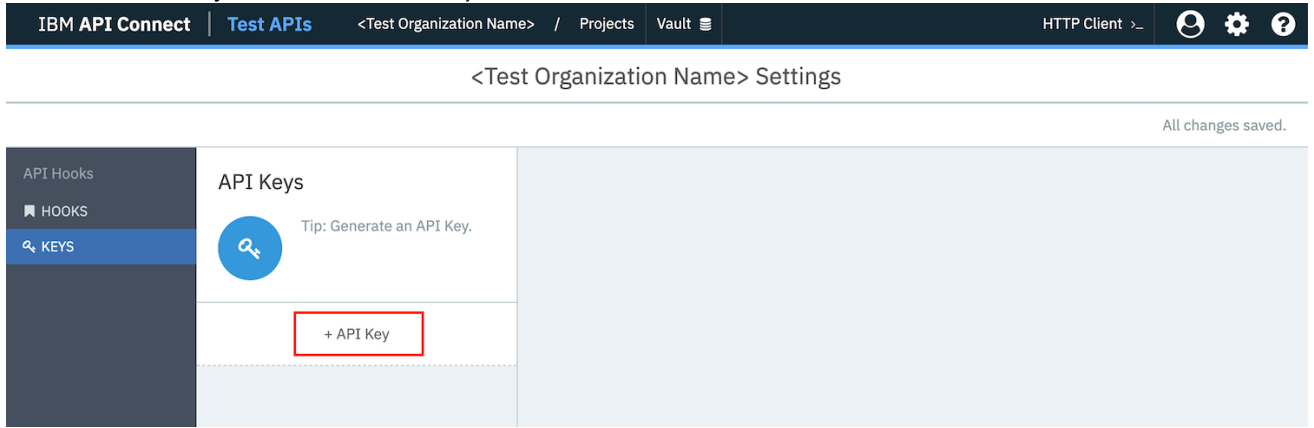

1. First navigate to the Test Organization settings page by clicking the **Cog** icon in the menu bar.

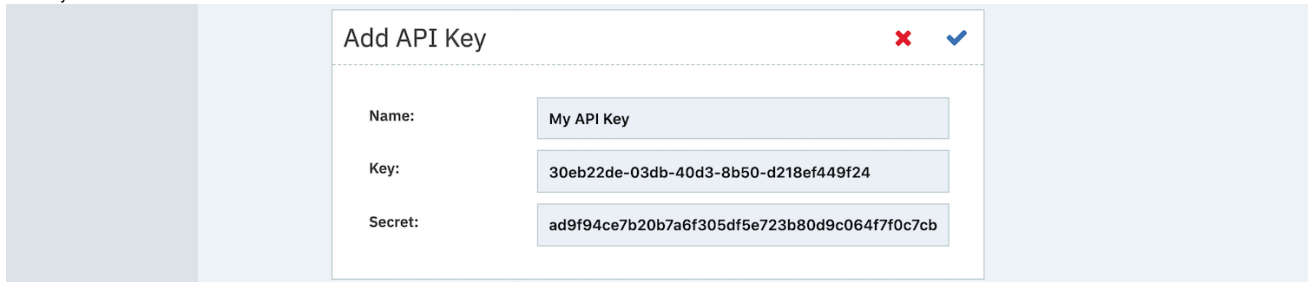

2. Within the Test Organization settings page, click the **KEYS** option under the API Hooks heading in the navigation menu.

3. Now click on the **+ API Key** button to create a new API Key.

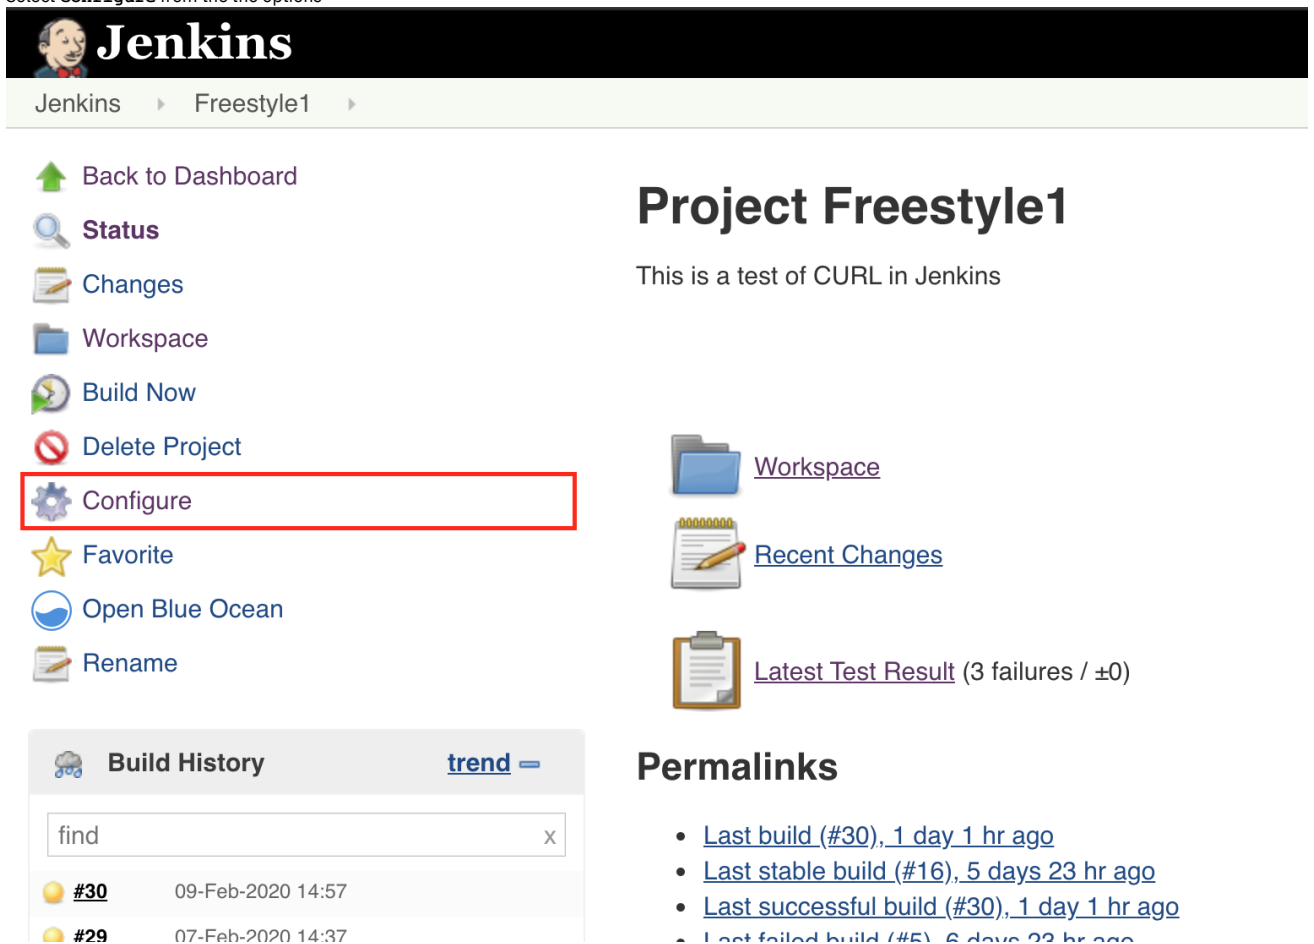

4. You will then be shown the generated **Key** and **Secret**. Make a note of both of these, ensure the **Secret** is noted as it cannot be retrieved in the future. Give your new API Key a name and then click the **confirm** icon to save it.

Creating a Jenkins build that invokes the API Hook

1. Create a Jenkins Project or navigate to an existing one
2. Select **Configure** from the the options

- Under **Build**, click **Add build step** dropdown and select **Execute Shell**

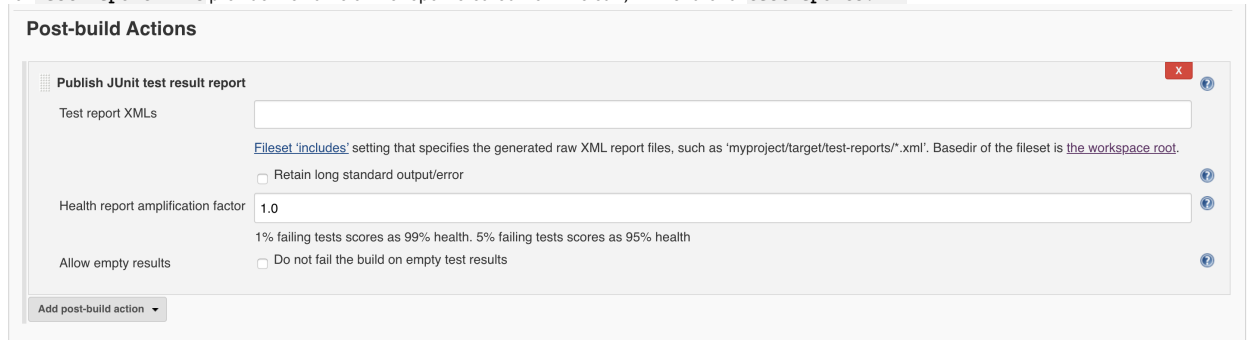

- Within the **Execute shell** block paste a **curl** command that will invoke the hook that was created in step 1

```
curl -XPOST
-H 'x-api-key: <API-KEY>'
-H 'x-api-secret: <API-SECRET>'
-H "Content-type: application/json"
-d '{ options: { JUnitFormat: true } }'
'<API-HOOK-URL>/tests/run'
>| testReports.xml
```

- Under **Post-build Actions**, click **Add post-build action** and in the dropdown select **Publish JUnit test results report**.

- For **Test report XMLs** provide the name of the report created from the curl, in this tutorial **testReports.xml**

- Save the project

Executing the build and reviewing the test results

1. Click **Build Now** on the project

Jenkins

Jenkins > Freestyle1 >

- Back to Dashboard
- Status
- Changes
- Workspace
- Build Now**
- Delete Project
- Configure
- Favorite
- Open Blue Ocean
- Rename

To expand upon this tutorial additional options and steps can be found under [Using API Hooks](#)

What you did in this tutorial

In this tutorial you completed the following activities:

- Created a API Hook
- Created a Key and Secret used for authenticating with a hook
- Invoked the API Hook using the Key and Secret to start a test and process the results

Tutorial: Using variables within a test

About this tutorial

In this tutorial, you will create a test case that uses both a variable defined in a dataset and define and use one within the test itself.

This tutorial will take you through the following testReports

1. Create a test using the HTTP Client
2. Modifying variables within data sets
3. Defining your own variable
4. Adding a new request to your test using the HTTP Client
5. Linking the requests with the variables

Creating a test with the HTTP Client

Using the HTTP Client it is possible to take the request and response and create a test case from these parts. The HTTP Client is accessible from either the top navigation bar or from inside a test case.

NOTE: test cases generated from the HTTP Client have no association with any specification document for the API that is being invoked, as such some details may be incorrect within the test case such as whether a given field is required or not.

Making the request in the HTTP Client

1. Go to the HTTP client using the Link
2. For the URL enter `https://<API Test hostname>/apitest/api/exmaples/retail/products`, this is an unauthenticated **GET** request, as such no additional values are required
3. Click **Send**

4. Once the response has returned you should see this:

The screenshot shows an API client interface. At the top, there are buttons for 'Save', 'Generate Test', and 'Import'. Below that, the request details are shown: Method 'GET', URL 'https://hub.atm-test.ibm.com/apitest/api/examples/retail/products', and buttons for 'Params', 'Send', and 'Clear'. The 'Response' section is expanded, showing a JSON body:

```
{
  "success": true,
  "status": 200,
  "content": {
    "act": "list",
    "products": [
      511,
      611,
      711
    ]
  }
}
```

 The status bar indicates 'HTTP Code: 200', 'Latency: 35', 'Fetch: 188', and 'Total Time: 223'.

5. Click **Generate Test**

6. Provide a Test name and either add a new Test Suite or select an existing one

The 'Generate Test' dialog box has a title bar with a red 'X' and a blue checkmark. It contains two main sections. The first section is labeled 'Name' and has a text input field containing 'Retail Products'. The second section is labeled 'Save to Test Suite' and has a dropdown menu with 'Create new test suite' selected. Below the dropdown, there is a list of existing test suites, with 'Retail Examples' visible.

7. Click save

This will automatically generate a test case based on your request and you should have a **GET** request with a number of assertions

Modifying variables within a Data sets

Having generated the test, you will see that the request will have a URL target of `$(endpointURL)` this is defined within the Global variables under Data Sets  Image of datasets

In cases of tests generated tests, the value of `endpointURL` is the complete URL that we called, however if we want to call other paths on that endpoint we will need to modify it so we can reuse it in cases where call a different URL

This is what we will have from the generated test from the previous step:

The endpoint currently uses the full path of `https://<API Test hostname>/apitest/api/exmaples/retail/products`, but later I will make a call to a different resource to `products`, so I want to trim this to make it more reusable

1. Selecting Edit variable on `endpointURL`

2. Update the value to be `https://<API Test hostname>/apitest/api/exmaples/retail`
3. Click **Save**

As we have updated the value of the input, we now need to fix the request as it will be missing `/products` from the endpoint

1. Click **Edit** on the **GET** Request
2. Add `/products` after the `${endpointURL}`
3. Click save

Have made the updates we can check the test is still valid by clicking  image of Run Test

and we should get the payload of

```
{
  "success": true,
  "status": 200,
  "content": {
    "act": "list",
    "products": [
      511,
      611,
      711
    ]
  }
}
```

Defining your own variable

The next step is to dig into the details of an individual product, based on one of the products ID we get back from `/products`

The IDs are process within the test case within the `For each loop` and accessible as `_1`, if we wanted to grab the `status` value we would to it in the way that assertion refers to it `payload.status`

1. Click **Add Components**

2. Click **Set (variable)**

Set (variable)

3. Provide the name of variables such as `productID`
4. Due to the processing the above values are treated as `floats`, but for the next call we need an integer a. Select **Language** for Mode b. Within **Content** provide the following groovy script `return Math.round(_1)` - this converts the float to an into
5. Move Set Variable to within the For Each loop

Adding a New request to an existing test with the HTTP client

Once you are in the Test Editor there are two ways to add a new request, either adding one from the list of components or by making or loading a request within the client within the test Editor

for this tutorial we will perform the request in client inside the test

1. Click HTTP Client icon

HTTP Client

2. In the URL field enter `https://<API Test hostname>/apitest/api/exmaples/retail/product?id=711`
3. Click **Send**
4. Click **Generate Test**

5. Click **Continue** on each screen and finally **close** - generation of endpointURL variable will fail as it already exists, this is to be expected
6. Edit the URL value in the new request to be `${endpointURL}/product`
7. Edit the Query Parameters **ID** reference variable to be the one we created in the previous stage `productID`
8. Click 

You have now completed a linked set of requests, to check that this is running correctly you can now run the test and check the request to see what parameter value was used

	GET get https://hub.atm-test-master.fyre.ibm.com/apitest/api/examples/retail/product?id=711
Latency: 25ms	Download: 24ms
STATUS: 200	
See Request	

Testing an API with the Policies editor

IBM® API Connect provides a basic test environment in the Policies editor so that you can ensure that your APIs are defined and implemented correctly.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note:

- If you are testing an OpenAPI 2.0 API, you can use either the Policies editor test tool described here, or you can use the Test tab. If you are testing an OpenAPI 3.0 API, only the Test tab is available; see [Using the Test tab to debug your API](#).
- If you are testing an API that contains references to API properties, only those references that are defined inside the API assembly are resolved and replaced with their corresponding values when you invoke the API in the assembly test tool; property references that are defined outside of the API assembly are not resolved. For more information on API properties, see [Setting API properties](#) (OpenAPI 2.0) or [Setting API properties](#) (OpenAPI 3.0).
- Due to Cross-Origin Resource Sharing (CORS) restrictions, the assembly test tool cannot be used with the Chrome or Safari browsers on the macOS Catalina platform.

Procedure

To test an API, complete the following steps.

1. If you are using API Designer, set the mode to Online using the Options menu  on the main page.
2. In the navigation pane, click  Develop, then select the APIs tab.
3. Click the title of the API that you want to work with.
4. Click the Gateway tab then, in the navigation pane, click Policies.
5. If you are testing the API for the first time and, when you created the API definition, you selected the Activate API option, your test setup will already be configured and you can proceed immediately to the next step to test your API. Otherwise, click Offline to toggle the API to the Online state. If you are retesting your API after making changes, the modified API will have been republished automatically on saving.
6. Click the Test icon .

Note:

 - The Test icon is active only if you have toggled your API to the Online state, as described in step 5.
 - The Catalog, Product, Plan, and application details displayed in the Setup pane reflect your configured API testing preferences; see [Specifying the testing preferences for an API](#).
7. In the Operation section, select the API operation that you want to test, then click Invoke.
The API response is displayed in the Response section.
Note: If you receive a message relating to an untrusted certificate, click the link provided, accept the certificate, then return to the test environment and click Invoke again. The message also mentions a lack of CORS support on the server, but this is just one possible cause for the connection failing.

Testing an API with the Local Test Environment

Use the Local Test Environment to test APIs on your local machine, without the need to connect to an API Connect management server. The Local Test Environment is a lightweight API Manager running on your local machine. It allows you to rapidly test APIs locally.

API Connect provides the following methods for testing an API on your local machine:

- Invoke the API from the API Designer UI application running in Online mode as described in [Testing an API](#).
- Call the API in the Local Test Environment with a cURL command, as described in the following sections.

Prerequisites

- The API Connect developer toolkit, including the API Designer user interface, installed. For installation and running instructions, see [Installing the toolkit](#).
- The Local Test Environment and the API Designer must be from the same API Connect fix pack release in order for them to work together.
- Docker installed.
Note: The Local Test Environment is not supported with Docker Version 18.09.x.
- A minimum of 4 GB of RAM available to Docker if a single gateway type is used, or 6 GB if both the DataPower® API Gateway and DataPower Gateway (v5 compatible) are used.
Note: As you increase the number of APIs that are published to your gateways, you will need to allocate further memory to Docker. You will also need to start the Local Test Environment with a larger database; see [apic-lte start](#).
- If you are using Windows, ensure that your C: drive (or the drive on which your HOME directory is located, if different), is enabled as a shared drive so that the Local Test Environment files are accessible to the Docker containers.

Installing the Local Test Environment

There are two options for installing the Local Test Environment:

- Each user downloads the Local Test Environment images to their local machine and installs the Local Test Environment from there.
- One user downloads the Local Test Environment images and uploads them to a private Docker registry, from where any user can install the Local Test Environment.

To install the Local Test Environment from your local machine, complete the following steps:

1. Open a browser and visit the [API Connect announcement page](#), search for your product version, and locate the "Downloads" table on the product announcement page. In the table, click the link to download each of the following files:
 - `apic-lte-images-version.tar.gz`, which contains all required Docker images.
Example: `apic-lte-images-10.0.2.tar.gz`
 - `apic-lte-platform-version`, which are binary files for the Mac OS X, Linux®, and Windows platforms.
Examples:
 - Mac OS X: `apic-lte-osx-10.0.2`
 - Linux: `apic-lte-linux-10.0.2`
 - Windows: `apic-lte-win-10.0.2`
2. On the Mac OS X or Linux platform, use the `chmod` command to make the binary file executable; for example:

```
chmod +x linux-apic-lte
```

3. Load the Docker images into your local Docker image repository by entering the following command:

```
docker load < apic-lte-images.tar.gz
```

Note: In all Local Test Environment commands that are used on the remainder of this page, replace *platform* with **osx**, **linux**, or **windows**, depending on your platform, as follows:

- Mac OS X: replace **platform-apic-lte** with **osx-apic-lte**
- Linux: replace **platform-apic-lte** with **linux-apic-lte**
- Windows: replace **platform-apic-lte** with **win-apic-lte**

To upload the Local Test Environment images to a private Docker registry, complete the following steps:

1. Download the **IBM_API_CONNECT_LOCAL_TEST_ENVIRO.zip** file as described in step 1.
2. Distribute the appropriate binary file to all users, according to the platform.
3. Upload the Local Test Environment to your private Docker registry; enter the following command:

```
platform-apic-lte registry-upload apic-lte-images.tar.gz registry_host
```

where *registry_host* is the host name or IP address of your private Docker registry. Now, any user can install and run the Local Test Environment as follows:

- a. If the private Docker registry requires authentication, log in by entering the following command:

```
docker login registry_host
```

- b. Load the Docker images into your local Docker image repository by entering the following command:

```
platform-apic-lte init registry_host
```

Starting the Local Test Environment

1. Start the Docker images by entering the following command:

```
platform-apic-lte start
```

Note:

- By default, the **platform-apic-lte start** command starts only a DataPower API Gateway. To also start a DataPower Gateway (v5 compatible), enter the following command:

```
platform-apic-lte start --datapower-gateway-enabled --datapower-api-gateway-enabled
```

- The Local Test Environment might fail to start with an error message that includes the strings **Error: certificate is not yet valid** and **CERT_NOT_YET_VALID**. The most likely cause is that the date and time setting is incorrect on the machine that is running the Local Test Environment. Ensure that the date and time setting is correct, before attempting the start command again. If you are using Docker for Windows, the clock in the Docker containers can become out of sync with the system clock, especially after a machine has been put in sleep mode. In this case, restarting Docker should fix the clock discrepancy; for more information, see <https://github.com/docker-for-win/issues/4526>.
- By default, the LTE starts with an empty backend database that does not contain the APIs and Products that might have been published during an earlier run of the LTE. To start the LTE with the backend database that was used during the previous run, use the flag **--keep-config**, for example, **platform-apic-lte start --keep-config**. When you use **--keep-config** any other flag that is specified for the start is ignored. Instead the same flags that were used during the earlier start are used, in particular the same gateways are enabled.

2. Verify that the Local Test Environment is installed and running correctly by entering the following commands:

- a. **platform-apic-lte status**

This output from this command shows the status of all components, and provides endpoint and authentication details, and should be similar to the following:

```
Container          Status
-----
apic-lte-apim      Up 3 minutes
apic-lte-datapower-gateway Not Running
apic-lte-datapower-api-gateway Up 2 minutes
apic-lte-db        Up 3 minutes
apic-lte-juhu      Up 3 minutes
apic-lte-lur       Up 3 minutes

- Platform API url: https://localhost:2000
- Admin user: username=admin, password=7iron-hide
- 'localtest' org owner: username=shavon, password=7iron-hide
- 'localtest' org sandbox test app credentials client id: 80963e74076afe50d346d76401c3c08a
- Datapower API Gateway API base url: https://localhost:9444/localtest/sandbox/
```

- b. **apic login --server localhost:2000 --username shavon --password 7iron-hide --realm provider/default-idp-2**

This command confirms that you can log in to the management server, and the response should be as follows:

```
Logged into localhost:2000 successfully
```

Note: If you have previously installed toolkit credentials, as detailed in [Installing the toolkit](#), attempting to log in to the Local Test Environment management server from the toolkit CLI will fail; you must first clear the credentials by using the following command:

```
apic client-creds:clear
```

The toolkit CLI will now use the default credentials for login to the toolkit Local Test Environment. If you subsequently log in to a management server in an API Connect cloud, the default toolkit credentials will also be used, rather than the credentials that are unique to that deployment. To use the unique credentials, re-install them by using the following command:

```
apic client-creds:set toolkit_credentials_file_path/credentials.json
```

where *credentials_file_path* is the location of the previously downloaded toolkit credentials JSON file. To determine whether you currently have any toolkit credentials installed, use the following command:

Preparing an API for testing in the Local Test Environment

To prepare an API for testing in the Local Test Environment, you must publish it to the Sandbox Catalog in the Local Test Environment. If you want to test an API that you already published, proceed to [Testing an API in the Local Test Environment](#), otherwise, complete the following steps:

1. Launch the API Designer user interface.
2. Open the required local directory; this is the directory in which your API and Product definition files will be stored.
3. Connect to the Local Test Environment. If you haven't previously connected to the Local Test Environment, click Add Another Cloud, then complete the following steps:
 - a. In the HOST URL field, enter `https://localhost:2000`, then click Next.
 - b. In the Username field, enter `shavon`, in the Password field enter `7iron-hide`, then click Sign in.

Note: If you are not able to connect to the Local Test Environment using `http://localhost:2000`, enter `http://127.0.0.1:2000` instead in the HOST URL field.

If you have previously connected to the Local Test Environment, click the existing tile to log in immediately.

The API Designer welcome page opens.

4. Click Develop APIs and Products, then click the API that you want to test. For details on how to configure an API definition, see [Developing your APIs and applications](#).
5. Move the activation slider control to the on position:

When the publish operation completes, your API is ready for testing.

Note: Whenever you make any changes to an API, you must republish it before retesting.

Testing an API in the Local Test Environment.

To test an API in the Local Test Environment, issue a REST API call to the following URL:

```
https://localhost:9444/localtest/sandbox/basepath/operation_path?client_id=lte_client_id
```

where:

- `basepath` is the base path that is configured in the API definition.
- `operation_path` is the path for the operation that you want to invoke, as configured in the API definition.
- `lte_client_id` is the client ID for the test application in the local test environment, as returned by the `platform-apic-lte status` command in step 2.

The following example show how to test the API that is created in the tutorial [Creating a proxy REST API definition](#), by using the `curl` utility; the API returns the details of bank branches:

```
curl -k https://localhost:9444/localtest/sandbox/branches/details?client_id=80963e74076afe50d346d76401c3c08a

```

Local Test Environment commands

The following table summarizes the Local Test Environment commands; use the `help` command to get full usage details for any command.

Table 1. Local Test Environment command summary

Command	Description
<code>platform-apic-lte help command</code>	Display help information for any command.
<code>platform-apic-lte init</code>	Download the Local Test Environment Docker images.
<code>platform-apic-lte start</code>	Start the Local Test Environment Docker images. Use the <code>--database-max-heap-size</code> parameter to set the size of the Local Test Environment database, in bytes; for example: <pre>linux-apic-lte start --database-max-heap-size 4096M linux-apic-lte start --database-max-heap-size 1G linux-apic-lte start --database-max-heap-size 1048576K linux-apic-lte start --database-max-heap-size 1073741824</pre> <p>The default value is 1024M.</p> <p>Tip: By default, the <code>platform-apic-lte start</code> command deletes all previous data and re-initializes the Local Test Environment configuration, so all your previous configuration, including published Products, is deleted. To retain the previous configuration, and to apply the same command parameters that were used in the previous <code>platform-apic-lte start</code> command, supply the <code>--keep-config</code> parameter.</p>

Command	Description
<code>platform-apic-lte status</code>	Display status information for the Local Test Environment components, and endpoint and authentication details.
<code>platform-apic-lte stop</code>	Stop the Local Test Environment Docker images.
<code>platform-apic-lte version</code>	Display Local Test Environment version information.

Troubleshooting the Local Test Environment

You can consult the log file for each Local Test Environment microservice or database by using the following command:

```
docker logs container-name
```

where *container-name* is one of the following:

- `apic-lte-juhu`: the authentication gateway
- `apic-lte-apim`: the API Management service
- `apic-lte-lur`: the Local User Registry
- `apic-lte-db`: the Postgres database of the API Management service
- `apic-lte-datapower-api-gateway`: the DataPower API Gateway
- `apic-lte-datapower-gateway`: the DataPower Gateway (v5 compatible)

You can access the gateway logs in either of the following ways:

- Use the gateway administration web UI:
 1. Open the page `https://localhost:web_ui_port` in a browser; for details of the required port value, see [Local Test Environment port values](#).
 2. Select the apiconnect domain and the WebGUI interface, and log in with user name `admin` and password `admin`.
 3. Click View Logs.
- Use the gateway administration CLI:
 1. Open an SSH connection by using the following command:

```
ssh -p gateway-ssh-port localhost
```

For details of the required port value, see [Local Test Environment port values](#). The user name is `admin` and the password is `admin`.
 2. Enter the command `switch domain apiconnect`.
 3. To view the gateway log, enter the command `show log`.
 4. To view the log for the communication between the gateway and the API management system, enter the command `show logging gwd-log`.

Local Test Environment port values

If any of the default port values for the Local Test Environment components conflict with ports already in use on your system, you can change them when you start the Local Test Environment by passing one or more `--component port_value` parameters to the `platform-apic-lte start` command, where:

- *component* is the Local Test Environment component whose port value you want to change.
- *port_value* is the required value.

For example:

```
platform-apic-lte start --datapower-api-gateway-api-port 9445
```

The following table lists the components, together with the corresponding *component* parameters, and the default port values:

Component	component parameter	Default port value
DataPower API Gateway API port	<code>datapower-api-gateway-api-port</code>	9444
DataPower API Gateway API Connect service port	<code>datapower-api-gateway-apic-service-port</code>	3001
DataPower API Gateway REST management port	<code>datapower-api-gateway-rest-management-port</code>	5555
DataPower API Gateway SSH port	<code>datapower-api-gateway-ssh-port</code>	9023
DataPower API Gateway administration web UI	<code>datapower-api-gateway-web-gui-port</code>	9091
DataPower API Gateway XML management port	<code>datapower-api-gateway-xml-management-port</code>	5551
DataPower Gateway (v5 compatible) API port	<code>datapower-gateway-api-port</code>	9443
DataPower Gateway (v5 compatible) API Connect service port	<code>datapower-gateway-apic-service-port</code>	3000
DataPower Gateway (v5 compatible) REST management port	<code>datapower-gateway-rest-management-port</code>	5554
DataPower Gateway (v5 compatible) SSH port	<code>datapower-gateway-ssh-port</code>	9022
DataPower Gateway (v5 compatible) administration web UI	<code>datapower-gateway-web-gui-port</code>	9090
DataPower Gateway (v5 compatible) XML management port	<code>datapower-gateway-xml-management-port</code>	5550
Platform API port	<code>platform-api-port</code>	2000

Testing an API with the Explorer tab

Use the Explorer tab in the API editor to see how your APIs look to a consumer in the Developer Portal. You can also use the Try it tool to test the behavior of the API.

Before you begin

To test an API in the Try it test tool, the API must be auto-published. If the API is not auto-published, the Try it tool isn't enabled in the Explorer.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

About this task

The Explorer tab in the API editor of the API Designer UI and API Manager UI enables you to view how your APIs look to an API consumer in the Developer Portal. You can check the descriptions of the different artifacts, and as well as any schemas or examples, and you can also test the behavior of the API by using the Try it tool.

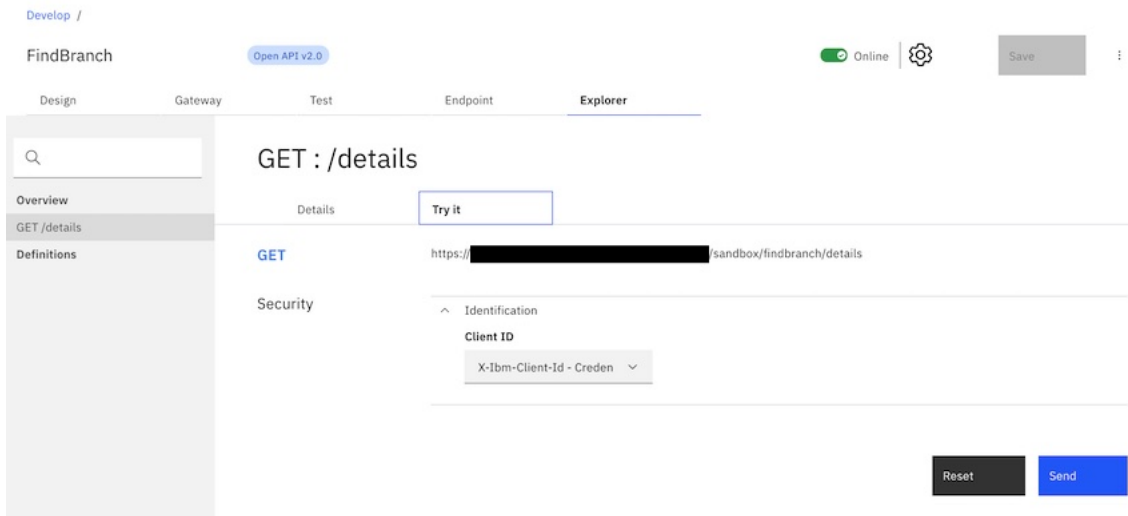

Note:

- You cannot use the Try it tool to test non-enforced APIs.

Procedure

To test an API by using the Try it tool, complete the following steps.

- If you are using API Designer, set the mode to Online using the Options menu  on the main page.
- In the navigation pane, click  Develop, then select the APIs tab.
- Click the title of the API that you want to work with.
The API editor is displayed.
- Click the Explorer tab.
An Overview of the API is displayed.
- Click the API artifacts in the side menu bar to explore the operations and definitions that are available in the API, including reviewing any examples and schemas.
- To test API behavior, click an operation in the side menu bar, and click the Try it tab.
The test pane for the operation is displayed, as shown in the following example:

- Provide any required API parameters, and click Send.
The API response is displayed in the Response section.
Note: If you receive a message relating to an untrusted certificate, click the link provided, accept the certificate, then return to the test environment and click Send again.

What to do next

When you are happy with the look and behavior of your API, you can stage the API to a Product in a Catalog. For more information, see [Staging an API](#).

Staging an API

The graphical wizard provides an option that adds the API to a Product and stages the Product in a Catalog. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see [Creating and configuring Catalogs](#).

Ensure that the Catalog has at least one gateway service configured.

Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see [Using syndication in IBM API Connect®](#).
To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product > Stage permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see [Creating and configuring Catalogs](#) or [Managing user access in a Space](#).

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI. Staging is not available when working offline in API Designer.

A Catalog is a staging target, and behaves as a logical partition of the DataPower® Gateway, and the Developer Portal.

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (<https://www.npmjs.com/package/@apidevtools/swagger-parser>).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
 - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either **X-IBM-Client-Id** or **X-IBM-Client-Secret**.
 - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.
 - De-referencing of local references in the definition file (that is, values of **\$ref** properties), and ensuring these are valid JSON Pointers within the file.

Note: If you are using Event Endpoint Management in Cloud Pak for Integration, similar validation is carried out for AsyncAPI documents. For more information, see the section about API document and enforcement in the [Cloud Pak for Integration documentation](#).

Note: If the OpenAPI file that defines your API uses a **\$ref** field to reference a fragment of OpenAPI code that is defined in a separate file, the **\$ref** field is replaced with the contents of the target file before the product that contains the API is staged or published (the **\$ref** field is supported only if you are using the API Connect for IBM Cloud developer toolkit). For more information, see [Using \\$ref to reuse code fragments in your OpenAPI files](#).

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
The Develop page opens.
2. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
3. You can stage an API either from the Develop listing page, or from within the API definition itself.
 - a. To stage an API from the Develop listing page, click the options menu icon  alongside the required API, and then select Stage.
 - b. To stage an API from within the API definition, complete the following steps:
 - i. Click the title of the API that you want to work with.
 - ii. Click the options menu icon:

- iii. Click Stage.
4. Choose one of the following actions:
 - To stage the API by adding it to a new Product:
 - Select New Product - Publish using a new product.
 - When prompted, enter a Title and Version.
 - The Product Name is automatically entered. The Name is the used to refer to the product in CLI commands. See [apic products](#).
 - Click Next.
 - To stage the API by adding it to an existing Product:
 - Select Existing Product - Publish using an existing product
 - Select the Product you want to use.
 - Click Next.
 5. On the Stage To page, select the Catalog to which you want to stage the Product.
Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to.
If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see [Logging into API Connect Designer](#).
For details of how to create a Catalog in a provider organization, see [Creating and configuring Catalogs](#).
 6. If, when the staged Product is subsequently published, you want it to be published only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see [API Connect gateway types](#).
 7. Click Stage.

Results

Your Product is staged to a Catalog. You can view the state of the Product in the Catalog in API Manager. If you staged the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click  Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Staged.

For information about the lifecycle of a product, see [The Product lifecycle](#).

If approval is required to stage Products in the Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is staged when the request is approved. If approval is not required, the Product is staged immediately.

For information on configuring Product lifecycle approvals for a Catalog, see [Creating and configuring Catalogs](#). For information on approving requests, see [Approving Product lifecycle and subscription requests](#).

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

Publishing an API

The user interface provides an option that adds an API to a Product and publishes the Product in a Catalog. Publishing a draft Product makes the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see [Creating and configuring Catalogs](#).

Ensure that the Catalog has at least one gateway service configured.

Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see [Using syndication in IBM API Connect®](#).

To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product Management permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see [Creating and configuring Catalogs](#) or [Managing user access in a Space](#).

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI. Publishing is not available when working offline in API Designer.

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (<https://www.npmjs.com/package/@apidetools/swagger-parser>).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
 - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either `X-IBM-Client-Id` or `X-IBM-Client-Secret`.
 - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.
 - De-referencing of local references in the definition file (that is, values of `$ref` properties), and ensuring these are valid JSON Pointers within the file.

Note: Products that contain an API with a Swagger property using `regex` that include lookahead assertions, such as "(?)" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!  
The multipart 'openapi' field contains an OpenAPI definition with validation errors.  
definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:  
0)  
400
```

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the product that contains the API is staged or published (the `$ref` field is supported only if you are using the API Connect for IBM Cloud developer toolkit). For more information, see [Using \\$ref to reuse code fragments in your OpenAPI files](#).

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
The Develop page opens.
2. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
3. You can publish an API either from the Develop listing page, or from within the API definition itself.
 - a. To publish an API from the Develop listing page, click the options menu icon  alongside the required API, and then select Publish.
 - b. To publish an API from within the API definition, complete the following steps:
 - i. Click the title of the API that you want to work with.
 - ii. Click the options menu icon:

iii. Click Publish.

4. Choose one of the following actions:

- To publish the API by adding it to a new Product:
 - Select New Product - Publish using a new product.
 - When prompted, enter a Title and Version.
 - The Product Name is automatically entered. The Name is used to refer to the product in CLI commands. See [apic products](#).
 - Click Next.
- To publish the API by adding it to an existing Product:
 - Select Existing Product - Publish using an existing product
 - Select the Product you want to use.

- Click Next.
5. Select the Catalog to which you want to publish the Product.
 6. If Spaces have been enabled in the selected Catalog, select the Space that you require.

Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to. If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see [Logging into API Connect Designer](#).

For details of how to create a Catalog in a provider organization, see [Creating and configuring Catalogs](#).
 7. If you want to publish the Product only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see [API Connect gateway types](#).
 8. Click Publish.

Results

Your Product is published to a Catalog. You can view the state of the Product in the Catalog in API Manager. If you published the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click  Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Published.

For information about the lifecycle of a product, see [The Product lifecycle](#).

If approval is required to publish Products in the Catalog, a publish approval request is sent, and the Product moves to the Pending state; the Product is published in the Catalog when the request is approved. If approval is not required, the Product is published immediately.

Note: If approval is required to stage Products to the Catalog, a stage approval request is sent. When the request is approved, the Product moves to the staged state and must be separately published in the Catalog. For information on publishing a staged Product in a Catalog, see [Publishing a Product](#). For information on configuring Product lifecycle approvals for a Catalog, see [Creating and configuring Catalogs](#). For information on approving requests, see [Approving Product lifecycle and subscription requests](#).

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

Notes:

- If an OpenAPI 3 API contains a response wildcard (which is not supported), publishing is disabled for that API. You must correct the problem before you can publish the API.
- If the Product contains an API that includes a user-defined policy that has not been imported into this Catalog, the publish will fail. The user-defined policy must be available in the required Catalog for the Product to be published successfully. For detailed instructions on how to import a user-defined policy into a Catalog, see [Importing a user-defined policy into a Catalog](#).

Creating a new version of an API definition

You can create multiple versions of an API definition and edit the versions independently by using IBM® API Connect.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note: If you want to publish a modified API to a production Catalog, you **must** create a new version of the API. You cannot publish an API to a production Catalog if there is already a published API with the same name and version.

Procedure

To create a new version of an API definition, complete the following instructions:

1. In the navigation pane, click  Develop, then select the APIs tab.
2. You can create a new version of an API definition either from the Develop page, or from within the API definition itself.
 - a. To create a new version of an API definition from the Develop page, complete the following steps:
 - i. Alongside the API version that you want to work with, click the options icon , then click Save as a new version. The Save API as a new version window opens.
 - ii. Enter your new version number, then click Save.
 - b. To create a new version of an API definition from within the API definition itself, complete the following steps:
 - i. Click the title of the API definition that you want to create a new version of.
 - ii. Click the options menu icon:

- iii. Click New Version, enter your new version number, then click Submit.

Note: The version corresponds to the `info.version` property value of the API's OpenAPI definition. The `version.release.modification` version numbering scheme is recommended, for example 1.0.0.

Results

You have created a new version of your API definition, which you can now edit independently of other versions. Each version of the API definition is listed separately on the APIs and Products page.

Related tasks

- [Creating an API definition](#)

Updating an API definition from a file

You can update an API by uploading a .yaml or .json file that contains the OpenAPI definition for the revised API.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The update operation completely replaces the previous API definition.

Procedure

To update an API from a file, complete the following steps:

1. In the navigation pane, click  Develop, then select the APIs tab.
2. Click the title of the API that you want to update.
3. Click the options menu icon:

4. Click Update, then either drag and drop the file or click the link to select the file from your local file system.
5. Click Submit, then click Save.

Updating a SOAP API

You can update the configuration of an existing SOAP API either by uploading a WSDL file, or by uploading a .zip archive that contains a primary WSDL file together with other WSDL or XSD files that it references.

About this task

You complete this task by using the browser based API Manager UI.

You can also use the API Connect developer toolkit CLI to update a SOAP API; for more information see [API development and management commands](#).

When you initiate the update action, the specified WSDL is parsed to find a service that matches the name of the API that you are updating. If a match is found, the WSDL service is converted into a YAML file that is used to update the API. If no match is found, an error message is displayed.

Only those sections of the API that are affected by the new WSDL are replaced, the other sections are unchanged.

Procedure

To update a SOAP API from a WSDL file or a .zip archive, complete the following steps:

1. In the navigation pane, click  Develop, then select the APIs tab.
2. Click the title of the SOAP API that you want to update.
3. Click the options menu icon:

4. Then click Update WSDL, and either drag and drop the file or click the link to select the file from your local file system.
The format of the WSDL file is validated. If the format is invalid, an error message is displayed.
5. Click Next.
The services in the selected API are displayed. If no match is found, an error message is displayed.
6. Click Upload.
The SOAP API is updated from the specified WSDL definition.
7. Click Save to save the updates.
8. If you updated a previously published API, you must publish it again for the change to take effect:
 - a. Click the Online/Offline toggle (shown in step 3) to set the API as Offline.
 - b. Click the toggle again to set the API back to Online, which publishes the API again.

Related tasks

- [Creating an API definition](#)

Renaming an API definition

By renaming an API definition, you change the **name** property that, together with the version, is used to uniquely identify the API definition in API Connect. The **name** property is initially generated automatically when you first create the API definition, based on the title, but you can later change it if desired.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **Api-Drafts:Edit** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see [Creating custom roles](#).

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Click the options menu icon:

4. To rename the API, select Rename.
Only this version of the API is renamed.
5. Enter the new name, then click Submit.
Note: If you previously added the API to a Product, it will no longer be recognized by that Product. You must open the Product and modify the **apis**: section on the Source tab as appropriate; for example:

```
apis:  
  newname1.0.0:  
    name: 'newname:1.0.0'
```

Changing an API rate limit

When you activate an API to make it available for testing, as described in [Activating an API](#), no rate limit is applied to restrict calls to the API. However, if desired, you can apply a rate limit to the API, or modify a previously applied rate limit. The rate limit defines the maximum number of calls allowed in a specified time period.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **Api-Drafts:Edit** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see [Creating custom roles](#).

Note: For information about rate limits and burst limits in API Connect, see [Understanding rate limits for APIs and Plans](#).

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Click the options menu icon:

4. Click Edit Rate Limit.
5. Select Unlimited to allow unrestricted calls to the API, or select Custom Rate Limit to define the required rate limit; use the supplied fields to define the maximum number of calls allowed in a specified time period; for example, 100 calls per 1 minute.
6. Click Submit when done.

Adding an OpenAPI extension to an API

You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An OpenAPI extension is imported into a Catalog, or to a Space within a Catalog, then added to the API schema.

Before you begin

Import the OpenAPI extension into the Sandbox Catalog, or into any Catalog to which the API that you are adding the extension to will be published; see [Importing an OpenAPI extension into a Catalog](#).

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the `Api-Drafts:Edit` permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see [Creating custom roles](#).

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Select the Gateway tab, expand Gateway and portal settings, then click Extensions.
4. Select the OpenAPI extensions that you want to use with this API, then click Save.
Note: The OpenAPI extensions listed are those that have been imported into the Catalog and gateway service defined in the testing preferences for the API; see [Importing an OpenAPI extension into a Catalog](#) and [Specifying the testing preferences for an API](#). You will also need to import the OpenAPI extension into any Catalog to which the API will be published.
5. Update the OpenAPI source for the API definition with the values for the fields as defined in your selected OpenAPI extension schema files, as follows:
 - a. Click the Source icon .
 - b. Add a property whose name must begin with `x-` and references the name of the OpenAPI extension that you created. Specify the values of the properties that were defined in the OpenAPI extension YAML file.
For an example, see [Referring to an extension in an API definition](#).
 - c. Click Save when done.

Downloading an API definition

You can download the details of your API definitions so that you can store them for later recovery.

Before you begin

To complete this task, you must have created an API definition. For more information, see [Creating an API definition](#).

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the `Drafts:View` permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see [Creating custom roles](#).

You can download REST APIs that were created by using [Creating a REST proxy API from a target service](#) for example. This download creates a .yaml file that defines the API.

You can download SOAP APIs that were created by using [Creating a REST proxy API from an existing WSDL service](#), or [Creating a SOAP proxy API from an existing WSDL service](#) for example. This download creates a .zip file that contains the WSDL definition and the YAML file that defines the API.

You can use the downloaded .yaml and .zip files to re-create your API. For information about creating an API from a .yaml file, see [Adding a REST API by importing an OpenAPI definition file](#). For information about creating an API from a .zip file, see [Adding a SOAP API by importing a zip file](#).

Procedure

To download a .yaml, or .zip file that contains the details of your API, complete the following steps:

1. In the navigation pane, click  Develop, then select the APIs tab.
2. Alongside the API version that you want to work with, click the options icon  and then click Download.
3. Save the file to the required location.

Results

You downloaded a .yaml, or .zip file with a representation of your API.

Deleting an API definition

You can delete an API definition that is no longer required.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **Api-Drafts:Edit** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see [Creating custom roles](#).

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
2. You can delete an API either from the Develop listing page, or from within the API definition itself.
 - a. To delete an API from the Develop listing page, click the options menu icon  alongside the required API, and then select Delete.
 - b. To delete an API from within the API definition, complete the following steps:
 - i. Click the title of the API definition that you want to work with.
 - ii. Click the options menu icon:

- iii. To delete just this version of the API, select Delete. To delete all versions of this API, select Delete API.

Note: If a Product was previously generated automatically from the API, by using the Activate API option, that Product will be deleted together with the API; such Products have the title *api_title* auto product.

3. Click Delete to confirm.

Using an options file when importing a WSDL service

When you create an API definition, or add a target WSDL service to an API definition, by importing a .zip file, you can specify additional directives by including an options file in the .zip file.

You can use an options file when importing a .zip file while performing any of the following tasks:

- Creating a REST proxy API; see [Creating a REST proxy API from an existing WSDL service](#).
- Creating a SOAP proxy API; see [Creating a SOAP proxy API from an existing WSDL service](#).
- Adding a target WSDL service to an API definition; see [Editing an API definition](#).

The options file is a YAML file, and must have the file name apiconnect.yaml.

You can include the following fields in the file:

Table 1. Fields that can be included in the apiconnect.yaml file

Field name	Value	Default	Description
<code>suppressExamples</code>	true or false	false	Suppress auto-generation of examples.
<code>wssecurity</code>	true or false	true	Enable generation of definitions for WS-Security headers.
<code>implicitHeaderFiles</code>	Array of XSD file locations		Additional schema files, not referenced in the WSDL, that are used to define additional SOAP headers.
<code>port</code>	The name attribute for a <code>wsdl:port</code> in a <code>wsdl:service</code> definition.		Create the API by using the information for the specified port. If the specified port does not exist, or refers to a REST/XML port rather than a SOAP port, the API creation fails. If no <code>port</code> field is present in the options file, API Connect creates the API by using the first SOAP port that it finds in the <code>wsdl:service</code> definition.

Example

```
suppressExamples: true
wssecurity: false
implicitHeaderFiles:
- xsdDir/schema1.xsd
- xsdDir/schema2.xsd
```

Variable references in API Connect

In API Connect you can reference different variables in your API definition.

When defining an API, creating a custom policy, or configuring another policy or logic construct, you can include references to context variables and properties.

Variable references are resolved either when the API is staged in a Product, for static variables that are fixed upon staging, or when the API is called, for variables that can change with each API call.

Types of variables

Context variables

A context variable is a variable relevant during an API call, for example, the input of the call, the path of the call, or the message during the call. A context variable is one of the variables that makes up that particular context.

Context variables can consist of more than one part, for example, `request.headers`.

For a list of available context variables, see [API Connect context variables](#).

API properties

An API property is a variable in an API where its value depends upon the Catalog in which the API is staged or published. By referencing an API property, you can use the same API definition in different Catalogs where there are small differences between the instances of the API between the Catalogs. For example, an assembly could contain an `if` construct that executes its case when a particular Catalog is used, determined from the value of the API property. API properties can also be used to hide a value such as a password by encoding the value.

API properties are referenced by name.

For a list of API properties, see [API properties](#)

For more information, see [Setting API properties](#) (OpenAPI 2.0) or [Setting API properties](#) (OpenAPI 3.0).

Note: Once defined, an API property is read only.

Catalog properties

A Catalog property is specific to a Catalog, and can be referenced in any of the API definitions in that Catalog. For more information, see [Creating and configuring Catalogs](#).

Notes:

- If you change the value of a Catalog property, any API that references that property must be republished for it use the new value.
- Catalog properties and API properties are not supported with global policies. Therefore, if you use such properties in a global policy, they are not replaced with the values specified in the Catalog or API property definitions.

Methods of referencing variables

You can get, or set, the value for a referenced variable.

- Get the value for a variable in either of the following ways:
 - Through the [GatewayScript](#) policy, run the `apim.getvariable()` API.
 - **API Gateway only** Through the [GatewayScript](#) policy, use the `context.get()` function; for more information, see [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#).
 - Through the [XSLT](#) policy, run a stylesheet that uses the `apim:getVariable` extension function.
 - In an assembly policy field that supports variable references, use the following syntax:

`$(variable)`
- Set the value for a variable in either of the following ways:
 - Through the [Set Variable](#) policy.
 - Through the [GatewayScript](#) policy, use the `apim.setvariable()` API.
 - **API Gateway only** Through the [GatewayScript](#) policy, use the `context.set()` function; for more information, see [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#).
 - Through the [XSLT](#) policy, run a stylesheet that uses the `apim:setVariable` extension element.

GatewayScript references

When you want to reference a variable in a GatewayScript context, use one of the following methods:

```
apim.getvariable(variable)
```

where *variable* is the name of the context variable or API property that you want to reference.

```
apim.setvariable(variable, value, action)
```

where

- *variable* is the name of the context variable or API property that you want to reference.
- *value* is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, use the following code:

```
var contentType = apim.getvariable('request.headers.content-type');  
apim.setvariable(variable, contentType, 'set');
```

This property is required only when `set` or `add` is specified as the action.

- *action* is the action that you want to apply to the variable. Valid options are:
 - `set`
 - `add`
 - `clear`

If no option is set, the default option of `set` is applied.

Use the `getvariable` method to retrieve the value of a context variable or API property, and the `setvariable` method to change one.

Some of the situations where you would use this type of reference are:

- GatewayScript policies. -For more information, see [GatewayScript](#).
- `if` logic constructs. For more information, see [if](#).
- User-defined policies. For more information, see [Authoring policies](#).

Stylesheet references

You can reference a variable by using functions and elements in an XSLT policy with the following syntax:

```
<xsl:variable name="variable_name" select="apim:getVariable(variable)" />
```

where *variable* is a literal value, another variable, or a valid XSLT XPath statement.

```
<xsl:call-template name="apim:setVariable">
  <xsl:with-param name="varName" select="variable"/>
  <xsl:with-param name="value" select="value"/>
  <xsl:with-param name="action" select="action"/>
</xsl:call-template>
```

where

- *variable* is the name of the context variable or API property that you want to reference. This can be a literal value, another variable, or a valid XSLT XPath statement.
- *value* is the string value that you want to set the variable to. This can be a literal value, another variable, or a valid XSLT XPath statement. This property is required only when **set** or **add** is specified as the action.
- *action* is the action that you want to apply to the variable. This can be a literal value, another variable, or a valid XSLT XPath statement. Valid options are:
 - **set**
 - **add**
 - **clear**

If no option is set, the default option of **set** is applied.

The following example sets a named variable to the value of the Content-Type header in a request:

```
<xsl:variable name="contentType" select="apim:getVariable('request.headers.content-type') " />
<xsl:call-template name="apim:setVariable">
  <xsl:with-param name="varName" select="'variable'"/>
  <xsl:with-param name="value" select="$contentType"/>
  <xsl:with-param name="action" select="'set'"/>
</xsl:call-template>
```

Inline references

In many situations you can make a simpler reference, by using the following syntax:

```
$(variable)
```

where *variable* is the name of the context variable or API property that you want to reference.

Some of the situations where you would use this type of reference are:

- The URL called by an **Invoke** or **Proxy** policy. For more information about the policies, see [Invoke](#) or [Proxy](#).
- A **Map** policy. For more information, see [Map](#).

Notes: The map policy can reference the following variables inline:

- Variables that are defined as inputs to the map policy and specified in the from field of a mapping.
- Context variable or API properties, provided that the `x-ibm-gateway-map-resolve-apic-variables` API property is not set to **false**. If an inline reference in a map policy resolves to a context variable or API property, it is immediately replaced by the corresponding value. For more information on the `x-ibm-gateway-map-resolve-apic-variables` API property, see [Properties controlling the map policy](#).

For more information on the use of inline references, and examples, see the following [About inline references](#) section.

About inline references

When you use an inline reference for a property value in an assembly policy, the variable reference is replaced with the corresponding string value at run time, before the property is evaluated. For example, consider the following incoming request, which has two headers and two query parameters (a **curl** command is used to illustrate the request):

```
curl --data-binary @request.json \
  -H 'Content-Type: application/json' \
  -H 'X-Environment: test' \
  http://apiserver/org/catalog/petstore/getPetDetails?petid=285&storeid=z03
```

If an **invoke** policy is configured as follows:

```
invoke:
  target-url: https://backend/GetPetInfo/$(request.parameters.storeid)/$(request.parameters.petid)
```

then the value of the **target-url** property is evaluated as `https://backend/GetPetInfo/z03/285`, and this is therefore the URL to which the **invoke** policy sends its request.

DataPower Gateway (v5 compatible) only

You can also use an inline reference in the **condition** property of a **switch** policy. Consider the following example:

```
- switch:
  case:
    - condition: "$(request.headers.X-Environment)" == "production"
      execute:
        - invoke:
            http://www.finance.com/base/stockquote
    - condition: "$(request.headers.X-Environment)" == "test"
      execute:
        - invoke:
            http://testserver1.finance.com/stockquote
```

Using the incoming request referred to previously, the value of the **X-Environment** header is **test**. The inline references are first evaluated, then the conditions are evaluated as JavaScript. Therefore, the first condition is evaluated as `"test" == "production"`, returning **false**, and the second condition is evaluated as `"test" == "test"`, returning **true**, so the **invoke** policy sends its request to `http://testserver1.finance.com/stockquote`.

Important: This example, which encloses the inline references inside double quotes, assumes that the API is deployed to the DataPower API Gateway. If you deploy the API to the DataPower Gateway (v5 compatible), then the double quotes are added implicitly when the inline references are evaluated, and you must therefore omit them from the **condition** property; the two conditions in this example would therefore be

```
condition: $(request.headers.X-Environment) == "production"
```

and

```
condition: $(request.headers.X-Environment) == "test"
```

However, as an alternative to using an inline reference in a `condition`, you can instead use pure JavaScript, as follows:

```
- switch:
  case:
    - condition: request.headers["X-Environment"] == "production"
      execute:
        - invoke:
            http://www.finance.com/base/stockquote
    - condition: request.headers["X-Environment"] == "test"
      execute:
        - invoke:
            http://testserver1.finance.com/stockquote
```

in which case the policy configuration will work correctly as-is in both types of gateway. For more information on the types of gateway, see [API Connect gateway types](#).

In addition to single strings, you can use an inline reference for a complete object. Consider the following example, which uses an inline reference in a `set-variable` policy:

```
- set-variable:
  actions:
    - set: saved.reqHdrs
      value: $(request.headers)
      type: string
```

Here, the `request.headers` structured JSON object is substituted with its corresponding string representation, and a variable named `reqHdrs` is therefore created, under the `saved` object, with a string value of `{ "Content-Type": "application/json", "X-Environment": "test", ... }`. However, if you are using the DataPower API Gateway, you can specify `type: any`, in which case the `set-variable` policy copies the value as-is, and `saved.reqHdrs` is created as a JSON object rather than a string:

```
- set-variable:
  actions:
    - set: saved.reqHdrs
      value: $(request.headers)
      type: any
```

You can reference a property in a JSON or XML request directly by name, by using the following syntax:

```
$(request.body.property_name)
```

For example, if the request contains `{ "account-number": 123 }` or `<account-number>123</account-number>` you can retrieve the value `123` by using the following inline reference:

```
$(request.body.account-number)
```

If the property value is within a nested property structure, you can reference it by concatenating the property names. For example, if the request contains `{ "account": { "balance": 123 } }` or `<account><balance>123</balance></account>` you can retrieve the value `123` by using the following inline reference:

```
$(request.body.account.balance)
```

Similarly, you can reference a property in a JSON or XML response by using the following syntax:

```
$(message.body.property_name)
```

Restriction: If you are using the DataPower API Gateway, you can reference properties in this way only if the format of the request or response is JSON; the mechanism is not supported with XML request or response formats. If you are using the DataPower Gateway (v5 compatible) the mechanism is supported with both JSON and XML formats.

API properties

Properties are used by the gateway to control behavior of certain policies. Typically, you provide properties, but the policy can also provide properties settings.

In IBM® API Connect, you can create API properties that consist of Catalog-specific values to eliminate the need for source code modifications. You can then reference the properties elsewhere in your API definition.

Pre-supplied API properties for various policies are shown in the tables.

A list of invoke related API properties that control the behavior of the invoke policy.

Table 1. Properties controlling the invoke policy

Property	Required	Description	Data type
IBM® API Connect 10.0.5.x LTS x-ibm-gateway-decode-request-params	No	If set to a value of <code>true</code> , any request parameters that are referenced by a variable definition on an invoke target-url are URL-decoded. The default behavior is to not decode any parameters, thereby sending them to the target URL without alteration.	Boolean

Property	Required	Description	Data type
<small>DataPower Gateway (v5 compatible only)</small> x-ibm-gateway- invoke- suppress- clientid	No	When set with a value of true , or not specified, the X-IBM-Client-Id HTTP header (if specified on the API request) is suppressed from being sent to the invoke target URL. When set with a value of false , the X-IBM-Client-Id HTTP header is no longer suppressed from being sent to the invoke target URL. This property is supported only by the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway then to achieve the same functionality add a header-control property to the invoke policy configuration in the OpenAPI definition for your API, as in the following examples. Suppress the X-Client-ID header as follows: <pre>- invoke: target-url: http://myhostname/mypath header-control: type: blacklist values: - ^X-Client-ID\$</pre> Suppress the userId query parameter as follows: <pre>- invoke: target-url: http://myhostname/mypath parameter-control: type: blacklist values: - ^userId\$</pre>	Boolean
<small>DataPower Gateway (v5 compatible only)</small> x-ibm-gateway- optimize-invoke	No	If set to false , prevents the replacement of the last invoke in a policy with proxy. Any value other than false (case insensitive) will result in the last invoke in a policy possibly being replaced by proxy when the API is executed in the gateway.	Boolean
<small>DataPower Gateway (v5 compatible only)</small> x-ibm-gateway- queryparam- encode-plus- char	No	If set to a value of true , all "+" characters in the query parameter values of the target-url of the Invoke and Proxy policies are encoded to "%2F". The default value is false .	Boolean
<small>DataPower Gateway (v5 compatible only)</small> x-ibm-gateway- api-enforce- response-limits	No	If set to a value of true , allows the JSON parser to be enforced on the response rule. If the response body size is higher than the JSON parser limit set in the DataPower domain, a status code of 500 is returned. Note: The x-ibm-gateway-api-enforce-response-limits property is supported by the DataPower Gateway (v5 compatible) but not by the DataPower API Gateway. However, if you are using the DataPower API Gateway, consider using a Parse policy in your API assembly to enforce these limits. For information on the different types of gateway, see API Connect gateway types .	Boolean
<small>DataPower Gateway (v5 compatible only)</small> x-ibm-gateway- invoke-emulate- v4-soap-error	No	IBM API Management Version 4.0 initiates a DataPower error when a SOAP fault is returned from a web service. IBM API Connect provides a mechanism to catch SOAP errors and does not initiate a DataPower error. For compatibility with APIs developed in IBM API Management Version 4.0, set this property to true only in the case where a gateway extension is expecting to handle a SOAP error in a post error rule. The default value is false . Note: This property is deprecated in favor of x-ibm-gateway-invoke-emulate-v4-invoke-error.	Boolean
<small>DataPower Gateway (v5 compatible only)</small> x-ibm-gateway- invoke-keep- payload	No	If set to a value of true , the invoke policy sends a payload on an HTTP DELETE method. This property is available for use with IBM DataPower Gateway version 7.7.1.1 and later. The default value is false .	Boolean
<small>DataPower Gateway (v5 compatible only)</small> x-ibm-gateway- invoke-emulate- v4-invoke-error	No	IBM API Management Version 4.0 initiates a DataPower error when a backend server error is returned, either a SOAP fault returned from a web service or a JSON or XML (non-SOAP) error from a restful service. IBM API Connect provides a mechanism to catch SOAP errors and operation errors and does not initiate a DataPower error when they occur. If no catch policy is configured, a generic error message is generated. For compatibility with APIs developed in IBM API Management Version 4.0, set this property to true only in the case where a gateway extension is expecting to handle a backend server error in a gateway extension post error rule or if the client of the API is expecting the backend server error to be returned. The default value is false .	Boolean

A list of map-related API properties that control the behavior of the map policy.

Table 2. Properties controlling the map policy

Property	Required	Description	Data type
<small>DataPower Gateway (v5 compatible only)</small> x-ibm-gateway- map-array-first- element-value	No	In IBM API Management Version 4.0, if a mapping source value is from an array then only the first value is output. In API Connect, the default behavior is to return an array of all array element values. To maintain compatibility with IBM API Management Version 4.0, set this API property to true to only return the first array element value.	Boolean
<small>DataPower Gateway (v5 compatible only)</small> x-ibm-gateway- map-resolve- apic-variables	No	By default, any API Connect variable that is found in the map configuration is resolved. For example, \$(request.headers.content-type) resolves to the request's content type header. Because searching for variables in every map property can be CPU intensive, you can choose not to resolve variables by setting this API property to false . If this property is not configured or is set to any other value, the existing behavior to search for these variables continues. Note that variable usage within a map value JavaScript snippet is not changed provided that the variables that are referenced come from a configured map input.	Boolean
<small>DataPower Gateway (v5 compatible only)</small> x-ibm-gateway- map-create- empty-array	No	This property controls how the map policy handles the output of an empty array; it can have the following values: <ul style="list-style-type: none"> all: Output all empty arrays, including empty children arrays. This is the default value if the property is not configured or has an invalid value. parent: Output only the current property's empty array value. Children map actions of this property are not attempted. none: Prevent any empty output array values from being produced. 	String

Property	Required	Description	Data type
<small>DataPower Gateway (5.5 compatibility only)</small> x-ibm-gateway-optimize-schema-definition	No	Set the value of this property to true to provide a performance improvement to the map policy when a very complex schema definition is referenced by a policy output definition; for example, some very complex schemas that are generated by importing a very complex WSDL schema. The map policy builds a schema from an API definition when a referenced definition is provided as the value of the schema. If the schema does not have references that generate a circular reference, setting this property to true might provide a performance benefit while generating the same schema as would otherwise have been generated. However, in cases where the schema is very complex, with many potentially circular references, the generated schema could be different because the enhanced schema handling processes circular references differently. In such cases therefore, you should examine the resulting output to determine if the performance benefit gained is not at the expense of a change in the map policy output. The default value of this property, is false , maintaining the existing behavior and performance.	Boolean
<small>DataPower Gateway (5.5 compatibility only)</small> x-ibm-gateway-map-null-value	No	Set the value of this API property to true to allow a property from a map policy's input data with a value of null to be mapped to the output document. By default, a property from a map policy's input data with a value of null is not mapped to the output document.	Boolean
<small>DataPower Gateway (5.5 compatibility only)</small> x-ibm-gateway-map-resolve-xmlinput-datatypes	No	XML input elements with numeric or boolean data have no metadata to indicate whether this data should be mapped as a string value or as the specific data type. If you set the value of this property to false , XML input elements are always mapped as a string. If you set the value to true , numeric or boolean XML input elements are mapped as the corresponding data type from the input schema. The default value is false .	Boolean
<small>DataPower Gateway (5.5 compatibility only)</small> x-ibm-gateway-map-xml-empty-element	No	This property controls how the map policy handles XML input empty elements and impacts JSON output when the input document is XML; it can have the following values: <ul style="list-style-type: none"> • string: The value for an empty XML element is considered to be an empty string. This is the default value if the property is not configured or has an invalid value. • null: The value for an empty XML element is considered to be null. A mapping of this element to a JSON output property does not occur unless the API property x-ibm-gateway-map-null-value is also specified with a value of true. • none: The empty XML element is ignored. • string-badgerfish: The value for an empty XML element is considered to be an empty string. The empty string value will be placed into a JSON badgerfish value property. • null-badgerfish: The value for an empty XML element is considered to be null. The null value will be placed into a JSON badgerfish value property. A mapping of this element to a JSON output property does not occur unless the API property x-ibm-gateway-map-null-value is also specified with a value of true. 	Boolean
<small>DataPower Gateway (5.5 compatibility only)</small> x-ibm-gateway-schema-definition-reference-limit	No	Set the value of this property to an integer value that specifies the maximum allowed number of iterations of a circular schema definition. The default value is 1, which means that circular schema definitions are not followed. The maximum possible value is 5. If you specify a value greater than 5, a value of 5 is assumed. If you specify a non-numeric value, a value of 1 is assumed.	String

Property	Required	Description	Data type
<small>DataPower Gateway (v5 compatible) only</small> x-ibm-gateway-map-emulate-v4-default-required-properties	No	<p>Set this property to true to have default values generated in the output for required properties that are either not mapped, or for which there is no input data present, in the following specific cases:</p> <ul style="list-style-type: none"> An array consists of objects that contain one or more required properties. An object which is optional has one or more child properties that are required. <p>By default, these required properties are not present in the output. If you set the x-ibm-gateway-map-emulate-v4-default-required-properties API property to true, these required properties will be present in the output. If the output schema defines a default property for the output property then the specified default value is used, otherwise a default value is assigned dependent on the data type, as follows:</p> <ul style="list-style-type: none"> String: empty string ("") Number: 0 Boolean: false Object: empty object Array: empty array <p>Example 1 The input data has the following array of objects:</p> <pre>[{"a": "value1"}, {"a": "value2", "b": "value3"}]</pre> <p>The output schema defines the output object as having two properties, a and b, of which b is required. The map policy defines the following mappings:</p> <ul style="list-style-type: none"> input.array.a to output.array.a input.array.b to output.array.b <p>If the x-ibm-gateway-map-emulate-v4-default-required-properties API property is set to true, and b is either not mapped or has no input data present, then b is assigned a default value of an empty string, and the output is as follows:</p> <pre>[{"a": "value1", "b": ""}, {"a": "value2", "b": "value3"}]</pre> <p>Example 2 The output schema defines the following structure:</p> <pre>{"a" : {"b" : {"c" : "value1", "d" : "value2"} } }</pre> <p>Property b is optional but property d within b is required.</p> <p>The map policy defines a mapping to output.a.b.c.</p> <p>If the x-ibm-gateway-map-emulate-v4-default-required-properties API property is set to true, and d is not mapped, then d is assigned a default value of an empty string, and the output is as follows:</p> <pre>{"a" : {"b" : {"c" : "value1", "d" : ""} } }</pre> <p>If the x-ibm-gateway-map-emulate-v4-default-required-properties API property is not specified or does not have a value of true, these required properties are not created in the output with their default values.</p>	Boolean
<small>DataPower Gateway (v5 compatible) only</small> x-ibm-gateway-map-post-process-json-output	No	<p>Set the value of this property to true to enable post processing of mapped JSON output. The post processing of JSON output will use the output schema to ensure that property values are of the same data type as that defined in the schema. It will also normalize output property values that have a Badgerfish JSON syntax due to object mapping of an XML input. Set the value to false for no post processing of mapped JSON output. The default value is false.</p>	Boolean
<small>DataPower Gateway (v5 compatible) only</small> x-ibm-gateway-map-emulate-v4-empty-json-object	No	<p>If a mapping fails because its input is not present and there is no default mapping configured, the default behavior is to not to make any change to the output mapping. Set the value of this property to true to create an empty object for the parent of the target mapping, emulating the behavior of IBM API Management Version 4.0.</p> <p>Example The map policy defines a mapping to output.a.b.c. If input data is present, the output is as follows:</p> <pre>{ "a": { "b": { "c": "inputvalue" } } }</pre> <p>If there is no input data, and the x-ibm-gateway-map-emulate-v4-empty-json-object API property is set to true, the output is as follows:</p> <pre>{ "a": { "b": { } } }</pre> <p>Properties a and b are created but the value of b is an empty object. The default value is false.</p>	Boolean

DataPower Gateway (v5 compatible) only

A list of proxy-related API properties that control the behavior of the proxy policy.

Table 3. Properties controlling the proxy policy

Property	Required	Description	Data type
x-ibm-gateway-proxy-suppress-clientid	No	<p>A setting of <code>false</code> activates the injection of the X-IBM-Client-Id HTTP header (if it is specified on the API request), or the <code>client_id</code> query parameter in the request URL, to the proxy target-url. If not specified, or set with a value of <code>true</code>, suppresses the sending of this parameter to the proxy target-url.</p> <p>This property is supported only by the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway then to achieve the same functionality add a <code>header-control</code> property to the <code>invoke</code> policy configuration in the OpenAPI definition for your API, as in the following examples.</p> <p>Suppress the <code>X-Client-ID</code> header as follows:</p> <pre>- proxy: target-url: http://myhostname/mypath header-control: type: blacklist values: - ^X-Client-ID\$</pre> <p>Suppress the <code>userId</code> query parameter as follows:</p> <pre>- proxy: target-url: http://myhostname/mypath parameter-control: type: blacklist values: - ^userId\$</pre>	Boolean
x-ibm-gateway-optimize-invoke	No	If set to <code>false</code> , prevents the replacement of the last invoke in a policy with proxy. Any value other than <code>false</code> (case insensitive) will result in the last invoke in a policy possibly being replaced by proxy when the API is executed in the gateway.	Boolean
x-ibm-gateway-queryparam-encode-plus-char	No	If set to a value of <code>true</code> , all "+" characters in the query parameter values of the target-url of Invoke and Proxy policies are encoded to "%2F". The default value is <code>false</code> .	Boolean
x-ibm-gateway-api-enforce-response-limits	No	If set to a value of <code>true</code> , allows the JSON parser to be enforced on the response rule. If the response body size is higher than the JSON parser limit set in the DataPower domain, a status code of 500 is returned.	Boolean

A list of API properties that control the behavior of the rate limit policy.

Table 4. Properties controlling the rate limit policy

Property	Required	Description	Data type
x-ibm-gateway-emulate-v4-plan-rate-limit	No	By default in IBM API Connect Version 10, if you configure a rate limit only for a Plan and not for the API operations within the Plan then a single rate limit threshold is set for the API as a whole, regardless of which operation in the API is requested. This behavior differs from IBM API Management Version 4.0 where the rate limit is set individually for each operation in the API. To change the Version 10 behavior to emulate the Version 4.0 behavior, set this API property to a value of <code>true</code> .	Boolean

A list of API properties that control the behavior of multiple policies.

Table 5. Properties controlling multiple policies

Property	Required	Description	Data type
<small>DataPower Gateway (v5 compatible) only</small> x-ibm-gateway-sourcecode-resolve-apic-variables	No	<p>If set to <code>true</code>, API Connect variable references are resolved. Set to <code>false</code> if you want the policy to ignore API Connect variable references.</p> <p>The default value is <code>true</code>.</p> <p>This property applies to the following policies:</p> <ul style="list-style-type: none"> Map GatewayScript XSLT if switch <p>Note: This property setting is overridden by the x-ibm-gateway-map-resolve-apic-variables API property setting for the Map policy.</p>	Boolean
<small>DataPower Gateway (v5 compatible) only</small> x-ibm-gateway-api-json-parse-error-handling	No	<p>If an API request or response payload includes valid JSON content that contains characters that cannot be represented in the JSON XML internal syntax that is used by the DataPower Gateway, set this property to <code>escape-unicode</code> to allow the payload to be accepted without parsing errors. If this property is not configured or is set to any other value, the payload is rejected as invalid JSON.</p> <p>This property applies to the API request payload, and to the API response payload when <code>x-ibm-gateway-api-enforce-response-limits</code> is enabled.</p>	String
<small>DataPower Gateway (v5 compatible) only</small> x-ibm-gateway-framework-preserve-escaped-reverse-solidus	No	By default, the string <code>\\</code> in a policy property is converted to a single <code>\</code> character. Set this property to <code>true</code> to preserve the string <code>\\</code> .	Boolean

Property	Required	Description	Data type
<small>DataPower Gateway (v5 compatible) only</small> x-ibm-gateway-inspect-request-headers	No	Causes an inspection of the HTTP headers in the API request to check for characters in the header values that are illegal XML characters; it can have the following values: <ul style="list-style-type: none"> default: There is no inspection for these characters in the header values. If one is present, the API request fails with an HTTP 500 Internal Server Error. sanitize: Any illegal XML characters in header values are replaced with a ? character. The API processing will continue. Any API that attempts to read <code>request.headers.<headername></code> will see the ? character in the value. However, the original protocol headers representing <code>message.headers</code> will still have the original character, which will be sent to an invoke or proxy backend server. bad-request: There will be an inspection for these characters in the header values. If one is present, the API request fails with an HTTP 400 Bad Request. <p>The default value is default.</p>	Boolean

A list of API properties that control the behavior of custom policies.

Table 6. Properties controlling custom policies

Property	Required	Description	Data type
<small>DataPower Gateway (v5 compatible) only</small> x-ibm-gateway-custom-policy-with-gws-action	No	If set to true , the <code>request.body</code> and <code>message.body</code> context variables will be populated for access by an <code>apim.getvariable('request.body')</code> or <code>apim.getvariable('message.body')</code> function call in a GatewayScript action of a custom policy. If the custom policy does not use a GatewayScript action that requires these variables to be populated, set this property to false or do not specify it. The default value is false .	Boolean

API policies and logic constructs

Policies and logic constructs are pieces of configuration that control a specific aspect of processing in the Gateway server during the handling of an API invocation at run time.

Policies are the building blocks of assembly flows, and they provide the means to configure capability, such as security, logging, routing of requests to target services, and transformation of data from one format to another. Policies can be configured in the context of an API or in the context of a Plan.

Logic constructs behave in a similar way to policies, but they affect how and which parts of the assembly are implemented without modifying the data flow of the assembly.

IBM® API Connect provides the following ways that you can create, configure, and apply policies and logic constructs:

Policies associated with a Plan

A Plan provides a mechanism for grouping API operations or subsets of operations from one or more APIs. You can set rate limiting policies on a Plan to specify how many requests an application is allowed to make during a specified time interval. You can also configure a policy for each operation that is included in a Plan. For more information, see [Working with Products](#).

Built-in policies

A built-in policy enables you to apply a pre-configured policy statement to an assembly to control processing capabilities in the Gateway server. Built-in policies are applied by using the API Designer assembly editor to add a built-in policy to your assembly and to configure the properties for that policy. For more information, see [Built-in policies](#).

Note: You can also apply built-in policies to your APIs by adding an **assembly** extension to your OpenAPI definition file. For more information, see [IBM extensions to the OpenAPI specification](#).

Logic constructs

A logic construct enables you to control the flow of data through your assembly during an API call. Like policies, logic constructs are applied to an API by using the API Designer assembly editor to add a logic construct to your assembly and to configure the behavior of the construct. For more information, see [Logic Constructs](#).

Note: You can also apply logic constructs to your APIs by adding an **assembly** extension to your OpenAPI definition file. For more information, see [IBM extensions to the OpenAPI specification](#).

User-defined policies

A user-defined policy enables you to create your own policies to control extra processing features in the Gateway server, such as security, or routing of requests. User-defined policies are created outside of API Connect and then imported into one or more Catalogs, so they can be applied to an operation in the same way as built-in policies. For more information, see [Authoring policies](#).

- [Built-in policies](#)

IBM API Connect includes a number of built-in policies that you can use to apply preconfigured policy statements to an operation to control an aspect of processing in the Gateway server when an API is invoked.

- [Logic Constructs](#)

IBM API Connect includes a number of logic constructs that you can use to apply preconfigured logic to an assembly to control the flow of data through your assembly when the API is called.

- [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#)

In the code for GatewayScript and XSLT policies in your API assemblies, you can use API context variables to work with the messages that are generated when an API is called.

- [User-defined policies](#)

Make a user-defined policy available to a Catalog, and apply that policy to a REST or SOAP API.

Built-in policies

IBM® API Connect includes a number of built-in policies that you can use to apply preconfigured policy statements to an operation to control an aspect of processing in the Gateway server when an API is invoked.

Note: Although some built-in policies can be used with both the DataPower® Gateway (v5 compatible) and the DataPower API Gateway, some policies are restricted to a particular Gateway. The following icons indicate which Gateway each policy can be used with:

-  Indicates that the policy can be run on the DataPower Gateway (v5 compatible).
-  Indicates that the policy can be run on the DataPower API Gateway.

For details of the two types of gateway, see [API Connect gateway types](#).

Built-in policies are configured in the context of an API. You can use the API Designer assembly editor to add a built-in policy to an API and to configure the properties for that policy.

You can also add built-in policies to an API by creating an OpenAPI definition file. For more information, see [Creating an OpenAPI definition file](#).

The following table shows the list of built-in policies that are available. The table contains links to configuration information for both the built-in policy definitions, and the OpenAPI policy definitions. The policies are the same, but they are created in different ways.

Table 1. Built-in policies

Built-in policy	OpenAPI policy	Description		
Activity Log	activity-log	Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity. Note: The Activity Log policy is not supported in the assembly for an API whose gateway type is DataPower API Gateway. Instead, you configure activity logging in the API design settings. For details, see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0).	✔	✔ Functionality provided in the API design; see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0)
Client Security	client-security	Provides a range of options for authenticating client access to your APIs, extending the capabilities of the OpenAPI specification.	✘	✔
GatewayScript	gatewayscript	Use the <code>gatewayscript</code> policy to execute a specified DataPower GatewayScript program.	✔	✔
Generate JWT	jwt-generate	Use the Generate JWT security policy in IBM API Connect to generate a JSON Web Token (JWT).	✔	✔
Validate JWT	jwt-validate	Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.	✔	✔
if	if	Use the <code>if</code> policy to apply a section of the assembly when a condition is fulfilled.	✔	✔ Functionality provided by switch
GraphQL introspect	graphql-introspect	Use the GraphQL introspect policy to introspect a GraphQL schema.	✘	✔
Invoke	invoke	Apply the Invoke policy to call another service from within your assembly. The response from the backend is stored either in the variable <code>message.body</code> or in the response object variable if it is defined. The policy can be used with JSON or XML data, and can be applied multiple times within your assembly.	✔	✔
JSON to XML	json-to-xml	Use the JSON to XML policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.	✔	✔
Log	log	Use the Log policy to customize or override the default activity logging configuration for an API.	✘	✔
Map	map	Use the Map policy to apply transformations to your assembly flow and specify relationships between variables.	✔	✔
operation-switch	operation-switch	Use the operation-switch policy to apply a section of the assembly to a specific operation.	✔	✔
OAuth	oauth	Use the OAuth policy to policy to perform OAuth processing based on defined OAuth provider settings.	✘	✔
Parse	parse	Use the Parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.	✘	✔
Proxy	proxy	Apply the Proxy policy to invoke another API within your assembly, particularly if the separate API contains a large payload. The response from the backend is stored in the <code>message.body</code> and in the response object variable if it is defined. Only one policy is permitted to be run per unique assembly flow.	✔	✔ Functionality provided by Invoke
Rate Limit	ratelimit	Use the Rate Limit policy to apply one or more rate or burst limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls that an application can make to an API in a specified time period.	✘	✔
Redaction Redaction - DataPower API Gateway Redaction - DataPower Gateway (v5 compatible)	redact - DataPower API Gateway redact - DataPower Gateway (v5 compatible)	Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.	✔	✔
Set Variable	set-variable	Use the Set Variable policy to set the value of a runtime variable, or to clear a runtime variable, or to add a header variable.	✔	✔

Built-in policy	OpenAPI policy	Description	DataPower Gateway	API Gateway
switch	switch	Use the switch policy to execute one of a number of sections of the assembly based on which specified condition is fulfilled.	✓	✓
throw	throw	Use the throw policy to throw an error when it is reached during the execution of an assembly flow.	✓	✓
User Security	user-security	Use the user-security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.	✗	✓
Validate Validate - DataPower API Gateway Validate - DataPower Gateway (v5 compatible)	validate - DataPower API Gateway validate - DataPower Gateway (v5 compatible)	Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.	✓	✓
Validate Username Token	validate-username token	Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.	✓	✗
XML to JSON	xml-to-json	Use the XML to JSON policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).	✓	✓
XSLT	xslt	Use the XSLT policy to apply an XSLT transform to the payload of the API definition.	✓	✓

[Including elements in your OpenAPI 2.0 API assembly](#), [Including elements in your OpenAPI 3.0 API assembly](#)

- **[Activity Log](#)**
Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.
- **[Client Security](#)**
The Client Security policy can be used to extend client authentication access for your APIs.
- **[Extract](#)**
Use the Extract policy to extract and transform data from fields in the API context.
- **[GatewayScript](#)**
Use the gatewayscript policy to execute a specified DataPower GatewayScript program.
- **[Generate JWT](#)**
Use the Generate JWT security policy in IBM API Connect to generate a JSON Web Token (JWT).
- **[Validate JWT](#)**
Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.
- **[GraphQL introspect](#)**
Use the GraphQL introspect policy to introspect a GraphQL schema.
- **[Invoke](#)**
Apply the Invoke policy to call another service from within your assembly. The response from the backend is stored either in the variable `message.body` or in the response object variable if it is defined. The policy can be used with JSON or XML data, and can be applied multiple times within your assembly.
- **[JSON to XML](#)**
Use the JSON to XML policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.
- **[Log](#)**
Use the Log policy to customize or override the default activity logging configuration for an API.
- **[Map](#)**
Use the Map policy to apply transformations to your assembly flow and specify relationships between variables.
- **[OAuth](#)**
An OAuth policy performs the requested OAuth processing based on the defined OAuth provider settings.
- **[Parse](#)**
Use the Parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.
- **[Proxy](#)**
Apply the Proxy policy to invoke another API within your assembly, particularly if the separate API contains a large payload. The response from the backend is stored in the `message.body` and in the response object variable if it is defined. Only one policy is permitted to be run per unique assembly flow.
- **[Rate Limit](#)**
Use the Rate Limit policy to apply one or more rate, burst, or count limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.
- **[Redaction - DataPower API Gateway](#)**
Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.
- **[Redaction - DataPower Gateway \(v5 compatible\)](#)**
Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.
- **[Set Variable](#)**
Use the Set Variable policy to set the value of a runtime variable, or to clear a runtime variable, or to add a header variable.
- **[User Security](#)**
Use the User Security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.
- **[Validate - DataPower API Gateway](#)**
Use the Validate policy to validate the payload in an assembly flow against a schema.
- **[Validate - DataPower Gateway \(v5 compatible\)](#)**
Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.
- **[Validate Username Token](#)**
Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.

- [Websocket Upgrade](#)
Use the Websocket Upgrade policy to process API requests and responses through a WebSocket connection.
- [XML to JSON](#)
Use the XML to JSON policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).
- [XSLT](#)
Use the XSLT policy to apply an XSLT transform to the payload of the API definition.

Activity Log

Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM® API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [activity-log](#).

Note that if you are using the DataPower API Gateway, you can configure your logging preferences by using the API design editor. For more information, see [Configuring activity logging](#) (OpenAPI 2.0) or [Configuring activity logging](#) (OpenAPI 3.0).

About

An API event record exists for each API execution event in the Gateway server. By default, the content type that is collected and stored in API event records is **activity** for when API execution completes successfully, and **payload** for when API execution completes with an error code. Apply the Activity Log policy to your assembly to change the type of content to log in these API event records. For more information about API event records, see [API event record fields](#).

Note: If payload logging is enabled, for the gateway to capture payloads buffering must also be enabled. Enable buffering as follows in the API YAML:

```
x-ibm-configuration:
  ...
  activity-log:
    enabled: true
    error-content: payload
    success-content: payload
  ...
  buffering: true
```

Note:

Activity log policies that call for logging of Analytics data upon success do not apply for the OAuth provider. The OAuth provider logs Analytics data for failure cases, but does not log successful cases.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Activity Log policy properties

Property label	Required	Description	Data type
Title	Yes	A title for the policy is required, but a default value, activity-log is provided.	string
Description	No	A description of the policy.	string
Content	Yes	Defines the type of content to be logged when the operation is successful. Valid values: <ul style="list-style-type: none"> • none: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • activity: Logs invocation only (only the resource URI is recorded). • header: Logs activity and header. • payload: Logs activity, header, and payload (the original request, if any, and the final response). The default value is activity .	string
Error content	No	Indicates what content to log if an error occurs. Valid values: <ul style="list-style-type: none"> • none: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • activity: Logs invocation only (only the resource URI is recorded). • header: Logs activity and header. • payload: Logs activity, header, and payload (the original request, if any, and the final response). The default value is payload .	string

Client Security

The Client Security policy can be used to extend client authentication access for your APIs.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [client-security](#).

About

You use the Client Security policy to create an assembly action that's separate from the OpenAPI specification, to allow for more options to authenticate an application. Note that you cannot use the client-security policy to perform rate-limiting enforcement.

In a client security action, you define the following settings.

- Control whether to stop processing if client security fails. When client security fails, stops assembly processing and returns an error.
- Control whether to require the client secret. When required, the secret is compared to the registered secret on the application that is identified by the client ID.
- Define the method to extract client credentials from the request.
 - For all methods except HTTP, use the ID Name and the Secret Name properties to specify the location that contains the ID and the location that contains the secret.
 - When Cookie, specify which cookie.
 - When Context Variable, specify which runtime context variable.
 - When Form, specify the form data.
 - When Header, specify which header.
 - When Query, specify which query parameter.
 - For the HTTP method, use the HTTP Type property to specify the format of the authorization header, which expects the Basic form in the **basic base64_id:secret** format.
- Define the method to authenticate the extracted client credentials. The supported methods are Native (this means by using IBM® API Connect), or by using a specified Third party user registry.
 - If Third party, use the User Registry Name property to specify the user-registry to authenticate the extracted client credentials. The supported registry types are LDAP and authentication URL.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Client Security policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is client-security .	string
Description	No	A description of the policy.	string
Stop on Error	Yes	If this setting is enabled, assembly processing stops if client security fails, and an error is returned. The check box is selected by default.	boolean
Secret Required	Yes	If this setting is enabled, the client secret must be sent in the request. The secret is compared to the registered secret on the application that is identified by the client ID. The check box is selected by default.	boolean
Credential Extraction Method	Yes	Select one of the following options to define how the calling application authenticates: <ul style="list-style-type: none">• Header: client ID and client secret credentials must be supplied in the request header.• Query: client ID and client secret credentials must be supplied as query parameters in the request URL.• Form: client ID and client secret credentials must be supplied as form data sent in a POST request.• Cookie: client ID and client secret credentials must be supplied in a header called Cookie.• HTTP: the calling application must authenticate by using basic authentication.• Context Variable: the credentials that are used for authenticating the client are obtained from context variables that you set in the assembly flow prior to the Client Security policy, by using a GatewayScript policy for example. The names of these context variables are determined by the values that you supply in the ID Name and Secret Name properties of the Client Security policy. The default value is Header.	string

Property label	Required	Description	Data type
ID Name	Yes, unless the selected value of Credential Extraction Method is HTTP	The name of the parameter whose value specifies the client ID. For all Credential Extraction Method options other than Context Variable and HTTP, the calling application must supply a parameter with this name, in the location defined by the Credential Extraction Method option. For the Context Variable option, this property specifies the name of a context variable. This property does not apply if the Credential Extraction Method is HTTP.	string
Secret Name	Yes, if Secret Required is enabled and the selected value of Credential Extraction Method is other than HTTP	The name of the parameter whose value specifies the client secret. For all Credential Extraction Method options other than Context Variable and HTTP, the calling application must supply a parameter with this name, in the location defined by the Credential Extraction Method option. For the Context Variable option, this property specifies the name of a context variable. This property does not apply if the Credential Extraction Method is HTTP.	string
HTTP Type	Yes, if the selected value of Credential Extraction Method is HTTP	The authentication type. Currently, the only available option is Basic.	
Authenticate Client Method	Yes	Select one of the following options: <ul style="list-style-type: none"> Native: only client ID and client secret are used to authenticate the client. If the selected value of Credential Extraction Method is HTTP then the calling application must supply the client ID for the user name, and the client secret for the password. Third party: a user registry is used to authenticate the client. If the selected value of Credential Extraction Method is other than HTTP then the calling application must supply the user name for the client ID, and the password for the client secret. <p>The default value is Native.</p>	string
User Registry Name	Yes, if the selected value of Authenticate Client Method is Third party	Select the user registry that will be used to authenticate the client. The supported registry types are LDAP and authentication URL.	string

API Gateway only

Extract

Use the Extract policy to extract and transform data from fields in the API context.

Before you begin

Table 1. Gateways that support this policy and the corresponding policy versions

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly editor. For details about how to configure the policy in your OpenAPI source, see [extract](#).

About this task

The Extract policy specifies the data source that contains the content to transform, the fields that contain the content, and expressions that define how to transform the content. You use a subset of JSONata notation to specify the fields to extract and transform. For more information, see [Constructing JSONata expressions to extract and transform data](#).

The input to the Extract policy must be parsed data. One way to produce parsed data is to add a Parse policy before the Extract policy in your assembly.

Procedure

- In the navigation pane, click  Develop, then select the APIs tab. The Develop page opens.
- Click the title of the API definition that you want to work with.
- Select the Gateway tab, then click Policies in the navigation pane. For more information about working with the assembly editor for an API, see [The assembly editor](#).
- Find the Extract policy in the palette, and drag the policy onto your canvas.
- Specify the following properties.

Table 2. Extract policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is extract .	string
Description	No	A description of the policy.	string
Root	Yes	The data source that contains the content to transform. The default value is message.body .	string
Capture	Yes	The path expression that identifies the field. The default setting is \$, which indicates the entire input.	string
Transform	Yes	The expression that defines how to transform the content.	string

- Specify a version for the policy by clicking the Source icon , and completing the **version** section of the policy YAML. For example:

```

execute:
- extract:
  version: 2.0.0
  title: extract
...

```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

Example

Transform the contents of the `account` field to include only the last 4 characters.

```

- extract:
  version: 2.0.0
  title: extract
  root: message.body
  extracts:
  - capture: $.members.policy.**.account
    transform: $substring($,-4)
  description: Include only the last 4 characters of the account field.

```

- [Constructing JSONata expressions to extract and transform data](#)

To extract and transform data from fields in the API context when using the Extract policy with the DataPower API Gateway, you supply a JSONata expression that defines the fields to extract and transform.

API Gateway only

Constructing JSONata expressions to extract and transform data

To extract and transform data from fields in the API context when using the Extract policy with the DataPower® API Gateway, you supply a JSONata expression that defines the fields to extract and transform.

Note: For a list of known limitations to DataPower API Gateway support for JSONata, see [Limitations to support for JSONata](#). The following JSONata functions are supported:

- Aggregation functions:
 - `$average(array)`
 - `$max(array)`
 - `$min(array)`
 - `$sum(array)`
- Array functions:
 - `$append(array1, array2)`
 - `$count(array)`
 - `$reverse(array)`
 - `$sort(array [, function])`
 - `$zip(array1, ...)`
- Boolean functions:
 - `$boolean(arg)`
 - `$exists(arg)`
 - `$not(arg)`
- Numeric functions:
 - `$abs(number)`
 - `$ceil(number)`
 - `$floor(number)`
 - `$formatBase(number [, radix])`
 - `$number(arg)`
 - `$power(base, exponent)`
 - `$round(number [, precision])`
 - `$sqrt(number)`
- Object functions:
 - `$keys(object)`
 - `$lookup(object, key)`
 - `$merge(array<object>)`
 - `$spread(object)`
 - `$type(value)`

In addition to the standard values returned by `$type()`, the API gateway implementation of `$type()` can return the following values: `binary`, `empty`, `graphql`, `stream`, or `xml`.
- String functions:
 - `$contains(str, pattern)`
 - `$join(array[, separator])`
 - `$length(str)`
 - `$lowercase(str)`
 - `$match(str, pattern [, limit])`
 - `$pad(str, width [, char])`
 - `$replace(str, pattern, replacement [, limit])`
 - `$split(str, separator [, limit])`
 - `$string(arg)`

- `$substring(str, start[, length])`
- `$substringAfter(str, chars)`
- `$substringBefore(str, chars)`
- `$trim(str)`
- `$uppercase(str)`

- You can use the following functional extensions to standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description
<code>\$header (name)</code>	<code>message.headers.name</code>	Message header
<code>\$httpVerb ()</code>	<code>request.verb</code>	HTTP method of the request
<code>\$operationID ()</code>	<code>api.operation.id</code>	ID of the operation
<code>\$operationPath ()</code>	<code>api.operation.path</code>	Path of the operation
<code>\$queryParameter ('name')</code>	<ul style="list-style-type: none"> ◦ <code>request.parameters.name.locations</code> The supported keyword is <code>query</code>. ◦ <code>request.parameters.name.values</code> 	Searches for the index of <code>query</code> in <code>request.parameters.name.locations</code> and returns <code>request.parameters.name.values[index]</code> , where <code>[index]</code> is the value for <code>query</code> in locations. Parameter values are not URL decoded.
<code>\$statusCode ()</code>	<code>message.status.code</code>	Status code
<code>\$storageType ([arg])</code>	<code>variable.body</code> You can specify any variable in the API context. When no variable is specified, the default variable <code>message.body</code> is used.	Storage type of the message. The supported values are <code>binary</code> , <code>empty</code> , <code>graphql</code> , <code>json</code> , <code>stream</code> , or <code>xml</code> .
<code>\$urlParameter ('name')</code>	<ul style="list-style-type: none"> ◦ <code>request.parameters.name.locations</code> The supported keywords are <code>path</code> and <code>query</code> ◦ <code>request.parameters.name.values</code> 	Searches for the index of <code>path</code> and <code>query</code> in <code>request.parameters.name.locations</code> and returns a single array that contains both <code>path</code> and <code>query</code> values from <code>request.parameters.name.values</code> . When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values. <code>http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese</code> The <code>\$urlParameter ('breed')</code> URL returns the following array of values. <code>[cats, adopt, Sphynx, Siamese]</code> In this example, the URL includes an API path that is configured as <code>/petstore/{breed}/{breed}</code> , where <code>breed</code> is configured to be a path parameter of the API path. As a result, <code>cats</code> and <code>adopt</code> are included in the output.
<code>\$xpath (path, xpathExpression)</code>	You can specify any writable variable in the API context. The <code>xpathExpression</code> must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. <code>\$xpath (\$, '//price')</code>

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
<code>\$gqlActiveOperation ([graphql_message])</code>	<code>message.body</code>	Gets the active operation found in the specified GraphQL message. The <code>operationName</code> must be the same as the name of the active operation.
<code>\$gqlAlias (graphql_field_node)</code>	<code>message.body</code>	Gets the alias of a GraphQL field node.
<code>\$gqlFragments ([graphql_message])</code>	<code>message.body</code>	Gets the fragments found in the specified GraphQL message.
<code>\$gqlName ([graphql_node])</code>	<code>message.body</code>	Gets the node name. For operations, the node name is the <code>operationName</code> . For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the <code>operationName</code> of <code>message.body</code> is retrieved.
<code>\$gqlOperations ([graphql_message])</code>	<code>message.body</code>	Gets the operations found in the specified GraphQL message.
<code>\$gqlType ([graphql_node])</code>	<code>message.body</code>	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

- You can use the `&` (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- `/` (division)
- `%` (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`

- >
- <=
- >=

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (*) and double asterisk (**) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- **query**
The entire GraphQL query including operations and fragments.
- **operationName**
For an anonymous operation, **operationName** can be empty.
- **~fragmentSpreadName**
- **on~typeCondition**
- **~~fragmentDefinitionName**

GatewayScript

Use the gatewayscript policy to execute a specified DataPower® GatewayScript program.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [gatewayscript](#).

About

The gatewayscript policy gives you built-in access to the DataPower Gateway module via variable **apim**.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. gatewayscript policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is gatewayscript .	string
Description	No	A description of the policy.	string
Source	Yes	The GatewayScript source code to execute. For example: <pre>var message = ['Hello', 'World!']; console.debug(message.join(' '));</pre>	string

Examples

The following examples show how the full OpenAPI for the policy looks in the source code.

Example one:

```
gatewayscript:
  title: writes message to DataPower log
  source: console.debug('Hello World!');
```

Example two:

```
gatewayscript:
  title: script written in multiple lines
  source: |
    var message = [ 'Hello', 'World!' ];
    console.debug(message.join(' '));
```

For more code examples, see [GatewayScript code examples](#) and, if you are using the DataPower API Gateway, [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#).

For general information on using GatewayScript, see the following topics in the DataPower product documentation:

- [GatewayScript APIs for API management](#)
- [Accessing and manipulating a variable in the API context](#)
- [OAuth context variables](#)

Errors

The following error can be thrown while the policy is being executed:

- **JavaScriptError** - a generic error that captures all errors that occur during the execution of the policy.
- [GatewayScript code examples](#)
Example GatewayScript code snippets to help the creation of a gatewayscript policy.

Related tasks

- [Creating a new REST OpenAPI definition](#)

GatewayScript code examples

Example GatewayScript code snippets to help the creation of a gatewayscript policy.

Attention:

- The mechanisms described here for interacting with the API Connect context are intended for v5-compatible gateways and also to provide v5 compatibility for APIs created for the API Gateway. However, if you are writing a GatewayScript policy or user-defined policy for a new API Gateway API, use the mechanisms described in [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#) for better performance and long-term support. For API Gateway APIs, the v5-compatibility functions listed here are to be used for v5 migration only.
- The GatewayScript functions that are listed here use the common name **apim** to call the methods. However, you can change the common name to one of your choice by using one or other of the following function calls depending on your gateway type:

```

DataPower Gateway (v5 compatible)  var name = require('local:///isp/policy/apim.custom.js'); // v5-Compatible Gateway
API Gateway                        var name = require('apim'); // DataPower API Gateway

```

where *name* is your chosen name; for example:

```
var apim = require('apim');
```

Access the assembly context

The following code snippets show examples of how to access the assembly context.

Example one returns the **request** context:

```
apim.getvariable('request');
```

Example two returns the header named **myheader**:

```
apim.getvariable('request.headers.myheader');
```

Example three shows how to set, add, or clear a context variable, in this case a message header:

```
apim.setvariable('message.headers.name', value, action)
```

where

- *name* is the name of the message header that you want to set, add, or clear.
- *value* is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the *value* as `request.headers.content-type`. This property is only required when **set** or **add** is specified as the action.
- *action* is the action that you want to apply to the variable. Valid options are:
 - **set**
 - **add**
 - **clear**

If no option is set, the default option of **set** is applied.

For a complete list of context variables, see [API Gateway context variables](#), and for more information about how to reference context variables in IBM API Connect see [Variable references in API Connect](#). If you are using the DataPower® API Gateway, see also [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#).

Read input synchronously

The following code snippets show examples of how to read input synchronously by using the **apim.getvariable** function to read data direct from a context. JSON input is returned as a JavaScript object. XML data is returned as a NodeList object (DOM).

Example one returns a synchronous read of the original request body into the variable that is called *json*:

```
var json = apim.getvariable('request.body');
```

Example two returns a synchronous read of the current message into the variable that is called *xml*:

```
var xml = apim.getvariable('message.body');
```

Note: If the content type of the data is neither XML nor JSON, the `apim.getvariable()` function returns a `NodeList` object consisting of one binary node, which must be converted to a string. If the content really is XML or JSON, you must then parse this string, as illustrated in the following example:

```
var data = apim.getvariable('request.body');

// if a nodelist was returned and the type is 13 (BLOB/Binary Node), convert it
// to a Buffer, which can then be converted to a string
if ((data.item && data.length > 0 && data.item(0).nodeType === 13)) {
  data = data.item(0).toBuffer().toString();
}

// if the string really is XML or JSON, then now add code to parse it with
// the appropriate XML or JSON parse function
.
.
.
```

Read input asynchronously

The following code snippets show the `apim.readInput()` calls that you can use to perform a JavaScript callback function to read input data asynchronously into a variable. JSON input is returned as a JavaScript object. XML data is returned as a `NodeList` object (DOM). Other types of input are returned as a `Buffer` object.

```
apim.readInput(callback(err,input) {});
apim.readInputAsJSON(callback(err,json) {});
apim.readInputAsXML(callback(err,nodelist) {});
apim.readInputAsBuffer(callback(err,buffer) {});
```

Note: The `apim.readInput()` function attempts to determine the input data type and call the appropriate `apim.readInputAsType()` function in order to return the data in the correct format. However, to ensure that the correct data type is returned, use the `apim.readInputAsType()` function.

The `apim.readInputAsType()` function reads the data from either the `INPUT` context (for example `session.INPUT`), or from a policy output context (for example `policy.output`), depending on whether a previous policy had been called that had written output to a policy output context. This function then calls the underlying IBM DataPower GatewayScript `readAsType` method on the relevant context to read the data, and then use JavaScript callbacks to return the data to a variable. For more information about DataPower methods, see [Gateway programming model and GatewayScript](#).

The following is an example of how to use the `apim.readInputAsJSON()` callback function to get data into a variable that is called `json`:

```
apim.readInputAsJSON(function (error, json) {
  if (error)
  {
    // handle error
  }
  else
  {
    // the json parameter will contain the json data that has been read
    // process the json object in some way and write to the output context
    if (json.test==='true')
    {
      // if json data contains a variable called test that is set to true, then also add some test data
      json.data = 'This is my test data'
    }
    session.output.write(json);
    // write to the output context
  }
});
```

Configure error information

The following code block shows an example of how to configure the policy implementation to produce error information by using the `apim.error()` function. In this example, `MyError` is thrown to the assembly flow. If there is a catch handler it catches this error, otherwise the assembly skips the execution of the flow and sends a `500 Internal Error` response.

```
apim.error('MyError', 500, 'Internal Error', 'Some error message');
```

where:

- `MyError` is the name of the error.
- `500` is the HTTP code of the required error message.
- `Internal Error` is the HTTP reason phrase for the error.
- `Some error message` is the suggested action for the user.

Accessing the caught exception in a catch block

The following example shows how, in the `catch` block of an API assembly, you can obtain the details of the current caught exception. A possible use would be to create a custom error response using the details of the caught exception.

```
let exception = apim.getError();
```

The function returns a JSON object; for example:

```
{
  "name": "OperationError",
  "message": "This is a thrown Operation Error",
  "policyTitle": "Throw Operation Error",
  "status": {
    "code": "500",
    "reason": "Internal Server Error"
  }
}
```

Write output

The following example shows how to write data into the output, in this case the JSON data '{ "status": "created" }', by using the `session.output.write` variable:

```
session.output.write('{ "status": "created" }');
```

The `session.output.write` variable is a standard GatewayScript method that writes data to the output context. For more information, see [Contexts and sessions](#). Use the following function to set the format of the content that is written to the `session.output` variable:

```
apim.output('application/type');
```

For example, if you were creating a policy that called:

```
session.output.write('<test>this is some xml data</test>');
```

the policy would write XML data to the output context. You would need to configure the policy to also call

```
apim.output('application/xml');
```

to tell the system that the output is XML. It can cause issues in the processing of the policy if the actual output context format, and the format that is specified in `apim.output`, are different.

Note: If you use `apim.setvariable` to manipulate `message.body`, you must immediately follow the `apim.setvariable` function call with an `apim.output` function call that specifies the content type of the payload that was written to `message.body` by `apim.setvariable`.

Generate JWT

Use the Generate JWT security policy in IBM® API Connect to generate a JSON Web Token (JWT).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [jwt-generate](#).

About

JSON Web Token (JWT) is a compact, URL-safe way of representing claims that are to be transferred between two parties. The Generate JWT policy enables you to generate claims and configure whether they are to be used as the payload of a JSON Web Signature (JWS) structure, or as the plain text of a JSON Web Encryption (JWE) structure. Specifying the cryptographic material for both the JWS and the JWE produces a nested JWT that is both digitally signed and encrypted. The JWT is then assigned to the Authorization header as a Bearer token (the default option), or to the runtime variable in the JSON Web Token (JWT) property, if specified.

Note:

- For algorithm types HS256, HS384, and HS512 the cryptographic objects referenced must be a Shared Secret Key.
- For algorithm types RS256, RS384, RS512, ES256, ES384, ES512, PS256, PS384, PS512 the cryptographic objects referenced must be a Crypto Key (private key).
- The cryptographic material can be provided through a JSON Web Key (JWK).
- If both a cryptographic object and a JWK are specified, the cryptographic object is used to sign the JWT.

Prerequisites

The following prerequisites apply:

- If you are using one or more cryptographic objects, they must be located in the API Connect domain on the DataPower appliance. The cryptographic objects must reference the Shared Secret Key or certificate that is needed to encrypt or sign the JWT contents.
- If a JSON Web Key (JWK) is being used, it must be referenced by a runtime variable.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Generate JWT policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is <code>jwt-generate</code> .	string

Property label	Required	Description	Data type
Description	No	A description of the policy.	string
JSON Web Token (JWT)	No	Runtime variable in which to place the JWT that is generated. The default value is: generated.jwt . However, if not set, the JWT that is generated is written to the Authorization Header as a Bearer token.	string
JWT ID Claim	No	Indicates whether a JWT ID (jti) claim should be added to the JWT. If selected, the property is set to true , and a UUID is generated and set as the JTI claim value.	boolean
Issuer Claim	Yes	Runtime variable from which the Issuer (iss) claim string can be retrieved. This claim represents the Principal that issued the JWT. The default value is: iss.claim	string
Subject Claim	No	Runtime variable from which the Subject (sub) claim string can be retrieved.	string
Audience Claim	No	Runtime variable from which the Audience (aud) claim string can be retrieved. Multiple variables are set by using a comma-separated string.	string
Validity Period	Yes	The length of time (in seconds), that is added to the current date and time, in which the JWT is considered valid. The default value is 3600 .	integer
Private Claims	No	Runtime variable from which a valid set of JSON claims can be retrieved. These claims are added to any set of claims specified previously.	string
Sign JWK variable name	No	Runtime variable that contains the JWK that is used to sign the JWT. ¹	string
Cryptographic Algorithm	No	The cryptographic algorithm to use. Valid values are: <ul style="list-style-type: none"> • HS256 • HS384 • HS512 • RS256 • RS384 • RS512 • ES256 • ES384 • ES512 • PS256 • PS384 • PS512 	string
Sign Crypto Object	No	The cryptographic object to use to sign the JWT. ¹	string
Encryption Algorithm	No	The encryption algorithm to use. Valid values are: <ul style="list-style-type: none"> • A128CBC-HS256 • A192CBC-HS384 • A256CBC-HS512 	string
Encrypt JWK variable name	No	Runtime variable that contains the JWK to use to encrypt the JWT.	string
Key Encryption Algorithm	No	The key encryption algorithm to use. Valid values are: <ul style="list-style-type: none"> • RSA1_5 • RSA-OAEP • RSA-OAEP-256 • dir • A128KW • A192KW • A256KW 	string
Encrypt Crypto Object	No	The cryptographic object to use to encrypt the claim.	string

Example

```
- jwt-generate:
  version: 1.0.0
  title: jwt-generate
  iss-claim: iss.claim
  exp-claim: 3600
  jwt: generated.jwt
  jti-claim: true
  sub-claim: sub.claim
  aud-claim: aud.claim
  private-claims: private.claims
  jws-jwk: jws.jwk
  jws-alg: HS256
  jws-crypto: jwsCryptoObjectName
  jwe-enc: A128CBC-HS256
  jwe-jwk: jwe.jwk
  jwe-alg: A128KW
  jwe-crypto: jweCryptoObjectName
```

Errors

The following error can be thrown while the policy is being executed:

- **RuntimeError** - a generic error that captures all errors that occur during the execution of the policy. Upon failure, the detailed error message that is received from the underlying JOSE module is written to the default system log as an error message. This detailed error message is also assigned to the runtime variable `jwt-generate.error-message`, so it can be retrieved via `catch`.

If a `catch` is not configured, in the case of a failure the Generate JWT policy returns an HTTP code 500 **Invalid-JWT-Generate** failure. The detailed error message from the underlying JOSE module can be found in the system log.

Attention: If you are an API developer who is troubleshooting a failure that one of your customers had with your API, consider the security risks before sending a customer the exact content of the log message. You can avoid the possibility of someone launching an attack based on the information that they receive from the log message by sending the customer only general information about the message.

Related information

- [Introduction to JSON Web Tokens](#)

¹ A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to sign the JWT. However, if both data types are specified, only the Crypto Object is used.

Validate JWT

Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [jwt-validate](#).

About

JSON Web Token (JWT) is a compact, URL-safe way of representing claims that are to be transferred between two parties. The Validate JWT policy enables you to secure access to your APIs by using JWT validation. For example, when an input request that contains a JWT in the header is received, the Validate JWT policy extracts the token, verifies, and decrypts (if appropriate) the signature, and validates the claim. If valid, the claim is put in a runtime variable (for subsequent use if required), and access is allowed to the API. If the claim is not valid, access is denied.

All claims that are specified in the Validate JWT policy are validated, but this is not necessarily all the claims that are contained in the JWT. Not all claims that are in the JWT must be validated, but if any one of the claims that are specified in the Validate JWT policy fail, the whole validation fails. If the validation succeeds, the full set of claims that are contained in the JWT are written to the runtime variable specified in the Output Claims property. Thereby allowing any subsequent action to use this runtime variable to further validate the full set of claims that were in the JWT, as necessary.

Note:

- If the original message was signed with a Shared Secret Key, the cryptographic object that is specified must also be a Shared Secret Key.
- If the original message was signed with a Private Key, the cryptographic object that is specified must be a Crypto Certificate (public certificate).
- The cryptographic material can be provided through a JSON Web Key (JWK).
- If a JWK header parameter is included in the header of the JWT, the parameter must match the JWK or cryptographic object that is specified in the policy, or the JWT validation will fail.
- If both a cryptographic object and a JWK are specified, the cryptographic object is used to decrypt or verify the JWT.
- The JWT validate action on the DataPower API Gateway can verify a JWT by using either a single JWK, or a JWK set.

Prerequisites

The following prerequisites apply:

- IBM® DataPower V7.5 with the Application Optimization (AO) option.
- If you are using one or more cryptographic objects, they must be located in the IBM API Connect domain on the DataPower appliance. The cryptographic objects must reference the Shared Secret Key or public certificate that is needed to decrypt the JWT contents or verify the signature.
- If a JSON Web Key (JWK), or JWK set, is being used, it must be referenced by a runtime variable.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Validate JWT policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is <code>jwt-validate</code> .	string
Description	No	A description of the policy.	string

Property label	Required	Description	Data type
JSON Web Token (JWT)	Yes	Context or runtime variable that contains the JWT to be validated. The default value is: <code>request.headers.authorization</code> . However, if this property is not set, the policy looks for the JWT in the <code>request.headers.authorization</code> location by default. Note: The format of the authorization header must be: <code>"Authorization: Bearer jwt-token"</code> where <code>jwt-token</code> is the encoded JWT.	string
Output Claims	Yes	Runtime variable to which the full set of claims that are contained in the JWT is assigned. The default value is: <code>decoded.claims</code> .	string
Issuer Claim	No	The Perl Compatible Regular Expressions (PCRE) to use to validate the Issuer (iss) claim.	string
Audience Claim	No	The PCRE to use to validate the Audience (aud) claim.	string
Decrypt Crypto Object	No	The cryptographic object (a shared key or certificate) to use to decode the claim. ¹	string
Decrypt Crypto JWK variable name	No	Runtime variable that contains the JWK to use to decrypt the JWT. ¹	string
Verify Crypto Object	No	The cryptographic object (a shared key or certificate) to use to verify the signature. ²	string
Verify Crypto JWK variable name	No	Runtime variable that contains the JWK, or JWK set, to use to verify the signature. ²	string

Example

```
- jwt-validate:
  version: 1.0.0
  title: jwt-validate
  jwt: request.headers.authorization
  output-claims: decoded.claims
  iss-claim: "'^data.*'"
  aud-claim: "'^id.*'"
  jwe-crypto: jweCryptoObjectName
  jwe-jwk: jwe.jwk
  jws-crypto: jwsCryptoObjectName
  jws-jwk: jws.jwk
```

Errors

The following error can be thrown while the policy is being executed:

- **RuntimeError** - a generic error that captures all errors that occur during the execution of the policy. Upon a validation failure, the detailed error message that is received from the underlying JOSE module is written to the default system log as an error message. This detailed error message is also assigned to the runtime variable `jwt-validate.error-message`, so it can be retrieved via `catch`.

If a catch is not configured, in the case of a validation failure the Validate JWT policy returns an HTTP code 500 **Invalid-JWT-Validate** failure. The detailed error message from the underlying JOSE module can be found in the system log.

Attention: If you are an API developer who is troubleshooting a failure that one of your customers had with your API, consider the security risks before sending a customer the exact content of the log message. You can avoid the possibility of someone launching an attack based on the information that they receive from the log message by sending the customer only general information about the message.

For examples, see [jwt-validate](#).

Related information

- [Introduction to JSON Web Tokens](#)

¹ A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to decrypt the JWT. However, if both data types are specified, only the Crypto Object is used.

² A JWK, or JWK set, and a Crypto Object are both valid ways of providing the cryptographic data necessary to verify the JWT. However, if both data types are specified, only the Crypto Object is used.

GraphQL introspect

Use the GraphQL introspect policy to introspect a GraphQL schema.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [graphql-introspect](#).

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. GraphQL introspect policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is <code>graphql-introspect</code> .	string
Description	No	A description of the policy.	string
Input	No	A variable in the API context that contains the input to introspect. The content of the <code>body</code> field of the variable is the input to introspect. By default, the variable name is <code>message</code> .	string
Output	No	A variable in the API context where the results of the introspection are stored. The content of the <code>body</code> field of the variable is the result of GraphQL introspection. The default variable name is the same as that of the variable specified in the Input field. Therefore, by default, the input of the introspection is overwritten by the output.	string

Invoke

Apply the Invoke policy to call another service from within your assembly. The response from the backend is stored either in the variable `message.body` or in the response object variable if it is defined. The policy can be used with JSON or XML data, and can be applied multiple times within your assembly.

Note: The Invoke policy does not support responses with multipart form data, that is, when the response is set to `Content-Type: multipart/related`.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.1 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.0.3.0 or later)

Configuring the Invoke policy for DataPower API Gateway

Follow these steps to configure the Invoke policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the Invoke policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see [Configuring the Invoke policy for DataPower Gateway \(v5 compatible\)](#). For information about the different types of gateway, see [API Connect gateway types](#). For details on how to configure the policy in your OpenAPI source, see [invoke](#).

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Select the Gateway tab, then click Policies in the navigation pane.
For more information about working with the assembly editor for an API, see [The assembly editor](#).
4. Find the Invoke policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Invoke policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is invoke .	string
Description	No	A description of the policy.	string
URL	Yes	Specifies a URL for the target service. For a SOAP API, a URL is added by default. Where possible, the Invoke URL value is pre-supplied from information that is defined in the imported WSDL.	string
Backend type	No	Select one of the following options to determine how the payload is sent to the backend. Detect Detect the message type and send the payload to the backend accordingly. XML Package the payload as XML and send. If the message type is not XML, the operation fails. JSON Package the payload as JSON and send. If the message type is not JSON, the operation fails. Binary Package the payload as binary and send, regardless of the message type. GraphQL Package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. The default value is Detect.	string
GraphQL send type(policy version 2.2.0 and later)	Yes, if Backend type is set to GraphQL or Detect, and HTTP Method is set to POST or Keep	Select one of the following values to determine how the GraphQL payload is sent to the back end. Detect Detect the message type and send the payload to the back end accordingly. GraphQL Package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. JSON Package the payload as JSON and send. If the message type is not GraphQL, the operation fails. Note: GraphQL send type is supported only if Backend type is set to GraphQL or Detect, and HTTP Method is set to POST or Keep.	string
TLS profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	Yes	The time to wait before a reply from the endpoint (in seconds). The default value is 60 .	integer
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code 301 Moved Permanently . If you select this checkbox, the invoke policy follows the URL redirection by making a further call to the URL specified in the Location header in the response. If you clear this checkbox, the invoke saves the 301 status code and the API call is considered to be complete. Note: The follow-redirect property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the invoke always follows the URL redirection; the proxy policy (not supported by the DataPower API Gateway) saves the 301 status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
HTTP Method	Yes	The HTTP method to use for the Invoke. The following values are valid. <ul style="list-style-type: none"> • Keep • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is GET . However, if set to Keep , or the property is removed from the source, the HTTP method from the incoming request is used.	string
HTTP Version (policy version 2.1.0 and later)	Yes	The HTTP version that will be used when connecting to the backend server. Select one of the following values. <ul style="list-style-type: none"> • HTTP/1.0 • HTTP/1.1 • HTTP/2 The default value is HTTP/1.1.	string
HTTP/2 Required (policy version 2.1.0 and later)	No	Select this checkbox to require that the server selects HTTP/2 during a TLS connection, otherwise the DataPower API Gateway rejects the connection and fails the request. For a non-TLS connection, a warning is logged stating that the requirement can't be enforced. This setting applies only if HTTP Version is set to HTTP/2.	boolean
Compression	No	Select this checkbox to enable Content-Encoding compression on upload. The checkbox is cleared by default.	boolean

Property label	Required	Description	Data type
Cache Type	No	<p>The cache type determines whether to cache documents, honoring or overriding the HTTP Cache Control directives received in the response from the target URL. This property takes effect only when a response is received, otherwise the policy always returns the non-expired response that was previously saved in cache. Valid values are:</p> <p>Protocol The cache behavior is determined by the Cache-Control headers on the response, in accordance with RFC 7234. To optimize performance, if the gateway receives more than one request for a resource that is not in the cache but could be cached when the response from the target URL is received, the gateway sends only one request to the target URL; the remaining requests are not processed until the response from the first request has been received and the cache behavior has been determined from this response. If the response indicates that caching is possible, the gateway responds to all waiting requests with the cached resource. If the response indicates that caching is not possible, the gateway sends all waiting requests to the target URL.</p> <p>Use this option only if you expect that responses from the target URL can be cached, in which case it should improve performance and limit the demand on the target URL. If, however, the target URL never indicates that the gateway should cache its response, performance might be impaired when compared to the No Cache option.</p> <p>No Cache Responses from the target URL are not cached on the gateway regardless of any caching headers returned. In this case, every request from the client is sent to the target URL. Use this option if you do not want to cache any of the backend responses on the gateway, or if it is unlikely that a response from the target URL will allow caching through the Cache-Control header settings.</p> <p>Time to Live This option is similar to the Protocol option except it allows you to specify the amount of time that you want the successful response from the invoke or proxy to remain in the cache. Use this option only if you expect that responses from the target URL can be cached.</p> <p>The default value is Protocol.</p>	string
Time to Live	No	<p>Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property Cache type is set to Time to Live. Enter a value in the range 5 - 31708800. The default value is 900.</p>	integer
Cache key	No	<p>Specifies the unique identifier of the document cache entry. If omitted, the entire URL string is used as the key.</p>	string
Allow WebSocket Upgrade (policy version 2.1.0 and later)	No	<p>Select this checkbox to allow an HTTP or HTTPS connection to be upgraded to the WebSocket protocol if the request received by the corresponding HTTP or HTTPS handler on the DataPower API Gateway uses WebSocket (ws) or WebSocket Secure (wss).</p> <p>Note:</p> <ul style="list-style-type: none"> This setting is available only for GraphQL APIs. The Allow WebSocket Upgrade setting is deprecated. To allow WebSocket upgrade requests that manage API processing data, define an assembly WebSocket upgrade policy. For more information, see Websocket Upgrade. 	boolean
Inject proxy headers	No	<p>If you select this checkbox, the invoke policy injects the X-Forwarded-For, X-Forwarded-To, X-Forwarded-Host, and X-Forwarded-Proto headers to the request that is sent to the target URL. The checkbox is cleared by default.</p>	boolean
Decode Request Params	No	<p>If you select this checkbox, any request parameters that are referenced by a variable definition on the target URL of the invoke policy are URL-decoded. The checkbox is cleared by default.</p>	boolean
QueryParam Encode	No	<p>If you select this checkbox, all "+" characters in the query parameter values of the target URL are encoded to %2F. The checkbox is cleared by default.</p>	boolean
Keep Payload	No	<p>If you select this checkbox, the invoke policy sends a payload on an HTTP DELETE method. The checkbox is cleared by default.</p>	boolean
Restrict to HTTP 1.0 (policy version 2.0.0 only)	No	<p>If you select this checkbox, HTTP transactions are restricted to version 1.0. The check box is cleared by default.</p>	boolean
Allow chunked uploads	No	<p>If you select this checkbox, chunked-encoded documents are sent to the server. When the HTTP 1.1 protocol is used, the body of the document can be delimited by either Content-Length or chunked encoding. While all servers can interpret Content-Length, many applications fail to understand chunked-encoded documents. For this reason, Content-Length is the standard method. The use of Content-Length interferes with the ability of the DataPower Gateway to fully stream. If you must stream full documents to the target server, enable this property.</p> <p>When enabled, the server must be RFC 2616 compatible. Unlike all other HTTP 1.1 features that can be negotiated down at run time, you must know beforehand that the target server is RFC 2616 compatible.</p> <p>The check box is selected by default.</p> <p>Note: Chunked encoding is not supported by the HTTP 1.0 protocol.</p>	boolean

Property label	Required	Description	Data type
Persistent Connection (policy version 2.3.0 and later)	No	Select this checkbox to enable HTTP persistent connections, allowing connection re-use. The checkbox is selected by default.	boolean
Header control	No	Specifies the headers in <code>message.headers</code> that you want to copy to the target URL. To prevent headers from being copied, complete the following steps. <ul style="list-style-type: none"> a. Select Blocklist. b. Click Add blocklist. c. In the empty field that is displayed, enter the header name. d. To add further headers, repeat the previous steps. To specify headers that you want to be copied, complete the following steps. <ul style="list-style-type: none"> a. Select Allowlist. b. Click Add allowlist. c. In the empty field that is displayed, enter the header name. d. To add further headers, repeat the previous steps. The values that you specify are in regular expression format. For example, to specify the Content-Type header, enter <code>^Content-Type\$</code> By default, Blocklist is selected, with no blocklist entries, meaning that all headers are copied.	string
Parameter control	No	Specifies the parameters in the incoming request that you want to be copied to the target URL. To prevent parameters from being copied, complete the following steps. <ul style="list-style-type: none"> a. Select Blocklist. b. Click Add blocklist. c. In the empty field that is displayed, enter the parameter name. d. To add further parameters, repeat the previous steps. To specify parameters that you want to be copied, complete the following steps. <ul style="list-style-type: none"> a. Select Allowlist. b. Click Add allowlist. c. In the empty field that is displayed, enter the parameter name. d. To add further parameters, repeat the previous steps. The values that you specify are in regular expression format. For example, if the incoming request is <code>http://apigw/org/sandbox/petstore/base?petid=100&display=detailed</code> and you specify a white list entry of <code>^petid\$</code> , the target URL at run time will be <code>http://myhost/mypath?storeid=3&petid=100</code> By default, Allowlist is selected, with no allowlist entries, meaning that no parameters are copied.	string
Stop on error	No	Select the errors that, if thrown during the policy execution, cause the assembly flow to stop. If there is a catch flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors selected for the Stop on error setting, or if the error thrown is not one of the selected errors, the policy execution is allowed to complete, and the assembly flow continues.	string
Response object variable	No	The name of a variable that will be used to store the response data from the request. By default, the invoke response, that is the body, headers, statusCode and statusMessage, is saved in the variable <code>message</code> . Use this property to specify an alternate location to store the invoke response. This variable can then be referenced in other actions, such as Map . Note: If you want the response to be saved in <code>message</code> , leave the Response object variable property blank, do not supply the value <code>message</code> .	string

6. Specify a version for the policy by clicking the Source icon , and completing the `version` section of the policy YAML. For example:

```
execute:
- invoke:
  version: 2.0.0
  title: invoke
  ...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

Example

```
- invoke:
  version: 2.0.0
  title: get the account status
  target-url: https://example.com/accounts/{id}?status={status}
  cache-response: time-to-live
  cache-putpost-response: true
  tls-profile: MyTLSProfile:1.0.0
  verb: POST
  timeout: 60
  compression: false
  username: MyUser
  password: MyPassword
  stop-on-error:
  - ConnectionError
  - OperationError
```

DataPower Gateway (v5 compatible) only

Configuring the Invoke policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the Invoke policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the Invoke policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see [Configuring the Invoke policy for DataPower API Gateway](#). For information about the different types of gateway, see [API Connect gateway types](#). For details on how to configure the policy in your OpenAPI source, see [invoke](#).

You might notice that the last invoke in their policy is replaced by a proxy. The replacement is sometimes done automatically by the IBM® API Connect DataPower Gateway to improve performance. The proxy is functionally equivalent to the invoke, but the API caller might notice the following differences when proxy is used.

- If the HTTP request made by the invoke or proxy gets a redirect (3xx) response:
 - invoke returns the response from following the redirect response.
 - proxy does not follow 3xx responses, and the redirect response is returned.
- The IBM API Connect test tool shows that proxy was used, but invoke appears in the Analytics latency records.
- The response from the proxy can contain different whitespace or escaping than a response from invoke. Despite the differences in the response, it is still valid.

If you want to prevent replacement of the last invoke in the assembly with proxy, you can set the API property `api.properties.x-ibm-gateway-optimize-invoke` to `false`. For more information, see [API properties](#).

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab. The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Select the Gateway tab, then click Policies in the navigation pane. For more information about working with the assembly editor for an API, see [The assembly editor](#).
4. Find the Invoke policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Invoke policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is <code>invoke</code> .	string
Description	No	A description of the policy.	string
URL	Yes	Specifies a URL for the target service. For a SOAP API, a URL is added by default. Where possible, the Invoke URL value is pre-supplied from information that is defined in the imported WSDL.	string
TLS profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	Yes	The time to wait before a reply from the endpoint (in seconds). The default value is <code>60</code> .	integer
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code 301 Moved Permanently . If you select this checkbox, the <code>invoke</code> policy follows the URL redirection by making a further call to the URL specified in the <code>Location</code> header in the response. If you clear this checkbox, the <code>invoke</code> saves the 301 status code and the API call is considered to be complete. Note: The <code>follow-redirect</code> property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the <code>invoke</code> always follows the URL redirection; the <code>proxy</code> policy (not supported by the DataPower API Gateway) saves the 301 status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
HTTP Method	Yes	The HTTP method to use for the Invoke. The following values are valid. <ul style="list-style-type: none">• Keep• GET• POST• PUT• DELETE• PATCH• HEAD• OPTIONS The default value is <code>GET</code> . However, if set to <code>Keep</code> , or the property is removed from the source, the HTTP method from the incoming request is used.	string
Compression	No	Select this checkbox to enable Content-Encoding compression on upload. The checkbox is cleared by default.	boolean

Property label	Required	Description	Data type
Cache Type	No	<p>The cache type determines whether to cache documents, honoring or overriding the HTTP Cache Control directives received in the response from the target URL. This property takes effect only when a response is received, otherwise the policy always returns the non-expired response that was previously saved in cache. Valid values are:</p> <p>Protocol The cache behavior is determined by the Cache-Control headers on the response, in accordance with RFC 7234. To optimize performance, if the gateway receives more than one request for a resource that is not in the cache but could be cached when the response from the target URL is received, the gateway sends only one request to the target URL; the remaining requests are not processed until the response from the first request has been received and the cache behavior has been determined from this response. If the response indicates that caching is possible, the gateway responds to all waiting requests with the cached resource. If the response indicates that caching is not possible, the gateway sends all waiting requests to the target URL.</p> <p>Use this option only if you expect that responses from the target URL can be cached, in which case it should improve performance and limit the demand on the target URL. If, however, the target URL never indicates that the gateway should cache its response, performance might be impaired when compared to the No Cache option.</p> <p>No Cache Responses from the target URL are not cached on the gateway regardless of any caching headers returned. In this case, every request from the client is sent to the target URL. Use this option if you do not want to cache any of the backend responses on the gateway, or if it is unlikely that a response from the target URL will allow caching through the Cache-Control header settings.</p> <p>Time to Live This option is similar to the Protocol option except it allows you to specify the amount of time that you want the successful response from the invoke or proxy to remain in the cache. Use this option only if you expect that responses from the target URL can be cached.</p> <p>The default value is Protocol.</p>	string
Time to Live	No	<p>Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property Cache type is set to Time to Live. Enter a value in the range 5 - 31708800. The default value is 900.</p>	integer
Cache key	No	<p>Specifies the unique identifier of the document cache entry. If omitted, the entire URL string is used as the key.</p>	string
Stop on error	No	<p>Select the errors that, if thrown during the policy execution, cause the assembly flow to stop. If there is a catch flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors selected for the Stop on error setting, or if the error thrown is not one of the selected errors, the policy execution is allowed to complete, and the assembly flow continues.</p>	string
Response object variable	No	<p>The name of a variable that will be used to store the response data from the request. By default, the invoke response, that is the body, headers, statusCode and statusMessage, is saved in the variable <i>message</i>. Use this property to specify an alternate location to store the invoke response. This variable can then be referenced in other actions, such as Map.</p> <p>Note: If you want the response to be saved in <i>message</i>, leave the Response object variable property blank, do not supply the value <i>message</i>.</p>	string

6. Specify a version for the policy by clicking the Source icon , and completing the **version** section of the policy YAML. For example:

```
execute:
- invoke:
  version: 1.0.0
  title: invoke
  ...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

Example

```
- invoke:
  version: 1.0.0
  title: get the account status
  timeout: 60
  verb: POST
  cache-response: time-to-live
  cache-ttl: 900
  stop-on-error:
    - ConnectionError
    - OperationError
  tls-profile: MyTLSProfile
  target-url: https://example.com/accounts/{id}?status={status}
  username: MyUser
  password: MyPassword
```

JSON to XML

Use the JSON to XML policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

The JSON to XML policy uses a simple convention, based on BadgerFish, to convert your API context payload from JSON to XML. The policy expects the JSON input to be in the same format as the BadgerFish convention, so the structure can be rebuilt in XML. No additional configuration is required. For more information about the BadgerFish convention, see [BadgerFish](#).

Note: The JSON to XML policy does convert the JSON structure { "a" : "hello" } (which is not BadgerFish convention) into `<a>hello`. Use the IBM® API Connect API Designer assembly view when you are creating your API definition to add a built-in policy to the flow.

The policy must be attached to the flow at the point at which you require the conversion to be performed. For example, if you need to convert a JSON-formatted request into an XML-formatted request, the policy must be attached to the request flow.

The policy reads input from the `message.body`, if that context exists, otherwise from the `request.body`, and then writes the output to the `message.body`.

Note: If you are using the DataPower API Gateway, the input to the JSON to XML policy must be parsed data. One way to produce parsed data is to use a [Parse](#) policy before a JSON to XML policy in your assembly flow, which provides explicit control of the parse action.

- [Configuring the JSON to XML policy for DataPower API Gateway](#)
Follow these steps to configure the JSON to XML policy for DataPower API Gateway in the assembly user interface.
- [Configuring the JSON to XML policy for DataPower Gateway \(v5 compatible\)](#)
Follow these steps to configure the JSON to XML policy for DataPower Gateway (v5 compatible) in the assembly user interface.

Configuring the JSON to XML policy for DataPower API Gateway

Follow these steps to configure the JSON to XML policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the JSON to XML policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see [Configuring the JSON to XML policy for DataPower Gateway \(v5 compatible\)](#). For more information about the different types of gateway, see [API Connect gateway types](#). For information about how to configure the policy in your OpenAPI source, see [json-to-xml](#).

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
The Develop page opens.
2. Click the title of the API definition that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
For more information about working with the assembly editor for an API, see [The assembly editor](#).
4. Find the JSON to XML policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is <code>json-to-xml</code> .	string
Description	No	A description of the policy.	string
Input	No	The input message to convert. Specify the name of a variable in the API context. <code>variableName.body</code> , the message payload, represents the JSON input to convert. The default value of the variable is <code>message</code> and <code>message.body</code> is the default input.	string
Output	No	The output message to store the conversion result. Specify the name of a variable in the API context. <code>variableName.body</code> represents the result of conversion from JSON format to XML format. When the specified input message is the default message, the default output is <code>message.body</code> . Otherwise, when the input message is the variable <code>my-message-variable</code> , for example, the default output is <code>my-message-variable.body</code> . The variable cannot be any read-only in the API context.	string
Conversion type	No	The conversion type that determines the target format of the output. The following options are available: <ul style="list-style-type: none"> • None: No conversion of the output takes place. • badgerFish: BadgerFish convention is used to determine the target conversion format of the output. 	string
Root XML Element Name	Yes	The root element name of the resultant XML document. This property is used only if the input JSON document is not hierarchical and has more than one uppermost level property, or if the Always output the root element checkbox is selected. The default value is <code>json</code> .	string

Property label	Required	Description	Data type
Always output the root element	Yes	Select this checkbox if you always want the policy to output the root element, even if it is not required to make the XML document well formed. The default value is false .	boolean
Element name for JSON array elements	No	The XML element name to be used for JSON array elements.	string

6. Specify a version for the policy by clicking the Source icon , and completing the **version** section of the policy YAML. For example:

```
execute:
- json-to-xml:
  version: 2.0.0
  title: json-to-xml
...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

Example

For example, the following simple JSON object

```
{ "a": { "$" : "hello" } }
```

becomes

```
<a>hello</a>
```

The following JSON object with an attribute

```
{ "a": { "$" : "hello", "@type" : "world" } }
```

becomes

```
<a type="world">hello</a>
```

DataPower Gateway (v5 compatible) only

Configuring the JSON to XML policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the JSON to XML policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the JSON to XML policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see [Configuring the JSON to XML policy for DataPower API Gateway](#). For more information about the different types of gateway, see [API Connect gateway types](#). For details on how to configure the policy in your OpenAPI source, see [json-to-xml](#).

Procedure

- In the navigation pane, click  Develop, then select the APIs tab.
The Develop page opens.
- Click the title of the API that you want to work with, or create a new API.
- Select the Gateway tab, then click Policies in the navigation pane.
For more information about working with the assembly editor for an API, see [The assembly editor](#).
- Find the JSON to XML policy in the palette, and drag the policy onto your canvas.
- Specify the following properties.

Table 1. Policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is json-to-xml .	string
Description	No	A description of the policy.	string
Root XML Element Name	Yes	The root element name of the resultant XML document. This property is used only if the input JSON document is not hierarchical and has more than one uppermost level property, or if the Always output the root element checkbox is selected. The default value is json .	string
Always output the root element	Yes	Select this checkbox if you always want the policy to output the root element, even if it is not required to make the XML document well formed. The default value is false .	boolean
Element name for JSON array elements	No	The XML element name to be used for JSON array elements.	string

6. Specify a version for the policy by clicking the Source icon , and completing the **version** section of the policy YAML. For example:

```
execute:
- json-to-xml:
```

```
version: 1.0.0
title: json-to-xml
...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

Example

For example, the following simple JSON object

```
{ "a": { "$" : "hello" } }
```

becomes

```
<a>hello</a>
```

The following JSON object with an attribute

```
{ "a": { "$" : "hello", "@type" : "world" } }
```

becomes

```
<a type="world">hello</a>
```

Log

Use the Log policy to customize or override the default activity logging configuration for an API.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [log](#).

About

By default, the logging of activity when an API is called, and the sending of the log data to the analytics server, is determined by the settings in the API definition, as described in [Configuring activity logging](#) (OpenAPI 2.0) or [Configuring activity logging](#) (OpenAPI 3.0). However, you can customize activity logging by adding a Log policy to the API assembly flow.

The Log policy enables you to gather all API analytics data for processing in your assembly, and to control what activity log data is sent to the analytics server. Here are some examples of the ways in which you can use the Log policy to customize API activity logging:

- Gather activity log data, use a Redaction policy to redact sensitive fields in the data, then send to the analytics server.
- Send different levels of analytics data depending on certain conditions; for example, the API operation that was called.
- Configure custom activity logging in a global policy that is applied to every API in a Catalog. For more information on global policies, see [Working with global policies](#).

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Log policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is <code>log</code> .	string
Description	No	A description of the policy.	string

Property label	Required	Description	Data type
Mode	Yes	<p>Select one of the following options:</p> <ul style="list-style-type: none"> Gather-only: gather all analytics data and write it to the <code>log</code> context variable, which populates the API event record on completion of the API execution. For more information on the fields in the <code>log</code> context variable, and the consequent API event record, see API event record fields. Send-only: perform the following actions: <ul style="list-style-type: none"> Read the data from the <code>log</code> context variable. Truncate all message payloads and convert to a textual representation. Send the data to the analytics server. Gather-and-send: perform a gather-only operation, immediately followed by a send-only operation. <p>If you use the Send-only or Gather-and-send option, data is buffered and sent to the analytics server in batches according to the time interval configured for the Analytics Endpoint on the DataPower API Gateway. For more information, see Configuring an analytics endpoint in the DataPower knowledge center.</p> <p>Note: If you are offloading to a third party analytics server, you can redact any aspect of the event data. If you are using API Connect analytics, you can redact only request and response payloads.</p>	string
<div style="border: 1px solid green; padding: 2px;">API Gateway only</div> Log Level	No	<p>The type of content to log. Enter one of the following values:</p> <ul style="list-style-type: none"> <code>none</code>: Indicates no logging. <code>activity</code>: Logs the invocation only, which is only the resource URI. <code>header</code>: Logs activity and header. <code>payload</code>: Logs activity, header, and payload. <code>default</code>: Use the log level setting defined in the API definition; for more information, see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0). This is the default value. <code>\$(value)</code>: An inline parameter in the format <code>\$(value)</code> to retrieve a value from the API context. 	

Map

Use the Map policy to apply transformations to your assembly flow and specify relationships between variables.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.5.0.0 or later)

In the DataPower API Gateway, the Map policy properties are saved in a temporary JSON file, which is read by the API Gateway service. The overall size of the JSON document of a large Map policy can exceed the limits defined in the default parse settings, causing the parse to fail. This happens typically with large in line schemas and large JavaScript Map action value properties. You can override this default parse setting by modifying the `parse-settings-reference` object within the Map policy. The `parse-settings-reference` value can be defined in the corresponding YAML source file.

Note:

If no parse setting is selected in the Map policy, the default parse setting is selected to parse the Map policy properties.

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [map](#).

About

Be aware that MAP decodes all parameter values to an ASCII character equivalent. If a MAP parameter contains entries such as `%nn`, the MAP output contains decoded values.

For information about the structure of a Map policy and its behavior, see [The Map policy structure](#).

For information about configuring a Map policy by using the user interface, see [Configuring the Map policy in the user interface](#).

For examples of YAML representations of different Map policy configurations, see [Map policy examples](#).

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Map policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The field is visible when editing inputs. The default value is <code>map</code> .	string
Description	No	A description of the policy. The field is visible when editing inputs.	string
Inputs	Yes	A list of variables that are inputs of the policy.	array (string)
Outputs	Yes	A list of variables that are outputs of the policy.	array (string)

Property label	Required	Description	Data type
Value	Yes	A GatewayScript program to be performed by the policy in order to map its inputs to its outputs, or to set the value of outputs.	string

Note: The map policy has other properties that are not displayed in the user interface. For a complete list of properties, see [map](#).

Related tasks

- [Creating a new REST OpenAPI definition](#)

The Map policy structure

The Map policy uses a structure within its OpenAPI definition to specify the behavior of the policy.

This topic contains the following sections:

- [Structure](#)
- [Input and output definitions](#)
- [Actions](#)
- [Script](#)
- [Fields](#)
- [References to inputs and outputs](#)
- [Accessing other contexts](#)

For map policy examples, see [Map policy examples](#).

Note: If you deploy your API to the DataPower® Gateway (v5 compatible) then, with the exception of client ID and client secret, the passing of form input as a parameter into an API is not supported. This restriction does not apply if you deploy your API to the DataPower API Gateway.

Structure

In addition to its title and description, a Map policy has the following four main sections:

inputs

A list of variables that form the input of the Map policy. Each input has a context variable in which the input variable is found, the variable's name within the Map policy, the content type of the variable, and the definition of the variable or a schema defining its structure.

outputs

A list of variables that form the output of the Map policy. These include a context variable where the output variable is found or should be created, the variable's name at output, and the definition of the variable or a schema defining its structure.

action

An array containing details of the actions to be performed in order. Each entry includes either a **set** or **create** field, which specifies the output variable or variables that are part of the action. An action can also contain a **from** field, which specifies the input variable or variables that are part of the action.

Each action also contains either a **value** field, when the output is set or created, or a **foreach** field and a new **actions** section, when further actions are nested within the first to set or create elements in a nested array.

options

The following property options are available for you to select:

- Include empty. If the check box is selected (the default option), empty XML elements are included in the output of the map policy. Clear the check box if you do not want empty XML elements to be included in the output of the map policy.
- Namespace inheritance. If the check box is selected (the default option), XML namespaces are inherited from the parent element. Clear the check box if you want the map policy to use explicit namespaces.
- Namespace inlining. If the check box is selected (the default option), XML namespaces will be inserted into the document where they are first used. Clear the check box if you want namespaces to all be defined on the root element.
- API Gateway only Resolve XML input data type. If the check box is selected, XML elements whose schema is configured as type boolean or numeric will be converted to that data type. Clear the check box (the default option) if you want all XML element values to be returned as a string.
- API Gateway only Parse XML output: If the check box is selected, the map policy will write XML output to `message.body` as a parsed XML document. By default, the XML will be output as an XML string. XML output to any other variable will always be written as an XML string.
- API Gateway only Empty XML element handling. This property controls how the map policy handles the output of an empty XML element. The following choices are available:
 - String (the default option): An empty XML element is handled as an empty string.
 - Null: An empty XML element is handled as a null value.
 - None: The data is ignored.
 - API Gateway only String Badgerfish: The value for an empty XML element is considered to be an empty string. The empty string value will be placed into a JSON badgerfish value property.
 - API Gateway only Null Badgerfish: The value for an empty XML element is considered to be null. The null value will be placed into a JSON badgerfish value property. A mapping of this element to a JSON output property does not occur unless the Allow null value option is selected.

- API Gateway only** Use only first array element. If the check box is selected, if an array is encountered in the traversal of the input, only the first element is used. Clear the check box (the default option) if you want the map policy to use all array elements.
- API Gateway only** Resolve API Connect variable references. If the check box is cleared (the default option), the map policy ignores API Connect variable references in the map properties. Select the check box if you want API Connect variable references found in the map properties to be resolved.
- API Gateway only** Allow null value. If the check box is selected, an input property value with a null value is mapped to the output document. Clear this check box (the default option) if you want the map policy to ignore null input values.
- API Gateway only** Optimize schema definition. If the check box is selected, complex schema types evaluation handles circular type references in an optimized manner. Clear this check box (the default option) to evaluate these schema types in a standard manner.
- API Gateway only** Create required child properties for array objects and mapped optional objects. If the check box is selected, default values are generated in the output for required properties that are either not mapped, or for which there is no input data present, in the following specific cases:
 - An array consists of objects that contain one or more required properties.
 - An object which is optional has one or more child properties that are required.

By default, these required properties are not present in the output. If you select this option, these required properties will be present in the output. If the output schema defines a **default** property for the output property then the specified default value is used, otherwise a default value is assigned dependent on the data type, as follows:

- String: empty string ("")
- Number: 0
- Boolean: false
- Object: empty object
- Array: empty array

Example 1

The input data has the following array of objects:

```
[{"a": "value1"}, {"a": "value2", "b": "value3"}]
```

The output schema defines the output object as having two properties, **a** and **b**, of which **b** is required. The map policy defines the following mappings:

- `input.array.a` to `output.array.a`
- `input.array.b` to `output.array.b`

If the check box is selected, and **b** is either not mapped or has no input data present, then **b** is assigned a default value of an empty string, and the output is as follows:

```
[{"a": "value1", "b": ""}, {"a": "value2", "b": "value3"}]
```

Example 2

The output schema defines the following structure:

```
{"a" : {"b" : {"c" : "value1", "d" : "value2"} } }
```

Property **b** is optional but property **d** within **b** is required.

The map policy defines a mapping to `output.a.b.c`.

If the check box is selected, and **d** is not mapped, then **d** is assigned a default value of an empty string, and the output is as follows:

```
{"a" : {"b" : {"c" : "value1", "d" : ""} } }
```

If the check box is not selected, these required properties are **not** created in the output with their default values.

- API Gateway only** Empty JSON array handling. This property controls how the map policy handles the output of an empty array. The following choices are available:
 - All (The default value): Output all empty arrays, including empty children arrays.
 - Parent: Output only the current property's empty array value. Children map actions of this property are not attempted.
 - None: Prevent any empty output array values from being produced.
- API Gateway only** Enable JSON post processing. Select this check box to enable post processing of mapped JSON output. The post processing of JSON output will use the output schema to ensure that property values are of the same data type as that defined in the schema. It will also normalize output property values that have a Badgerfish JSON syntax due to object mapping of an XML input. The check box is cleared by default, meaning that there is no post processing of mapped JSON output.
- API Gateway only** Schema definition circular reference limit. Set the value of this property to an integer value that specifies the maximum allowed number of iterations of a circular schema definition. The default value is 1, which means that circular schema definitions are not followed. The maximum possible value is 5.
- Severity level for input data log messages; This property specifies the severity level for log messages that relate to input data. The following choices are available:
 - error
 - warn
 - info
- API Gateway only** Create empty parent object for failed mapping. If a mapping fails because its input is not present and there is no default mapping configured, the default behavior is to not to make any change to the output mapping. Select this check box to create an empty object for the parent of the target mapping, emulating the behavior of IBM® API Management Version 4.0.

Example

The map policy defines a mapping to `output.a.b.c`.

If input data is present, the output is as follows:

```
{
  "a": {
    "b": {
```

```

    "c": "inputvalue"
  }
}

```

If there is no input data, and the Create empty parent object for failed mapping option is selected, the output is as follows:

```

{
  "a": {
    "b": {
    }
  }
}

```

Properties **a** and **b** are created but the value of **b** is an empty object. The check box is cleared by default.

Input and output definitions

You define the inputs and outputs of your Map policy in their own sections. Each input or output is an element in the array `inputs` or `outputs` and is defined by a name, a schema definition or reference, and a variable within the context from which it should be read or to which it should be written. After they have been defined, inputs and outputs are referenced by the name provided in the definition, not by the name of the variable.

The following example shows the inputs and outputs sections of a Map policy.

```

inputs:
  input_string:
    schema:
      type: string
      variable: request.parameters.name_in
  input_integer:
    schema:
      type: integer
      variable: request.parameters.age_in
outputs:
  output:
    schema:
      $ref: '#/definitions/output'
    variable: message.body

```

The `schema` field specifies the schema that describes the variable and can be a simple type, a reference to a definition, or an inline schema definition.

The `variable` field describes the variable and the context that should be assigned to the input or output variable during the execution of the map policy.

Actions

The fields included in the `actions` section are used in the following ways:

set

Use the `set` field when you want to assign the result of the `value` field to the output variable specified in the `set` field, replacing the existing value of the output variable. You can specify only one output variable, although this variable can be an array or object.

create

Use the `create` field when you want to use the result of the `value` field to create a new entry for the output array specified in the `create` field, appending it to the array. You can specify only one output variable, although this variable can be an array or object.

from

Specify which variables are used in the action as either a single variable or an array of variables, where a variable can be an array or an object. The `from` field is not included if no inputs are used.

value

Use GatewayScript to provide a script that produces output variables. When a single input is mapped to a single output, the `value` field can be omitted and the variable in `from` is set or created as the variable in `set` or `create` respectively.

default

Provide a static value, or an inline variable reference, to be applied to the output when no input value is provided. For information on inline variable references, see [Inline references](#).

foreach

Specify a variable if you want to execute the associated `actions` field for each entry of the array. The variable can be from the input or output of the Map policy.

actions

Use the `actions` field to nest actions within an action. Because another action could achieve the same result if applied only once, it is primarily for use with the `foreach` field.

Script

In a `value` or `default` field, use GatewayScript to write the behavior of the action to which the `value` field belongs.

Include the script in single quotation marks. For example: `'4 + 5'` or `'variable_1.toUpperCase()'`.

For information about GatewayScript, see [Gateway programming model and GatewayScript](#)

Fields

from, set, and create

Each action must have a single `set` or `create` field that specifies the output variable to which the action is applied. Each action can also have a `from` field containing one or more entries that are used to specify the input variable or variables that are used in the action.

The `set` and `create` fields are both used to assign values to the output variable.

- **set** replaces the current value of the output variable or creates the variable if it does not already exist.
- **create** appends a new array entry to the output variable.

For **set** and **create**, use `output_variable_name.variable_name` to specify which of your defined output variables to use, where `output_variable_name` is as defined in the outputs section of the Map policy and `variable_name` refers to an optional field that belongs to the output variable.

For **from**, use `input_variable_name.variable_name` to specify which of your defined output variables to use, where `input_variable_name` is as defined in the outputs section of the Map policy and `variable_name` refers to an optional field that belongs to the output variable.

foreach

Use the **foreach** field to specify an input array for which the following **actions** or **value** field will be executed for each entry of the array.

For example:

```
foreach: input.in
actions:
  actions
```

where `input.in` is an input variable that is an array and `actions` is one or more actions in the same format as the parent section. In this example the instructions specified in `actions` are executed once for each array entry of `input.in`.

Referencing the input variable specified in the **foreach** field references the array entry that the current iteration corresponds to.

If a single variable is used in the **foreach** field instead of an array, the following **actions** or **value** field will be applied to or based upon the single variable once and then the loop will terminate.

References to inputs and outputs

Reference variables from the **from** field either by name or by using a number preceded by a '\$' and enclosed in parentheses. The variables are numbered from 1, where 1 is the first variable in the array, or the only variable when the **from** field lists only a single variable. For example:

```
value: '$(1) + $(2)'
```

or

```
value: '$(variable_1) + $(variable_2)'
```

where each `variable` is a variable that is included in the **from** field.

During a **foreach** loop, you can reference `$(0)`. The `$(0)` variable begins a **foreach** loop empty but, after an iteration, becomes equivalent to the output of the iteration and can then be referenced again. In this manner, you can apply an array to a single value. For example:

```
- set: out.total
from: in.input
foreach: in.input
value: '$(0) + $(in.input)'
```

where `out.total` is referenced by `$(0)`. In each iteration, the current value of `out.total` and the current array entry of `in.input` are summed, and the value of `out.total` is set as this summation.

When using a **foreach** to operate on an array, if the elements of the array do not have named fields, you can use `$(this)` to reference the current level of nesting.

Accessing other contexts

At any point within your Map policy's **value** or **default** fields, you can access the context of the API call using the syntax `$(context.variable)`.

Alternatively, you can include the variables from other contexts when you define an input to your map policy and then reference it as you would any other input variable.

For a list of available context variables, see [API Connect context variables](#).

Configuring the Map policy in the user interface

The assemble view in API Designer provides a visual representation of the relations between the inputs and outputs of your Map policy.

Procedure

To configure your Map policy, complete the following steps:

1. Click the Map policy in the canvas of the Assemble view.
The property sheet opens.
2. Click the Edit inputs icon  in the Input column.
3. Add an input variable.
 - a. Click + input.
 - b. In the Context variable field for an input, provide the location of your input variable in the context of the assembly. For a list of context variables, see [API Connect context variables](#).
 - c. In the Name field for an input, provide a name for your input for use within only the Map policy.
Note:
You must ensure that the name that you provide does not exactly match the value of the Context variable field, or the result might be unpredictable.
 - d. Optional: In the Content type field, specify the type of your input. If None is selected, the content type is treated as JSON.
 - e. In the Definition field for an input, provide the type of the variable.
The type can be one from a standard set of types, a definition that you have created for your API, or you can select Inline schema to provide a schema as one of the following options:
 - YAML

- JSON
- Generate from sample JSON
- Generate from sample XML

If you select Object or Array, you can create a schema through the user interface after you have clicked Done and returned to the main view of the property sheet.

- Optional: To remove a variable, click the corresponding Remove input icon .
- After you have added all of your input variables, click Done.
- Click the Edit outputs icon  in the Output column.
- Add an output variable.
 - Click + output.
 - In the Context variable field for an output, provide the location of your output. This location can be a new context or one already established during the assembly. For a list of context variables, see [API Connect context variables](#).
 - In the Name field for an output, provide a name for your variable to use within the Map policy and when it is included in its context at output.

Note:
You must ensure that the name that you provide does not exactly match the value of the Context variable field, or the result might be unpredictable.
 - Optional: In the Content type field, specify the type of your input. If None is selected, the content type is treated as JSON.
 - In the Definition field for an output, provide the type of the variable.
The type can be one from a standard set of types, a definition that you have created for your API, or you can select Inline schema to provide a schema as one of the following options:
 - YAML
 - JSON
 - Generate from sample JSON
 - Generate from sample XML

If you select Object or Array, you can create a schema through the user interface after you have clicked Done and returned to the main view of the property sheet.

- Optional: To remove a variable, click the corresponding Remove output icon .
- After you have added all of your output variables, click Done.
- Optional: If you selected Object or Array for the type of an input or output, create an inline schema definition through the user interface by completing the following steps:

- For an Array, click add item. Provide a type for the item and then click the Add icon .
- For an Object, click add property. Provide a name and type for the property and then click the Add icon .

For objects and arrays created in this manner, you can continue to add items and properties, which can themselves be objects and arrays.

- To connect an input variable to an output variable, click the circle that is directly before the input variable and then click the circle that is directly before the output variable.
A green line is drawn, linking the two variables together. You can connect multiple inputs to a single output, and a single input can be connected to multiple outputs.
- To configure an output, whether it has inputs connected to it or not, click the circle directly before the output variable without first clicking on a circle for an input variable.
The Configure mapping window opens.
- Optional: In the Mapped from section of the window, you can view which inputs are mapped to the output you are editing. To remove an input, click the Remove input icon  alongside the input.
If the output is part of an array, further configuration options are available. The array, or levels of array in the case of a multidimensional array, can be created by iterating arrays on the input side of the mapping. For each level of your array, select which array on the input side is to be iterated. In the Value field, you can use `$(this)` to reference elements of an array that are not named within the array.
- Optional: In the Value field, use GatewayScript to configure how any inputs are transformed to produce the output.
For more information about valid code, see the [Script](#) section of the [The Map policy structure](#) topic.
- Optional: In the Default field, provide a static value, or an inline variable reference, to be applied to the output when no input value is provided. For information on inline variable references, see [Inline references](#).
- Optional: To delete all mappings to the output, click Delete.
- When you have configured your outputs, click OK.
- Optional: Click the Settings icon in the Map column.
 - Optional: Provide a Title and Description for your Map policy.
 - To control the XML output of the map policy, select the following options as required:

Include empty

If the check box is selected (the default option), empty XML elements are included in the output of the map policy. Clear the check box if you do not want empty XML elements to be included in the output of the map policy.

Namespace inheritance

If the check box is selected (the default option), XML namespaces are inherited from the parent element. Clear the check box if you want the map policy to use explicit namespaces.

Namespace inlining

If the check box is selected (the default option), XML namespaces will be inserted into the document where they are first used. Clear the check box if you want namespaces to all be defined on the root element.

API Gateway only

Resolve XML input data type

If the check box is selected, XML elements whose schema is configured as type boolean or numeric will be converted to that data type. Clear the check box (the default option) if you want all XML element values to be returned as a string.

API Gateway only

Parse XML output

If the check box is selected, the map policy will write XML output to `message.body` as a parsed XML document. By default, the XML will be output as an XML string. XML output to any other variable will always be written as an XML string.

Note: These options effect the XML output only and have no effect on the JSON data.

-  From the Empty XML element handling list, select one of the following options to control how the map policy handles the output of an empty XML element:

- String (the default option): An empty XML element is handled as an empty string.
- Null: An empty XML element is handled as a null value.
- None: The data is ignored.
- **API Gateway only** String Badgerfish: The value for an empty XML element is considered to be an empty string. The empty string value will be placed into a JSON badgerfish value property.
- **API Gateway only** Null Badgerfish: The value for an empty XML element is considered to be null. The null value will be placed into a JSON badgerfish value property. A mapping of this element to a JSON output property does not occur unless the Allow null value option is selected.

d. **API Gateway only** Select the following general configuration options as required:

Use only first array element

If the check box is selected, then if an array is encountered in the traversal of the input, only the first element is used. Clear the check box (the default option) if you want the map policy to use all array elements.

Resolve API Connect variable references

If the check box is cleared (the default option), the map policy ignores API Connect variable references in the map policies. Select the check box if you want API Connect variable references found in the map properties to be resolved.

Allow null value

If the check box is selected (the default option), an input property value with a null value is mapped to the output document. Clear this check box (the default option) if you want the map policy to ignore null input values.

Optimize schema definition

If the check box is selected, complex schema types evaluation handles circular type references in an optimized manner. Clear this check box (the default option) to evaluate these schema types in a standard manner.

API Gateway only

Enable JSON post processing

If the check box is selected, post processing of mapped JSON output is enabled. The post processing of JSON output will use the output schema to ensure that property values are of the same data type as that defined in the schema. It will also normalize output property values that have a Badgerfish JSON syntax due to object mapping of an XML input. The check box is cleared by default, meaning that there is no post processing of mapped JSON output.

API Gateway only

Create empty parent object for failed mapping

API Gateway only

Use this setting to control the behavior if a mapping fails because its input is not present and there is no default mapping configured.

The default behavior is to make no change to the output, but if you select this check box an empty object is created for the parent of the target mapping, emulating the behavior of IBM API Management Version 4.0.

Example

The map policy defines a mapping to `output.a.b.c`.

If input data is present, the output is as follows:

```
{
  "a": {
    "b": {
      "c": "inputvalue"
    }
  }
}
```

If there is no input data, and the Create empty parent object for failed mapping option is selected, the output is as follows:

```
{
  "a": {
    "b": {
    }
  }
}
```

Properties `a` and `b` are created but the value of `b` is an empty object.

The check box is cleared by default.

Create required child properties for array objects and mapped optional objects

If the check box is selected, default values are generated in the output for required properties that are either not mapped, or for which there is no input data present, in the following specific cases:

- An array consists of objects that contain one or more required properties.
- An object which is optional has one or more child properties that are required.

By default, these required properties are not present in the output. If you select this option, these required properties will be present in the output. If the output schema defines a `default` property for the output property then the specified default value is used, otherwise a default value is assigned dependent on the data type, as follows:

- String: empty string ("")
- Number: 0
- Boolean: false
- Object: empty object
- Array: empty array

Example 1

The input data has the following array of objects:

```
[{"a": "value1"}, {"a": "value2", "b": "value3"}]
```

The output schema defines the output object as having two properties, `a` and `b`, of which `b` is required. The map policy defines the following mappings:

- `input.array.a` to `output.array.a`
- `input.array.b` to `output.array.b`

If the check box is selected, and **b** is either not mapped or has no input data present, then **b** is assigned a default value of an empty string, and the output is as follows:

```
[{"a": "value1", "b": ""}, {"a": "value2", "b": "value3"}]
```

Example 2

The output schema defines the following structure:

```
{"a" : {"b" : {"c" : "value1", "d" : "value2"} } }
```

Property **b** is optional but property **d** within **b** is required.

The map policy defines a mapping to `output.a.b.c`.

If the check box is selected, and **d** is not mapped, then **d** is assigned a default value of an empty string, and the output is as follows:

```
{"a" : {"b" : {"c" : "value1", "d" : ""} } }
```

If the check box is not selected, these required properties are **not** created in the output with their default values.

- e. API Gateway only From the Empty JSON array handling list, select one of the following options to control how the map policy handles the output of an empty array:
- All (the default option): Output all empty arrays, including empty children arrays.
 - Parent: Output only the current property's empty array value. Children map actions of this property are not attempted.
 - None: Prevent any empty output array values from being produced.
- f. From the Severity level for input data log messages list, select one of the following options to specify the severity level for log messages that relate to input data:
- error
 - warn
 - info
- g. API Gateway only Set the Schema definition circular reference limit field to an integer value that specifies the maximum allowed number of iterations of a circular schema definition. The default value is 1, which means that circular schema definitions are not followed. The maximum possible value is 5.
- h. Click Save when done.

Results

You have configured a Map policy to transform and map variables in your assembly flow.

Map policy examples

Examples of the OpenAPI definitions of Map policies.

- [One to one mapping](#)
- [Many to one mapping](#)
- [A simple transformation using the value field](#)
- [Mapping from multiple contexts into a new context](#)
- [Mapping to an inline schema definition](#)
- [Mapping with a default value](#)
- [Mapping an array into a single value](#)
- [Mapping array elements to an array](#)
- [Using the advanced XML options](#)

One to one mapping

The following example:

- maps parameters from the request's query to an object in the message body.
- maps one strings directly to a single string.
- maps one integer directly to a single integer.

The referenced definition, `output`, defines an object containing a string, name, and an integer, age.

```
- map:
  title: 1-1 map
  inputs:
    input_string:
      schema:
        type: string
        variable: request.parameters.name_in # the location of the variable, named "name_in" and found in the query
parameters of the request
    input_integer:
      schema:
        type: integer
        variable: request.parameters.age_in # another variable in the query parameters of the request
  outputs:
    output:
      schema:
        $ref: '#/definitions/output' # a schema definition reference to use for the output. The schema is for the
whole of the message body.
        variable: message.body
  actions:
    - set: output.name_out # in the actions section, variables are referenced by their name within the map policy
```

```

    from: input_string # if a value field is not used, the mapping is direct with the input value used for the
output variable
  - set: output.age_out # because the 'output' variable is itself an object, further references are made to
variables that it contains
    from: input_integer

```

Many to one mapping

The following example:

- maps parameters from the request's query to an object in the message body.
- maps two strings to a single string by concatenating them.
- maps two integers to a single integer by summing them.

The referenced definition, `output`, defines an object containing a string and an integer.

```

- map:
  title: many-1 map
  inputs:
    input_string_1:
      schema:
        type: string
        variable: request.parameters.first_name
    input_string_2:
      schema:
        type: string
        variable: request.parameters.last_name
    input_integer_1:
      schema:
        type: integer
        variable: request.parameters.balance_1
    input_integer_2:
      schema:
        type: integer
        variable: request.parameters.balance_2
  outputs:
    output:
      schema:
        $ref: '#/definitions/output'
        variable: message.body
  actions:
    - set: output.full_name
      from:
        - input_string_1
        - input_string_2
      value: |
        var retValue = undefined;
        if ($(input_string_1) !== undefined && $(input_string_2) !== undefined) {
          retValue = $(input_string_1).toUpperCase() + ' ' + $(input_string_2).toUpperCase()
        }
        retValue;
    - set: output.total_balance
      from:
        - input_integer_1
        - input_integer_2
      value: |
        var i1 = 0;
        var i2 = 0;
        if ($(input_integer_1) !== undefined) i1 = $(input_integer_1);
        if ($(input_integer_2) !== undefined) i2 = $(input_integer_2);
        i1 + i2;

```

A simple transformation using the value field

The following example:

- maps a parameter from the request's query to an object in the message body.
- maps one string featuring lowercase characters to a single string containing only uppercase characters.

The referenced definition, `output`, defines an object containing a single string.

```

- map:
  title: Uppercase map
  inputs:
    input_lowercase:
      schema:
        type: string
        variable: request.parameters.name_in
  outputs:
    output_uppercase:
      schema:
        $ref: '#/definitions/output'
        variable: message.body
  actions:
    - set: output_uppercase.name_out
      from: input_lowercase
      value: $(input_lowercase).toUpperCase() # the input variable is referenced and calls the toUpperCase method to
produce a value for the output variable

```

Mapping from multiple contexts into a new context

The following example:

- maps an integer from the request's header to an integer in a new message body.
- maps a string from the message's body to the body of a new custom context, named *new_context*.

```
- map:
  title: Context map
  inputs:
    input_integer:
      schema:
        type: integer
        variable: request.headers.age_in # the 'age_in' header of the request is used as an input
    input_string:
      schema:
        type: string
        variable: message.body.name_in # as is the 'name_in' field of the request body
  outputs:
    output_integer:
      schema:
        type: integer
        variable: message.body.age_out
    output_string:
      schema:
        type: string
        variable: new_context.body.name_internal # the context named 'new_context' is created by the map policy and
exists only while the assembly is processed
  actions:
    - set: output_string
      from: input_string
    - set: output_integer
      from: input_integer
```

Mapping to an inline schema definition

The following example:

- maps parameters from the request's headers to an object in the message body, which is defined within the map policy.
- maps one string directly to a single string.
- maps one integer directly to a single integer.

```
- map:
  title: Inline schema map
  inputs:
    input_integer:
      schema:
        type: integer
        variable: request.headers.age_in
    input_string:
      schema:
        type: string
        variable: request.headers.name_in
  outputs:
    output:
      schema: # instead of a simple type or a reference to a definition, an inline YAML definition
is used
      type: object
      properties:
        name_out:
          type: string
          name: name_out
        age_out:
          type: integer
          format: int32
          name: age_out
      title: output
      variable: message.body
  actions:
    - set: output.age_out
      from: input_integer
    - set: output.name_out
      from: input_string
```

Mapping with a default value

The following example:

- maps one string directly to a single string.
- provides a default value for the output string if a valid input string is not provided.

```
- map:
  title: Default Map
  inputs:
    input_string:
      schema:
        type: string
        variable: request.headers.name_in
  outputs:
    output_string:
      schema:
        type: string
        variable: message.body.name_out
  actions:
```

```

- set: output_string
  from: input_string
  default: John Smith # the default field is specified in the same way as a value, in this case
providing a fixed value

```

Mapping an array into a single value

The following map policy:

- maps a single array of integers into a single integer.
- sums the integers in the array.
- `$(0)` represents the accumulated output because map evaluates all array element values.

```

- map:
  title: Summation map
  inputs:
    input:
      schema:
        $ref: '#/definitions/balance_array_in'
      variable: request.body
  outputs:
    output:
      schema:
        type: integer
        variable: message.body.total_balance_out # instead of using a full schema definition of the message body, a
single variable in the message body is specified
  actions:
    - set: output
      from: input
      foreach: input # the foreach field specifies that each value of the array 'input' is to be iterated over
      value: $(0)+$(input) # the $(0) reference is the accumulated value of the 'output' variable

```

Mapping array elements to an array

The following map policy:

- maps an array, whose elements are objects containing two integers, to an array, whose entries contain a single integer field.
- maps an array to an array of the same length.
- takes the difference of the values of the integers in each array element to create a single integer in each array element.

```

- map:
  title: Array summation
  inputs:
    input:
      schema:
        $ref: '#/definitions/balance_and_credit_array'
      variable: request.body
  outputs:
    output_array:
      schema:
        type: array
        variable: message.body
  actions:
    - create: output_array
      from: input
      foreach: input
      actions:
        - set: total_balance_out
          from: # inside the actions section, variables inside the array elements being
iterated over are used
            - integer_in_1
            - integer_in_2
          value: $(integer_in_1)-$(integer_in_2) # the difference of the variables is taken for each array entry
of 'input'

```

Using the advanced XML options

The following example:

- does not include empty elements in the output of the map policy.
- uses explicit name spaces rather than inheriting name spaces from the parent element
- indicates that all namespace declarations will be placed on the root XML element.
- uses all array elements rather than only the first
- ignores API Connect variable references
- maps input property values with a null value to the output document
- handles circular type references in an optimized manne

```

actions:
- set: output, two
  from: input, one
options:
  includeEmptyXMLElements: false
  namespaceInheritance: false
  inlineNamespaces: false
  mapArrayFirstElementValue: false
  mapResolveApicVariables: false
  mapNullValue: true

```

```
mapOptimizeSchemaDefinition: true
mapCreateEmptyArray: parent
```

OAuth

An OAuth policy performs the requested OAuth processing based on the defined OAuth provider settings.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [oauth](#).

About

By adding an assembly OAuth policy, you specify the OAuth provider settings to use to perform the requested OAuth processing and the supported OAuth processing components.

Note: You add an OAuth policy to the assembly in a native OAuth provider. For more information, see the following topics:

- [Editing the native OAuth provider configuration using the API Editor](#) (Cloud Manager UI)
- [Editing the native OAuth provider configuration using the API Editor](#) (API Manager UI)

You can specify the settings through one or more of the following methods.

- URL reference
- Literal configuration
- Object reference

When you use more than one method to specify the same aspect of the OAuth provider settings, the following precedence rules apply to enforce the settings dynamically for the incoming transactions.

- URL reference takes precedence over any existing literal configuration or object reference.
- Literal configuration takes precedence over any existing object reference.

You can configure the policy to support one or more of the following processing components:

Validate request

Validates the authorization request from the client.

Generate authorization code

Generates the authorization code for the client, which represents the resource owner's authorization that grants access to the requested resource.

Verify authorization code

Verifies the authorization code from the client.

Verify refresh token

Verifies the refresh token that is presented by the client.

Generate access token

Generates the access token to the client when the authorization code or refresh token is verified.

Introspect token

Introspects the token to determine its state and, when active, its metadata.

When the policy does not support a processing component but that processing is requested, the unsupported component is not run.

You can include multiple OAuth policies in your OAuth provider assembly. For example, your assembly might include the following flow:

1. OAuth policy that validates the request.
2. GatewayScript policy.
3. OAuth policy that generates authorization code.

For more information, see [Example - using multiple OAuth policies in an OAuth provider assembly](#) and [OAuth context variables](#).

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. OAuth policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is <code>oauth</code> .	string
Description	No	A description of the policy	string
Default OAuth Provider Settings Object	Yes	The name of an existing OAuth provider that defines the required settings.	string
Dynamic OAuth configuration from a URL	No	A URL to a document that contains serialized XML or JSON properties that defines OAuth token generate settings.	string

Property label	Required	Description	Data type
Dynamic OAuth configuration from a literal string	No	A literal string that contains serialized XML or JSON properties that defines OAuth token generate settings.	string
Supported OAuth components	No	Select the OAuth components that are supported by this policy.	string

Overriding the default OAuth provider settings

You can use either the Dynamic OAuth configuration from a literal string property or the Dynamic OAuth configuration from a URL property to dynamically override any OAuth provider configuration settings defined by the Default OAuth Provider Settings Object property.

For example, to override the access token expiration time with a value of 200 seconds, include the following configuration in either the literal string or the document at the specified URL:

```
<OAuthProviderSettings><APICAccessTokenTTL>200</APICAccessTokenTTL></OAuthProviderSettings>
```

For a list of all OAuth provider settings, refer to the `OAuthProviderSettings` management schema, defined in the `xml-mgmt.xsd` file located in the `store: directory` on the DataPower API Gateway.

If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see [Logging into API Connect Designer](#).

- [Example - using multiple OAuth policies in an OAuth provider assembly](#)
This example demonstrates the use of multiple OAuth policies in the assembly flow for a native OAuth provider.

Related tasks

- [Creating a new REST OpenAPI definition](#)

- [API Connect context variables](#)

Example - using multiple OAuth policies in an OAuth provider assembly

This example demonstrates the use of multiple OAuth policies in the assembly flow for a native OAuth provider.

The example is based on the default assembly that is generated when you create a native OAuth provider, and is customized with the addition of `gatewayscript` policies that use [OAuth context variables](#) to manipulate the OAuth flow. For details on creating a native OAuth provider, see [Configuring a native OAuth provider](#).

It has the following assembly flow:

The following sections describe the OpenAPI source code that underlies each of the policies in the assembly; for the complete assembly code, download [multiple_oauth_policies.txt](#).

Sample policy to add a custom scope

The `add_scope` policy is a `gatewayscript` policy that adds a custom scope to the request.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
  version: 2.0.0
  title: add_scope
  source: |-
    // Add another custom scope to the request
    let scope = context.get("request.parameters.scope.values[0]");
    if (scope)
      context.set("oauth.processing.scope", scope + " custom");
```

Validate the initial OAuth request

The first `process_request` policy is an `oauth` policy that processes the initial request and verifies that the request is valid. The result of the processing is stored automatically in the `oauth.processing` context variables for use, as required, by the next OAuth policy in the assembly flow.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
  title: process_request
  version: 2.0.0
  description: >-
    This oauth policy performs all OAuth/OpenID Connect protocol steps
    that are needed for OAuth Validation by default. The inputs and
    outputs of each of the steps are driven by documented context
    variables. Add or remove the Supported OAuth Components as required.
  oauth-provider-settings-ref:
    default: custom-form
  supported-oauth-components:
    - OAuthValidateRequest
```

Sample policy to modify the scope

The `modify_scope` policy is a `gatewayscript` policy that modifies the scope depending on the calling application.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
  version: 2.0.0
  title: modify_scope
  source: |-
    let admin_id = '1f1a2aa4-db9f-4423-b2f1-e2572b12123a';

    // Check application and modify the scope
    let app = context.get("oauth.processing.client_id");
    let scope = context.get("oauth.processing.scope");
    if (app === admin_id) {
      context.set("oauth.processing.scope", scope + " admin");
    } else {
      context.set("oauth.processing.scope", scope + " customer");
    }
}
```

Branch conditionally according to the OAuth path

The `path_branch` policy is a `switch` policy that branches according to the different OAuth paths to process the resource owner.

The underlying OpenAPI source YAML is as follows:

```
- switch:
  version: 2.0.0
  title: path_branch
  case:
    - condition: ($operationPath() = '/oauth2/token')
      execute:
        .
        .
        .
        definition of the user_security and other_grants policies
        .
        .
    - condition: ($operationPath() = '/oauth2/authorize')
      execute:
        .
        .
        .
        definition of the user_password and implicit_authcode policies
        .
        .
    - otherwise:
        .
        .
        .
        definition of the other_endpoints policy
        .
        .
```

Process the user name and password, and enable grant type component

The following two policies operate on the token endpoint.

- The `user_password` policy for password grant type processes the user name and password from the `x-www-form-urlencoded` body. The authentication method is derived from the User Security settings in the OAuth provider; see [Configuring user security for a native OAuth provider](#).
- The `other_grants` policy is an `oauth` policy that enables the `OAuthGenerateAccessToken`, `OAuthVerifyAZCode`, `OAuthVerifyRefreshToken`, and `OAuthCollectMetadata` components to perform the operations for client credentials, authorization code, refresh token, and password grant types.

The underlying OpenAPI source YAML is as follows:

```

- user-security:
  title: user_password
  version: 2.0.0
  description: ''
  factor-id: default
  extract-identity-method: context-var
  user-context-var: request.parameters.username.values
  pass-context-var: request.parameters.password.values
  ei-stop-on-error: false
  user-auth-method: auth-url
  au-stop-on-error: false
  auth-url: 'http://httpbin.org/basic-auth/user/pass'
  user-az-method: authenticated
  az-stop-on-error: true
  auth-response-headers-pattern: (?)*x-api*
  auth-response-header-credential: X-API-Authenticated-Credential
- oauth:
  title: other_grants
  version: 2.0.0
  description: >-
    This oauth policy performs all OAuth/OpenID Connect
    protocol steps that are needed for token path by default.
    The inputs and outputs of each of the steps are driven by
    documented context variables. Add or remove the Supported
    OAuth Components as required.
  oauth-provider-settings-ref:
    default: custom-form
  supported-oauth-components:
    - OAuthGenerateAccessToken
    - OAuthVerifyAZCode
    - OAuthVerifyRefreshToken
    - OAuthCollectMetadata

```

Perform authorization checks, and enable grant type components

These following two policies operate on the authorize endpoint.

- The `user_security` policy configuration is derived from the User Security settings in the OAuth provider; see [Configuring user security for a native OAuth provider](#).
- The `implicit_authcode` policy is an `oauth` policy that enables the `OAuthGenerateAZCode`, `OAuthGenerateAccessToken`, and `OAuthCollectMetadata` components to perform the operations for the implicit and authorization code grant types.

The underlying OpenAPI source YAML is as follows:

```

- user-security:
  title: user security
  version: 2.0.0
  description: >-
    This user security policy performs EI(basic) and AU(auth
    url) check for oauth assembly. Change the security check
    method as required
  factor-id: default
  extract-identity-method: basic
  ei-stop-on-error: true
  user-auth-method: auth-url
  au-stop-on-error: true
  user-az-method: authenticated
  az-stop-on-error: true
  auth-response-headers-pattern: (?)*x-api*
  auth-response-header-credential: X-API-Authenticated-Credential
  auth-url: 'http://httpbin.org/basic-auth/user/pass'
- oauth:
  title: implicit_authcode
  version: 2.0.0
  description: >-
    This oauth policy performs all OAuth/OpenID Connect
    protocol steps that are needed for az code path by
    default. The inputs and outputs of each of the steps are
    driven by documented context variables. Add or remove the
    Supported OAuth Components as required.
  oauth-provider-settings-ref:
    default: custom-form
  supported-oauth-components:
    - OAuthGenerateAZCode
    - OAuthGenerateAccessToken
    - OAuthCollectMetadata

```

Process all other endpoints

The `otherwise` condition catches all other endpoints such as the introspect and revoke endpoints. The `other_endpoints` policy in the `otherwise` condition is an `oauth` policy that enables the `OAuthIntrospectToken`, and `OAuthRevokeTokencomponents` components to perform the operations for introspect and revoke.

The underlying OpenAPI source YAML is as follows:

```

- oauth:
  title: other_endpoints
  version: 2.0.0
  description: >-
    This oauth policy performs all OAuth/OpenID Connect
    protocol steps that are needed for all other paths by
    default. The inputs and outputs of each of the steps are
    driven by documented context variables. Add or remove the

```

```
Supported OAuth Components as required.
oauth-provider-settings-ref:
  default: custom-form
supported-oauth-components:
  - OAuthIntrospectToken
  - OAuthRevokeToken
```

Parse

Use the Parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0
	2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)
	2.2.0 (DataPower API Gateway Version 10.5.0.5 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [parse](#).

About Parse

With the parse policy, you can retrieve parse settings by using the following methods in increasing order of precedence.

1. Specify a valid parse settings configuration from which to retrieve its properties as the default parse settings.
Note: If you change the default name, you must separately configure a corresponding ParseSettings object on the DataPower API Gateway.
2. Specify a literal string as serialized XML or JSON properties as parse settings. These properties take precedence over any existing default properties. The literal string must be XML or JSON formatted.
 - The XML format is "`<ParseSettings><propertyName>propertyValue</propertyName></ParseSettings>`".
 - The JSON format is "`{ \"ParseSettings\" : { \"propertyName\" : propertyValue } }`".
3. A URL that represents a named context from which to retrieve the serialized XML or JSON properties as parse settings. These properties take precedence over any existing literal or default properties.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Parse policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is parse .	string
Description	No	A description of the policy.	string
Use Content Type	No	If this setting is enabled and the parse setting is configured to detect the document type, the parse operation uses the Content-Type specified in the request headers. If this setting is enabled and the document type in the parse setting is configured for either JSON or XML, the parse operation uses the Content-Type specified in the request headers and fails if the Content-Type in the request headers does not match the parse setting. Enabling this setting is applicable only when the expected Content-Type is either JSON or XML. If this setting is not enabled, the parse operation uses either the document type that is specified in the parse setting, or the detected document type if the parse setting is configured to detect the document type. The check box is cleared by default.	boolean
Parse settings object reference	No	An existing valid object from which to retrieve default property values for the dynamic object.	string

Property label	Required	Description	Data type
Document type	No	<p>The type of document to parse. Select one of the following options:</p> <ul style="list-style-type: none"> Detect: the document type is detected and the payload is parsed accordingly. This type is the default option. JSON: the payload is parsed as JSON. XML: the payload is parsed as XML. GraphQL: parsing is performed in one of the following ways: <ul style="list-style-type: none"> As GraphQL in the body of a POST request. The GraphQL is in the following format: <pre> { me { name } } </pre> As a JSON string in the body of a POST request that contains a GraphQL query. The JSON object is in the following format: <pre> { "query": "query MyData (\$idVar: Int!) { user (id: \$idVar) { name }}", "operationName": "MyData", "variables": {"idVar": 123} } </pre> Through the URL query of a GET request. The URL is in the following format: <pre> https://myapi/graphql?query={me{name}} </pre> <p>The following example includes the <code>variables</code> and <code>operationName</code> properties, with URL encoding (line-breaks are for table formatting only, your value will not include line-breaks):</p> <pre> https://hostname/basepath/graphql?query=query%20fetchAccounts%20(\$limit:%20Int)%20{accounts(limit:%20\$limit)%20{name{first,last}}&variables={"limit":100}&operationName=fetchAccounts </pre> <p>Query variables in a GET request can be sent as a JSON string in a query parameter called <code>variables</code>. If the query contains several named operations, an <code>operationName</code> query parameter is required to determine which operation is to be executed.</p>	string
Maximum document size	No	<p>Optionally, the maximum document size in bytes of a JSON, XML, or GraphQL input document that the parse operation accepts. This setting provides threat protection by enforcing the maximum document size. Enter a value in the range 0 - 5368709121. A document is rejected when its size exceeds the maximum size. A value of 0 indicates an unlimited document size. When set to 0, the operation result does not return the document size. The default value is 4194304.</p>	integer
Maximum nesting depth	No	<p>Optionally, the maximum nesting depth of an XML, JSON, or GraphQL message that the parse operation accepts. This setting provides threat protection by enforcing limits in the message.</p> <ul style="list-style-type: none"> When XML, it is the maximum level of element depth. When JSON, it is the maximum level of nested label-value pairs, the maximum number of nested arrays, or the maximum number of combination of label-value pairs and arrays. When GraphQL, it is the maximum level of nested selection sets. <p>Enter a value in the range 0 - 4096. A document is rejected when its nesting depth exceeds the maximum depth. A value of 0 indicates unlimited nesting depth. When set to 0, the operation result does not return the nesting depth.</p> <p>The default value is 512.</p>	integer
Maximum width	No	<p>Optionally, the maximum width of the payload that the parse operation accepts.</p> <ul style="list-style-type: none"> When the input document is XML, this property specifies the maximum number of attributes for an element or the maximum number of child elements for an element. When the input document is JSON, this property specifies the maximum number of properties on a JSON object or the maximum number of JSON items in a JSON array. When the input document is GraphQL, this property specifies the maximum number of selections in a selection set. <p>Enter a value in the range 0 - 65535. The document is rejected when its width exceeds the maximum width. A value of 0 indicates unlimited width. When set to 0, the operation result does not return the width of the document.</p> <p>The default value is 4096.</p>	integer
Maximum name length	No	<p>Optionally, the maximum name length in bytes in a document that the parse operation accepts.</p> <ul style="list-style-type: none"> For XML, it is the length of the name portion of a tag. For JSON, it is the length of the label portion of the JSON label-value pair. For GraphQL, it is the maximum length of the identifiers, including field names and directive names. <p>The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 8192. A document is rejected when its name length exceeds the maximum length. A value of 0 indicates unlimited name length. When set to 0, the operation result does not return the name length of a document.</p> <p>The default value is 256.</p>	integer

Property label	Required	Description	Data type
Maximum value length	No	<p>Optionally, the maximum value length in bytes in a document that the parse operation accepts.</p> <ul style="list-style-type: none"> For XML, it is the length of an attribute or the length of a text value. For JSON and GraphQL, it is the length of a string value. <p>The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 5368709121. A document is rejected when its value length exceeds the maximum length. A value of 0 indicates unlimited value length. When set to 0, the operation result does not return the value length of a document.</p> <p>The default value is 8192.</p>	integer
Maximum number of unique names	No	<p>Optionally, the maximum number of unique names in a JSON or XML document that the parse operation accepts.</p> <ul style="list-style-type: none"> For XML, it is the number of unique XML local names. For JSON, it is the number of unique JSON labels. <p>Enter a value in the range 0 - 1048575. A document is rejected when the number of unique names in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique names. When set to 0, the operation result does not return the number of unique names in a document.</p> <p>The default value is 1024.</p>	integer
Maximum number of unique prefixes	No	<p>Optionally, the maximum number of unique XML namespace prefixes in a document that the parse operation accepts. This limit counts multiple prefixes defined for the same namespace, but does not count multiple namespaces defined in different parts of the input document under a single prefix. Enter a value in the range 0 - 262143. A document is rejected when the number of unique prefixes in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique prefixes. When set to 0, the operation result does not return the number of unique prefixes in a document.</p> <p>The default value is 1024.</p>	integer
Maximum number of unique namespaces	No	<p>Optionally, the maximum number of unique XML namespace URIs that the parse operation accepts. This limit counts all XML namespaces, regardless of how many prefixes are used to declare them. Enter a value in the range 0 - 65535. A document is rejected when the number of unique namespaces in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique namespaces. When set to 0, the operation result does not return the number of unique namespaces in a document.</p> <p>The default value is 1024.</p>	integer
Maximum number length	No	<p>Optionally, the maximum number of bytes in the value portion of a JSON label-value pair when the value is a number. The number must be a contiguous string of bytes that contain no white space. The number can include a minus sign and a positive or negative exponent. Enter a value in the range 0 - 256. A document is rejected when the number length in the document exceeds the maximum length. A value of 0 indicates unlimited number length. When set to 0, the operation result does not return the number length in a document.</p> <p>The default value is 128.</p>	integer
Parse settings literal configuration	No	A literal string as serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing default properties.	string
Parse settings URL reference	No	A URL that represents a named context from which to retrieve the serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing literal or default properties.	string
Message for parsing	No	The name of a variable in the API context. The content of the body field of the variable is the input to the policy. The default variable name is message .	string
Message for resulting parsed data	No	The name of a variable in the API context. The content of the body field of the variable is the output of the parse operation. The parse metrics of the parsed document can be stored in a different part of the message. The default variable name is the same as the input name, so by default the input message is overwritten by the output message.	string

Use the YAML source to set the following option.

Property	Required	Description	Data type
strict-utf8-encoding	No	<p>For JSON documents, whether to enforce strict UTF-8 encoding throughout the entire document.</p> <ul style="list-style-type: none"> When on, the entire document is checked for valid UTF-8 encoding. When off, only the first few bytes are checked for proper encoding. The rest of the document is assumed to be in the same encoding. <p>The default value is off.</p>	boolean

For examples, see [parse](#).

Proxy

Apply the Proxy policy to invoke another API within your assembly, particularly if the separate API contains a large payload. The response from the backend is stored in the **message.body** and in the response object variable if it is defined. Only one policy is permitted to be run per unique assembly flow.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0

Gateway	Policy version
DataPower API Gateway, functionality provided by Invoke	

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [proxy](#).

About

Only one Proxy policy is permitted to be run per unique flow of your assembly. More than one Proxy policy can be applied, if they are contained in mutually exclusive branches of the assembly.

You can use the Proxy policy to return multipart form data, that is, when the response is set to `Content-Type: multipart/related`. However, Proxy must be the last policy in the assembly, otherwise the response that is received can be manipulated during subsequent steps, thereby causing the multipart form data to be lost.

The proxy policy, if inside a conditional policy, must be the **final** policy to be executed in the API. If you need further processing afterward, use the [invoke](#) policy rather than the proxy policy.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Proxy policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is <code>proxy</code> .	string
Description	No	A description of the policy.	string
Invoke URL	Yes	Specifies a URL for the target service. For a SOAP API, a URL is added by default. Where possible, the Proxy URL value is pre-supplied from information that is defined in the imported WSDL.	string
TLS profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	Yes	The time to wait before a reply back from the endpoint (in seconds). The default value is <code>60</code> .	integer
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
HTTP Method	Yes	The HTTP method to use for the proxy. Valid values are: <ul style="list-style-type: none"> Keep GET POST PUT DELETE PATCH HEAD OPTIONS The default value is <code>Keep</code> . By using <code>Keep</code> , or removing the property from the source, the HTTP method from the incoming request is used.	string
Compression	No	Select this check box to enable Content-Encoding compression on upload. The check box is cleared by default.	boolean

Property label	Required	Description	Data type
Cache Type	No	<p>The cache type determines whether to cache documents, honoring or overriding the HTTP Cache Control directives received in the response from the target URL. This property takes effect only when a response is received, otherwise the policy always returns the non-expired response that was previously saved in cache. Valid values are:</p> <p>Protocol The cache behavior is determined by the Cache-Control headers on the response, in accordance with RFC 7234. To optimize performance, if the gateway receives more than one request for a resource that is not in the cache but could be cached when the response from the target URL is received, the gateway sends only one request to the target URL; the remaining requests are not processed until the response from the first request has been received and the cache behavior has been determined from this response. If the response indicates that caching is possible, the gateway responds to all waiting requests with the cached resource. If the response indicates that caching is not possible, the gateway sends all waiting requests to the target URL.</p> <p>Use this option only if you expect that responses from the target URL can be cached, in which case it should improve performance and limit the demand on the target URL. If, however, the target URL never indicates that the gateway should cache its response, performance might be impaired when compared to the No Cache option.</p> <p>No Cache Responses from the target URL are not cached on the gateway regardless of any caching headers returned. In this case, every request from the client is sent to the target URL. Use this option if you do not want to cache any of the backend responses on the gateway, or if it is unlikely that a response from the target URL will allow caching through the Cache-Control header settings.</p> <p>Time to Live This option is similar to the Protocol option except it allows you to specify the amount of time that you want the successful response from the invoke or proxy to remain in the cache. Use this option only if you expect that responses from the target URL can be cached.</p> <p>The default value is Protocol.</p>	string
Time to Live	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property Cache type is set to Time to Live . Enter a value in the range 5 - 31708800. The default value is 900.	integer
Cache key	No	Specifies the unique identifier of the document cache entry. If omitted, the entire URL string is used as the key.	string
Stop on error	No	Select the errors that, if thrown during the policy execution, cause the assembly flow to stop. If there is a catch flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors selected for the Stop on error setting, or if the error thrown is not one of the selected errors, the policy execution is allowed to complete, and the assembly flow continues.	string
Response object variable	No	The name of a variable that will be used to store the response data from the request. This variable can then be referenced in other actions, such as 'Map'.	string
X-Forwarded header	No	<p>This header can be provided by</p> <ol style="list-style-type: none"> If X-Forwarded-Host exists, processing continues. If it does not exist prior to calling the proxy policy, it is set with the value of the Host header. The X-Forwarded-For header is always set, in all cases. This header maintains breadcrumbs, showing a comma-separated list of IPs, from the client through any preceding proxy. If all three of X-Forwarded-Host, X-Forwarded-Port, and X-Forwarded-Proto headers are missing at the time of calling the proxy policy, they are set automatically. To prevent this, set X-Forwarded-Host header to some value before calling the proxy policy. 	string

API Gateway only

Rate Limit

Use the Rate Limit policy to apply one or more rate, burst, or count limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0
	2.1.0 (DataPower API Gateway Version 10.0.1.0 or later)
	2.2.0 (DataPower API Gateway Version 10.0.2.0 or later)
	2.3.0 (DataPower API Gateway Version 10.5.0.0)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [ratelimit](#).

About

The defined rate, burst, and count limits are applied to whatever follows in the assembly flow. For example, if a Rate Limit policy is placed before an Invoke policy, and the call made by the Invoke policy exceeds the limits defined by the Rate Limit policy, the API call itself fails.

Note: For information about rate limits and burst limits in API Connect, see [Understanding rate limits for APIs and Plans](#).

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Rate Limit policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is <code>ratelimit</code> .	string
Description	No	A description of the policy.	string
Source	Yes	The location of all the rate limit, burst limit, and count limit definitions that are included in this policy. Select one of the following options: <ul style="list-style-type: none"> • Catalog by Name: the limits to be applied are defined in the appropriate <code>api-collection</code> object on the DataPower API Gateway, which is the object that represents your API Connect Catalog in the gateway configuration. For details of how to configure a rate, burst, or count limit in the <code>api-collection</code> object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. • Plan by Name: the limits to be applied are assembly burst limits or assembly count limits defined on the Plan to which the calling application is subscribed. For details on how to configure assembly burst limits and assembly count limits in a Plan, see Editing a draft Product. Note: The following conditions apply to a Plan by Name rate limit policy: <ul style="list-style-type: none"> ◦ Every Plan that contains the API that is being limited must have the named rate limit applied. ◦ A Plan by Name rate limit policy cannot be used with automatically generated Products. • Gateway by Name: the limits to be applied are defined in the <code>apigw</code> object, named <code>apiconnect</code>, on the DataPower API Gateway gateway. For details of how to configure a rate, burst, or count limit in the <code>apigw</code> object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. • Plan Default: the rate and burst limits that are applied are the default ones configured in the Plan to which the calling application is subscribed. For details on how to configure default Plan rate and burst limits, see Editing a draft Product. Note: The use of this option does not disable any automatic preflow rate limit policy that might be in place, and could result in the application of the rate limiting being repeated. For more information on preflow policies, see Customizing the preflow policies. 	string
Rate Limit Name	Yes ¹	If Source property is set to Catalog by Name, the name of a rate limit as defined in the DataPower API Gateway configuration, To display the Rate Limit Name field, click Add Rate Limit; you can add as many rate limits as you want. ¹ You must provide at least one rate, burst, or count limit.	string

Property label	Required	Description	Data type
Burst Limit Name	Yes ²	<p>If Source property is set to Catalog by Name, the name of a burst limit as defined in the DataPower API Gateway configuration.</p> <p>If Source is set to Plan by Name, the name of an assembly burst limit in a Plan.</p> <p>To display the Burst Limit Name field, click Add Burst Limit; you can add as many burst limits as you want.</p> <p>²You must provide at least one rate, burst, or count limit.</p>	string
Count Limit Name	Yes ³	<p>If Source property is set to Catalog by Name, the name of a count limit as defined in the DataPower API Gateway configuration.</p> <p>If Source is set to Plan by Name, the name of an assembly count limit in a Plan.</p> <p>To display the Count Limit Name field, click Add Count Limit; you can add as many count limits as you want.</p> <p>³You must provide at least one rate, burst, or count limit.</p>	string
Operation	No	<p>For a rate limit, select one of the following options:</p> <ul style="list-style-type: none"> Consume: the policy reduces the balance of available requests that remain in the interval defined by the rate limit specified in the Rate Limit Name field. The amount by which the remaining balance is reduced is the value that results from the weight expression defined in the specified rate limit. Replenish: the policy increases the balance of available requests that remain in the interval defined by the rate limit specified in the Rate Limit Name field. The amount by which the remaining balance is increased is the value that results from the weight expression defined in the specified rate limit. <p>The purpose of the replenish operation is to restore an appropriate amount of remaining balance in cases where the amount calculated by an earlier consume operation turns out to be too high. For example, for an assembly rate limit with a limit of 100, a consume operation with a weight of 60 uses 60 requests, leaving 40 requests remaining for the interval. If the weight expression in the subsequent replenish operation computes to 15, meaning that the weight expression calculated that the actual request usage was only 45, the replenish operation increases the remaining requests by 15, to a remaining balance of 55.</p> <p>Note that the replenish operation cannot increase the remaining requests allowed beyond the original limit defined in the assembly rate limit scheme. In this example, a replenish operation cannot replenish requests beyond 100. A replenish operation is skipped if the weight expression evaluates to a value of less than 1.</p> <p>The default value is Consume.</p> <p>For a count limit, select one of the following options:</p> <ul style="list-style-type: none"> Increment: the current count is incremented by the value that results from the weight expression defined in the count limit specified in the Count Limit Name field. Decrement: the current count is decremented by the value that results from the weight expression defined in the count limit specified in the Count Limit Name field. <p>By default, the count limit is automatically decremented at the end of the API assembly by the total amount incremented during the assembly, minus any decrement operations that are defined in the assembly. You do not need to explicitly define decrement operations unless you want the decrements to occur at specific points in the assembly. However, if the auto decrement feature has been explicitly disabled in the count limit configuration, you must include a corresponding decrement operation, otherwise when the count limit is reached all future calls are blocked. For more information on configuring a count limit, see Configuring a rate, burst, or count limit on the DataPower API Gateway.</p> <p>The default value is Increment.</p> <p>For a burst limit, the only option is Consume, meaning that the limit applied is that defined in the burst limit specified in the Burst Limit Name field.</p>	string

- [Configuring a rate, burst, or count limit on the DataPower API Gateway](#)

If you want to include a rate limiting policy in your API assembly flow, you must first configure the required rate, burst, and count limits on the Gateway. Rate and burst limits restrict the number of calls that an application can make to API in specified time period, while count limits impose a strict limit on the total number of calls.

Configuring a rate, burst, or count limit on the DataPower API Gateway

Rate and burst limits restrict the number of calls that an application can make to API in specified time period, while count limits impose a strict limit on the total number of calls.

About this task

You configure rate, burst, and count limits on the DataPower® API Gateway by defining them in one or more configuration files that you package and then add to the Gateway as a Gateway extension.

You define *Catalog scoped* rate, burst, and count limits in the appropriate **api-collection** object on the DataPower API Gateway, which is the object that represents your API Connect Catalog in the gateway configuration. The defined rate, burst, and count limits will be available to be included in [Rate Limit](#) policies in the assembly flows of all the APIs that are published to that Catalog.

You define *Gateway scoped* rate, burst, and count limits in the appropriate **apigw** object on the DataPower API Gateway. The defined rate, burst, and count limits will be available to be included in [Rate Limit](#) policies in the assembly flows of all the APIs that are published to that Gateway.

Note:

- Only one Gateway extension can be in use at any one time, so you should package all required rate, burst, and count limits in a single Gateway extension.
- To apply a Catalog scoped or Gateway scoped rate, burst, or count limit, it must be referenced in a [Rate Limit](#) policy in an API assembly.
- You should ensure that all rate, burst, and count limit names are unique across all your Plans and Catalogs. When an API is called, information about any rate, burst, or count limits (such as name, limiting criteria, and remaining number of calls) is returned in the HTTP headers of the response. If two or more limit definitions with exactly the same name are applied during the invocation of an API, information about only **one** of them is returned. However, **all** limiting criteria are applied.

Procedure

1. Create a `.cfg` file that includes the DataPower API Gateway CLI commands that define the rate, burst, or count limit.

To define a rate limit, use the **assembly-rate-limit** command. To define a burst limit, use the **assembly-burst-limit** command. To define a count limit, use the **assembly-count-limit** command. For details of the command parameters, see [assembly-rate-limit](#), [assembly-burst-limit](#), and [assembly-count-limit](#) in the DataPower product documentation.

Example 1: Configuring a Catalog scoped rate limit

```
top; config;
switch apiconnect;

api-collection myorg_mycatalog_collection
  assembly-rate-limit 30perlmin 30 1 minute on off on on off off "" "my.vars.expected-amount - my.vars.actual-amount"
exit
```

In this example, the **assembly-rate-limit** command specifies a rate limit name, and the API call limits that you want to impose, 30 calls per minute in this case. The final, optional argument, `"my.vars.expected-amount - my.vars.actual-amount"`, is a weight expression. You use weight expressions in cases where you want to restore an appropriate amount of remaining rate limit balance when an earlier usage calculation in your assembly flow turns out to be too high. You define two rate limiting policies in your assembly flow, one with a **consume** operation, and a subsequent one with a **replenish** operation that restores some of the remaining rate limit balance if appropriate. The weight expression calculates the amounts to be consumed or replenished; for more information, see [Rate Limit](#).

The **api-collection** command specifies the **api-collection** object in which you want to configure the rate, burst, or count limits. The name of the **api-collection** object has the following format:

```
org_catalog_collection
```

where:

- `org` is the name of the provider organization that contains your Catalog.
- `catalog` is the name of the Catalog.

This **api-collection** object name is assigned automatically by the Gateway the first time that a Product is published to the Catalog.

Example 2: Configuring a Catalog scoped count limit

```
top; config;
switch apiconnect;

api-collection myorg_mycatalog_collection
  assembly-count-limit maxsixty 60 1 on on off off off off "" "1" off
exit
```

The final argument is the **autodecrement** property that controls whether the count limit is automatically decremented at the end of an API assembly. The default value is **on**, meaning that at the end of the assembly the count limit is automatically decremented by the total amount incremented during the assembly, minus any decrement operations that are defined in the assembly. You do not need to explicitly define decrement operations unless you want the decrements to occur at specific points in the assembly.

Example 3: Configuring a Gateway scoped rate limit

```
top; config;
switch apiconnect;

apigw apigw_object_name
  assembly-rate-limit 30perlmin 30 1 minute on off on on off off "" "my.vars.expected-amount - my.vars.actual-amount"
exit
```

The **apigw** command specifies the name of the **apigw** object in which you want to configure the rate, burst, or count limits; the **apigw** object name is the same as the name of the API Connect domain in your DataPower API Gateway configuration.

2. Package the `.cfg` file in a `.zip` file.
You can package multiple `.cfg` files in a single `.zip` file if you want; the `.cfg` files must all be at the root of the `.zip` file.
3. Add the `.zip` file to the DataPower API Gateway as a Gateway extension. For details, see [Configuring your Gateway server extensions](#).

What to do next

Apply the rate, burst, or count limits to an API by adding a [Rate Limit](#) policy to the API assembly flow.

Related information

- [Gateway extension guidelines - DataPower API Gateway.](#)

Redaction - DataPower API Gateway

Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This page describes the Redaction policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see [Redaction - DataPower Gateway \(v5 compatible\)](#).

For information on the different types of gateway, see [API Connect gateway types](#).

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [redact - DataPower API Gateway](#).

Note: With the DataPower API Gateway, the input to the Redaction policy must be parsed data. One way to produce parsed data is to use a [Parse](#) policy before a Redaction policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Redaction policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is redact .	string
Description	No	A description of the policy.	string
Root	No	Specifies the data source that contains the content to redact or remove. If no value is entered in the Root field, the action is applied to the entire API context. You can use any supported JSONata path expression. If you want to apply the action to either request or response data, specify a value of <code>message.body</code> . The actual content to which the action is applied then depends on the positioning of the Redaction policy in the overall assembly flow; for example: <ul style="list-style-type: none"> • If positioned at the beginning, the action is applied to the client request. • If positioned after an Invoke policy, the action is applied to the response from the back end. • If positioned at the end, the action is applied to the response that is returned to the client. If, in your assembly flow, the Redaction policy is used after a Log policy that specifies Gather-only mode, specify a Root value of <code>log.request_body</code> for the logged request payload, or <code>log.response_body</code> for the logged response payload.	string
Path	Yes	Specifies a JSONata path expression that identifies the content to redact or remove from the source. For more information, see Constructing JSONata expressions to redact fields	string
Action	No	Specifies whether you want to remove or redact the content. Choose one of the following options: <ul style="list-style-type: none"> • Remove: Completely removes the specified fields. • Redact: Redacts (obfuscates with "*"s) the fields to block out the data. The default value is Redact. Note: If a numerical value is being redacted, the redacted value is depicted as ***** and the type is changed to string .	string

Tip: You can optionally click Add action to specify JSONata expressions for additional fields that you want to remove or redact from the specified content source.

- [Constructing JSONata expressions to redact fields](#)

To define a field for redaction or removal when using the Redaction policy with the DataPower API Gateway, you supply a JSONata expression that defines the path to the field that you want to redact or remove.

Constructing JSONata expressions to redact fields

To define a field for redaction or removal when using the Redaction policy with the DataPower® API Gateway, you supply a JSONata expression that defines the path to the field that you want to redact or remove.

Note: For a list of known limitations to DataPower API Gateway support for JSONata, see [Limitations to support for JSONata](#).
The following JSONata functions are supported:

- Aggregation functions:
 - `$average(array)`
 - `$max(array)`
 - `$min(array)`
 - `$sum(array)`
- Array functions:
 - `$append(array1, array2)`
 - `$count(array)`
 - `$reverse(array)`
 - `$sort(array [, function])`
 - `$zip(array1, ...)`
- Boolean functions:
 - `$boolean(arg)`
 - `$exists(arg)`
 - `$not(arg)`
- Numeric functions:
 - `$abs(number)`
 - `$ceil(number)`
 - `$floor(number)`
 - `$formatBase(number [, radix])`
 - `$number(arg)`
 - `$power(base, exponent)`
 - `$round(number [, precision])`
 - `$sqrt(number)`
- Object functions:
 - `$keys(object)`
 - `$lookup(object, key)`
 - `$merge(array<object>)`
 - `$spread(object)`
 - `$type(value)`

In addition to the standard values returned by `$type()`, the API gateway implementation of `$type()` can return the following values: `binary`, `empty`, `graphql`, `stream`, or `xml`.
- String functions:
 - `$contains(str, pattern)`
 - `$join(array[, separator])`
 - `$length(str)`
 - `$lowercase(str)`
 - `$match(str, pattern [, limit])`
 - `$pad(str, width [, char])`
 - `$replace(str, pattern, replacement [, limit])`
 - `$split(str, separator [, limit])`
 - `$string(arg)`
 - `$substring(str, start[, length])`
 - `$substringAfter(str, chars)`
 - `$substringBefore(str, chars)`
 - `$trim(str)`
 - `$uppercase(str)`
- You can use the following functional extensions to standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description
<code>\$header(name)</code>	<code>message.headers.name</code>	Message header
<code>\$httpVerb()</code>	<code>request.verb</code>	HTTP method of the request
<code>\$operationID()</code>	<code>api.operation.id</code>	ID of the operation
<code>\$operationPath()</code>	<code>api.operation.path</code>	Path of the operation
<code>\$queryParameter('name')</code>	<ul style="list-style-type: none"> ◦ <code>request.parameters.name.locations</code> The supported keyword is <code>query</code>. ◦ <code>request.parameters.name.values</code> 	Searches for the index of <code>query</code> in <code>request.parameters.name.locations</code> and returns <code>request.parameters.name.values[index]</code> , where <code>[index]</code> is the value for <code>query</code> in locations. Parameter values are not URL decoded.
<code>\$statusCode()</code>	<code>message.status.code</code>	Status code
<code>\$storageType([arg])</code>	<code>variable.body</code> You can specify any variable in the API context. When no variable is specified, the default variable <code>message.body</code> is used.	Storage type of the message. The supported values are <code>binary</code> , <code>empty</code> , <code>graphql</code> , <code>json</code> , <code>stream</code> , or <code>xml</code> .

Extension	Variable	Description
<code>\$urlParameter('name')</code>	<ul style="list-style-type: none"> <code>request.parameters.name.locations</code> The supported keywords are <code>path</code> and <code>query</code> <code>request.parameters.name.values</code> 	<p>Searches for the index of <code>path</code> and <code>query</code> in <code>request.parameters.name.locations</code> and returns a single array that contains both <code>path</code> and <code>query</code> values from <code>request.parameters.name.values</code>. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded.</p> <p>For example, the following URL contains both path and query parameter values.</p> <pre>http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese</pre> <p>The <code>\$urlParameter('breed')</code> URL returns the following array of values.</p> <pre>[cats, adopt, Sphynx, Siamese]</pre> <p>In this example, the URL includes an API path that is configured as <code>/petstore/{breed}/{breed}</code>, where <code>breed</code> is configured to be a path parameter of the API path. As a result, <code>cats</code> and <code>adopt</code> are included in the output.</p>
<code>\$xpath(path, xpathExpression)</code>	You can specify any writable variable in the API context. The <code>xpathExpression</code> must be a literal string.	<p>Allows use of XPath expressions. The following example specifies all price elements in the source.</p> <pre>\$xpath(\$, '//price')</pre>

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
<code>\$gqlActiveOperation([graphql_message])</code>	<code>message.body</code>	Gets the active operation found in the specified GraphQL message. The <code>operationName</code> must be the same as the name of the active operation.
<code>\$gqlAlias(graphql_field_node)</code>	<code>message.body</code>	Gets the alias of a GraphQL field node.
<code>\$gqlFragments([graphql_message])</code>	<code>message.body</code>	Gets the fragments found in the specified GraphQL message.
<code>\$gqlName([graphql_node])</code>	<code>message.body</code>	Gets the node name. For operations, the node name is the <code>operationName</code> . For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the <code>operationName</code> of <code>message.body</code> is retrieved.
<code>\$gqlOperations([graphql_message])</code>	<code>message.body</code>	Gets the operations found in the specified GraphQL message.
<code>\$gqlType([graphql_node])</code>	<code>message.body</code>	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

- You can use the `&` (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- `/` (division)
- `%` (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- `query`
The entire GraphQL query including operations and fragments.
- `operationName`
For an anonymous operation, `operationName` can be empty.
- `~fragmentSpreadName`
- `on~typeCondition`
- `~~fragmentDefinitionName`

You can define the path in either of the following ways:

- [Use a JSONata expression](#)
- [Use the `\$xpath\(\)` JSONata extension](#)

Using a JSONata expression

The path specified by the JSONata expression is relative to any value specified for the `root` property of the Redaction policy. If the `root` property has no value or is absent, begin the expression with the absolute content path. If the `root` property has a value then you can either begin the expression with `$` to use the `root` path directly, or you can provide a sub-path relative to the `root` path.

JSONata expressions can be used with content that is in either JSON or XML format.

Example 1

If the `root` property of the Redaction policy has no value or is absent, use the following expression to redact or remove all occurrences of the `price` field in the request and response data:

```
message.body.**.price
```

Example 2

If the `root` property of the Redaction policy has the value `log.request_body`, use the following expression to redact or remove all occurrences of the `price` field, specifically within an `item` element, in the logged request payload:

```
$.item.price
```

Example 3

If the `root` property of the Redaction policy has the value `log`, use the following expression to redact or remove all occurrences of the `price` field in the logged response payload:

```
response_body.**.price
```

The `**` descendant wildcard traverses all descendants at all hierarchical levels.

Using the `$xpath()` JSONata extension

The `$xpath()` function has the following format:

```
$xpath(content_path, xpath_expression)
```

where:

- `content_path` is the path to the content that contains the field that you want to redact or remove.
- `xpath_expression` is the XPath expression that defines the field that you want to redact or remove.

The `content_path` is relative to any value specified for the `root` property of the Redaction policy. If the `root` property has no value or is absent, provide the absolute content path. If the `root` property has a value then you can either provide the value `$` for the `content_path` parameter to use the `root` path directly, or you can provide a sub-path relative to the `root` path.

The `$xpath()` function can be used only with content that is in XML format.

Example 1

If the `root` property of the Redaction policy has no value or is absent, use the following expression to redact or remove all occurrences of the `price` field in the request and response data:

```
$xpath(message.body, '//price')
```

Example 2

If the `root` property of the Redaction policy has the value `log.request_body`, use the following expression to redact or remove all occurrences of the `price` field, specifically within an `item` element, in the logged request payload:

```
$xpath($, 'item/price')
```

Example 3

If the `root` property of the Redaction policy has the value `log`, use the following expression to redact or remove all occurrences of the `price` field in the logged response payload:

```
$xpath(response_body, '//price')
```

The `//` expression in the second parameter selects all occurrences anywhere in the content.

DataPower Gateway (v5 compatible)

Redaction - DataPower Gateway (v5 compatible)

Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This topic describes the Redaction policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see [Redaction - DataPower API Gateway](#).

For information on the different types of gateway, see [API Connect gateway types](#).

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [redact - DataPower Gateway \(v5 compatible\)](#).

About

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Redaction policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is redact .	string
Description	No	A description of the policy.	string
Path	Yes	Specifies an XPath expression that defines the field to remove or redact. You can construct an XPath expression that is based on JSON or XML depending on whether your API requests and responses use a JSON or an XML format. If the payload is JSON, use the DataPower XML representation of the JSON content (JSONx) to construct the expression. Note: Use a JSONx representation only to identify the XPath expressions for the fields to remove or redact. Do not change the format of any response bodies in API Manager. To learn more about constructing XPath expressions that are based on JSON or XML, see Constructing XPath expressions to redact fields .	string
Action	Yes	Specifies whether you want to remove or redact the field. Valid values: <ul style="list-style-type: none"> remove: Completely removes the specified field. redact: Redacts (obfuscates with "*"s) the field to block out the data. The default value is redact . Note: If a numerical value is being redacted, the redacted value is depicted as ***** and the type is changed to string .	string
From	Yes	Specifies where to remove or redact the specified field from. Valid values: <ul style="list-style-type: none"> all: Removes or redacts the specified field from the Request body, the Response body, and the activity logs. request: Removes or redacts the specified field from the Request body. response: Removes or redacts the specified field from the Response body. logs: Removes or redacts the specified field from the activity logs. The default value is all . Optionally click Add item to specify additional values.	string

Tip: You can optionally click Add item to specify XPath expressions for additional fields that you want to remove or redact from the Request body, Response body, and logs.

- [Constructing XPath expressions to redact fields](#)

To define a field for redaction when using the DataPower Gateway (v5 compatible), you supply an XPath expression that specifies the field that you want to redact. If your API requests and responses use XML format, you can base your XPath statements directly on the XML content. If your API requests and responses use JSON format, you must use the DataPower XML representation of the JSON content, JSONx, to construct your XPath expression.

DataPower Gateway (v5 compatible) only

Constructing XPath expressions to redact fields

To define a field for redaction when using the DataPower® Gateway (v5 compatible), you supply an XPath expression that specifies the field that you want to redact. If your API requests and responses use XML format, you can base your XPath statements directly on the XML content. If your API requests and responses use JSON format, you must use the DataPower XML representation of the JSON content, JSONx, to construct your XPath expression.

About this task

The following sections provide examples for constructing XPath expressions to redact a field; examples are provided for API responses in both XML and JSON format:

XPaths for XML

Consider the following example of an XML response:

```
<xml>
  <primaryAddress>
    <streetAddress>21 2nd Street</streetAddress>
    <city>New York</city>
    <state>NY</state>
    <postalCode>10021</postalCode>
  </primaryAddress>
  <secondaryAddress>
    <streetAddress>412 Brooklyn Avenue</streetAddress>
    <city>New Jersey</city>
    <state>NJ</state>
    <postalCode>12302</postalCode>
  </secondaryAddress>
</xml>
```

To redact "streetAddress" in the preceding example the XPath expression would be: `//streetAddress` where the components of the expression have the following meaning:

Expression	Meaning
<code>//</code>	search anywhere in the XML structure
<code>//streetAddress</code>	search anywhere in the XML structure for an element of type "streetAddress"

The XML response that results from applying this XPath expression is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<xml>
  <primaryAddress>
    <streetAddress>*****</streetAddress>
    <city>New York</city>
    <state>NY</state>
    <postalCode>10021</postalCode>
  </primaryAddress>
  <secondaryAddress>
    <streetAddress>*****</streetAddress>
    <city>New Jersey</city>
    <state>NJ</state>
    <postalCode>12302</postalCode>
  </secondaryAddress>
</xml>
```

Note: Both incidences of "streetAddress" have been redacted.

To redact one specific incidence of "streetAddress" in the initial example, the XPath expression would be: `//secondaryAddress/streetAddress` where the components of the expression have the following meaning:

Expression	Meaning
<code>//secondaryAddress</code>	search anywhere in the XML structure for an element of type "secondaryAddress"
<code>//secondaryAddress/streetAddress</code>	search under the preceding element for a child element of type "streetAddress"

The XML response that results from applying this XPath expression is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<xml>
  <primaryAddress>
    <streetAddress>21 2nd Street</streetAddress>
    <city>New York</city>
    <state>NY</state>
    <postalCode>10021</postalCode>
  </primaryAddress>
  <secondaryAddress>
    <streetAddress>*****</streetAddress>
    <city>New Jersey</city>
    <state>NJ</state>
    <postalCode>12302</postalCode>
  </secondaryAddress>
</xml>
```

Note: Only the secondary address has been redacted.

XPaths for JSON

Consider the following example of a JSON response:

```
{
  "primaryAddress": {
    "streetAddress": "21 2nd Street",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  },
  "secondaryAddress": {
    "streetAddress": "412 Brooklyn Avenue",
    "city": "New Jersey",
    "state": "NJ",
    "postalCode": 12302
  }
}
```

Unlike the preceding XML example, to construct an XPath for this example you must use the corresponding DataPower XML representation, JSONx. The JSONx equivalent of this JSON response is as follows:

```
<json:object xsi:schemaLocation="http://www.datapower.com/schemas/json jsonx.xsd"
xmlns:json="http://www.ibm.com/xmlns/prod/2009/jsonx" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <json:object name="primaryAddress">
    <json:string name="streetAddress">21 2nd Street</json:string>
    <json:string name="city">New York</json:string>
    <json:string name="state">NY</json:string>
    <json:number name="postalCode">10021</json:number>
  </json:object>
  <json:object name="secondaryAddress">
    <json:string name="streetAddress">412 Brooklyn Avenue</json:string>
    <json:string name="city">New York</json:string>
    <json:string name="state">NY</json:string>
    <json:number name="postalCode">10021</json:number>
  </json:object>
</json:object>
```

To redact the element "streetAddress" from the preceding JSONx structure, the XPath expression would be: `//*[@name='streetAddress']` where the components of the expression have the following meaning:

Expression	Meaning
<code>//*[</code>	find any element anywhere in the structure
<code>[@name='streetAddress']</code>	this element has a 'name' property with value "streetAddress"

The JSON response that results from applying this XPath expression is as follows:

```
{
  "primaryAddress": {
    "streetAddress": "*****",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  },
  "secondaryAddress": {
    "streetAddress": "*****",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  }
}
```

Note: All incidences of "streetAddress" have been redacted in the preceding JSON structure.

To redact a specific occurrence of the "streetAddress" element, the XPath expression would be: `//*[@name='secondaryAddress']/*[@name='streetAddress']` where the components of the expression have the following meaning:

Expression	Meaning
<code>//*[</code>	find any element anywhere in the structure
<code>//*[@name='secondaryAddress']</code>	find an element anywhere in the structure that is named "secondaryAddress"
<code>//*[@name='secondaryAddress']/*[@name='streetAddress']</code>	find a child element of any type (/*) where the child element has a name of "streetAddress"

The JSON response that results from applying this XPath expression is as follows:

```
{
  "primaryAddress": {
    "streetAddress": "21 2nd Street",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  },
  "secondaryAddress": {
    "streetAddress": "*****",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  }
}
```

Note: Only the street address for the secondary address has been redacted.

What to do next

See [Including elements in your OpenAPI 2.0 API assembly](#), [Including elements in your OpenAPI 2.0 API assembly](#) to learn how to apply a redact policy using XPath.

Set Variable

Use the Set Variable policy to set the value of a runtime variable, or to clear a runtime variable, or to add a header variable.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [set-variable](#).

- [API Connect context variables](#)

Configuring the Set Variable policy for DataPower API Gateway

Follow these steps to configure the Set Variable policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the Set Variable policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see [Configuring the Set Variable policy for DataPower Gateway \(v5 compatible\)](#). For more information about the different types of gateway, see [API Connect gateway types](#). For information about how to configure the policy in your OpenAPI source, see [set-variable](#).

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
For more information about working with the assembly editor for an API, see [The assembly editor](#).
4. Find the Set Variable policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Set Variable policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is set-variable .	string
Description	No	A description of the policy.	string
Action	Yes	Defines what action to apply on a runtime variable. Choose one of the following values: <ul style="list-style-type: none"> • Set: Indicates that you want to set a runtime variable to a string value. Can be used to set new headers or to override existing values. • Add: Indicates that you want to add a header variable. Can be used only to set new headers or to append a new entry of the same header name. • Clear: Indicates that you want to delete a runtime variable. Can be used to remove a header when the data is processed in the assembly flow. The default value is Set.	string
Set, Add, or Clear	Yes	Specifies the name of the variable that you want to set, add or clear, depending on the selected Action.	string
Type	Yes	Select the data type of the variable. Choose one of the following values: <ul style="list-style-type: none"> • any • string • number • boolean For all values other than any, the value is validated against the specified data type.	string
Value	Yes*	Allocates this value to the specified variable. Can be a literal value, or another variable. * Value is required only when Set or Add is specified as the action. For example, to <i>set</i> a named variable of billing-hostname to a literal value, you can specify the Value as acme.com . As another example, to <i>set</i> a named variable to the value of the Content-Type header in a request, you can specify the Value entry as \$(request.headers.content-type) . If the selected value of the Type field is boolean, select the Value check box to indicated a value of true . Note: You can only set single string elements. Values are retrieved as strings and therefore you cannot clone a complete nodeset.	string

6. Specify a version for the policy by clicking the Source icon , and completing the **version** section of the policy YAML. For example:

```
execute:
- set-variable:
```

```
version: 2.0.0
title: set-variable
...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

Example

For examples, see [set-variable](#).

DataPower Gateway (v5 compatible) only

Configuring the Set Variable policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the Set Variable policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the Set Variable policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see [Configuring the Set Variable policy for DataPower API Gateway](#). For more information about the different types of gateway, see [API Connect gateway types](#). For details on how to configure the policy in your OpenAPI source, see [set-variable](#).

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
For more information about working with the assembly editor for an API, see [The assembly editor](#).
4. Find the Set Variable policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Set Variable policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is set-variable .	string
Description	No	A description of the policy.	string
Action	Yes	Defines what action to apply on a runtime variable. Choose one of the following values: <ul style="list-style-type: none"> • Set: Indicates that you want to set a runtime variable to a string value. Can be used to set new headers or to override existing values. • Add: Indicates that you want to add a header variable. Can be used only to set new headers or to append a new entry of the same header name. • Clear: Indicates that you want to delete a runtime variable. Can be used to remove a header when the data is processed in the assembly flow. The default value is Set.	string
Set, Add, or Clear	Yes	Specifies the name of the variable that you want to set, add or clear, depending on the selected Action.	string
Type	Yes	Select the data type of the variable. Choose one of the following values: <ul style="list-style-type: none"> • string • number • boolean The value is validated against the specified data type.	string
Value	Yes*	Allocates this value to the specified variable. Can be a literal value, or another variable. * Value is required only when Set or Add is specified as the action. For example, to <i>set</i> a named variable of billing-hostname to a literal value, you can specify the Value as acme.com . As another example, to <i>set</i> a named variable to the value of the Content-Type header in a request, you can specify the Value entry as \$(request.headers.content-type) . If the selected value of the Type field is boolean, select the Value check box to indicated a value of true . Note: You can only set single string elements. Values are retrieved as strings and therefore you cannot clone a complete nodeset.	string

6. Specify a version for the policy by clicking the Source icon , and completing the **version** section of the policy YAML. For example:

```
execute:
- set-variable:
  version: 1.0.0
  title: set-variable
...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

Example

For examples, see [set-variable](#).

User Security

Use the User Security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [user-security](#).

About

When you define an assembly user security action, you can define the processing for identity-extraction, authentication, and authorization or you can selectively disable any of these this aspects of processing. When disabled, this processing aspect is skipped.

When identity-extraction is enabled, the following methods are supported.

- Use basic authentication, which requires no additional configuration.
- Use context variables. For this method, specify which variable contains the user name and password.
- Use a redirect. For this method, specify the URL fragment to redirect to, and the time allowed to process.
- Use an HTML login form. For this method, specify whether to use the default or custom form and the time allowed to submit the form. For a custom form, specify the location of the form and the TLS client profile to secure the connection to the remote server.

When authentication is enabled, the following methods are supported.

- Contact an LDAP server. For this method, specify which server to contact.
- Send a request to an authentication endpoint. For this method, specify the URL of the endpoint, the TLS client profile to secure the connection, the pattern to select which response header to add, and the response header that contains the authenticated credentials.

When authorization is enabled, the following methods are supported.

- Implicitly accept any previously authenticated users, which requires no additional configuration.
- Use an HTML authorization form. For this method, specify whether to use the default or custom form and the time allowed to submit the form. For a custom form, specify the location of the form and the TLS client profile to secure the connection to the remote server.

You can attach this policy to the REST API flow.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. User Security policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is <code>user-security</code> .	string
Description	No	A description of the policy.	string
Factor ID	No	The identity that identifies the results of factor-authentication in the API context.	string

Property label	Required	Description	Data type
Extract Identity Settings	Yes	<p>Select the method that is used to extract the user credentials. The following options are available:</p> <p>Basic Use basic authentication; no additional configuration is required.</p> <p>Context Variable The credentials are provided by API Connect context variables; specify the following properties:</p> <ul style="list-style-type: none"> • Username content variable: the context variable that is used to obtain the user name. • password context variable: the context variable that is used to obtain the password. <p>HTML Form Use forms based identity-extraction. Select whether to use the default form or a custom form. For a custom form, specify the following properties:</p> <ul style="list-style-type: none"> • Custom form endpoint: the location of the form. • Custom form TLS profile: the TLS client profile that is used to secure the connection to the remote server. <p>In the HTML form time limit field, specify the time allowed to submit the form.</p> <p>Redirect Use a redirect for identity-extraction; specify the following properties:</p> <ul style="list-style-type: none"> • Redirect URL: the URL fragment to which to redirect the request to obtain user credentials. • Redirect time limit: the time allowed for the transaction to complete. <p>Disabled Identity-extraction is disabled; this aspect of processing is skipped.</p> <p>Select Stop on error to halt assembly processing in the event of identity-extraction failure.</p>	string
Authenticate User Settings	Yes	<p>Select the authentication method. The following options are available:</p> <p>Authentication URL The credentials are authenticated by an external endpoint; specify the following properties:</p> <ul style="list-style-type: none"> • Authentication URL: the URL of the authentication endpoint. • Authentication TLS profile: the TLS client profile that is used to secure the connection to the authentication endpoint. • Authentication response header pattern: the pattern that is used to select which response headers to add to the API context. • Authentication response header credential: the response header that contains the authenticated user credentials. <p>LDAP The credentials are authenticated by an LDAP user registry; from the LDAP registry list, select the required registry.</p> <p>Disabled Authentication is disabled; this aspect of processing is skipped.</p> <p>Select Stop on error to halt assembly processing in the event of authentication failure.</p>	string
Authorize User Settings	Yes	<p>Select the authorization method. The following options are available:</p> <p>authenticated Implicitly accept any previously authenticated users; no additional configuration is required.</p> <p>HTML Form The user provides authorization through an HTML form. Select whether to use the default form or a custom form. For a custom form, specify the following properties:</p> <ul style="list-style-type: none"> • Custom form endpoint: the location of the form. • Custom form TLS profile: the TLS client profile that is used to secure the connection to the remote server. <p>In the Dynamic table entries field, enter the name of a context variable that specifies the scopes that are to be added automatically to the authorization consent form.</p> <p>In the HTML form time limit field, specify the time allowed to submit the form.</p> <p>Disabled Authorization is disabled; this aspect of processing is skipped.</p> <p>Select Stop on error to halt assembly processing in the event of authorization failure.</p>	string

Validate - DataPower API Gateway

Use the Validate policy to validate the payload in an assembly flow against a schema.

Gateway support

Note: This page describes the Validate policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see [Validate - DataPower Gateway \(v5 compatible\)](#).

For information on the different types of gateway, see [API Connect gateway types](#).

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0
	2.1.0 (DataPower API Gateway Version 10.0.1.0 or later)
	2.2.0 (DataPower API Gateway Version 10.0.2.0 or later)
	2.3.0 (DataPower API Gateway Version 10.0.2.0 or later)
	2.4.0 (DataPower API Gateway Version 10.0.4.0 or later)
	2.5.0 (DataPower API Gateway Version 10.5.0.0 or later)
	2.6.0 (DataPower API Gateway Version 10.5.0.2 or later)
	2.7.0 (DataPower API Gateway Version 10.5.0.3 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [validate - DataPower API Gateway](#).

About

Position this policy where required in the assembly flow as follows:

- To validate the original input, position a Validate policy at the start of your flow.
- To validate an intermediate response that is returned from other invoke actions or tasks, position a Validate policy after those actions or tasks.
- To validate the response that is returned to the client application, position a Validate policy after the task that collates the response.

Note: With the DataPower API Gateway, the input to the Validate policy must be parsed data. One way to produce parsed data is to use a [Parse](#) policy before a Validate policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Validate policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is validate .	string
Description	No	A description of the policy.	string
Input	No	Specifies the name of a variable in the API context. The content of the body field of the variable, which is represented by variable_name.body , is the input data to validate. By default, the variable name is message .	string
Output	No	Specifies the name of a variable in the API context. <ul style="list-style-type: none"> • If the validation passes, the body field of the output variable, which is represented by variable_name.body, stores the output of the assembly validate action. • If the schema to validate is a JSON schema, the validation also adds any default values that are missing from the payload. • If the validation fails, no output is stored. • If an output variable is not specified, the results of the assembly validate action are not saved. 	string

Property label	Required	Description	Data type
Validate against	Yes	<p>Specifies the schema to be used for validating the payload. Select one of the following values:</p> <ul style="list-style-type: none"> definition: Select this value if you want to use a previously defined schema to validate the payload that is returned from other invoke actions or tasks in the assembly flow. From the Definition Object list, select the required schema. For information on defining a schema for an OpenAPI 2.0 API definition, see Defining schemas for an API. For information on defining a schema for an OpenAPI 3.0 API definition, see Defining schema components. URL: the schema is identified by a URL location. <ul style="list-style-type: none"> In the JSON Schema URL field, enter the URL of the JSON schema to be used for validating a JSON payload. From the XML Validation Mode list, select how XML validation is to be performed: <ul style="list-style-type: none"> None: no XML payload validation is required. xsd: an XML schema will be used to validate an XML payload. In the XML Schema URL field, enter the URL of the XML schema. wsdl: a WSDL schema will be used to validate a SOAP payload. In the WSDL URL field, enter the URL of the WSDL schema. soap-body: validate the body of a SOAP message against the XML schema only. <p>Note: The following limitations apply to schemas used for JSON validation, which include JSON schemas and OpenAPI documents that are used as schemas for validation. Exceeding these limits can impact compilation performance and is not supported.</p> <ul style="list-style-type: none"> Maximum of 6,500 lines. Each key and each item in an array count as a line. Maximum recursion depth of 250. Maximum of 3,000 items in enum lists. WSDL: (available with a SOAP service based API only) use the XML schema in the WSDL file associated with the API operation or the API path. body-param: validate the request input against the schema definition that is specified in the TYPE field for the request parameter for this operation. For information about how to create a request parameter, see Defining parameters for an operation. response-param: validate the response to be returned to the client application, against the schema definition that is specified in the SCHEMA field for the response parameter for this operation. For information about how to create a response parameter, see Defining responses for an operation. GraphQL: (available for a GraphQL proxy API only) validate the payload against the GraphQL schema that has been imported into the GraphQL proxy API. In addition, either the GraphQL query or response, depending on the input, is analyzed against the GraphQL schema to calculate the cost, and the result is placed in the API context. For more information on GraphQL proxy APIs, see Creating a GraphQL proxy API and GraphQL context variables. 	string
XSLT version	No	The XSLT processor version. The default value is XSLT10.	string
Strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
Profile rule	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
Debug rule	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
Streaming rule	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
Attempt streaming rule	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
Minimum output escaping rule	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
Maximum stack size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer
WS-I Basic Profile validation	No	<p>The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn.</p> <p>Ignore Disables conformance checking.</p> <p>Warn Logs warnings for violations.</p> <p>Fail Forces conformance. Fails if the file contains any violation.</p>	string

Property label	Required	Description	Data type
Validate message body	No	The validation behavior for the <code>soap:Body</code> . The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message headers	No	The validation behavior for the <code>soap:Header</code> . The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message fault details	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Require wrappers on fault details specified by type	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
Specifically allow <code>xsi:type='SOAP-ENC:Array'</code> rule	No	Whether to allow the schema to accept most uses of elements with <code>xsi:type='SOAP-ENC:Array'</code> consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the <code>xsi:type</code> attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, <code>xsi:type</code> is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from <code>SOAP-ENC:Array</code> . The opposite is the normal allowable case. By default, elements with <code>xsi:type='SOAP-ENC:Array'</code> are not accepted.	boolean
Validate SOAP 1.1 encoding rule	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as <code>@id</code> and <code>@href</code> are allowed even if they are not allowed by the schema, and <code>@href</code> values are checked to ensure that they have a corresponding <code>@id</code> element. By default, the extra validation is not performed.	boolean
Wildcards ignore <code>xsi:type</code> rule	No	Whether <code>xs:any</code> elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an <code>xsi:type</code> attribute on it. This option ignores those <code>xsi:type</code> attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, <code>xsi:type</code> attributes are not ignored.	boolean
Strict SOAP envelope version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
Debug XACML policy	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean
Accept MTOM/XOP optimized messages	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an <code>xop:Include</code> reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. <ul style="list-style-type: none"> When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as <code>xs:base64Binary</code> or <code>xs:string</code>, but the message contains an <code>xop:Include</code> element instead. When enabled, an <code>xop:Include</code> element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The <code>xop:Include</code> element itself will be validated according to the built-in schema in <code>store:///schemas/xop.xsd</code>. 	boolean

For examples, see [validate - DataPower API Gateway](#).

Related tasks

- [Creating a new REST OpenAPI definition](#)

DataPower Gateway (v5 compatible)

Validate - DataPower Gateway (v5 compatible)

Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.

Gateway support

Note: This topic describes the Validate policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see [Validate - DataPower API Gateway](#).

For information on the different types of gateway, see [API Connect gateway types](#).

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [validate - DataPower Gateway \(v5 compatible\)](#).

Restriction:

- The schema that represents the XML can reference only one XML namespace.
- The schema cannot reference polymorphic XML elements.
- The validation works on the `message.body` variable and not any other output/context variable. If the invoke policy contains a configured response object variable, then `message.body` is not set, and validate is not able to act.
- If you use the `multipleOf` keyword in a schema definition for the API then, due to rounding behavior, the specified value must satisfy the following conditions, otherwise the validation fails when the API is called:
 - The value must not be less than 0.0000009999999999999999848869.
 - If the value is greater than 1, the amount before the decimal point must not be greater than 999999999999999934463.

About

You can attach this policy to the following API flow:

- REST

Position this policy where required in the assembly flow as follows:

- To validate the original input, position a Validate policy at the start of your flow.
- To validate an intermediate response that is returned from other invoke actions or tasks, position a Validate policy after those actions or tasks.
- To validate the response that is returned to the client application, position a Validate policy after the task that collates the response.

You can apply a different OpenAPI schema definition to each Validate policy either by choosing from the set of schema definitions that is specified at the API level, or the schema definition at the operation level.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Validate policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is <code>validate</code> .	string
Description	No	A description of the policy.	string
Definition	Yes	Specifies the schema definition to be used for validating the payload. Valid values: <ul style="list-style-type: none"> • <code>request</code>: Select this value to validate the request input against the schema definition that is specified in the TYPE field for the request parameter for this operation. For information about how to create a request parameter, see Configuring an operation. • <code>response</code>: Select this value to validate the response to be returned to the client application, against the schema definition that is specified in the SCHEMA field for the response parameter for this operation. For information about how to create a response parameter, see Configuring an operation. • <code>#/definitions/definition_name</code>: Select this value for a previously defined schema definition to be used to validate the payload that is returned from other invoke actions or tasks in the assembly flow. For information on defining a schema for an API definition, see Editing an API definition. 	string

Validate Username Token

Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0 1.1.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [validate-username-token](#).

About

A WS-Security UsernameToken enables a user identity to be passed securely over a multi-point message path. The Validate Username Token policy extracts the UsernameToken element from the request payload, authenticates the extracted username and password, and provides access to the protected resource based on the authentication result. The policy has two authentication methods: Lightweight Directory Access Protocol (LDAP) user registry, or Authentication URL.

The Validate Username Token policy supports both passwordText and passwordDigest types of password. When the authentication method is Authentication URL with a passwordDigest, a basic authentication header that contains a Base64 encoded username and passwordDigest is sent to the URL. In addition, a custom header named X-IBM-PasswordType is set with a value of digest. The following table shows the authentication process based on password type:

Table 2. Authentication URL process by password type

passwordText	passwordDigest
Authentication: Basic base64(username:password)	Authentication: Basic base64(username:passwordDigest) X-IBM-PasswordType: 'digest'

Position this policy where required in the assembly flow as follows:

- To validate the original input, position a Validate Username Token policy at the start of your flow.
- To validate an intermediate response that is returned from other invoke actions or tasks, position a Validate Username Token policy after those actions or tasks.
- To validate the response that is returned to the client application, position a Validate Username Token policy after the task that collates the response.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 3. Validate Username Token policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is validate-username-token .	string
Description	No	A description of the policy.	string
Authentication type (policy version 1.0.0 only)	Yes	The authentication type to use to validate the UsernameToken. Valid values: <ul style="list-style-type: none"> • Authentication URL: Select this value to validate the user credentials against an authentication URL. • LDAP registry: Select this value to validate the user credentials against an LDAP user registry. The default value is: Authentication URL .	string
Authentication URL (policy version 1.0.0 only)	Yes	The authentication URL to use to validate the UsernameToken user credentials against. Note: This property is required only if Authentication type is set to Authentication URL .	string
TLS profile (policy version 1.0.0 only)	No	The TLS profile to use for the secure transmission of data to the authentication URL. Note: This property is available only if Authentication type is set to Authentication URL .	string
LDAP registry name (policy version 1.0.0 only)	Yes	The name of the LDAP user registry to validate the UsernameToken user credentials against. You can select a name from the drop-down list, or type a name manually. Note: This property is required only if Authentication type is set to LDAP registry .	string
User Registry Name (policy version 1.1.0 and later)	Yes	Select the LDAP or Authentication URL registry to use to validate the UsernameToken.	string
LDAP search attribute ¹	Yes	The name of the LDAP user password attribute. Note: This property is required only for an LDAP user registry.	string

Examples

The following example shows an LDAP user registry authentication:

```
- validate-usnametoken:  
  version: 1.0.0  
  title: "validate-usnametoken"  
  auth-type: "LDAP Registry"  
  ldap-registry: "wstest"  
  ldap-search-attribute: "userPassword"
```

The following example shows an Authentication URL definition:

```
- validate-usnametoken:  
  version: 1.0.0  
  title: "validate-usnametoken"  
  auth-type: "Authentication URL"  
  auth-url: "https://www.google.com"  
  tls-profile: "default-ssl-profile"
```

Errors

The policy returns an HTTP 200 status code when successful, and the input payload is copied to the output flow. For all failure types the policy returns an HTTP 500 status code, and the output contains the SOAP fault.

Tip: If there are authentication failures, try verifying the LDAP user registry configuration as follows:

- Ensure Search (DN) is set as the communication method.
- Ensure Authenticated Bind is set so that specific permissions are required to search the registry.
- Ensure the Admin DN and Password fields are correctly completed for the Distinguished Name (DN) of a user authorized to carry out searches in the LDAP directory.
- Ensure that a combination of Base DN, Prefix, and Suffix are set, such that they fully describe the user DN. For example:
 - For a user named: `cn=alice, dc=ibm, dc=com`

```
BaseDN: dc=ibm  
Prefix: cn=alice  
Suffix: dc=com
```

where the user DN is calculated as: Prefix + BaseDN + Suffix.

- [Creating an LDAP registry](#)
- [Authenticating by using your enterprise user registry](#)

¹ When authenticating with LDAP and passwordText, the policy uses the username and password as LDAP bind credentials. However, when authenticating with LDAP and passwordDigest, the digest itself cannot be used for authentication. Instead, an LDAP search for the username is performed by using the administrator's distinguished name (DN) and password, and an attribute corresponding to the contents of the ldap-search-attribute is retrieved. A hash of the contents of this attribute (along with the Nonce and Created attributes, as in the WS-Security UsernameToken profile specification) is then compared to the passwordDigest.

Websocket Upgrade

Use the Websocket Upgrade policy to process API requests and responses through a WebSocket connection.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

- [Configuring the Websocket Upgrade policy for DataPower API Gateway](#)
Follow these steps to configure the Websocket Upgrade policy for DataPower API Gateway in the assembly user interface.

Follow these steps to configure the Websocket Upgrade policy for DataPower Gateway (v5 compatible) in the assembly user interface.

API Gateway only

Configuring the Websocket Upgrade policy for DataPower API Gateway

Follow these steps to configure the Websocket Upgrade policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the Websocket Upgrade policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see [Configuring the Websocket Upgrade policy for DataPower Gateway \(v5 compatible\)](#). For more information about the different types of gateway, see [API Connect gateway types](#).

For information about how to configure the policy in your OpenAPI source, see [websocket-upgrade](#).

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
For more information about working with the assembly editor for an API, see [The assembly editor](#).
4. Find the Websocket Upgrade policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Websocket Upgrade policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is websocket-upgrade .	string
Description	No	A description of the policy.	string
URL	Yes	Specify the URL to be invoked.	string
TLS Profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is 60 .	integer
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code 301 Moved Permanently . If you select this check box, the invoke policy follows the URL redirection by making a further call to the URL specified in the Location header in the response. If you clear this check box, the invoke saves the 301 status code and the API call is considered to be complete. Note: The follow-redirect property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the invoke always follows the URL redirection; the proxy policy (not supported by the DataPower API Gateway) saves the 301 status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
Inject proxy headers	No	If you select this check box, the invoke policy injects the X-Forwarded-For , X-Forwarded-To , X-Forwarded-Host , and X-Forwarded-Proto headers to the request that is sent to the target URL. The check box is cleared by default.	boolean
Decode Request Params	No	If you select this check box, any request parameters that are referenced by a variable definition on the target URL of the invoke policy are URL-decoded. The check box is cleared by default.	boolean
QueryParam encode	No	If you select this check box, all "+" characters in the query parameter values of the target URL are encoded to %2F. The check box is cleared by default.	boolean
Header control	No	Specifies the headers in message.headers that you want to copy to the target URL. To prevent headers from being copied, complete the following steps: a. Select Blocklist. b. Click Add blocklist. c. In the empty field that is displayed, enter the header name. d. To add further headers, repeat the previous steps. To specify headers that you want to be copied, complete the following steps: a. Select Allowlist. b. Click Add allowlist. c. In the empty field that is displayed, enter the header name. d. To add further headers, repeat the previous steps. The values that you specify are in regular expression format. For example, to specify the Content-Type header, enter ^Content-Type\$ By default, Blocklist is selected, with no blocklist entries, meaning that all headers are copied.	string

Property label	Required	Description	Data type
Parameter control	No	<p>Specifies the parameters in the incoming request that you want to be copied to the target URL. To prevent parameters from being copied, complete the following steps:</p> <ol style="list-style-type: none"> Select Blocklist. Click Add blocklist. In the empty field that is displayed, enter the parameter name. To add further parameters, repeat the previous steps. <p>To specify parameters that you want to be copied, complete the following steps:</p> <ol style="list-style-type: none"> Select Allowlist. Click Add allowlist. In the empty field that is displayed, enter the parameter name. To add further parameters, repeat the previous steps. <p>The values that you specify are in regular expression format.</p> <p>For example, if the incoming request is</p> <pre>http://apigw/org/sandbox/petstore/base?petid=100&display=detailed</pre> <p>and you specify a white list entry of <code>^petid\$</code>, the target URL at run time will be</p> <pre>http://myhost/mypath?storeid=3&petid=100</pre> <p>By default, Allowlist is selected, with no allowlist entries, meaning that no parameters are copied.</p>	string
Request assembly	No	<p>The request processing assembly. For details on configuring an assembly in the execute section, see execute. For example:</p> <pre>request-assembly: execute . . policy assembly . .</pre>	object
Response assembly	No	<p>The response processing assembly. For details on configuring an assembly in the execute section, see execute. For example:</p> <pre>response-assembly: execute . . policy assembly . .</pre>	object

6. Specify a version for the policy by clicking the Source icon , and completing the **version** section of the policy YAML. For example:

```
execute:
- websocket-upgrade:
  version: 2.0.0
  title: websocket-upgrade
...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

DataPower Gateway (v5 compatible) only

Configuring the Websocket Upgrade policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the Websocket Upgrade policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the Websocket Upgrade policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see [Configuring the Websocket Upgrade policy for DataPower API Gateway](#). For more information about the different types of gateway, see [API Connect gateway types](#). For details on how to configure the policy in your OpenAPI source, see [websocket-upgrade](#).

Procedure

- In the navigation pane, click  Develop, then select the APIs tab. The Develop page opens.
- Click the title of the API that you want to work with, or create a new API.
- Select the Gateway tab, then click Policies in the navigation pane. For more information about working with the assembly editor for an API, see [The assembly editor](#).
- Find the Websocket Upgrade policy in the palette, and drag the policy onto your canvas.

5. Specify the following properties.

Table 1. Websocket Upgrade policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is websocket-upgrade .	string
Description	No	A description of the policy.	string
URL	Yes	Specify the URL to be invoked.	string
TLS Profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is 60 .	integer
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code 301 Moved Permanently . If you select this check box, the invoke policy follows the URL redirection by making a further call to the URL specified in the Location header in the response. If you clear this check box, the invoke saves the 301 status code and the API call is considered to be complete. Note: The follow-redirect property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the invoke always follows the URL redirection; the proxy policy (not supported by the DataPower API Gateway) saves the 301 status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
Inject proxy headers	No	If you select this check box, the invoke policy injects the X-Forwarded-For , X-Forwarded-To , X-Forwarded-Host , and X-Forwarded-Proto headers to the request that is sent to the target URL. The check box is cleared by default.	boolean
Decode Request Params	No	If you select this check box, any request parameters that are referenced by a variable definition on the target URL of the invoke policy are URL-decoded. The check box is cleared by default.	boolean
QueryParam encode	No	If you select this check box, all "+" characters in the query parameter values of the target URL are encoded to %2F. The check box is cleared by default.	boolean
Request assembly	No	The request processing assembly. For details on configuring an assembly in the execute section, see execute . For example: <pre>request-assembly: execute . . policy assembly . .</pre>	object
Response assembly	No	The response processing assembly. For details on configuring an assembly in the execute section, see execute . For example: <pre>response-assembly: execute . . policy assembly . .</pre>	object

6. Specify a version for the policy by clicking the Source icon , and completing the **version** section of the policy YAML. For example:

```
execute:
- websocket-upgrade:
  version: 1.0.0
  title: websocket-upgrade
...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

XML to JSON

Use the XML to JSON policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

The XML to JSON policy uses a simple convention, based on BadgerFish, to convert your API context payload from XML to JSON. The XML content is preserved, including the attributes and namespaces. No additional configuration is required. For more information about the BadgerFish convention, including some examples, see [BadgerFish](#).

Use the API Designer assembly view when you are creating your API definition to add a built-in policy to the flow.

The policy must be attached to the flow at the point at which you require the conversion to be performed. For example, if you need to convert an XML-formatted request into a JSON-formatted request, the policy must be attached to the request flow.

The policy reads input from the `message.body`, if that context exists, otherwise from the `request.body`, and then writes the output to the `message.body`.

Note: If you are using the DataPower API Gateway, the input to the XML to JSON policy must be parsed data. One way to produce parsed data is to use a [Parse](#) policy before an XML to JSON policy in your assembly flow, which provides explicit control of the parse action.

Examples

For example, the following simple XML object

```
<a>hello</a>
```

becomes

```
{ "a": { "$" : "hello" } }
```

The following XML object with an attribute

```
<a type="world">hello</a>
```

becomes

```
{ "a": { "$" : "hello", "@type" : "world" } }
```

For examples, see [xml-to-json](#).

- [Configuring the XML to JSON policy for DataPower API Gateway](#)
Follow these steps to configure the XML to JSON policy for DataPower API Gateway in the assembly user interface.
- [Configuring the XML to JSON policy for DataPower Gateway \(v5 compatible\)](#)
Follow these steps to configure the XML to JSON policy for DataPower Gateway (v5 compatible) in the assembly user interface.

Configuring the XML to JSON policy for DataPower API Gateway

Follow these steps to configure the XML to JSON policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the XML to JSON policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see [Configuring the Set Variable policy for DataPower Gateway \(v5 compatible\)](#). For more information about the different types of gateway, see [API Connect gateway types](#). This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [xml-to-json](#).

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
For more information about working with the assembly editor for an API, see [The assembly editor](#).
4. Find the XML to JSON policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. XML to JSON policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is <code>xml-to-json</code> .	string
Description	No	A description of the policy.	string
Input	No	The input message to convert. Specify the name of a variable in the API context. <code>variableName.body</code> , the message payload, represents the XML input to convert. The default value of the variable is <code>message</code> and <code>message.body</code> is the default input.	string
Output	No	The output message to store the conversion result. Specify the name of a variable in the API context. <code>variableName.body</code> represents the result of conversion from XML format to JSON format. When the specified input message is the default message, the default output is <code>message.body</code> . Otherwise, when the input message is the variable <code>my-message-variable</code> , for example, the default output is <code>my-message-variable.body</code> . The variable cannot be any read-only in the API context.	string
Conversion type	No	The conversion type that determines the target format of the output. The following options are available: <ul style="list-style-type: none"> • badgerFish: BadgerFish convention is used to determine the target conversion format of the output. • apicv5: apicv5 convention is used to determine the target conversion format of the output. 	string

6. Specify a version for the policy by clicking the Source icon `</>`, and completing the `version` section of the policy YAML. For example:

```
execute:
- xml-to-json:
  version: 2.0.0
  title: xml-to-json
...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

- Click Save.

Example

For example, the following simple XML object

```
<a>hello</a>
```

becomes

```
{ "a": { "$" : "hello" } }
```

The following XML object with an attribute

```
<a type="world">hello</a>
```

becomes

```
{ "a": { "$" : "hello", "@type" : "world" } }
```

For more examples, see [xml-to-json](#).

DataPower Gateway (v5 compatible) only

Configuring the XML to JSON policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the XML to JSON policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the XML to JSON policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see [Configuring the XML to JSON policy for DataPower API Gateway](#). For more information about the different types of gateway, see [API Connect gateway types](#). This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [xml-to-json](#).

Procedure

- In the navigation pane, click  Develop, then select the APIs tab.
The Develop page opens.
- Click the title of the API that you want to work with, or create a new API.
- Select the Gateway tab, then click Policies in the navigation pane.
For more information about working with the assembly editor for an API, see [The assembly editor](#).
- Find the XML to JSON policy in the palette, and drag the policy onto your canvas.
- Specify the following properties.

Table 1. XML to JSON policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is <code>xml-to-json</code> .	string
Description	No	A description of the policy.	string

- Specify a version for the policy by clicking the Source icon , and completing the `version` section of the policy YAML. For example:

```
execute:
- xml-to-json:
  version: 1.0.0
  title: xml-to-json
...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

- Click Save.

Example

For examples, see [xml-to-json](#).

XSLT

Use the XSLT policy to apply an XSLT transform to the payload of the API definition.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.4.0 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [xslt](#).

Note: If you are using the DataPower API Gateway, the input to the XSLT policy must be parsed data. One way to produce parsed data is to use a [Parse](#) policy before an XSLT policy in your assembly flow, which provides explicit control of the parse action.

For examples of the OpenAPI definitions of XSLT policies, see [XSLT policy examples](#).

For more examples of how to use XSLT to access and modify properties and context, see [Implementation code examples](#) and, if you are using the DataPower API Gateway, [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#).

Errors

The following error can be thrown while the policy is being executed:

- **TransformError** - a generic error that captures all errors that occur during the execution of the policy.
- [Configuring the XSLT policy for DataPower API Gateway](#)
Follow these steps to configure the XSLT policy for DataPower API Gateway in the assembly user interface.
- [Configuring the XSLT policy for DataPower Gateway \(v5 compatible\)](#)
Follow these steps to configure the XSLT policy for DataPower Gateway (v5 compatible) in the assembly user interface.
- [XSLT policy examples](#)
Examples of the OpenAPI definitions of XSLT policies.
- [Implementation code examples](#)
Example XSLT and GatewayScript code snippets.

Configuring the XSLT policy for DataPower API Gateway

Follow these steps to configure the XSLT policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the XSLT policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see [Configuring the XSLT policy for DataPower Gateway \(v5 compatible\)](#). For more information about the different types of gateway, see [API Connect gateway types](#).

For information about how to configure the policy in your OpenAPI source, see [xslt](#).

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
For more information about working with the assembly editor for an API, see [The assembly editor](#).
4. Find the XSLT policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. XSLT policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is xslt .	string
Description	No	A description of the policy.	string

Property label	Required	Description	Data type
Input	No	Indicates whether this XSLT input document uses the context current payload, or if there is no input. The check box is cleared by default, which indicates that there is no input.	boolean
Serialize output	No	If you select this option, the output tree that is generated by the XSLT policy is serialized. The content of <code>message.body</code> is updated with the serialized binary data rather than the XML tree. The check box is cleared by default, which indicates that the output tree is not serialized.	boolean
Source	Yes	The XSLT transform source to execute.	string
XSLT version	No	The XSLT processor version. The default value is XSLT10.	string
Strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
Profile rule	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
Debug rule	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
Streaming rule	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
Attempt streaming rule	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
Minimum output escaping rule	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
Maximum stack size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer
WS-I Basic Profile validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string
Validate message body	No	The validation behavior for the <code>soap:Body</code> . The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message headers	No	The validation behavior for the <code>soap:Header</code> . The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message fault details	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string

Property label	Required	Description	Data type
Require wrappers on fault details specified by type	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
Specifically allow xsi:type='SOAP-ENC:Array' rule	No	Whether to allow the schema to accept most uses of elements with <code>xsi:type='SOAP-ENC:Array'</code> consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the <code>xsi:type</code> attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, <code>xsi:type</code> is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from <code>SOAP-ENC:Array</code> . The opposite is the normal allowable case. By default, elements with <code>xsi:type='SOAP-ENC:Array'</code> are not accepted.	boolean
Validate SOAP 1.1 encoding rule	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
Wildcards ignore xsi:type rule	No	Whether <code>xs:any</code> elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an <code>xsi:type</code> attribute on it. This option ignores those <code>xsi:type</code> attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, <code>xsi:type</code> attributes are not ignored.	boolean
Strict SOAP envelope version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
Debug XACML policy	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean
Accept MTOM/XOP optimized messages	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an <code>xop:Include</code> reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. <ul style="list-style-type: none"> When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as <code>xs:base64Binary</code> or <code>xs:string</code>, but the message contains an <code>xop:Include</code> element instead. When enabled, an <code>xop:Include</code> element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The <code>xop:Include</code> element itself will be validated according to the built-in schema in <code>store:///schemas/xop.xsd</code>. 	boolean

6. Specify a version for the policy by clicking the Source icon , and completing the `version` section of the policy YAML. For example:

```
execute:
- xslt:
  version: 2.1.0
  title: xslt
...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

DataPower Gateway (v5 compatible) only

Configuring the XSLT policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the XSLT policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the XSLT policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see [Configuring the XSLT policy for DataPower API Gateway](#). For more information about the different types of gateway, see [API Connect gateway types](#). For details on how to configure the policy in your OpenAPI source, see [xslt](#).

Procedure

- In the navigation pane, click  Develop, then select the APIs tab. The Develop page opens.
- Click the title of the API that you want to work with, or create a new API.
- Select the Gateway tab, then click Policies in the navigation pane. For more information about working with the assembly editor for an API, see [The assembly editor](#).
- Find the XSLT policy in the palette, and drag the policy onto your canvas.
- Specify the following properties.

Table 1. XSLT policy properties

Property label	Required	Description	Data type
----------------	----------	-------------	-----------

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is <code>xslt</code> .	string
Description	No	A description of the policy.	string
Input	No	Indicates whether this XSLT input document uses the context current payload, or if there is no input. The check box is cleared by default, which indicates that there is no input.	boolean
Source	Yes	The XSLT transform source to execute.	string

6. Specify a version for the policy by clicking the Source icon , and completing the `version` section of the policy YAML. For example:

```
execute:
- xslt:
  version: 1.0.0
  title: xslt
  ...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

XSLT policy examples

Examples of the OpenAPI definitions of XSLT policies.

- [Simple example with no context current payload](#)
- [Concatenation and transformation](#)
- [Obtain query parameter values and refer to context variables](#)
- [Return DataPower object name associated with a client TLS profile](#)

Attention:

- The mechanisms described here for interacting with the API Connect context are intended for v5-compatible gateways and also to provide v5 compatibility for APIs created for the API Gateway. However, if you are writing an XSLT policy or user-defined policy for a new API Gateway API, use the mechanisms described in [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#) for better performance and long-term support. For API Gateway APIs, the v5-compatibility functions listed here are to be used for v5 migration only.
- The XML specification <https://www.w3.org/TR/xml/> does not specify a preferred order for XML namespace (XMLNS) attributes. Best practice is to not rely upon the sequence of XMLNS attributes if you write custom parsing code.

Simple example with no context current payload

The following is an example of where the XSLT input document does not use the context current payload (there is no input):

```
- xslt:
  title: example xslt
  source: |
    <xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
      <xsl:template match="/">
        <Hello>World!</Hello>
      </xsl:template>
    </xsl:stylesheet>
```

Concatenation and transformation

The following example shows a more complex XSLT transform source, where the stylesheet concatenates two input strings and transforms the third input string to the IP address of the client:

```
- xslt:
  title: xslt
  input: true
  source: |
    <?xml version="1.0" encoding="UTF-8"?>
    <xsl:stylesheet
      xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
      xmlns:xalan="http://xml.apache.org/xslt"
      xmlns:fn="http://www.w3.org/2005/xpath-functions"
      xmlns:dp="http://www.datapower.com/extensions"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xmlns:xs4xs="http://www.w3.org/2001/XMLSchema"
      xmlns:io="http://xformMessage"
      xmlns:map="http://xformMessage/xform"
      xmlns:msl="http://www.ibm.com/xmlmap"
      exclude-result-prefixes="fn dp dp map xalan msl"
      version="1.0">
    <xsl:output method="xml" encoding="UTF-8" indent="no"/>

    <!-- root wrapper template -->
    <xsl:template match="/">
      <msl:datamap>
        <xsl:choose>
          <xsl:when test="not(msl:datamap/dataObject[1]/@xsi:nil)">
            <xsl:element name="dataObject">
              <xsl:attribute name="xsi:type">
                <xsl:value-of select="'io:data'"/>
              </xsl:attribute>
```

```

        <xsl:call-template name="map:xform">
          <xsl:with-param name="data" select="msl:datamap/dataObject[1]"/>
        </xsl:call-template>
      </xsl:element>
    </xsl:when>
    <xsl:otherwise>
      <xsl:element name="dataObject">
        <xsl:attribute name="xsi:type">
          <xsl:value-of select="'io:data'"/>
        </xsl:attribute>
        <xsl:attribute name="xsi:nil">
          <xsl:text>true</xsl:text>
        </xsl:attribute>
      </xsl:element>
    </xsl:otherwise>
  </xsl:choose>
</msl:datamap>

    </NumberTwo>
  </xsl:if>
  <!-- a simple data mapping: "$data/NumberThree" (int) to "NumberThree" (int) -->
  <xsl:if test="$data/NumberThree">
    <NumberThree>
      <xsl:value-of select="$data/NumberThree"/>
    </NumberThree>
  </xsl:if>
</xsl:template>

```

```

<!-- ***** Utility Templates ***** -->
<!-- copy the namespace declarations from the source to the target -->
<xsl:template name="copyNamespaceDeclarations">
  <xsl:param name="root"/>
  <xsl:for-each select="$root/namespace::*[not(name() = '')]">
    <xsl:copy/>
  </xsl:for-each>
</xsl:template>
</xsl:stylesheet>

```

Obtain query parameter values and refer to context variables

The following example shows a complete OpenAPI source file. The API includes an XSLT policy that obtains a query parameter value in XSLT, and also uses the `getvariable` method to retrieve the value of the context variable `request.headers.user-agent`.

```

swagger: '2.0'

  { $tlsClientProfile }"/>
</xsl:template>

</xsl:stylesheet>

```

For more examples of how to use XSLT to access and modify properties and context, see [Implementation code examples](#) and, if you are using the DataPower® API Gateway, [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#).

Implementation code examples

Example XSLT and GatewayScript code snippets.

Note: If you are using GatewayScript, you must include one or other of the following commands depending on your gateway type:

```

DataPower Gateway (v5 compatible) var apic = require('./apim.custom.js');
API Gateway var apic = require('apim');

```

where *apic* is the common name used for the GatewayScript examples in this topic. However, *apic* could be any given name of your choice, for example you could use:

```
var apim = require('./apim.custom.js');
```

and then you would start your calls with `apim`.

- [Access to input properties code snippet](#)
- [Access to runtime context code snippet](#)
- [Access to input payload code snippet](#)
- [Access to HTTP headers code snippet](#)
- [Modify the payload code snippet](#)
- [Configure error information code snippet](#)
- [Accessing the caught exception in a catch block](#)
- [Set variables code snippet](#)

Access to input properties code snippet

The following code block shows an example of how to access the input properties by using the XSLT `policyProperties()` function. The example defines a property that is named `a_property`, which is declared as an integer value, but is retrieved in XSLT as text.

```

<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible) <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/>
  API Gateway <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">
    <xsl:variable name="p" select="apim:policyProperties()" />
    <xsl:message>
      The value of my input property is
      <xsl:value-of select="$p/a_property" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>

```

If you are using GatewayScript, call the following function:

```
apic.getPolicyProperty (propertyName)
```

where *propertyName* is the name of the input property that you want to access. If the input property name is blank, the action will return all input properties.

Access to runtime context code snippet

The following code block shows an example of how to access the runtime context by using the XSLT `getContext()` function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
    href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
  />

  <xsl:include
    href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">
    <xsl:variable name="client-id" select="apim:getContext('client.app.id') " />
    <xsl:message>
      The calling application is
      <xsl:value-of select="$client-id" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, call the following function:

```
apic.getContext (varName)
```

where *varName* is the name of the context variable that you want to access.

For a complete list of context variables, see [API Gateway context variables](#). If you are using the DataPower® API Gateway, see also [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#).

Access to input payload code snippet

The following code block shows an example of how to access the input payload by using the XSLT `payloadRead()` function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
    href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
  />

  <xsl:include
    href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">
    <xsl:variable name="input" select="apim:payloadRead() " />
    <xsl:message>
      The input payload is
      <xsl:copy-of select="$input" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, call the following function:

```
apic.readInput (callback)
```

A callback is required because the actual payload read is asynchronous. The callback method is called when the payload is ready.

This function returns an XML node-set that contains the payload of the request. If the payload is in JSON format, a JSONx node-set is returned that can then be manipulated within an XSLT or GatewayScript stylesheet. If the payload is not in JSON or XML format, the node-set that is returned is empty.

The following example shows how to use the `payloadType()` function to determine what type of payload (XML or JSONx) will be returned by the XSLT `payloadRead()` function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
```

```

<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/>
<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

<xsl:template match="/">
  <xsl:variable name="payloadType" select="apim:payloadType()" />
  <xsl:message>
    <xsl:text>Payload type is [</xsl:text>
    <xsl:value-of select="$payloadType" />
    <xsl:text>]</xsl:text>
  </xsl:message>
</xsl:template>

</xsl:stylesheet>

```

Access to HTTP headers code snippet

The following code block shows an example of how to access the HTTP headers in XSLT by using the `getContext()` function.

```

<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/>
  <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">
    <xsl:variable name="content-type" select="apim:getContext('request.headers.content-type')" />
    <xsl:message>
      The request content type is
      <xsl:value-of select="$content-type" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>

```

If you are using GatewayScript, call the following function:

```
apic.getContext(request.headers.headerName)
```

where `headerName` maps to the name of the header you want to access.

Note: Access or modification of HTTP headers by using DataPower extensions, such as `dp:set-request-header`, is not advisable, as such actions might yield unexpected results when the policy is combined with other policies and assembly steps.

Modify the payload code snippet

The output from a user-defined policy must be an XML node-set, which represents an XML or SOAP message, or a JSON message by using JSONx. The following code block shows an example of how to modify the payload in XSLT. To assist the API Gateway policy framework to accept the new or transformed message, call the `apim-output` template, as shown in the following example.

```

<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:apim="http://www.ibm.com/apimanagement"
  xmlns:jsonx="http://www.ibm.com/xmlns/prod/2009/jsonx">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/>
  <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">
    <!-- Creates a JSON document (empty object is for simplicity) -->
    <jsonx:object>
    </jsonx:object>

    <!-- Indicates the media type of the output being produced -->

    <xsl:call-template name="apim:output">
      <xsl:with-param name="mediaType" select="'application/json'" />
    </xsl:call-template>
  </xsl:template>

</xsl:stylesheet>

```

where `mediaType`:

- `'application/json'` is when the output is written in JSONx format.
- `'application/xml'` is when the output is written in XML format.

If you are using GatewayScript, call the following function:

```
apic.output(mediaType)
```

where `mediaType` is:

- `application/json` is when the output is written in JSONx format.
- `application/xml` is when the output is written in XML format.

Specifying the media type allows the next steps in the assembly flow to understand how to process the new payload.

Tip: The output from a user-defined policy must be XML or JSONx. JSONx is an IBM standard format to represent JSON as XML. One way to convert output GatewayScript JSON data into JSONx, is to add a **Convert Query Params to XML** action to follow the GatewayScript action within the same policy rule. The **Convert Query Params to**

XML action must have an **Input Conversion** with the **Default**

Encoding set to **JSON**. The output from the GatewayScript action must be the input for the **Convert Query Params to XML** action for JSONx to be produced.

Configure error information code snippet

The following XSLT code block shows an example of how to configure the policy implementation to produce error information by calling the `apim-error` template.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:apim="http://www.ibm.com/apimanagement">

  <!-- Contains the APIM functions -->
  <xsl:import
    href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xml"
  />

  <xsl:include
    href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xml" />

  <!-- Indicates this policy has a failure and provides
    additional information for the client application -->
  <xsl:template match="/">
    <xsl:call-template name="apim:error">
      <xsl:with-param name="httpCode" select="'401'" />
      <xsl:with-param name="httpReasonPhrase" select="'Unauthorized'" />
      <xsl:with-param name="errorMessage" select="'Please select a Plan'" />
    </xsl:call-template>
  </xsl:template>
</xsl:stylesheet>
```

where:

- `httpCode` is the code of the required error message.
- `httpReasonPhrase` is the reason for the error.
- `errorMessage` is the suggested action for the user.

If you are using GatewayScript, call the following function:

```
apic.error(name, httpCode, httpReasonPhrase, message)
```

where:

- `name` is the name of the error.
- `httpCode` is the code of the required error message.
- `httpReasonPhrase` is the reason for the error.
- `message` is the suggested action for the user.

Accessing the caught exception in a catch block

The following XSLT code block shows an example of how, in the `catch` block of an API assembly, you can obtain the details of the current caught exception. A possible use would be to create a custom error response using the details of the caught exception.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:apim="http://www.ibm.com/apimanagement"
  xmlns:apigw="http://www.ibm.com/xmlns/datapower/2017/11/apigateway"
  extension-element-prefixes="dp">
  <xsl:exclude-result-prefixes="dp apim">
  <xsl:exclude-result-prefixes="dp apim apigw">

  <xsl:output method="xml" />
```

```

<!-- Contains the APIM functions -->
<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_local:isp_policy_apim.custom.xsl"
/>
<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_store:dp_apim.custom.xsl" />

<xsl:template match="/">
  <xsl:variable name="exception" select="apim:getError()" />
  <xsl:variable name="exception" select="apigw:get-error()" />
  <!-- output desired error message based on the exception -->
  <myError>
    <errorReason><xsl:value-of select="$exception/error/message" /></errorReason>
  </myError>

  <!-- Propagate the HTTP status code and reason phrase from the exception -->
  <xsl:call-template name="apim:setVariable">
    <xsl:with-param name="varName" select="'message.status.code'"/>
    <xsl:with-param name="value" select="$exception/error/status/code"/>
    <xsl:with-param name="action" select="'Set'"/>
  </xsl:call-template>

  <xsl:call-template name="apim:setVariable">
    <xsl:with-param name="varName" select="'message.status.reason'"/>
    <xsl:with-param name="value" select="$exception/error/status/reason"/>
    <xsl:with-param name="action" select="'Set'"/>
  </xsl:call-template>
</xsl:template>
</xsl:stylesheet>

```

The `apim:getError()` and `apigw:get-error()` functions return an XML node set; for example:

```

<?xml version="1.0" encoding="UTF-8"?>
<error>
  <name>RuntimeException</name>
  <message>This is a thrown Runtime Error</message>
  <policyTitle>Throw Runtime Error</policyTitle>
  <status>
    <code>500</code>
    <reason>Internal Server Error</reason>
  </status>
</error>

```

If you are using GatewayScript, call the following function:

```
apim.getError()
```

which returns a JSON object; for example:

```

{
  "name": "OperationError",
  "message": "This is a thrown Operation Error",
  "policyTitle": "Throw Operation Error",
  "status": {
    "code": "500",
    "reason": "Internal Server Error"
  }
}

```

Set variables code snippet

The following XSLT code block shows an example of how to set a runtime variable to a specified string value by calling the `setVariable` template.

```

<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">
  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_local:isp_policy_apim.custom.xsl"
/>
  <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_store:dp_apim.custom.xsl" />

  <xsl:template match="/">
    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'serviceEndpoint'"/>
      <xsl:with-param name="value" select="'https://endpoint.host.com/data'"/>
    </xsl:call-template>
    <xsl:message>
      <xsl:text>Variable [ </xsl:text>
      <xsl:value-of select="'serviceEndpoint'"/>
      <xsl:text>] set to [ </xsl:text>

```

```

    <xsl:value-of select="'https://endpoint.host.com/data'" />
    <xsl:text>]</xsl:text>
  </xsl:message>
</xsl:template>

```

```
</xsl:stylesheet>
```

where:

- **varName** is the name of the runtime variable that you want to set a value to.
- **value** is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the **value** as `$(request.headers.content-type)`.

If you are using GatewayScript, call the following function:

```
apic.setvariable(varName, varValue, action)
```

where:

- **varName** is the name of the runtime variable that you want to set a value to, or that you want to add or clear.
- **varValue** is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the **varValue** as `request.headers.content-type`. This property is only required when **set** or **add** is specified as the action.
- **action** is the action that you want to apply to the variable. Valid options are:
 - **set**
 - **add**
 - **clear**

If no option is set, the default option of **set** is applied.

The following XSLT example shows how to retrieve the value of a runtime variable by using the `getVariable()` function.

```

<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagerment" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
    href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
  />
  <xsl:include
    href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">
    <xsl:variable name="varValue" select="apim:getVariable('serviceEndpoint')" />
    <xsl:message>
      <xsl:text>Variable [
    <xsl:value-of select="'serviceEndpoint'" />
    <xsl:text>] = [
    <xsl:value-of select="$varValue" />
    <xsl:text>]</xsl:text>
    </xsl:message>
  </xsl:template>
</xsl:stylesheet>

```

where

- **varValue** is the name of the runtime variable that you want to retrieve a value for.

If you are using GatewayScript, call the following function:

```
apic.getvariable(varName)
```

where **varName** is the name of the runtime variable that you want to retrieve a value for.

Logic Constructs

IBM® API Connect includes a number of logic constructs that you can use to apply preconfigured logic to an assembly to control the flow of data through your assembly when the API is called.

Logic constructs are configured in the context of an API. You can use the API Designer assembly editor to add a logic construct to an API and to configure the properties for that construct.

The logic constructs are described in the following subtopics:

- **if**
Use the if construct to apply a section of the assembly when a condition is fulfilled.
- **operation-switch**
Use the operation-switch component to apply a section of the assembly to a specific operation.
- **switch**
Use the switch component to execute one of a number of sections of the assembly based on which specified condition is fulfilled.

- [throw](#)
Use the throw policy to throw an error when it is reached during the execution of an assembly flow.

Related concepts

- [The assembly editor](#)

if

Use the if construct to apply a section of the assembly when a condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by switch	

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [if](#).

An if construct provides a way to branch an API's assembly when a specified condition is fulfilled. Each if construct contains a section of the assembly that is only executed when the script within the construct returns a **true** value.

When using the assemble view's property sheet, use the Condition field to write your condition that returns **true** or **false**.

If you want one or more policies or constructs to be executed when the condition of the if construct is fulfilled, drag the new policy or construct onto one of the dashed boxes that are displayed within the if construct. Constructs and policies included in the if construct are part of the case that is executed when the condition of the if construct is returned as true.

For information about the OpenAPI implementation of an if construct, see [if](#).

In the Condition field, use the form `apim.getvariable('context.location.variable')` to reference your variables, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable.

Construct property details

You can configure a construct's properties in the property sheet in the assemble view.

Table 2. The properties of an if construct

Property	Required	Description
Title	No	A custom title for your construct when it is displayed in the canvas. If a title is not specified, if is used by default.
Description	No	A description of your construct, it is not displayed on the canvas.
Condition	Yes	Use GatewayScript to provide conditions. A list of context variables that you can use to generate conditions can be found in API Connect context variables .

operation-switch

Use the operation-switch component to apply a section of the assembly to a specific operation.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [operation-switch](#).

An operation-switch component provides a way to branch an API's assembly depending on the operation that is called. For each case, a separate piece of the assembly is applied to the operations that belong to the case.

When using the assemble view's property sheet, click the Case field to view suggested operations. Type in the Case field to refine the list of suggested operations.

Each case behaves as an assembly. To add components to a case, drag the component from the palette to the area included in the operation-switch component. Dashed boxes are displayed where the component can be included in the case.

For information about the OpenAPI implementation of an operation-switch component, see [operation-switch](#).

Restriction: Nesting an operation-switch component inside an if or switch construct, or another operation-switch component, is **not** supported.

Component property details

You can configure a component's properties in the property sheet in the assemble view.

Table 2. The properties of an operation-switch component

Property	Required	Description
Title	No	A custom title for your component when it is displayed in the canvas. If a title is not specified, <code>operation-switch</code> is used by default.
Description	No	A description of your component, it is not displayed on the canvas.
Case	Yes	Each case includes one or more operations to which the branch provided by the operation switch applies.

switch

Use the switch component to execute one of a number of sections of the assembly based on which specified condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [switch](#).

A switch construct provides a way to branch an assembly based on multiple conditions. Each switch component contains multiple cases, each corresponding to a section of the assembly that is only executed when the condition or operation specified by the case is met or used. Additionally, an otherwise case executes when no other case is fulfilled.

Add new cases by clicking + Case and add an "otherwise" case by clicking + Otherwise.

If multiple cases are fulfilled, the highest priority case will be executed. Change the priority of cases by clicking the Move up ↑ and Move down ↓ icons.

To configure a case to be executed if a specific operation is called, use the search operations field and select your operation from the list. You can refine the results of the search by typing in the search operations field.

To configure a case to be executed based on a GatewayScript condition, click edit condition and enter your script in the "Condition editor" window. When you have supplied a script, you can edit your script either in the Condition field or by clicking edit condition.

If you are using the DataPower Gateway (v5 compatible), you enter your condition as GatewayScript directly in a code area in the Condition editor. If you are using DataPower API Gateway, the Condition editor provides a script builder to help you construct your condition script; for more information, see [Using the switch policy condition editor](#).

To delete a case, click the Remove case icon .

If you want one or more policies or constructs to be executed when the condition of a case is fulfilled, drag the new policy or construct onto one of the dashed boxes that are displayed within the case's section of the switch construct.

Note: A switch case **must** contain at least one policy, otherwise the Gateway server returns an error.

Construct property details

You can configure a construct's properties in the property sheet in the assemble view.

Table 2. The properties of a switch construct

Property	Required	Description
Title	No	A custom title for your construct when it is displayed in the canvas. If a title is not specified, <code>switch</code> is used by default.
Description	No	A description of your construct, it is not displayed on the canvas.
case	Yes (one or more)	Specify one or more operations or write a script for a condition.  Use the Condition editor to construct your condition script. See Using the switch policy condition editor .  Use GatewayScript to provide conditions. You can reference variables by using the form <code>apim.getvariable('context.location.variable')</code> , where <code>context</code> is the context that you want to reference, <code>location</code> is the location of the variable within that context, and <code>variable</code> is the name of the variable. A list of context variables that you can use to generate conditions can be found in API Connect context variables .
otherwise	No	Add an otherwise case if you want to execute a section of the assembly when no other cases are fulfilled.

- [Using the switch policy condition editor](#)

The switch policy condition editor provides a user interface to help you build the conditions for the `case` clauses in a switch policy.

Using the switch policy condition editor

The switch policy condition editor provides a user interface to help you build the conditions for the `case` clauses in a switch policy.

You build a condition script by using the Add Group and Add Condition options, together with operator selections, and pre-supplied function selections. The Output field shows the resultant condition script, and updates dynamically as you build your condition.

Adding conditions

When you open the policy condition editor, an initial condition is pre-supplied ready for you to configure.

Use the drop-down list to select the function that you want to begin your condition.

The following JSONata functions are supported:

- Aggregation functions:
 - `$average(array)`
 - `$max(array)`
 - `$min(array)`
 - `$sum(array)`
- Array functions:
 - `$append(array1, array2)`
 - `$count(array)`
 - `$reverse(array)`
 - `$sort(array [, function])`
 - `$zip(array1, ...)`
- Boolean functions:
 - `$boolean(arg)`
 - `$exists(arg)`
 - `$not(arg)`
- Numeric functions:
 - `$abs(number)`
 - `$ceil(number)`
 - `$floor(number)`
 - `$formatBase(number [, radix])`
 - `$number(arg)`
 - `$power(base, exponent)`
 - `$round(number [, precision])`
 - `$sqrt(number)`
- Object functions:
 - `$keys(object)`
 - `$lookup(object, key)`
 - `$merge(array<object>)`
 - `$spread(object)`
 - `$type(value)`
In addition to the standard values returned by `$type()`, the API gateway implementation of `$type()` can return the following values: `binary`, `empty`, `graphql`, `stream`, or `xml`.
- String functions:
 - `$contains(str, pattern)`
 - `$join(array[, separator])`
 - `$length(str)`
 - `$lowercase(str)`
 - `$match(str, pattern [, limit])`
 - `$pad(str, width [, char])`
 - `$replace(str, pattern, replacement [, limit])`
 - `$split(str, separator [, limit])`
 - `$string(arg)`
 - `$substring(str, start[, length])`
 - `$substringAfter(str, chars)`
 - `$substringBefore(str, chars)`
 - `$trim(str)`
 - `$uppercase(str)`
- You can use the following functional extensions to standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description
<code>\$header(name)</code>	<code>message.headers.name</code>	Message header
<code>\$httpVerb()</code>	<code>request.verb</code>	HTTP method of the request
<code>\$operationID()</code>	<code>api.operation.id</code>	ID of the operation
<code>\$operationPath()</code>	<code>api.operation.path</code>	Path of the operation

Extension	Variable	Description
<code>\$queryParameter('name')</code>	<ul style="list-style-type: none"> <code>request.parameters.name.locations</code> The supported keyword is <code>query</code>. <code>request.parameters.name.values</code> 	Searches for the index of <code>query</code> in <code>request.parameters.name.locations</code> and returns <code>request.parameters.name.values[index]</code> , where <code>[index]</code> is the value for <code>query</code> in locations. Parameter values are not URL decoded.
<code>\$statusCode()</code>	<code>message.status.code</code>	Status code
<code>\$storageType([arg])</code>	<code>variable.body</code> You can specify any variable in the API context. When no variable is specified, the default variable <code>message.body</code> is used.	Storage type of the message. The supported values are <code>binary</code> , <code>empty</code> , <code>graphql</code> , <code>json</code> , <code>stream</code> , or <code>xml</code> .
<code>\$urlParameter('name')</code>	<ul style="list-style-type: none"> <code>request.parameters.name.locations</code> The supported keywords are <code>path</code> and <code>query</code> <code>request.parameters.name.values</code> 	Searches for the index of <code>path</code> and <code>query</code> in <code>request.parameters.name.locations</code> and returns a single array that contains both <code>path</code> and <code>query</code> values from <code>request.parameters.name.values</code> . When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values. <code>http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese</code> The <code>\$urlParameter('breed')</code> URL returns the following array of values. <code>[cats, adopt, Sphynx, Siamese]</code> In this example, the URL includes an API path that is configured as <code>/petstore/{breed}/{breed}</code> , where <code>breed</code> is configured to be a path parameter of the API path. As a result, <code>cats</code> and <code>adopt</code> are included in the output.
<code>\$xpath(path, xpathExpression)</code>	You can specify any writable variable in the API context. The <code>xpathExpression</code> must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. <code>\$xpath(\$, '//price')</code>

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
<code>\$gqlActiveOperation([graphql_message])</code>	<code>message.body</code>	Gets the active operation found in the specified GraphQL message. The <code>operationName</code> must be the same as the name of the active operation.
<code>\$gqlAlias([graphql_field_node])</code>	<code>message.body</code>	Gets the alias of a GraphQL field node.
<code>\$gqlFragments([graphql_message])</code>	<code>message.body</code>	Gets the fragments found in the specified GraphQL message.
<code>\$gqlName([graphql_node])</code>	<code>message.body</code>	Gets the node name. For operations, the node name is the <code>operationName</code> . For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the <code>operationName</code> of <code>message.body</code> is retrieved.
<code>\$gqlOperations([graphql_message])</code>	<code>message.body</code>	Gets the operations found in the specified GraphQL message.
<code>\$gqlType([graphql_node])</code>	<code>message.body</code>	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

- You can use the `&` (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- `/` (division)
- `%` (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- `query`
The entire GraphQL query including operations and fragments.

- **operationName**
For an anonymous operation, **operationName** can be empty.
- **~fragmentSpreadName**
- **on~typeCondition**
- **~~fragmentDefinitionName**

You can also use the following functional extensions to standard JSONata notation. Each extension corresponds to a part of the API context.

Extension	Variable	Description
<code>\$header (name)</code>	<code>message.headers.name</code>	Message header
<code>\$httpVerb ()</code>	<code>request.verb</code>	HTTP method of the request
<code>\$operationID ()</code>	<code>api.operation.id</code>	ID of the operation
<code>\$operationPath ()</code>	<code>api.operation.path</code>	Path of the operation
<code>\$queryParameter ('name')</code>	<ul style="list-style-type: none"> • <code>request.parameters.name.locations</code> • <code>request.parameters.name.values</code> 	Returns the value of a request query parameter given the parameter name. The function searches the <code>request.parameters.name.locations</code> array for the index position of the value <code>query</code> , and returns <code>request.parameters.name.values[index]</code> , where <code>index</code> is the index position. Parameter values are not URL decoded.
<code>\$statusCode ()</code>	<code>message.status.code</code>	Status code
<code>\$storageType ([arg])</code>	<p>variable.body You can specify any variable in the API context. When no variable is specified, the default variable <code>message.body</code> is used.</p> <ul style="list-style-type: none"> • <code>binary</code> • <code>json</code> • <code>stream</code> • <code>xml</code> 	Storage type of the message. The supported values are:
<code>\$urlParameter ('name')</code>	<ul style="list-style-type: none"> • <code>request.parameters.name.locations</code> • <code>request.parameters.name.values</code> 	<p>Given a request parameter name, returns the parameter values for all occurrences of that parameter as a path parameter or query parameter.</p> <p>The function searches the <code>request.parameters.name.locations</code> array for the index positions of the values <code>path</code> and <code>query</code>, and returns, in a single array, the <code>request.parameters.name.values[index]</code> values for all identified index positions. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded.</p> <p>For example, the following URL contains both path and query parameter values: <code>http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese</code></p> <p>The function call <code>\$urlParameter ('breed')</code> returns the following array of values: <code>[cats, adopt, Sphynx, Siamese]</code></p> <p>In this example, the URL includes an API path that is configured as <code>/petstore/{breed}/{breed}</code>, where <code>breed</code> is configured to be a path parameter of the API path. As a result, <code>cats</code> and <code>adopt</code> are included in the output.</p>
<code>\$xpath (path, xpathExpression)</code>	You can specify any writable variable in the API context. The <code>xpathExpression</code> must be a literal string.	Allows use of XPath expressions

After you select the function, additional fields are displayed, depending on the selected function, so that you can complete the condition. For example, if you select the function `$httpVerb ()`, a comparison operator selection list is displayed (= or !=), together with a list of HTTP verbs to select on the right hand side of the expression (`GET`, `PUT`, `POST`, `DELETE`, `HEAD`, `OPTIONS`, or `PATCH`).

If you select NOT, your condition is negated with a `$not` function.

To add further conditions, click Add Condition; you then select whether to insert an `and` or an `or` operator between this condition and the preceding one.

To group two or more conditions inside parentheses, click Add Group, then add your conditions to the group; you then select whether to insert an `and` or an `or` operator between this group and the preceding condition or group.

To write your own condition from scratch, select Custom, then enter your script in the field provided.

Example

To build the following condition:

```
($statusCode () != 200 and ($httpVerb () = 'GET' or $httpVerb () = 'PUT'))
```

complete these steps in the condition editor:

1. Select `$statusCode ()`, select != for the comparison operator, and enter `200` in the field on the right hand side of the condition.
2. Click Add Group.
3. In the new group sub pane that is displayed, click Add Condition.
4. Select `httpVerb ()`, leave the comparison operator as =, and select `GET` on the right hand side of the condition.
5. Click Add Condition in the group sub pane again.
6. Select `httpVerb ()`, leave the comparison operator as =, and select `PUT` on the right hand side of the condition.
7. For the comparison operator between the two conditions, select `or`.

Simple condition statements

The following examples show conditions that use a single function.

This example uses the `$httpVerb()` extension to specify the HTTP method of the request.

```
$httpVerb()="GET"
```

This example uses the `$operationPath()` extension to specify the path of the operation.

```
$operationPath()="/base/path-2"
```

This example uses the `$operationID()` extension to specify the operation ID.

```
$operationID()="test-gatewayscript-GET"
```

This example uses the `$statusCode()` extension to specify the message status code.

```
$statusCode()=200
```

This example uses the `$header(name)` extension to specify the content type of the message header.

```
$header("Content-Type")="application/json"
```

Combining conditions with logical operators

You can use `and` and `or` operators to combine multiple functions in a single condition.

This example specifies an HTTP GET request and an API operation path equal to `test-gatewayscript-GET`.

```
$httpVerb()="GET" and $operationPath()="test-gatewayscript-GET"
```

This example specifies either a `POST` or `PUT` request.

```
$httpVerb()="POST" or $httpVerb()="PUT"
```

This example specifies an API operation ID equal to `test-gatewayscript_POST` and a message status code equal to `200`, or an API operation ID equal to `test-gatewayscript-GET` and a message status code equal to `500`.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) or ($operationID()="test-gatewayscript-GET" and $statusCode()=500)
```

This example specifies an API operation ID equal to `test-gatewayscript-POST` and a message status code equal to `200` with an API operation path equal to `/base/path-2`.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) and $operationPath()="/base/path-2"
```

This example specifies a message header content type equal to `text/plain` and a message header length equal to `300`, or a message status code equal to `200`.

```
($header("Content-Type")="text/plain" and $header("Content-Length")=300) or $statusCode()= 200
```

throw

Use the throw policy to throw an error when it is reached during the execution of an assembly flow.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see [throw](#).

When the throw policy is encountered, the specified error and error message is produced.

If a catch has been configured that the error produced by the throw policy fulfills, the catch will be triggered.

If no catch is triggered by the thrown error, then a `500 Internal Server Error` is returned to the API caller.

Component property details

You can configure a component's properties in the property sheet in the assemble view.

Table 2. The properties of a throw component

Property	Required	Description
Title	No	A custom title for your component when it is displayed in the canvas. If a title is not specified, throw is used by default.
Error name	Yes	The error name that is thrown by the policy.

Property	Required	Description
API Gateway only Error status code (policy version 2.1.0 and later)	No	Specify the HTTP status code for the error. You can use the <code>\$(variable)</code> format to reference the <code>message.status.code</code> API context variable.
API Gateway only Error status reason (policy version 2.1.0 and later)	No	Specify the HTTP reason phrase for the error. You can use the <code>\$(variable)</code> format to reference the <code>message.status.reason</code> API context variable.
Error message	No	The error message that is returned with the error name.
API Gateway only		

Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway

In the code for GatewayScript and XSLT policies in your API assemblies, you can use API context variables to work with the messages that are generated when an API is called.

All API context variables are stored in a JSON-like tree; each context variable is a node in this tree. A non-leaf node can be either an object or an array, while a leaf node can be a number, string, boolean, or document; a document can contain an XML document, BLOB, Stream, or another JSON document.

Each context variable has a name and a value. You can access a context variable by name when using the GatewayScript and XSLT APIs. Dot notation is used to access a context variable, reflecting the position of the corresponding node in the JSON-like tree; for example, `request.headers.Host`. Where a node name contains special characters, bracket notation is supported; for example, `request.headers['Content-Type']`.

For the GatewayScript policy, all the APIs for the DataPower® API Gateways are in the `context` module, which is a global module. You can therefore access the `context` module directly, you do not need to use the `require()` function first.

For the XSLT policy, the APIs are in the `http://www.ibm.com/xmlns/datapower/2017/11/apigateway` namespace; to use these APIs you must declare this namespace.

Attention: The mechanisms described here for interacting with the API Connect context are preferred and provide the best performance if you are writing new GatewayScript or XSLT policies, or if you are authoring user-defined policies. However, for v5-compatible gateways and v5 compatibility for APIs created for the API Gateway, the preferred mechanisms are as described in [GatewayScript code examples](#) and [XSLT policy examples](#).

- [Accessing context variables](#)
- [About payloads](#)
- [Manipulating the message headers](#)
- [Manipulating the message status - examples](#)
- [Accessing the message body](#)
- [Rejecting the session](#)

Accessing context variables

GatewayScript examples

To read the `client.app.id` context variable:

```
var clientID = context.get('client.app.id');
```

To set the value of a context variable:

```
context.set('my.vars.amount', 100);
```

The resulting tree has the following structure:

```
{ "my": { "vars": { "amount": 100 } } }
```

To delete the node `my.vars`, and all its child nodes:

```
context.clear('my.vars');
```

The resulting tree has the following structure:

```
{ "my": { } }
```

XSLT examples

To read the `client.app.id` context variable:

```
<xsl:variable name="clientID" select="apigw:get-variable('client.app.id')"/>
```

To set the value of a context variable:

```
<apigw:set-variable name="'my.vars.amount'" value="100"/>
```

The resulting tree has the following structure:

```
{ "my": { "vars": { "amount": 100 } } }
```

To delete the node `my.vars`, and all its child nodes:

```
<apigw:clear-variable name="'my.vars'"/>
```

The resulting tree has the following structure:

```
{ "my": { } }
```

About payloads

When the assembly flow for an API call begins, the following two message objects are predefined in the API context tree:

- **request**: holds the information for the original payload; the **request** message is a read-only object.
- **message**: holds the information for the current payload.

Typically, a message object has **headers** and **body** properties. For the current payload, the **message** message object might have **variables** and **status** properties, and other properties created during the execution of the assembly.

The following example shows the general structure of a typical message:

```
{
  "headers": {
    "Content-Type": "application/xml",
    "X-Client-ID": "1234567890"
  },
  "variables": {
    "amount": 123,
    "name": "xyz"
  },
  "status": {
    "code": 200,
    "reason": "OK"
  },
  "body": <XML/Blob/Stream/JSON Document>
}
```

Manipulating the message headers

GatewayScript examples

To delete a header:

```
context.message.header.remove('X-My-Header');
```

To read a header:

```
var reqType = context.request.header.get('Content-Type');
var currType = context.message.header.get('Content-Type');
```

To set a header:

```
context.message.header.set('Content-Type', 'application/json');
```

To iterate through the headers:

```
var reqHdrs = context.request.headers;
for (var h in reqHdrs) {
  console.log('>>> Reading the request header: ', h, '=', reqHdrs[h]);
}

var currHdrs = context.message.headers;
for (var h in currHdrs) {
  console.log('>>> Reading the current header: ', h, '=', currHdrs[h]);
}
```

To create a message context called **headersContext**, if one doesn't already exist, and add to it a boolean context variable called **HelloWorld**, with the value **true**:

```
var ctx = context.getMessage("headersContext") || context.createMessage("headersContext");
ctx.setVariable('HelloWorld', true);
```

The **setVariable** call writes the variable into **headersContext.variables>HelloWorld**; therefore a condition statement in any subsequent **switch** policy should check for **headersContext.variables>HelloWorld** rather than **headersContext>HelloWorld**.

To read the context variable in any subsequent **gatewayscript** policy, use the following call:

```
ctx.getVariable("HelloWorld")
```

Note: If you are either migrating an API from IBM® API Connect Version 5.0, or from the DataPower Gateway (v5 compatible), to the DataPower API Gateway, or you are configuring a new API for the DataPower API Gateway, creating a message context, rather than using the context variable mechanism described in [Accessing context variables](#), is the preferred option. In the case of migration, it most closely matches the behavior of IBM API Connect Version 5.0, and **setVariable** and **getVariable** calls will continue to work without modification.

Creating a message context is also the preferred option if you are creating a new API for the DataPower API Gateway because it most closely aligns the API context with the way that various native DataPower API Gateway policies process it.

XSLT examples

To delete a header:

```
<apigw:clear-header message="message" name="X-My-Header" />
```

To read a header:

```
<xsl:variable name="reqType" select="apigw:get-header('request', 'Content-Type')"/>
<xsl:variable name="currType" select="apigw:get-header('message', 'Content-Type')"/>
```

To set a header:

```
<apigw:set-header name="Content-Type" value="text/xml" />
```

To get all headers:

```
<xsl:variable name="allReqHdrs" select="apigw:all-headers('request')"/>
<xsl:variable name="allCurrHdrs" select="apigw:all-headers('message')"/>
```

Manipulating the message status - examples

Note: Only the `message` object has the status property, not the `request` object.

GatewayScript examples

To read the status code and reason phrase:

```
var code = context.message.statusCode;
var reason = context.message.reasonPhrase;
```

To update the status code:

```
context.message.statusCode = 400; //integer, update the code, with default reason
```

To update the status code and reason phrase in a single operation:

```
context.message.statusCode = '200 Wonderful'; //string, update code along with customized reason
```

Note: The `context.message.reasonPhrase` context variable is read-only.

XSLT examples

To read the status code and reason phrase:

```
<xsl:variable name="code" select="apigw:get-variable('message.status.code')"/>
<xsl:variable name="reason" select="apigw:get-variable('message.status.reason')"/>

<apigw:set-variable name="message.status.code" value="200"/>
<apigw:set-variable name="message.status.reason" value="OK"/>
```

Accessing the message body

Note: The request body is read-only.

GatewayScript examples

To read the request body:

```
context.request.body.readAsJSON(function(error, json) {});
context.request.body.readAsXML(function(error, xml) {});
context.request.body.readAsBuffer(function(error, buffer) {});
```

To read the message body:

```
context.message.body.readAsJSON(function(error, json) {});
context.message.body.readAsXML(function(error, xml) {});
context.message.body.readAsBuffer(function(error, buffer) {});
```

To write the message body and update the content type accordingly:

```
// text response
context.message.body.write("Hello world.");
context.message.header.set('Content-Type', "text/plain");

// JSON response
var pet = { "kind": "dog", "age": 3, "color": "black" };
context.message.body.write(pet);
context.message.header.set('Content-Type', "application/json");

// XML response
var resp = "<order><id>100</id><timestamp>20181231</timestamp><status>fulfilled</status></order>";
context.message.body.write(resp);
context.message.header.set('Content-Type', "text/xml");
```

XSLT examples

Note:

- There is no XSLT API to write the message body; the output of the stylesheet transformation is used to update `message.body`.
- To read the request body or the message body, you must parse `message.body` with a [Parse](#) policy before the XSLT policy is executed. At the beginning of the assembly flow, `message.body` contains `request.body` so, after parsing `message.body`, you can then read the request from `message.body`.
- If the XSLT input document uses the context current payload, `message.body` is used for the input document `'/'` that can be accessed from the XSLT policy if `message.body` has been parsed as XML in advance; this is determined by the `input` property of the XSLT policy, see [xslt](#).

Read the message body:

```
<xsl:variable name="currentPayload" select="apigw:read-payload('message')"/>
```

Read the message body when the `input` property of the XSLT policy is set to `true`:

```
<xsl:variable name="currentPayload" select="/" />
```

Rejecting the session

Note: After the session is rejected, the API assembly flow is stopped and a fault response is returned, unless a catch handler is defined.

GatewayScript example

To reject the session with an error name and message, and update the status reason and code:

```
context.reject('CustomError', 'You are not authorized to make this API call');
context.message.statusCode = '401 Unauthorized';
```

XSLT example

To reject the session with an error name and message, and update the status reason and code:

```
<apigw:reject identifier="CustomError" status-code="401" reason="Unauthorized">You are not authorized to make this API call</apigw:reject>
```

- [Manipulating attachments in a message object](#)

The message object provides APIs and properties to manipulate message attachments.

API Gateway only

Manipulating attachments in a message object

The message object provides APIs and properties to manipulate message attachments.

If the assembly includes a parse policy, attachments in the request or response of a multipart message can be manipulated and sent back to the client. By default, the response is sent to the client in multipart format. Alternatively, you can clear `context.message.attachments` to discard the attachments and send only `message.body` to the client.

Note: If the assembly does not include a parse policy, the following processing rules apply.

- For a multipart request where the `message.body` variable is not changed, the invoke policy keeps and passes the attachments to the server.
- For a multipart request or response where the `message.body` variable is not changed, the result API action passes the attachments as the final response.
- If the `message.body` variable is changed, attachments are discarded.

- [Retrieving an attachment](#)
- [Appending an attachment to the message](#)
- [Retrieving the number of attachments in an array](#)
- [Removing an attachment from the message](#)
- [Reading, accessing, and manipulating the body of an attachment](#)
- [Manipulating the headers of an attachment](#)

Retrieving an attachment

GatewayScript examples

Retrieve the attachment by index location.

```
context.message.attachments[1]
```

Retrieve the attachment by looking up the value of `pic1` in the `Content-Id` header.

```
context.message.attachments['cid:pic1']
```

Retrieve the attachment by looking up the value of `uri1` in the `Content-Location` header.

```
context.message.attachments['uri1']
```

Appending an attachment to the message

GatewayScript example

```
var headers = JSON.parse ( '{ "Content-Type": "text/xml; charset=utf-8", "Content-Id": "<data>" }' );
context.message.attachments.append(headers, 'Hello world.');
```

Retrieving the number of attachments in an array

Example

```
for (var i = 0; i < context.message.attachments.count; i++) {
  context.message.attachments[i].header.set('X-Foo', 'bar');
}
```

Removing an attachment from the message

GatewayScript examples

Remove the attachment by index location.

```
context.message.attachments.remove(1)
```

Remove the attachment by looking up the value of `pic1` in the `Content-Id` header.

```
context.message.attachments.remove('cid:pic1')
```

Remove the attachment by looking up the value of `uri1` in the `Content-Location` header.

```
context.message.attachments.remove('uri1')
```

Reading, accessing, and manipulating the body of an attachment

GatewayScript examples

To read the payload of an attachment in binary and return the contents as either a **Buffer**, **Buffers**, **JSON**, or **XML NodeList** object:

```
context.message.attachments[0].body.readAsBuffer(function(errorObject,bufferObject){})
context.message.attachments[0].body.readAsBuffers(function(errorObject,buffersObject){})
context.message.attachments[0].body.readAsJSON(function(errorObject,jsonObject){})
context.message.attachments[0].body.readAsXML(function(errorObject,nodeList){})
```

To write content **Hello world** to the current payload of the attachment:

```
message.attachments[0].body.write("Hello world")
```

Manipulating the headers of an attachment

GatewayScript examples

To retrieve the values of the whole attachment headers:

```
context.message.attachments[0].headers
```

To retrieve the value of the named header of the attachment:

```
context.message.attachments[0].header.get();
```

To delete the current **Content-Type** header of the attachment.

```
context.message.attachments[0].header.remove('Content-Type');
```

You can set the value of the named header of an attachment. The header can be coalesced and noncoalesced. Take the following code as an example.

```
context.message.attachments[0].header.set('MyCookie', ['cookie1', 'cookie2']);
```

If the value type is array, the **MyCookie** header is noncoalesced and it is present with different entries in HTTP header.

```
MyCookie: cookie1
MyCookie: cookie2
```

User-defined policies

Make a user-defined policy available to a Catalog, and apply that policy to a REST or SOAP API.

A policy is a piece of configuration that controls a specific aspect of processing in the Gateway server during the handling of an API invocation at run time. IBM® API Connect provides built-in policies for many capabilities, including logging, redaction, proxy, and transformations, but you can also create user-defined policies to provide more processing control.

The following information outlines how to create and manage user-defined policies:

Creating a user-defined policy

A user-defined policy is created outside of API Connect by using a standard development tool, but the policy must conform to a particular schema. For information about how to create a policy, see [Authoring policies](#).

Note: If you are running your policies on a DataPower® Gateway, you must ensure that the DataPower processing to be controlled by the user-defined policy, is supported by the level of IBM DataPower Gateway that the policy will be run on. When using the GatewayScript actions, the minimum DataPower firmware that should be used is version 7.2.0.

Importing a user-defined policy into API Connect

To make a user-defined policy available to an API, the policy must be imported into one or more Catalogs in the API Manager. If you also want to be able to apply the policy to your policy assembly in API Designer, you will have to import that policy into the developer toolkit environment.

Make your policy accessible to API Designer by using the developer toolkit. For detailed instructions, see [Packaging and importing your policies into IBM API Connect](#).

Make your policy available by using the API Manager UI. For detailed instructions, see:

- [Importing a user-defined policy into a Catalog](#). If you want to create a new Catalog and import a user-defined policy as part of the configuration, follow the instructions in [Creating and configuring Catalogs](#).
- [Packaging and importing your policies into IBM API Connect](#).

Note: You must import a user-defined policy into every Catalog in API Manager that you require the policy to run in.

Applying a user-defined policy to an API

Apply a user-defined policy to an API definition by using the assemble view in API Designer or API Manager, to add the component to your assembly and configure its properties. For detailed instructions, see [Including elements in your OpenAPI 2.0 API assembly](#), [Including elements in your OpenAPI 2.0 API assembly](#).

Deleting a user-defined policy

Delete a user-defined policy from a Catalog, by clicking the Delete icon next to the policy in the associated Catalog in API Manager.

Tags in API Connect

There are a number of forms of tagging in IBM® API Connect.

- You can create tags in an API that are visible in its OpenAPI definition and can be used to filter operations in the Developer Portal.
- You can tag items in the Developer Portal so that they can be searched for.

Tags within an API

The OpenAPI specification allows the inclusion of tags in an API definition, and you can create these tags through the API Manager user interface. You can assign tags to an operation within an API.

Tags that are assigned to an operation can be used to group the operations of an API in the Developer Portal, by using the filter options for the API. These tags are visible to anyone who can view any of the Products to which the API belongs.

For more information, see [Editing an OpenAPI 2.0 API definition](#) and [Configuring an operation](#).

Note: Though you can tag the API itself in the API Setup section, by using this method the tag is not visible in the Developer Portal.

Tags in the Developer Portal

An administrator can assign tags to items in the Developer Portal, which are then available through the API Products search function in the Developer Portal.

For more information, see [Editing tags for a specific item](#) and [Managing tags in the Developer Portal](#).

Working with Products

In IBM® API Connect, Plans and APIs are grouped together in Products, with which you can manage the availability and visibility of APIs and Plans.

The following diagram demonstrates how Products, Plans, and APIs relate to one another.

Note: Plans belong to only one Product, but they can possess different APIs to other Plans within the same Product, and they can share APIs with Plans from any Product.

Figure 1. The hierarchy of Products, Plans, and APIs.

Products provide a method by which you can group APIs into a package that is intended for a particular use. Additionally, they contain Plans, which can be used to differentiate between different offerings. Plans can share APIs, but whether subscription approval is required depends upon the Plan itself. Additionally, you can enforce

rate limits through these Plans, or through operations within the APIs of a Plan that override the rate limit of the Plan. You can also assign different subscription costs to your Plans to differentiate the rates of API calls. For more information, see [Monetizing your Products](#).

To make an API available to an application developer, it must be included in a Plan. You can create Plans only within Products, and these Products are then published in a Catalog. A lifecycle manager can then control the availability and visibility of APIs and Plans through the API Manager. By using the API Manager, you can specify the Plans that an application developer is able to subscribe to through the Developer Portal. The application developer can only subscribe to one Plan from a specific Product. Multiple Plans within a single Product are useful in that they can fulfill similar purposes but with differing levels of performance and cost. For example, you can have a "Demo Plan", which makes a single API available free of charge, and a "Full Plan" which makes several APIs available with a monthly subscription cost.

As well as controlling which APIs an application developer can use, different Plans can be used to implement different rate limits. A rate limit can be implemented as a default rate that is shared across an entire Plan, or can be set for specific operations of an API within that Plan, exempting them from the shared Plan rate limit. Different Plans can have differing rate limits, both between operations and for the overall limit. This is useful for providing differing levels of service to customers. For example, a "Demo Plan" might enforce a rate limit of ten calls per minute, while a "Full Plan" might permit up to 1000 calls per second.

In addition, you can apply burst limits to your Plans, to prevent usage spikes that might damage infrastructure. Multiple burst limits can be set per Plan, at second and minute time intervals. You can also set multiple rate limits per Plan and per operation, at second, minute, hour, day, and week time intervals.

Note:

- Applying a rate limit at the Plan level creates a default rate limit that is shared across all the operations within the Plan. If you need to set specific rate limits for specific operations, you must set these within the operations themselves and these settings will override the setting at the Plan level.
- The test application that is used by the API Manager test tool is not subject to rate limits if you have enabled automatic subscriptions for the Catalog in which you are testing. For more information, see [Working with Catalogs](#)

API Connect also supports the implementation of multiple versions of Products. You can choose version numbers and use them to aid the development of your Products and Plans.

Note: The version for a Product is distinct from the version of any APIs that are contained in the associated Plans. Plans cannot themselves have their own version, they use the version of their parent Product.

- [Creating a draft Product](#)
Create a draft Product to collect a set of APIs and Plans into one offering that you make available to your developers. A Plan includes rate limit settings that can be applied to the Plan as a whole, or specified for each operation in an API. Through Products and Plans, you have greater control over what APIs your developers have access to, and the subscription terms.
- [Downloading a draft Product](#)
You can download the details of your draft Product so that you can store them for later recovery.
- [Importing a draft Product](#)
You can create a Product by importing a Product definition in a .yaml file.
- [Searching for a draft Product](#)
Quickly locate a draft API or Product by searching on the title and version.
- [Editing a draft Product](#)
After initially creating a draft Product, you can continue to further configure the Product, or you can make configuration changes later.
- [Staging a draft Product](#)
Stage a draft Product to a Catalog to create a specific version of that Product, before publishing. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers.. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.
- [Publishing a draft Product](#)
Publish a draft Product to make the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.
- [Creating a new version of your Product](#)
You can have multiple versions of a Product in IBM API Connect. These versions can occupy any of the lifecycle stages, which facilitates development.
- [Specifying the gateway type for a Product](#)
You can edit the Product configuration to specify a gateway type.
- [Deleting a draft Product](#)
You can delete draft Products that are no longer required.
- [Organizing your Products into categories](#)
You can organize your Products into categories. The Products that you categorize are displayed within the Developer Portal, in their defined categories.

Related information

- [Working with Products in the API Manager](#)

Creating a draft Product

Create a draft Product to collect a set of APIs and Plans into one offering that you make available to your developers. A Plan includes rate limit settings that can be applied to the Plan as a whole, or specified for each operation in an API. Through Products and Plans, you have greater control over what APIs your developers have access to, and the subscription terms.

Before you begin

Define your APIs. For more information, see [Creating an API definition](#).

Tip: As well as using the method described in this task, you can also create a Product when you create an API. If you create an API by using the developer toolkit command line editor, a Product is automatically created for you. You can then change any of the Product settings by opening your new Product in the Products page of the API Designer.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you first create your Product, it has *draft* status. When you have finished configuring your draft Product, you stage it to a Catalog so that the APIs in the Product can be made available to your application developers.

Procedure

To create a Product, complete the following steps:

1. In the navigation pane, click  Develop, select the Products tab, then click Add Product.
The Add Product page opens.
2. Select New Product, then click Next.
3. On the Info page, complete the following steps:
 - a. Enter the Title and Version of the Product and, optionally, a description. A Name is entered automatically.
Note: The value in the Name field is a single string that is used to identify the Product in developer toolkit CLI commands. The Title is used for display. To view the CLI commands to manage draft Products, see [apic draft-products](#).
 - b. Click Next.
4. On the APIs page, select the APIs that you want to include in the Product. You can include only APIs whose gateway type matches the gateway type of the Product, or APIs for which the Enforced option is disabled, meaning that the API is not managed on an API Connect gateway. If you select an incompatible API whose gateway type does not match the gateway type of the Product, a warning message is displayed and you cannot save your changes until you clear the incompatible selection. For more information on gateway types, see [API Connect gateway types](#), [Specifying the gateway type for a Product](#), and [Specifying the gateway type for an API definition](#).
5. Click Next.
6. On the Plans page, complete the following steps:
 - a. Optional: Change the Title, Description, or Rate limit settings for the default Plan.
 - b. Optional: To add further Plans, click Add, then scroll down and modify the Plan settings as required.
 - c. Click Next.
7. To have the Product published to the Sandbox Catalog automatically after creation, select Publish product.
Note: The publish option is not available in the API Designer UI.
8. If Publish product is selected, you can select which gateway service the Product is published to. By default, the Product is published to all relevant gateway services.
9. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to.
If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product. For information about how to create and manage consumer organizations and consumer organization groups, see [Administering Consumer organizations](#).

Visibility can also be set at the Catalog or Space level. For more information, see [Configuring Product visibility in a Catalog](#).
10. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product.
If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product. If you selected custom visibility, only the consumer organizations and consumer organization groups selected there are available for adding to the custom subscribability list. For information about how to create and manage consumer organizations and consumer organization groups, see [Administering Consumer organizations](#).
Note: If you select custom visibility or subscribability, the consumer organizations and consumer organization groups that you can choose from are those in the Sandbox Catalog for the management server and provider organization that you are connected to. If you want to specify consumer organizations or groups that are in another Catalog, or in a Space, publish the Product to that Catalog or Space, then configure the visibility or subscribability there; for details, see [Changing the availability of a Product](#).
If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see [Logging into API Connect Designer](#).

If you are working offline in API Designer, you must type in the exact name of the organization or group.

For more information about consumer organizations in a Catalog, see [Administering Consumer organizations](#).
11. Click Next to create your Product.
 - a. To further configure your Product, click Edit Product.
For details, see [Editing a draft Product](#)
 - b. If you do not want to configure your Product further at this time, click the initial Develop link in the breadcrumb trail to return to the Develop page; you can then move on immediately to another task.
For details on how to configure your Product later, see [Editing a draft Product](#).

Results

You have created a draft Product, and specified a set of APIs and Plans into one offering that you can now make available to your developers.

What to do next

Stage your Product to a Catalog. For more information, see [Staging a draft Product](#).

Related tasks

- [Creating a new version of your Product](#)

Downloading a draft Product

You can download the details of your draft Product so that you can store them for later recovery.

Before you begin

To complete this task, you must have created a draft Product. For more information, see [Creating a draft Product](#).

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the `Product-Drafts:Edit` permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see [Creating custom roles](#).

You can download the details of your Product as a .yaml file. This file can be used to re-create your Product, although it includes only references to APIs, not the API definitions themselves. This function does not provide a way to export an entire implementation. For information about creating a Product from a .yaml file, see [Importing a draft Product](#).

Procedure

To download a .yaml file containing details of your Product, complete the following instructions:

1. In the navigation pane, click  Develop.
2. Select the Products tab.
3. Alongside the Product version that you want to work with, click the options icon  and then click Download.
4. Save the file to the required location.

Results

You have downloaded a .yaml representation of your Product.

Related tasks

- [Importing a draft Product](#)

Related information

- [Creating a Product](#)

Importing a draft Product

You can create a Product by importing a Product definition in a .yaml file.

Before you begin

To complete this task, you must have a .yaml representation of a Product. This can be created as described in the [Downloading a draft Product](#) task.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can import details of your Product as a .yaml file. This file can be used to re-create your Product, although it includes only references to APIs, not the API definitions themselves. This function does not provide a way to import an entire implementation.

You can import the file from your local file system.

Procedure

To create a Product from a .yaml file, complete the following instructions:

1. In the navigation pane, click  Develop.
2. Select the Products tab.
3. Click Add > Product.
4. Select Existing Product, then click Next.
5. To import a file from your local file system, you can either drag and drop your files, or click Browse and select the file that you want to use. The wizard checks the validity of the YAML, and displays a message indicating successful validation.
6. Click Next.
7. To have the Product published to the Sandbox Catalog automatically after creation, select Publish product.
8. Click Next to create your Product.
 - a. To further configure your Product, click Edit Product. For details, see [Editing a draft Product](#)
 - b. If you do not want to configure your Product further at this time, click the initial Develop link in the breadcrumb trail to return to the Develop page; you can then move on immediately to another task. For details on how to configure your Product later, see [Editing a draft Product](#).

Results

You have imported a Product from a .yaml file. If the same APIs and versions of APIs as referenced in the file are present, then they will be included in the Product.

Importing a Product in this way does not include the API definitions, only references to them.

Related tasks

- [Downloading a draft Product](#)

Searching for a draft Product

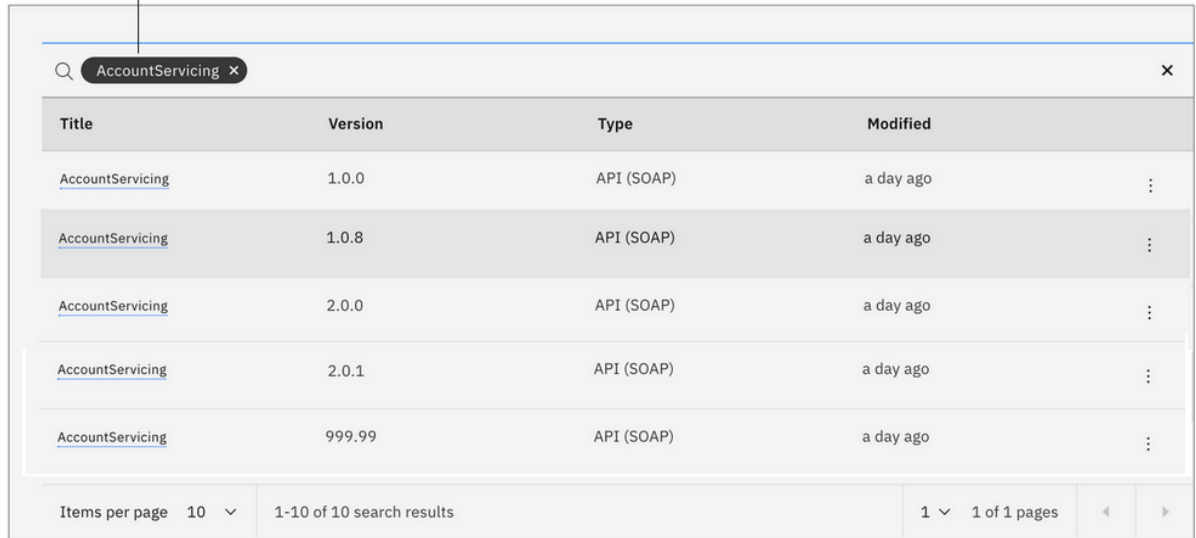

Quickly locate a draft API or Product by searching on the title and version.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

On the Develop page, type your search string into the search field and click  (or press Enter) to run the search.

The search returns a list of APIs (or Products) that most closely resemble your keywords, rather than limiting the results to identical matches. The following image shows a search string that includes "AccountServicing". The results include all draft APIs and Products with a title that is similar to the search text, with duplicates sorted by creation date.

Search text entered with no parameters

Title	Version	Type	Modified
AccountServicing	1.0.0	API (SOAP)	a day ago
AccountServicing	1.0.8	API (SOAP)	a day ago
AccountServicing	2.0.0	API (SOAP)	a day ago
AccountServicing	2.0.1	API (SOAP)	a day ago
AccountServicing	999.99	API (SOAP)	a day ago

Items per page 10 1-10 of 10 search results 1 of 1 pages

Resources with a name, title, or version that are not similar to the search text are not included in the results. If you select a resource type to search for but do not specify any keywords, the results are sorted by title and then by creation date. For example, if you search for Products but do not include any keywords, then all Products appear in the results table.

Search text

The search is case insensitive. Trailing spaces and accents (for example: é, è, â) are ignored. For best results, provide as much of the title and version as possible in your search text. Detailed search strings return more accurate results. Results include all titles that are similar to your search string, and not just identical matches.

What's included in the search?

The scope of the search includes the API or Product Title, Name and Version fields. The search applies only to the current provider organization (displayed in the product banner's Organization field).

You can optionally restrict your search to Products only, or to a specific type of API. Click in the search field and then in the "Types" list that displays, select Product or an API type (REST or SOAP).

How are results displayed?

Search results display as a table, sorted by API or Product title and version. If the results overflow onto additional pages, navigate between pages using the standard page controls that follow the table. When you clear the search, APIs and Products are listed alphabetically by title and, within each title, by newest version first.

Editing a draft Product

After initially creating a draft Product, you can continue to further configure the Product, or you can make configuration changes later.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

During the initial creation of a Product, the Product creation wizard guides you to enter the minimum configuration settings, and then provides an Edit Product button. You have the option to specify additional configuration immediately, or to return to Product to edit it later. This topic describes how to specify additional configuration in either case.

Procedure

To edit a draft Product, complete the following steps:

1. Access the Product Setup page in one of the following ways:
 - After completing the initial creation of the Product, click Edit Product.
 - In the navigation pane, click Develop, then select the Products tab.
 - Click the title of the Product that you want to edit.
2. On the Product Setup page, you can make the following configuration changes:
 - a. In the Info section, change the Title, Version, or Summary.
 - b. Use the Contact, Terms of Service, and License sections to enter the corresponding details as required.
 - c. Change the gateway type. For more information, see [API Connect gateway types](#) and [Specifying the gateway type for a Product](#).
 - d. Click Save to save your changes.
3. Optional: Specify Product metadata to be displayed with the Product in the Developer Portal:
 - a. Click the Source tab to see the OpenAPI source for the Product.
 - b. Add the custom attribute `x-name`:
`value` into the `info` section. For example:

```
info:  
  version: 1.0.0  
  title: Multi Plans  
  name: multi-plans  
  x-customarg: This is the custom value  
  ...
```

Where `customarg` is the name of the custom metadata, and `This is the custom value` is the information content.

c. Click Save.

When the Product is published in the Developer Portal, the custom metadata is displayed with the Product. For example:

4. Click Visibility, then make the following changes as required:
 - a. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to. If you select Custom, complete the following steps:
 - Select the Catalog for which you want to control visibility.
 - Use the Search organizations and groups field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be visible to. For information about how to create and manage consumer organizations and consumer organization

groups, see [Administering Consumer organizations](#).

- b. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product.

If you select Custom, complete the following steps:

- Select the Catalog for which you want to control subscribability.
- Use the Search organizations and groups field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be subscribable to. If you selected custom visibility, only the consumer organizations and consumer organization groups selected there are available for adding to the custom subscribability list. For information about how to create and manage consumer organizations and consumer organization groups, see [Administering Consumer organizations](#).

Note:

- If you select custom visibility or subscribability, only 10 search results are displayed in the selection list for the consumer organizations and consumer organization groups. If necessary, enter a more specific search string to refine the search.
- Although the title of each organization or group is displayed, followed by the name in parentheses, in the table of selected organizations and groups only the name is displayed

- a. Click Save to save your changes.

Note: You can change the visibility and subscribability settings when you publish the Product; see [Publishing a draft Product](#). You can also change the settings in the Catalog to which the Product is published; see [Changing the availability of a Product](#).

5. To specify the APIs that you want to include in the Product, click APIs, then complete the following steps.:

- a. Click Edit.

All draft APIs are listed.

- b. Select the APIs that you want to include. You can include only APIs whose gateway type matches the gateway type of the Product, or APIs for which the Enforced option is disabled, meaning that the API is not managed on an API Connect gateway. If you select an incompatible API whose gateway type does not match the gateway type of the Product, a warning message is displayed and you cannot save your changes until you clear the incompatible selection. For more information on gateway types, see [API Connect gateway types](#), [Specifying the gateway type for a Product](#), and [Specifying the gateway type for an API definition](#).

- c. Click Save when done.

The selected APIs are listed.

Note: To make an API available to application developers, you must include it in a Plan.

6. Optional: Add billing integration to the Product. Click Plans, and in the Billing integration section, select the billing integration resource that you want to apply to the Product.

In the Plans section, you can then either edit the Default Plan to add pricing information, or create a new Plan with pricing information. For more information about billing integration, see [Monetizing your Products](#).

7. Optional: Add one or more Plans to the Product, or modify an existing Plan. Note that a default plan is automatically created for you, with a rate limit of 100 API calls per hour.

Note: If you enable event endpoints in Cloud Pak for Integration, rate limits do not apply to AsyncAPIs associated with a plan.

- a. Click Plans.

- b. To add a new Plan, click Add. To modify an existing Plan, click the options icon  alongside the required Plan, then click Edit.

- c. Specify the Title of the Plan and, optionally, a description. A Name is entered automatically.

Note: The value in the Name field is a single string that is used to identify the Plan in developer toolkit CLI commands. The Title is used for display.

- d. Specify whether your Plan requires subscription approval. If you want subscriptions by developers to require approval, select the Approval check box; otherwise, ensure the check box is cleared.

- e. In the Plan pricing section, you can add pricing information by completing the following steps:

- i. Change the toggle to On for Plan pricing. The Plan pricing definition section is displayed.

- ii. If you want to include any free trial days in your Plan, select Include free trial days, and then enter the number of trial days that a subscriber can use the Plan without charge, after which their billing cycle begins.

- iii. Select the Currency for the billing process use.

- iv. Enter the Price per month to bill the subscriber for. If the selected currency supports fractional units, enter the price including any fractional units, such as cents.

For more information about Product billing integration, see [Defining a Product with billing integration](#).

- f. In the Plan Rate Limits section, you can modify a rate limit, and click Add to add further rate limits. You can set multiple rate limits, at second, minute, hour, day, and week time intervals. To remove a rate limit, click the corresponding delete icon .

Note: For information about rate limits and burst limits in API Connect, see [Understanding rate limits for APIs and Plans](#).

- g. In the Plan Burst Limits section, you can modify a burst limit, and click Add to add further burst limits. You use burst limits to prevent usage spikes that might

damage infrastructure. You can set multiple burst limits, at second and minute intervals. To remove a burst limit, click the corresponding delete icon .

Rate and burst limits work together to manage network traffic for the APIs covered under a Plan. A Plan can have multiple rate and burst limits, but it is recommended that each time interval be assigned only one set of limits. Adjust the rate and burst limits to allow for maximum traffic without overloading your network. The **rate limit** sets the maximum amount of sustainable, ongoing traffic for accessing the APIs on your network within a time interval (for example, one day). The **burst limit** sets the maximum short-term traffic volume for your network within a time interval (per second or minute).

The **burst limit** allows for short bursts of increased traffic. When the **burst limit** is exceeded, all subsequent API calls are rejected until the start of the next **burst limit interval**. The **burst limit counter** is reset to zero at the start of the next interval, which allows API calls to be accepted again. These API calls count toward the **rate limit counter**, but the resetting of the **burst limit counter** does not affect the **rate limit counter**.

The **rate limit** is the number of API calls allowed in a time interval, for example, 1000 calls per day. When the **rate limit** is exceeded, and Hard limit is enabled, all subsequent API calls will be rejected. The **rate limit counter** is reset to zero at the start of the next **rate limit interval**, which allows API calls to be accepted again. If Hard limit is disabled, all subsequent API calls are still accepted, and a message is logged stating that the **rate limit** has been exceeded. This is referred to as a "soft limit."

Hard limit affects only the **rate limit**, as illustrated by the following scenarios:

Scenario A

Table 1. Hard limit enabled

Hard limit	Burst limit	Rate limit
ON	100 calls/minute	1000 calls/day

- If a user calls an API 100 times in one minute, the **burst limit** is reached. The 101st call (and any subsequent calls) within the same minute will be rejected. Once the minute is up, the **burst limit counter** is reset. All API calls are tallied toward the **rate limit** of 1000 calls per day. The resetting of the **burst limit counter** does not affect the **rate limit counter**.

- If a user calls the API 99 times per minute, they will not hit the **burst limit**. They will eventually hit the 1000 calls per day rate limit, and the 1001st call will be rejected until the end of the same one day **rate limit interval**. During the period of time when API calls are rejected due to the daily **rate limit** being exceeded, the **burst limit** will not be activated since the calls are already rejected.
- Both **burst limits** and **rate limits** are applied per consumer.

Scenario B

Table 2. Hard limit disabled

Hard limit	Burst limit	Rate limit
OFF	100 calls/minute	1000 calls/day

- As in Scenario A, if a user calls the API 100 times in one minute, the 101st call within the same minute will be rejected, until that minute is up and the counter resets. These calls count toward the 1000 calls per day **rate limit** as well.
- If a user calls the API 99 times per minute, they will not hit the **burst limit**. They will eventually hit the 1000 calls per day **rate limit**, and the 1001st call will be accepted (since there is no hard limit). A message will be logged for each subsequent call until the time interval (one day) is up and the counter resets. During the remainder of the day, the **burst limit** will still be enforced, and calls will be rejected once the number of calls exceeds the 100 calls per minute within any given minute.
- Both burst limits and rate limits are applied per consumer.

Note: When Hard limit is unchecked, the **rate limit** is considered a "soft limit." With a soft limit, calls are not rejected after the **rate limit** is reached. Instead, a message is recorded in the log file. With a soft limit, the **burst limit** still rejects API calls after it is exceeded.

- To include in the Plan all the APIs that were included in the Product in step 5, select Same as product in the Plan APIs section.
- In the GraphQL Rate Limits section you can configure rate limits that will be applied to any GraphQL proxy APIs that are added to the Product. The following rate limits are available:

graphql-field-cost

Applies a limit to the total calculated field cost of GraphQL query calls made to the GraphQL proxy APIs in this Plan.

graphql-design-request

Applies a limit to the total number of calls of any of the following types made to the GraphQL proxy APIs in this Plan:

- Requests sent to the **graphql/cost** endpoint for retrieving the cost of a GraphQL query. For more information, see [Enabling the cost endpoint for a GraphQL API](#).
- Standard introspection requests sent to the **/graphql** endpoint. For more information, see [Supporting introspection for a GraphQL API](#).
- HTML web browser requests for a GraphQL editor sent to the **/graphql** endpoint. For more information, see [Enabling the GraphQL editor for a GraphQL API](#).

graphql-input-type-cost

Applies a limit to the total calculated input type cost of GraphQL query calls made to the GraphQL proxy APIs in this Plan.

graphql-type-cost

Applies a limit to the total calculated type cost of GraphQL query calls made to the GraphQL proxy APIs in this Plan.

The calculated costs depend on weighting factors applied to the types and fields in the GraphQL schema. For details on the GraphQL proxy API, and configuring type and field weights, see [Creating a GraphQL proxy API](#) and [Using the GraphQL schema editor](#).

- To define one or more assembly burst limits or assembly count limits, click Add in the Assembly Burst Limits or Assembly Count Limits section as appropriate. For a burst limit you specify the maximum number of calls allowed in a specified time period, for a count limit you specify a maximum call limit. The name that you supply is for use in a Rate Limit policy in an API assembly, enabling the policy to define the burst or count limit that is to be applied; for more information, see [Rate Limit](#).
- To select the APIs that you want to include in the Plan, select Customize the plan API list in the Plan APIs section, then click Edit. The Edit plan APIs window opens. The APIs that are available for selection are those that were included in the Product in step 5. Use the check boxes to specify the required APIs, then click Save when done.
- To select specific API operations to include in the Plan, click the options icon  alongside the required API, then click Edit operation list. The Select operations you want to include window opens. Use the check boxes to specify the required operations, then click Save when done.
- To remove an API from the Plan, click the options icon  alongside the required API in the Plan APIs section, then click Remove.
- For any GraphQL APIs in the Plan, if you want to prevent subscribers to this Plan from using certain types or fields, complete the following steps:
 - Click the options icon  alongside the required GraphQL API in the Plan APIs section, then click Edit show/hide settings.
 - To prevent use of a GraphQL type, clear the check box selection alongside that type.
 - To prevent use of a field in a type, expand the type then clear the check box selection alongside that field.
 - When done, click Next. A summary window opens. If the operation is permitted, any related elements that will also be hidden are listed; for example, if you hide a type, and that type is referenced as the data type of a field on another type, that field is also hidden. If the operation is not permitted, an explanation is displayed.
 - If the operation is permitted, click Done to apply your changes. If the operation is not permitted, either click Cancel to close the window or click Back and amend your settings.

You can use the Edit show/hide settings option to change existing settings; you can hide additional types or fields, and you can show types or fields that were previously hidden.

- To define rate limits for specific API operations, select Override plan rate limits for individual operation in the Plan APIs section; for further details, see [Defining rate limits for an API operation](#)
- Click Save to save your changes.

8. Optional: Specify Plan metadata to be displayed with the Plan in the Developer Portal:

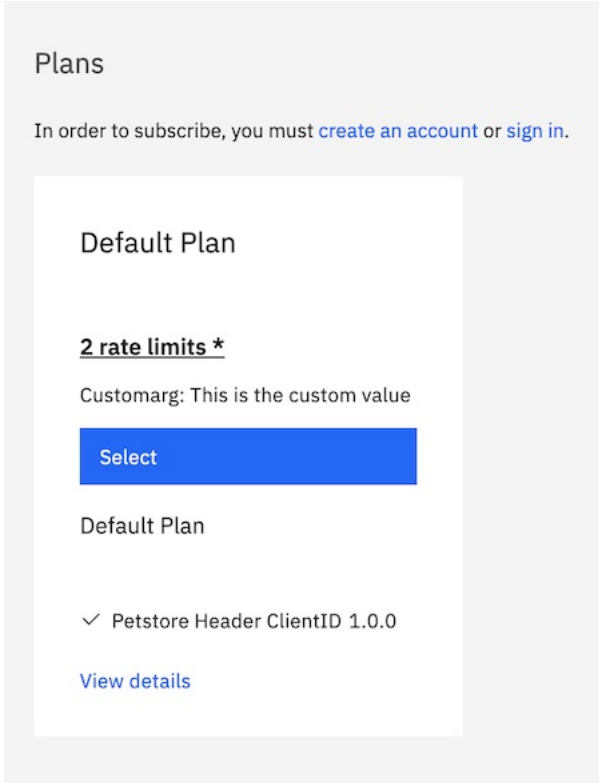

- Click the Source tab to see the OpenAPI source for the Plan.
- Add the custom attribute **x-name**: **value** into the appropriate **plan** section. For example:

```
...
plans:
  default-plan:
    title: Default Plan
    description: Default Plan
    x-customarg: This is the custom value
    rate-limits:
      default:
        value: 100/1hour
        hard-limit: false
        minute:
```

```
value: 20/1minute
hard-limit: false
apis:
  petstore-header-clientid1.0.0: {}
...
```

Where *customarg* is the name of the custom metadata, and *This is the custom value* is the information content.
c. Click Save.

When the Plan is published in the Developer Portal, the custom metadata is displayed with the Plan. For example:

Note: After adding custom metadata to a Plan, if you need to edit the Plan details further, you must do this in the Source view, or the custom metadata will be deleted.

9. Optional: Click Categories, then define any categories that you want to organize your Product into. Click Save to save any updates.

By organizing your Products into categories, you can provide a hierarchical display for your Products in the Developer Portal. For more information, see [Organizing your Products into categories](#).

What to do next

Stage your Product to a Catalog. For more information, see [Staging a draft Product](#).

- [Defining rate limits for an API operation](#)

For any Plan in a draft Product, you can apply one or more rate limits to a specific operation on any of the APIs in that Plan.

Related tasks

- [Creating a new version of your Product](#)

Related reference

Defining rate limits for an API operation

For any Plan in a draft Product, you can apply one or more rate limits to a specific operation on any of the APIs in that Plan.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

During the initial creation of a Product, the Product creation wizard guides you to enter the minimum configuration settings, and then provides an Edit Product button. You have the option to specify additional configuration immediately, or to return to Product to edit it later. This topic describes how to specify additional configuration in either case.

Note: For information about rate limits and burst limits in API Connect, see [Understanding rate limits for APIs and Plans](#).

Procedure

1. Access the Product Setup page in one of the following ways:
 - After completing the initial creation of the Product, click Edit Product.
 - In the navigation pane, click Develop, then select the Products tab.
 - Click the title of the Product that you want to edit.
2. Click Plans.
3. Click the options icon  alongside the required Plan, then click Edit.
4. Scroll down to the Plan APIs section, then select Override plan rate limits for individual operation. The Override Rate Limits section is displayed.
5. Click Add. The Override plan rate limits window opens.
6. Select the API, and the specific operation in that API, to which you want to apply rate limits. By default, calls to the operation are unlimited.
7. To apply one or more rate limits to the operation, select Rate Limits.
8. To define a rate limit, click Add.
9. Supply a name for the rate limit, and define the maximum number of calls allowed in a specified time period; for example, 100 calls per 1 minute. If you select HARD LIMIT and the limit is exceeded, subsequent calls are rejected, otherwise calls are still accepted and a message is logged.
10. Click Save when done. An entry for the operation is listed in the Override Rate Limits section.
11. To modify the rate limiting definition for an operation, click the options icon  alongside the required operation, then click Edit Operation; to delete it, click Remove.
12. Click Save to save your changes.

Staging a draft Product

Stage a draft Product to a Catalog to create a specific version of that Product, before publishing. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers.. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see [Creating and configuring Catalogs](#).

Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see [Using syndication in IBM API Connect®](#).

To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product > Stage permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see [Creating and configuring Catalogs](#) or [Managing user access in a Space](#).

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI. Staging is not available when working offline in API Designer.

A Catalog is a staging target, and behaves as a logical partition of the DataPower® Gateway, and the Developer Portal.

You stage a Product so that the appropriate approvals, internally within the organization, can be given for it to then be published. For information on configuring Product lifecycle approvals for a Catalog, see [Creating and configuring Catalogs](#). For information on approving requests, see [Approving Product lifecycle and subscription requests](#). For information on publishing a Product, see [Publishing a Product](#).

You cannot re-stage an existing Product version to a production Catalog. If you update an API, you must create a new version of that API. Then, create a new version of the Product so that it includes the newer version of the API. For more information on creating new versions of APIs and Products, see [Creating a new version of an API definition](#) and [Creating a new version of your Product](#). If Spaces are enabled in a production Catalog, you cannot re-stage the same API or Product version to any Space in the Catalog.

You can, however, re-stage a Product version to the Sandbox Catalog, or other non-production Catalog, for ease of iterative testing. Note that when you re-stage a Product version to a non-production Catalog, any application subscriptions are deleted; this is done to facilitate scripted deployment in a continuous integration environment, where the re-creation of application subscriptions will be controlled by the scripts. If Spaces are enabled in a non-production Catalog and you re-stage a Product version to a different Space to the one in which it was previously staged, it is removed from the previous Space and staged to the newly specified Space. If billing integration is enabled in a Product, you cannot re-stage the same Product version into a non-production, or production, Catalog. For more information about billing integration, see [Monetizing your Products](#).

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (<https://www.npmjs.com/package/@apidevtools/swagger-parser>).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
 - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either **X-IBM-Client-Id** or **X-IBM-Client-Secret**.
 - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.

- De-referencing of local references in the definition file (that is, values of `$ref` properties), and ensuring these are valid JSON Pointers within the file.

Note: If you are using Event Endpoint Management in Cloud Pak for Integration, similar validation is carried out for AsyncAPI documents. For more information, see the section about API document and enforcement in the [Cloud Pak for Integration documentation](#).

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the product that contains the API is staged or published (the `$ref` field is supported only if you are using the API Connect for IBM Cloud developer toolkit). For more information, see [Using \\$ref to reuse code fragments in your OpenAPI files](#).

Procedure

To stage a Product, complete the following steps:

1. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
2. In the navigation pane, click  Develop.
3. Select the Products tab.
4. You can stage a Product either from the Develop listing page, or from within the Product itself.
 - a. To stage a Product from the Develop listing page, click the options menu icon  alongside the required Product version, and then select Stage.
 - b. To stage a Product from within the Product itself, complete the following steps:
 - i. Click the Product version that you want to work with.
 - ii. Click the options menu icon:

- iii. Select Stage.
5. Select the Catalog to which you want to stage the Product.
 6. If Spaces have been enabled in the selected Catalog, select the Space that you require.

Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to. If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see [Logging into API Connect Designer](#).

For details of how to create a Catalog in a provider organization, see [Creating and configuring Catalogs](#).
 7. If, when the staged Product is subsequently published, you want it to be published only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see [API Connect gateway types](#).
 8. Click Stage.

Results

Your Product is staged to a Catalog. You can view the state of the Product in the Catalog in API Manager. If you staged the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click  Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Staged.

For information about the lifecycle of a product, see [The Product lifecycle](#).

If approval is required to stage Products in the Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is staged when the request is approved. If approval is not required, the Product is staged immediately.

For information on configuring Product lifecycle approvals for a Catalog, see [Creating and configuring Catalogs](#). For information on approving requests, see [Approving Product lifecycle and subscription requests](#).

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

What to do next

- Publish your Product for application developers to access it in the Developer Portal. For more information, see [Publishing a Product](#).

Related information

- [Managing your Products](#)
- [Removing a Product from a Catalog](#)
- [Working with Products in the API Manager](#)

Publishing a draft Product

Publish a draft Product to make the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see [Creating and configuring Catalogs](#).

Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see [Using syndication in IBM API Connect®](#).

To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product Management permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see [Creating and configuring Catalogs](#) or [Managing user access in a Space](#).

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI. Publishing is not available when working offline in API Designer.

You cannot re-publish a Product version to a production Catalog, you must create a new version of the Product for publication; see [Creating a new version of your Product](#). If Spaces are enabled in a production Catalog, you cannot re-publish the same Product version to any Space in the Catalog, neither the same Space nor a different Space.

You can, however, re-publish a Product version to the Sandbox Catalog, or other non-production Catalog, for ease of iterative testing. When you re-publish a Product version to a non-production Catalog, you can choose whether or not to preserve any application subscriptions; deleting subscriptions can facilitate scripted deployment in a continuous integration environment, where the re-creation of application subscriptions will be controlled by the scripts.

If Spaces are enabled in a non-production Catalog and you re-publish a Product version to a different Space to the one in which it was previously published, it is removed from the previous Space and published to the newly specified Space.

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (<https://www.npmjs.com/package/@apidevtools/swagger-parser>).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
 - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either `X-IBM-Client-Id` or `X-IBM-Client-Secret`.
 - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.
 - De-referencing of local references in the definition file (that is, values of `$ref` properties), and ensuring these are valid JSON Pointers within the file.

Note: If you are using Event Endpoint Management in Cloud Pak for Integration, similar validation is carried out for AsyncAPI documents. For more information, see the section about API document and enforcement in the [Cloud Pak for Integration documentation](#).

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the product that contains the API is staged or published (the `$ref` field is supported only if you are using the API Connect for IBM Cloud developer toolkit). For more information, see [Using \\$ref to reuse code fragments in your OpenAPI files](#).

Procedure

To publish a Product, complete the following steps:

1. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
2. In the navigation pane, click  Develop.
3. Select the Products tab.
4. You can publish a Product either from the Develop listing page, or from within the Product itself.
 - a. To publish a Product from the Develop listing page, click the options menu icon  alongside the required Product version, and then select Publish. If you are re-publishing a Product to non-production Catalog, and the Product has application subscriptions, the Publish option deletes them. To preserve application subscriptions, click Publish (Preserve Subscriptions) instead.

Note: If there are any existing subscriptions to the Product, the Publish (Preserve Subscriptions) operation will fail if you remove any consumer organizations or consumer organization groups from the Product visibility or subscribability settings; you can, however, add further organizations or groups. For information on managing visibility and subscribability settings, see [Editing a draft Product](#).

For information on consumer organization groups, see [Working with consumer organization groups](#).
 - b. To publish a Product from within the Product itself, complete the following steps:
 - i. Click the Product version that you want to work with.
 - ii. Click the options menu icon:

 - iii. Select Publish.
5. Select the Catalog to which you want to publish the Product. You must have a compatible gateway type associated with the catalog to proceed, as described in [Creating and configuring Catalogs](#).
6. If Spaces have been enabled in the selected Catalog, select the Space that you require.

Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to. If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see [Logging into API Connect Designer](#).

For details of how to create a Catalog in a provider organization, see [Creating and configuring Catalogs](#).
7. If you want to publish the Product only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see [API Connect gateway types](#).
8. The Visibility and Subscribability sections display the visibility and subscribability settings that have been configured for the draft Product, but you can modify these before publishing if required; proceed as follows:
 - a. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to. If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be visible to. For information about how to create and manage consumer organizations and consumer organization groups, see [Administering Consumer organizations](#).

- b. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product.

If you select Custom, use the Search organizations and groups field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be subscribable to. If you selected custom visibility, only the consumer organizations and consumer organization groups selected there are available for adding to the custom subscribability list. For information about how to create and manage consumer organizations and consumer organization groups, see [Administering Consumer organizations](#).

Note:

- If you select custom visibility or subscribability, only 10 search results are displayed in the selection list for the consumer organizations and consumer organization groups. If necessary, enter a more specific search string to refine the search.
- If custom visibility or subscribability has already been configured in the draft Product, the titles that are displayed in the table of selected organizations and groups are derived by taking the names that are defined in the draft Product and finding the corresponding titles in the Catalog that has been selected as the publish target.

9. Click Publish.

Results

Your Product is published to a Catalog. The state of the Product is shown as Published in the header of the Product itself, and you can click Published to see which Catalogs or Spaces the Product is published to.

You can also view the state of the Product in the Catalog in API Manager. If you published the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click  Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Published.

For information about the lifecycle of a product, see [The Product lifecycle](#).

If approval is required to publish Products in the Catalog, a publish approval request is sent, and the Product moves to the Pending state; the Product is published in the Catalog when the request is approved. If approval is not required, the Product is published immediately.

Note: If approval is required to stage Products to the Catalog, a stage approval request is sent. When the request is approved, the Product moves to the staged state and must be separately published in the Catalog. For information on publishing a staged Product in a Catalog, see [Publishing a Product](#).

For information on configuring Product lifecycle approvals for a Catalog, see [Creating and configuring Catalogs](#). For information on approving requests, see [Approving Product lifecycle and subscription requests](#).

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

Creating a new version of your Product

You can have multiple versions of a Product in IBM® API Connect. These versions can occupy any of the lifecycle stages, which facilitates development.

Before you begin

Create your Product and assign it a version. For more information, see [Creating a draft Product](#).

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can create multiple versions of a Product, and these versions can be named according to your own preferences, and function as distinct Products when staged.

Procedure

To create a new version of a Product, complete the following steps:

1. In the navigation pane, click  Develop.
2. Select the Products tab.
3. Alongside the Product version that you want to work with, click the options icon , then click Save as a new version. The Save Product as a new version window opens.
4. Enter your new version number, then click Save.

Results

Your Product is saved as a new version.

Related information

- [Managing your Products](#)

- [Working with Products in the API Manager](#)

Specifying the gateway type for a Product

You can edit the Product configuration to specify a gateway type.

Before you begin

IBM® API Connect supports two gateway types: DataPower® Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

In addition, Event Endpoint Management in Cloud Pak for Integration provides the Event Gateway Service for handling incoming requests to consume from a stream of events.

For more information on how to choose which gateway type to use, see [API Connect gateway types](#).

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can specify the gateway type for a Product.

Products can use only one type of gateway, and the APIs in the Product must use the same type of gateway. See [Specifying the gateway type for an API definition](#).

When you create a new Product, or import a Product definition that has no gateway type configured, the gateway type defaults according to the gateway types of the gateway services that are enabled in your Sandbox Catalog, as indicated in the following table.

Table 1. Default gateway type for a new Product

Gateway Service enablement in Sandbox Catalog	Default gateway type for new Product
No gateway services enabled	DataPower API Gateway
At least one gateway service of each type enabled	DataPower API Gateway
One or more gateway services only of type DataPower API Gateway enabled	DataPower API Gateway
One or more gateway services only of type DataPower Gateway (v5 compatible) enabled	DataPower Gateway (v5 compatible)

If you import a Product definition that already has a gateway type configured, that gateway type is retained.

For details of how to enable gateway services in a Catalog, see [Creating and configuring Catalogs](#).

Procedure

To specify the gateway type for a Product, complete the following steps:

1. Ensure that you know the type of gateway that your APIs are configured to use.
2. In the navigation pane, click  Develop, then select the Products tab.
3. Click the title of the Product you want to update.
4. On the Product Setup page, go to the Gateway Type section. Select the gateway type for your Product:
 - DataPower Gateway (v5 compatible)
 - DataPower API Gateway
 - Event Gateway

Note:

You can only select the gateway type that satisfies the selected enforced APIs in your Product. To change the APIs included in your product, see [Editing a draft Product](#).

5. Click Save to retain your changes.

Deleting a draft Product

You can delete draft Products that are no longer required.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the `Product-Drafts:Edit` permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see [Creating custom roles](#).

Note:

- Deleting a draft Product does not remove it from any Catalogs to which it has been published. For details on how to remove a Product from a Catalog, see [Removing a Product from a Catalog](#).
- You cannot directly delete a Product that was generated automatically from an API with the Activate API option; these Products have the title `api_title` auto product. To delete such Products, delete the API from which it was generated; the Product is deleted together with the API. For more information, see [Deleting an API definition](#).

Procedure

1. In the navigation pane, click  Develop.
2. Select the Products tab.
3. Alongside the Product version that you want to delete, click the options icon  and then click Delete.

Organizing your Products into categories

You can organize your Products into categories. The Products that you categorize are displayed within the Developer Portal, in their defined categories.

Before you begin

Your role must have the necessary permissions to stage and publish Products.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

By organizing your Products into categories, you can provide a hierarchical display for your Products in the Developer Portal.

Note: Organizing Products into a hierarchical view in the API Designer or API Manager UI is different to tagging in the Developer Portal.

Procedure

1. In the navigation pane, click  Develop, then select the Products tab..
2. Click the title of the Product that you want to work with.
3. Click Categories.
4. In the Categories text box, enter the hierarchical taxonomy path that you want your Product to follow, in the following format:

```
top_level_element / next_level_element / x_level_element
```

For example:

```
Animals / Fluffy / Cat
```

5. After you have completed entering the category specifications for the Product, click Save.

What to do next

- Publish the Product; see [Publishing a draft Product](#).
- After publishing the Product, you can, in the Developer Portal, display Products in the categories that you have defined. For more information, see [Displaying APIs and Products in categories](#).

Creating and validating API and Product definitions by using the CLI

The developer toolkit of IBM® API Connect provides a command line interface that you can use to create and publish API and Product definitions, and also to validate YAML or JSON definitions.

The following topics explain how to use the command line interface to create an OpenAPI definition file, create a Product definition file, and validate a YAML or JSON definition.

- [Creating an OpenAPI definition file](#)
APIs are defined in OpenAPI definition files, in YAML format. You can create a default OpenAPI definition file by using the **create** command and then modify it by using an editor of your choice.
- [Specifying a gateway type for an API definition](#)
An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). API definitions must specify which type of gateway the API uses.
- [Referring to an extension in an API definition](#)
To refer to an OpenAPI extension in your API definition YAML (or JSON) file, add an **extensions** key under **x-ibm-configuration**.
- [Using \\$ref to reuse code fragments in your OpenAPI files](#)
If you deploy an API to an IBM API Connect Management server by using the developer toolkit command line, you can use the **\$ref** field in your OpenAPI YAML and JSON API definition files to reference a fragment of OpenAPI code that is defined in a separate file. When API Connect processes the source API definition file, the **\$ref** field is replaced with the contents of the target file.
- [Creating a Product definition file](#)
You define a Product by creating a Product definition file.
- [Using x-ibm-languages to create multilingual API and Product documentation](#)
Create multilingual API and Product documentation by using the **x-ibm-languages** extension in your API and Product OpenAPI definitions.
- [Using x-example to control the examples displayed in the Developer Portal](#)
OpenAPI does not support the use of **example** attributes on parameters, only on request and response objects and their properties. To allow API Developers to be able to control the examples displayed in the portal you can use **x-example** in OpenAPI parameters.
- [Using x-embedded-doc to add additional documentation to products and APIs](#)
You can use **x-embedded-doc** to add additional documentation to a product or an API as part of their definition.

- [Using x-pathaliases to give consistent URLs for products and APIs](#)
You can use `x-pathaliases` to assign a URL to a product or an API.
- [Validating the YAML or JSON definition of an API or Product](#)
You can validate a YAML or JSON definition by using the IBM API Connect developer toolkit.
- [Creating and using API and Product definitions templates](#)
You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition.

Related reference

- [API development and management commands](#)

Creating an OpenAPI definition file

APIs are defined in OpenAPI definition files, in YAML format. You can create a default OpenAPI definition file by using the `create` command and then modify it by using an editor of your choice.

You can stage or publish the API directly to a Catalog in API Manager by referencing the API in a Product definition file, and then using the `apic products:publish` command to publish the Product. You can also create a draft API in API Manager by using the `apic draft-apis:create` command.

You can create an API in the CLI by running `apic create:api`, and supplying additional arguments on the command line.

Another option is to create an API interactively in the command line by running `apic create:api` and following the prompts.

You can see further details and available options for the `apic create:api` command by running:

```
apic create:api --help
```

IBM provides an extension to the OpenAPI specification; this extension is described in [IBM extensions to the OpenAPI specification](#).

Note: Products that contain an API with a Swagger property using `regex` that include lookahead assertions, such as "(?" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
  definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:
0)
400
```

Creating an API definition from a template

You can use a custom Handlebars template to create an API by using the following command:

```
apic create:api --template template_filename --title api_title
```

where `template_filename` is the name of the Handlebars template to use, and `api_title` is the title of your API.

An API template file must have a `.hbs` file name extension. You can create a template from scratch, or start with the example (default) API template provided in [API and Product definition template examples](#).

You can create multilingual API and Product documentation by using an `x-ibm-languages` extension directly in the OpenAPI definition. For more information, see [Using x-ibm-languages to create multilingual API and Product documentation](#).

- [IBM extensions to the OpenAPI specification](#)
You use the `x-ibm-configuration` object in your OpenAPI definition file to add extensions that are specific to IBM API Connect.

Related reference

- [API development and management commands](#)

IBM extensions to the OpenAPI specification

You use the `x-ibm-configuration` object in your OpenAPI definition file to add extensions that are specific to IBM® API Connect.

The `x-ibm-configuration` extension has the following structure:

```
x-ibm-configuration:
  enforced: enforced_boolean
  phase: Phase
  testable: test_boolean
  cors:
    enabled: cors_boolean
  activity-log:
    activity_logging_extension
  assembly:
    execute:
      - assembly_component
  gateway: gateway_type
  type: api_type
```

```

properties:
  properties_extension
catalogs:
  catalogs_extension

```

The following table lists the various extensions used by API Connect, whether they are required, a description of their use and behavior, and their type.

Table 1. IBM extensions

Extension	Required	Description	Type
phase	No	Use the phase extension to describe the maturity of the API. It can take the following values: <ul style="list-style-type: none"> identified: the API is in the early conceptual phase and is neither fully designed nor implemented. specified: the API has been fully designed and passed an internal milestone but has not yet been implemented. realized: the API is in the implementation phase. 	String
testable	No	Use the testable extension to specify whether the API can be tested using the test tool in the Developer Portal.	Boolean
enforced	No	Use the enforced extension to specify if the API Connect gateway is used to enforce the API. <ul style="list-style-type: none"> true indicates that the API Connect gateway is used to enforce the API. false indicates that the API Connect gateway is not used to enforce the API. 	Boolean
cors	No	Use the cors extension to specify whether CORS access control is used for the API. The extension has an enabled field which is a Boolean.	Object (with a single Boolean field)
API Gateway only activity-log	No	Use the activity-log extension to configure your logging preferences for the API activity that is stored in Analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.	Object
assembly	No	Use the assembly extension to describe the application of policies and logic to an API. It contains an execute field that contains an array of policies that are applied in order. It can contain a catch field that contains an array of error cases to be caught. For information about use of the execute field, see execute . For information about use of the catch field, see catch .	Object
gateway	No	Use the gateway extension to specify which type of gateway you want to use. If you are using the DataPower® Gateway (v5 compatible) or DataPower API Gateway, it must be included and take one of the following values: <ul style="list-style-type: none"> datapower-gateway (DataPower Gateway (v5 compatible)) datapower-api-gateway (DataPower API Gateway) For information about types of gateways, see API Connect gateway types .	String
type	No	The type extension takes one of the following values: <ul style="list-style-type: none"> rest wSDL 	
properties	No	Use the properties extension to define properties for use in an API.	Object (properties)
catalogs	No	Use the catalogs extension to define Catalog-specific values for properties defined in the properties extension.	Object (catalogs)

The following example shows the **x-ibm-extension** section of an API that is enforced by API Connect, is in the realized state, is testable through the test tool in the Developer Portal, has CORS access control enabled, and has a simple assembly that invokes a URL and then redacts a field from the request or response.

```

x-ibm-configuration:
  enforced: true
  phase: realized
  testable: true
  cors:
    enabled: true
  assembly:
    execute:
      - invoke:
          title: Example Invoke
          target-url: 'https://example.com/api'
          description: Example description
      - redact:
          actions:
            - action: redact
              from:
                - request
                - response
              path: /**[@name='secondaryAddress']/*[@name='streetAddress']
  properties:
    ID:
      value: 1234
      description: An ID to be used for validating.
      encoded: false
  catalogs:
    Sandbox:
      properties:
        ID: 5678

```

- [catch](#)
Use the **catch** extension to catch errors that occur during an API call.
- [properties](#)
Use the **properties** extension to define properties for referencing in an API.

- **catalogs**
Use the **catalogs** extension to assign catalog-specific values to properties defined in the **properties** section.
- **activity-log**
If you're using the DataPower API Gateway, you can use the **activity-log** extension to configure your logging preferences for the API activity that is stored in Analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.

execute

The execute field of an assembly has the following structure:

```
execute:
- Policy_1
- Policy_2
```

Note: Although some built-in policies can be used with both the DataPower® Gateway (v5 compatible) and the DataPower API Gateway, some policies are restricted to a particular Gateway. The following icons indicate which Gateway each policy can be used with:

-  Indicates that the policy can be run on the DataPower Gateway (v5 compatible).
-  Indicates that the policy can be run on the DataPower API Gateway.

For details of the two types of gateway, see [API Connect gateway types](#).

The following table describes the possible policies and logic constructs that can be included in an execute field.

Table 1. execute properties

Property	Required	Description	Data Type		
activity-log	No	Use the activity-log policy to log information that relates to the calling of API operations.	object (activity-log)	✓	✓ Functionality provided by the activity-log extension
client-security	No	Provides a range of options for authenticating client access to your APIs, extending the capabilities of the OpenAPI specification.	object (client-security)	✗	✓
gatewayscript	No	Include a GatewayScript program.	object (gatewayscript)	✓	✓
graphql-introspect	No	Use the graphql-introspect policy to introspect a GraphQL schema.	object (graphql-introspect)	✗	✓
if	No	Use the if policy to execute a section of the assembly only when a condition is fulfilled.	object (if)	✓	✓ Functionality provided by switch
invoke	No	Use the invoke policy to call an API. The last invoke in your policy might be replaced by a proxy automatically to improve performance. To disable this, see: API properties .	object (invoke)	✓	✓
json-to-xml	No	Convert payload from JSON to XML.	object (json-to-xml)	✓	✓
jwt-generate	No	Generate a JSON Web Token (JWT).	object (jwt-generate)	✓	✓
jwt-validate	No	Validate a JSON Web Token (JWT).	object (jwt-validate)	✓	✓
log	No	Use the log policy to customize or override the default activity logging configuration for an API.	object (log)	✗	✓
map	No	Use the map policy to transform variables.	object (map)	✓	✓
operation-switch	No	Use the operation-switch policy when you want to execute alternative policy assemblies, conditional on the operation that is being called.	object (operation-switch)	✓	✓
oauth	No	Use the oauth policy to perform OAuth processing based on defined OAuth provider settings.	object (oauth)	✗	✓
parse	No	Use the parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.	object (parse)	✗	✓
proxy	No	Proxy a service.	object (proxy)	✓	✓ Functionality provided by invoke
ratelimit	No	Use the ratelimit policy to apply one or more rate or burst limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls that an application can make to an API in a specified time period.	object (ratelimit)	✗	✓
redact	No	Use the redact policy to completely remove or to redact specified fields from the request body, the response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.	object (redact - DataPower API Gateway redact - DataPower Gateway (v5 compatible))	✓	✓
set-variable	No	Use the set-variable policy to set a runtime variable to a string value, or to add or clear a runtime variable.	object (set-variable)	✓	✓
switch	No	Use the switch policy to execute one of a number of sections of the assembly based on which specified condition is fulfilled.	object (switch)	✓	✓

Property	Required	Description	Data Type	DataPower Gateway	API Gateway
throw	No	Use the throw policy to specify points at which an error should be thrown.	object (throw)	✓	✓
user-defined-policy	No	You can apply your own user-defined policies to your APIs.	object (User-defined policies)	✓	✓
user-security	No	Extract a user's credentials, authenticate those credentials, and obtain authorization from the user.	object (user-security)	✗	✓
validate	No	Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.	object (validate - DataPower API Gateway , validate - DataPower Gateway (v5 compatible))	✓	✓
validate-username-token	No	Validate a WS-Security UsernameToken.	object (validate-username-token)	✓	✗
xml-to-json	No	Convert payload from XML to JSON.	object (xml-to-json)	✓	✓
xslt	No	Apply an XSLT transform to the payload.	object (xslt)	✓	✓

The following example shows an execute field for an assembly that invokes a URL and then redacts a field from the request or response.

```
execute:
- invoke:
  title: Example Invoke
  target-url: 'https://example.com/api'
  description: Example description
- redact:
  actions:
  - action: redact
    from:
    - request
    - response
  path: /**[@name='secondaryAddress']/**[@name='streetAddress']
```

activity-log

Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM® API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Activity Log](#).

Note: If you are using the DataPower API Gateway, you configure your logging preferences by using the [activity-log](#) extension.

About

The activity-log policy has the following format:

```
- activity-log:
  version: version
  title: title
  description: description
  content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
```

Apply this policy by adding an assembly extension with an execute field to your OpenAPI definition file.

You can also apply an activity-log policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see [Activity Log](#) in the built-in policies section.

Note: If payload logging is enabled, for the gateway to capture payloads buffering must also be enabled.

```
activity-log:
  success-content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
  enabled: is_activity_logging_enabled
  buffering: true
```

Properties

The following table describes the policy properties:

Table 2. Activity Log policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	A title for the policy.	string

Property	Required	Description	Data type
description	No	A description of the policy.	string
content	Yes	<p>Defines the type of content to be logged when the operation is successful.</p> <p>Valid values:</p> <ul style="list-style-type: none"> none: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. activity: Logs invocation only (only the resource URI is recorded). header: Logs activity and header. payload: Logs activity, header, and payload (the original request, if any, and the final response). <p>The default value is activity.</p>	string
error-content	No	<p>Indicates what content to log if an error occurs.</p> <p>Valid values:</p> <ul style="list-style-type: none"> none: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. activity: Logs invocation only (only the resource URI is recorded). header: Logs activity and header. payload: Logs activity, header, and payload (the original request, if any, and the final response). <p>The default value is payload.</p>	string

Example 1

```
# use defaults
- activity-log:
  version: 1.0.0
  title: default activity logging
```

Example 2

```
- activity-log:
  version: 1.0.0
  title: no logging for successful calls
  content: none
  error-content: activity
```

client-security

The client-security policy can be used to extend client authentication access for your APIs.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Client Security](#).

About

You use the client-security policy to create an assembly action that's separate from the OpenAPI specification, to allow for more options to authenticate an application. Note that you cannot use the client-security policy to perform rate-limiting enforcement.

In a client security action, you define the following settings.

- Control whether to stop processing if client security fails. When client security fails, stops assembly processing and returns an error.
- Control whether to require the client secret. When required, the secret is compared to the registered secret on the application that is identified by the client ID.
- Define the method to extract client credentials from the request.
 - For all methods except **http**, use the **id-name** and the **secret-name** properties to specify the location that contains the ID and the location that contains the secret.
 - When **cookie**, specify which cookie.
 - When **context-var**, specify which runtime context variable.
 - When **form**, specify the form data.
 - When **header**, specify which header.
 - When **query**, specify which query parameter.
 - For the **http** method, use the **http-type** property to specify the format of the authorization header, which expects the **basic** form in the **basic base64 id:secret** format.
- Define the method to authenticate the extracted client credentials. The supported methods are **native** (this means by using IBM® API Connect), or by using a specified **third-party** user registry.
 - If **third-party**, use the **user-registry** property to specify the user-registry to authenticate the extracted client credentials. The supported registry types are LDAP and authentication URL.

Properties

The client-security policy has the following format:

```
- client-security:
  version: version
  title: title
  description: description
  stop-on-error: is_processing_stopped_on_client_security_failure
  secret-required: is_client_secret_required_in_request
  extract-credential-method: method_for_supplying_credentials
  id-name: parameter_that_specifies_client_id
  secret-name: parameter_that_specifies_client_secret
  http-type: authentication_type
  client-auth-method: method_for_client_authentication
  user-registry: user_registry_for_client_authentication
```

Table 2. client-security policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
stop-on-error	Yes	If set to true , assembly processing stops if client security fails, and an error is returned.	boolean
secret-required	Yes	If set to true , the client secret must be sent in the request. The secret is compared to the registered secret on the application that is identified by the client ID.	boolean
extract-credential-method	Yes	Specify one of the following values to define how the calling application authenticates: <ul style="list-style-type: none"> • header: client ID and client secret credentials must be supplied in the request header. • query: client ID and client secret credentials must be supplied as query parameters in the request URL. • form: client ID and client secret credentials must be supplied as form data sent in a POST request. • cookie: client ID and client secret credentials must be supplied in a header called Cookie. • http: the calling application must authenticate by using basic authentication. • context-var: the credentials that are used for authenticating the client are obtained from context variables that you set in the assembly flow prior to the Client Security policy, by using a gatewayscript policy for example. The names of these context variables are determined by the values that you supply in the id-name and secret-name properties of the client-security policy. 	string
id-name	Yes, unless extract-credential-method is set to http	The name of the parameter whose value specifies the client ID. For all values of extract-credential-method other than context-var and http , the calling application must supply a parameter with this name, in the location defined by the extract-credential-method setting. For context-var , this property specifies the name of a context variable. This option does not apply if the extract-credential-method property is set to http .	string
secret-name	Yes, if secret-required is set to true and extract-credential-method is other than http	The name of the parameter whose value specifies the client secret. For all values of extract-credential-method other than context-var and http , the calling application must supply a parameter with this name, in the location defined by the extract-credential-method setting. For context-var , this property specifies the name of a context variable. This option does not apply if the extract-credential-method property is set to http .	string
http-type	Yes, if extract-credential-method is set to http	The authentication type. Currently, this must be set to basic .	string
client-auth-method	Yes	Specify one of the following values: <ul style="list-style-type: none"> • native: only client ID and client secret are used to authenticate the request. If extract-credential-method is set to http then the calling application must supply the client ID for the user name, and the client secret for the password. • third-party: a user registry is used to authenticate the client. If extract-credential-method is set to a value other than http then the calling application must supply the user name for the client ID, and the password for the client secret. 	string
user-registry	Yes, if the client-auth-method is set to third-party	Specify the value of the name property of the user registry that will be used to authenticate the client. The supported registry types are LDAP and authentication URL.	string

client-security policy example

```
- client-security:
  version: 2.0.0
  title: client-security
  stop-on-error: true
  secret-required: true
  extract-credential-method: cookie
  id-name: my-client-id
  secret-name: my-client-secret
  client-auth-method: third-party
  user-registry: myauthurl
```

extract

Use the extract policy to extract and transform data from fields in the API context.

Gateway support

Table 1. Gateways that support this policy and the corresponding policy versions

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Extract](#).

About

The extract policy specifies the data source that contains the content to transform, the fields that contain the content, and expressions that define how to transform the content. You use a subset of JSONata notation to specify the fields to extract and transform. For more information, see [Constructing JSONata expressions to extract and transform data](#).

The input to the extract policy must be parsed data. One way to produce parsed data is to add a parse policy before the extract policy in your assembly.

The extract policy has the following format:

```
- extract:
  version: 2.0.0
  title: title
  root: data source
  extracts:
    - capture: path expression that identifies the field
      transform: expression that defines how to transform the content
      .
      .
      .
  description: description
```

Apply this policy by adding an `assembly` extension with an `execute` field to your OpenAPI definition file.

Properties

Table 2. extract policy properties

Property label	Required	Description	Data type
version	Yes	The policy version number. You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.	string
title	Yes	The title of the policy. The default value is <code>extract</code> .	string
description	No	A description of the policy.	string
root	Yes	The data source that contains the content to transform. The default value is <code>message.body</code> .	string
capture	Yes	The path expression that identifies the field. The default setting is <code>\$</code> , which indicates the entire input.	string
transform	Yes	The expression that defines how to transform the content.	string

Example

Transform the contents of the `account` field to include only the last 4 characters.

```
- extract:
  version: 2.0.0
  title: extract
  root: message.body
  extracts:
    - capture: $.members.policy.**.account
      transform: $substring($,-4)
  description: Include only the last 4 characters of the account field.
```

gatewayscript

Use the gatewayscript policy to execute a specified DataPower GatewayScript program.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [GatewayScript](#).

About

The gatewayscript policy has the following structure:

```
- gatewayscript:  
  version: version  
  title: Title  
  description: Description  
  source: Script
```

Properties

The following table describes the policy properties:

Table 2. gatewayscript policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
source	Yes	The GatewayScript source code to execute.	string

Example

The following is an example of a simple gatewayscript policy:

```
- gatewayscript:  
  version: 1.0.0  
  title: Example_GatewayScript  
  source: console.debug('Hello World!');  
  description: A simple GatewayScript policy.
```

For more information about how to use a gatewayscript policy, see [GatewayScript](#) in the built-in policies section.

For more code examples, see [GatewayScript code examples](#) and, if you are using the DataPower API Gateway, [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#).

For general information on using GatewayScript, see the following topics in the DataPower product documentation:

- [GatewayScript APIs for API management](#)
- [Accessing and manipulating a variable in the API context](#)
- [OAuth context variables](#)

Related concepts

- [Variable references in API Connect](#)

graphql-introspect

Use the graphql-introspect policy to introspect a GraphQL schema.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [GraphQL introspect](#).

Properties

Table 2. graphql-introspect policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
input	No	A variable in the API context that contains the input to introspect. The content of the body field of the variable is the input to introspect. By default, the variable name is message .	string
output	No	A variable in the API context where the results of the introspection are stored. The content of the body field of the variable is the result of GraphQL introspection. The default variable name is the same as that of the variable specified for the input field. Therefore, by default, the input of the introspection is overwritten by the output.	string

Example

```
- graphql-introspect:
  version: 2.0.0
  title: introspect the accounts graphql schema
  input: message
```

if

Use the if construct when you want to execute a portion of your assembly only when a specific condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by switch	

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [if](#).

About

The if policy has the following format:

```
- if:
  version: version
  title: title
  description: description
  condition: 'condition_1'
  execute:
    policy_assembly_1 ...
```

In the condition field, use the form `apim.getvariable('context.location.variable')` to reference your variables, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable.

The **execute**: section can define any policy assembly, including further if policies. For more information, see [execute](#).

Properties

Table 2. if policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
condition	Yes	A script that returns true or false . Use GatewayScript for a DataPower Gateway implementation. For information about the context variables you can use and how to reference them in your script, see API Connect context variables .	string
execute	Yes	The policy assembly that you want to execute if the condition returns true . For more information, see execute .	string

Example

```
# carry out different redaction actions depending on the operation

- if:
  version: 1.0.0
  title: clear_region_and_set_body
  condition: 'apim.getvariable('request.body.secret') == true'
  execute:
    - redact:
      title: remove secret field
      actions:
        - action: remove
          from: all
          path: /document/user/secret
```

invoke

Use the invoke policy to call an API.

Gateway support

Restriction: It is not possible to cache a request that includes the Authorization request header.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0
	2.1.0 (DataPower API Gateway Version 10.0.1.1 or later)
	2.2.0 (DataPower API Gateway Version 10.0.2.0 or later)
	2.3.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Invoke](#).

About

The invoke policy does not support responses with multipart form data, that is, when the response is set to Content-Type: multipart/related.

The invoke policy has the following format:

```
- invoke:
  version: version
  title: title
  description: description
  target-url: URL_of_target_API
  backend-type: how_payload_is_sent_to_backend
  tls-profile: TLS_profile_to_be_used
  verb: method_type
  timeout: timeout_value_in_seconds
  compression: is_data_to_be_compressed
  username: username_if_authentication_required
  password: password_if_authentication_required
  output: location_of_the_invoke_result
  cache-key: unique_identifier_of_the_document_cache_entry
  cache-response: cache_behavior
  cache-putpost-response: response_caching_behavior
  cache-ttl: cache_time_to_live
  inject-proxy-headers: are_proxy_headers_sent_to_target_url
  decode-request-params: are_request_parameters_decoded
  encode-plus-char: are_plus_characters_encoded
  keep-payload: is_payload_sent_on_delete
  use-http-10: are_transactions_restricted_to_http_1.0
  chunked-uploads: are_chunked_encoded_documents_sent_to_the_server
  persistent-connection: are_persistent_connections_enabled
  header-control:
    .
    .
    .
    headers_to_copy_to_target_url
    .
    .
  parameter-control:
    .
    .
    .
    parameters_to_copy_to_target_url
    .
    .
  follow-redirects: url_redirection_behavior
  stop-on-error: errors_that_stop_the_flow
```

Properties

The following table describes the properties of the invoke policy.

Table 2. Invoke policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
target-url	Yes	The URL of the target API.	string

Property	Required	Description	Data type
API Gateway only backend-type	No	Specify one of the following values to determine how the payload is sent to the backend: <ul style="list-style-type: none"> detect: detect the message type and send the payload to the backend accordingly. xml: package the payload as XML and send. If the message type is not XML, the operation fails. json: package the payload as JSON and send. If the message type is not JSON, the operation fails. binary: package the payload as binary and send, regardless of the message type. graphql: package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. <p>The default value is detect.</p>	string
API Gateway only graphql-send-type (policy version 2.2.0 and later)	Yes, if backend-type is set to graphql or detect , and verb is set to POST or keep .	Specify one of the following values to determine how the GraphQL payload is sent to the back end: <ul style="list-style-type: none"> detect: detect the message type and send the payload to the back end accordingly. graphql: package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. json: package the payload as JSON and send. If the message type is not GraphQL, the operation fails. <p>Note: graphql-send-type is supported only if backend-type is set to graphql or detect, and verb is set to POST or keep.</p>	string
tls-profile	No	Specifies a TLS profile to use for the secure transmission of data. Note: If you want to edit the API in the source view, make sure that the tls-profile value follows this format: name:version. For instance, it should look like nameofmynstlsclientprofile:1.0.0.	string
verb	No	The operation method type. Valid values: <ul style="list-style-type: none"> GET POST PUT DELETE PATCH HEAD OPTIONS <p>The default value is GET. However, if the property is omitted from the source, the HTTP method from the incoming request is used.</p>	string
timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is 60 .	integer
API Gateway only http-version (policy version 2.1.0 and later)	Yes	The HTTP version that will be used when connecting to the backend server. Valid values: <ul style="list-style-type: none"> HTTP/1.0 HTTP/1.1 HTTP/2 	string
API Gateway only http2-required (policy version 2.1.0 and later)	No	Set this property to true to require that the server selects HTTP/2 during a TLS connection, otherwise the DataPower API Gateway rejects the connection and fails the request. For a non TLS connection, a warning is logged stating that the requirement can't be enforced. This setting applies only if http-version is set to HTTP/2 .	boolean
compression	No	Specifies whether data is to be compressed by using compress before it is uploaded. The default value is false .	boolean
username	No	The username to use for HTTP Basic authentication.	string
password	No	The password to use for HTTP Basic authentication.	string
output	No	The name of a variable that will be used to store the response data from the request. By default, the invoke response, that is the body, headers, statusCode and statusMessage, is saved in the variable <i>message</i> . Use this property to specify an alternate location to store the invoke response. This variable can then be referenced in other actions, such as map . Note: If you want the response to be saved in <i>message</i> , leave the output property blank, do not supply the value <i>message</i> .	string
cache-key	No	Specifies the unique identifier of the document cache entry.	string
API Gateway only websocket-upgrade (policy version 2.1.0 and later)	No	Set this property to true to allow an HTTP or HTTPS connection to be upgraded to the WebSocket protocol if the request received by the corresponding HTTP or HTTPS handler on the DataPower API Gateway uses WebSocket (ws) or WebSocket Secure (wss). Note: <ul style="list-style-type: none"> This property is available only for GraphQL APIs. The websocket-upgrade property is deprecated. To allow WebSocket upgrade requests that can manage API processing data, define an assembly WebSocket upgrade policy. For more information, see websocket-upgrade. 	boolean

Property	Required	Description	Data type
cache-response	No	The cache response type. Valid values: <ul style="list-style-type: none"> protocol: The cache behavior is defined by the Cache-Control headers on the request and response. no-cache: Specifies that there is no caching. However, if the document is already in the cache, the document is retrieved from the cache. time-to-live: Specifies that the response stays in the cache for the specified time. The default value is protocol .	string
cache-putpost-response	No	Specifies whether to cache the response from POST and PUT requests. Caching the response from POST and PUT requests can reduce server load and reduce latency in the response to the client request. The default value is false .	boolean
cache-ttl	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property cache-response is set to time-to-live . Enter a value in the range 5 - 31708800. The default value is 900 .	integer
API Gateway only inject-proxy-headers	No	When set to true, the invoke policy injects the X-Forwarded-For , X-Forwarded-To , X-Forwarded-Host , and X-Forwarded-Proto headers to the request that is sent to the target-url . The default value is false .	boolean
API Gateway only decode-request-params	No	When set to true, any request parameters that are referenced by a variable definition on the target-url of the invoke policy are URL-decoded. The default value is false .	boolean
API Gateway only encode-plus-char	No	When set to true, all "+" characters in the query parameter values of the target-url are encoded to %2F. The default value is false .	boolean
API Gateway only keep-payload	No	When set to true, the invoke policy sends a payload on an HTTP DELETE method. The default value is false .	boolean
API Gateway only use-http-1.0 (policy version 2.0.0 only)	No	When set to true, HTTP transactions are restricted to version 1.0. The default value is false .	boolean
API Gateway only chunked-uploads	No	If you set this property to true , chunked-encoded documents are sent to the server. When the HTTP 1.1 protocol is used, the body of the document can be delimited by either Content-Length or chunked encoding. While all servers can interpret Content-Length , many applications fail to understand chunked-encoded documents. For this reason, Content-Length is the standard method. The use of Content-Length interferes with the ability of the DataPower Gateway to fully stream. If you must stream full documents to the target server, enable this property. When enabled, the server must be RFC 2616 compatible. Unlike all other HTTP 1.1 features that can be negotiated down at run time, you must know beforehand that the target server is RFC 2616 compatible. The default value is true . Note: Chunked encoding is not supported by the HTTP 1.0 protocol.	boolean
API Gateway only persistent-connection (policy version 2.3.0 and later)	No	Set this property to true to enable HTTP persistent connections, allowing connection re-use. The default value is true .	boolean
API Gateway only header-control: type values	No	Specifies the headers in message.headers that you want to copy to the target URL. If the type property is set to blocklist , the values property lists the headers that you don't want to be copied. If the values property is empty then all headers are copied. If the type property is set to allowlist , the values property lists the headers that you want to be copied. The items that are listed in the values property are in regular expression format. The values are not case-sensitive. The default value of the header-control property is header-control: type: blocklist values: [] See header-control examples	object
API Gateway only parameter-control: type values	No	Specifies the parameters in the incoming request that you want to be copied to the target URL. If the type property is set to blocklist , the values property lists the parameters that you don't want to be copied. If the type property is set to allowlist , the values property lists the parameters that you want to be copied. If the values property is empty then no parameters are copied. The items that are listed in the values property are in regular expression format. The values are not case-sensitive. The default value of the parameter-control property is parameter-control: type: allowlist values: [] See parameter-control examples	object

Property	Required	Description	Data type
<div style="border: 1px solid green; padding: 2px;">API Gateway only</div> follow-redirect	No	Specifies the behavior if the back-end server returns the HTTP status code 301 Moved Permanently . If this property is set to true , the invoke policy follows the URL redirection by making a further call to the URL specified in the Location header in the response. If this property is set to false , the invoke saves the 301 status code and the API call is considered to be complete. Note: The follow-redirect property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the invoke always follows the URL redirection; the proxy policy (not supported by the DataPower API Gateway) saves the 301 status code and completes the API call without following the URL redirection.	boolean
stop-on-error	No	List the errors that, if thrown during the policy execution, cause the flow to stop. If there is a catch flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors specified for the Stop on error property, or if the error thrown is not one of the specified errors, the policy execution is allowed to complete, and the assembly flow continues.	string

Example

```
- invoke:
  version: 2.0.0
  title: get the account status
  target-url: https://example.com/accounts/{id}?status={status}
  cache-response: time-to-live
  cache-putpost-response: true
  tls-profile: MyTLSProfile:1.0.0
  verb: POST
  timeout: 60
  compression: false
  username: MyUser
  password: MyPassword
  stop-on-error:
    - ConnectionError
    - OperationError
```

API Gateway only

header-control examples

```
# copy all headers to the target URL

- invoke:
  target-url: http://myhost/mypath
  header-control:
    type: blocklist
    values: []

# copy all headers except X-Client-ID and Content-Type

- invoke:
  target-url: http://myhost/mypath
  header-control:
    type: blocklist
    values:
      - ^X-Client-ID$
      - ^Content-Type$

# copy no headers

- invoke:
  target-url: http://myhost/mypath
  header-control:
    type: allowlist
    values: []

# copy only the Content-Type header

- invoke:
  target-url: http://myhost/mypath
  header-control:
    type: allowlist
    values:
      - ^Content-Type$
```

API Gateway only

parameter-control examples

```
# copy no request parameters to the target URL

- invoke:
  target-url: http://myhost/path?storeid=3
  parameter-control:
    type: allowlist
    values: []

# append the petid parameter to the target URL
# if the incoming request is http://apigw.org/sandbox/petstore/base?petid=100&display=detailed,
# the target URL at runtime will be http://myhost/mypath?storeid=3&petid=100

- invoke:
  target-url: http://myhost/path?storeid=3
  parameter-control:
    type: allowlist
```

```
values:
- ^petid$
```

json-to-xml

Use the json-to-xml policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [JSON to XML](#).

About

The json-to-xml policy has the following structure:

```
- json-to-xml:
  version: version
  title: Title
  description: Description
```

Note: If you are using the DataPower API Gateway, the input to the json-to-xml policy must be parsed data. One way to produce parsed data is to use a [parse](#) policy before a json-to-xml policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. Policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
API Gateway only input	No	The input message to convert. Specify the name of a variable in the API context. variableName.body , the message payload, represents the JSON input to convert. The default value of the variable is message and message.body is the default input.	string
API Gateway only output	No	The output message to store the conversion result. Specify the name of a variable in the API context. variableName.body represents the result of conversion from JSON format to XML format. When the specified input message is the default message, the default output is message.body . Otherwise, when the input message is the variable my-message-variable , for example, the default output is my-message-variable.body . The variable cannot be any read-only in the API context.	string
API Gateway only conversionType	No	The conversion type that determines the target format of the output. The following options are available: <ul style="list-style-type: none">None: No conversion of the output takes place.badgerFish: BadgerFish convention is used to determine the target conversion format of the output.	string
root-element-name	Yes	The root element name of the resultant XML document. This property is used only if the input JSON document is not hierarchical and has more than one uppermost level property, or if the always-output-root-element property is set to true .	
always-output-root-element	Yes	Select this property to true you always want the policy to output the root element, even if it is not required to make the XML document well formed.	boolean
unnamed-element-name	No	The XML element name to be used for JSON array elements.	string

Example

The following is an example of a json-to-xml policy:

```
- json-to-xml:
  version: 1.0.0
  title: JSON to XML transform
  description: Transforms JSON message body to XML format
```

jwt-generate

Use the Generate JWT security policy in IBM® API Connect to generate a JSON Web Token (JWT).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Generate JWT](#).

About

The jwt-generate policy has the following structure:

```
- jwt-generate:
  version: version
  title: title
  description: description
  jwt: json_web_token
  jti-claim: jwt_id_claim
  iss-claim: issuer_claim
  exp-claim: validity_period
  sub-claim: subject_claim
  aud-claim: audience_claim
  jws-jwk: sign_jwk_variable_name
  jws-alg: cryptographic_algorithm
  jws-crypto: sign_crypto_object
  jwe-enc: encryption_algorithm
  jwe-jwk: encrypt_jwk_variable_name
  jwe-alg: key_encryption_algorithm
  jwe-crypto: encrypt_crypto_object
```

Properties

The following table describes the policy properties:

Table 2. Generate JWT policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
jwt	No	Runtime variable in which to place the JWT that is generated. The default value is: generated.jwt . However, if not set, the JWT that is generated is written to the Authorization Header as a Bearer token.	string
jti-claim	No	Indicates whether a JWT ID (jti) claim should be added to the JWT. If selected, the property is set to true , and a UUID is generated and set as the JTI claim value.	boolean
iss-claim	Yes	Runtime variable from which the Issuer (iss) claim string can be retrieved. This claim represents the Principal that issued the JWT. The default value is: iss.claim	string
sub-claim	No	Runtime variable from which the Subject (sub) claim string can be retrieved.	string
aud-claim	No	Runtime variable from which the Audience (aud) claim string can be retrieved. Multiple variables are set by using a comma-separated string.	string
exp-claim	Yes	The length of time (in seconds), that is added to the current date and time, in which the JWT is considered valid. The default value is 3600 .	integer
private-claims	No	Runtime variable from which a valid set of JSON claims can be retrieved. These claims are added to any set of claims specified previously.	string
jws-jwk	No	Runtime variable that contains the JWK that is used to sign the JWT. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to sign the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jws-alg	No	The cryptographic algorithm to use. Valid values are: <ul style="list-style-type: none"> • HS256 • HS384 • HS512 • RS256 • RS384 • RS512 • ES256 • ES384 • ES512 • PS256 • PS384 • PS512 	string
jws-crypto	No	The cryptographic object to use to sign the JWT. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to sign the JWT. However, if both data types are specified, only the Crypto Object is used.	string

Property	Required	Description	Data type
jwe-enc	No	The encryption algorithm to use. Valid values are: <ul style="list-style-type: none"> A128CBC-HS256 A192CBC-HS384 A256CBC-HS512 	string
jwe-jwk	No	Runtime variable that contains the JWK to use to encrypt the JWT.	string
jwe-alg	No	The key encryption algorithm to use. Valid values are: <ul style="list-style-type: none"> RSA1_5 RSA-OAEP RSA-OAEP-256 dir A128KW A192KW A256KW 	string
jwe-crypto	No	The cryptographic object to use to encrypt the claim.	string

Example

The following is an example of a jwt-generate policy:

```
- jwt-generate:
  version: 1.0.0
  title: jwt-generate
  iss-claim: iss.claim
  exp-claim: 3600
  jwt: generated.jwt
  jti-claim: true
  sub-claim: sub.claim
  aud-claim: aud.claim
  private-claims: private.claims
  jws-jwk: jws.jwk
  jws-alg: HS256
  jws-crypto: jwsCryptoObjectName
  jwe-enc: A128CBC-HS256
  jwe-jwk: jwe.jwk
  jwe-alg: A128KW
  jwe-crypto: jweCryptoObjectName
```

For more information about how to use a jwt-generate security policy, see [Generate JWT](#) in the built-in policies section.

jwt-validate

Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Validate JWT](#).

Note:

- If the original message was signed with a Shared Secret Key, the cryptographic object that is specified must also be a Shared Secret Key.
- If the original message was signed with a Private Key, the cryptographic object that is specified must be a Crypto Certificate (public certificate).
- The cryptographic material can be provided through a JSON Web Key (JWK).
- If a JWK header parameter is included in the header of the JWT, the parameter must match the JWK or cryptographic object that is specified in the policy, or the JWT validation will fail.
- If both a cryptographic object and a JWK are specified, the cryptographic object is used to decrypt or verify the JWT.
- The JWT validate action on the DataPower API Gateway can verify a JWT by using either a single JWK, or a JWK set.

About

The jwt-validate policy has the following structure:

```
- jwt-validate:
  version: version
  title: title
  description: description
  jwt: json_web_token
  output-claims: output_full_set_of_jwt_claims
  iss-claim: issuer_claim
  aud-claim: audience_claim
  jwe-crypto: decrypt_crypto_object
```

```
jwe-jwk: decrypt_crypto_jwk_variable_name
jws-crypto: verify_crypto_object
jws-jwk: verify_crypto_jwk_variable_name
```

Properties

The following table describes the policy properties:

Table 2. Validate JWT policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
jwt	Yes	Context or runtime variable that contains the JWT to be validated. The default value is: <code>request.headers.authorization</code> . However, if this property is not set, the policy looks for the JWT in the <code>request.headers.authorization</code> location by default. Note: The format of the authorization header must be: <code>"Authorization: Bearer jwt-token"</code> where <code>jwt-token</code> is the encoded JWT.	string
output-claims	Yes	Runtime variable to which the full set of claims that are contained in the JWT is assigned. The default value is: <code>decoded.claims</code> .	string
iss-claim	No	The Perl Compatible Regular Expressions (PCRE) to use to validate the Issuer (iss) claim.	string
aud-claim	No	The PCRE to use to validate the Audience (aud) claim.	string
jwe-crypto	No	The cryptographic object (a shared key or certificate) to use to decode the claim. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to decrypt the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jwe-jwk	No	Runtime variable that contains the JWK to use to decrypt the JWT. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to decrypt the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jws-crypto	No	The cryptographic object (a shared key or certificate) to use to verify the signature. A JWK, or a JWK set, and a Crypto Object are both valid ways of providing the cryptographic data necessary to verify the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jws-jwk	No	Runtime variable that contains the JWK, or a JWK set, to use to verify the signature. A JWK, or a JWK set, and a Crypto Object are both valid ways of providing the cryptographic data necessary to verify the JWT. However, if both data types are specified, only the Crypto Object is used.	string

Example

The following is an example of a `jwt-validate` policy:

```
- jwt-validate:
  version: 1.0.0
  title: jwt-validate
  jwt: request.headers.authorization
  output-claims: decoded.claims
  iss-claim: "'^data.*'"
  aud-claim: "'^id.*'"
  jwe-crypto: jweCryptoObjectName
  jwe-jwk: jwe.jwk
  jws-crypto: jwsCryptoObjectName
  jws-jwk: jws.jwk
```

For more information about how to use a `jwt-validate` security policy, see [Validate JWT](#) in the built-in policies section.

log

Use the `log` policy to customize or override the default activity logging configuration for an API.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Log](#).

About

The `log` policy has the following format:

```

- log:
  version: version
  title: title
  description: description
  mode: activity_logging_actions
  log-level: type_of_content_to_log

```

Properties

The following table describes the properties of the log policy.

Table 2. log policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
mode	Yes	<p>Specify one of the following values:</p> <ul style="list-style-type: none"> gather-only: gather all analytics data and write it to the <code>log</code> context variable, which populates the API event record on completion of the API execution. For more information on the fields in the <code>log</code> context variable, and the consequent API event record, see API event record fields. send-only: perform the following actions: <ul style="list-style-type: none"> Read the data from the <code>log</code> context variable. Truncate all message payloads and convert to a textual representation. Send the data to the analytics server. gather-and-send: perform a gather-only operation, immediately followed by a send-only operation. <p>If you use the Send-only or Gather-and-send option, data is buffered and sent to the analytics server in batches according to the time interval configured for the Analytics Endpoint on the DataPower API Gateway. For more information, see Configuring an analytics endpoint in the DataPower knowledge center.</p> <p>Note: If you are offloading to a third party analytics server, you can redact any aspect of the event data. If you are using API Connect analytics, you can redact only request and response payloads.</p>	string
log-level	No	<p>The type of content to log. Specify one of the following values:</p> <ul style="list-style-type: none"> none: Indicates no logging. activity: Logs the invocation only, which is only the resource URI. header: Logs activity and header. payload: Logs activity, header, and payload. default: Use the log level setting defined in the API definition; for more information, see activity-log. This is the default value. \$(value): An inline parameter in the format <code>\$(value)</code> to retrieve a value from the API context. 	string

Example

```

- log:
  version: 2.0.0
  title: Gather activity log data for processing
  mode: gather-only

```

map

Use the map policy to transform your assembly flow and specify relationships between variables.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0
	2.1.0 (DataPower API Gateway Version 10.5.0.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Map](#).

About

For information about the use and structure of the map policy, see [The Map policy structure](#). For more information about API properties that affect the map policy, see [API properties](#).

The map policy has the following format:

```

- map
  version: version
  title: title
  description: description

```

```

inputs:
- input_1:
  variable: context_1
  $ref: '#/definitions/definition_1'
- input_2
  variable: context_2
  type: type_2
  content: content_type

outputs:
- output_3
  variable: context_3
  type: type_3

actions:
- set: output_3.output_property_3
  from: input_1.input_property_1

- set: output3.output_property_3
  from:
  - input1.input_property_1
  - input2.input_property_2
  value: 'script_A'
  default: 'default_A'

- create: output3.output_property_3
  from: input1.input_property_1
  foreach: input1.input_property_1
  actions:
  - further_actions
options:
.
.
.
advanced_XML_and_general_configuration_options
.
.
.

```

Properties

Table 2.

Property	Required	Description	Data type	Belongs to
version	Yes	The policy version number.	string	N/A
title	No	A title for the policy.	String	N/A
description	No	A policy description.	String	N/A
inputs	No	An array listing the inputs of the map policy.	Object	N/A
outputs	Yes	An array listing the outputs of the map policy.	Object	N/A
variable	Yes	A reference to the context variable that is the location of the input or output variable..	String	inputs or outputs
\$ref	Yes ¹	A reference to the definition of the type of the variable.	String	inputs or outputs
type	Yes ¹	The type of the variable.	String	inputs or outputs
content	No	The content type of the variable: <code>application/xml</code> or <code>application/json</code> . If <code>None</code> is selected, or the field is not included, then the type is treated as JSON.	String	inputs or outputs
actions	Yes	Lists actions to be performed by the map policy.	Object	N/A
set	Yes ²	Specifies by name the output variable that is to be set to a value by the action.	String	actions
create	Yes ²	Specifies by name the output variable that is to have a value appended to it by the action.	String	actions
from	No	Specifies by name any input variables used by the action.	String	actions
value	No	Contains a script that maps and transforms input variables into output variables.	String	actions
default	No	Contains a static value, or an inline variable reference, to be applied to the output when no input value is provided. For information on inline variable references, see inline references .	String	actions
foreach	No	Specifies by name an array for which further actions should be performed for each element.	String	actions
includeEmptyXMLElements	No	If set to <code>true</code> , empty XML elements are included in the output of the map policy. Set to <code>false</code> if you do not want empty XML elements to be included in the output of the map policy. The default value is <code>true</code> .	Boolean	options
namespaceInheritance	No	If set to <code>true</code> , XML namespaces are inherited from the parent element. Set to <code>false</code> if you want the map policy to use explicit namespaces. The default value is <code>true</code> .	Boolean	options
inlineNamespaces	No	If set to <code>true</code> , XML namespaces will be inserted into the document where they are first used. Set to <code>false</code> if you want namespaces to all be defined on the root element. The default value is <code>true</code> .	Boolean	options
API Gateway only mapResolveXMLInputDataType	No	If set to <code>true</code> , XML elements whose schema is configured as type boolean or numeric will be converted to that data type. Set to <code>false</code> if you want all XML element values to be returned as a string.	Boolean	options
API Gateway only mapParseXMLOutput	No	If set to <code>true</code> , the map policy will write XML output to <code>message.body</code> as a parsed XML document. By default, the XML will be output as an XML string. XML output to any other variable will always be written as an XML string. The default value is <code>false</code> .	Boolean	options

Property	Required	Description	Data type	Belongs to
<div style="border: 1px solid green; padding: 2px; display: inline-block;">API Gateway only</div> mapXMLEmptyElement	No	<p>This property controls how the map policy handles the output of an empty XML element. Specify one of the following values:</p> <ul style="list-style-type: none"> string (the default option): An empty XML element is handled as an empty string. null: An empty XML element is handled as a null value. none: The data is ignored. <div style="border: 1px solid green; padding: 2px; display: inline-block;">API Gateway only</div> string-badgerfish: The value for an empty XML element is considered to be an empty string. The empty string value will be placed into a JSON badgerfish value property. <div style="border: 1px solid green; padding: 2px; display: inline-block;">API Gateway only</div> null-badgerfish: The value for an empty XML element is considered to be null. The null value will be placed into a JSON badgerfish value property. A mapping of this element to a JSON output property does not occur unless the mapNullValue property is set to true. 	String	options
<div style="border: 1px solid green; padding: 2px; display: inline-block;">API Gateway only</div> mapArrayFirstElementValue	No	<p>If set to true, then if an array is encountered in the traversal of the input, only the first element is used. Set to false if you want the map policy to use all array elements. The default value is false.</p>	Boolean	options
<div style="border: 1px solid green; padding: 2px; display: inline-block;">API Gateway only</div> mapResolveApicVariables	No	<p>If set to true, API Connect variable references found in the map properties are resolved. Set to false if you want the map policy to ignore API Connect variable references in the map policies. The default value is false.</p>	Boolean	options
<div style="border: 1px solid green; padding: 2px; display: inline-block;">API Gateway only</div> mapNullValue	No	<p>If set to true, an input property value with a null value is mapped to the output document. Set to false if you want the map policy to ignore null input values. The default value is false.</p>	Boolean	options
<div style="border: 1px solid green; padding: 2px; display: inline-block;">API Gateway only</div> mapOptimizeSchemaDefinition	No	<p>If set to true, complex schema types evaluation handles circular type references in an optimized manner. Set to false to evaluate these schema types in a standard manner. The default value is false.</p>	Boolean	options
<div style="border: 1px solid green; padding: 2px; display: inline-block;">API Gateway only</div> mapEmulateV4DefaultRequiredProps	No	<p>If set to true, default values are generated in the output for required properties that are either not mapped, or for which there is no input data present, in the following specific cases:</p> <ul style="list-style-type: none"> An array consists of objects that contain one or more required properties. An object which is optional has one or more child properties that are required. <p>By default, these required properties are not present in the output. If you set this property to true, these required properties will be present in the output. If the output schema defines a default property for the output property then the specified default value is used, otherwise default value is assigned dependent on the data type, as follows:</p> <ul style="list-style-type: none"> String: empty string ("") Number: 0 Boolean: false Object: empty object Array: empty array <p>Example 1</p> <p>The input data has the following array of objects:</p> <pre>[{"a": "value1"}, {"a": "value2", "b": "value3"}]</pre> <p>The output schema defines the output object as having two properties, a and b, of which b is required. The map policy defines the following mappings:</p> <ul style="list-style-type: none"> input.array.a to output.array.a input.array.b to output.array.b <p>If this property is set to true, and b is either not mapped or has no input data present, then b is assigned a default value of an empty string, and the output is as follows:</p> <pre>[{"a": "value1", "b": ""}, {"a": "value2", "b": "value3"}]</pre> <p>Example 2</p> <p>The output schema defines the following structure:</p> <pre>{"a" : {"b" : {"c" : "value1", "d" : "value2"} } }</pre> <p>Property b is optional but property d within b is required.</p> <p>The map policy defines a mapping to output.a.b.c.</p> <p>If this property is set to true, and d is not mapped, then d is assigned a default value of an empty string, and the output is as follows:</p> <pre>{"a" : {"b" : {"c" : "value1", "d" : ""} } }</pre> <p>If this property is set to false, these required properties are not created in the output with their default values.</p> <p>The default value is false.</p>	Boolean	options

Property	Required	Description	Data type	Belongs to
API Gateway only mapEnablePostProcessingJSON	No	If set to true , mapped JSON output is post processed. The post processing of JSON output will use the output schema to ensure that property values are of the same data type as that defined in the schema. It will also normalize output property values that have a Badgerfish JSON syntax due to object mapping of an XML input. Set to false if you want no post processing of mapped JSON output. The default value is false .	Boolean	options
API Gateway only mapCreateEmptyArray	No	This property controls how the map policy handles the output of an empty array. Specify one of the following values: <ul style="list-style-type: none"> all: Output all empty arrays, including empty children arrays. parent: Output only the current property's empty array value. Children map actions of this property are not attempted. none: Prevent any empty output array values from being produced. The default value is all .	String	options
API Gateway only mapReferenceLimit	No	Set the value of this property to an integer value that specifies the maximum allowed number of iterations of a circular schema definition. The default value is 1, which means that circular schema definitions are not followed. The maximum possible value is 5. If you specify a value greater than 5, a value of 5 is assumed. If you specify a non-numeric value, a value of 1 is assumed.	String	options
messagesInputData	No	This property defines the severity level for log messages that relate to input data. Specify one of the following values: <ul style="list-style-type: none"> error warn info 	String	options
API Gateway only mapEmulateV4EmptyJSONObject	No	If a mapping fails because its input is not present and there is no default mapping configured, the default behavior is to not to make any change to the output mapping. Set this property to true to create an empty object for the parent of the target mapping, emulating the behavior of IBM® API Management Version 4.0. Example The map policy defines a mapping to output.a.b.c . If input data is present, the output is as follows: <pre> { "a": { "b": { "c": "inputvalue" } } } </pre> If there is no input data, and the mapEmulateV4EmptyJSONObject option is set to true , the output is as follows: <pre> { "a": { "b": { } } } </pre> Properties a and b are created but the value of b is an empty object. The default value is false .	Boolean	options

¹ There must be one of \$ref or type in the description of a variable.

² There must be one of set or create in an actions field.

Example

```

- map:
  version: 1.0.0
  title: Output mapping
  inputs:
    Monthly_cost:
      schema:
        type: double
      variable: loan_invoke.body.monthly_payment
      content: application/json
    Duration:
      schema:
        type: integer
      variable: request.parameters.duration
  outputs:
    Quote_Output:
      schema:
        $ref: '#/definitions/Quote_Output'
      variable: message.body
      content: application/json
  actions:
    - set: Quote_Output.monthly_repayment
      from: Monthly_cost

```

```

value: ''
- set: Quote_Output.total_cost
  from:
    - Duration
    - Monthly_cost
  value: '$(Duration)*$(Monthly_cost)'
description: Maps and transforms contexts to the operation output.
options:
  includeEmptyXMLElements: false

operation-switch

Use the operation-switch construct when you want to execute alternative policy assemblies, conditional on the operation that is being called.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [operation-switch](#).

About

An operation can be described with a **verb/path** pair, or with an **operationId**. The **operationIds** are strings, or names, that are defined in the OpenAPI document.

The operation-switch policy has the following format:

```

- operation-switch:
  version: version
  title: title
  description: description
  case:
    - operations:
      - verb: operation_verb_1_1
        path: operation_path_1_1
      - verb: operation_verb_1_2
        path: operation_path_1_2
      .
      .
      further verb/path combinations
      .
      .
    execute:
      policy_assembly_1 ...
    - operations:
      - verb: operation_verb_2_1
        path: operation_path_2_1
      - verb: operation_verb_2_2
        path: operation_path_2_2
      .
      .
      further verb/path combinations
      .
      .
    execute:
      policy_assembly_2 ...
      .
      .
    - operations:
      - operationID_3_1

```

```

- operationID_3_2
- operationID_3_3
.
.
.
  further operationIDs
.
.
.
execute:
  policy_assembly_3 ...
.
.
.
  further operations sections
.
.
.

```

For each `operations:` section, if the operation that is being called matches any of the `verb/path` combinations or `operationId` strings listed in that `operations:` section, then the policy assembly that is defined in the `execute:` section is executed. Therefore, each `operations:` section defines execution of a policy assembly conditional on the operation that is being called.

You can have as many `operations:` sections as you want, and each `operations:` section can have one or more `verb/path` combinations or `operationId` strings.

The `execute:` section can define any policy assembly, including further operation-switch policies.

Properties

Table 2. operation-switch policy properties

Property	Required	Description	Data type	Contained in
version	Yes	The policy version number	string	N/A
title	No	A title for the policy.	string	N/A
description	No	A policy description.	string	N/A
case	Yes	An array containing different cases, each entry contains an operations and execute field.	array (object)	N/A
operations	Yes	The operations to which a case applies.	object	case
verb	No	An operation verb. Valid values: <ul style="list-style-type: none"> • GET • POST • PUT • DELETE • HEAD • PATCH • OPTIONS 	string	operations
path	No	A relative path to an individual endpoint. For example, <code>/account_status</code> .	string	operations
operationID	No	The operation is defined in OpenAPI. The policy operation refers to the OpenAPI operation.	string	operations
execute	Yes	The policy assembly that you want to execute if the operation that is being called matches any one of the <code>verb/path</code> combinations. For more information, see execute .	string	case

Example

Example that defines match operations with `verb/path` combinations:

carry out different redaction actions depending on the operation

```

- operation-switch:
  version: 1.0.0
  title: clear_region_and_set_body
  case:
    - operations:
      - verb: GET
        path: /account_details
      execute:
        - redact:
            title: remove secret field
            actions:
              - action: remove
                from: all
                path: /document/user/secret
    - operations:
      - verb: GET
        path: /account_status
      execute:
        - redact:
            title: redact address
            actions:
              - action: redact
                from: response
                path: /*[@name='secondaryAddress']/*[@name='streetAddress']

```

Example that defines match operation with `operationIDs`:

```
# match on operationIDs

- operation-switch:
  title: customer_actions
  case:
    - operations:
      - getCustomerByName
      - deleteCustomer
      - addACustomer
    execute:
      .
      .
      .
```

oauth

Use the oauth policy to policy to perform OAuth processing based on defined OAuth provider settings.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [OAuth](#).

About

The oauth policy has the following format:

```
- oauth:
  version: version
  title: title
  description: description
  oauth-provider-settings-ref:
    .
    .
    .
  references_to_oauth_settings
  .
  .
  .
  supported-oauth-components:
  - oauth_component_1
  - oauth_component_2
  .
  .
  .
```

Note: You add an oauth policy to the OpenAPI source in a native OAuth provider. For more information, see the following topics:

- [Editing the native OAuth provider configuration using the API Editor](#) (Cloud Manager UI)
- [Editing the native OAuth provider configuration using the API Editor](#) (API Manager UI)

Properties

Table 2. oauth policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A description of the policy.	string
oauth-provider-settings-ref: default	Yes	The name of an existing OAuth provider that defines the required settings.	string
oauth-provider-settings-ref: url	No	A URL to a document that contains serialized XML or JSON properties that defines OAuth token generate settings. URL reference takes precedence over any existing literal configuration or object reference.	string
oauth-provider-settings-ref: literal	No	A literal string that contains serialized XML or JSON properties that defines OAuth token generate settings. Literal configuration takes precedence over any existing object reference.	string

Property	Required	Description	Data type
supported-oauth-components:	Yes	Specify the OAuth components that are supported by this policy, as follows:	string
- oauth_component_1		- OAuthValidateRequest Validates the authorization request from the client.	
- oauth_component_2		- OAuthGenerateAZCode Generates the authorization code for the client, which represents the resource owner's authorization that grants access to the requested resource.	
.		- OAuthVerifyAZCode Verifies the authorization code from the client.	
.		- OAuthVerifyRefreshToken Verifies the refresh token that is presented by the client.	
.		- OAuthCollectMetadata Collects metadata about a client for later user interaction	
.		- OAuthGenerateAccessToken Generates the access token to the client when the authorization code or refresh token is verified.	
.		- OAuthIntrospectToken Introspects the token to determine its state and, when active, its metadata.	

Overriding default OAuth provider settings

You can use either the `literal` property or the `url` property to dynamically override any OAuth provider configuration settings to dynamically override any OAuth provider configuration settings defined by the `default` property.

For example, to override the access token expiration time with a value of 200 seconds, include the following configuration in either the literal string or the document at the specified URL:

```
<OAuthProviderSettings><APICAccessTokenTTL>200</APICAccessTokenTTL></OAuthProviderSettings>
```

For a list of all OAuth provider settings, refer to the `OAuthProviderSettings` management schema, defined in the `xml-mgmt.xsd` file located in the store: directory on the DataPower API Gateway.

If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see [Logging into API Connect Designer](#).

oauth policy example

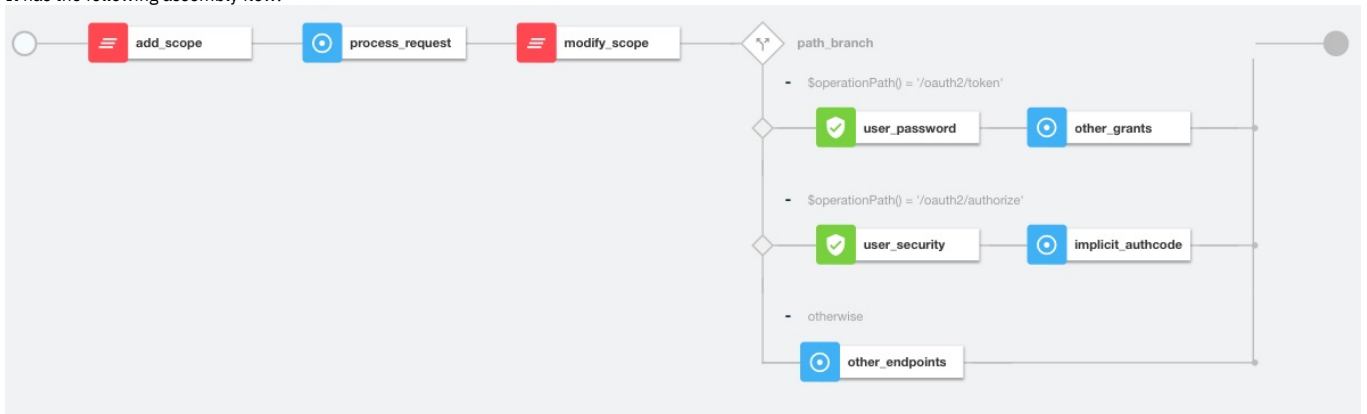

```
- oauth:
  version: 2.0.0
  title: my-oauth-policy
  oauth-provider-settings-ref:
    default: my-oauth
  supported-oauth-components:
    - OAuthGenerateAZCode
    - OAuthGenerateAccessToken
    - OAuthIntrospectToken
    - OAuthVerifyAZCode
    - OAuthVerifyRefreshToken
```

Example - using multiple OAuth policies in an OAuth provider assembly

This example demonstrates the use of multiple OAuth policies in the assembly flow for a native OAuth provider.

The example is based on the default assembly that is generated when you create a native OAuth provider, and is customized with the addition of `gatewayscript` policies that use [OAuth context variables](#) to manipulate the OAuth flow. For details on creating a native OAuth provider, see [Configuring a native OAuth provider](#).

It has the following assembly flow:

The following sections describe the OpenAPI source code that underlies each of the policies in the assembly; for the complete assembly code, download [multiple_oauth_policies.txt](#).

Sample policy to add a custom scope

The `add_scope` policy is a `gatewayscript` policy that adds a custom scope to the request.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
  version: 2.0.0
  title: add_scope
  source: |-
    // Add another custom scope to the request
    let scope = context.get("request.parameters.scope.values[0]");
    if (scope)
      context.set("oauth.processing.scope", scope + " custom");
```

Validate the initial OAuth request

The first `process_request` policy is an `oauth` policy that processes the initial request and verifies that the request is valid. The result of the processing is stored automatically in the `oauth.processing` context variables for use, as required, by the next OAuth policy in the assembly flow.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
  title: process_request
  version: 2.0.0
  description: >-
    This oauth policy performs all OAuth/OpenID Connect protocol steps
    that are needed for OAuth Validation by default. The inputs and
    outputs of each of the steps are driven by documented context
    variables. Add or remove the Supported OAuth Components as required.
  oauth-provider-settings-ref:
    default: custom-form
  supported-oauth-components:
    - OAuthValidateRequest
```

Sample policy to modify the scope

The `modify_scope` policy is a `gatewayscript` policy that modifies the scope depending on the calling application.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
  version: 2.0.0
  title: modify_scope
  source: |-
    let admin_id = '1f1a2aa4-db9f-4423-b2f1-e2572b12123a';

    // Check application and modify the scope
    let app = context.get("oauth.processing.client_id");
    let scope = context.get("oauth.processing.scope");
    if (app === admin_id) {
      context.set("oauth.processing.scope", scope + " admin");
    } else {
      context.set("oauth.processing.scope", scope + " customer");
    }
  }
```

Branch conditionally according to the OAuth path

The `path_branch` policy is a `switch` policy that branches according to the different OAuth paths to process the resource owner.

The underlying OpenAPI source YAML is as follows:

```
- switch:
  version: 2.0.0
  title: path_branch
  case:
    - condition: ($operationPath() = '/oauth2/token')
      execute:
        .
        .
        .
        definition of the user_security and other_grants policies
        .
        .
    - condition: ($operationPath() = '/oauth2/authorize')
      execute:
        .
        .
        .
        definition of the user_password and implicit_authcode policies
        .
        .
    - otherwise:
      .
```

```
.  
.  
definition of the other_endpoints policy  
.  
.
```

Process the user name and password, and enable grant type component

The following two policies operate on the token endpoint.

- The `user_password` policy for password grant type processes the user name and password from the `x-www-form-urlencoded` body. The authentication method is derived from the User Security settings in the OAuth provider; see [Configuring user security for a native OAuth provider](#).
- The `other_grants` policy is an `oauth` policy that enables the `OAuthGenerateAccessToken`, `OAuthVerifyAZCode`, `OAuthVerifyRefreshToken`, and `OAuthCollectMetadata` components to perform the operations for client credentials, authorization code, refresh token, and password grant types.

The underlying OpenAPI source YAML is as follows:

```
- user-security:  
  title: user_password  
  version: 2.0.0  
  description: ''  
  factor-id: default  
  extract-identity-method: context-var  
  user-context-var: request.parameters.username.values  
  pass-context-var: request.parameters.password.values  
  ei-stop-on-error: false  
  user-auth-method: auth-url  
  au-stop-on-error: false  
  auth-url: 'http://httpbin.org/basic-auth/user/pass'  
  user-az-method: authenticated  
  az-stop-on-error: true  
  auth-response-headers-pattern: (?)*x-api*  
  auth-response-header-credential: X-API-Authenticated-Credential  
- oauth:  
  title: other_grants  
  version: 2.0.0  
  description: >-  
    This oauth policy performs all OAuth/OpenID Connect  
    protocol steps that are needed for token path by default.  
    The inputs and outputs of each of the steps are driven by  
    documented context variables. Add or remove the Supported  
    OAuth Components as required.  
  oauth-provider-settings-ref:  
    default: custom-form  
  supported-oauth-components:  
    - OAuthGenerateAccessToken  
    - OAuthVerifyAZCode  
    - OAuthVerifyRefreshToken  
    - OAuthCollectMetadata
```

Perform authorization checks, and enable grant type components

These following two policies operate on the authorize endpoint.

- The `user_security` policy configuration is derived from the User Security settings in the OAuth provider; see [Configuring user security for a native OAuth provider](#).
- The `implicit_authcode` policy is an `oauth` policy that enables the `OAuthGenerateAZCode`, `OAuthGenerateAccessToken`, and `OAuthCollectMetadata` components to perform the operations for the implicit and authorization code grant types.

The underlying OpenAPI source YAML is as follows:

```
- user-security:  
  title: user_security  
  version: 2.0.0  
  description: >-  
    This user security policy performs EI(basic) and AU(auth  
    url) check for oauth assembly. Change the security check  
    method as required  
  factor-id: default  
  extract-identity-method: basic  
  ei-stop-on-error: true  
  user-auth-method: auth-url  
  au-stop-on-error: true  
  user-az-method: authenticated  
  az-stop-on-error: true  
  auth-response-headers-pattern: (?)*x-api*  
  auth-response-header-credential: X-API-Authenticated-Credential  
  auth-url: 'http://httpbin.org/basic-auth/user/pass'  
- oauth:  
  title: implicit_authcode  
  version: 2.0.0  
  description: >-  
    This oauth policy performs all OAuth/OpenID Connect  
    protocol steps that are needed for az code path by  
    default. The inputs and outputs of each of the steps are  
    driven by documented context variables. Add or remove the  
    Supported OAuth Components as required.  
  oauth-provider-settings-ref:  
    default: custom-form  
  supported-oauth-components:
```

- OAuthGenerateAZCode
- OAuthGenerateAccessToken
- OAuthCollectMetadata

Process all other endpoints

The `otherwise` condition catches all other endpoints such as the introspect and revoke endpoints. The `other_endpoints` policy in the `otherwise` condition is an `oauth` policy that enables the `OAuthIntrospectToken`, and `OAuthRevokeTokencomponents` components to perform the operations for introspect and revoke.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
  title: other_endpoints
  version: 2.0.0
  description: >-
    This oauth policy performs all OAuth/OpenID Connect
    protocol steps that are needed for all other paths by
    default. The inputs and outputs of each of the steps are
    driven by documented context variables. Add or remove the
    Supported OAuth Components as required.
  oauth-provider-settings-ref:
    default: custom-form
  supported-oauth-components:
    - OAuthIntrospectToken
    - OAuthRevokeToken
```

- [Configuring a native OAuth provider](#)

parse

Use the parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0
	2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)
	2.2.0 (DataPower API Gateway Version 10.5.0.5 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Parse](#).

About parse

The parse policy has the following format:

```
- parse:
  version: version
  title: title
  description: description
  use-content-type: request_header_usage_setting
  parse-settings-reference:
    .
    .
    .
  references_to_parse_settings
    .
    .
    .
  input: input_message
  output: output_message
```

Properties

Table 2. parse policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string

Property	Required	Description	Data type
description	No	A description of the policy.	string
use-content-type	No	<p>If this setting is enabled and the parse setting is configured to detect the document type, the parse operation uses the Content-Type specified in the request headers.</p> <p>If this setting is enabled and the document type in the parse setting is configured for either JSON or XML, the parse operation uses the Content-Type specified in the request headers and fails if the Content-Type in the request headers does not match the parse setting.</p> <p>Enabling this setting is applicable only when the expected Content-Type is either JSON or XML.</p> <p>If this setting is not enabled, the parse operation uses either the document type specified in the parse setting, or the detected document type if the parse setting is configured to detect the document type.</p> <p>The default value is false.</p>	boolean
parse-settings-reference-default	No	An existing valid object from which to retrieve default property values for the dynamic object.	string
document_type	No	<p>The type of document to parse. Specify one of the following values:</p> <ul style="list-style-type: none"> detect: the document type is detected and the payload is parsed accordingly. This type is the default option. JSON: the payload is parsed as JSON. XML: the payload is parsed as XML. graphql: parsing is performed in one of the following ways: <ul style="list-style-type: none"> As GraphQL in the body of a POST request. The GraphQL is in the following format: <pre>{ me { name } }</pre> As a JSON string in the body of a POST request that contains a GraphQL query. The JSON object is in the following format: <pre>{ "query": "query MyData (\$idVar: Int!) { user (id: \$idVar) { name }}", "operationName": "MyData", "variables": {"idVar": 123} }</pre> Through the URL query of a GET request. The URL is in the following format: <pre>https://myapi/graphql?query={me{name}}</pre> <p>The following example includes the variables and operationName properties, with URL encoding:</p> <pre>https://hostname/basepath/graphql? query=query%20fetchAccounts%20(\$limit:%20Int)%20(accounts(limit:%20\$limit) %20{name{first,last}})&variables={"limit":100}&operationName=fetchAccounts</pre> <p>Query variables in a GET request can be sent as a JSON string in a query parameter called variables. If the query contains several named operations, an operationName query parameter is required to determine which operation is to be executed.</p>	string
max_doc_size	No	<p>Optionally, the maximum document size in bytes that the parse operation accepts. This setting provides threat protection by enforcing the maximum document size. Enter a value in the range 0 - 5368709121. A document is rejected when its size exceeds the maximum size. A value of 0 indicates an unlimited document size. When set to 0, the operation result does not return the document size. This setting is applicable to JSON, XML, or GraphQL input documents.</p> <p>The default value is 4194304.</p>	integer
max_nesting_depth	No	<p>Optionally, the maximum nesting depth of an XML, JSON, or GraphQL message that the parse operation accepts. This setting provides threat protection by enforcing limits in the message.</p> <ul style="list-style-type: none"> When XML, it is the maximum level of element depth. When JSON, it is the maximum level of nested label-value pairs, the maximum number of nested arrays, or the maximum number of combination of label-value pairs and arrays. When GraphQL, it is the maximum level of nested selection sets. <p>Enter a value in the range 0 - 4096. A document is rejected when its nesting depth exceeds the maximum depth. A value of 0 indicates unlimited nesting depth. When set to 0, the operation result does not return the nesting depth.</p> <p>The default value is 512.</p>	integer

Property	Required	Description	Data type
max_width	No	<p>Optionally, the maximum width of the payload that the parse operation accepts.</p> <ul style="list-style-type: none"> When the input document is XML, this property specifies the maximum number of attributes for an element or the maximum number of child elements for an element. When the input document is JSON, this property specifies the maximum number of properties on a JSON object or the maximum number of JSON items in a JSON array. When the input document is GraphQL, this property specifies the maximum number of selections in a selection set. <p>Enter a value in the range 0 - 65535. The document is rejected when its width exceeds the maximum width. A value of 0 indicates unlimited width. When set to 0, the operation result does not return the width of the document.</p> <p>The default value is 4096.</p>	integer
max_name_length	No	<p>Optionally, the maximum name length in bytes in a document that the parse operation accepts.</p> <ul style="list-style-type: none"> For XML, it is the length of the name portion of a tag. For JSON, it is the length of the label portion of the JSON label-value pair. For GraphQL, it is the maximum length of the identifiers, including field names and directive names. <p>The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 8192. A document is rejected when its name length exceeds the maximum length. A value of 0 indicates unlimited name length. When set to 0, the operation result does not return the name length of a document.</p> <p>The default value is 256.</p>	integer
max_value_length	No	<p>Optionally, the maximum value length in bytes in a document that the parse operation accepts.</p> <ul style="list-style-type: none"> For XML, it is the length of an attribute or the length of a text value. For JSON and GraphQL, it is the length of a string value. <p>The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 5368709121. A document is rejected when its value length exceeds the maximum length. A value of 0 indicates unlimited value length. When set to 0, the operation result does not return the value length of a document.</p> <p>The default value is 8192.</p>	integer
max_unique_names	No	<p>Optionally, the maximum number of unique names in a JSON or XML document that the parse operation accepts.</p> <ul style="list-style-type: none"> For XML, it is the number of unique XML local names. For JSON, it is the number of unique JSON labels. <p>Enter a value in the range 0 - 1048575. A document is rejected when the number of unique names in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique names. When set to 0, the operation result does not return the number of unique names in a document.</p> <p>The default value is 1024.</p>	integer
max_unique_prefixes	No	<p>Optionally, the maximum number of unique XML namespace prefixes in a document that the parse operation accepts. This limit counts multiple prefixes defined for the same namespace, but does not count multiple namespaces defined in different parts of the input document under a single prefix. Enter a value in the range 0 - 262143. A document is rejected when the number of unique prefixes in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique prefixes. When set to 0, the operation result does not return the number of unique prefixes in a document.</p> <p>The default value is 1024.</p>	integer
max_unique_namespaces	No	<p>Optionally, the maximum number of unique XML namespace URIs that the parse operation accepts. This limit counts all XML namespaces, regardless of how many prefixes are used to declare them. Enter a value in the range 0 - 65535. A document is rejected when the number of unique namespaces in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique namespaces. When set to 0, the operation result does not return the number of unique namespaces in a document.</p> <p>The default value is 1024.</p>	integer
max_number_length	No	<p>Optionally, the maximum number of bytes in the value portion of a JSON label-value pair when the value is a number. The number must be a contiguous string of bytes that contain no white space. The number can include a minus sign and a positive or negative exponent. Enter a value in the range 0 - 256. A document is rejected when the number length in the document exceeds the maximum length. A value of 0 indicates unlimited number length. When set to 0, the operation result does not return the number length in a document.</p> <p>The default value is 128.</p>	integer
strict-utf8-encoding	No	<p>For JSON documents, whether to enforce strict UTF-8 encoding throughout the entire document.</p> <ul style="list-style-type: none"> When on, the entire document is checked for valid UTF-8 encoding. When off, only the first few bytes are checked for proper encoding. The rest of the document is assumed to be in the same encoding. <p>The default value is off.</p>	boolean
parse-settings-reference: literal	No	<p>A literal string as serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing default properties.</p>	string
parse-settings-reference: url	No	<p>A URL that represents a named context from which to retrieve the serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing literal or default properties.</p>	string

Property	Required	Description	Data type
input	No	The name of a variable in the API context. The content of the body field of the variable is the input to the policy. The default variable name is message .	string
output	No	The name of a variable in the API context. The content of the body field of the variable is the output of the parse operation. The parse metrics of the parsed document can be stored in a different part of the message. The default variable name is the same as the input name, so by default the input message is overwritten by the output message.	string

parse policy example

```
- parse:
  version: 2.0.0
  title: my-parse-policy
  use-content-type: true
  parse-settings-reference:
    default: my-parse
  input: input-message
  output: output-message
```

parse-settings-reference: literal example

In XML:

```
- parse:
  version: 2.0.0
  title: parse
  parse-settings-reference:
    default: apic-default-parsesettings
    literal: <ParseSettings><DocumentType>xml</DocumentType></ParseSettings>
```

In JSON:

```
- parse:
  version: 2.0.0
  title: parse
  parse-settings-reference:
    default: apic-default-parsesettings
    literal: { \"ParseSettings\" : { \"propertyName\" : propertyValue } }
```

proxy

Apply the proxy policy to proxy another API within your operation, particularly if you need to call a large payload.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by Invoke	

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Proxy](#).

About

Keep the following considerations in mind regarding the proxy policy.

- Only one proxy policy is permitted to be called per assembly.
- More than one proxy policy can be applied, if they are contained in mutually exclusive branches of the assembly.
- You can use the proxy policy to return multipart form data, that is, when the response is set to `Content-Type: multipart/related`. However, proxy must be the final policy in the assembly, otherwise the response that is received is manipulated causing the multipart form data to be lost.
- The proxy policy, if inside a conditional policy, must be the **final** policy to be executed in the API. If you need further processing afterward, use the [invoke](#) policy rather than the proxy policy.
- The Proxy policy does not currently attempt to rewrite a Location header that is returned from the back end.

The proxy policy has the following structure:

```
- proxy:
  version: version
  title: title
  description: description
  target-url: URL_of_target_API
  tls-profile: TLS_profile_to_be_used
  verb: method_type
  http-version: HTTP_version
  timeout: timeout_value_in_seconds
  compression: is_data_to_be_compressed
  username: username_if_authentication_required
```

```

password: password_if_authentication_required
output: location_of_the_proxy_result
cache-key: unique_identifier_of_the_document_cache_entry
cache-response: cache_behavior
cache-putpost-response: response_caching_behavior
cache-ttl: cache_time_to_live
stop-on-error: errors_that_stop_the_flow

```

Properties

The table describes the properties of the proxy policy.

Table 2. Proxy policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
target-url	Yes	The URL of the target API.	string
tls-profile	No	The TLS profile to be used.	string
verb	No	The operation method type. Valid values: <ul style="list-style-type: none"> Keep GET POST PUT DELETE PATCH HEAD OPTIONS The default value is Keep .	string
http-version	No	The HTTP version. The default value is 1.1 .	string
timeout	No	The timeout value in seconds. The default value is 60 .	integer
compression	No	Specifies whether data is to be compressed by using gzip before it is uploaded. The default value is false .	boolean
username	No	The user name, if authentication is required.	string
password	No	The password, if authentication is required.	string
output	No	Specifies the location of the proxy result. By default, the proxy result, that is the body, headers, statusCode and statusMessage, is saved in the variable context.message . The assembly developers can specify an additional location to store the proxy result with the output property.	string
cache-key	No	Specifies the unique identifier of the document cache entry.	string
cache-response	No	The cache response type. Valid values: <ul style="list-style-type: none"> protocol: The cache behavior is defined by the Cache-Control headers on the request and response. no-cache: Specifies that there is no caching. However, if the document is already in the cache, the document is retrieved from the cache. time-to-live: Specifies that the response stays in the cache for the specified time. The default value is protocol .	string
cache-putpost-response	No	Specifies whether to cache the response from POST and PUT requests. Caching the response from POST and PUT requests can reduce server load and reduce latency in the response to the client request. The default value is false .	boolean
cache-ttl	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property cache-response is set to time-to-live . Enter a value in the range 5 - 31708800. The default value is 900 .	integer
stop-on-error	No	List the errors that, if thrown during the policy execution, cause the flow to stop. If there is a catch flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors specified for the Stop on error property, or if the error thrown is not one of the specified errors, the policy execution is allowed to complete, and the assembly flow continues.	string

API Gateway only

ratelimit

Use the ratelimit policy to apply one or more rate, burst, or count limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
---------	----------------

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.0 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.5.0.0)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Rate Limit](#).

About

The defined rate, burst, and count limits are applied to whatever follows in the assembly flow. For example, if a ratelimit policy is placed before an invoke policy, and the call made by the invoke policy exceeds the limits defined by the ratelimit policy, the API call itself fails.

The ratelimit policy has the following format:

```
- ratelimit:
  version: version
  title: title
  description: description
  source: rate_and_burst_limit_location
  rate-limit: rate_limits_to_apply
  burst-limit: burst_limits_to_apply
```

Properties

The following table describes the properties of the ratelimit policy.

Table 2. ratelimit policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
source	Yes	The location of all the rate limit, burst limit, and count limit definitions that are included in this policy. Specify one of the following values: <ul style="list-style-type: none"> catalog-named: the rate or burst limits to be applied are defined in the appropriate api-collection object on the DataPower API Gateway, which is the object that represents your API Connect Catalog in the gateway configuration. For details of how to configure a rate, burst, or count limit in the api-collection object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. plan-named: the limits to be applied are assembly burst limits or assembly count limits defined on the Plan to which the calling application is subscribed. For details on how to configure assembly burst limits and assembly count limits in a Plan, see Editing a draft Product. Note: The following conditions apply to a plan-named rate limit policy: <ul style="list-style-type: none"> Every Plan that contains the API that is being limited must have the named rate limit applied. A plan-named rate limit policy cannot be used with automatically generated Products. gateway-named: the limits to be applied are defined in the apigw object, named apiconnect, on the DataPower API Gateway gateway. For details of how to configure a rate, burst, or count limit in the apigw object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. plan-default: the rate and burst limits that are applied are the default ones configured in the Plan to which the calling application is subscribed. For details on how to configure default Plan rate and burst limits, see Editing a draft Product. Note: The use of this option does not disable any automatic preflow rate limit policy that might be in place, and could result in the application of the rate limiting being repeated. For more information on preflow policies, see Customizing the preflow policies. 	string
rate-limit	Yes ¹	If the source property is set to catalog-named , a list of rate limit names as defined in the DataPower API Gateway configuration, ¹ You must provide at least one rate, burst, or count limit.	string
burst-limit	Yes ²	If the source property is set to catalog-named , a list of burst limit names as defined in the DataPower API Gateway configuration. If source is set to plan-named , a list of names of assembly burst limits defined in a Plan. ² You must provide at least one rate, burst, or count limit.	string
count-limit	Yes ³	If source property is set to catalog-named , a list of count limit names as defined in the DataPower API Gateway configuration. If source is set to plan-named , a list of names of assembly count limits defined in a Plan. ³ You must provide at least one rate, burst, or count limit..	string

Property	Required	Description	Data type
operation	No	<p>For a rate limit, specify one of the following values:</p> <ul style="list-style-type: none"> consume: the policy reduces the balance of available requests that remain in the interval defined by the rate limit specified by the <code>rate-limit</code> property. The amount by which the remaining balance is reduced is the value that results from the weight expression defined in the specified rate limit. replenish: the policy increases the balance of available requests that remain in the interval defined by the rate limit specified by the <code>rate-limit</code> property. The amount by which the remaining balance is increased is the value that results from the weight expression defined in the specified rate limit. <p>The purpose of the replenish operation is to restore an appropriate amount of remaining balance in cases where the amount calculated by an earlier consume operation turns out to be too high. For example, for an assembly rate limit with a limit of 100, a consume operation with a weight of 60 uses 60 requests, leaving 40 requests remaining for the interval. If the weight expression in the subsequent replenish operation computes to 15, meaning that the weight expression calculated that the actual request usage was only 45, the replenish operation increases the remaining requests by 15, to a remaining balance of 55.</p> <p>Note that the replenish operation cannot increase the remaining requests allowed beyond the original limit defined in the assembly rate limit scheme. In this example, a replenish operation cannot replenish requests beyond 100. A replenish operation is skipped if the weight expression evaluates to a value of less than 1.</p> <p>The default value is consume.</p> <p>For a count limit, specify one of the following values:</p> <ul style="list-style-type: none"> inc: the current count is incremented by the value that results from the weight expression defined in the count limit specified by the <code>count-limit</code> property. dec: the current count is decremented by the value that results from the weight expression defined in the count limit specified in the <code>count-limit</code> field. <p>By default, the count limit is automatically decremented at the end of the API assembly by the total amount incremented during the assembly, minus any decrement operations that are defined in the assembly. You do not need to explicitly define decrement operations unless you want the decrements to occur at specific points in the assembly. However, if the auto decrement feature has been explicitly disabled in the count limit configuration, you must include a corresponding decrement operation, otherwise when the count limit is reached all future calls are blocked. For more information on configuring a count limit, see Configuring a rate, burst, or count limit on the DataPower API Gateway.</p> <p>The default value is inc.</p> <p>For a burst limit, the only possible value is consume, meaning that the limit applied is that defined in the burst limit specified by the <code>burst-limit</code> field.</p>	string

Example

```
- ratelimit:
  version: 2.0.0
  title: Apply rate and burst limits
  source: catalog-named
  rate-limit:
    - 30perMinute
    - 2000per3Hours
  burst-limit:
    - 5per10Seconds
```

redact - DataPower API Gateway

Use the redact policy to completely remove or to redact specified fields from the request body, the response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This page describes the redact policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see [redact - DataPower Gateway \(v5 compatible\)](#).

For information on the different types of gateway, see [API Connect gateway types](#).

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Redaction - DataPower API Gateway](#).

About

The redact policy has the following format:

```
- redact:
  version: version
  title: title
  description: description
  redactions:
    - action: remove_or_redact
      path: JSONata_expression_for_field_to_remove_or_redact
      .
      .
      .
  root: content_source
```

Note: With the DataPower API Gateway, the input to the redact policy must be parsed data. One way to produce parsed data is to use a [parse](#) policy before a redact policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the properties of the redact policy.

Table 2. redact policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
root	No	Specifies the data source that contains the content to which the redact or remove action applies. If the root property is omitted, the action is applied to the entire API context. You can use any supported JSONata path expression. If you want to apply the action to either request or response data, specify a value of <code>message.body</code> . The actual content to which the action is applied then depends on the positioning of the redact policy in the overall assembly flow; for example: <ul style="list-style-type: none">• If positioned at the beginning, the action is applied to the client request.• If positioned after an invoke policy, the action is applied to the response from the back end.• If positioned at the end, the action is applied to the response that is returned to the client. If, in your assembly flow, the redact policy is used after a log policy that specifies <code>gather-only</code> for the mode property, specify a root value of <code>log.request_body</code> for the logged request payload, or <code>log.response_body</code> for the logged response payload.	string
path	Yes	Specifies a JSONata path expression that identifies the fields to redact or remove from the source. For more information, see Constructing JSONata expressions to redact fields	string
action	Yes	Specifies whether you want to remove or redact the content. Supply one of the following values: <ul style="list-style-type: none">• remove: Completely removes the specified fields.• redact: Redacts (obfuscates with "*"s) the fields to block out the data. The default value is redact . Note: If a numerical value is being redacted, the redacted value is depicted as ***** and the type is changed to string .	string

Example

Specify separate remove and redact actions

```
- redact:
  version: 2.0.0
  title: remove price, redact author
  redactions:
    - action: remove
      path: xpath($, '//price')
    - action: redact
      path: $.**.author"
  root: message.body
```

DataPower Gateway (v5 compatible)

redact - DataPower Gateway (v5 compatible)

Use the redact policy to completely remove or to redact specified fields from the request body, the response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This page describes the redact policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see [redact - DataPower API Gateway](#).

For information on the different types of gateway, see [API Connect gateway types](#).

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Redaction - DataPower Gateway \(v5 compatible\)](#).

About

The redaction policy has the following format:

```
- redact:
  version: version
  title: title
  description: description
  actions:
    - action: remove_or_redact
      from:
        - where the redaction is to be applied
          path: XPath_expression_for_field_to_remove_or_redact
            .
            .
            .
            further action/from/path combinations
            .
            .
            .
```

You can specify as many `action/from/path` combinations as you want.

Properties

The following table describes the policy properties:

Table 2. redact policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
action	No	Specifies whether you want to remove or redact the fields. Valid values: <ul style="list-style-type: none">remove: Completely removes the specified fields.redact: Redacts (obfuscates with "*"s) the fields to block out the data. The default value is redact . Note: If a numerical value is being redacted, the redacted value is depicted as ***** and the type is changed to string .	string
from	No	Determines where the redaction is to be applied. Valid values: <ul style="list-style-type: none">all: Apply the redaction to the request body, the response body, and the activity logs.request: Apply the redaction to the request body only.response: Apply the redaction to the response body only.logs: Apply the redaction to the activity logs only. You can supply one or more values. The default value is all .	string
path	Yes	Specifies an XPath expression that defines the fields to remove or redact. You can construct an XPath expression that is based on JSON or XML depending on whether your API requests and responses use a JSON or an XML format. If the payload is JSON, use the DataPower XML representation of the JSON content (JSONx) to construct the expression. Note: Use a JSONx representation only to identify the XPath expressions for the fields to remove or redact. Do not change the format of any response bodies in API Manager. To learn more about constructing XPath expressions that are based on JSON or XML, see Constructing XPath expressions to redact fields .	string

Example

```
# Specify separate remove and redact actions
```

```
- redact:
  version: 1.0.0
```

```

title: remove secret field, redact address
actions:
- action: remove
  from:
  - all
  path: /document/user/secret
- action: redact
  from:
  - request
  - response
  path: /**[@name='secondaryAddress']/*[@name='streetAddress']

```

set-variable

Use the set-variable policy to set the value of a runtime variable, or to add or clear a runtime variable.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Set Variable](#).

About

The set-variable policy has the following format:

```

- set-variable:
  version: version
  title: title
  description: description
  actions:
  - action_type: variable_name
    value: value
    type: data_type

```

Properties

Table 2. set-variable policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
actions	Yes	Lists the actions to be performed by the set-variable policy.	array
set	Yes ¹	For setting a variable. specifies the name of the variable that you want to set. ¹ One of the properties set, add, or clear is required.	string
add	Yes ²	For adding a variable. specifies the name of the variable that you want to add. ² One of the properties set, add, or clear is required.	string
clear	Yes ³	For clearing a variable. specifies the name of the variable that you want to clear. ³ One of the properties set, add, or clear is required.	string
value	Yes ⁴	Allocates this value to the specified variable. Can be a literal value, or another variable. ⁴ value is required only when set or add is specified as the action.	string
API Gateway only type	Yes	Specifies the data type of the variable. Valid values: <ul style="list-style-type: none"> • any • string • number • boolean For all values other than any , the value is validated against the specified data type. If the data type is specified as boolean , the value property must be set to true or false .	string

Example 1

```

# clear a variable

set-variable:
  version: 1.0.0
  title: clear_region
  actions:
  - clear: message.headers.region

```

Example 2

```
# set a variable to the value of an API Gateway context variable

set-variable:
  version: 2.0.0
  title: set content type
  actions:
    - set: message.headers.contenttype
      value: $(message.headers.content-type)
      type: string
```

Example 3

```
# add a variable

assembly:
  execute:
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - value: testing add
            add: message.headers.jja
            type: string
```

switch

Use the switch component to execute one of a number of sections of the assembly based on which specified condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [switch](#).

About

The switch policy has the following format:

```
- switch:
  version: version
  title: switch
  description: 'Description'
  case:
    - condition: Script_1
      execute:
        Assembly_Section_1
    - condition: Script_2
      execute:
        Assembly_Section_2
    - otherwise:
        Assembly_Section_3
```

The **execute** section can define any policy assembly, including further switch policies. For more information, see [execute](#).

Properties

Table 2. switch policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
case	Yes	Contains the condition and execute pairs of the switch policy.	string
condition	Yes (one or more)	A script that returns true or false .  Use the JSONata expression language to define your condition. See Writing switch condition scripts - DataPower API Gateway .  Use GatewayScript to define your condition. See Writing switch condition scripts - DataPower Gateway (v5 compatible) .	string
execute	Yes (one per condition)	The policy assembly that you want to execute if the condition returns true . For more information, see execute .	string

Property	Required	Description	Data type
otherwise	No	The case you want to execute if no other cases are fulfilled. It functions in the same manner as an execute property. For more information, see execute .	string

For examples, see one or other of the following topics, depending on which gateway type you are using:

- [Writing switch condition scripts - DataPower API Gateway](#)
- [Writing switch condition scripts - DataPower Gateway \(v5 compatible\)](#)

Writing switch condition scripts - DataPower API Gateway

You write condition scripts for the switch policy in the DataPower® API Gateway by using the JSONata expression language.

The payload of the message must be parsed before you can use JSONata in a switch policy condition. Therefore, a parse policy must precede the switch policy. You can then use a JSONata condition on the parsed content that is stored in the `body` field of the output variable. The default variable is `message`. For example, if the output variable is `message`, you can use the JSONata condition `$exists(message.body.username)` on the parsed content.

The following JSONata functions are supported:

- Aggregation functions:
 - `$average(array)`
 - `$max(array)`
 - `$min(array)`
 - `$sum(array)`
- Array functions:
 - `$append(array1, array2)`
 - `$count(array)`
 - `$reverse(array)`
 - `$sort(array [, function])`
 - `$zip(array1, ...)`
- Boolean functions:
 - `$boolean(arg)`
 - `$exists(arg)`
 - `$not(arg)`
- Numeric functions:
 - `$abs(number)`
 - `$ceil(number)`
 - `$floor(number)`
 - `$formatBase(number [, radix])`
 - `$number(arg)`
 - `$power(base, exponent)`
 - `$round(number [, precision])`
 - `$sqrt(number)`
- Object functions:
 - `$keys(object)`
 - `$lookup(object, key)`
 - `$merge(array<object>)`
 - `$spread(object)`
 - `$type(value)`
In addition to the standard values returned by `$type()`, the API gateway implementation of `$type()` can return the following values: `binary`, `empty`, `graphql`, `stream`, or `xml`.
- String functions:
 - `$contains(str, pattern)`
 - `$join(array[, separator])`
 - `$length(str)`
 - `$lowercase(str)`
 - `$match(str, pattern [, limit])`
 - `$pad(str, width [, char])`
 - `$replace(str, pattern, replacement [, limit])`
 - `$split(str, separator [, limit])`
 - `$string(arg)`
 - `$substring(str, start[, length])`
 - `$substringAfter(str, chars)`
 - `$substringBefore(str, chars)`
 - `$trim(str)`
 - `$uppercase(str)`
- You can use the following functional extensions to standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description
<code>\$header(name)</code>	<code>message.headers.name</code>	Message header
<code>\$httpVerb()</code>	<code>request.verb</code>	HTTP method of the request
<code>\$operationID()</code>	<code>api.operation.id</code>	ID of the operation

Extension	Variable	Description
<code>\$operationPath()</code>	<code>api.operation.path</code>	Path of the operation
<code>\$queryParameter('name')</code>	<ul style="list-style-type: none"> <code>request.parameters.name.locations</code> The supported keyword is <code>query</code>. <code>request.parameters.name.values</code> 	Searches for the index of <code>query</code> in <code>request.parameters.name.locations</code> and returns <code>request.parameters.name.values[index]</code> , where <code>[index]</code> is the value for <code>query</code> in locations. Parameter values are not URL decoded.
<code>\$statusCode()</code>	<code>message.status.code</code>	Status code
<code>\$storageType([arg])</code>	<code>variable.body</code> You can specify any variable in the API context. When no variable is specified, the default variable <code>message.body</code> is used.	Storage type of the message. The supported values are <code>binary</code> , <code>empty</code> , <code>graphql</code> , <code>json</code> , <code>stream</code> , or <code>xml</code> .
<code>\$urlParameter('name')</code>	<ul style="list-style-type: none"> <code>request.parameters.name.locations</code> The supported keywords are <code>path</code> and <code>query</code> <code>request.parameters.name.values</code> 	Searches for the index of <code>path</code> and <code>query</code> in <code>request.parameters.name.locations</code> and returns a single array that contains both <code>path</code> and <code>query</code> values from <code>request.parameters.name.values</code> . When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values. <code>http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese</code> The <code>\$urlParameter('breed')</code> URL returns the following array of values. <code>[cats, adopt, Sphynx, Siamese]</code> In this example, the URL includes an API path that is configured as <code>/petstore/{breed}/{breed}</code> , where <code>breed</code> is configured to be a path parameter of the API path. As a result, <code>cats</code> and <code>adopt</code> are included in the output.
<code>\$xpath(path, xpathExpression)</code>	You can specify any writable variable in the API context. The <code>xpathExpression</code> must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. <code>\$xpath(\$, '//price')</code>

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
<code>\$gqlActiveOperation([graphql_message])</code>	<code>message.body</code>	Gets the active operation found in the specified GraphQL message. The <code>operationName</code> must be the same as the name of the active operation.
<code>\$gqlAlias(graphql_field_node)</code>	<code>message.body</code>	Gets the alias of a GraphQL field node.
<code>\$gqlFragments([graphql_message])</code>	<code>message.body</code>	Gets the fragments found in the specified GraphQL message.
<code>\$gqlName([graphql_node])</code>	<code>message.body</code>	Gets the node name. For operations, the node name is the <code>operationName</code> . For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the <code>operationName</code> of <code>message.body</code> is retrieved.
<code>\$gqlOperations([graphql_message])</code>	<code>message.body</code>	Gets the operations found in the specified GraphQL message.
<code>\$gqlType([graphql_node])</code>	<code>message.body</code>	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

- You can use the `&` (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- `/` (division)
- `%` (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- `query`
The entire GraphQL query including operations and fragments.

- **operationName**
For an anonymous operation, **operationName** can be empty.
- **~fragmentSpreadName**
- **on~typeCondition**
- **~~fragmentDefinitionName**

You can also use the following functional extensions to standard JSONata notation. Each extension corresponds to a part of the API context.

Extension	Variable	Description
<code>\$header (name)</code>	<code>message.headers.name</code>	Message header
<code>\$httpVerb ()</code>	<code>request.verb</code>	HTTP method of the request
<code>\$operationID ()</code>	<code>api.operation.id</code>	ID of the operation
<code>\$operationPath ()</code>	<code>api.operation.path</code>	Path of the operation
<code>\$queryParameter ('name')</code>	<ul style="list-style-type: none"> • <code>request.parameters.name.locations</code> • <code>request.parameters.name.values</code> 	Returns the value of a request query parameter given the parameter name. The function searches the <code>request.parameters.name.locations</code> array for the index position of the value <code>query</code> , and returns <code>request.parameters.name.values [index]</code> , where <code>index</code> is the index position. Parameter values are not URL decoded.
<code>\$statusCode ()</code>	<code>message.status.code</code>	Status code
<code>\$storageType ([arg])</code>	<p>variable.body You can specify any variable in the API context. When no variable is specified, the default variable <code>message.body</code> is used.</p> <ul style="list-style-type: none"> • <code>binary</code> • <code>json</code> • <code>stream</code> • <code>xml</code> 	Storage type of the message. The supported values are:
<code>\$urlParameter ('name')</code>	<ul style="list-style-type: none"> • <code>request.parameters.name.locations</code> • <code>request.parameters.name.values</code> 	<p>Given a request parameter name, returns the parameter values for all occurrences of that parameter as a path parameter or query parameter. The function searches the <code>request.parameters.name.locations</code> array for the index positions of the values <code>path</code> and <code>query</code>, and returns, in a single array, the <code>request.parameters.name.values [index]</code> values for all identified index positions. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded.</p> <p>For example, the following URL contains both path and query parameter values: <code>http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese</code></p> <p>The function call <code>\$urlParameter ('breed')</code> returns the following array of values: <code>[cats, adopt, Sphynx, Siamese]</code></p> <p>In this example, the URL includes an API path that is configured as <code>/petstore/{breed}/{breed}</code>, where <code>breed</code> is configured to be a path parameter of the API path. As a result, <code>cats</code> and <code>adopt</code> are included in the output.</p>
<code>\$xpath (path, xpathExpression)</code>	You can specify any writable variable in the API context. The <code>xpathExpression</code> must be a literal string.	Allows use of XPath expressions

Simple condition statements

The following examples show conditions that use a single function.

This example uses the `$httpVerb ()` extension to specify the HTTP method of the request.

```
$httpVerb ()="GET"
```

This example uses the `$operationPath ()` extension to specify the path of the operation.

```
$operationPath ()="/base/path-2"
```

This example uses the `$operationID ()` extension to specify the operation ID.

```
$operationID ()="test-gatewayscript-GET"
```

This example uses the `$statusCode ()` extension to specify the message status code.

```
$statusCode ()=200
```

This example uses the `$header (name)` extension to specify the content type of the message header.

```
$header ("Content-Type")="application/json"
```

Combining conditions with logical operators

You can use **and** and **or** operators to combine multiple functions in a single condition.

This example specifies an HTTP GET request and an API operation path equal to `test-gatewayscript-GET`.

```
$httpVerb()="GET" and $operationPath()="test-gatewayscript-GET"
```

This example specifies either a **POST** or **PUT** request.

```
$httpVerb()="POST" or $httpVerb()="PUT"
```

This example specifies an API operation ID equal to **test-gatewayscript_POST** and a message status code equal to **200**, or an API operation ID equal to **test-gatewayscript-GET** and a message status code equal to **500**.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) or ($operationID()="test-gatewayscript-GET" and $statusCode()=500)
```

This example specifies an API operation ID equal to **test-gatewayscript-POST** and a message status code equal to **200** with an API operation path equal to **/base/path-2**.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) and $operationPath()="/base/path-2"
```

This example specifies a message header content type equal to **text/plain** and a message header length equal to **300**, or a message status code equal to **200**.

```
($header("Content-Type")="text/plain" and $header("Content-Length")=300) or $statusCode()= 200
```

Example switch policy

```
- switch:
  version: 2.0.0
  title: switch
  case:
    - condition: ($statusCode() = 200)
      execute:
        - invoke:
            title: invoke
            timeout: 60
            verb: GET
            cache-response: protocol
            cache-ttl: 900
            target-url: 'https://example.com/1'
    - condition: ($statusCode() != 200 and ($httpVerb() = 'GET' or $httpVerb() = 'PUT'))
      execute:
        - invoke:
            title: invoke
            timeout: 60
            verb: GET
            cache-response: protocol
            cache-ttl: 900
            target-url: 'https://example.com/2'
    - otherwise:
      - set-variable:
          title: set-variable
          actions:
            - set: message.body
              value: Default result
              description: 'Set the default result for the otherwise case'
```

DataPower Gateway (v5 compatible) only

Writing switch condition scripts - DataPower Gateway (v5 compatible)

You write condition scripts for the **switch** policy in the DataPower® Gateway (v5 compatible) by using GatewayScript.

To reference variables in your **switch** conditions, use the form `apim.getvariable('context.location.variable')`, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable.

to define a **switch** condition based on the operation called, use one of the following forms:

```
- condition: "((request.verb=='GET') &&(api.operation.path=='/path-1'))"
```

```
- condition: "((api.operation.id=='Operation_ID'))"
```

where the context variables `request.verb` and `api.operation.path` retrieve the HTTP verb and the path segment of the API and operation that you want your case to apply to, while `api.operation.id` retrieves the operation ID of your operation, if one has been specified.

For information about the context variables you can use and how to reference them in your script, see [API Connect context variables](#).

Example switch policy

```
- switch:
  version: 1.0.0
  title: switch
  case:
    - condition: message.status.code===200
      execute:
        - invoke:
            title: invoke
            timeout: 60
            verb: GET
            cache-response: protocol
            cache-ttl: 900
            target-url: 'https://example.com/1'
```

```

- condition: ((request.verb==='GET') &&(api.operation.path===' /path-2')) || ((request.verb==='GET') &&
(api.operation.path===' /path-1'))
  execute:
    - invoke:
      title: invoke
      timeout: 60
      verb: GET
      cache-response: protocol
      cache-ttl: 900
      target-url: 'https://example.com/2'
    - otherwise:
      - set-variable:
        title: set-variable
        actions:
          - set: message.body
            value: Default result
            description: Set the default result for the otherwise case

```

throw

Use the throw construct to throw an error when it is reached during an assembly flow, usually as a result of a condition being reached.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [throw](#).

About

The throw policy has the following format:

```

- throw:
  title: title
  name: 'error_name'
  error-status-code: http_status_code_for_error
  error-status-reason: http_reason_phrase_for_error
  message: error_message

```

When the throw policy is encountered, the specified error and error message is returned. If a catch has been configured that the error produced by the throw policy fulfills, the catch will be triggered.

Properties

Table 2. throw policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
name	Yes	The name of the error to be thrown.	string
 error-status-code (policy version 2.1.0 and later)	No	Specify the HTTP status code for the error. You can use the <code>\$(variable)</code> format to reference the <code>message.status.code</code> API context variable.	integer
 error-status-reason (policy version 2.1.0 and later)	No	Specify the HTTP reason phrase for the error. You can use the <code>\$(variable)</code> format to reference the <code>message.status.reason</code> API context variable.	string
message	No	The message to accompany the error.	string

Example

```

- throw:
  version: 1.0.0
  title: throw
  name: '404'
  message: Not found

```

User-defined policies

You can apply your own user-defined policies to your APIs.

The policy configuration that you add to the OpenAPI definition file must conform to the schema that you defined in the YAML file that describes the policy, and will have the following general format:

```

policy_name:
  property1: value1
  property2: value2
  .
  .
  .

```

For details on user-defined policies, and how to describe and implement them, see [Authoring policies](#).

user-security

Use the user-security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [User Security](#).

About

The user-security policy has the following format:

```

- user-security:
  version: version
  title: title
  description: description
  factor-id: factor ID
  extract-identity-method: method_used_to_extract_credentials
  .
  .
  .
  properties_specific_to_the_specified_identity_extraction_method
  .
  .
  .
  user-auth-method: authentication_method
  .
  .
  .
  properties_specific_to_the_specified_authentication_method
  .
  .
  .
  user-az-method: authorization_method
  .
  .
  .
  properties_specific_to_the_specified_authorization_method
  .
  .
  .

```

Properties

Table 2. user-security policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
factor-id	No	The identity that identifies the results of factor-authentication in the API context.	string

Property	Required	Description	Data type
extract-identity-method	Yes	<p>Select the method that is used to extract the user credentials. The following options are available:</p> <p>basic Use basic authentication; no additional configuration is required.</p> <p>context-var The credentials are provided by API Connect context variables; specify the following properties:</p> <ul style="list-style-type: none"> • user-context-var: the context variable that is used to obtain the user name. • pass-context-var: the context variable that is used to obtain the password. <p>html-form Use forms based identity-extraction. You can use the default form or a custom form. To use the default form, specify ei-default-form: true. To use a custom form, specify ei-default-form: false and supply the following properties:</p> <ul style="list-style-type: none"> • ei-custom-form: the location of the form. • ei-custom-form-tls-client-profile: the TLS client profile that is used to secure the connection to the remote server. <p>Use the ei-form-time-limit property to specify the time allowed to submit the form.</p> <p>redirect Use a redirect for identity-extraction; specify the following properties:</p> <ul style="list-style-type: none"> • redirect-url: the URL fragment to which to redirect the request to obtain user credentials. • redirect-time-limit: the time allowed for the transaction to complete. <p>disabled Identity-extraction is disabled; this aspect of processing is skipped.</p> <p>Specify ei-stop-on-error: true to halt assembly processing in the event of identity-extraction failure. This field is required if identity extraction is not disabled.</p>	string
user-auth-method	Yes	<p>Select the authentication method. The following options are available:</p> <p>auth-url The credentials are authenticated by an external endpoint; specify the following properties:</p> <ul style="list-style-type: none"> • auth-url: the URL of the authentication endpoint. • auth-tls-client-profile: the TLS client profile that is used to secure the connection to the authentication endpoint. • auth-response-headers-pattern: the pattern that is used to select which response headers to add to the API context. • auth-response-header-credential: the response header that contains the authenticated user credentials. <p>ldap The credentials are authenticated by an LDAP user registry; use the ldap-registry property to specify the required registry.</p> <p>disabled Authentication is disabled; this aspect of processing is skipped.</p> <p>Specify au-stop-on-error: true to halt assembly processing in the event of user authentication failure. This field is required if authentication is not disabled.</p>	string
user-az-method	Yes	<p>Select the authorization method. The following options are available:</p> <p>authenticated Implicitly accept any previously authenticated users; no additional configuration is required.</p> <p>html-form The user provides authorization through an HTML form. You can use the default form or a custom form. To use the default form, specify az-default-form: true. To use a custom form, specify az-default-form: false.</p> <p>Supply the following properties:</p> <ul style="list-style-type: none"> • az-table-dynamic-entries: the name of a context variable that specifies the scopes that are to be added automatically to the authorization consent form. • az-form-time-limit: the time allowed to submit the form. <p>For a custom form, supply the following properties:</p> <ul style="list-style-type: none"> • az-custom-form: the location of the form. • az-custom-form-tls-client-profile: the TLS client profile that is used to secure the connection to the remote server. <p>disabled Authorization is disabled; this aspect of processing is skipped.</p> <p>Specify az-stop-on-error: true to halt assembly processing in the event of user authorization failure. This field is required if authorization is not disabled.</p>	string

Example

```
# basic authentication with LDAP registry

- user-security:
  version: 2.0.0
  title: user-security
  factor-id: default
  extract-identity-method: basic
  ei-stop-on-error: true
  user-auth-method: ldap
  ldap-registry: corporate-ldap
  au-stop-on-error: true
  user-az-method: authenticated
  az-stop-on-error: true
```

validate - DataPower API Gateway

Use the validate policy to validate the payload in an assembly flow against a schema.

Gateway support

Note: This page describes the validate policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see [validate - DataPower Gateway \(v5 compatible\)](#).

For information on the different types of gateway, see [API Connect gateway types](#).

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0
	2.1.0 (DataPower API Gateway Version 10.0.1.0 or later)
	2.2.0 (DataPower API Gateway Version 10.0.2.0 or later)
	2.3.0 (DataPower API Gateway Version 10.0.2.0 or later)
	2.4.0 (DataPower API Gateway Version 10.0.4.0 or later)
	2.5.0 (DataPower API Gateway Version 10.5.0.0 or later)
	2.6.0 (DataPower API Gateway Version 10.5.0.2 or later)
	2.7.0 (DataPower API Gateway Version 10.5.0.3 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Validate - DataPower API Gateway](#).

About

The validate policy has the following format:

```
- validate:
  version: version
  title: title
  description: description
  validate-against: validation_mechanism
  .
  .
  .
  properties_specific_to_the_specified_validation_mechanism
  .
  .
  .
```

Apply this policy by adding an assembly extension with an execute field to your OpenAPI definition file.

Note: With the DataPower API Gateway, the input to the validate policy must be parsed data. One way to produce parsed data is to use a [parse](#) policy before a validate policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. validate policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string

Property	Required	Description	Data type
input	No	Identifies a variable in the API context. The content of the body field of the variable, which is represented by variable_name.body , is the input data to validate. By default, the variable name is message .	string
output	No	Specifies the name of a variable in the API context. <ul style="list-style-type: none"> If the validation passes, the body field of the output variable, which is represented by variable_name.body, stores the output of the assembly validate action. If the schema to validate is a JSON schema, the validation also adds any default values that are missing from the payload. If the validation fails, no output is stored. If an output variable is not specified, the results of the assembly validate action are not saved. 	string
validate-against	Yes	Specifies the schema to be used for validating the payload. Valid values: <ul style="list-style-type: none"> definition: A previously defined schema will be used to validate the payload that is returned from other invoke actions or tasks in the assembly flow. In addition, supply a definition property to specify the required schema. url: the schema is identified by a URL location. In addition, supply the following properties: <ul style="list-style-type: none"> json-schema field: the URL of the JSON schema to be used for validating a JSON payload. xml-validation-mode, specify one of the following values to define how an XML payload is validated: <ul style="list-style-type: none"> xsd: use an XML schema; in addition, supply an xml-schema property that specifies the URL of the XML schema. wSDL: use a WSDL schema; in addition, supply an xml-schema property that specifies the URL of the WSDL schema to be used for validating a SOAP payload.. soap-body: validate the body of a SOAP message against the XML schema only. <p>Note: The following limitations apply to schemas used for JSON validation, which include JSON schemas and OpenAPI documents that are used as schemas for validation. Exceeding these limits can impact compilation performance and is not supported.</p> <ul style="list-style-type: none"> Maximum of 6,500 lines. Each key and each item in an array count as a line. Maximum recursion depth of 250. Maximum of 3,000 items in enum lists. <ul style="list-style-type: none"> wSDL: (use with a SOAP service based API only) use the XML schema in the WSDL file associated with the API operation or the API path. body-param: validate the request input against the schema definition that is specified in the schema property for the request parameter for this operation. response-param: validate the response to be returned to the client application, against the schema definition that is specified in the schema property for the response parameter for this operation. graphql: (use with a GraphQL proxy API only) validate the payload against the GraphQL schema that has been imported into the GraphQL proxy API. In addition, either the GraphQL query or response, depending on the input, is analyzed against the GraphQL schema to calculate the cost, and the result is placed in the API context. <p>For more information on GraphQL proxy APIs, see Creating a GraphQL proxy API and GraphQL context variables.</p>	string
xslt-version	No	The XSLT processor version. The default value is XSLT10.	string
strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
profile	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
debug	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
stream	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
try-stream	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
minimum-escaping	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
stack-size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer

Property	Required	Description	Data type
ws-validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string
wsdl-validate-body	No	The validation behavior for the soap:Body . The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
wsdl-validate-headers	No	The validation behavior for the soap:Header . The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
wsdl-validate-faults	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
wsdl-wrapped-faults	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
allow-soap-enc-array	No	Whether to allow the schema to accept most uses of elements with xsi:type='SOAP-ENC:Array' consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the xsi:type attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, xsi:type is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from SOAP-ENC:Array . The opposite is the normal allowable case. By default, elements with xsi:type='SOAP-ENC:Array' are not accepted.	boolean
validate-soap-enc-array	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
wildcards-ignore-xsi-type	No	Whether xs:any elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an xsi:type attribute on it. This option ignores those xsi:type attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, xsi:type attributes are not ignored.	boolean
wsdl-strict-soap-version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
xacml-debug	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean

Property	Required	Description	Data type
allow-xop-include	No	<p>Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an xop:Include reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled.</p> <ul style="list-style-type: none"> When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as xs:base64Binary or xs:string, but the message contains an xop:Include element instead. When enabled, an xop:Include element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The xop:Include element itself will be validated according to the built-in schema in store:///schemas/xop.xsd. 	boolean

You can also apply a validate policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see [Validate - DataPower API Gateway](#) in the built-in policies section.

Example 1

```
- validate:
  version: 2.0.0
  title: 'validate, response parameter schema'
  validate-against: response-param
```

Example 2

```
- validate:
  version: 2.0.0
  title: 'validate, predefined schema'
  validate-against: definition
  definition: '#/definitions/RouteOutput'
```

Example 3

```
- validate:
  version: 2.0.0
  title: 'validate, JSON and XML schema URLs'
  validate-against: url
  json-schema: 'https://my.json.schema'
  xml-validation-mode: xsd
  xml-schema: 'https://my.xml.schema'
```

DataPower Gateway (v5 compatible)

validate - DataPower Gateway (v5 compatible)

Use the validate policy to validate the payload in an assembly flow against a schema.

Gateway support

Note: This page describes the validate policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see [validate - DataPower API Gateway](#).

For information on the different types of gateway, see [API Connect gateway types](#).

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Validate - DataPower Gateway \(v5 compatible\)](#).

Restriction:

- The schema that represents the XML can reference only one XML namespace.
- The schema cannot reference polymorphic XML elements.
- The validation works on the **message.body** variable and not any other output/context variable. If the invoke policy contains a configured response object variable, then **message.body** is not set, and validate is not able to act.
- If you use the **multipleOf** keyword in a schema definition for the API then, due to rounding behavior, the specified value must satisfy the following conditions, otherwise the validation fails when the API is called:
 - The value must not be less than 0.000009999999999999999848869.
 - If the value is greater than 1, the amount before the decimal point must not be greater than 999999999999999934463.

About

The validate policy has the following format:

```
- validate:
  version: version
  title: title
  description: description
  definition: swagger_schema_definition_to_be_used
```

Apply this policy by adding an assembly extension with an execute field to your OpenAPI definition file.

Properties

The following table describes the policy properties:

Table 2. validate policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
definition	Yes	The schema to be used to validate the payload. Valid values: <ul style="list-style-type: none"> request: Select this value to validate the request input against the schema definition that is specified in the Type field for the request parameter for this operation. For information about how to create a request parameter, see Configuring an operation. response: Select this value to validate the response to be returned to the client application, against the schema definition that is specified in the Schema field for the response parameter for this operation. For information about how to create a response parameter, see Configuring an operation. The name of a schema definition, in the following format: <pre>#/definitions/schema_name</pre> The schema must be defined in the definitions: section of your OpenAPI file. 	string

You can also apply an validate policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see [Validate - DataPower Gateway \(v5 compatible\)](#), in the built-in policies section.

Example 1

```
validate:
  version: 1.0.0
  title: validate the response
  definition: #/definitions/RouteOutput
```

validate-username token

Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0 1.1.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [Validate Username Token](#).

About

The validate-username token policy has the following format:

```
- validate-username token:
  version: version
  title: title
  description: description
  auth-type: Authentication URL or LDAP Registry (policy version 1.0.0 only)
  auth-url: authentication_url_to_use (policy version 1.0.0 only)
  tls-profile: tls_profile_to_use (policy version 1.0.0 only)
  ldap-registry: name_of_the_ldap_user_registry (policy version 1.0.0 only)
  registry: name_of_the_ldap_or_authurl_user_registry (policy version 1.1.0 and later)
  ldap-search-attribute: name_of_the_ldap_user_password_attribute
```

Properties

The following table describes the policy properties:

Table 2. Validate Username Token policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
auth-type (policy version 1.0.0 only)	Yes	The authentication type to use to validate the UsernameToken. Valid values: <ul style="list-style-type: none"> Authentication URL: Specify this value to validate the user credentials against an authentication URL. LDAP registry: Specify this value to validate the user credentials against an LDAP user registry. The default value is: Authentication URL .	string
auth-url (policy version 1.0.0 only)	Yes	The authentication URL to use to validate the UsernameToken user credentials against. Note: This property is required only if Authentication type is set to Authentication URL .	string
tls-profile (policy version 1.0.0 only)	No	The TLS profile to use for the secure transmission of data to the authentication URL. Note: This property is available only if Authentication type is set to Authentication URL .	string
ldap-registry (policy version 1.0.0 only)	Yes	The name of the LDAP user registry to validate the UsernameToken user credentials against. Note: This property is required only if Authentication type is set to LDAP registry .	string
registry (policy version 1.1.0 and later)	Yes	The name of the LDAP or Authentication URL registry to use to validate the UsernameToken.	string
ldap-search-attribute	Yes	The name of the LDAP user password attribute. Note: This property is required only for an LDAP user registry.	string

Examples

The following example shows an LDAP user registry authentication:

```
- validate-username-token:
  version: 1.0.0
  title: "validate-username-token"
  auth-type: "LDAP Registry"
  ldap-registry: "wstest"
  ldap-search-attribute: "userPassword"
```

The following example shows an Authentication URL definition:

```
- validate-username-token:
  version: 1.0.0
  title: "validate-username-token"
  auth-type: "Authentication URL"
  auth-url: "https://www.google.com"
  tls-profile: "default-ssl-profile"
```

For more information about how to use a validate-username-token security policy, see [Validate Username Token](#) in the built-in policies section.

websocket-upgrade

Use the websocket-upgrade policy to process API requests and responses through a WebSocket connection.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [WebSocket Upgrade](#).

The websocket-upgrade policy has the following format:

```
- websocket-upgrade:
  version: version
  title: title
  description: description
  target-url: URL_of_target_API
  tls-profile: TLS_profile_to_be_used
  timeout: timeout_value_in_seconds
  follow-redirects: redirect_behavior_on_301_error
  username: username_if_authentication_required
  password: password_if_authentication_required
  inject-proxy-headers: are_proxy_headers_sent_to_target_url
  decode-request-params: are_request_parameters_decoded
  encode-plus-char: are_plus_characters_encoded
  header-control:
  .
  .
  headers_to_copy_to_target_url
  .
```

```

parameter-control:
.
.
.
parameters_to_copy_to_target_url
.
.
.

```

Properties

Table 2. websocket-upgrade policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
target-url	Yes	Specify the URL to be invoked.	string
tls-profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is 60 .	integer
follow-redirects	No	Specifies the behavior if the back-end server returns the HTTP status code 301 Moved Permanently . If this property is set to true , the invoke policy follows the URL redirection by making a further call to the URL specified in the Location header in the response. If this property is set to false , the invoke saves the 301 status code and the API call is considered to be complete. Note: The follow-redirect property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the invoke always follows the URL redirection; the proxy policy (not supported by the DataPower API Gateway) saves the 301 status code and completes the API call without following the URL redirection.	boolean
username	No	The username to use for HTTP Basic authentication.	string
password	No	The password to use for HTTP Basic authentication.	string
inject-proxy-headers	No	When set to true, the invoke policy injects the X-Forwarded-For , X-Forwarded-To , X-Forwarded-Host , and X-Forwarded-Proto headers to the request that is sent to the target-url . The default value is false .	boolean
decode-request-params	No	When set to true, any request parameters that are referenced by a variable definition on the target-url of the invoke policy are URL-decoded. The default value is false .	boolean
encode-plus-char	No	When set to true, all "+" characters in the query parameter values of the target-url are encoded to %2F. The default value is false .	boolean
header-control: type values	No	Specifies the headers in message.headers that you want to copy to the target URL. If the type property is set to blocklist , the values property lists the headers that you don't want to be copied. If the values property is empty then all headers are copied. If the type property is set to allowlist , the values property lists the headers that you want to be copied. The items that are listed in the values property are in regular expression format. The values are not case-sensitive. The default value of the header-control property is header-control: type: blocklist values: [] See header-control examples	object
parameter-control: type values	No	Specifies the parameters in the incoming request that you want to be copied to the target URL. If the type property is set to blocklist , the values property lists the parameters that you don't want to be copied. If the type property is set to allowlist , the values property lists the parameters that you want to be copied. If the values property is empty then no parameters are copied. The items that are listed in the values property are in regular expression format. The values are not case-sensitive. The default value of the parameter-control property is parameter-control: type: allowlist values: [] See parameter-control examples	object
request-assembly: execute . . . policy assembly . . .	No	The request processing assembly. For details on configuring an assembly in the execute section, see execute .	object

Property	Required	Description	Data type
response-assembly: execute . . . policy assembly . . .	No	The response processing assembly. For details on configuring an assembly in the <code>execute</code> section, see execute .	object

Example

```
- websocket-upgrade:
  version: 2.0.0
  title: websocket-upgrade
  timeout: 60
  target-url: 'https://my.websocket.upgrade.com'
  secure-gateway: false
  follow-redirects: true
  inject-proxy-headers: true
  decode-request-params: false
  encode-plus-char: true
  response-assembly:
    execute:
      - parse:
          version: 2.0.0
          title: parse
          parse-settings-reference:
            default: apic-default-parsesettings
          description: Parse the response from the backend server
```

header-control examples

```
# copy all headers to the target URL

- invoke:
  target-url: http://myhost/mypath
  header-control:
    type: blocklist
    values: []

# copy all headers except X-Client-ID and Content-Type

- invoke:
  target-url: http://myhost/mypath
  header-control:
    type: allowlist
    values:
      - ^X-Client-ID$
      - ^Content-Type$

# copy no headers

- invoke:
  target-url: http://myhost/mypath
  header-control:
    type: allowlist
    values: []

# copy only the Content-Type header

- invoke:
  target-url: http://myhost/mypath
  header-control:
    type: allowlist
    values:
      - ^Content-Type$
```

parameter-control examples

```
# copy no request parameters to the target URL

- invoke:
  target-url: http://myhost/path?storeid=3
  parameter-control:
    type: allowlist
    values: []

# append the petid parameter to the target URL
# if the incoming request is http://apigw/org/sandbox/petstore/base?petid=100&display=detailed,
# the target URL at runtime will be http://myhost/mypath?storeid=3&petid=100

- invoke:
  target-url: http://myhost/path?storeid=3
  parameter-control:
    type: allowlist
    values:
      - ^petid$
```

xml-to-json

Use the xml-to-json policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [XML to JSON](#).

About

The xml-to-json policy has the following structure:

```
- xml-to-json:  
  version: version  
  title: Title  
  description: Description
```

Note: If you are using the DataPower API Gateway, the input to the xml-to-json policy must be parsed data. One way to produce parsed data is to use a [parse](#) policy before an xml-to-json policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. Policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
<small>API Gateway only</small> input	No	The input message to convert. Specify the name of a variable in the API context. variableName.body , the message payload, represents the JSON input to convert. The default value of the variable is message and message.body is the default input.	string
<small>API Gateway only</small> output	No	The output message to store the conversion result. Specify the name of a variable in the API context. variableName.body represents the result of conversion from JSON format to XML format. When the specified input message is the default message, the default output is message.body . Otherwise, when the input message is the variable my-message-variable , for example, the default output is my-message-variable.body . The variable cannot be any read-only in the API context.	string
<small>API Gateway only</small> conversionType	No	The conversion type that determines the target format of the output. The following options are available: <ul style="list-style-type: none">badgerFish: BadgerFish convention is used to determine the target conversion format of the output.apicv5: apicv5 convention is used to determine the target conversion format of the output.	string

Example

The following is an example of a xml-to-json policy:

```
- xml-to-json:  
  version: 1.0.0  
  title: XML to JSON transform  
  description: Transforms XML message body to JSON format
```

xslt

Use the xslt policy to apply an XSLT transform to the payload of the API definition.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.4.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see [XSLT](#).

About

The xslt policy has the following structure:

```
- xslt:
  version: version
  title: Title
  description: Description
  input: Input_True_False
  source: Transform
```

Note: If you are using the DataPower API Gateway, the input to the xslt policy must be parsed data. One way to produce parsed data is to use a [parse](#) policy before an xslt policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. xslt policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
input	No	Indicates whether this XSLT input document uses the context current payload, or if there is no input. The default value is false .	boolean
 serialize-output	No	If set to true , the output tree that is generated by the XSLT policy is serialized. The content of <code>message.body</code> is updated with the serialized binary data rather than the XML tree. The default value is false .	boolean
source	Yes	The XSLT transform source to execute.	string
 xslt-version	No	The XSLT processor version. The default value is XSLT10.	string
 strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
 profile	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
 debug	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
 stream	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
 try-stream	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
 minimum-escaping	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
 stack-size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer
 wsi-validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string
 wsd-validate-body	No	The validation behavior for the <code>soap:Body</code> . The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string

Property	Required	Description	Data type
API Gateway only wsdl-validate-headers	No	The validation behavior for the <code>soap:Header</code> . The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
API Gateway only wsdl-validate-faults	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
API Gateway only wsdl-wrapped-faults	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
API Gateway only allow-soap-enc-array	No	Whether to allow the schema to accept most uses of elements with <code>xsi:type='SOAP-ENC:Array'</code> consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the <code>xsi:type</code> attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, <code>xsi:type</code> is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from <code>SOAP-ENC:Array</code> . The opposite is the normal allowable case. By default, elements with <code>xsi:type='SOAP-ENC:Array'</code> are not accepted.	boolean
API Gateway only validate-soap-enc-array	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
API Gateway only wildcards-ignore-xsi-type	No	Whether <code>xs:any</code> elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an <code>xsi:type</code> attribute on it. This option ignores those <code>xsi:type</code> attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, <code>xsi:type</code> attributes are not ignored.	boolean
API Gateway only wsdl-strict-soap-version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
API Gateway only xacml-debug	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean
API Gateway only allow-xop-include	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an <code>xop:Include</code> reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. <ul style="list-style-type: none"> When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as <code>xs:base64Binary</code> or <code>xs:string</code>, but the message contains an <code>xop:Include</code> element instead. When enabled, an <code>xop:Include</code> element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The <code>xop:Include</code> element itself will be validated according to the built-in schema in <code>store:///schemas/xop.xsd</code>. 	boolean

You can also apply an xslt policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see [XSLT](#) in the built-in policies section.

For examples of the OpenAPI definitions of xslt policies, see [XSLT policy examples](#) in the built-in policies section.

For more examples of how to use XSLT to access and modify properties and context, see [Implementation code examples](#) and, if you are using the DataPower API Gateway, [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#).

catch

Use the `catch` extension to catch errors that occur during an API call.

The `catch` extension takes the following form:

```
catch:
- errors:
  - Error_1
  - Error_2
- execute:
  assembly_1
- errors:
  - Error_3
- execute:
  assembly_2
- default:
  assembly_3
```

The following table shows the properties of the `catch` extension:

Table 1. The properties of the `catch` extension

Property	Required	Description	Type
<code>errors</code>	Yes	The errors for which the catch will activate. For a list of errors, see Error cases supported by assembly catches .	Array (String)
<code>execute</code>	Yes	The section of the assembly that will execute when the catch is activated.	Array (Object)
<code>default</code>	No	The section of the assembly that will execute when an error does not trigger other catches. It behaves in the same manner and has the same structure as <code>execute</code> .	Array (Object)

The following is an example of a `catch` extension:

```
catch:
- errors:
  - ConnectionError
  - JavaScriptError
  execute:
  - activity-log:
    title: activity-log
    content: activity
    error-content: payload
- default:
  - activity-log:
    title: activity-log
    content: activity
    error-content: payload
```

properties

Use the `properties` extension to define properties for referencing in an API.

The `properties` extension has the following structure:

```
properties:
  property_1:
    value: default_value_1
    description: description_1
    encoded: encoded_boolean_1
  property_2:
    value: default_value_2
    description: description_2
    encoded: encoded_boolean_2
```

The following table lists the fields found in the `properties` extension:

Table 1. The properties extension

Property	Required	Description	Data type
<code>property</code>	Yes	The name of the property. It is used when referencing the property. Note that this is the field name, not the contents of the field.	Object
<code>value</code>	No	The default value that the property takes. It can be empty.	String
<code>description</code>	No	The description of the property. It can be empty.	String
<code>encoded</code>	No	Specifies whether to encode the value of this property.	Boolean

The following example shows a sample `properties` field:

```
properties:
  ID:
    value: 1234
    description: An ID to be used for validating.
    encoded: false
```

catalogs

Use the `catalogs` extension to assign catalog-specific values to properties defined in the `properties` section.

The `catalogs` section has the following structure:

```
catalogs:
  catalog_name_1:
    properties:
      property_name_1: value_1
      property_name_2: value_2
  catalog_name_2:
    properties:
      property_name_1: value_3
```

The following table lists the fields found in the `catalogs` extension:

Table 1. Catalogs properties

Property	Required	Description	Data type
<code>catalog_name</code>	Yes	The name of the catalog. It must match a catalog in API Manager. Note that this is the field name, not the contents of the field.	Object
<code>properties</code>	Yes	This field contains any properties that are to be set.	Object
<code>property_name</code>	Yes	The field name is the property to be set and must match a property defined in the <code>properties</code> extension. It contains the value of the property for the catalog to which the field belongs. If, in the <code>properties</code> extension, it has been specified as encoded, this will be encoded when saved or staged by IBM® API Connect.	String

The following is an example of a `catalogs` extension:

```
catalogs:
  Sandbox:
    properties:
      ID: 5678
```

activity-log

If you're using the DataPower® API Gateway, you can use the `activity-log` extension to configure your logging preferences for the API activity that is stored in Analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.

An API event record exists for each API execution event in the Gateway server. By default, the content type that is collected and stored in API event records is `activity` for when API execution completes successfully, and `payload` for when API execution completes with an error code. When you compose your API definition, you can change the type of content to log in these API event records. For more information about API event records, see [API event record fields](#).

Note that if you're using the DataPower Gateway (v5 compatible), you can configure your logging preferences by using an `activity-log` policy in your API assembly. For more information, see [activity-log](#).

The `activity-log` extension takes the following form:

```
activity-log:
  success-content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
  enabled: is_activity_logging_enabled
```

Note: If payload logging is enabled, for the gateway to capture payloads buffering must also be enabled.

```
activity-log:
  success-content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
  enabled: is_activity_logging_enabled
  buffering: true
```

The following table shows the properties of the `activity-log` extension:

Table 1. The properties of the activity-log extension

Property	Required	Description	Type
<code>success-content</code>	No	Defines the type of content to be logged when the operation is successful. Valid values: <ul style="list-style-type: none"> <code>none</code>: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. <code>activity</code>: Logs invocation only (only the resource URI is recorded). <code>header</code>: Logs activity and header. <code>payload</code>: Logs activity, header, and payload (the original request, if any, and the final response). The default value is <code>activity</code> .	String
<code>error-content</code>	No	Indicates what content to log when an error occurs. Valid values: <ul style="list-style-type: none"> <code>none</code>: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. <code>activity</code>: Logs invocation only (only the resource URI is recorded). <code>header</code>: Logs activity and header. <code>payload</code>: Logs activity, header, and payload (the original request, if any, and the final response). The default value is <code>payload</code> .	String
<code>enabled</code>	No	Indicates whether activity logging is enabled or disabled.	Boolean

Example 1

Override the default activity logging settings:

```
activity-log:
  success-content: none
  error-content: header
  enabled: true
```

Example 2

Turn off activity logging:

```
activity-log:
  enabled: false
```

Specifying a gateway type for an API definition

An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). API definitions must specify which type of gateway the API uses.

Before you begin

IBM® API Connect supports two gateway types: DataPower Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see [API Connect gateway types](#).

About this task

You must specify which type of gateway each API uses. APIs can use only one type of gateway.

When you modify your API definitions to use a specific gateway type, you must ensure that each policy and policy version in the API are supported by the gateway type. DataPower Gateway (v5 compatible) and DataPower API Gateway each support policies that the other gateway type does not. In some cases, the same policy is supported by both gateway types, but with a different version number.

For example, DataPower Gateway (v5 compatible) supports version **1.0.0** of the **invoke** policy, but DataPower API Gateway requires version **2.0.0**.

For information on policies, see [execute](#).

For information on policy versions, see the documentation for each individual policy. For example, to review the **invoke** policy, see [invoke](#).

Procedure

1. Edit the API definition YAML file and add the gateway type. For example:

- DataPower Gateway (v5 compatible):

```
gateway: datapower-gateway
```

- DataPower API Gateway

```
gateway: datapower-api-gateway
```

Note: If your API YAML file includes the **gateway**: property, the **enforced**: property must be set to **true**

2. Ensure that the policies, including policy versions, in your APIs are supported by the gateway type. Review the list of policies on the [execute](#) page. If necessary, review the individual policy pages to determine the supported version number.
3. Ensure that any Product that uses this API is configured to use the same gateway type. See [Specifying a gateway type for your Product](#).

Referring to an extension in an API definition

To refer to an OpenAPI extension in your API definition YAML (or JSON) file, add an **extensions** key under **x-ibm-configuration**.

Before you begin

Add the OpenAPI extension to any Catalogs that the API is to be published to, by importing its definition file; for details, see [Working with OpenAPI extensions](#). If the target Catalog does not contain the OpenAPI extension then attempts to publish the API to it will fail.

About this task

The following example shows an extension definition file that defines a bank branch, in YAML format:

```
extension: '1.0.0'

info:
  title: Banking services
  name: banking
  version: 1.0.0
  description: Banking extensions
  contact:
    name: IBM API Connect
    url: https://apiconnect.ibm.com/
    email: myname@ibm.com

portal-visible: true

properties:
  title: "Branch"
  type: "object"
  properties:
    Branch type:
      type: "string"
      enum:
        - "ATM"
        - "Walk in"
    location:
      type: "object"
      title: "Location"
      properties:
        city:
          type: "string"
          default: "San Francisco"
        state:
          type: "string"
          default: "CA"
        citystate:
          type: "string"
          description: "This is generated automatically from the previous two fields"
          template: "{{city}}, {{state}}"
          watch:
            city: "location.city"
            state: "location.state"
      required:
        - Branch type
```

Procedure

1. Edit the API definition YAML file and add the reference. For example:

```
x-ibm-configuration:
  .
  .
  .
  extensions:
    banking: 1.0.0
```

2. In your API definition file, add a property whose name must begin with `x-` and references the name of the extension you created. Specify the values of the properties that were defined in the OpenAPI extension YAML file. The following example uses the banking extension:

```
.
.
.
x-banking:
  Branch type: ATM
  location:
    city: San Francisco
    state: CA
    citystate: 'San Francisco, CA'
```

Using `$ref` to reuse code fragments in your OpenAPI files

If you deploy an API to an IBM® API Connect Management server by using the developer toolkit command line, you can use the `$ref` field in your OpenAPI YAML and JSON API definition files to reference a fragment of OpenAPI code that is defined in a separate file. When API Connect processes the source API definition file, the `$ref` field is replaced with the contents of the target file.

Use the following syntax in your source YAML file:

```
$ref: path_to_file_containing_code_fragment
```

Use the following syntax in your source JSON file:

```
{
  $ref: path_to_file_containing_code_fragment
}
```

```
}
```

For example:

```
$ref: code_fragments/my_fragment.yaml  
  
{  
  "$ref": "code_fragments/my_fragment.json"  
}
```

The replacement of the `$ref` field with the target code fragment occurs when you perform any of the following actions on the API defined by the source API definition file:

- Stage or publish an API to an API Connect Management server by using the **apic publish** command. For more information, see [Publishing APIs and applications](#).
- Validate the API definition YAML file by using the **apic validate** command. For more information, see [Validating the YAML or JSON definition of an API or Product](#).

Important: You cannot insert a `$ref` field at the root level of your OpenAPI file.

Example 1

A source YAML file contains the following OpenAPI code:

```
swagger: '2.0'  
info:  
  version: 1.0.0  
  title: Branches  
  x-ibm-name: Branches  
  description: Provides operations relating to BankA branch information.  
basePath: /branches  
paths:  
  /details:  
    get:  
      responses:  
        - $ref: code_fragments/paths.yaml#/details/get/responses  
        .  
        .  
        .
```

The file `paths.yaml` contains the following OpenAPI code fragment:

```
details:  
  get:  
    responses:  
      '200':  
        description: 200 OK defined in $ref file  
        schema:  
          $ref: '#/definitions/branch'  
        summary: Branch details  
        description: Retrieve details of the current branches of BankA.
```

When API Connect processes the source YAML file, the `$ref` field is replaced with the target code fragment, yielding the following OpenAPI code:

```
swagger: '2.0'  
info:  
  version: 1.0.0  
  title: Branches  
  x-ibm-name: Branches  
  description: Provides operations relating to BankA branch information.  
basePath: /branches  
paths:  
  /details:  
    get:  
      responses:  
        '200':  
          description: 200 OK  
          schema:  
            $ref: '#/definitions/branch'  
          summary: Branch details  
          description: Retrieve details of the current branches of BankA.  
        .  
        .  
        .
```

Example 2

Example of a reference to an external file that contains just the parameter details:

```
openapi: 3.0.0  
  
info:  
  version: 3.0.1  
  title: BeamUp API  
  x-ibm-name: BeamUpAPI  
servers:  
  - url: /  
paths:  
  /customers:  
    get:  
      parameters:  
        - $ref: tests/fixtures/api/referenceFile.yaml  
      responses:  
        200:  
          description: An array of customers
```

```

    content:
      application/json:
        schema:
          type: object
          properties:
            customerID:
              type: string
            customerName:
              type: string
  .
  .
  .

```

The file `referenceFile.yaml` contains the following OpenAPI code fragment:

```

name: page
in: query
description: page of results to return
required: true
schema:
  type: integer

```

Example of a reference to an external file that contains the parameters inside a path code fragment:

```

openapi: 3.0.0

info:
  version: 3.0.1
  title: BeamUp API
  x-ibm-name: BeamUpAPI
servers:
  - url: /
paths:
  /customers:
    get:
      parameters:
        - $ref: tests/fixtures/api/referenceFileWithPath.yaml#/customers/get/parameters
      responses:
        200:
          description: An array of customers
          content:
            application/json:
              schema:
                type: object
                properties:
                  customerID:
                    type: string
                  customerName:
                    type: string

```

The file `referenceFileWithPath.yaml` contains the following OpenAPI code fragment:

```

customers:
  get:
    parameters:
      name: page
      in: query
      description: page of results to return
      required: true
      schema:
        type: integer

```

Creating a Product definition file

You define a Product by creating a Product definition file.

About this task

You can create a Product definition file in either of the following ways:

- Create the file in an editor of your choice.
- Create a Product definition file by using the `apic create:product` command and then modify it. You can base your Product definition file on the default Product template or on your own custom template.

This topic describes the syntax that is needed for both options and also the structure needed when the file is created in the editor. For details on what you can include in the product definition file, see [Product definition schema](#).

You can create a Product in the CLI by running `apic create:product` and supplying additional arguments on the command line. For example, you can enter the following text in a single command:

```

apic create:product --name product_name --title product_title --filename product_file_name.yaml
--apis "filename_of_api1.yaml filename_of_api2.yaml"

```

where:

- `product_name` is the name for your new Product.
- `product_title` is the title of your new Product.
- `product_file_name.yaml` is the name of the yaml file that is created for your new Product.
- `filename_of_api1.yaml` is the file name of one of the APIs that is used within the new Product.

- `filename_of_api2.yaml` is the file name of one of the APIs that is used within the new Product.

Another option is to create a Product interactively in the command line by running `apic create:product` and following the prompts.

You can see further details and available options for the `apic create:product` command by entering the command:

```
apic create:product --help
```

You can also create a Product from a custom Handlebars template by using the following command:

```
apic create:product --template template_filename --title product_title
```

where `template_filename` is the name of the Handlebars template to use, and `product_title` is the title of your Product. A Product template file must have a `.hbs` file name extension. You can create a template from scratch, or start with the example (default) Product template provided in [API and Product definition template examples](#). A Product definition file contains the following sections:

- The specification version
- An information section
- A visibility section
- An APIs section
- A Plans section

In this topic, YAML is used, but the instructions can be adapted to use JSON. Both `.yaml` and `.yml` file extensions are supported, but the use of the `.yaml` file extension is recommended by [yaml.org](#).

Note: All keys and enumeration values that are specified in this topic are case-sensitive.

Procedure

Structure your Product definition file by completing the following steps:

1. Set the specification version by adding the following line to the beginning of the file: `product: 1.0.0`.
This line specifies the template version, and is always `product: 1.0.0`.
Note: The specification version is distinct from your Product version. The specification version refers to this YAML file, while the Product version is by your discretion.
2. Include an information section with details about the Product, as described in [Completing the information section of your Product description](#).
3. Include a visibility section that specifies who can view and subscribe to the Product, as described in [Specifying the visibility of your Product](#).
4. Include an APIs section that references the APIs to be included in the Product, as described in [Referencing the APIs for your Product](#).
5. Include a Plans section that described the Plans you want include in your Product, as described in [Describing Plans in your Product](#).

Results

You have completed a YAML representation of your Product. A complete example with full indentation can be found in [An example YAML representation of a Product](#).

You can create multilingual API and Product documentation by using an `x-ibm-languages` extension directly in the OpenAPI definition. For more information, see [Using x-ibm-languages to create multilingual API and Product documentation](#).

- [Product definition schema](#)
The product definition schema defines the properties (and their data types) that you can include in a product definition file.
- [Converting a Product YAML file to use DataPower API Gateway](#)
IBM API Connect now supports DataPower® API Gateway. You can optionally specify this gateway type in your Product YAML file.

Completing the information section of your Product description

Provide users with information about your Product.

About this task

The information section of a YAML representation of a Product contains the Product's name and version. It can also include contact and license details.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.

An example information section for a YAML representation of a Product can be found at the end of this topic. An example of a complete YAML representation of a Product can be found in [An example YAML representation of a Product](#).

Procedure

To complete the information section of your Product description, complete the following steps.

1. Begin the section and provide a name, title, description, and version number; use the following syntax:

```

info:
  version: Product_Version
  title: Product_Title
  name: Short_Name
  summary: Product_Description

```

where:

- *version* is the version number of the policy.
Tip: The **version.release.modification** version numbering scheme is recommended, for example 1.0.0.
- *Product_Title* is the title of the Product. Any string can be used, but the title should be kept short so that it can be displayed in the API Manager user interface.
- *Short_Name* is the short name for the policy. It must be a single word and contain only alphanumeric characters, and the - (dash) and _ (underscore) characters. The name is case-sensitive, and should be 20 characters or fewer so that it can be displayed in the API Manager user interface of IBM API Connect.
- *Product_Description* is a short description of the policy. Any string can be used.

2. Optional: Under info, supply contact information; use the following syntax:

```

contact:
  name: Contact_Name
  url: 'Contact_URL'
  email: Contact_email

```

where:

- *Contact_Name* is the name of the contact for this Product.
- *Contact_URL* is the URL for contact your organization.
- *Contact_email* is an email for contacting your organization.

3. Optional: Under info, add license information for your Product; use the following syntax:

```

license:
  name: License_Name
  url: 'License_URL'

```

where:

- *License_Name* is the name of the license that applied to your Product.
- *License_URL* is the URL at which information about the license can be accessed.

4. Optional: Under info, add your terms of service; use the following syntax:

```
termsOfService: Terms
```

where *Terms* is a string that details the terms of service for using your Product.

Results

You have completed the information section of your Product's YAML representation. It should have the following form:

```
info:
  version: Product_Version
  title: Product_Title
  name: Short_Name
  description: Product_Description
  contact:
    name: Contact_Name
    url: 'Contact_URL'
    email: Contact_email
  license:
    name: License_Name
    url: 'License_URL'
  termsOfService: Service_Terms
```

where all variables are as described in previously in this topic. The indentation must be as in the example.

Specifying a gateway type for your Product

Product definitions must specify which type of gateway the Product uses.

Before you begin

IBM® API Connect supports two gateway types: DataPower® Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see [API Connect gateway types](#).

About this task

You can specify the gateway type for a Product.

Products can use only one type of gateway, and the APIs in the Product must use the same type of gateway. See [Specifying a gateway type for an API definition](#).

Procedure

1. Determine the gateway type that is configured for the APIs in your Product. The Product gateway type must match the APIs gateway type. To review the APIs for your Product, see [Referencing the APIs for your Product](#).

2. Edit the Product definition file (YAML source) to add the gateway type you want to use:

- DataPower Gateway (v5 compatible):

```
gateways:
  datapower-gateway
```

- DataPower API Gateway

```
gateways:
  datapower-api-gateway
```

3. Ensure that the policies, including policy versions, in the APIs in your Product are supported by the gateway type. Review the list of policies on the [execute](#) page. If necessary, review the individual policy pages to determine the supported version number.

Related information

- [DataPower API Gateway porting notes](#)

Converting a Product YAML file to use DataPower API Gateway

IBM® API Connect now supports DataPower® API Gateway. You can optionally specify this gateway type in your Product YAML file.

Before you begin

IBM API Connect provides two gateway types, DataPower Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see [API Connect gateway types](#).

About this task

Product definitions can specify only one type of gateway. The type of gateway must match the gateway type that is used by the APIs that are included in the product. If you want to take advantage of the capabilities of DataPower API Gateway, you can easily modify your existing Product definitions to specify it as the gateway type.

Procedure

1. Verify that the APIs in the product specify DataPower API Gateway as the gateway type, and that the APIs have been converted for use with the DataPower API Gateway.
2. Open the Product YAML file for editing.
For example:

```
product: '1.0.0'
info:
  name: testprod
  title: testprod
  version: 1.0.0
  .
  .
```

3. Add a `gateways` setting, and specify `datapower-api-gateway`.
For example:

```
product: '1.0.0'
info:
  name: testprod
  title: testprod
  version: 1.0.0
gateways:
- datapower-api-gateway
  .
  .
```

4. Save the modified YAML file.

Specifying the visibility of your Product

How to set the availability of your Product by specifying its visibility and subscribability levels.

About this task

The visibility section of your Product's YAML representation determines who can view and subscribe to your Product in IBM® API Connect.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.

An example visibility section of a YAML representation of a Product can be found at the end of this topic. An example of a complete YAML representation of a Product can be found in [An example YAML representation of a Product](#).

Procedure

To complete the visibility section of your Product description, complete the following steps:

1. Title the section by adding `visibility`:
2. Under `visibility`, specify who can `view` the Product; use the following syntax:

```
view:
  enabled: View_Toggle
  type: View_Audience
  tags: View_Tag
  orgs: View_Organizations
```

where

- `View_Toggle` determines whether the Product is visible to anybody or not. It must be `true` or `false`. If `false`, the Product will not be visible in the Developer Portal.
- `View_Audience` must be `public`, in which case the Product is visible to anybody who uses the Developer Portal, `authenticated`, in which case the Product is visible to anybody registered through the Developer Portal, or `custom`, in which case the Product is visible to a specified group of users. You can specify these custom users as one or more consumer organizations in the `orgs` section, and as one or more consumer organization groups in the `tags` section.
- The `View_Tag` specifies the consumer organization groups that can view the Product if `View_Audience` is set to `custom`. If `View_Audience` is not set to `custom`, do not include `tags`. If `View_Audience` is `custom`, you can specify groups in the following manner:

```
tags:
  - Organization group 1
  - Organization group 2
```

where the *Organization group* variables are the names of the groups that are to be allowed to view the Product. Note that when a Product is published, the `tags`: property name becomes `group_urls`:, and the content is changed to URL strings.

- *View_Organizations* specifies the consumer organizations that can view the Product if *View_Audience* is set to `custom`. If *View_Audience* is not set to `custom`, do not include `orgs`:. If *View_Audience* is `custom`, you can specify organizations in the following manner:

```
orgs:
  - Organization 1
  - Organization 2
```

where the *Organization* variables are the names of the organizations that are to be allowed to view the Product. Note that when a Product is published, the `orgs`: property name becomes `org_urls`:, and the content is changed to URL strings.

3. Under `visibility`:, specify who can **subscribe** to your Product's Plans; use the following syntax:

```
subscribe:
  enabled: Subscribe Toggle
  type: Subscribe Audience
  tags: Subscribe Tag
  orgs: Subscribe Organizations
```

where:

- *Subscribe_Toggle* must be `true` or `false`. If `false`, no developers will be able to subscribe to the Product.
- *Subscribe_Audience* must be `authenticated`, in which case the Product's Plans can be subscribed to by anybody who is registered through the Developer Portal, or `custom`, in which case the Product's Plans can be subscribed to by a specified group of users.
- The *Subscribe_Tag* specifies the consumer organization groups that can subscribe to the Product's Plans if *Subscribe_Audience* is set to `custom`. If *Subscribe_Audience* is not set to `custom`, omit it or set as `[]`. If *Subscribe_Audience* is `custom`, you can specify groups in the following manner:

```
tags:
  - Organization group 1
  - Organization group 2
```

where the *Organization group* variables are the names of the groups that are to be allowed to subscribe to the Product. Note that when a Product is published, the `tags`: property name becomes `group_urls`:, and the content is changed to URL strings.

- *Subscribe_Organizations* specifies the organizations that can subscribe to the Product's Plans if *Subscribe_Audience* is set to `custom`. If *Subscribe_Audience* is not set to `custom`, omit it or set as `[]`. If *Subscribe_Audience* is `custom`, you can specify organizations in the following manner:

```
orgs:
  - Organization 1
  - Organization 2
```

where the *Organization* variables are the names of the organizations that are to be allowed to subscribe to the Product. Note that when a Product is published, the `orgs`: property name becomes `org_urls`:, and the content is changed to URL strings.

Note: If a Product is to be available for subscription, it must already be visible. As a result, for the subscription audience to be `authenticated`, the view audience cannot be `custom`.

Results

You have completed the visibility section of your Product's YAML representation. It should have the following form:

```
visibility:
  view:
    enabled: View Toggle
    type: View Audience
    tags:
      - View Tag 1
      - View Tag 2
    orgs:
      - Organization 1
      - Organization 2

  subscribe:
    enabled: Subscribe Toggle
    type: Subscribe Audience
    tags:
      - Subscribe Tag 1
      - Subscribe Tag 2
    orgs:
      - Organization 1
      - Organization 2
```

where all variables are as described previously in this topic. The indentation must be as in the example.

What to do next

You can also define Product visibility at a Catalog or Space level. For more information, see [Configuring Product visibility at a Catalog or Space level](#).

Related information

- [Configuring Product visibility at a Catalog or Space level](#)

Referencing the APIs for your Product

Detail the file paths for the APIs you want to include in your Product in IBM® API Connect.

About this task

Before an API can be included in a Plan, it must first be referenced in the APIs section of your Product description.

Procedure

Begin the APIs section and reference the APIs you want to include in your Product. The syntax that you use depends on which user interface you are using, as follows:

- API Designer:

```
apis:  
  API_1_NameAPI_1_Version  
    $ref: API_1_File_Path  
  API_2_NameAPI_2_Version  
    $ref: API_2_File_Path
```

- API Manager:

```
apis:  
  API_1_NameAPI_1_Version  
    name: 'API_1_Name:API_1_Version'  
  API_2_NameAPI_2_Version  
    name: 'API_2_Name:API_2_Version'
```

where

- the *API_n_Name* variables are the case-sensitive names of your APIs.
- the *API_n_Version* variables are the versions of your APIs.
- the *API_n_File_Path* variables are the file paths for the YAML files containing OpenAPI representations of your APIs.

The following example shows a complete sample APIs section:

```
apis:  
  api11.0.0:  
    name: 'api1:1.0.0'  
  api21.0.0:  
    name: 'api2:1.0.0'  
  api31.0.0:  
    name: 'api3:1.0.0'
```

For more information about creating OpenAPI definitions, see [Creating an OpenAPI definition file](#).

The indentation must be as in the examples and the APIs must have been created before they can be referenced.

Results

You have referenced the APIs that are to be included in your Product. An example of a complete YAML representation of a Product can be found in [An example YAML representation of a Product](#).

Describing Plans in your Product

Describe the Plans that you want to include in your IBM® API Connect Product and which APIs they will contain, as well as any rate limits that apply.

About this task

A Plan contains APIs and their operations. It can be used to implement rate limits and tailor visibility.

Note: If you are using more than one DataPower® server in a Gateway service, then to properly calculate API calls for rate limits the servers must be able to communicate with each other by using SLM peer groups, using either SLM unicast peering or SLM multicast peering depending on your network configuration. For more information, see [SLM peering](#).

In addition, you can apply burst limits to your Plans, to prevent usage spikes that might damage infrastructure. Multiple burst limits can be set per Plan, at second and minute time intervals. You can also set multiple rate limits per Plan and per operation, at second, minute, hour, day, and week time intervals.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.

Two example Plan descriptions from a YAML representation of a Product can be found at the end of this topic. An example of a complete YAML representation of a Product can be found in [An example YAML representation of a Product](#).

Procedure

To describe your Plans, include APIs in them, and set rate limits for Plans or specific operations, complete the following instructions:

1. Begin the Plans section with `plans`:
2. Under Plans, begin the description of your first Plan by providing a name, description, and specifying whether approval is required for subscription requests; use the following syntax:

```
plans:  
  Plan_Name:  
    title: Plan Title  
    description: Plan Description  
    approval: Approval Toggle
```

where:

- *Plan_Name* is the name of the Plan. It must be a single word and contain only alphanumeric characters, and the - (dash) and _ (underscore) characters. The name is case-sensitive, and should be 20 characters or fewer so that it can be displayed in the API Manager user interface.
- *Plan_Title* is the title of the Plan. Any string can be used, but the title should be kept short so that it can be displayed in the API Manager user interface.
- *Plan_Description* is a description of your Plan.
- *Approval_Toggle* must be either `true`, in which case approval is needed for subscription requests, or `false`, in which case subscriptions are automatically approved.

3. Optional: Under your Plan, add multiple burst and rate limits that will be shared across all the operations in the Plan; use the following syntax:

Note: For information about rate limits and burst limits in API Connect, see [Understanding rate limits for APIs and Plans](#).

```
rate-limits:
  Name:
    value: Rate_Limit
    hard-limit: Limit_Toggle
  Name:
    value: Rate_Limit
    hard-limit: Limit_Toggle
burst-limits:
  Name:
    value: Burst_Limit
```

where:

- *Name* is the name of the limit.
- *Rate_Limit* is your rate limit. It can be for multiples of seconds, minutes, hours, days, or weeks, written as `second`, `minute`, `hour`, `day`, and `week` respectively; do not use the plural forms of the words. Use the syntax: `1/2minute`. If the time unit is singular, then it is not necessary to precede it with a number, for example, `1/minute`. If you do not want to apply a rate limit, set *Rate_Limit* as `unlimited`.
- *Limit_Toggle* must be `true` or `false`. If `true`, API calls by a developer will fail if the rate limit is exceeded. This step is not necessary if you have set *Rate_Limit* to `unlimited`.
- *Burst_Limit* is your burst limit. It can be for multiples of seconds or minutes, written as `second` or `minute`; do not use the plural forms of the words.

Note:

- Applying a rate limit at the Plan level creates a default rate limit that is shared across all the operations within the Plan. If you need to set specific rate limits for specific operations, you must set these within the operations themselves and these settings will override the setting at the Plan level.
- The test application that is used by the API Manager test tool is not subject to rate limits if you have enabled automatic subscriptions for the Catalog in which you are testing. For more information, see [Working with Catalogs](#)

4. Under your Plan, specify which APIs are to be included.

Reference APIs by name and version, as follows:

```
apis:
  API_1_nameAPI_1_version: {}
  API_2_nameAPI_2_version: {}
```

where

- the *API_n_name* variables are the case-sensitive names of your APIs.
- the *API_n_version* variables are the versions of your APIs.

5. Optional: If you want to include only a subset of an API's operations, list the operations that are to be included; use the following syntax:

```
apis:
  API_nameAPI_version:
    operations:
      - operation: Operation_1_Verb
        path: Operation_1_Path
      - operation: Operation_2_Verb
        path: Operation_2_Path
```

where

- the *Operation_n_Path* variables are the paths of operations that is to be included. The dash is required for each new operation.
- the *Operation_n_Verb* variables are the appropriate REST verbs for the operations.

6. Optional: If you want to specify multiple rate limits for a single operation; use the following syntax:

```
apis:
  API_nameAPI_version:
    operations:
      - operation: Operation_Verb
        path: Operation_Path
        rate-limits:
          Name:
            value: Operation_Limit
            hard-limit: Operation_Limit_Toggle
          Name:
            value: Operation_Limit
            hard-limit: Operation_Limit_Toggle
```

where:

- *Operation_Limit* is the rate limit that you want to apply to your operation. It can be for multiples of seconds, minutes, hours, days, or weeks, written as `second`, `minute`, `hour`, `day`, and `week` respectively; do not use the plural forms of the words. Use the syntax: `1/2minute`. If the time unit is singular, then it is not necessary to precede it with a number, for example, `1/minute`. If you do not want to apply a rate limit, set *Operation_Limit* as `unlimited`.
- *Operation_Limit_Toggle* must be `true` or `false`. If `true`, API calls by a developer will fail if the rate limit is exceeded. This step is not necessary if you have set *Operation_Limit* to `unlimited`.

Results

You have described the Plans that are to be included in your Product. Your Plans section should be similar to the following scenarios.

If you have enforced a rate limit for your Plan and not specified individual operations, your Plans section should have the following form:

```
plans:
  Plan_Name:
```

```

title: Plan Title
description: Plan Description
approval: Approval_Toggle
rate-limits:
  Name:
    value: Limit
    hard-limit: Limit_Toggle
apis:
  API_1_nameAPI_1_version: {}
  API_2_nameAPI_2_version: {}

```

If you have enforced rate limits at the Plan level and want to include two operations, with a separate rate limit one for one of the operations, your Plans section should have the following form:

```

plans:
  Plan Name:
    title: Plan Title
    description: Plan Description
    approval: Approval_Toggle
    rate-limits:
      Name:
        value: API_Limit
        hard-limit: API_Limit_Toggle
    burst-limits:
      Name:
        value: Burst_limit
    apis:
      API_nameAPI_version:
        operations:
          - operation: Operation_1_Verb
            path: Operation_1_Path
            rate-limits:
              Name:
                value: Operation_Limit
                hard-limit: Operation_Limit_Toggle
          - operation: Operation_2_Verb
            path: Operation_2_Path

```

In both examples, variables are as in the previous steps and the indentation must be as presented.

The following example shows a complete sample Plans section:

```

plans:
  default:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/hour
        hard-limit: false
  my-plan:
    title: my_plan
    rate-limits:
      Default rate-limit:
        value: 50/1hour
        hard-limit: false
    burst-limits:
      Default burst-limit:
        value: 10/1second
    apis:
      api21.0.0:
        operations:
          - operation: get
            path: /path2
      api31.0.0:
        operations:
          - operation: get
            path: /path3
            rate-limits:
              limit3:
                value: 10/1second
                hard-limit: true
              limit4:
                value: 100/1hour
                hard-limit: true
      api11.0.0: {}

```

An example YAML representation of a Product

Products in IBM® API Connect can be represented by using a YAML file in a similar fashion to how APIs can be represented by using OpenAPI.

The following code describes a complete Product, with sample values.

```

info:
  version: 1.0.0
  title: SampleProduct
  name: SampleProduct
  summary: This is a sample product
gateways:
  - datapower-gateway

```

```

product: 1.0.0
visibility:
  view:
    enabled: true
    type: public
    tags: []
    orgs: []
  subscribe:
    enabled: true
    type: authenticated
    tags: []
    orgs: []
plans:
  default:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/hour
        hard-limit: false
  newplan:
    title: NewPlan
    rate-limits:
      low:
        value: 10/1hour
        hard-limit: true
    burst-limits:
      Default burst-limit:
        value: 10/1second
apis:
  SampleAPI:
    name: 'Sampleapi:1.0.0'

```

Using `x-ibm-languages` to create multilingual API and Product documentation

Create multilingual API and Product documentation by using the `x-ibm-languages` extension in your API and Product OpenAPI definitions.

You can scale your API initiatives to a global user base, while still maintaining a single API definition. Translations are custom configured and controlled, so that they can be tailored to both your API documentation and the API consumer. The extensions that are used in API Connect are added directly to the YAML file as `x-ibm-languages`. These extensions are then used in the Developer Portal, so that whatever language the Developer Portal is set to reflects the translations that are contained in the API and Product definitions.

Add the following syntax into your API or Product YAML file at every point that you require some translated text:

```

x-ibm-languages:
  item_name:
    language_code: translated_text

```

Where:

- `item_name` is the name of the item that you want to translate, for example `summary`.
- `language_code` is the ISO code for the translation language. Supported languages with their ISO codes are listed in the following table.

Table 1. List of supported language codes

Language	Code
Chinese, simplified	zh_cn
Chinese, traditional	zh_tw
Dutch	nl
English	en
French	fr
German	de
Italian	it
Japanese	ja
Korean	ko
Portuguese	pt
Spanish	es
Turkish	tr

- `translated_text` is the translated text that you want to be displayed for the item in the Developer Portal.

Note: The Developer Portal automatically assumes that the default language in the OpenAPI definition is English. If you want to use a different default language in the definition, you must provide both the English translation and the default language text in the `x-ibm-languages` extension sections of your OpenAPI definition, by using the following syntax:

```

x-ibm-languages:
  item_name:
    en: English translated text
    default_language_code: default_language_text

```

For an example of how to write an OpenAPI YAML file with French as the default language, see the [Examples](#) section.

Examples

An example API OpenAPI YAML file that contains the `fr` language extension, where English is the default language:

```
swagger: '2.0'
info:
  x-ibm-name: climbing-weather-api
  title: Climbing Weather API
  version: 1.0.0
  x-ibm-languages:
    title:
      fr: Climat d'escalade
schemes:
  - https
host: $(catalog.host)
consumes:
  - application/json
produces:
  - application/json
x-ibm-configuration:
  assembly:
    execute:
      - invoke:
          target-url: 'https://1234.com'
          title: 3 day forecast invocation
          cache-response: time-to-live
          cache-key: $(request.search)
  gateway: datapower-gateway
  enforced: true
  testable: true
  phase: realized
  cors:
    enabled: true
paths:
  /weather/forecast:
    get:
      summary: Retrieve the 3 day forecast for a location
      description: Retrieve the locations weather forecast descriptions for the next 3 days and nights
      operationId: getWeather
      x-ibm-languages:
        summary:
          fr: Récupérer la prévision de 3 jours pour un emplacement
        description:
          fr: Récupérer les descriptions des prévisions météo pour les 3 prochains jours et les nuits
      tags:
        - Weather
      parameters:
        - name: zip
          type: string
          in: query
          description: A 5 number zip code
          x-ibm-languages:
            description:
              fr: Un code postal à 5 numéros
        - name: country
          type: string
          in: query
          description: A 2 letter country code

    description:
      fr: "Vous voulez donc encore plus d'appels?"
    rate-limits:
      25 calls per day:
        hard-limit: true
        value: 25/1day
100-calls-per-day:
  title: 100 Calls every day
  description: 'You get 100 calls each and every day!'
  x-ibm-languages:
    title:
      fr: "100 appels par jour"
    description:
      fr: "Vous recevez 100 appels chaque jour"
  apis: {}
  rate-limits:
    100 Calls per day:
      hard-limit: true
      value: 100/1day

```

An example of how to write an OpenAPI YAML file with French as the default language:

```

info:
  name: climat-d-escalade
  title: Climat d'escalade
  version: 1.0.0
  x-ibm-languages:
    title:
      en: Climbing Weather API
      fr: Climat d'escalade
  ...

```

This example shows that both the default French language, and the English language translation, must be provided in the `x-ibm-languages` section.

Using `x-example` to control the examples displayed in the Developer Portal

OpenAPI does not support the use of `example` attributes on parameters, only on request and response objects and their properties. To allow API Developers to be able to control the examples displayed in the portal you can use `x-example` in OpenAPI parameters.

In this example, you cannot use `example` as it isn't supported by the OpenAPI spec, but you can use `x-example`.

```

- name: city
  in: query
  required: false
  type: string
  maxLength: 50
  description: "Location"
  x-example: "New York"

```

An `example` attribute is honored where set and allowed by the spec. If `example` is not found, `default` is honored where set and allowed by the spec. An `x-example` attribute is honored if found, if not found, a random example to match the schema is generated.

If the spec allows you to use `example`, then you should use it in preference to `x-example`.

Using `x-embedded-doc` to add additional documentation to products and APIs

You can use `x-embedded-doc` to add additional documentation to a product or an API as part of their definition.

You can embed additional documentation pages within the api swagger documentation. These pages can be base64 encoded strings or markdown strings of the html content of the page. These pages show up in the navigation, on the left side, underneath the overview for that product or API, and above the paths. Any styling that is needed to theme the documentation can be included in the Developer Portal custom theme.

Embedded docs for products and APIs

You can embed documentation for individual products and APIs by specifying an additional `x-embedded-doc` object in the product or API specification.

Field name	Type	Description
name	string	Required, the name of the embedded document
title	string	Required, The display title of the embedded document
format	string	Optional, the format of the embedded document content value. Values are <code>b64html</code> or <code>md</code> . Default value is <code>md</code> .
content	string	The base64 encoded html of page, or, the markdown string.
docs	x-embedded-doc	Additional embedded documentation. If no content is specified for parent, then the first child is the content that is shown.

Hierarchies of documents are supported by nesting of further doc properties. Language support is available by using `x-ibm-languages`.

Examples

Documentation can be added to an api, by using the following JSON:

```
"x-embedded-doc": [
  {
    "name": "introduction",
    "title": "Introduction",
    "format": "md",
    "content": "# some markdown"
  },
  {
    "name": "concepts",
    "title": "Concepts",
    "format": "md",
    "content": "## more markdown"
  },
  {
    "name": "authentication",
    "title": "Authentication",
    "docs": [{
      "name": "auth_clientid_secret",
      "title": "Obtaining a Client ID and Secret",
      "format": "md",
      "content": "### even more markdown"
    },
    {
      "name": "auth_bearertoken",
      "title": "Getting and Using a Bearer Token",
      "format": "md",
      "content": "#### yet more markdown"
    }
  ]
}
]
```

Alternatively, by using base 64 encoded HTML:

```
"x-embedded-doc": [
  {
    "name": "introduction",
    "title": "Introduction",
    "format": "b64html",
    "content": "PGFydGljbGUgaWQ9ImIudHJvZHVjdGlvb3IyZxc3M...."
  },
  {
    "name": "concepts",
    "title": "Concepts",
    "format": "b64html",
    "content": "PGFydGljbGUgaWQ9ImNvbmlkHRzIiBjbGFzZD0icGFnZSI...."
  },
  {
    "name": "authentication",
    "title": "Authentication",
    "docs": [{
      "name": "auth_clientid_secret",
      "title": "Obtaining a Client ID and Secret",
      "format": "b64html",
      "content": "PGFydGljbGUgaWQ9ImNsaWVudC1pZC1zZWNyZX...."
    },
    {
      "name": "auth_bearertoken",
      "title": "Getting and Using a Bearer Token",
      "format": "b64html",
      "content": "ICA8YXJ0aWNsZSBpZD0iYmVhcmVvLXRva2VuIiBjbGFz...."
    }
  ]
}
]
```

Or mixed formats:

```
"x-embedded-doc": [
  {
    "name": "introduction",
    "title": "Introduction",
    "format": "b64html",
    "content": "PGFydGljbGUgaWQ9ImIudHJvZHVjdGlvb3IyZxc3M...."
  }
]
```

```

},
{
  "name": "concepts",
  "title": "Concepts",
  "format": "md",
  "content": "# some markdown"
}
]

```

An example of some `x-embedded-doc` code and how it might render:

```

x-embedded-doc:
- name: document
  title: Interesting
  format: b64html
  content: >-
    PGFydGljbGUgaWQ9ImNsaWVudC1pZ...=
securityDefinitions:
  api_key:
    type: apiKey
    in: header
    name: api_key

```

Using x-pathalias to give consistent URLs for products and APIs

You can use `x-pathalias` to assign a URL to a product or an API.

The information section of a YAML representation of a Product or API can include `x-pathalias`. This option can be useful as it allows the same URL to be used on different revisions of your product. It also allows the use of a vanity URL, which might better represent the branding of your site, or make the URL easier to pronounce.

In this example, you set an API called `Climbing weather API` in product `Weather watch` to have a URL of `portalURL/product/weather/api/climbing`.

Product information:

```
info:
  version: 1.0.0
  title: Weather watch
  name: weather-watch
```

```
x-pathalias: weather
```

API information:

```
info:  
title: Climbing Weather API  
x-ibm-name: climbing-weather-api  
version: 1.0.0  
x-pathalias: climbing
```

Validating the YAML or JSON definition of an API or Product

You can validate a YAML or JSON definition by using the IBM® API Connect developer toolkit.

Before you begin

To complete the steps that are described in this topic, you must have installed the developer toolkit. For more information, see [Installing the toolkit](#).

Procedure

To perform validation by using the developer toolkit, enter the following command:

```
apic validate filename
```

where *filename* is the file name of the API definition file you want to validate.

- Include `--product-only` to validate only a Product definition and not any APIs that it references.
- Include `--no-extensions` to validate only the default OpenAPI section of the API and none of its extensions.

Note:

- If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the draft API is created with the `apic drafts:validate` command. For more information, see [Using \\$ref to reuse code fragments in your OpenAPI files](#).
- Products that contain an API with a Swagger property using `regex` that include lookahead assertions, such as "(?)" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!  
The multipart 'openapi' field contains an OpenAPI definition with validation errors.  
definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0,  
col: 0)  
400
```

Related concepts

- [Creating an OpenAPI definition file](#)

Creating and using API and Product definitions templates

You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition.

Before you begin

To complete the steps that are described in this topic, you must have installed the IBM® API Connect developer toolkit. For more information, see [Installing the toolkit](#).

Procedure

1. Create a Product or API definition template, either from scratch, or by copying one of the examples provided in [API and Product definition template examples](#). The template file must have `.hbs` filename extension, and may contain any of the handlebars variables described in [Template variables for API and Product definitions](#).
2. To create a Product or API definition from a template, enter the following command:

```
apic create:[api | product] --template template_file --title [api_title | product_title] options
```

where *template_file* is the template `.hbs` file to use, *api_title* or *product_title* is the title of the API or Product to create, and *options* is any additional command-line options. The path to the template file can be either an absolute path or relative to the location where the command is executed.

When the Product or API definition is created, the value of each command-line option is substituted for the corresponding handlebars template variable. For example, the value of the required `--title` option is substituted for the `info.title` field in the template file. The command creates an API or Product definition YAML file with the name specified in the `--name` option. If you don't supply the `--name` option, the command derives the name of the API or Product YAML file from the specified title by down-casing the title and replacing spaces with dashes.

Working with global policies

Use global policies to configure policy assemblies that are called just before, or just after, each of your API assemblies is called, or when an error is thrown. You can upload global policies into each of the gateway services in your Catalogs, and then designate, for each gateway service, which global policy should be called before an API assembly is called, after an API assembly is called, or if an error occurs when an API assembly is called. The designated global policies are applied to all the APIs that are deployed to the associated gateway service.

Prerequisites

IBM® DataPower® Gateway version that is compatible with your deployed version of API Connect.

To complete the global policy management tasks described in this topic, you must be the owner of the provider organization, or be assigned a role that has the **Settings:Manage** permission. The pre-supplied Administrator role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see [Creating custom roles](#).

Overview

For each of the gateway services in a Catalog, a global policy that you want to be called before any API assembly is called is designated as a *pre-request* global policy, and a global policy that you want to be called after any API assembly is called is designated as a *post-response* global policy. A policy that you want to be called when an error is thrown is called an *error* global policy. You can upload as many global policies into a gateway service as you want, but you can designate at most one global policy to be pre-request, one to be post-response, and one to be an error, at any one time.

Note:

- If you are using the DataPower Gateway (v5 compatible), there can be only one **proxy** policy across the combined pre-request, API, and post-response assembly flows.
- Catalog properties, as described in [Creating and configuring Catalogs](#), and API properties, as described in [Setting API properties](#), are not supported with global policies. Therefore, if you use such properties in a global policy, they are **not** replaced with the values specified in the API or Catalog property definitions.

A global policy is defined in a .yaml file. The global policy file specifies the policy assembly that you want to call. A global policy file has the following structure:

```
global-policy: 1.0.0

info:
  name: global_policy_name
  title: global_policy_title
  version: global_policy_version

gateways:
  - gateway_type

assembly:
  - policy_assembly_to_be_called
```

where *gateway_type* has the value `datapower-gateway` if you want to use the global policy in a DataPower Gateway (v5 compatible), and `datapower-api-gateway` if you want to use the global policy in a DataPower API Gateway. For more information on the different types of gateway, see [API Connect gateway types](#).

Note: Error global policies are supported only by the DataPower API Gateway, not by the DataPower Gateway (v5 compatible).

The **assembly** section for a pre-request or post-response global policy can contain any valid API assembly flow. For more information, see the [execute](#) section.

The **assembly** section for an error global policy can only contain a **catch** extension in the assembly, an **execute** section is not valid. For details of the **catch** extension, see [catch](#).

Sample global policy .yaml file for pre-request or post-reponse

```
global-policy: 1.0.0

info:
  name: sample-policy
  title: Sample Policy
  version: 2.0.0

gateways:
  - datapower-api-gateway

assembly:
  execute:
    - invoke:
        target-url: http://myhost.com/mytarget
  version: 2.0.0

catch:
  - errors:
```

```

- ConnectionError
execute:
- activity-log:
  title: activity-log
  content: activity
  error-content: payload
  version: 2.0.0

```

Sample error global policy .yaml file

Note: An error global policy .yaml file can contain only a `catch` extension in the assembly.

```

global-policy: 1.0.0

info:
  name: sample-error-policy
  title: Sample Error Policy
  version: 2.0.0

gateways:
- datapower-api-gateway

assembly:
  catch:
  - errors:
    - ConnectionError
    execute:
    - activity-log:
      title: activity-log
      content: activity
      error-content: payload
      version: 2.0.0
  - errors:
    - SOAPError
    execute:
    - xslt:
      version: 2.0.0
      title: xslt
      input: true
      source: |-
        <!-- Placeholder -->
        <xsl:stylesheet xmlns:xsl=''/>

```

Logging in to the Management server

You work with global policies by using developer toolkit CLI commands. Before you can run the commands, you must log in to your management server from the CLI. Use the following command:

```

apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider

```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```

apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm

```

For example,

```

apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
- title: API Manager Local User Registry
  realm: provider/default-idp-2
- title: Corporate LDAP user registry
  realm: provider/corporate-ldap

```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.

For full details of the `apic login` command, see [Logging in to a management server](#).

Uploading a global policy to a gateway service

You upload a global policy to a gateway service by using the `apic global-policies:create` command. The command has the following format:

```

apic global-policies:create --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name --server mgmt_endpoint_url --scope scope [--space space] filename

```

where:

- `catalog_name` is the value of the `name` property of the Catalog that contains the gateway service to which you want to upload the global policy.
- `gateway_service_name` is the value of the `name` property of the gateway service.
- `organization_name` is the value of the `name` property of the provider organization that contains the Catalog.
- `mgmt_endpoint_url` is the platform API endpoint URL.
- `scope` has one of the following values:
 - `catalog` if the Catalog does not have Spaces enabled.
 - `space` if the Catalog has Spaces enabled. If you specify `space` for the `--scope` parameter you must also supply the `--space` parameter to specify the Space that contains the gateway service.

- (optional) *space* is the name of the Space that contains the gateway service. The `--space` parameter is required if the Catalog has Spaces enabled, in which case you must also include `--scope space` in the command.
- *filename* is the name of the global policy .yaml file that you want to upload.

Note: If Spaces are enabled in a Catalog, a global policy that you apply to one Space is applied to **all** Spaces; you cannot apply a global policy to an individual Space in the Catalog. Any subsequent updates are also applied to all Spaces.

You can confirm the global policies that have been uploaded by using the `apic global-policies:list-all` command, which has the following format:

```
apic global-policies:list-all --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name
--server mgmt_endpoint_url --scope scope [--space space]
```

For reference details of the `apic global-policies` commands, see [apic global-policies](#).

Designating the pre-request global policy

To designate the pre-request policy for a gateway service, complete the following steps:

1. Write the URL of the required global policy to a .yaml file by using the following command:

```
apic global-policies:get --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name
--server mgmt_endpoint_url --scope scope [--space space] policy_name:policy_version --fields url
```

where *policy_name:policy_version* specifies the name and version number of the required global policy, as defined in the global policy .yaml file that was originally uploaded to the gateway service.

The value of the URL is written to a file called GlobalPolicy.yaml.

2. Edit the GlobalPolicy.yaml file and replace the string `url` with `global_policy_url`. The resulting file has the following format:

```
global_policy_url: >-
  https://server_host_name/api/catalogs/catalog_id/configured-gateway-services/gateway_service_id/global-
  policies/policy_id
```

3. Designate the global policy to be the pre-request policy by using the following command:

```
apic global-policy-prehooks:create --catalog catalog_name --configured-gateway-service gateway_service_name --org
organization_name --server mgmt_endpoint_url --scope scope [--space space] GlobalPolicy.yaml
```

To replace the designated pre-request global policy with another policy, repeat steps [1](#) and [2](#), then use the `apic`

`global-policy-prehooks:update` command. To remove the pre-request global policy designation, use the `apic global-policy-prehooks:delete` command.

For reference details of the `apic global-policy-prehooks` commands, see [apic global-policy-prehooks](#).

By default, whenever an API is called, a series of policies, called the *preflow* policies, are invoked prior to the policy assembly configured in the API definition. However, by using a pre-request global policy you can, if required, fully customize the behavior of these policies, controlling if and when they are invoked, and with what customization. For more information, see [Customizing the preflow policies](#).

Designating the post-response global policy

To designate the post-response policy for a gateway service, complete the following steps:

1. Write the URL of the required global policy to a .yaml file by using the following command:

```
apic global-policies:get --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name
--server mgmt_endpoint_url --scope scope [--space space] policy_name:policy_version --fields url
```

where *policy_name:policy_version* specifies the name and version number of the required global policy, as defined in the global policy .yaml file that was originally uploaded to the gateway service.

The value of the URL is written to a file called GlobalPolicy.yaml.

2. Edit the GlobalPolicy.yaml file and replace the string `url` with `global_policy_url`. The resulting file has the following format:

```
global_policy_url: >-
  https://server_host_name/api/catalogs/catalog_id/configured-gateway-services/gateway_service_id/global-
  policies/policy_id
```

3. Designate the global policy to be the post-response policy by using the following command:

```
apic global-policy-posthooks:create --catalog catalog_name --configured-gateway-service gateway_service_name --org
organization_name --server mgmt_endpoint_url --scope scope [--space space] GlobalPolicy.yaml
```

To replace the designated post-response global policy with another policy, repeat steps [1](#) and [2](#), then use the `apic`

`global-policy-posthooks:update` command. To remove the post-response global policy designation, use the `apic global-policy-posthooks:delete` command.

For reference details of the `apic global-policy-posthooks` commands, see [apic global-policy-posthooks](#).

Designating the error global policy

The error global policy is applied to an error caught in the API pre-request, assembly, and post-response stages unless any of those stages has its own error rule defined for the same error, in which case that error rule takes priority.

To designate the error global policy for a gateway service, complete the following steps:

1. Write the URL of the required global policy to a .yaml file by using the following command:

```
apic global-policies:get --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name
--server mgmt_endpoint_url --scope scope [--space space] policy_name:policy_version --fields url
```

where `policy_name:policy_version` specifies the name and version number of the required global policy, as defined in the global policy `.yaml` file that was originally uploaded to the gateway service.

The value of the URL is written to a file called `GlobalPolicy.yaml`.

2. Edit the `GlobalPolicy.yaml` file and replace the string `url` with `global_policy_url`. The resulting file has the following format:

```
global_policy_url: >-
  https://server_host_name/api/catalogs/catalog_id/configured-gateway-services/gateway_service_id/global-
  policies/policy_id
```

3. Designate the global policy to be the error policy by using the following command:

```
apic global-policy-errors:create --catalog catalog_name --configured-gateway-service gateway_service_name --org
organization_name --server mgmt_endpoint_url --scope scope [--space space] GlobalPolicy.yaml
```

To replace the designated error global policy with another policy, repeat steps 1 and 2, then use the `apic global-policy-errors:update` command. To remove the error global policy designation, use the `apic global-policy-errors:delete` command.

For reference details of the `apic global-policy-errors` commands, see [apic global-policy-errors](#).

Customizing the preflow policies

By default, whenever an API is called, a series of policies, called the *preflow* policies, are invoked prior to the policy assembly configured in the API definition. However, by using a global policy you can, if required, fully customize the behavior of these policies, controlling if and when they are invoked, and with what customization.

Before you begin

- For details on how to configure and deploy a global policy, see [Working with global policies](#).
- For details on how to avoid authentication errors on a WSDL action, see the IBM troubleshooting tech note, [API Connect HTTP GET ?WSDL retrieval returns "401 - Unauthorized Invalid client id or secret"](#).

Default preflow policies

The following preflow policies are invoked by default:

- `cors`: handles cross-origin resource sharing (CORS) requests for the API; invoked if CORS is enabled in the API definition settings.
- `wsdl`: handles WSDL requests.
- `html-page`: for a GraphQL API, if the GraphQL editor option is enabled, returns the GraphQL HTML page.
- `client-identification`: examines the API key credentials that are carried in the API request and matches the API Plan through which the target API is made available to the client.
- `ratelimit`: enforces the rate limit scheme that is configured for the matching API Plan. When the rate limit is reached, the request is rejected.
- `security`: performs the authentication and authorization checks that are required by the target API and operation. If the security requirement is not fulfilled, the request is rejected.

Configuring a global policy to customize the preflow policies

To customize the preflow policies, complete the following steps:

1. add the following property to the `info` section of your global policy `.yaml` file:

```
mode: mode_type
```

Where `mode_type` is one of the following options:

- `after-builtin` - this means that your preflow policies are applied after the default preflow policies.
- `before-builtin` - this means that your preflow policies are applied before the default preflow policies.
- `full-custom` - this means that you must explicitly add the preflow policies to the assembly of your global policy. You can, however, remove, reposition, or replace any of the preflow policies as required.

2. Configure the policies in your global policy assembly as required.

An `after-builtin` global policy example:

```
global-policy: 1.0.0
info:
  name: foo-example
  title: foo-example
  version: 2.0.0
  mode: after-builtin
gateways:
- datapower-api-gateway
assembly:
  execute:
  - set-variable:
    version: 2.0.0
    title: set-variable
    actions:
    - set: message.headers.X-Flexible-Preflow
      value: 'Hello reboot global policy 1 on catalog 1 this policy will be executed after all default builtins'
      type: string
```

A `before-builtin` global policy example:

```
global-policy: 1.0.0
info:
  name: foo-example
```

```

title: foo-example
version: 2.0.0
mode: before-builtin
gateways:
- datapower-api-gateway
assembly:
execute:
- set-variable:
  version: 2.0.0
  title: set-variable
  actions:
  - set: message.headers.X-Flexible-Preflow
    value: 'Hello reboot global policy 1 on catalog 1 this policy will be executed before all default builtin
policies'
  type: string

```

A full-custom global policy example:

```

global-policy: 1.0.0
info:
name: preflow-4-actions
title: preflow-4-actions
version: 2.0.0
mode: full-custom
gateways:
- datapower-api-gateway
assembly:
execute:
- cors:
  version: 2.0.0
  title: cors-in-preflow
- wsdl:
  title: default-wsdl
- html-page:
  title: html-page-in-preflow
  output: message
  version: 2.0.0
- helloworld:
  version: 1.0.0
  title: helloworld
- client-identification:
  version: 2.0.0
  title: ci-in-preflow
- ratelimit:
  version: 2.0.0
  title: assembly-rt-in-preflow
  source: plan-default
- security:
  version: 2.0.0
  title: sec-in-preflow
- set-variable:
  version: 2.0.0
  title: set-variable
  actions:
  - set: message.headers.X-Flexible-Preflow
    value: 'Hello reboot with 4 actions'
    type: string

```

3. Deploy your global policy as a [pre-request global policy](#).

Reference

Reference information for developing your APIs in API Connect, including context variables, and template variables.

Note: For product-wide reference material, including command-line tool and REST APIs documentation, see [Reference information for IBM® API Connect](#).

- [API Connect context variables](#)
List of IBM API Connect context variables that you can reference when defining default parameter values in an assembly operation, or by using the `getContext()` function when defining a policy.
- [OAuth context variables](#)
You can customize the OAuth security flow in a native OAuth provider by adding multiple OAuth policies to the assembly. Each OAuth policy takes input from context variables and writes output to context variables. By using these OAuth context variables you can manipulate the original request, and process the output from an OAuth policy.
- [Error cases supported by assembly catches](#)
Several error cases that can be returned by the assembly are available to the catch function.
- [API and Product definition template examples](#)
You can use template files when creating API and Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition. This topic provides the default Handlebar templates used by `apic` to create Products and APIs as examples you can use to copy and customize for your own use.
- [Template variables for API and Product definitions](#)
You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition.

API Connect context variables

List of IBM® API Connect context variables that you can reference when defining default parameter values in an assembly operation, or by using the `getContext ()` function when defining a policy.

The following tables are presented:

- [General context variables](#).
- [OAuth context variables - DataPower Gateway \(v5 compatible\)](#).
- [Application certificate context variables](#).
- [API activity logging context variables](#).
- [GraphQL context variables](#).

For more information about implementing an assembly component, see [Including elements in your OpenAPI 2.0 API assembly](#), [Including elements in your OpenAPI 2.0 API assembly](#), and for information about how to reference context variables in API Connect see [Variable references in API Connect](#) and [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#).

For more information about creating a user-defined policy, see [Authoring policies](#).

General context variables

Note:

- For plan variables (such as `plan.name` or `plan.version`), plan information is available only when the requested operation requires identification and the client passes the authentication check.
- If you deploy your API to the DataPower® Gateway (v5 compatible) then, with the exception of client ID and client secret, the passing of form input as a parameter into an API is not supported. This restriction does not apply if you deploy your API to the DataPower API Gateway.

Table 1. API Connect context variables

Name	Description	Permission
API Gateway only <code>api.catalog.id</code>	The ID of the Catalog in which the API is published.	Read/write
API Gateway only <code>api.catalog.name</code>	The name of the Catalog in which the API is published.	Read/write
API Gateway only <code>api.catalog.path</code>	The path segment that represents this Catalog.	Read/write
<code>api.endpoint.address</code>	The address of the API Gateway endpoint.	Read/write
<code>api.endpoint.hostname</code>	The host name of the API Gateway endpoint, as requested by the application.	Read/write
API Gateway only <code>api.id</code>	The identifier of the API.	Read/write
<code>api.name</code>	The name of the API; this corresponds to the <code>x-ibm-name</code> field in the OpenAPI definition for the API.	Read/write
<code>api.operation.id</code>	The ID of the operation.	Read/write
<code>api.operation.path</code>	The path of the operation.	Read/write
<code>api.org.id</code>	The organization ID of the API provider.	Read/write
<code>api.org.name</code>	The organization short name of the API provider.	Read/write
<code>api.properties.propertyname</code>	The name of a custom API property. Property values are Catalog specific. Note: <ul style="list-style-type: none"> • You have write permission to a custom property only from the user interface, not from GatewayScript. • To access a Catalog specific property value from GatewayScript, you must refer to the property by using the following syntax: <pre>apim-catalog-name</pre> where <i>catalog</i> is the name of the Catalog, and <i>name</i> is the property name. For example: <pre>var mypropertyvalue = \$(apim-mycatalog-mypropertyname)</pre> 	Read/write
<code>api.root</code>	The API base path.	Read/write
<code>api.type</code>	The API type; REST or SOAP.	Read/write
<code>api.version</code>	The version string of the API.	Read/write
<code>client.app.id</code>	The client ID or application key that is received on the request.	Read/write
API Gateway only <code>client.app.lifecycle-state</code>	The lifecycle status of the calling client application. The possible values are as follows: <ul style="list-style-type: none"> • DEVELOPMENT • PRODUCTION (default) 	Read/write

Name	Description	Permission
API Gateway only client.app.metadata.key	<p>The string value of an application metadata key, where <i>key</i> is the name of the key.</p> <p>You can add metadata keys to an application by using either the apic apps:create or the apic apps:update command; you include the metadata keys in the configuration file parameter that is passed to the command.</p> <p>For example:</p> <pre>apic apps:create myapp.yaml --server myserver.com --org myorg --catalog mycatalog --consumer-org mycorg</pre> <p>where myapp.yaml contains the following:</p> <pre>name: myapp title: My test application metadata: key1: value1 key2: value2 key3: value3 key4: value4 key5: value5</pre> <p>You can then retrieve the value of a metadata key in an API assembly policy by using a context variable such as the following:</p> <pre>client.app.metadata.key3</pre> <p>Note that adding application metadata might impact gateway trans performance.</p>	Read/write
client.app.name	The name of the application that is identified as having issued the request.	Read/write
client.app.secret	The client secret that is received in the request.	Read/write
client.app.type	The type of the client application that issued the request.	Read/write
client.org.id	The unique identification key of the organization that owns this application.	Read/write
client.org.name	The name of the organization that owns this application.	Read/write
API Gateway only client.result	The result of the client security policy, which is SUCCESS or FAILURE .	Read/write
API Gateway only client.third_party.type	The type of user registry used for third-party authentication of the extracted client credentials. The possible values are LDAP and auth-url .	Read/write
API Gateway only client.third_party.headers	The array of headers added to the request that was sent to that API authentication URL during third-party authentication.	Read/write
API Gateway only client.third_party.response.authenticated	The third-party authentication results. The possible values are as follows: <ul style="list-style-type: none"> true: the authentication was successful. false: the authentication failed. 	Read/write
API Gateway only client.third_party.response.user	The user for third-party authentication.	Read/write
API Gateway only client.title	The title for the credentials that are received in the request.	Read/write
DataPower Gateway (v5 compatible) only env.name	The name of the Catalog in which the API is published.	Read/write
DataPower Gateway (v5 compatible) only env.path	The path segment that represents this Catalog.	Read/write
API Gateway only error.message	The message text for the error.	Read/write
API Gateway only error.name	The name of the error.	Read-only
API Gateway only log	The transaction data gathered in an assembly log action.	Read/write
message.attachments	The array of attachments in a multipart message.	Read/write
message.attachments[].body	The attachment payloads in a multipart message.	Read/write
message.attachments[].headers	The attachment headers in a multipart message.	Read/write
message.body	The payload of the request or response message. Note: The message.body context variable is not supported with getContext () function. Use the getvariable () function instead.	Read/write
message.headers.name	The value of the current named header of the message or of the current named header of the root part of a multipart message. The <i>name</i> segment is case-insensitive.	Read/write
API Gateway only message.original.headers.name	The value of the original named header of the HTTP message. When the assembly contains an invoke action, the value is automatically populated by the original named header of the response message from the invoked URL. The <i>name</i> segment is case-insensitive.	Read-only
API Gateway only message.package.headers.name	The value of the current named header of the multipart message. The <i>name</i> segment is case-insensitive.	Read/write
message.status.code	The HTTP status code of the response.	Read/write
message.status.reason	The HTTP reason phrase of the response.	Read/write

Name	Description	Permission
API Gateway only <code>message.variables.name</code>	The value of a property in the message. For example, when <code>myvar</code> is the property in the message, you can retrieve the value of the <code>myvar</code> property by reading <code>message.variables.myvar</code> .	Read/write
<code>plan.name</code>	The name of the plan.	Read/write
<code>plan.id</code>	The unique identifier of the plan.	Read/write
<code>plan.rate-limit</code>	The rate limit of the plan, which is the number of API calls per time interval.	Read/write
API Gateway only <code>plan.rate-limit[index].hard-limit</code>	The hard limit setting for the rate limit scheme that is identified by <code>[index]</code> .	Read/write
API Gateway only <code>plan.rate-limit[index].value</code>	The value of the rate limit scheme that is identified by <code>[index]</code> . The syntax is <code>rate/interval</code> .	Read/write
<code>plan.spaceId</code>	The unique identifier of the space that the plan is contained within.	Read/write
<code>plan.spaceName</code>	The name of the space that the plan is contained within.	Read/write
<code>plan.version</code>	The version number of the plan.	Read/write
<code>request.authorization</code>	The parsed HTTP <code>authorization</code> header.	Read-only
<code>request.body</code>	The payload from the incoming request.	Read-only
<code>request.content-type</code>	Normalized content-type value.	Read-only
<code>request.date</code>	A date object that represents approximately when the request was received by the Gateway.	Read-only
<code>request.headers.name</code>	The value of the original named header of the HTTP request, or the value of the current named header of the root part of a multipart request. The <code>name</code> segment is case-insensitive. The request header can be modified only in preflow policies. For more information, see Customizing the preflow policies .	Read/write
API Gateway only <code>request.original.headers.name</code>	The value of the original named header of the HTTP request. This variable is created only when the request header is modified. The <code>name</code> segment is case-insensitive.	Read-only
API Gateway only <code>request.package.headers.name</code>	The value of the named header of the multipart request. The <code>name</code> segment is case-insensitive.	Read-only
API Gateway only <code>request.parameters</code>	You can obtain your incoming parameters from path and query parameters.	
API Gateway only <code>request.parameters.name.locations</code>	An array of strings that specify the parameter types associated with the parameter specified in name. The supported keywords for parameter types are as follows. <code>formData</code> The parameter is in the body as form data <code>header</code> The parameter is in the request header <code>path</code> The parameter is in the path <code>query</code> The parameter is in the query	Read-only
API Gateway only <code>request.parameters.name.values</code>	An array containing values of the parameter types associated with the parameter specified in name. For example, when the first value is <code>path</code> in <code>request.parameters.myparam.locations[]</code> , the first value in <code>request.parameters.myparam.values[]</code> is the array of path values associated with <code>myparam</code> . Request parameters can be modified only in preflow policies. For more information, see Customizing the preflow policies .	Read/write
API Gateway only <code>request.original.parameters.name.values</code>	An array containing the original values of the parameter types associated with the parameter specified in <code>name</code> . This variable is created only when a request parameter value is modified.	Read-only
<code>request.path</code>	The path section of the <code>request.uri</code> that starts with the base path of the API, including the <code>'/'</code> character that begins the base path.	Read-only
API Gateway only <code>request.protocol</code>	The protocol that is used to receive the request: <code>http</code> or <code>https</code> .	Read-only
<code>request.querystring</code>	The request query string without the leading question mark.	Read-only
<code>request.search</code>	The request query string with the leading question mark.	Read-only
<code>request.uri</code>	The full HTTP request URI from the application.	Read-only
<code>request.verb</code>	The HTTP verb of this request.	Read-only
API Gateway only <code>session.apiGateway</code>	The gateway that receives the request.	Read-only
API Gateway only <code>session.apiGatewayName</code>	The name of the API gateway as defined in the API Manager.	Read-only
API Gateway only <code>session.clientAddress</code>	The address of the client that sent the request.	Read-only
API Gateway only <code>session.domainName</code>	The name of the domain that the gateway belongs to.	Read-only

Name	Description	Permission
API Gateway only <code>session.globalTransactionID</code>	The global transaction ID in the logs.	Read-only
API Gateway only <code>session.localAddress</code>	The address of the gateway on the DataPower® Gateway.	Read-only
API Gateway only <code>session.timeStarted</code>	The time that the gateway started to process the request.	Read-only
API Gateway only <code>session.transactionID</code>	The transaction ID of the gateway request.	Read-only
<code>system.datetime</code>	Returns a string that represents the current date and time in the system time zone of the gateway.	Read-only
<code>system.time</code>	Returns a string that represents the current time in the system time zone of the gateway.	Read-only
<code>system.time.hour</code>	Returns a number 0 - 23 inclusive, representing the hour of the current time in the system time zone of the gateway.	Read-only
<code>system.time.minute</code>	Returns a number 0 - 59 inclusive representing the minute of the current time in the system time zone of the gateway.	Read-only
<code>system.time.seconds</code>	Returns a number 0 - 59 inclusive representing the seconds of the current time in the system time zone of the gateway.	Read-only
<code>system.date</code>	Returns a string that represents the current date in the system time zone of the gateway.	Read-only
<code>system.date.day-of-week</code>	Returns a number 1 - 7 (Monday to Sunday) inclusive representing the day of the week in the system time zone of the gateway.	Read-only
<code>system.date.day-of-month</code>	Returns a number 1 - 31 representing the day of the month in the system time zone of the gateway.	Read-only
<code>system.date.month</code>	Returns a number 1 - 12 representing the month in the system time zone of the gateway.	Read-only
<code>system.date.year</code>	Returns a four-digit number that represents the year in the system time zone of the gateway.	Read-only
<code>system.timezone</code>	Returns a system time zone ISO 8601 identifier for the gateway, which might include a sign, a two-digit hour, and minutes. For example, <code>-04:00</code> .	Read-only

OAuth context variables - DataPower Gateway (v5 compatible)

The OAuth context variables described in this section apply only to the DataPower Gateway (v5 compatible). For details of the OAuth context variables that apply to the DataPower API Gateway, see [OAuth context variables](#).

Table 2. OAuth context variables (DataPower Gateway (v5 compatible)).

Note: Most OAuth context variables are available only when IBM API Connect is acting as the OAuth resource server. However, the `oauth.introspect` variables are also available when integrating with third party providers.

Name	Description
<code>oauth.access-token</code>	If the request is authenticated with OAuth, this variable contains the access token string.
<code>oauth.miscinfo</code>	This variable contains information explicitly included in the Authentication URL and Metadata URL headers. For more information, see Authenticate URL .
<code>oauth.not-after</code>	If the request is authenticated with OAuth, this variable contains the date when the token expires.
<code>oauth.not-before</code>	If the request is authenticated with OAuth, this variable contains the date when the token was issued.
<code>oauth.resource-owner</code>	If the request is authenticated with OAuth, this variable contains the name of the resource owner.
<code>oauth.scope</code>	If the request is authenticated with OAuth, this variable contains the scope of this access token.
<code>oauth.introspect.active</code>	Always available to introspection. Boolean value.
<code>oauth.introspect.response</code>	Always available to introspection. Shows the complete current response payload. Example payload value: <code>{"active":true, "client_id", "xxx-xxx", "token_type", "bearer", "scope":"neon"}</code>
Other variables might be available from the third party, in the form of: <code>oauth.introspect.<variable></code>	Decoding the previous example payload, the following variables are made available for further processing. <code>oauth.introspect.client_id: xxx-xxx</code> <code>oauth.introspect.token_type: bearer</code> <code>oauth.introspect.scope: neon</code>

Application certificate context variables

The following table describes context variables that are available when a certificate is used to verify access to an API, although these will vary depending on the signature mechanism that is being used; for more information, see the [Internet X.509 Public Key Infrastructure Certificate and CRL Profile specification](#).

Table 3. Application certificate context variables

Name	Description
<code>application.certificate.Base64</code>	Base64 format.
<code>application.certificate.fingerprint</code>	Fingerprint
<code>application.certificate.Version</code>	Version
<code>application.certificate.SerialNumber</code>	Serial number
<code>application.certificate.SignatureAlgorithm</code>	Signing algorithm
<code>application.certificate.Issuer</code>	The issuer of the certificate
<code>application.certificate.Subject</code>	Subject
<code>application.certificate.NotBefore</code>	Not valid before this date
<code>application.certificate.NotAfter</code>	Not valid after this date
<code>application.certificate.SubjectPublicKeyAlgorithm</code>	Algorithm for the subject public key
<code>application.certificate.SubjectPublicKeyBitLength</code>	Length for the subject public key

Name	Description
<code>application.certificate.KeyValue.type</code>	Various context variables that depend on the algorithm and key. The following are possible context variables: <ul style="list-style-type: none"> <code>application.certificate.KeyValue.RSAKeyValue.Modulus</code> <code>application.certificate.KeyValue.RSAKeyValue.Exponent</code>

API activity logging context variables

If activity logging is enabled for an API, a `log` context variable is created; the `log` context variable contains the data relating to an API execution event. On completion of API execution, the `log` context variable is written to an API event record that is stored for subsequent access by API analytics. For details of the fields contained in the `log` context variable, see [API event record fields](#).

The way in which you enable and configure activity logging depends on the type of gateway you are using, as follows:

- If you are using the DataPower API Gateway, you configure activity logging in the API configuration settings; see [Configuring activity logging](#) (OpenAPI 2.0) or [Configuring activity logging](#) (OpenAPI 3.0).
- If you are using the DataPower Gateway (v5 compatible), you configure activity logging by adding an [Activity Log](#) policy to the API assembly.

The activity logging configuration defines the default content of the `log` context variable, but you can modify it in an API assembly; for example:

- Add your own data values by using a [Set Variable](#) policy.
- Remove or redact data values by using a Redaction policy; see [Redaction - DataPower API Gateway](#) or [Redaction - DataPower Gateway \(v5 compatible\)](#).
- API Gateway only Modify or replace the `log` context variable by using a [Log](#) policy.

GraphQL context variables

The GraphQL query and response variables generated from API processing and assembly actions are stored in the API context in the `message.attributes.graphql` context variables.

Table 4. GraphQL context variables

Name	Description
<code>message.attributes.graphql</code>	The query and response attributes of the GraphQL message.
<code>message.attributes.graphql.query</code>	The attributes of a GraphQL query, including the query string, operation name, and variables.
<code>message.attributes.graphql.query.query</code>	The GraphQL query string.
<code>message.attributes.graphql.query.variables</code>	The map of GraphQL variables.
<code>message.attributes.graphql.query.operationName</code>	The name of the operation to execute.
<code>message.attributes.graphql.query.operationType</code>	The type of the operation to execute.
<code>message.attributes.graphql.request</code>	The attributes of the GraphQL request.
<code>message.attributes.graphql.request.fieldCost</code>	The weighted sum of the cost of all fields accessed in the query. The cost of each field access is configured in the schema. This count includes fields whose field costs are not set to 0.0.
<code>message.attributes.graphql.request.fieldCounts</code>	The maximum number of times that each field can be retrieved by the given query. This number is equal to the number of times that the resolver responsible for producing the value of the field is required to run. This count includes fields whose field costs are not set to 0.0.
<code>message.attributes.graphql.request.typeCost</code>	The weighted sum of the cost of all types retrieved in the query. The cost of each type is configured in the schema. This count includes types whose type costs are not set to 0.0.
<code>message.attributes.graphql.request.typeCounts</code>	The maximum number of times that a value of each type can be retrieved by the given query. This count includes types whose type costs are not set to 0.0.
<code>message.attributes.graphql.response.fieldCost</code>	The weighted sum of the cost of all fields in the response to the query. The cost of each field access is configured in the schema. If this sum cannot be calculated based on the analysis configuration in the request, the field cost is expressed as the maximum integer value that can be assigned.
<code>message.attributes.graphql.response.fieldCounts</code>	The number of times that each field was retrieved in the response to the query. This number is equal to the number of times that the resolver responsible for producing the value of the field is required to run. If this sum cannot be calculated based on the analysis configuration in the request, the field count is expressed as the maximum integer value that can be assigned.
<code>message.attributes.graphql.response.typeCost</code>	The weighted sum of the cost of all types in the response to the query. The cost of each type is configured in the schema. If this sum cannot be calculated based on the analysis configuration in the request, the type cost is expressed as the maximum integer value that can be assigned.
<code>message.attributes.graphql.response.typeCounts</code>	The number of times that a value of each type was contained in the response to the query. If this sum cannot be calculated based on the analysis configuration in the request, the type count is expressed as the maximum integer value that can be assigned.

Name	Description
<code>message.attributes.parse.GraphQLIntrospection</code>	The introspection type of the assembly GraphQL introspect action. When a GraphQL query is parsed, this context variable is populated with one of the following values: <ul style="list-style-type: none"> <code>not-introspection</code> <code>custom-introspection</code> <code>default-introspection</code>

Related concepts

- [Variable references in API Connect](#)

OAuth context variables

You can customize the OAuth security flow in a native OAuth provider by adding multiple OAuth policies to the assembly. Each OAuth policy takes input from context variables and writes output to context variables. By using these OAuth context variables you can manipulate the original request, and process the output from an OAuth policy.

Note: The OAuth context variables described here apply only to the DataPower® API Gateway. For details of the OAuth context variables that apply to the DataPower Gateway (v5 compatible), see [OAuth context variables - DataPower Gateway \(v5 compatible\)](#).

There are two main types of OAuth context variables:

- [Information variables](#), outputs of an OAuth policy.
- [Processing variables](#), processed during the execution of an OAuth policy.

Information variables

These context variables are outputs of an OAuth policy. They are not used in the processing of the OAuth action.

`oauth.result`

The result of the latest action; returns **SUCCESS** or **FAILURE**.

`oauth.settings.variable_name`

Basic settings from the OAuth provider. The following context variables are available:

```
oauth.settings.allowed_scopes
oauth.settings.access_token_ttl
oauth.settings.authorization_code_ttl
oauth.settings.refresh_token_ttl
oauth.settings.refresh_token_limit
oauth.settings.maximum_consent_ttl
```

`oauth.executed_components[0].variable_name`

The components that have executed in this transaction, with their result. If a failure occurs then the error and error description will be added. The following context variables are available:

```
oauth.executed_components[0].result
oauth.executed_components[0].type
oauth.executed_components[0].error_description
oauth.executed_components[0].error
```

The possible values for the `type` variable are as follows:

```
ValidateRequestComponent
GenerateAZCodeComponent
VerifyAZCodeComponent
VerifyRefreshTokenComponent
GenerateAccessTokenComponent
IntrospectTokenComponent
RevokeTokenComponent
CollectMetaDataComponent
```

The following example shows a corresponding JSON extract from the OAuth context:

```
"executed_components": [
  {
    "type": "ValidateRequestComponent",
    "result": "SUCCESS"
  },
  {
    "type": "GenerateAccessTokenComponent",
    "result": "SUCCESS"
  }
]
```

`oauth.verified_access_token.variable_name`

The token that was verified in the security requirement for a native OAuth provider. The following context variables are available:

```
oauth.verified_access_token.access_token
oauth.verified_access_token.client_id
oauth.verified_access_token.consented_on
oauth.verified_access_token.consented_on_text
```

```
oauth.verified_access_token.grant_type
oauth.verified_access_token.misc_info
oauth.verified_access_token.not_after
oauth.verified_access_token.not_after_text
oauth.verified_access_token.not_before
oauth.verified_access_token.not_before_text
oauth.verified_access_token.one_time_use
oauth.verified_access_token.resource_owner
oauth.verified_access_token.scope
```

`oauth.third_party.variable_name`

The token that was verified in the security requirement for a third party OAuth provider. Provides the following information:

- The response headers from the external, third-party OAuth provider.
- The body of response from the external, third-party OAuth provider.
- Whether the response is cached. When cached, the value is `true`. When not cached, the value is `false`.

The following context variables are available:

```
oauth.third_party.headers
oauth.third_party.response
oauth.third_party.cached
```

`oauth.code.variable_name`

The code that was generated during the execution of a component of type `GenerateAZCodeComponent`. The following context variables are available:

```
oauth.code.client_id
oauth.code.code
oauth.code.redirect_uri
oauth.code.resource_owner
oauth.code.scope
```

`oauth.token.variable_name`

The token that was generated during the execution of a component of type `GenerateAccessTokenComponent`. The following context variables are available:

```
oauth.token.token_type
oauth.token.access_token
oauth.token.scope
oauth.token.expires_in
oauth.token.consented_on
oauth.token.redirect_uri
oauth.token.resource_owner
oauth.token.client_id
oauth.token.refresh_token
oauth.token.refresh_token_expires_in
oauth.token.refresh_token_count
```

`oauth.introspect.variable_name`

The token that was introspected during execution of a component of type `IntrospectTokenComponent`. The following context variables are available:

```
oauth.introspect.active
oauth.introspect.scope
oauth.introspect.client_id
oauth.introspect.resource_owner
oauth.introspect.token_type
oauth.introspect.grant_type
oauth.introspect.ttl
oauth.introspect.expires
oauth.introspect.expires_text
oauth.introspect.iat
oauth.introspect.not_before
oauth.introspect.not_before_text
oauth.introspect.consented_on
oauth.introspect.consented_on_text
oauth.introspect.one_time_use
```

`oauth.external_manager.variable_name`

Token management when using an external token manager. Provides the following information:

- The response headers from the external management server.
- The response JSON body from the external management server.
- When caching is enabled, whether the response is found in the cache or set in the cache. When caching is not enabled, that the response is not set in the cache.

The following context variables are available:

```
oauth.external_manager.headers
oauth.external_manager.response
oauth.external_manager.cached
```

Processing variables

These context variables are processed during the execution of an OAuth policy in your API assembly. If they are set prior to any OAuth policy then the value overrides what was sent in the request. They can also be modified between OAuth policies to manipulate the next component that executes. The following context variables are available:

```
oauth.processing.assertion
oauth.processing.client_id
oauth.processing.client_secret
oauth.processing.grant_type
oauth.processing.redirect_uri
oauth.processing.scope
oauth.processing.response_type
oauth.processing.state
```

```

oauth.processing.resource_owner
oauth.processing.refresh_token
oauth.processing.code
oauth.processing.token
oauth.processing.token_type_hint
oauth.processing.nonce
oauth.processing.max_age
oauth.processing.oidc_values_requested
oauth.processing.id_token_requested
oauth.processing.oidc_signing_algorithm
oauth.processing.code_challenge
oauth.processing.code_challenge_method
oauth.processing.code_verifier

oauth.processing.metadata.access_token
oauth.processing.metadata.payload
oauth.processing.metadata.azcode_miscinfo

oauth.processing.verified_code.client_id
oauth.processing.verified_code.resource_owner
oauth.processing.verified_code.misc_info
oauth.processing.verified_code.scope
oauth.processing.verified_code.is_verified
oauth.processing.verified_code.nonce

oauth.processing.verified_refresh_token.client_id
oauth.processing.verified_refresh_token.resource_owner
oauth.processing.verified_refresh_token.misc_info
oauth.processing.verified_refresh_token.scope
oauth.processing.verified_refresh_token.refresh_token_count
oauth.processing.verified_refresh_token.is_verified
oauth.processing.verified_refresh_token.one_time_use
oauth.processing.verified_refresh_token.grant_type

```

The following example shows the OpenAPI source code for a `gateway-script` policy that executes before an OAuth policy in your API assembly and adds a custom scope to the request:

```

// Add another custom scope to the request
let scope = context.get("request.parameters.scope.values[0]");
if (scope)
  context.set("oauth.processing.scope", scope + " custom");

```

The following example shows the OpenAPI source code for a `gateway-script` policy that between OAuth policies in your assembly and modifies the scope depending on the resource owner:

```

// Check resource owner and modify the scope
let owner = context.get("oauth.processing.resource_owner");
let scope = context.get("oauth.processing.scope");

if (owner === 'admin') {
  context.set("oauth.processing.scope", scope + " admin");
} else {
  context.set("oauth.processing.scope", scope + " customer");
}

```

Advanced scope context variables

The following context variables are used in OAuth advanced scope checking. They are populated by the values entered in the Endpoint and TLS Client Profile fields for the Application scope check and Owner scope check in the native OAuth provider configuration. Do not change these values as this might result in incorrect advanced scope operation.

For information on scope configuration, see [Configuring scopes for a native OAuth provider](#). For information on advanced scope checking, see [Scope](#).

```

oauth.advscope.app.url
oauth.advscope.app.tls-profile
oauth.advscope.own.url
oauth.advscope.own.tls-profile

```

Custom error context variables

These context variables are used to stop OAuth processing and specify the respective error details. They can be used before OAuth processing takes place.

```

oauth.custom_error.status.code
oauth.custom_error.status.reason
oauth.custom_error.message
oauth.custom_error.description

```

Error cases supported by assembly catches

Several error cases that can be returned by the assembly are available to the catch function.

ConnectionError

- An error occurred while establishing a connection to another URL.
- JavaScriptError
 - An error occurred while executing JavaScript or GatewayScript in a policy.
- PropertyError
 - An error occurred due to an incorrect property during an invoke call or during the execution of a set-variable policy when an action was not set, add, or clear.
- RedactionError
 - An error occurred during the redaction of a field as part of a redact policy.
- TransformError
 - An error occurred during a transformation policy.
- RuntimeError
 - An otherwise unspecified error occurred.
- BadRequestError
 - An error occurred while trying to access the request. This is not supported by the default catch; to catch this condition, specify it in your catch definition.
- SOAPError
 - A SOAP Fault response was received as the result of a web service invoke request.
- OperationError
 - An invoke request received a response with an unsuccessful HTTP status code.
- ValidateError
 - An error occurred while trying to schema validate a message payload.
- API Gateway only AssemblyRateLimitError
 - The request exceeds the transaction count threshold specified in the API's Plan.
- UnauthorizedError
 - The API cannot be invoked based on the client ID and/or client secret provided, or id/secret were specified in the wrong location. This is not supported by the default catch; to catch this condition, specify it in your catch definition.
- ForbiddenError
 - The application making the API request has been disabled or is not active. This is not supported by the default catch; to catch this condition, specify it in your catch definition.

API and Product definition template examples

You can use template files when creating API and Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition. This topic provides the default Handlebar templates used by **apic** to create Products and APIs as examples you can use to copy and customize for your own use.

Default API definition template (OpenAPI 2.0)

The following example template, which is for an OpenAPI 2.0 API definition, is the default template that developer toolkit uses when you create an API definition. Copy this example template into your own template file (which must have the `.hbs` extension), then edit it for your purposes. Template variables are enclosed by double curly braces, for example `{{name}}`. For information on template variables, see [Template variables for API and Product definitions](#). For more information on Handlebars, see <https://handlebarsjs.com/>.

description: |

- This endpoint allows requesting an access token following one of the flows below:
- Authorization Code (exchange code for access token)
- Client Credentials (2-legged, there isnt resource owner information)
- Resource Owner Password Credentials (2-legged, client provides resource owner name and password)
- Refresh Token (exchange refresh token for a new access code)

The table below indicates the required parameters for each specific grant_type options.
Empty cells indicate a parameter is ignored for that specific grant type.

Client authentication:

- Confidential clients should authenticate using HTTP Basic Authentication. Alternatively, they may post their client_id and client_secret information as a formData parameter.
- Public clients should send their client_id as formData parameter.

grant_type	code	client_credentials	password	refresh_token
client_id	required*	required*	required*	required*
client_secret	required*	required*	required*	required*
code	required			
redirect_uri	required			
username			required	
password			required	
scope		optional	optional	
refresh_token				required

The implicit grant requests, see /oauth2/authorize.

Template variables for API and Product definitions

You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition.

Product definition variables

The following table describes the Handlebars template variables that can be used in a product definition file. For more information on Handlebars, see <https://handlebarsjs.com/>. Product definition template files must have a `.hbs` filename extension.

Table 1. Product definition Handlebars template variables

Variable	Type	Description
{{apis}}	Array of string	The APIs to which the product definition refers. After substitution, the array values become the values of <code>apis.routes[n].\$ref</code> fields, for example: <pre> apis: 'routes': \$ref: apidef.yaml ... </pre>
{{name}}	String	Value of <code>info.x-ibm-name</code> field.
{{title}}	String	Value of <code>info.title</code> field.
{{version}}	String	Value of <code>info.version</code> field.

API definition variables

The following table describes the Handlebars template variables that can be used in an API definition file. For more information on Handlebars, see <https://handlebarsjs.com/>. API definition template files must have a `.hbs` filename extension.

Table 2. API definition Handlebars template variables

Variable	Type	Description
{{basepath}}	String	Base path on which the API is served, which is relative to the <code>host</code> .
{{definitions}}	OpenAPI definitions object converted to a YAML string ("stringified").	For a LoopBack API, contains data types that can be consumed and produced by operations. These data types can be primitives, arrays or models.
{{definitionsObj}}	OpenAPI definitions object converted to a YAML string ("stringified").	For a LoopBack API, contains data types that can be consumed and produced by operations. These data types can be primitives, arrays or models.
{{hostname}}	String	Value of the <code>host</code> field.
{{name}}	String	Value of <code>info.x-ibm-name</code> field.
{{paths}}	OpenAPI paths object	For a LoopBack API, contains the relative paths to the individual endpoints. The path is appended to <code>{basePath}</code> to construct the full URL.
{{pathsObj}}	OpenAPI paths object	For a LoopBack API, contains the relative paths to the individual endpoints. The path is appended to <code>{basePath}</code> to construct the full URL.
{{schemes}}	Array of string	Transfer protocol of the API. Values must be one of: <code>"http"</code> , <code>"https"</code> , <code>"ws"</code> , or <code>"wss"</code> .
{{targeturl}}	String	Value of <code>x-ibm-configuration.assembly.execute[invoke]</code> . Default is <code>\$(runtime-url)\$(request.path)</code> .
{{title}}	String	Value of <code>info.title</code> field.
{{version}}	String	Value of <code>info.version</code> field.

Managing your APIs

You manage your APIs by using the API Manager user interface of IBM® API Connect. You can also analyze your API usage by using the analytics that are provided and socialize your APIs in a developer portal.

Why use APIs?

Whether you are a business user, an IT user, or an application developer, APIs are increasingly important to your business. You can use an API to publicize your company. The assets, data, or services of your company can be provided to external application developers to expand your enterprise and open new markets.

The API Manager UI provides a solution for companies to manage APIs for private internal APIs, and public external APIs. This on-premises offering provides the capabilities that are required so that you can externalize and manage your services as REST or SOAP APIs.

What do you need to know?

Depending on your role, you can complete different tasks relating to managing your API Catalogs and these are outlined in the documentation. Each task is covered in the order that they are executed.

Each task introduces new features of the API Manager UI as they become relevant to the Catalog that you are building.

For security reasons, your session times out after a period of inactivity.

Before you start, check that the browser you are using is supported and meets the required minimum levels; for details, open the [Detailed system requirements for a specific product](#) page, search for the IBM API Connect product, then select the required version.

The ways in which you can manage your APIs are described in the following subtopics:

- [API management checklist](#)
A summary, with links, of the key tasks for managing APIs in IBM API Connect.
- [Activating your API Manager user account](#)
Before you can access the API Manager user interface of IBM API Connect, you must activate the user account that your Cloud Manager administrator invited you to join.
- [Accessing the API Manager user interface](#)
The IBM API Connect API Manager user interface provides a range of options for working with your APIs and Products, and managing security.
- [Searching for items in API Manager](#)
Use the search feature in IBM API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.
- [Working with Catalogs](#)
Products must be staged to a Catalog and then published; application developers are able to access the APIs in a Product by being members of consumer organizations to which the Product is made available. In API Connect, you can create multiple Catalogs. Catalogs are useful for separating Products and APIs for testing before you make them available to consumer organizations. The syndication feature in API Connect means that you can also publish a Product to a Space in a Catalog.
- [Using syndication in API Connect](#)
With the API Connect syndication feature, you can partition your Catalogs into *Spaces*. Each Space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that Space, enabling each team to manage their APIs independently.
- [Working with Products](#)
In IBM API Connect, Plans and APIs are grouped together in Products.
- [Working with APIs](#)
For a specific Product, you can work with the APIs that are contained in the Plans in that Product.
- [Working with Plans](#)
After a Product has been published to a Catalog, you can work with the Plans in that Product.
- [Working with consumer organizations](#)
Manage the consumer organizations that access your APIs and Plans when their users sign up to use the IBM API Connect Developer Portal.
- [Working with developer applications](#)
You can work with the applications that have been registered in the Developer Portal associated with a Catalog.
- [Working with application subscriptions](#)
You can work with the subscriptions to the Plans in all the Products in a specific Catalog. Plan subscriptions are created by application developers in the Developer Portal.
- [Security and authentication](#)
In API Manager, you can use TLS profiles to secure the transmission of data between the management server and other API Connect subsystems and external services, and also configure user registries to securely authenticate your Catalogs and APIs.
- [API Analytics](#)
You can use API Connect to filter, sort, and aggregate your API event data. You can present the results within correlated charts, tables, and maps to help you manage service levels, set quotas, establish controls, set up security policies, manage communities, and analyze trends.
- [Administering user access](#)
If you have permission to administer users in IBM API Connect, you can add and delete users. After users are removed from an organization through deletion, the user account remains in API Manager.
- [Changing your API Manager password](#)
You can change your API Manager password in IBM API Connect.
- [Resolving login problems by increasing HTTP header size](#)
You can resolve login problems for the API Manager UI by increasing the maximum HTTP client header size.
- [Reviewing a gateway's processing status](#)
Review the processing status for the Gateway services that are enabled in your API Connect Catalogs and Spaces.
- [Reference](#)
Reference information for the API Manager component in IBM API Connect.

API management checklist

A summary, with links, of the key tasks for managing APIs in IBM® API Connect.

Task	Description
Activate your API Manager user account	To connect to a Management server using the API Manager user interface, you must be an owner or a member of a provider organization.
Log in to the API Manager user interface	After you have activated your account, you can log in to your Management server from the API Manager user interface.
Configure your Catalogs	APIs are published to a Catalog to make them available to application developers. The URLs for API calls, and for the Developer Portal, are specific to a particular Catalog. By default, a <i>sandbox</i> Catalog is provided for API testing, but you can create your own Catalogs; for example, a production Catalog for hosting APIs that are ready for full use.
Manage the membership of your Catalogs	You can add users to your Catalogs, and assign roles and permissions to control their level of access.
Configure API security	You can configure user registries of various types for authenticating API access, TLS profiles for securing data transmission over HTTPS, and OAuth providers for securing third-party website or application access to APIs.
Manage your Products	Move your Products through their lifecycle, from initially staging a Product to a Catalog, through to publishing to make the Product version available to your application developers, and to eventual retiring and archiving. You can also display analytics information, and control who can see or subscribe to your Products.
Manage user access to your provider organization	You can add users to your provider organization, remove users, and assign roles and permissions.
Partition your Catalogs into Spaces for syndication	With the syndication feature, you can partition your Catalogs into <i>Spaces</i> . Each Space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that Space, enabling each team to manage their APIs independently.

Activating your API Manager user account

Before you can access the API Manager user interface of IBM® API Connect, you must activate the user account that your Cloud Manager administrator invited you to join.

Before you begin

The Cloud Manager administrator invited you to join API Connect .

Procedure

1. Complete the following steps to create your API Manager account:

If the Identity Provider uses LDAP

An invitation email with an activation link is sent. Click the activation link, or paste it in a browser, to log in directly with your user credentials. Upon authentication, the API Connect user record is updated from the backend identity provider.

If the Identity Provider uses a local registry

An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your first name, last name and password. Passwords must have a minimum of 8 characters and contain characters from at least three of the four following categories:

- Uppercase letters
- Lowercase letters
- Numbers
- Special characters (for example: ! # \$ %)

Note:

- The email address that you enter on the sign up page must match the email address to which the invitation email was sent, otherwise the account activation fails.
- If you previously had an account that the administrator removed, and they are inviting you again, you must re-activate your account by using the Sign In option on the page, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail.

If the Identity Provider uses an authentication URL

An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your credentials, which then become your user name and password. Upon authentication, the API Connect user record is updated from the backend identity provider.

If multiple user registries are available for selection on the sign up page, then make sure that the correct registry for your API Manager account is selected. You might need to ask your administrator which user registry is appropriate for your account.

For information on configuring user registries and making them available for API Manager login, see [User registries overview](#) and [Selecting user registries for Cloud Manager and API Manager](#).

2. Click Sign up to complete your registration, then click Sign in to open the API Manager login page.

Results

You have created your API Connect account.

What to do next

Log in to the API Manager user interface and, depending on your role, start to work with Catalogs, consumer organizations, APIs and Products.
To access the API Manager login page in the future, use the following URL:

`https://host/manager`

where *host* is the fully qualified host name or IP address of the Management server.

Accessing the API Manager user interface

The IBM® API Connect API Manager user interface provides a range of options for working with your APIs and Products, and managing security.

To log in to the API Manager user interface, complete the following steps:

1. In a web browser, enter the following URL:

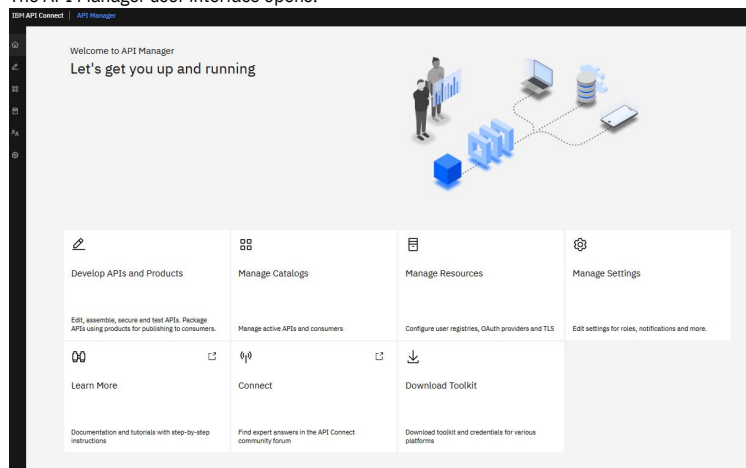

`https://host/manager`

where *host* is the fully qualified host name or IP address of the Management server.

2. If your cloud contains multiple user registries, then select the user registry that contains the login credentials for your API Manager account. You might need to ask your administrator which user registry is appropriate for your account.
For information on configuring user registries and making them available for API Manager login, see [User registries overview](#) and [Selecting user registries for Cloud Manager and API Manager](#).

3. Enter your user name and password, then click Sign in.

The API Manager user interface opens:

Depending on your role, you can now start to work with Catalogs, consumer organizations, APIs and Products.

Searching for items in API Manager

Use the search feature in IBM® API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.

Search is available from any page in API Manager and can be accessed by typing in the search field in the page banner, or by clicking  Search in the navigation list.

Using Search

The Search feature is available on all pages of the API Manager. To start searching, just type a string into the Search field and press Enter. Whenever you press Enter in the Search field, the Search page displays with results and additional options. If you press Enter in an empty Search field, or click  Search in the navigation list, then the Search page displays a list all items. If you type a string before pressing Enter, the page displays the results from the corresponding search.

Search results include all items that contain the search string in a text field. For example, suppose you searched for "Crafted". The results might look like the following image, with items that don't match the search string exactly, but do include the string in a text field such as a title or a name.

By default, the search returns all types of items that contain the string. Sort results on a particular column by clicking the column header.

When you find an item you want to work with, click the . . . actions menu next to the item's "Modified" date to see what you can do. The list of possible actions depends on the item's type.

You can limit the search results by selecting an item type from the list that displays before the results. Click More to view additional types. If you select a type from the More menu, it replaces a type in the list.

If you want to refine the search further, click Options. On the Options panel, click Catalogs to Search and select which catalogs to search (the default is all catalogs). You can select up to 5 catalogs for a limited search.

You can also choose whether only exact matches (the complete string) are included in results, or items containing similar strings are also included.

Working with Catalogs

Products must be staged to a Catalog and then published; application developers are able to access the APIs in a Product by being members of consumer organizations to which the Product is made available. In API Connect, you can create multiple Catalogs. Catalogs are useful for separating Products and APIs for testing before you make them available to consumer organizations. The syndication feature in API Connect means that you can also publish a Product to a Space in a Catalog.

A Catalog is a staging target, and behaves as a logical partition of the gateway and the Developer Portal. The URL for API calls and the Developer Portal are specific to a particular Catalog. In a typical configuration, an API provider organization uses a development Catalog for testing APIs under development and a production Catalog for hosting APIs that are ready for full use. A common approach is to have a development cloud with a development Catalog, a few test Catalogs and a production cloud that might have its own test Catalog.

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a sub-catalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see [Using syndication in API Connect](#).

Note:

Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: **A user already exists with this email address.**

For more information on using the Developer Portal, see [Developer Portal: Socialize your APIs](#).

- [Creating and configuring Catalogs](#)
These instructions describe how to create and configure Catalogs in IBM API Connect.
- [Configuring Product visibility at a Catalog or Space level](#)
How to set a limit on the visibility for all Products that are published to a Catalog or Space.
- [Configuring sub paths for Developer Portal sites](#)
You can increase the specificity of a IBM API Connect Developer Portal site URL by using sub paths.
- [Managing Catalog membership](#)
Manage Catalog membership by adding new users to the Catalog and assigning roles to the users.
- [Importing a user-defined policy into a Catalog](#)
You can make your user-defined policy available to API developers by importing it into an IBM API Connect Catalog, or a Space in a Catalog.
- [Importing an OpenAPI extension into a Catalog](#)
You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An extension is imported into a Catalog, or a Space in a Catalog, then added to the API schema.
- [Retaining Version 5 vanity endpoint behavior in a Catalog](#)
The behavior of vanity endpoints in a Catalog has changed in API Connect Version 10 compared with Version 5. However, you can modify your Catalog settings to retain the Version 5 behavior.

Creating and configuring Catalogs

These instructions describe how to create and configure Catalogs in IBM® API Connect.

Before you begin

You must have Catalog create permissions to complete this task. For more information about permissions, see [API Connect user roles](#).

Notes:

- As the user who creates the Catalog, you are automatically the Catalog owner and have all Catalog permissions.
- If you configure a new user registry for authenticating users to the Developer Portal, you must also complete the onboarding section in the Catalog, to make the registry available to Developer Portal users. See Step [15](#) for details.
- Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: **A user already exists with this email address.**

Procedure

To create and configure your Catalog, complete the following steps:

1. Log in to API Manager and click  Manage.
2. Create the Catalog.
You can create the Catalog in either of the following ways:
Specify the owner, then configure the Catalog:
 - a. Click Add > Create catalog.
 - b. In the Catalog Owner field, select the owner of the Catalog; by default, you are the owner. You can specify any user who is a member of the provider organization.
 - c. Continue from step [3](#) to configure the Catalog.Send an invitation email, with an activation link, to the intended Catalog owner:
 - a. Click Add > Invite catalog owner.
 - b. Enter the email address of the Catalog owner, then click Invite.
 - c. On receipt of the email, the Catalog owner must activate the Catalog and configure it:
 - i. Open the activation link, complete the sign up form, and sign in to the API Manager UI.
 - ii. Click Manage Catalogs, click the Catalog name that was provided on the sign up form, then click the Catalog settings tab.
 - iii. Continue from step [6](#) to configure the Catalog.
3. Enter the Catalog Title. A Name is entered automatically and cannot be changed.
Note: The value in the Name field is a single string that is used to identify the Catalog in developer toolkit CLI commands. The Title is used for display; you can change the title but the name does not change.
To view the CLI commands to manage Catalogs, see [apic catalogs](#).
4. Click Create.
Your new Catalog is displayed on the Manage page.
5. To continue to configure your Catalog, select the Catalog on the Manage page, then click the Catalog settings tab.
6. To configure the general settings for the Catalog, click Overview, then proceed with the following steps:
 - a. By default, the new Catalog is a development Catalog. To use the Catalog in production, set the Production Mode slider control to the On position, then click Confirm.
In a development Catalog, all publish operations are forced, and any conflicts are resolved automatically. If you republish a previously published Product version it is overwritten without warning, allowing you, for example, to repeatedly republish the same Product version during testing. If Spaces are enabled in a development Catalog and you republish a previously published Product version to a different Space, it is removed from the previous Space.

A development Catalog behaves the same as any other Catalog with regard to requiring approval for staging and publishing actions, if the Catalog has been configured to require approval.

Note: In a production Catalog, the following conditions apply:
 - You cannot publish a Product to the Catalog if there is already a Product in the Catalog with the same name and version. Instead, you must create a new version of the Product for publication; see [Creating a new version of your Product](#). If Spaces are enabled in a production Catalog, you cannot publish a Product with the same name and version to more than one Space in the Catalog.
 - If this new Product contains one or more modified APIs, you **must** create new versions of the APIs for inclusion in the Product; see [Creating a new version of an API definition](#). If the Product contains a modified API and there is already a published API of the same name and version, the changes will **not** be published.
 - b. To enable the partition of this Catalog into Spaces, set the Spaces slider control to the On position, then click Confirm.
For more information, see [Using syndication in IBM API Connect](#).
 - c. If the Catalog is the default staging Catalog, move the Default slider control to the On position, then click Confirm. Then, calls to APIs that are published to the Catalog can use a shorter URL that does not include the Catalog name.
Note: You can enable Default only for one Catalog. If another Catalog is already set as the default Catalog you will be unable to enable the setting on this Catalog without first disabling the setting on the other Catalog.
7. To transfer ownership of the Catalog to a different user, click Overview, then proceed with the following steps:
 - a. Click Edit.
 - b. From the Select owner user drop-down menu, select the user who will become the new owner.
 - c. If Spaces are enabled in the Catalog then to also have the ownership of all Spaces in the Catalog transferred to the new Catalog owner, select Also transfer ownership of owned Spaces.
 - d. Click Save when done.Note:
 - To have permission to change the Catalog owner, you must be either the Catalog owner, or the owner of the provider organization that contains the Catalog.
 - When the ownership changes, the new owner is assigned administration privileges for the Catalog, and the previous owner has their administration privileges removed. If required, you can restore the privileges to the previous owner as described in [Managing Catalog membership](#).
 - The ownership can be transferred only to a user who is already a member of the Catalog. To transfer to a new user or another existing user, that user must previously have been added or invited to the Catalog, as described in [Managing Catalog membership](#).
8. To configure the gateway service settings for the Catalog, click Gateway Services, then proceed with the following steps:
Note: If Spaces are enabled in the Catalog then you configure the gateway settings for the Spaces, **not** for the Catalog as a whole.
 - a. Click Edit.
 - b. Select the gateway services that you want to use with this Catalog.

Gateway services are configured by using the Cloud Manager UI. For details, see [Registering a gateway service](#). If any Catalog default gateway services have been configured, they will already be selected when you create a new Catalog; see [Configuring default gateway services for Catalogs](#). The TYPE column indicates the gateway type for each gateway service listed, DataPower® Gateway (v5 compatible), DataPower API Gateway, or Event Gateway Service if you have Event Endpoint Management enabled in Cloud Pak for Integration. For more information, see [API Connect gateway types](#).

c. Click Save to save your changes.

You publish APIs by adding them to a Product and then publishing the Product to a Catalog. To be able to publish Products to a Catalog, the Catalog must be assigned at least one gateway service so that the APIs in the Product are available to be called at a gateway service endpoint. You can assign more than one gateway service to a Catalog, and they can be of mixed types: DataPower API Gateway, DataPower Gateway (v5 compatible), and Event Gateway Service.

A Product is gateway type specific: DataPower API Gateway, DataPower Gateway (v5 compatible), or Event Gateway Service. By default, when you publish a Product to a Catalog, it is published to all the assigned gateway services of the same gateway type as the Product, but you can choose to publish the Product only to selected gateway services, of that type, at publish time; see [Publishing a draft Product](#) for more information. The APIs in the Product will be available to be called at all the specified gateway service endpoints.

If you select two or more Gateway services then, for analytics data to be available in the Developer Portal for this Catalog, the Gateway services must all be associated with the **same** analytics service. If the set of associated analytics services for the selected gateway services includes two or more different analytics services then the Developer Portal does **not** display analytics data. An analytics service is associated with a gateway service in the Cloud Manager user interface; see [Associating an analytics service with a gateway service](#).

Note: You can also configure the gateway service settings for the Catalog by using the developer toolkit CLI; for details, see [apic configured-gateway-services](#).

9. To specify the Product lifecycle state changes for which you want to enforce approval, complete the following steps:

a. Click Lifecycle Approvals in the Catalog settings navigation pane, then click Edit.

b. Select the required state changes, then click Save when done.

For example, if you select Publish and leave the other check boxes cleared, approval is required when anyone attempts to publish a Product, but no approval is required for any of the other lifecycle state changes.

Note: Approval for Product lifecycle state changes in a Catalog is disabled by default. You must explicitly enable the Product lifecycle state changes that you want to enforce.

c. To allow the originator of a Product lifecycle change to approve it themselves, move the Task self approval slider control to the On position.

Note: In a development Catalog, the originator of a Product lifecycle change can **always** approve it themselves. In a production Catalog, the originator of a Product lifecycle change can approve it themselves only if the Catalog setting Task self approval is enabled.

10. Click Save.

11. To configure the publish validations that are performed when a Product is published, complete the following steps:

a. Click Publish validations in the Catalog settings navigation pane.

b. Click Edit, and select or clear the validation check boxes as required.

The following validation options can be selected:

- Publishing APIs with empty paths is not allowed.
- Validate custom policy schema in assembly.
- Validate the references inside the API and perform additional OpenAPI validations.
- Publishing APIs with duplicate base paths is not allowed.

12. Click Save.

13. To configure the permissions that each role in API Manager has, complete the following steps:

a. Click Roles in the Catalog settings navigation pane.

To see the current permissions for a role, expand the role.

b. Click the options icon  alongside the role that you want to work with, then click Edit.

c. Select or clear the permissions check boxes as required.

To ensure a role can manage user-defined policies, select Manage for the Settings permission.

To grant a role the permission to approve a specific lifecycle state change, select the state change in the Product-Approval section.

Note: You cannot remove a permission that has been assigned to the role at the provider organization level. However, you can add permissions that haven't been assigned at the provider organization level.

d. Click Save when done.

14. To configure the default role permissions for consumer organizations that are created in this Catalog, complete the following steps:

a. Click Role Defaults in the Catalog settings navigation pane.

To see the current default permissions for a role, expand the role.

b. Click the options icon  alongside the role that you want to work with, then click Edit.

c. Select or clear the permissions check boxes as required.

d. Click Save when done.

e. To create a new role and assign default permissions to it, click Add, name the role and assign permissions, then click Save.

15. To manage the onboarding of API consumers into this Catalog, complete the following steps:

a. Click Onboarding in the Catalog settings navigation pane.

b. To select the registries that are used to authenticate users of the Developer Portal associated with this Catalog, click Edit in the Catalog User Registries section, select the required registries, then click Save.

For details on how to configure a user registry, see [Authenticating by using your enterprise user registry](#).

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

c. To set a default registry, click the options icon  alongside the required registry, then select Set default.

When an API consumer signs up to the Developer Portal, the specified registry is used by default, with the option to select another registry.

d. To allow API consumers to complete their own sign-up process to the Developer Portal, move the Self service onboarding slider control to the On position. If this option is disabled, an API consumer cannot sign-up without an invitation from a consumer organization owner.

e. To require approval for all new self service onboarding to the Developer Portal, move the Self service onboarding approval slider control to the On position. If this option is enabled, then any attempt by an API consumer to sign-up to the Developer Portal results in an approval request being sent. This request is displayed in the Task tab in the Catalog for the associated Developer Portal, from where the request can be approved or declined.

Note that Self service onboarding approval is honored whenever a consumer organization is created. So, even if an API consumer has already been approved to access a Developer Portal with a specific consumer organization, if they then try to create another consumer organization in the same Developer Portal,

their request will still go through the approval process.

Note: To enable self-service onboarding approval, you must also complete the following tasks:

- Configure the user registry to require the user's email address.
 - Configure the OIDC apps to send the user's email address for approval.
- f. To configure the ability for API consumers to invite collaborators and assign them to roles, click Edit in the Consumer invitation and roles section, select the options required, and click Save.
 - g. To configure the timeout for activation links that are sent in email invitations to application developers, click Edit in the Invitation Timeout section, specify the timeout length, then click Save.
 - h. To override the timeouts set by consumer organization invitations, enable the Override consumer organization's invitation timeout with catalog invitation timeout setting by moving the slider to the On position.
The catalog's own timeout setting will be used instead.

16. To specify the user registries that are used to secure access to APIs in this Catalog, and to add the user registry to the Sandbox Catalog, complete the following steps:

- a. Click the Catalog settings tab, and then select API User Registries.
- b. Click Edit and select the user registries you want to use.
For details on how to configure a user registry, see [Authenticating by using your enterprise user registry](#).
- c. Click Save when done.

Note:

- Only LDAP and Authentication URL registries can be used to secure access to APIs; therefore, only registries of these types are listed and available for selection.
- If Spaces are enabled in the Catalog then you specify the user registries for the Spaces, **not** for the Catalog as a whole. If you specify a user registry in one Space in a Catalog, it is deployed to the gateway services across all Spaces in that Catalog.
For more information about enabling and managing Spaces, see [Using syndication in API Connect](#)

17. To specify the OAuth Providers that can be used to secure access to APIs in this Catalog, complete the following steps:

Note:

- If you want to specify an OAuth provider for a Catalog, ensure that the Sandbox Catalog is configured to use the same OAuth provider
- Any resources that the OAuth provider references, such as API user registries or TLS client profiles, must also be enabled in the Catalog
- If Spaces are enabled in the Catalog then you specify the OAuth providers for the Spaces, **not** for the Catalog as a whole. If you specify an OAuth provider in one Space in a Catalog, it is deployed to the gateway services across all Spaces in that Catalog.
For more information about enabling and managing Spaces, see [Using syndication in API Connect](#).

- a. Click OAuth Providers in the Catalog settings navigation pane.
- b. Click Edit, then select the OAuth providers that you want to use.
To configure an OAuth provider, see either [Configuring a native OAuth provider](#) using Cloud Manager or [Configuring a native OAuth provider](#) using API Manager.

- c. Click Save when done.

18. Optional: Configure vanity API endpoints for your Catalog.

For any API, there are two possible endpoints to consider:

- The gateway endpoint at which the API is invoked.
- The endpoint that is visible to the consumer in the Developer Portal.

If you do not configure vanity endpoints, these two endpoints are the same, and point to the gateway endpoint at which an API is invoked.

To have an endpoint visible to the consumer that is different to the gateway endpoint, you configure a vanity endpoint. A vanity endpoint represents the endpoint by which an API is known externally; that is, the endpoint that is published to the Developer Portal and is used by an application developer to invoke the API. The way in which the gateway endpoints for an API are determined depends on the OpenAPI version of the API, as follows:

(OpenAPI 2.0): For any enforced API in API Connect, the gateway endpoint formats for the API are as follows:

- If the OpenAPI definition has no **host** field, the API endpoint has the following format:

```
https://gateway_service_host/provider_organization/catalog/basepath
```

- If the OpenAPI definition has a **host** field (for example, **petstore.com**), the host is appended to the path after the **provider_organization/catalog** segments, and the API endpoint has the following format:

```
https://gateway_service_host/provider_organization/catalog/host_field_value/basepath
```

Note: This is a change in behavior from IBM API Connect Version 5.0, where the **host** field is not included in the API endpoint.

In these endpoint URLs, the variables are as follows:

- **gateway_service_host** is the host name of the gateway service on which the API is running.
- **provider_organization** is the value of the **name** field of the provider organization that contains the Catalog in which the API is published.
- **catalog** is the value of the **name** field of the Catalog in which the API is published.
- **basepath** is the value of the **basepath** field in the OpenAPI definition for the API.
- **host_field_value** is the value of the host field in the OpenAPI definition for the API.

API Gateway only **(OpenAPI 3.0):** If the API is enforced by the DataPower API Gateway, the value specified for the first **url** entry in the **servers** array in the OpenAPI definition of the API is used to determine the **basepath** element of the API endpoint, as follows:

- a. If a relative URL is specified for the server URL, that value is used as-is for the **basepath**, and the API endpoint has the following format:

```
https://gateway_service_host/provider_organization/catalog/basepath
```

- b. If a full URL is specified for the server URL, the scheme (**http://** or **https://**) is ignored by the DataPower API Gateway, and the remaining host name and **basepath** are used to form the API endpoint as follows:

```
https://gateway_service_host/provider_organization/catalog/host_name/basepath
```

In these endpoint URLs, the variables are as follows:

- **gateway_service_host** is the host name of the gateway service on which the API is running.
- **provider_organization** is the value of the **name** field of the provider organization that contains the Catalog in which the API is published.
- **catalog** is the value of the **name** field of the Catalog in which the API is published.
- **host_name** is the value of the host name in the server URL.

- *basepath* is the value of the **basepath** derived from the server URL.

For details on configuring the server URL in an OpenAPI 3.0 API definition, see [Defining servers for an API](#), [Defining servers for a Path](#), and [Defining servers for an operation](#).

Note: You can change your Catalog settings to use the IBM API Connect Version 5.0 endpoint behavior, including support for a feature known as *host to catalog mapping*, whereby an API can be invoked without having to include the provider organization or Catalog in the URL path; see [Retaining Version 5 vanity endpoint behavior in a Catalog](#).

To configure vanity API endpoints, so that you can publish endpoints that are different to these gateway endpoints, complete the following steps:

- Click API Endpoints in the Catalog settings navigation pane. The Vanity API Endpoint page opens.
 - Click Edit.
 - To display the current API base endpoint settings, select Display vanity endpoint.
 - Select the required Preference setting. Choose one of the following settings:
 - **Catalog priority:** Any host defined in the OpenAPI definition of the API is ignored and all API endpoints always point to the endpoints that you define here. For example, suppose you define a vanity API endpoint, with Catalog priority preference, to be `https://prod.acme.com/`. Then the API endpoint will be `https://prod.acme.com/basepath`.
The way in which the **basepath** is determined depends on the OpenAPI version of the API, as follows:
 - **(OpenAPI 2.0):** The **basepath** is taken from the **basepath** field in the OpenAPI definition.
 - **API Gateway only (OpenAPI 3.0):** The **basepath** is taken from the first **url** entry in the **servers** array in the OpenAPI definition, ignoring any scheme (`http://` or `https://`) and host name.
 - **API priority:** The host defined in the OpenAPI definition for the API takes precedence. For example, suppose you define a vanity API endpoint, with API priority preference, to be `https://api.acme.com/`. Then the following rules determine the endpoint that is used when an API is called:
 - If the OpenAPI definition has a host defined, `test.acme.com` for example, then that value is used to determine the API endpoint. For example: `https://test.acme.com/basepath`.
 - If the OpenAPI definition has no host defined, the API endpoint will be `https://api.acme.com/basepath`, as determined by the vanity API endpoint setting.
- The way in which any defined host is determined depends on the OpenAPI version of the API, as follows:
- **(OpenAPI 2.0):** The host is taken from the **host** field in the OpenAPI definition.
 - **API Gateway only (OpenAPI 3.0):** The host is taken from the host name in the first **url** entry in the **servers** array in the OpenAPI definition.
- Supply one or more endpoints, as follows:
 - If you selected Catalog priority, click Add to enter one or more endpoints URLs, and an optional summary for each. Any of the endpoint URLs can be used to invoke an API.
 - If you selected API priority, enter the endpoint URL, and an optional summary.

Note: After configuring your Catalog to support your vanity URL, you must configure your external network to map the vanity endpoints to the corresponding gateway endpoints. This typically includes the following:

- A DNS mapping to ensure that the vanity host resolves to the gateway.
- Additional URL routing for the API as required.

For example, if your gateway has a default domain name of `apigw.dc.zone.mycompany.com` and an IP address of `29.12.141.150`, then the generic DNS configuration might look like:

```
api.acme.com. CNAME apigw.dc.zone.mycompany.com.
```

or

```
api.acme.com. A 29.12.141.150
```

Consult your network administrator and the DNS provider's documentation to do this configuration.

- To configure the TLS client profiles that are used with this Catalog, complete the following steps:

Note: If Spaces are enabled in the Catalog then you configure the TLS client profiles for the Spaces, **not** for the Catalog as a whole. If you configure a TLS client profile in one Space in a Catalog, it is deployed to the gateway services across all Spaces in that Catalog. For more information about enabling and managing Spaces, see [Using syndication in API Connect](#).

 - Click TLS Client Profiles in the Catalog settings navigation pane.
 - Click Edit, then select the TLS client profiles that you want to use with this Catalog.
For details on how to create a TLS client profile, see [Creating a TLS client profile](#).
 - Click Save when done.
- To configure the Developer Portal, complete the following steps:
 - Click Portal in the Catalog settings navigation pane, then click Create.
 - Select the portal service that you want to use with this Catalog.
Portal services are configured by using the Cloud Manager UI. For details, see [Registering a portal service](#).
 - Optionally, override the default generated portal URL.
The URL must have the following format:
`https://host_name.portal.com`
where `host_name.portal.com` must resolve to the IP address of the Developer Portal machine.
For example:
`https://myhost.mydomain.com`

Important:

 - The URL must be unique across all Catalogs.
 - Mixed-case names are supported for resource names, however, portal endpoint URLs can support only lower-case. If a provider organization is created with a mixed-case name, you must edit the default generated portal URL to make the provider organization name lower-case in the URL.

To implement sub paths into your site URL, see [Sub paths for Developer Portal sites](#).

 - Select the portal service that you want to use with this Catalog.
For more information on using the Developer Portal, see [Developer Portal: Socialize your APIs](#).
 - Click Create to save your changes.

Note: The account profile for the owner of the Catalog must have an email address specified to receive the creation notification, otherwise the Developer Portal creation operation will fail. To check whether your account profile has an email address, and specify a value, complete the following steps:

- Click the User icon , and then select My Account.

b. Check the contents of the Email field, and specify a value if necessary, then click Save.

Note: If you want to edit the portal service or URL, or delete the portal site, return to this portal settings page, click the options icon , and click Edit or Delete.

21. To define Catalog properties, complete the following steps:

- a. Click Properties in the Catalog settings navigation pane, then click Create.
- b. Enter the property Name and Value, then click Create.

The properties that you define can be referenced in any of the API definitions in this Catalog. It is also possible to define properties that are specific to an API definition; see [Setting API properties](#). For information on how to reference a property in an API definition, see [Variable references in API Connect](#).

Note:

- If you define a Catalog property of the same name as an API property, the API property takes precedence over the Catalog property.
- If you change the value of a Catalog property, any API that references that property must be republished for it use the new value.

22. Optional: To configure the visibility of Products that are published to a Catalog or a Space, see [Configuring Product visibility at a Catalog or Space level](#).

What to do next

Import your own policies into the Catalog. For details, see [Importing a user-defined policy into a Catalog](#).

Note: When you import a policy, its implementation is imported into all Gateway devices associated with the Gateway service that hosts the Catalog. Additionally, API Connect modifies some object names and file locations to mark them with the appropriate Catalog name and policy version.

For more information about how to create and manage user-defined policies, see [User defined policies](#).

Configuring Product visibility at a Catalog or Space level

How to set a limit on the visibility for all Products that are published to a Catalog or Space.

Before you begin

To configure Product visibility at the Catalog or Space level, you must be assigned to a role that has the Settings, Manage permission for that Catalog or Space. For more information on assigning Catalog permissions to a role, see [Creating and configuring Catalogs](#).

Note: All references in this topic to a Catalog can also be applied to a Space in a Catalog, unless specified otherwise. For more information about Spaces, see [Using syndication in API Connect](#).

About this task

The availability of a Product to users is determined by both the visibility setting (that covers which users can view the Product), and the subscribability setting (that covers which users can subscribe to the Product). When you create a draft Product, you typically define the visibility and subscribability in the Product document; see [Specifying the visibility of your Product](#), and [Creating a draft Product](#) for details.

Note: After a Product is published, its visibility and subscribability can be changed in the Catalog in the API Manager UI. For more information, see [Changing the availability of a Product](#).

You can define a Catalog or Space setting to control the visibility of all of the Products that are published to that Catalog or Space, as described in the following instructions. When this Catalog or Space setting is enabled, it can be used for the following two purposes:

- The setting can ensure that any Product published to that Catalog or Space, cannot have a visibility setting that exceeds the visibility limit set at the Catalog or Space level.
- The setting can also be used as the default visibility setting for all Products that are published to that Catalog or Space.

When you're publishing a Product, the visibility setting can come from the following four places:

1. Product override; set during the API Manager UI sequence to publish a Product. If this setting is used, it supersedes any visibility setting in the draft Product.
2. Product document; set in the draft Product.
3. Catalog or Space setting. If Product visibility is enabled in the Catalog or Space, and the visibility is not set by a Product override or in the Product document, then the Catalog or Space visibility setting is used as the default setting. This setting can also be used as a limiter, to ensure that any Product that is published cannot exceed the Catalog or Space visibility setting.
4. Default setting. If there are no other visibility settings, then the following default visibility and subscribability settings are used:

```
visibility: {
  view: {
    enabled: true,
    type: 'public',
    orgs: []
  },
  subscribe: {
    enabled: true,
    type: 'authenticated',
    orgs: []
  }
}
```

The following table shows which Product level visibility settings are allowed, if the Catalog level visibility setting is enabled.

Table 1. Relationship between the Catalog level visibility settings, and the Product level visibility settings.

Catalog level visibility setting	Product level visibility setting
Public.	Public, Authenticated, or Custom.
Authenticated.	Authenticated, or Custom.
Custom.	Custom. Note that the Product level visibility organization and group URLs are limited by the Catalog level organization and group URLs.

The following table shows how the Product subscribe setting is limited by the Product visibility level. The basic premise to remember, is that if a Product is to be available for subscription, it must be visible. For example, if you want the subscription audience to be `authenticated`, the visibility audience cannot be `custom`.

Table 2. Relationship between the Product visibility settings, and the Product subscribe settings.

Product visibility level	Product subscribe setting
Public.	Authenticated, or Custom.
Authenticated.	Authenticated, or Custom.
Custom.	Custom. Note that the Product subscribe organization and group URLs are limited by the Product visibility organization and group URLs.

Note:

- Changes to the Catalog visibility setting affects only future Product publishes. There is no change to Products that are already published.
- Any updates to the visibility of a Product are always verified against the Catalog visibility setting, as the Catalog visibility setting sets the maximum visibility level that is allowed. Therefore, if Product visibility is enabled in a Catalog, and the visibility setting of a Product is less restrictive than is set in the Catalog, then the Product publish to that Catalog will fail. For example, if the Catalog visibility setting is **authenticated**, then any Products that are published to that Catalog cannot have a visibility setting of **public**.
- You can also modify the Catalog visibility settings by using the API Connect REST APIs; see the [API Connect REST API documentation](#).

Procedure

- To modify the Catalog or Space visibility settings by using the API Manager UI, complete the following steps.

1. Open the Catalog that you want to work with.
2. Click the Catalog settings tab.
3. Click Product visibility in the side navigation bar.
4. Set the Enable product visibility toggle to On.
5. Select the organization or groups that you want the Products in the Catalog to be visible to.

You can select from the following options:

- Public - Products are visible to all users.
- Authenticated - Products are visible only to users who have successfully authenticated.
- Custom - Products are visible only to the consumer organizations and groups that you specify.

6. Click Save.

- To modify the Catalog or Space visibility settings by using the developer toolkit CLI, complete the following steps.

1. Log in to your API Connect Management server as a member of a provider organization, by using the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

Where:

- `mgmt_endpoint_url` is the platform API endpoint URL.
- `user_id` is the user ID that you want to log in with. The user ID must be a member of a provider organization. This is an ID that you could also use to log in to the API Manager user interface.
- `password` is the password that is associated with the supplied user ID.
- `identity_provider` is the identity provider that is used to authenticate the supplied user ID.

For example:

```
apic login --server platform-api.myserver.com --username myuser --password mypassword --realm provider/myldap
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
- title: API Manager Local User Registry
  realm: provider/default-idp-2
- title: Corporate LDAP user registry
  realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.

For full details on how to log in to your management server from the CLI, see [Logging in to the management server](#).

2. Define your visibility settings by creating a YAML file with the following structure:

```
allowed_product_visibility: {
  view: {
    enabled: true_or_false,
    type: 'visibility_type',
    org_urls: [],
    group_urls: []
  },
  subscribe: {
    enabled: false,
    type: 'authenticated'
  }
}
```

Where, in the `view` section of the `allowed_product_visibility` property:

- `enabled` - can be set to `true` or `false`. The default setting is `false`.
If set to `true` then any Product that is published to that Catalog or Space can have only a visibility that is the same or more restrictive than is configured in the `type` setting. If no visibility is set in the Product document, then the Catalog or Space setting is used as the default for the publish. If you want to always use the Catalog or Space setting as the default, then you must ensure that a Product visibility is not set.
Note: If you are creating draft Products, and no visibility is set, then the value from the `allowed_product_visibility` field in the Sandbox Catalog is used as the default.
If set to `false`, the feature is disabled, and the Product visibility settings that are defined in the Product document are used.

- **type** - if **enabled** is set to **true**, then this property specifies the maximum visibility of the Products that are published to this Catalog or Space. Valid settings are:
 - **public** - Products are visible to all users.
 - **authenticated** - Products are visible only to users who have successfully authenticated.
 - **custom** - Products are visible only to the consumer organizations and groups that are specified in **org_urls** and **group_urls**.
- **org_urls** - if **type** is set to **custom**, then this property specifies the URLs of the consumer organizations that you want the Products to be visible to. Otherwise, leave empty.
- **group_urls** - if **type** is set to **custom**, then this property specifies the URLs of the consumer organization groups that you want the Products to be visible to. Otherwise, leave empty.

The **subscribe** section cannot be edited at the Catalog or Space level. Subscribability is defined in the Product document **subscribe** section, and must be at least as restrictive as **authenticated**. For more information, see [Specifying the visibility of your Product](#).

3. Modify your Catalog settings by using the following command:

```
apic catalog-settings:update --server mgmt_endpoint_url --catalog catalog_name --org organization_name filename
```

Where *filename* is the name of the YAML file that you created in step 2.

Note: If Spaces are enabled for the Catalog, then the visibility settings must be set at the Space level by using the **--space** option.

4. Confirm your updated Catalog settings by using the following command:

```
apic catalog-settings:get --server mgmt_endpoint_url --catalog catalog_name --org organization_name --output -
```

- [Creating and configuring Catalogs](#)

Configuring sub paths for Developer Portal sites

You can increase the specificity of a IBM® API Connect Developer Portal site URL by using sub paths.

By adding additional text to the URL of a Developer Portal site, you can create more site permutations for an organization. Developer Portal site URLs must be unique across all Catalogs.

Important:

- Sub paths are case-sensitive.
- The Developer Portal host name must contain only **lowercase** characters.

You can create a Developer Portal in the following format:

```
https://host_name.portal.com/sub_path_1/sub_path_2/.../sub_path_n
```

Where *sub_path* can be any text that you want to implement to specify your site URL. There is no limit to the number of sub paths that you can have for the first site that you want to create.

However, you must not create overlaps in the naming of your URLs. A URL of one site must not be able to be confused with pages belonging to another site. For example, if you create the following site URL:

```
https://host_name.portal.com/bank/safe/dollar
```

Then, you cannot have the following site URL permutations:

```
https://host_name.portal.com/bank/safe
```

or

```
https://host_name.portal.com/bank/safe/dollar/cent
```

However, you can lengthen or shorten a site URL if you change a single sub path value, or the *host_name.portal.com* value. For example, if you created the following site URL:

```
https://host_name.portal.com/bank/safe/dollar
```

Then, you can create the following site URL permutations:

```
https://host_name.portal.com/bank/euro
```

and

```
https://host_name.portal.com/bank/euro/vault/cent
```

Important: If you already have a site URL that ends in *sub_path* texts, you cannot create a new site URL with the sub path text at the start.

For example, if you create the following site URL:

```
https://host_name.portal.com/bank
```

then, you cannot create the following site URL:

```
https://bank.host_name.portal.com
```

Managing Catalog membership

Manage Catalog membership by adding new users to the Catalog and assigning roles to the users.

Before you begin

To manage Catalog members in the API Manager, you must be assigned to a role that has the Member_>_Manage permission for that Catalog. For more information on assigning Catalog permissions to a role, see [Creating and configuring Catalogs](#).

About this task

The Catalog owner can invite members of the provider organization work with the Catalog in the API Manager. The invited users are called "Catalog members" and are different from consumer users who are members of [consumer organizations](#).

Procedure

1. In the navigation pane of the API Manager UI, click  Manage, then select the Catalog that you want to work with.
2. Click the Members tab.
3. To add an existing user, click Add_>_Add member. To add a new user, click Add_>_Invite member.
If you are using the Add member option, you can add any user who is already a member of another Catalog, or of a Space, in the provider organization, and is neither currently a member of this Catalog, nor the Catalog owner.
4. Enter the email address of a new user, or search for, and select, an existing user.
5. Select the roles that you want to assign to the user.
For details of the roles and the default permissions assigned to them, see [API Connect user roles](#). For details on how to create your own roles, see [Creating custom roles](#).
If Spaces are enabled in the Catalog, any role that you assign to the user at the Catalog level is assigned automatically to the user in all Spaces in that Catalog. Furthermore, if a user had originally been assigned a role only in a specific Space in a Catalog and you subsequently assign the user that role at the Catalog level, the Space specific role assignment is lost and the user now has that role in all Spaces in the catalog.
Note: You can subsequently change the roles assigned to a user by selecting or clearing the appropriate check boxes alongside that user on the Members tab. If a user was originally added to the provider organization, rather than to the Catalog itself, the following conditions apply:
 - Any role assigned to the user at the provider organization level is assigned automatically to the user in all Catalogs, and cannot be removed at the Catalog level.
For details on adding a user to a provider organization, see [Adding provider organization users and assigning roles](#).
 - In the Catalog, the user has the permissions that are configured for the role at the Catalog level.
 - Any role that hasn't been assigned to the user at the provider organization level can be assigned to the user at the Catalog level.
6. If you are adding an existing user, click Add. If you are adding a new user, click Invite.

Importing a user-defined policy into a Catalog

You can make your user-defined policy available to API developers by importing it into an IBM® API Connect Catalog, or a Space in a Catalog.

About this task

For instructions, see [Defining, packaging, and publishing a catalog-scoped policy for the API Gateway](#).

Importing an OpenAPI extension into a Catalog

You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An extension is imported into a Catalog, or a Space in a Catalog, then added to the API schema.

Before you begin

You must possess Catalog edit permissions to complete this task.

About this task

This task describes how to import an OpenAPI extension into a Catalog by using the browser based API Manager user interface. Alternatively, you can use the developer toolkit CLI; see [Working with OpenAPI extensions](#).

For an example of an extension schema file, see [Referring to an extension in an API definition](#).

Procedure

1. In the navigation pane of the API Manager UI, click  Manage, then select the Catalog that you want to work with.
2. If Spaces are enabled in the Catalog, select the Space that you want to work with by completing the following steps:
 - a. Click the Spaces tab.
 - b. Select the Space that you want to work with.
3. Click the Catalog settings tab if you are working in a Catalog, or the Space settings tab if you are working in a Space.
4. Click Gateway services.

5. Alongside the Gateway service that you want to work with, click the options icon  and then click View extensions.
6. Click Upload then upload the extension file as indicated, either by dragging and dropping the file, or by browsing and selecting it. The extension schema file will be either a JSON or YAML file.
7. Click Upload when done.

Results

The user-defined extension is now imported into a Catalog or Space, and can be used when developing an API by using the API editor in either the API Designer or the API Manager user interface.

What to do next

Add the OpenAPI extension to your APIs as required; see [Adding an OpenAPI extension to an API](#).

Retaining Version 5 vanity endpoint behavior in a Catalog

The behavior of vanity endpoints in a Catalog has changed in API Connect Version 10 compared with Version 5. However, you can modify your Catalog settings to retain the Version 5 behavior.

About this task

A vanity endpoint represents the endpoint by which an API is known externally; that is, the endpoint that is published to the Developer Portal and is used by an application developer to invoke the API.

You can modify your Catalog settings to define vanity endpoints that retain the API Connect Version 5 behavior.

You can modify the Catalog settings in either of the following ways:

- [Use the API Manager user interface.](#)
- [Use the developer toolkit CLI.](#)

You can also use the API Connect REST APIs; see the [API Connect REST API documentation](#).

Procedure

- To modify the Catalog settings to retain Version 5 vanity endpoint behavior by using the API Manager user interface, complete the following steps:
 1. Click API Endpoints in the Catalog settings navigation pane. The Vanity API Endpoint page opens.
 2. Click Edit, then select v5 legacy behavior.
 3. To use the API Connect URLs, select Use gateway URLs. To configure a vanity endpoint, select Display vanity endpoint then provide the following information:
 - Endpoint: The URL of your vanity endpoint.
 - Gateway Uri: The URL of the gateway service that is enabled in the Catalog and is associated with the vanity endpoint; select from the list provided.
 - Summary: An optional description of the vanity endpoint.
- To modify the Catalog settings to retain Version 5 vanity endpoint behavior by using the developer toolkit CLI, complete the following steps:
 1. Log in to your API Connect Management server as a member of a provider organization, by using the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.
- *user_id* is the user ID that you want to log in with. The user ID must be a member of a provider organization. This is an ID that you could also use to log in to the API Manager user interface.
- *password* is the password associated with the supplied user ID.
- *identity_provider* is the identity provider that is used to authenticate the supplied user ID.

For example:

```
apic login --server platform-api.myserver.com --username myuser --password mypassword --realm provider/myldap
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
- title: API Manager Local User Registry
  realm: provider/default-idp-2
- title: Corporate LDAP user registry
  realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`. For full details on how to log in to your management server from the CLI, see [Logging in to the management server](#).

2. Define the configuration for your vanity endpoint by creating a YAML file with the following structure:

```

legacy_endpoint_behavior: enabled
v5_endpoint_substitution_behavior:
  base_endpoints:
    - endpoint: vanity_endpoint_url
      description: description
      gateway_service_url: gateway_service_url
unenforced_api_base_endpoint: unenforced_api_base_endpoint

```

where:

- the `legacy_endpoint_behavior: enabled` setting specifies that the Catalog retains API Connect Version 5 behavior. A Catalog can support either Version 5 behavior or Version 10 behavior but not both.
- `vanity_endpoint_url` is the URL of your vanity endpoint.
Note: API Connect Version 5 supports only the host name in a vanity endpoint URL; a URL of the form `https://host_name/path` is not supported. Therefore the vanity endpoint URL that you supply here must contain only a host name; for example, `https://vanity.com`.
- `description` (optional) is a description of your vanity endpoint.
- `gateway_service_url` is the URL of the gateway service that is enabled in the Catalog and is associated with the vanity endpoint.
Note: You can determine the gateway service URL by using the following command:

```

apic configured-gateway-services:list --scope catalog --catalog catalog_name --server mgmt_endpoint_url --org organization_name

```

where:

- `gateway_service_name` is the name of the gateway service.
- `catalog_name` is the name of the Catalog.
- `organization_name` is the name of the provider organization that contains the Catalog.

The command output lists all the gateway services that are enabled in the Catalog, together with their gateway service URLs.

- `unenforced_api_base_endpoint` (optional) is a custom API URL that specifies the URL for APIs that are deployed to a third party gateway.

Note: `base_endpoints:` is an array. You can configure multiple vanity endpoints by defining multiple `endpoint:` entries.

3. Modify your Catalog settings by using the following command:

```

apic catalog-settings:update --server mgmt_endpoint_url --catalog catalog_name --org organization_name filename

```

where `filename` is the name of the YAML file that you created in step 2.

4. Confirm your updated Catalog settings by using the following command:

```

apic catalog-settings:get --server mgmt_endpoint_url --catalog catalog_name --org organization_name --output -

```

Using syndication in API Connect

With the API Connect syndication feature, you can partition your Catalogs into *Spaces*. Each Space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that Space, enabling each team to manage their APIs independently.

When you stage or publish an API to a Catalog that has Spaces enabled, you specify the Space within that Catalog that you want to stage or publish to. However, application developers that access the Developer Portal for the Catalog are unaware of the Space partitioning of the Catalog and see the APIs as a coordinated offering.

Each Space has its own Product lifecycle management, subscription approvals, and analytics data. You use Space specific access control to restrict user access to each Space; for example, a developer in the Flights team is able to stage APIs only to the Flights Space.

Example

A travel company, AcmeAir, has separate API provider development teams for each of the following areas of their business:

- Flights
- Hotels
- Payments
- User Profiles

They have an AcmeAir corporate Catalog, with its associated corporate Developer Portal. They partition their Catalog into separate Spaces, one for each development team.

Spaces are described in detail in the following sections:

- [Enabling Spaces in a Catalog](#)
To use the syndication feature in IBM API Connect, you must enable Spaces in any Catalog in which you require syndication capabilities.
- [Creating, modifying, and deleting Spaces](#)
You use the API Manager user interface to create a new Space in a Catalog, modify the configuration, and owner of a Space, and delete a Space from a Catalog.
- [Working with Spaces](#)
If Spaces are enabled in an IBM API Connect Catalog, you can select a specific Space to work with in the API Manager user interface. This enables you to manage the Products and APIs that are specific to that Space, and control user access to the Space.

Enabling Spaces in a Catalog

To use the syndication feature in IBM® API Connect, you must enable Spaces in any Catalog in which you require syndication capabilities.

Before you begin

If Spaces are enabled for a Catalog, Products (and their associated APIs) can be published only to a Space within that Catalog. For information about publishing, see [Staging a Product](#) for publishing by using the API Designer, and see [Publishing APIs](#) for publishing by using the developer toolkit.

Note: You cannot enable Spaces in a Catalog to which one or more Products have already been staged or published. If the Catalog does contain staged or published Products, first complete the following steps for each Product in the Catalog:

1. Remove all staged Products.
2. Retire, then remove, all published Products.

After enabling Spaces, re-stage or re-publish Products, and re-create application subscriptions, as required.

About this task

By default, Spaces are disabled in a Catalog. You enable Spaces by modifying the Catalog settings. After Spaces are enabled for a Catalog, a default Space is automatically created that inherits all of the configuration settings from the Catalog.

Note: You can also enable Spaces by using the developer toolkit CLI; for details, see [apic spaces](#).

Procedure

To enable Spaces in a Catalog, complete the following steps:

1. In the navigation pane of the API Manager UI, click  Manage, then select the Catalog that you want to work with.
2. Click the Catalog settings tab.
3. Set the Spaces slider control to the On position.
4. In the Enable Spaces window, click Enable.

Results

Spaces are enabled for your Catalog, and a default Space is created that automatically inherits all of the configuration settings from the Catalog. The Catalog owner is also the owner of the default Space.

What to do next

You can modify Space settings, and create more Spaces; see [Creating, modifying, and deleting Spaces](#) and [Working with Spaces](#) for more information.

Creating, modifying, and deleting Spaces

You use the API Manager user interface to create a new Space in a Catalog, modify the configuration, and owner of a Space, and delete a Space from a Catalog.

Before you begin

Navigate to the Spaces page of the Catalog containing the Space you want to work with, by completing the following steps:

1. In the navigation pane of the API Manager UI, click  Manage, then select the Catalog that you want to work with.
2. Click the Spaces tab.

Note: You can also enable Spaces by using the developer toolkit CLI; for details, see [apic spaces](#).

Procedure

- To create a new Space, complete the following steps:
 1. Click Add > Add a new Space.
 2. In the Space Details window, enter the Title of the Space and, optionally, a descriptive summary. A Name is entered automatically.
Note: The value in the Name field is a single string that is used to identify the Space in developer toolkit CLI commands. The Title is used for display. To view the CLI commands to manage Spaces, see [apic spaces](#).
 3. Click Create to create the Space.

Note:

 - As the user who creates the Space, you are automatically the Space owner and have all Space permissions.
 - When you create a new Space, it does not automatically inherit all of the configuration settings from the Catalog. So you should check and modify the settings as necessary.
- To modify the details of a Space, complete the following steps:
 1. On the Spaces page, select the Space whose details you want to modify, then click Space settings.
 2. Use the options in the navigation pane to modify the details as required.
The following types of resource can be enabled in a Space:
 - Gateway services
 - API user registries
 - OAuth providers
 - TLS client profiles

Note:

 - If you enable a resource of any of the following types in one Space in a Catalog, it is deployed to the gateway services across all Spaces in that Catalog:
 - API user registries
 - OAuth providers
 - TLS client profiles
 - If you deploy any of the following types of resource to a gateway in a Space, it is actually deployed to the gateway at Catalog scope:
 - Custom policy
 - Global policy
 - Global policy pre-hook
 - Global policy post-hook
 - Gateway extension
- To change the owner of a Space, complete the following steps:
 1. On the Spaces page, select the Space whose details you want to modify.
 2. Click the Space settings tab to open the Space details page, then click Edit.
 3. From the Select owner user drop-down menu, select the user who will become the new owner.
 4. Click Save when done.

Note:

 - To have permission to change the Space owner, you must be either the Catalog owner, the Space owner, or the owner of the provider organization that contains the Space.
 - When the ownership changes, the new owner is assigned administration privileges for the Space, and the previous owner has their administration privileges removed. If required, you can restore the privileges to the previous owner as described in [Managing Space membership](#).
 - The ownership can be transferred only to a user who is already a member of the Space or Catalog. To transfer to a new user or another existing user, that user must previously have been added or invited to the Space, as described in [Managing Space membership](#), or to the Catalog, as described in [Managing Catalog membership](#).
- To delete a Space, complete the following steps:
 1. On the Spaces page, click the Manage icon  for the Space that you want to delete.
 2. Click Delete, then click Confirm to confirm deletion.

Note:

 - You cannot delete a Space to which one or more Products have been staged or published.
 - If there is only one Space in a Catalog, you cannot delete it, but you can disable Spaces for the Catalog. However, you cannot disable Spaces in a Catalog to which one or more Products have already been staged or published. If any of the Spaces in the Catalog do contain staged or published Products, first complete the following steps for the Products in each of the Spaces:
 1. Remove all staged Products.
 2. Retire, then remove, all published Products.Then, to disable Spaces for the Catalog, complete the following steps:
 1. Click the Catalog settings tab in the Catalog.
 2. Set the Spaces slider control to the Off position.After disabling Spaces, re-stage or re-publish Products, and re-create application subscriptions, as required.

Working with Spaces

If Spaces are enabled in an IBM® API Connect Catalog, you can select a specific Space to work with in the API Manager user interface. This enables you to manage the Products and APIs that are specific to that Space, and control user access to the Space.

Procedure

To work with a Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click  Manage, then select the Catalog that you want to work with.
2. Click the Spaces tab.
3. Select the Space that you want to work with.

What to do next

For details of the Space management tasks, see the following subtopics:

- [Managing Products in a Space](#)
If Spaces are enabled in an IBM API Connect Catalog, you can use the API Manager user interface to separately manage the Products that are staged or published to each Space.
- [Managing subscription requests in a Space](#)
If Spaces are enabled in an IBM API Connect Catalog, you can approve, or deny, individual requests to subscribe to Plans in Products that are published to the Space.
- [Managing application subscriptions in a Space](#)
If Spaces are enabled in an IBM API Connect Catalog, you can use the API Manager user interface to separately manage the application subscriptions to Plans in the Products that are published to a Space.
- [Managing Space membership](#)
If Spaces are enabled in an IBM API Connect Catalog, you can manage the members within the Space. You manage Space membership by adding new users to the Space and assigning roles to the users.
- [Managing user access in a Space](#)
If Spaces are enabled in an IBM API Connect Catalog, you can manage the access that users have within the Space. You manage access by specifying the permissions that are assigned to user roles.
- [Managing Gateways in a Space](#)
If Spaces are enabled in a Catalog, you can separately control which Gateway services are used by each of the Spaces in the IBM API Connect Catalog.

Managing Products in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can use the API Manager user interface to separately manage the Products that are staged or published to each Space.

Before you begin

To manage Products in a Space in the API Manager UI, a user must be assigned a role that has the Products, Manage permission. For more information on assigning Space permissions to a role, see [Managing user access in a Space](#).

Procedure

To manage the Products that are staged or published to a specific Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click  Manage, then select the Catalog that you want to work with.
2. Click the Spaces tab.
3. Select the Space that you want to work with.

What to do next

For details of the management tasks that you can perform on the Products in the Space, see [Working with Products](#).

Managing subscription requests in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can approve, or deny, individual requests to subscribe to Plans in Products that are published to the Space.

Before you begin

To manage Space subscription requests in the API Manager UI, a user must be assigned a role that has the Subscription Approvals, Manage permission. For more information on assigning Space permissions to a role, see [Managing user access in a Space](#).

Procedure

To manage the subscription requests in a Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click  Manage, then select the Catalog that you want to work with.
2. Click the Spaces tab.

3. Select the Space that you want to work with.
4. Click the Tasks tab.
The Tasks page lists only the subscription requests for the selected Space.

What to do next

For details on how to manage approvals, see [Approving Product lifecycle and subscription requests](#).

Managing application subscriptions in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can use the API Manager user interface to separately manage the application subscriptions to Plans in the Products that are published to a Space.

Before you begin

To manage application subscriptions in the API Manager UI, a user must be assigned a role that has the Subscriptions_>Manage permission. For more information on assigning Space permissions to a role, see [Managing user access in a Space](#).

Procedure

1. In the navigation pane of the API Manager UI, click  Manage, then select the Catalog that you want to work with.
2. Click the Spaces tab.
3. Select the Space that you want to work with.
4. In the navigation pane of the API Manager UI, click the Applications tab.
All applications that have been registered in the Developer Portal associated with this Space are listed.
5. Click the options icon  alongside the application you want to work with, then click View Subscriptions.

What to do next

For details of the management tasks that you can perform on application subscriptions in a Space, see [Working with application subscriptions](#).

Managing Space membership

If Spaces are enabled in an IBM® API Connect Catalog, you can manage the members within the Space. You manage Space membership by adding new users to the Space and assigning roles to the users.

Before you begin

To manage Space members in the API Manager UI, a user must be assigned a role that has the Child_>Manage permission for the Catalog that contains the Space. For more information on assigning Space permissions to a role, see [Managing user access in a Space](#).

About this task

Note: You can add the same user to two or more Spaces and assign different roles in each, allowing a user to have differing levels of access in different Spaces.

Procedure

1. In the navigation pane of the API Manager UI, click  Manage, then select the Catalog that you want to work with.
2. Click the Spaces tab.
3. Select the Space that you want to work with.
4. Click the Members tab.
5. To add an existing user, click Add_>Add member. To add a new user, click Add_>Invite member.
If you are using the Add member option, you can add any user who is already a member of another Space, or of a Catalog, in the provider organization, and is neither currently a member of this Space, nor the Space owner.
6. Enter the email address of a new user, or search for, and select, an existing user.
7. Select the roles that you want to assign to the user.
For details of the roles and the default permissions assigned to them, see [API Connect user roles](#). For details on how to create your own roles, see [Creating custom roles](#).

If a user was originally added either to the provider organization, or to the Catalog that contains the Space, rather than to the Space itself, the following conditions apply:

- Any role assigned to the user at the provider organization or Catalog level is assigned automatically to the user in all Spaces, and cannot be removed at the Space level.
For details on adding a user to a provider organization, see [Adding provider organization users and assigning roles](#).
For details on adding a user to a Catalog, see [Managing Catalog membership](#).
- In the Space, the user has the permissions that are configured for the role at the Space level.
For details on configuring role permissions for a Space, see [Managing user access in a Space](#).

- Any role that hasn't been assigned to the user at the provider organization or Catalog level can be assigned at the Space level
- Note: You can subsequently change the roles assigned to a user by selecting or clearing the appropriate check boxes alongside that user on the Members page.
8. If you are adding an existing user, click Add. If you are adding a new user, click Invite.

Managing user access in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can manage the access that users have within the Space. You manage access by specifying the permissions that are assigned to user roles.

Before you begin

To manage Space permissions in the API Manager UI, a user must be assigned a role that has the Child_>_Manage permission for the Catalog that contains the Space. For information on adding users to a Space and assigning user roles, see [Managing Space membership](#).

Procedure

1. In the navigation pane of the API Manager UI, click  Manage, then select the Catalog that you want to work with.
2. Click the Spaces tab.
3. Select the Space that you want to work with.
4. Click the Space settings tab.
5. Click Roles, click the options icon  alongside the role whose permissions you want to modify, then click Edit.
6. Select the required permissions, then click Save.

Managing Gateways in a Space

If Spaces are enabled in a Catalog, you can separately control which Gateway services are used by each of the Spaces in the IBM® API Connect Catalog.

Before you begin

To manage Space Gateway settings in the API Manager UI, a user must be assigned a role that has the Child_>_Manage permission for the Catalog that contains the Space. For information on adding users to a Space and assigning user roles, see [Managing Space membership](#).

About this task

Note: If Spaces are enabled in a Catalog then you configure the Gateway settings for each Space separately, **not** for the Catalog as a whole.

Procedure

To manage the Gateway settings for a Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click  Manage, then select the Catalog that you want to work with.
2. Click the Spaces tab.
3. Select the Space that you want to work with.
4. Click the Space settings tab.
5. Click Gateway services.
The Gateway services that are currently enabled for the Space are listed.
6. To change the Gateway service configuration for the Space, click Edit, then select which Gateway services you want the Space to use.
7. Click Save to save your changes.

Related information

- [Configuring the initial Gateway service](#)

Working with Products

In IBM API Connect, Plans and APIs are grouped together in Products.

Information about managing Products in the API Manager UI can be found in the following topics.

- [The Product lifecycle](#)

When you manage your Product versions, you move them through a series of lifecycle states. From initially staging a Product version to a Catalog, through to publishing to make the Product version available to your application developers, and to eventual retiring and archiving. The syndication feature in IBM API Connect means that Product lifecycle states can also be managed within Spaces in the associated Catalog.

- [Monetizing your Products](#)

In addition to offering free Plans for your customers to use your Products, you can also define Plans that automatically bill your customers who are using your Products in IBM API Connect.

- [Managing your Products](#)

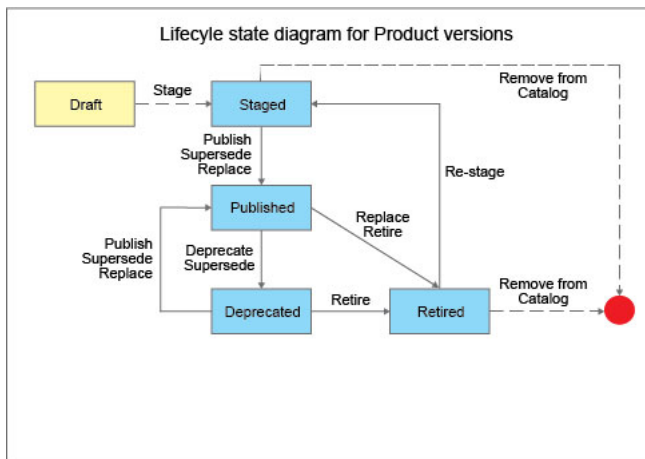

You can manage your Products in API Manager by using the Products page of the associated Catalog. In this view, you can move the Products through their lifecycle and control who can see or subscribe to the Products. The syndication feature in IBM API Connect means that Products can also be managed by using the Products tab of the associated Space.

The Product lifecycle

When you manage your Product versions, you move them through a series of lifecycle states. From initially staging a Product version to a Catalog, through to publishing to make the Product version available to your application developers, and to eventual retiring and archiving. The syndication feature in IBM® API Connect means that Product lifecycle states can also be managed within Spaces in the associated Catalog.

Product lifecycle state diagram

The following diagram shows the possible lifecycle states for a Product version, and the Product management operations that move a Product version from one lifecycle state to another. For example, the Retire operation moves a Product version from the Published to the Retired state.

Note: The same Product lifecycle states apply irrespective of whether your Product is managed within a Catalog, or within a Space in a Catalog. For more information about the syndication feature, see [Using syndication in API Connect](#).

If approval is required for a Product management operation, an approval request is sent and the Product version moves to the pending state. When the request is approved, the operation is completed and the Product version moves to the next lifecycle state. If approval is not required, the operation is completed immediately.

Note: Approval is not required for the following lifecycle state transitions:

- Retired to Staged.
- Deprecated to Published.

For information on configuring Product lifecycle approvals for a Catalog, see [Creating and configuring Catalogs](#). For information on approving requests, see [Approving Product lifecycle and subscription requests](#).

Note:

- Approval for Product lifecycle state changes in a Catalog is disabled by default. You must explicitly enable the Product lifecycle state changes that you want to enforce.
- Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
- You can view the history of Product lifecycle requests and approvals, by clicking the options icon  alongside the Product that you want to work with, and selecting View Approval History.

The following sections describe the various lifecycle states for a Product version.

Note: All references in this topic to a Catalog, can also be applied to a Space in a Catalog, unless specified otherwise.

Draft

The draft state for a Product or API is when a Product or API definition is not deployed and is not associated with any Catalog.

Staged

When you stage a Product, a copy of the Product version is deployed to the target Catalog. Staged is the initial state when you publish a Product. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers. For more information about staging a Product, see [Staging a Product](#).

You stage a Product so that the appropriate approvals, internally within the organization, can be given for it to then be published. For information on configuring Product lifecycle approvals for a Catalog, see [Creating and configuring Catalogs](#). For information on approving requests, see [Approving Product lifecycle and subscription requests](#). For information on publishing a Product, see [Publishing a Product](#).

Published

When you publish a Product, a fixed copy of the Product version is deployed to the target Catalog. The Product version is visible to, and subscribable by, the targeted developers or communities. When a Product is published in a Catalog, the visibility and subscription settings can be changed for the published version of that Product. Any further changes require a new version of the Product to be staged and published before they take effect.

If you replace a Published Product with a Staged or Deprecated Product, the replacement Product is published, and the replaced Product is retired.

If you supersede a Published Product with a Staged or Deprecated Product, the superseding Product is published, and the superseded Product is deprecated.

For more information about publishing a Product, see [Publishing a Product](#).

Note: If you want to update a Product, you must republish it. The `products:update` command only updates a Product's metadata.

Deprecated

When you deprecate a Product, the Product version is visible only to developers whose applications are currently subscribed. No new subscriptions to the Plans in the Product are possible. For more information about deprecating Products, see [Deprecating a Product](#).

A Product is also deprecated if you supersede it with another Product. For more information, see [Superseding a Product with another Product](#).

Retired

When you retire a Product, the Product version can neither be viewed nor can its Plans be subscribed to, and all of the associated APIs are taken offline. For more information about retiring Products, see [Retiring a Product](#).

A Product is also retired if you replace it with another Product. For more information, see [Replacing a Product with another Product](#).

Monetizing your Products

In addition to offering free Plans for your customers to use your Products, you can also define Plans that automatically bill your customers who are using your Products in IBM® API Connect.

API Connect includes a subscription billing feature that allows API providers to define pricing Plans in their API Products, and monetize their API offerings. If a Product contains a pricing Plan, API consumers must enter their payment information into the Developer Portal before they can subscribe to that Plan.

API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product Plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.

You can define both free Plans and paid Plans within the same Product. To charge your customers more for greater access to your APIs, you can create multiple Plans with different tiers of prices and rate-limits. For example, an introductory Plan might have a low monthly price and restrictive rate-limiting, while a higher tier Plan might couple a higher monthly price with less restrictive rate limiting controls. Your customers can then select the Plan that is appropriate for their usage rates. As your customers have different needs for the use of your Products, so you can offer different levels of service. For example, a smaller customer might need a rate of only 5 API calls per hour, whereas a larger company might need a rate of 1000 API calls per hour. You can create the Plans that are appropriate for your customers, and they can subscribe to the service and pricing Plan that is appropriate for them.

Restriction: The following limitations apply to the subscription billing feature:

- Billing and monetization requirements vary by country, where IBM and the independent cloud billing provider, Stripe, cannot guarantee every country requirement is supported. Country requirements change, and are out of scope for this document. Some limitations on storing and passing fields to the Stripe billing provider might exist, when fields are unique to a subset of countries. For example, the passing of a billing address from API Connect to Stripe, which is required by some EU countries due to GDPR and taxation laws, is not currently supported.
- Two data center disaster recovery configurations including the optional billing microservice are not supported at this time.
- After a configured billing resource is in use by a Catalog, it might not be possible to remove it. Do not add your Stripe test keys to production Catalogs. If you want to prototype with your non-production Stripe keys, create a separate temporary Catalog.
- If an API consumer deletes their payment method, or their credit card expires, or their card is out of credit after they have initially subscribed and prepaid for their first month, there is no mechanism to alert the provider organization or suspend API access automatically in response. Provider organizations can monitor their Stripe dashboards for non-payment events and, if necessary, notify the consumer, suspend the application for that subscription, or cancel the API Connect subscription manually. The URL of the API Connect subscription is saved in the metadata of the Stripe subscription object, to assist in reverse lookups.
- Suspending an application does not automatically pause the billing cycles of the subscriptions for that application.
- You can republish a Product that includes billing only when the Catalog Production mode is set to On.

Though much of the procedure is the same for setting up a paid Plan and a free Plan, there are some extra actions that are needed before you can start defining paid Plans. See the following topics for more information:

1. First, you must configure a billing integration resource for your provider organization; see [Adding a billing integration resource](#).
2. Before you can publish a Product Plan with pricing to a Catalog, you must add your billing integration resource to that Catalog; see [Adding a billing integration resource to a Catalog](#).
3. Also before you can publish to a Catalog, an administrator must enable the Stripe payment method module in the Developer Portal for that Catalog; see [Configuring Stripe in the Developer Portal](#).
4. After the Catalog and Developer Portal are configured, you can create Products that include pricing Plans; see [Defining a Product with billing integration](#).

Note:

- Before you can create billing resources in provider organizations, the billing microservice must be enabled on your management system by your system administrator. See [Configuring monetization on VMware](#) and [Configuring monetization on Kubernetes](#) for more information.
- You can also create and manage billing integration resources by using the developer toolkit CLI. For more information, see [Command-line tool reference for the developer toolkit](#).

Adding a billing integration resource

To enable the monetization of your Product Plans, you must add a billing integration resource in your IBM® API Connect provider organization that defines the configuration data needed to synchronize with an external subscription billing system.

Before you begin

To use Stripe as your credit card processing vendor, you must have port 443 open to HTTPS communication between the Stripe API and your Developer Portal management and the Management cluster servers. See [Firewall requirements on Kubernetes](#) and [Firewall requirements on VMware](#) for more information about this requirement.

Before you can create billing resources in provider organizations, the billing microservice must be enabled on your management system by your system administrator. See [Configuring monetization on VMware](#) and [Configuring monetization on Kubernetes](#) for more information.

You must either be the provider organization owner, or have `Settings: Manage` permissions, to complete this task.

You must have an account with Stripe to be able to complete this task. If you do not already have a Stripe account, you can set one up at: www.stripe.com.

About this task

API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product Plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system. When API consumers subscribe to Product Plans with billing in the Developer Portal, they set up automatic payments through a credit card registered with Stripe. To enable this billing process, you must first specify your Stripe account information by creating a billing integration resource. The subscription payment amount is processed from the account that is provided by the API consumer, and credited to the account that you provide as the API provider.

Important: Each Stripe account comes with two sets of API keys, one for testing, and one for production. Each set of API keys has a distinct namespace for Stripe objects. Test API keys cannot see objects created by production API keys, and vice versa. You cannot switch the API keys of one of your billing integrations with the keys from another account, or swap your test and production keys over, as that would prevent API Connect from resolving the Stripe objects that were created by using the old keys. If you want to use your Stripe test keys, you must create a separate Catalog for testing, and not add your Stripe test keys to production Catalogs.

Procedure

To create a billing integration resource, complete the following steps:

1. In the API Manager, click  Resources.
2. Ensure that you are in the provider organization to which you want to add the billing integration.
3. Select Billing, and then click Add.
The Add billing integration page for Stripe integration is displayed.
4. Enter a Title for your billing integration.
5. The Name is auto-generated based on the Title that you enter, and is a single string that can be used in developer toolkit CLI commands.
6. Enter the Publishable key and Secret key for your Stripe account.
Refer to your Stripe dashboard to get your publishable key and secret key; see <https://dashboard.stripe.com/apikeys>.
7. Click Add to create your billing integration resource.

Results

Your new billing integration resource is listed in the table on the Billing dashboard. The table also displays the state of the job queue for the billing integration. Any issues with the job queue are displayed in this table. See [Billing integration resource job queues](#) for more information.

What to do next

To be able to publish monetized Product Plans, you must add the billing integration resource to your Catalog, and to the Sandbox Catalog. See [Adding a billing integration resource to a Catalog](#) for details.

Billing integration resource job queues

Billing integration resources use job queues to manage the bulk Product lifecycle operations in IBM® API Connect.

Subscription billing systems such as Stripe, typically provide APIs that support updating a single resource at a time. However, IBM API Connect has Product lifecycle operations that can modify many resources in a single transaction, such as migrating a set of subscriptions from one Product to another Product. In order to bridge the mismatch between these two APIs, API Connect adds a job queue to each billing integration resource in your provider organization. Jobs on this queue are responsible for mapping bulk operations to a series of API calls against the subscription billing system. Jobs run one at a time, in the order that they were created. When a job completes it's deleted from the queue, and the next job runs. When all of the jobs in the queue complete running and the queue is empty, the data model of the subscription billing system should be up-to-date with the changes made in API Connect.

There are potential issues when moving this type of synchronization to background jobs. Network connectivity, outages at the billing provider, or rolling of the API keys of the billing system, could all cause the job queue to be blocked if the root issue does not resolve by itself in the span of an hour. If a job encounters an error, such as a network connectivity error, the job is retried up to five times over the course of 70 minutes, before changing the state of the job from Running to either Blocked or Failed. Only when the state of the head job is blocked or failed, will the Retry Blocked Jobs action appear in the options menu. So if an error is shown but the job is still attempting to run, you need to wait up to 70 minutes before the Retry Blocked Jobs action appears.

The job queue status can be viewed in the table on the Billing dashboard. The table lists any blocked jobs, and the error that is blocking them. If the error indicates that your API keys are no longer valid, you must update your billing resource to contain the correct values. After the root cause is resolved, you can click the  options menu on the row of the billing integration resource, and click Retry Blocked Jobs. This action retries the jobs on the job queue. After a few minutes the number of jobs should go down. Note that you can click the Refresh icon  to refresh the results from the server.

- [Monetizing your Products](#)

Adding a billing integration resource to a Catalog

To be able to publish monetized Product Plans, you must add a billing integration resource to your Catalogs.

Before you begin

You must have created a billing integration resource. See [Adding a billing integration resource](#) for details.

You must either be the provider organization owner, or have `Settings: Manage permissions`, to complete this task.

About this task

Before you can publish any Products that include pricing Plans, you must add the billing integration resource to the Catalog where you will create the monetized Products. When API consumers subscribe to Product Plans with billing in the Developer Portal, they set up automatic payments through a credit card registered with Stripe. To enable this billing process, after you have specified your Stripe account in a billing integration resource, you must then apply that resource to your Catalogs. The subscription payment amount is processed from the account that is provided by the API consumer, and credited to the account that is provided in the billing integration resource.

Note:

- Before you can publish a monetized Product Plan to a Catalog, the Stripe payment method module in the Developer Portal must also be enabled; see [Configuring Stripe in the Developer Portal](#).
- Each Stripe account comes with two sets of API keys, one for testing, and one for production. Each set of API keys has a distinct namespace for Stripe objects. Test API keys cannot see objects created by production API keys, and vice versa. You cannot switch the API keys of one of your billing integrations with the keys from another account, or swap your test and production keys over, as that would prevent API Connect from resolving the Stripe objects that were created by using the old keys. If you want to use your Stripe test keys, you must create a separate Catalog for testing, and not add your Stripe test keys to production Catalogs.

Procedure

To add a billing integration resource to a Catalog, complete the following steps:

1. In the API Manager, click  Manage.
2. Select the Catalog tile on the Manage page that you want to update, then click the Catalog settings tab.
3. Select Billing, and then click Edit.
4. Select the billing integration resource that you want to apply to the Catalog, and click Save. You should apply only one billing integration resource to each production Catalog.
The billing integration resource is now listed in the Billing section.

Results

The billing integration resource is added to the Catalog.

What to do next

The Stripe payment method module must be enabled in the Developer Portal for that Catalog; see [Configuring Stripe in the Developer Portal](#) for details.

After both the Catalog and the Developer Portal are configured, you can create Products with pricing Plans. See [Defining a Product with billing integration](#) for more information.

Defining a Product with billing integration

To monetize your APIs, you must create Product Plans with pricing information that allow API consumers to subscribe to your Plans with integrated billing.

Before you begin

You must have a billing integration resource, and this resource must be added to the Catalog that you want to publish your Product to, as well as to the Sandbox Catalog. See [Adding a billing integration resource](#), and [Adding a billing integration resource to a Catalog](#) for details.
