$ oc get cm -n apic -l vendor=crunchydata
```

NAME	DATA	AGE
production-mgmt-mymgmtsite123-postgres-config	0	2d21h
production-mgmt-mymgmtsite123-postgres-leader	0	2d21h
production-mgmt-mymgmtsite123-postgres-pgbouncer-cm	2	2d21h
production-mgmt-mymgmtsite123-postgres-pgha-config	5	2d21h

Procedure

For each type of postgres resource, check to see if any resources are available and if so, delete the resources:

- pods:

```
oc get pods -n <APIC_namespace> -l vendor=crunchydata
oc delete pods -n <APIC_namespace> -l vendor=crunchydata
```

- deployments:

```
oc get deployments -n <APIC_namespace> -l vendor=crunchydata
oc delete deployments -n <APIC_namespace> -l vendor=crunchydata
```

- Jobs:

```
oc get jobs -n <APIC_namespace> -l vendor=crunchydata
oc delete jobs -n <APIC_namespace> -l vendor=crunchydata
```

- roles:

```
oc get roles -n <APIC_namespace> -l vendor=crunchydata
oc delete roles -n <APIC_namespace> -l vendor=crunchydata
```

- rolebindings:

```
oc get rolebindings -n <APIC_namespace> -l vendor=crunchydata
oc delete rolebindings -n <APIC_namespace> -l vendor=crunchydata
```

- secrets:

```
oc get secrets -n <APIC_namespace> -l vendor=crunchydata
oc delete secrets -n <APIC_namespace> -l vendor=crunchydata
```

- cm:

```
oc get cm -n <APIC_namespace> -l vendor=crunchydata
oc delete cm -n <APIC_namespace> -l vendor=crunchydata
```

- pgtasks

```
oc get pgtasks.crunchydata.com -n <APIC_namespace> -l vendor=crunchydata
oc delete pgtasks.crunchydata.com -n <APIC_namespace>
```

- pgreplica:

```
oc get pgreplica -n <APIC_namespace> -l vendor=crunchydata
oc delete pgreplica -n <APIC_namespace> -l vendor=crunchydata
```

VMware

Use the instructions in this section to install, upgrade, and maintain API Connect on VMware.

Attention:

Although API Connect 10.0.5.0 is not supported to run on VMware, support for VMware is available from API Connect 10.0.5.1 and later.

- [Planning your deployment](#)
Before you install API Connect, understand deployment options and requirements for endpoints, load balancing, certificates, and firewalls.
- [Installing API Connect](#)
Use these instructions to install or upgrade a deployment of API Connect on VMware.
- [Upgrading API Connect](#)
Upgrade API Connect on VMware to a newer version.
- [Maintaining API Connect](#)
You can use utilities to complete maintenance tasks such as backup, restore, and certificate management in a VMware environment.

Planning your deployment

Before you install API Connect, understand deployment options and requirements for endpoints, load balancing, certificates, and firewalls.

- [Deployment overview for endpoints](#)
When deploying API Connect, you will create one or more endpoints for the subsystems and then configure certificates or mutual TLS for most endpoints.
- [Planning your deployment topology and profiles](#)
When you install on VMware, API Connect provides a choice of deployment configurations for capacity and high availability (HA). These configurations are named 'deployment profiles' and there are several pre-defined profiles to choose from.
- [Enable JWT instead of mTLS](#)
Use JWT to authenticate communication between API Connect subsystems, instead of mTLS.
- [Firewall requirements on VMware](#)
Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on VMware.
- [Load balancer configuration in a VMware deployment](#)
When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect OVA deployment.
- [A two data center deployment strategy on VMware](#)
An overview of the two data center disaster recovery deployment strategy in API Connect.
- [Planning your Analytics deployment](#)
Plan your IBM API Connect Analytics deployment by reviewing options for topology, data modifications, and storage.
- [API Connect TLS certificate best practices](#)
Best practices for configuring and managing TLS certificates in an API Connect deployment on VMware.

Deployment overview for endpoints

When deploying API Connect, you will create one or more endpoints for the subsystems and then configure certificates or mutual TLS for most endpoints.

Configuring endpoints

Subsystem	Endpoints	Description	Certificates	
Management	cloud-admin-ui	Configured using APICUP installer. Endpoint on the management server for communication with the Cloud Manager user interface.	cloud-admin-ui	
	api-manager-ui	Configured using APICUP installer. API Manager URL endpoint on the management server for communication with the API Manager user interface.	api-manager-ui	
	consumer-api	Configured using APICUP installer. Platform REST API endpoint for running consumer APIs on the management server.	consumer-api	
	platform-api	Configured using APICUP installer. Platform REST API endpoint for running admin and provider APIs on the management server.	platform-api	
	hub	Automated Testing Behavior UI and API endpoint. External Frontend/Ingress, port 443	hub-endpoint	
	turnstile	Automated Testing Behavior UI and API endpoint. External Frontend/Ingress, port 443	turnstile-endpoint	
Portal	portal-admin	Configured using APICUP installer. Corresponds to Management Endpoint entered in Cloud Manager. Requires a TLS profile configured with mutual TLS.	mutual TLS	
	portal-www	Configured using APICUP installer. Portal Web site URL entered in Cloud Manager. Used publicly to access Portal.	portal-www-ingress	
Analytics	analytics-client	This is a legacy certificate, it is not used from v10.0.5 onwards.	mutual TLS	
	analytics-ingestion	Configured using APICUP installer. The analytics-ingestion endpoint must be entered in the Cloud Manager UI when registering the analytics service. It is also used by the Gateway service to push data to the Analytics service. Requires a TLS profile configured with mutual TLS.	mutual TLS	
Gateway	apic-gw-service	Configured using APICUP installer. This is the endpoint the gateway uses for network communication. Enter this endpoint as the Management Endpoint entered in Cloud Manager.	apic-gw-service-ingress	
	api-gateway	Configured using APICUP installer. This is the endpoint the gateway uses for API traffic. Enter this endpoint as the API Invocation Endpoint in Cloud Manager.	api-gateway-ingress	

The endpoints are configured by the installation Operator. They are set for each subsystem. Endpoints are also entered when configuring the Topology for the Gateway, Portal, and Analytics subsystems in Cloud Manager.

For instructions on configuring endpoints and installing into an OVA environment, see [Installing API Connect](#).

Configuring certificates

All TLS certificates are automatically generated, but you can customize your user-facing certificates, see [API Connect TLS certificate best practices](#).

Configuring mutual TLS

Mutual TLS is configured for TLS profiles in Cloud Manager. See [Creating a TLS Server Profile](#).

Configuring a proxy

If a Developer Portal is deployed externally to the management server zone, it does not have access to the consumer and product APIs. You need to configure a proxy to enable communication. For more information, see [Configuring a proxy](#).

Planning your deployment topology and profiles

When you install on VMware, API Connect provides a choice of deployment configurations for capacity and high availability (HA). These configurations are named 'deployment profiles' and there are several pre-defined profiles to choose from.

High availability versus disaster recovery

High availability focuses on minimizing the loss of service that is experienced by users during a hardware or software failure. Disaster recovery (DR) focuses on the procedures for recovering a system after a catastrophic hardware, software, or operator failure. Consider the following two metrics:

Recovery Time Objective (RTO)

The RTO is the time that it is acceptable for a system to be unavailable after a disaster.

Recovery Point Objective (RPO)

DR solutions are usually based on restoring from a backup. This means that the system can only be recovered to the state it was in when the last backup was taken, and not to the state it was in at the instant the disaster occurred. The RPO measures how far back in time the recovery point is, and therefore how much new data is lost. An RPO of zero would assert that no data is lost, but such a solution is often a compromise against the cost and performance of the system.

To achieve high availability in your API Connect VMware deployment, the three replica deployment profiles should be used, where each API Connect component is distributed across three virtual machines (VMs). However, this topology requires a low network latency between the VMs that is often unachievable between geographically separated data centers. To overcome this limitation, API Connect provides a two data center deployment solution that has both a low Recovery Time Objective (RTO), and a low Recovery Point Objective (RPO).

Deployment options

API Connect is composed of three components: Management, Portal, and Analytics, and the DataPower Gateway supporting program, see [API Connect components](#). Each of these components includes a set of deployment profiles to cover different capacity and availability requirements.

Note: Throughout this document, the Management, Portal, and Analytics components, and the Gateway supporting program are also referred to as "subsystems".

The naming convention of the deployment profiles is **nAxcb.mC** where:

- **nA** indicates the number (A) of VMs (nodes) that are deployed to support the profile. The term "node" is used to refer to a VM instance (n1 means one node, n3 means three nodes).
- **cB** indicates the minimum number of virtual cores (B) required on the VM to deploy the profile.
- **mC** indicates the minimum amount of memory (C) in GB required by the profile on the VM.

API Connect components have two profile types: one replica and three replica:

- The one replica profile is a single node profile and is also known as the **n1** profile. It consists of a single VM for each component. This deployment type is recommended for development or testing where high availability is not a requirement.
- The three replica profiles consist of a cluster of three VMs for each component. This profile is also referred to as the **n3** profile. Each VM runs a replica of the component's microservices, and if a VM fails, the replicas on the other two VMs continue serving requests.

The available profiles for the Management, Portal, and Analytics components are:

- **Management**
n1xc4.m16, n3xc4.m16.
- **Portal**
n1xc2.m8, n1xc4.m16, n1xc8.m16, n3xc3.m8, n3xc4.m8, n3xc8.m16.
- **Analytics**
n1xc2.m16, n1xc4.m32, n1xc6.m48, n3xc4.m16, n3xc4.m32, n3xc6.m48, n3xc8.m64.

For information about gateway CPU and memory, refer to *Deploying the OVA on a VMware hypervisor* in the appropriate version of the [DataPower documentation](#).

Additional points:

- Deployment profiles do not have to be the same for each component. For example, you can have a three replica deployment of the Management component that is configured with a one replica deployment of the Portal component.
- It is possible to change the deployment profile of an existing installation, but all endpoints in your deployment must remain the same. This means that you should use a load-balancer or logical DNS records when you do the initial one replica deployment. For example, if you installed a one replica deployment and used the portal VM hostname as the portal management registration endpoint, this endpoint cannot change when you move it to a three replica deployment. For more information, see [Changing deployment profiles on VMware](#). If you want to change the deployment profile and the endpoints, you can use the form factor migration procedure: [Migrating from v10 to v10 on a different form factor](#).
- Multiple Portal, Analytics, and Gateway component instances can be added with either configuration. For example, you can have a one replica Management component that is configured with two Portal services: a three replica Portal component, and a one replica Portal component.

Two data center disaster recovery

API Connect deployments can operate across two data centers in an active/warm-standby configuration. Each data center has a complete API Connect installation. The active data center processes all user operations. The warm-standby data center does not process user operations but maintains its management and portal component databases in synchronization with the active data center. If a failure occurs at the active data center, the warm-standby data center can become active with a manual failover operation. For more information on the two data center disaster recovery configuration, see: [A two data center deployment strategy on VMware](#).

Enable JWT instead of mTLS

Use JWT to authenticate communication between API Connect subsystems, instead of mTLS.

If your network infrastructure requires that load-balancers implement TLS termination, then mTLS between API Connect subsystems can be disabled and JSON Web Token (JWT) security can be used instead.

Note: Although mTLS is disabled, the network communication is still secured with standard TLS, which does not require passthrough to be enabled on the load-balancers. The following communication flows can be secured with JWT:

- Management initiated communication to portal, analytics, and gateway subsystems. From v10.0.5.3 and later.
- Analytics ingestion: The flow of API event records from the gateway to the analytics subsystem. From v10.0.5.4 and later.
Note: If the gateway is under a high transaction load and sending many API events to the analytics subsystem, the enablement of JWT might impact the performance of your analytics subsystem. It is recommended to run performance tests under your expected analytics load before you decide to use JWT for the analytics ingestion path.

With JWT enabled, the portal, gateway, and analytics subsystems verify the JSON Web Token (JWT) sent from the management subsystem when it initiates communication with them. The analytics subsystem verifies the JWT sent from the gateway with incoming API event data. The subsystems that receive the token contact a JSON Web Key Set (JWKS) URL to verify it. The JWKS URL is hosted by the management subsystem, in a subpath of the management subsystem's platform REST API.

You can configure JWT instead of mTLS during installation, as documented in [Installing API Connect](#), or you can configure JWT after installation: [Use JWT security instead of mTLS between subsystems](#).

If you disable mTLS, you must enable JWT. It is not possible to configure API Connect with both mTLS and JWT disabled.

Firewall requirements on VMware

Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on VMware.

Required Ports between zones

The following network diagram example helps to explain which ports must be configured in an API Connect network. Specific ports must be configured to enable the communication between the various zones, both public and private, in a network.

The ports specified in the diagram are default ports. Check your deployment to understand which communication, if any, is configured to use non-default ports.

Table 1. Key for the network diagram example.
The following table lists the port numbers with a usage description.

	Usage description	Default port number
1	API request/response – Users invoking the provided APIs.	443 HTTPS from Public zone to Gateway zone
2	DataPower® administration – Internal operators who are managing the Gateway servers.	22 SSH, 9090 HTTPS from Protected zone to Gateway zone
3	API Manager – Internal business users who are defining and monitoring APIs.	443 HTTPS from Protected zone to Management zone
4	Cloud Manager – Internal operators who are administering the Cloud.	22 SSH, 443 HTTPS from Protected zone to Management zone
5	Developer Portal administration – Internal operators who are managing the Portal servers.	22 SSH, 443 HTTPS from Protected zone to Management zone
6	Gateway servers post traffic to Analytics service.	443 HTTPS from Gateway servers to Analytics service
7	Push configuration – Management servers communicate bi-directionally with Gateway servers.	3000 and 443 HTTPS Management servers to and from Gateway servers for webhook delivery. Port 3000 is the default port for apic-gw-service, and this is the port Management uses to communicate with Gateway. Port 443 is the default port for the platform-api endpoint, which apic-gw-service uses to communicate with Management.
8	Push configuration/webhooks – Management servers push configuration and webhooks to the Developer Portal.	443 HTTPS Management servers to Developer Portal servers for webhook delivery
9	Pull configuration/make API calls – Developer Portal servers pull configuration and call REST APIs.	443 HTTPS from Developer Portal servers to Management servers within Management zone
10	Developer Portal – External developers who are accessing the Developer Portal.	443 HTTPS from Public zone to Developer Portal management zone. The reverse proxy/DataPower WAF for incoming web traffic to the Developer Portal cluster must be a transparent proxy - no modification of the portal URL, port, host name or path is allowed.
11	Push API definition to Management server. Pick up credential for microservice code push.	443 HTTPS from Protected zone to Management zone

	Usage description	Default port number
12	Analytics offload	Port will depend on type of plugin and protocol used for the offload. Some possible protocols are: HTTP, HTTPS, TCP, UDP, KAFKA
13	Analytics accesses NTP	Standard NTP
14	Analytics access DNS	Standard DNS
15	Management service queries Analytics service	443 HTTPS within Management zone
16	The Portal service invokes an API (GET) on the Analytics service to retrieve data.	443 HTTPS within Management zone
17	External billing service – Management cluster connecting to external billing service (when configured for billing). If you are using Stripe as your external billing service, you must enable connections with the Stripe API at: https://stripe.com/files/jps/jps_api.json . You can also view the Stripe IP addresses at the following URL: https://stripe.com/docs/jps .	443 HTTPS from Management zone to Public zone
18	Developer Portal cluster must be able to access its own site endpoints.	443 HTTPS from Portal zone to Public zone

Firewall port requirements on VMware

The following tables lists ports that must be open in both cluster and non-clustered deployments.

Note that clustered VMware environment deployments require additional ports. See [Firewall enabled ports for clustered OVA deployments](#)

Table 2. Firewall port requirements common to all subsystems

Subsystem	Ports and description
Ports that must be open on all API Connect subsystems	<p>The following ports must be open on the Management Server, Analytics, and Developer Portal subsystems, whether in a cluster or not.</p> <ul style="list-style-type: none"> • 53 (outbound) DNS • 123 (outbound) NTP • 179 (inbound and outbound) BIRD routing daemon - VMware environments (OVA) deployments. Used for communication over TCP between servers either within the same subsystem or across different subsystems. • 443 (inbound and outbound) Used by all subsystems for communication with other subsystems • 2020 (inbound) status request. Used for communication over TCP between servers within the same subsystem. • 9177 (inbound and outbound) Member list (group membership) for API Connect <code>apic</code> daemon communication. Used for communication over both TCP and UDP, between servers within the same subsystem. • 9178 (inbound and outbound) API server, for API Connect <code>apic</code> daemon communication. Used for communication over TCP from between servers, both within the same subsystem and across different subsystems. Also used for communication between the <code>apicup</code> configuration utility and servers (this is the only port used by <code>apicup</code>).

Each subsystem uses ports in addition to the ports in [Table 2](#). See the following table.

Table 3. Additional firewall port requirements for each subsystem

Subsystem	Ports and description
Management Service	<p>Management Service uses the ports in Table 2 plus:</p> <ul style="list-style-type: none"> • 22 remote backup server port (inbound, configurable) If backups are configured to use another port, ensure that the port is open. See Backing up the management subsystem in VMware environments. <p>Note: this port does not have to be open between the management server and the portal server.</p> <ul style="list-style-type: none"> • SMTP server port (outbound), typically 25 • 161 (inbound) SNMP. Over UDP. • LDAP server port (if using LDAP user registry), typically 389 (outbound) • In a clustered deployment, the Management Services uses additional ports. See Firewall enabled ports for clustered OVA deployments. <p>The Automated test behavior application must be able to invoke (outbound) any port that a test system might present an API on. It can be bound to a particular port (if it is the same in all environments) or to a range of ports (to cover all of the ports it might invoke).</p>
Developer Portal	<p>The Developer Portal uses the ports listed in Table 2, plus:</p> <ul style="list-style-type: none"> • 22 - A remote backup server port (inbound, configurable) If backups are configured to use another port, ensure that the port is open. See Backing up and restoring the Developer Portal in a Kubernetes environment. <p>Note: this port does not have to be open between the management server and the portal server.</p> <ul style="list-style-type: none"> • In a clustered deployment, the Developer Portal uses additional ports. See Firewall enabled ports for clustered OVA deployments.
Analytics	<p>The Analytics subsystem uses the ports listed in Table 2, plus:</p> <ul style="list-style-type: none"> • 161 for SNMP is required for both non-clustered and clustered deployments. UDP, inbound only. • In a non-clustered deployment, no additional ports are required. • Analytics supports an optional configuration for offload of data. This configuration might require additional outbound ports to be open. • In a clustered deployment, the Analytics subsystem uses additional ports. See Firewall enabled ports for clustered OVA deployments.

Subsystem	Ports and description
Gateway Server	<p>The Gateway Server uses these ports in both non-clustered and clustered deployments:</p> <ul style="list-style-type: none"> • 161 (inbound) SNMP. UDP protocol. Not needed if SNMP not enabled. • 162 (outbound) SNMP traps • 3000 (inbound) Gateway Service local port (configurable) • 5550 (inbound) XML management port (configurable) • 5554 (inbound) REST management port (if enabled; configurable) • 9022 (inbound) Gateway SSH (if enabled; configurable) • 9090 (inbound) Web GUI console (if enabled; configurable) • 9443 (inbound) Gateway local port (configurable) • In a clustered deployment, the Gateway Server uses additional ports. See Firewall enabled ports for clustered OVA deployments.

Communications inside the Gateway cluster

There are a number of important points to note regarding the communications within the Gateway cluster.

- We advise that you use the same port for all Gateway servers within a cluster.
- Gateway servers communicate with each other to synchronize invocation counts.
- All Gateway servers in a Gateway cluster must be able to reach all of the other Gateway servers in the same Gateway cluster.
- Gateway servers in a Gateway cluster do not directly communicate with Gateway servers in a different Gateway cluster.
- All Gateway servers must be able to reach the management subsystem platform API endpoint, which was configured during the installation of your API Connect environment.

Ethernet interface usage

To separate network traffic, you can use two or more Ethernet interfaces on the DataPower appliance on which a Gateway server is installed. For example, you can use one interface for internal IBM API Connect communications, and another for processing incoming API calls.

Port requirement for Stripe billing service

All Management servers and Developer Portal servers must be able to communicate HTTPS content with the external billing service when billing is configured. If you are using Stripe as your external billing service, you must enable HTTPS communication on port 443 with the Stripe API: https://stripe.com/files/ips/ips_api.json. Note: API Connect does not support using webhooks with Stripe. You can see a list of the Stripe IP addresses at: <https://stripe.com/docs/ips>.

- [Firewall enabled ports for clustered OVA deployments](#)
In a clustered OVA deployment of API Connect, specific ports must be configured for communication between members of each API Connect subsystem.
- [Load balancer ports for clustered OVA deployments](#)
When you deploy a load balancer with a clustered deployment, in a VMware environment, you must ensure that the necessary ports are open.

Related concepts

- [Load balancer ports for clustered OVA deployments](#)

Firewall enabled ports for clustered OVA deployments

In a clustered OVA deployment of API Connect, specific ports must be configured for communication between members of each API Connect subsystem.

OVA deployments require the common ports that are listed in [Firewall requirements on Kubernetes](#). When the VMs are clustered, additional ports are used for communication between the members of the subsystems in the cluster.

All ports must be enabled inbound and outbound.

Table 1. Firewall enabled ports for clustered VMware environment deployments

Subsystem	Ports
Ports that must be open between all subsystem VMs	<p>442, 2379, 2380, 6443, 6444, 9099, 10248, 10249, 10250, 10251, 10252, 10254, 10256, 10257, 10259</p> <p>These ports must be open between all servers within a given subsystem. For example, from management server to management server, or from portal server to portal server, or from analytics server to analytics server. These ports are not used for communication between subsystems.</p> <p>You might need additional ports for Kubernetes-proxied services. The default range is 30000 - 32767. Since the ports in use can change dynamically, ensure that the default range is open.</p>
Additional ports that must be open between Management Service VMs	Port 8088 is required if the Automated testing behavior application is deployed for the Management Service VMs.
Additional ports that must be open between Developer Portal VMs	3009, 3010, 3306, 3307, 4443, 4444, 4567, 4568, 30865
Additional ports that must be open between Gateway Service VMs	16380, 16381, 26380, 26381
Additional ports that must be open between Analytics VMs	No additional ports are needed.

These internal ports are not used for communication between VMs. Ensure that they are open on the VM server locally.

Table 2. Internal ports reserved by API Connect

Subsystem	Ports
Reserved local ports on all subsystem VMs	8383, 8686, 8080, 8443, 30000:59999
Management Service VMs	2000, 2001, 2002, 2005, 2006, 2007, 2008, 2022, 3003, 3004, 3006, 3007, 3011, 3023, 4150, 4151, 4171, 4222, 5432, 6222, 7777, 8084, 8222, 8404
Portal Service VMs	3058, 3059, 3060, 3061
Analytics VMs	4443, 5000, 5601, 9200, 9300

Note: The ports should support IP-in-IP (protocol 4), per <https://docs.projectcalico.org/getting-started/kubernetes/requirements>.

Load balancer ports for clustered OVA deployments

When you deploy a load balancer with a clustered deployment, in a VMware environment, you must ensure that the necessary ports are open.

The load balancer needs port 443 for all API Connect subsystems (Management, Analytics, Developer Portal, DataPower Gateway).

Load balancer configuration in a VMware deployment

When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect OVA deployment.

Before you begin

Note:

- This article does not apply to the IBM® DataPower® Gateway component that is a part of the IBM API Connect solution.
- This article applies to third-party software that IBM does not control. As such, the software may change and this information may become outdated.

About this task

API Connect can be deployed on a single node cluster. In this case the ingress endpoints are host names for which the DNS resolution points to the single IP address of the corresponding node hosting a particular subsystem, and no load balancer is required. For high availability, it is recommended to have at least a three node cluster. With three nodes, the ingress endpoints cannot resolve to a single IP address. A load balancer should be placed in front of an API Connect subsystem to route traffic.

Because it is difficult to add nodes once endpoints are configured, a good practice is to configure a load balancer even for single node deployments. With the load balancer in place, you can easily add nodes when needed. Add the node to the list of servers pointed to by the load balancer to avoid changing the ingress endpoints defined during the installation of API Connect.

To support Mutual TLS communication between the API Connect subsystems, configure the load balancer with **SSL Passthrough** and **Layer 4** load balancing. In order for Mutual TLS to be performed directly by the API Connect subsystems, the load balancer should leave the packets unmodified, as is accomplished by Layer 4. Following is a description of the communication between the endpoints that are configured with Mutual TLS:

- API Manager (with the client certificate portal-client) communicates with the Portal Admin endpoint portal-admin (with the server certificate portal-admin-ingress)
- API Manager (with the client certificate analytics-ingestion-client) communicates with the Analytics Ingestion endpoint analytics-ingestion (with the server certificate analytics-ingestion-ingress)

Note: From v10.0.5.3, it is possible to disable mTLS and use JWT instead, which allows the load-balancers to do TLS termination. For more information, see [Enable JWT instead of mTLS](#).

Set endpoints to resolve to the load balancer

When configuring a load balancer in front of the API Connect subsystems, the ingress endpoints are set to host names that resolve to a load balancer, rather than to the host name of any specific node. For an overview of endpoints, see [Deployment overview for endpoints and certificates](#).

Use this example configuration as a guideline to determine the best way to configure the load balancer for your deployment.

Procedure

• Appliance deployment

In this example configuration, the API Connect Management, Portal, Analytics and Gateway subsystems are deployed as three node clusters in Standard mode. An HAProxy load balancer is used. The load balancer is configured with ssl-passthrough and with upstream selection based on SNI. DNS resolution is configured to resolve the endpoints to the IP address of the load balancer. If a single HAProxy node is used, then all endpoints must resolve to the IP address of the single HAProxy. The following example endpoints require DNS resolution for this example:

- api-manager-ui.sample.example.com
- cloud-admin-ui.sample.example.com
- consumer-api.sample.example.com
- platform-api.sample.example.com
- admin.portal.sample.example.com
- web.portal.sample.example.com
- analytics.ingestion.sample.example.com
- api-gateway.sample.example.com
- apic-gw-service.sample.example.com

Following is an example HAProxy configuration for one HAProxy node distributing traffic to Management and Portal clusters:

Note:

- o When you configure a load balancer in front of a Management subsystem, specify timeouts of at least 240 seconds. Note that large deployments might need larger values.

The default timeout is typically 50 or 60 seconds, which is not long enough to avoid **409 Conflict** or **504 Gateway Timeout** errors. The **409 Conflict** error can occur when the time needed to complete an operation is sufficiently long that a second request gets issued.

For example, to specify 240 seconds when using HAProxy as a load balancer, set `timeout client` and `timeout server` to `240000`.

- o Ensure that the load balancer is configured to support the cipher `TLS_ECDHE_RSA_WITH_AES256_GCM_SHA384 (0xc030)`. When the Developer Portal, as a client, calls back to `platform-api-endpoint` or `consumer-api-endpoint` of the management subsystem, it sends only a single cipher in the Client Hello. The cipher is `TLS_ECDHE_RSA_WITH_AES256_GCM_SHA384 (0xc030)`. The SSL Handshake will fail if this cipher is not configured (supported) on the client's load balancer.

```
# This sample HAProxy configuration file configures one HAProxy node to distribute traffic to
# Management, Portal, Analytics, and Gateway clusters. Another option is to configure one HAProxy
# node per cluster.
```

```

- The following diagram depicts a typical layout for a load balancer in front of three API Connect subsystems, with each subsystem containing three Appliance/OVA

A two data center deployment strategy on VMware

An overview of the two data center disaster recovery deployment strategy in API Connect.

The two data center disaster recovery (2DCDR) deployment configuration provides continuous replication of the management and portal subsystem databases to a warm-standby deployment in another data center.

Important: The 2DCDR deployment adds complexity to the API Connect installation procedures, and all subsequent maintenance procedures such as backup, restore, and upgrade.

2DCDR is only recommended if you are concerned about a complete site outage, and want to be able to switch to standby management and portal subsystems in a different data center as quickly as possible.

The following list covers some scenarios where 2DCDR might appear to be the best strategy, but simpler alternatives are available:

- If you are concerned about a gateway outage due to data center failure.
In this case, you can create a gateway service in a different data center and register it with the management subsystem in your main data center. If your main data center fails, your remote gateway continues to process calls to your published APIs.
- If you are concerned about a management or portal subsystem failure (rather than a complete data center failure).
In this case, you can use the disaster recovery procedures to restore the management and portal subsystems.
- If you are concerned about your users not being able to access the management and portal subsystems during a data center outage.
In this case, you can maintain another data center as a cold-standby, where you have the API Connect CR YAML files, custom secrets, and database backups ready for deployment and restoration.

The cold-standby data center must have the same network configuration as your main data center so that all the endpoints in your management and portal subsystem backups are valid there.

Copy your management and portal CRs, custom secrets, and database backups to your cold-standby data center as regularly as you take these backups.

Key points of the two data center disaster recovery (DR) solution

- Two data center DR is an active/warm-standby deployment for the API Manager and Developer Portal services, and must use manual failover.
- Two DataPower® Gateway subsystems must be deployed to provide high availability for the gateway service. However, this scenario doesn't provide high availability for the analytics service.
- If high availability is required for the analytics service, two analytics subsystems must be configured, one per gateway subsystem, but with this configuration Developer Portal analytics isn't possible.
- Data consistency is prioritized over data availability.
- Latency between the two data centers must be less than 80 ms.
- Replication of the API Manager is asynchronous, so it is possible that the most recent updates do not transfer to the warm-standby data center if there is an active data center failure.
- Replication of the Developer Portal is synchronous, and therefore the latency is limited to 80 ms or less.
- The API Manager and the Developer Portal services in the two data centers must use the same deployment profile.
- The deployment in each data center is effectively an instance of the same API Connect deployment - therefore, the endpoints and certificates must all be the same.
- It is not possible to use the Automated API behavior testing application ([Installing the Automated API behavior testing application](#)) in a two data center disaster recovery configuration.

Deployment architecture

A two data center deployment model is optimized for data consistency ahead of data availability, and must use manual failover when a fault occurs. For high availability of Management and Portal subsystems ensure that you use a three replica deployment profile. For more information on deployment profiles, see: [Planning your deployment topology and profiles](#).

To achieve high availability for the DataPower Gateway, you must deploy two gateway subsystems. One subsystem in the active data center, and a separate subsystem in the warm-standby data center. Publish all Products and APIs to both gateway subsystems. The gateway subsystems are independent, and so are insulated if an issue occurs in one of them. A global dynamic router can then be used to route traffic to one gateway subsystem or the other. If high availability is also required for the analytics service, two analytics subsystems must be configured, one per gateway subsystem, but with this configuration Developer Portal analytics isn't possible.

Dynamic routing

Note: A dynamic routing device, such as a load balancer, is required to route traffic to either data center. However, neither this device nor its configuration is part of the API Connect offering. Contact IBM Services if you require assistance with configuring a dynamic router.

The dynamic router configuration must handle the traffic between the subsystems and between the data centers. For example, the consumer API calls from the Developer Portal to API Manager must transfer through a dynamic router so that the Developer Portal can use a single endpoint regardless of which data center API Manager is active in. The same is needed for calls to the Platform and Admin APIs from the other subsystems, as well as for incoming UI traffic for the Developer Portal UI, Cloud Manager UI, and API Manager UI.

The dynamic router must support SSL passthrough, so that it routes the Mutual TLS (mTLS) connections between API Manager and the Developer Portal, and between API Manager and the DataPower Gateway. The router should not do TLS termination, it should do layer 4 based routing by using SNI.

Note: From v10.0.5.3, it is possible to disable mTLS and use JWT instead, which allows the load-balancers to do TLS termination. For more information, see [Enable JWT instead of mTLS](#).

Service status

When a failure occurs, it is common practice to display an interstitial system outage web page. The dynamic router can be configured to display this web page when there is a failure, while the manual failover to the warm-standby data center is taking place.

Deployment profiles

Both one replica and three replica deployment profiles can be used with two data center DR, but they must be the same at each data center. For more information about the deployment profiles, see [Requirements for initial deployment on VMware](#).

For more information about a two data center DR deployment, see the following topics:

VMware

- [Installing a two data center deployment on VMware](#)
- [Maintaining a two data center deployment](#) (including information about normal operation data flows)
 - [Failure handling of a two data center deployment](#)
 - [Recovering from a failover of a two data center deployment](#)
 - [Backup and restore considerations for a two data center deployment](#)
 - [Upgrading a two data center deployment](#)

Planning your Analytics deployment

Plan your IBM® API Connect Analytics deployment by reviewing options for topology, data modifications, and storage.

Planning your Analytics topology is an important step in ensuring a successful and scalable solution. After you plan your overall API Connect topology, you should plan the Analytics subsystem deployment by choosing a topology, planning any data modifications, and estimating the amount internal storage that is needed for the deployment.

- [Planning the Analytics deployment profile](#)
Begin planning your API Connect Analytics deployment by choosing a deployment profile.
- [Planning to offload data to a third-party system](#)
Review the considerations for offloading data from your IBM API Connect Analytics deployment to a third-party system for additional storage and analysis.
- [Planning to disable internal storage](#)
Review considerations for disabling local storage and offloading all data in your API Connect Analytics deployment.
- [Planning to modify your analytics data](#)
Review how you can optionally customize the analytics data in your API Connect Analytics deployment before storing it.
- [Estimating internal storage space](#)
If you plan to store data locally in your IBM API Connect Analytics deployment, estimate disk space requirements.

Planning the Analytics deployment profile

Begin planning your API Connect Analytics deployment by choosing a deployment profile.

Deployment profile

The first decision you must make is which **deployment-profile** you want to use. The available deployment profiles for analytics are: **n1xc2.m16**, **n1xc4.m32**, **n1xc6.m48**, **n3xc4.m16**, **n3xc4.m32**, **n3xc6.m48**, **n3xc8.m64**.

For more information on deployment profiles, see [Planning your deployment topology and profiles](#).

Planning to offload data to a third-party system

Review the considerations for offloading data from your IBM® API Connect Analytics deployment to a third-party system for additional storage and analysis.

The analytics event data that is generated by the Gateway and collected by the analytics subsystem can be offloaded to a third-party service in real-time. The third-party service can provide enhanced monitoring, alerting, storage, and/or analysis, in addition to what the built-in Analytics subsystem provides. Multiple target systems are supported, and the data can be modified prior to offloading.

APIC supports offloading analytics data to the following third-party systems:

- HTTP(s) endpoints
- OpenSearch
- Elasticsearch
- Apache Kafka
- Syslog servers

For instructions on configuring your offload settings, see [Offloading data to a third-party system](#).

If you do not need internal storage and only want to use the third-party system for working with your analytics data, consider disabling internal storage entirely as explained in [Planning to disable internal storage](#).

Planning to disable internal storage

Review considerations for disabling local storage and offloading all data in your API Connect Analytics deployment.

The Analytics subsystem provides a complete solution for routing, storing, and viewing the analytics data. However, you might not need the internal storage and viewing solution, especially if you are primarily using a third-party system for data offloading. In this scenario, you can greatly reduce your CPU and memory costs by disabling internal storage.

Important: It is not possible to change this configuration after installation. You must decide on whether you want to disable internal storage before installation. With this approach, data that is offloaded is not viewable in the API Manager and Developer Portal UIs.

For more information on disabling internal storage, see [Disabling internal storage](#).

Planning to modify your analytics data

Review how you can optionally customize the analytics data in your API Connect Analytics deployment before storing it.

You can create filters to customize the analytics data before storing in external or internal storage. Filters allow you to add new fields, modify existing fields, or remove fields from the data. You can do this globally for the entire Analytics subsystem, or you can do it conditionally for a specific API. By default, filters are defined at the global level, so unless you include conditionals, changes are applied to every piece of data flowing through the pipeline.

For information on adding filters to the Analytics configuration to modify your data, see [Modifying your analytics data](#).

Note: If you want to modify the data for specific APIs rather than all incoming data, you can use gateway scripts or the **set-variable** policy, as described here: [Modifying analytics API event data](#).

What fields can you modify?

The fields that are available for you to interact with are described in [API event record fields](#). Each API defined in the Management subsystem and published to your Gateway has its own success and error log policies. The log policy settings determine what data is available for customization. Be sure to verify the existence of a field before trying to modify it; otherwise your pipeline might fail.

Modifying fields is a complex operation and can cause problems with your data. It is highly recommended that you remove fields entirely (instead of modifying them) if you need to sanitize data. If you want to change the format of an existing field, you should create a new, unique field.

Important: Do not change the data type of existing fields or modify fields critical to the Analytics subsystem's operations and access control. Doing so can cause problems with retrieving or storing data. The following fields are restricted:

- org_id
- catalog_id
- space_id

- developer_org_id
- datetime
- @timestamp

The service for the data pipeline is based on Elastic Logstash, which provides [a set of predefined filter plugins](#) that you can use for modifying data. However, the plugins are third-party software that IBM does not control, so IBM cannot guarantee support for them.

Estimating internal storage space

If you plan to store data locally in your IBM® API Connect Analytics deployment, estimate disk space requirements.

This information applies only to data that is stored in API Connect Analytics and not to data that is offloaded to a third-party system. The formula and guidelines are based on known information about how the Analytics service stores data, and cannot be directly applied to any other storage system.

Use the following guidelines to calculate a rough estimate of the amount disk space you need for storing stateful data in the API Connect Analytics subsystem.

Data storage: calculate how much data you want to store

The amount of disk space needed for storing analytics data is determined by the following factors:

Number of copies of the analytics data

Each copy of the analytics data must live on a separate node. The number of nodes in your deployment (based on your chosen profile in [Planning the Analytics deployment profile](#)) determines the number of copies of analytics data that is stored in your deployment. With the three replica deployment profile, analytics data is replicated to three nodes (two replicas and one primary copy of the data) for storage. In the one replica profile, you only need to store one copy of the data.

Number of copies of data:

```
Copies of data = [1 | 3]
```

Number of days that data is retained

By default, analytics data is retained for 90 days, but you can [modify the retention setting](#) as needed. Make sure you know how long you want to store the data before attempting to calculate required disk space.

Number of days that data is retained:

```
Data retention = [90 days | preferred length]
```

Amount of each type of data stored

The required storage space for each type of logging is highly dependent on your APIs and usage. For each API, you can [Configure activity logging](#) for the API activity, header, and payload. You can also [customize the data](#) to add, redact, or remove fields, which also impacts the amount of data that you store.

To estimate storage needs, calculate the average size of each type of log. When calculating your estimates, remember that the header logging size is the sum of activity logging size and the average size of your headers. The payload logging size is the sum of the header logging size and the average size of your payloads. Typically the average size of an activity logged event is 600-1000 bytes depending on the uniqueness and complexity of your analytics data. This number is highly dependent on your APIs and your implementations. For a rough estimate, you can use an average of 800 bytes per activity logged event.

If you choose to add fields, calculate the average size of the new fields as well, and add that number to all types of log policies. If you choose to remove fields, you should not subtract this size from the log policies unless you are also removing headers and/or payloads.

Amount of each type of data that is stored:

```
Activity log bytes per call = [600-1000 bytes]
Header log bytes per call = Activity log bytes per call + Average size of headers
Payload log bytes per call = Header log bytes per call + Average size of payloads
```

Percentage of each type of data

Estimate the percentage of each type of log (activity, header, payload) for all API calls.

If you follow best practices of using only activity logging for production environments and using only payload logging for test environments, this number is easy to determine. If you use different log policies per API, and they depend on "success" or "error" factors, the percentage is more difficult to determine. Typically, if you do not use an all-or-nothing method for logging, error rates range from 3% to 25% with subsequent payload logging in test and production environments. However, this is entirely dependent on your use case and your APIs.

Percentage of each type of data that is stored:

```
% of Activity log = [0, 100 or other estimate]
% of Header log = [0, 100 or other estimate]
% of Payload log = [0, 100 or other estimate]
```

Estimated number of API calls per month

When planning your API Connect deployment, this number is helpful. When estimating analytics storage, this number is vital because it is directly correlated to how much storage you need for your deployment.

If you do not know the number of calls per month, but you do know the number of calls per second, use the following formula to convert it to calls per month:

```
Calls per month = Calls per second * 86400 seconds per day * 30 days per month
```

Number of API calls per month:

```
Calls per month = [any estimate]
```

Calculating your disk space requirement

Estimate the disk space requirement for each storage node by completing following calculations.

Formula

$$\text{Bytes per call} = (\% \text{ of Activity Log} * \text{Activity Log bytes per call}) + (\% \text{ of Header Log} * \text{Header Log bytes per call}) + (\% \text{ of Payload Log} * \text{Payload Log bytes per call})$$

$$\text{Calls per retention period} = \text{Calls per month} * (\text{Number of days retained} / 30 \text{ days per month})$$

$$\text{Storage for API calls} = \text{Calls per retention period} * \text{Bytes per call} * \text{Copies of data}$$

$$\text{Total storage} = \text{Storage for API calls} + \text{Overhead}$$

$$\text{Storage per node} = \text{Total storage} / \text{Nodes}$$

Details

1. Bytes per call:

Estimate the number of bytes that are logged for a single copy of each API call. This can be calculated from the prerequisites of the percentage of each data type and the amount of each data type stored.

$$\text{Bytes per call} = (\% \text{ of Activity Log} * \text{Activity Log bytes per call}) + (\% \text{ of Header Log} * \text{Header Log bytes per call}) + (\% \text{ of Payload Log} * \text{Payload Log bytes per call})$$

2. Calls per retention period:

Calculate the anticipated number of API calls per retention period. This can be calculated from the prerequisites of the estimated calls per month and your desired data retention.

$$\text{Calls per retention period} = \text{Calls per month} * (\text{Number of days retained} / 30 \text{ days per month})$$

3. Storage for API Calls:

Calculate the storage needed for all copies of your api calls for your retention period. This can be calculated from steps 1 and 2, as well as the prerequisite of your total copies of your data.

$$\text{Storage for API calls} = \text{Calls per retention period} * \text{Bytes per call} * \text{Copies of data}$$

4. Total Storage:

Calculate the total storage you need by adding buffer space to the value from step 3. The Analytics service requires some overhead space to complete its operations; for example, to contain system data and temporary debug header or payload logging. In addition, allowing extra space provides a buffer in case you underestimated the number of calls, or experience an unexpected increase.

There is no specific value for the buffer because it's based on your own situation. One approach is to use a value that rounds the Storage for API calls result from step 3 to the next whole number. Make sure the rounding leaves you with a comfortable amount of additional space. For example, if the result from step 3 is 380 GB, then adding 20 GB to reach 400 GB is probably not sufficient and you should consider rounding to a larger value such as 500 GB.

$$\text{Total storage} = \text{Storage for API calls} + \text{Buffer}$$

5. Storage per node:

Calculate the total storage amount required per storage node. The number of storage nodes is dependent on your deployment profile. For the one replica profile, use 1. For the three replica profile, it defaults to 3.

$$\text{Storage per node} = \text{Total storage} / \text{Nodes}$$

Remember: This result is only an estimate. You should monitor the use of space over time and adjust storage as needed.

Save this information for when you are completing the installation steps. You specify the disk size when you deploy the OVA file: [Deploying the Analytics subsystem OVA file](#).

Example

Deployment information:

Copies of data = 3
 Data retention = 90 days
 Activity log bytes per call = 850 bytes
 Header log bytes per call = 15k bytes
 Payload log bytes per call = 30.5k bytes
 % of Activity log = 100%
 % of Header log = 0%
 % of Payload log = 0%
 Calls per month = 64 million

Formula:

$$\text{Bytes per call} = (\% \text{ of Activity Log} * \text{Activity Log bytes per call}) + (\% \text{ of Header Log} * \text{Header Log bytes per call}) + (\% \text{ of Payload Log} * \text{Payload Log bytes per call})$$

$$\text{Calls per retention period} = \text{Calls per month} * (\text{Number of days retained} / 30 \text{ days per month})$$

$$\text{Storage for API calls} = \text{Calls per retention period} * \text{Bytes per call} * \text{Copies of data}$$

$$\text{Total storage} = \text{Storage for API calls} + \text{Overhead}$$

$$\text{Storage per node} = \text{Total storage} / \text{Nodes}$$

Details:

1. Bytes per call = 850 bytes

$$(100\% \text{ of Activity Log} * 850 \text{ bytes}) + (0\% \text{ of Header Log} * 15\text{k bytes}) + (0\% \text{ of Payload Log} * 30.5 \text{ bytes})$$

2. Calls per retention period = 192 million calls

$$64 \text{ million calls per month} * (90 \text{ days retained} / 30 \text{ days per month})$$

3. Storage for API calls = 489.6 GB

$$192 \text{ million calls per period} * 850 \text{ bytes per call} * 3 \text{ copies of data}$$

4. Total storage = 600 GB

$$489.6\text{GB storage} + \text{Buffer}$$

Since rounding to 500 GB only provides 10.4 GB of extra space, consider rounding to 600 GB instead.

5. Storage per node = 200 GB

In this example, the estimated disk needed on each node is 200GB.

API Connect TLS certificate best practices

Best practices for configuring and managing TLS certificates in an API Connect deployment on VMware.

API Connect generates TLS certificates during installation that are used to secure all network communication to, from, and within your API Connect deployment.

The TLS server certificates that secure the user-facing endpoints of your API Connect deployment can be replaced with your own organization's certificates. For example, if you want portal users to see your organization's certificate instead of the auto-generated API Connect certificate, you can update the certificate that secures the `portal-www` endpoint to use your own certificate.

If more than one endpoint is set to the same host, the certificates associated with the endpoints should be set to the same.

The following table lists all the user-facing certificates in API Connect:

Table 1. User-facing endpoint certificates.

Certificate name	Description
<code>portal-www-ingress</code>	The <code>portal-www-ingress</code> certificate is a user-facing ingress certificate that is returned to users when they attempt to access developer portal sites. The endpoint is called <code>portal-www</code> in the portal subsystem configuration.
<code>api-manager-ui</code>	The <code>api-manager-ui</code> certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Manager UI. The endpoint in the management subsystem configuration uses the same name: <code>api-manager-ui</code> . The hostnames for which the certificate is valid must include the <code>api-manager-ui</code> endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <code>store.acme.com</code> , the certificate can be one that is valid for hostnames that match <code>*acme.com</code> . Requires EKU <code>serverAuth</code> .
<code>cloud-admin-ui</code>	The <code>cloud-admin-ui</code> certificate is a user-facing ingress certificate that is returned to users when they attempt to access the Cloud Manager UI. The endpoint in the management subsystem configuration uses the same name: <code>cloud-admin-ui</code> . The hostnames for which the certificate is valid must include the <code>cloud-admin-ui</code> endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <code>store.acme.com</code> , the certificate can be one that is valid for hostnames that match <code>*acme.com</code> . Requires EKU <code>serverAuth</code> .
<code>consumer-api</code>	The <code>consumer-api</code> certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at organization scope. The endpoint in the management subsystem configuration uses the same name: <code>consumer-api</code> . The hostnames for which the certificate is valid must include the <code>consumer-api</code> endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <code>store.acme.com</code> , the certificate can be one that is valid for hostnames that match <code>*acme.com</code> . Requires EKU <code>serverAuth</code> .
<code>platform-api</code>	The <code>platform-api</code> certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at cloud scope. The endpoint in the management subsystem configuration uses the same name: <code>platform-api</code> . The hostnames for which the certificate is valid must include the <code>platform-api</code> endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <code>store.acme.com</code> , the certificate can be one that is valid for hostnames that match <code>*acme.com</code> . Requires EKU <code>serverAuth</code> .
<code>hub</code>	Used by the Automated API behavior testing application. User-facing ingress certificate for the <code>hub-endpoint</code> .
<code>turnstile</code>	Used by the Automated API behavior testing application. User-facing ingress certificate for the <code>turnstile-endpoint</code> .

Note: For more information about the non-user facing certificates used in API Connect, see [TLS certificate concepts and operations](#)

- [Customizing your user-facing certificates](#)
How to set the user-facing endpoints of API Connect to use your own TLS server certificates.

Customizing your user-facing certificates

How to set the user-facing endpoints of API Connect to use your own TLS server certificates.

Before you begin

Identify the user-facing certificates that you want to customize: [User-facing certificates](#).

Ensure that you have certificate, key, and CA PEM files for each certificate you want to customize. The PEM files must not be password-protected.

For example, to customize the certificate that secures the Cloud Manager UI, you must have the following PEM files: `cloud-admin-ui-cert.pem`, `cloud-admin-ui-key.pem`, `cloud-admin-ui-ca.pem`

User-facing certificates must meet the following requirements:

- Specify Extended Key Usage (EKU) of `serverAuth`.
- Include the Subject Alternative Name (SAN) of the endpoint that they secure.
- If the certificate is signed by an intermediate CA, then the `ca.pem` file must contain the full chain to root CA.

About this task

You update the user-facing certificates with the `apicup` command.

You can set custom user-facing certificates during installation, or you can update them after installation, replacing the default certificates that are generated.

Procedure

1. If you are updating a user-facing certificate after installation, you must first clear the default certificate that was created:

```
apicup certs set <subsystem name> <certificate name> --clear
```

For example, to clear the certificate that secures the Cloud Manager UI:

```
apicup certs set mgmt cloud-admin-ui --clear
```

2. Set the user-facing certificate with the `apicup certs set` command, supplying the PEM files for your new certificate:

```
apicup certs set <subsystem name> <certificate name> <cert file> <key file> <ca file>
```

For example:

```
apicup certs set mgmt cloud-admin-ui cert.pem key.pem ca.pem
```

3. If you are updating the certificate after installation, then apply the update with `apicup subsys install`

```
apicup subsys install <subsystem name>
```

4. You can verify that the certificate is updated with `apicup certs list`:

```
apicup certs list <subsystem name>
```

Example output:

```
Common certificates
=====
```

Name	Summary	Validation errors
----	-----	-----
...		

```
Subsystem def-management certificates
=====
```

Name	Summary	Validation errors
----	-----	-----
...		
cloud-admin-ui	CN: cloud-admin-ui SubjectKeyId: 9E:8B:FA:7E:92:70:EC:86:2F:C3:3A:20:E8:13:EA:F4 AuthorityKeyId: E4:AB:09:FF:A9:7D:D3:70:DD:AD:69:C4:A4:34:8D:96	
...		

Note: Along with the user-facing certificates, the `apicup certs list` command outputs details of other internal API Connect certificates and secrets that you should not update.

If you see validation errors in `apicup certs list` output, check [Certificate validation reference](#).

If you want to revert to using automatically generated user-facing certificates, then you can clear and regenerate the certificates by following these steps:

1. Clear the certificate:

```
apicup certs set <subsystem name> <certificate name> --clear
```

Repeat for all certificates that you want to clear.

2. Generate new certificates for all the cleared certificates:

```
apicup certs generate <subsystem name>
```

3. If you are updating the certificate after installation, then apply the update with `apicup subsys install`:

```
apicup subsys install <subsystem name>
```

Installing API Connect

Use these instructions to install or upgrade a deployment of API Connect on VMware.

- [IBM API Connect Version 10 software product compatibility requirements](#)
Ensure that you install the minimum API Connect operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.
- [Requirements for initial deployment on VMware](#)
Review the requirements and considerations for deploying in a VMware environment.

- [API Connect licenses](#)
When you install a new version of API Connect on VMware, you must accept a new license.
- [What's new for v10 installation](#)
Summary of installation changes for API Connect v10 on VMware.
- [First steps for deploying in a VMware environment](#)
The first steps in deploying in a VMware environment are to obtain the API Connect distribution files and to create a project directory.
- [Signature verification by using PGP](#)
You can verify the integrity of files to ensure that they originated from IBM and are not modified.
- [Deploying the Management virtual appliance](#)
You can create a virtual server by deploying the relevant IBM API Connect OVA file on a VMware virtual server. Create all of the virtual servers that you want to use in your cloud.
- [Deploying the Analytics virtual appliance](#)
Install the IBM API Connect Analytics subsystem.
- [Deploying the Developer Portal virtual appliance](#)
You create a Developer Portal node by deploying the Developer Portal OVA template. After you deploy the Developer Portal OVA template, you can install the Developer Portal.
- [Deploying DataPower Gateway virtual appliance](#)
API Connect uses IBM DataPower® Gateway to provide the gateway service.
- [Post-deployment steps](#)
When all subsystems are deployed, use the admin account to access the Cloud Manager administrative console and begin configuration. Optionally, take VMware snapshots of the VMs.
- [Installing a two data center deployment on VMware](#)
How to install a two data center disaster recovery (2DCDR) deployment on VMware.

IBM API Connect Version 10 software product compatibility requirements

Ensure that you install the minimum API Connect operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.

Generating a Software Product Compatibility Report

To generate an API Connect requirements report, complete the following steps:

1. Open the [Detailed system requirements for a specific product](#) page on the IBM Software Product Compatibility Reports site.
2. Search for the IBM API Connect product.
3. In the Search results list, select IBM API Connect.
4. From the Version list, select the required version.
5. Use the Filters to refine the contents of the requirements report.
6. Click Submit to generate your requirements report.

Important: When reviewing the report to determine your deployment needs, you should treat the stated CPU and memory requirements as reserved VMware capacity. For example, if the system requirements are 4 CPU and 16GB RAM, then those resources should be available at all times from the underlying hardware and should not be coming from an over-committed pool of resources.

Requirements for initial deployment on VMware

Review the requirements and considerations for deploying in a VMware environment.

- [Deployment requirements on VMware](#)
- [Disk space requirements](#)
- [API Connect configuration on VMware](#)
- [Passwords and certificates](#)
- [Setting and using a hashed default password](#)
- [DataPower Gateway for API Connect on VMware](#)

Deployment requirements on VMware

- Ensure you have supported software requirement versions. See [IBM API Connect Version 10 software product compatibility requirements](#)
Attention: API Connect is not supported on a FIPS-enabled environment.
- Do not change the hardware version of the OVA during installation. Do not attempt to use an unsupported version, even if VMware indicates compatibility with other versions. For example, when deploying API Connect, the VMware UI for the APIC OVAs might show information like:

Table 1.

Property	Value
Guest OS	Ubuntu Linux (64-bit)
Compatibility	ESXi 5.5 and later (VM version 10)
VMware Tools	Yes
CPUs	4
Memory	16 GB

Although the **Compatibility** field shows **ESXi 5.5 and later (VM version 10)**, API Connect supports only the versions listed in [IBM API Connect Version 10 software product compatibility requirements](#). Do not change the VM version of the OVA. Ensure that the **Compatibility** field values are not changed, and remain **ESXi 5.5 and later (VM version 10)**.

Attempts to modify the VMware compatibility may typically result in failure to boot the OVA, as per <https://kb.vmware.com/s/article/52683>.

- Ensure that your operating system has one of the supported utilities for creating ISOs. The apicup installer uses `mkisofs` on Linux, and `hdiutil` on macOS. For Windows, you need software that creates ISO files using `mkisofs`, such as CDRTools. Verify that the utility you will use is located in a directory that is referenced by the PATH environment setting for your operating system. When creating the ISO, if you encounter the message **Error: unable to create config ISO for host**, verify that you have sufficient permissions to run the command.
- **Important:** Use a single `apicup` project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.

The original project directory created with `apicup` during the initial product installation (for example, `myProject`) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. Note that the endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored or upgraded system. A good practice is to back up the original project directory to a location from where it can always be retrieved.

Endpoints for the components cannot change between deployments. However, the endpoints for the VMware hosts can be modified for the new deployment.

- For each subsystem, gather the following networking settings, which you will need to supply during configuration:

Table 2.

Required information	Value for your system
IP address of the server	
Domain of the server	
IP addresses of the name servers	
IP address of the network gateway (not DataPower® gateway) for the server	
Name of the Ethernet interface	
VLAN	

Some virtualization environments require additional information when you create and configure virtual machines. For example, it might be necessary to assign a specific VLAN ID, Resource Pool, or Datastore. Please refer to information provided by your virtualization environment administrators.

Disk space requirements

- For Version 10, the data disk requirement for the management server is 200 GB. The boot disk requires 100 GB, so a minimum of 300 GB is needed for the management subsystem. You specify the data disk size in [Deploying the Management subsystem OVA file](#) when you deploy the OVF template in the VMware vSphere Web Client.
- The Developer Portal disk requirements vary with usage scenarios. See [Table 1](#).
- Before you install, review all the minimum hardware requirements listed on the Hardware tab in the Software Product on the Compatibility Reports for API Connect. Follow the instructions in [IBM API Connect Version 10 software product compatibility requirements](#).

API Connect configuration on VMware

- API Connect cannot be deployed on NFS.
- The timezone for API Connect pods is set to UTC. In API Connect deployments on VMware, the operating system timezone is also set to UTC. Do not change the timezone for the pods or the operating system.
- Ensure that the time settings match (within a few seconds) between the machine running `apicup` and the VMware Host clock. To verify the VMware host clock setting, see <https://kb.vmware.com/s/article/1003736>.

If the clocks are too different, the installation can fail because of invalid certificates due to time discrepancies.

- Deploying multiple similar subsystems in a single namespace is not supported. For example, deploying two management subsystems, `mgmt1`, `mgmt2` in a single namespace where `apiconnect` operator is installed.
- API Connect requires a dedicated IP range for deployment of the Kubernetes pod and Kubernetes service networks. These IP addresses cannot conflict with IP addresses used by other resources in your deployment, such as SMTP servers or user registries. The default values are 172.16.0.0/16 and 172.17.0.0/16, respectively. If a /16 subnet overlaps with existing IPs on the network, a CIDR as small as /22 is acceptable. If the default ranges conflict with other programs, you can modify the API Connect ranges during initial installation. Note that you cannot modify them once an appliance has been deployed. Follow the instructions for your subsystem if you want to modify either of the IP ranges.

- Only static IP addresses that are specified during the `apicup` project configuration before the installation of the OVAs are supported.
- Designated host names must have wildcard aliases or host aliases, which ensures that the different endpoints work together. For example, `*.hostname.mycompany.com`.
- Endpoints cannot contain the underscore character "_" or uppercase characters.
- Host names that are used to create endpoints cannot contain the underscore character "_" or uppercase letters.
- Kubernetes ingress limits the character set for DNS names to not support the underscore character "_". This means you cannot specify underscores in domain names that are used as endpoints. For example, `my_domain.bar.com` and `my.domain_abc.com` are not supported for `<xxx>.<hostname>.<domainname>`, and will cause an error. For example:

```
Invalid value: "my_domain.bar.com": a DNS-1123 subdomain must consist of lowercase alphanumeric characters, '-' or '.', and must start and end with an alphanumeric character (e.g. 'example.com', regex used for validation is '[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*')
```

- Note that you cannot change host names or DNS names on a running cluster.
- For Analytics, the installer specifies a default value of 16 GB for `es-max-memory-gb`. The minimum value for this setting is 12 GB.
- Decide the `deployment-profile` to use for the installation. See [Planning your deployment topology and profiles](#). Use of three replica deployment-profile is supported only on installations with three or more nodes. Installations with less than three nodes must use a one replica deployment-profile.

Note that a deployment-profile is set for each subsystem type: Management, Analytics, and Developer Portal.

- For additional considerations for configuring clusters, see [Configuring API Connect subsystems in a cluster](#). Important: For best performance it is recommended that the network latency between any 2 nodes be as low as possible. Do not configure nodes from the same subsystem cluster across multiple data centers with a high latency network. A high latency network is one that experiences more than 30ms latency between nodes.

- Configure a remote server for logging. Follow these instructions: [Configuring remote logging for a VMware deployment](#). Pods are terminated during an upgrade, and the logs will be lost if not stored remotely.

Passwords and certificates

- When creating configuration files for use in generating an ISO image for VMware, ensure that your working directories are secure. The VMware configuration requires an ISO image that contains a plain text password to be used to unlock the VMware data disk. This means that the API Connect project configuration file `apiconnect-up-v10.yml`, and the `/user-data` directory for each host, contain the passwords you specified. This configuration information is used to create the ISO image that you combine with the `..ova` distribution files when deploying (unlocking) the VMware data disk.
- You can use `apicup` to specify an `ssh` keyfile that contains a public certificate for using `ssh` to log in to a virtual machine. Logging in through `ssh` is preferred because it is more secure than password-based login.
- Default certificates are generated for each subsystem by the `apicup subsys install` command. If certificates are not explicitly set using the `apicup certs set` command, then default certificates are automatically generated by `apicup`. See [API Connect TLS certificate best practices](#).

Setting and using a hashed default password

During configuration of the Management, Analytics, and Developer Portal subsystems, you create a password to use to log in to the management console for the first time. You must use a password hashing utility to hash the password. You then use `apicup` to assign this hashed password to the subsystem. These configuration steps ensure that the password is not stored in plain text on the data disk.

The syntax of the `apicup` command is:

```
apicup subsys set mgmt default-password='hashed_password'
```

Usage notes:

- The `default-password` is for the `apicadm` user account on the Appliance.
- The password for `apicadm` can be used **only** to log in through the VMware console. You cannot use it to `ssh` into the Appliance as an alternative to using the `ssh-keyfiles`. Interactive login for `ssh` is disabled.
- The `default-password` value configured is only used during initial installation (first boot) of each virtual appliance. Changing the value, then regenerating the ISO, and attaching the new ISO to the virtual appliance does not change the `apicadm` password.
- The `default-password` must be hashed. If it is plain text, you will not be able to log into the Appliance through the VMware console. When you use `apicup` to set or get `default-password`, `apicup` ensures that the hash type of the password is one of the following:
 - MD5
 - SHA1
 - SHA256
 - SHA512
 - BCRYPT
 - MD5-Crypt
- When using `apicup` to set a default password for a subsystem, be aware of syntax differences between operating systems. Windows requires double-quotes. Linux and OSX require single quotes.

Operating system	Command syntax
Linux or OSX	<code>apicup subsys set mgmt default-password='hashed_password'</code>
Windows	<code>apicup subsys set mgmt default-password="hashed_password"</code>

- You can use the `passwd` command (on the appliance) to change the `apicadm` password.
- When using the VMware Remote console to login to the appliance, be aware that the keyboard layout is English. This can cause a problems with hashed passwords, if you created the ISO on a system with a different keyboard layout and you used special characters or symbols. Passwords are hashed when you set the password that you enter to log into your Management appliance for the first time, and when you create hosts.

DataPower Gateway for API Connect on VMware

- Installation and configuration of DataPower Gateway on an appliance (physical or virtual) is completed after you install the API Connect subsystems. For the gateway service in a VMware environment, use the instructions in [Deploying DataPower Gateway virtual appliance](#).
- Ensure that DataPower Gateway firmware version you plan to install is compatible with the API Connect Management server version.

Note:

You can use any combination of API Connect 10.0.5.x with DataPower Gateway 10.5.0.x or DataPower API Gateway 10.5.0.x.

Before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in [IBM API Connect Version 10 software product compatibility requirements](#) to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software, Integration Middleware, and view the list of compatible DataPower Gateway versions.

API Connect licenses

When you install a new version of API Connect on VMware, you must accept a new license.

Setting the License ID on VMware

Each license has a unique identifier called a `License ID`. Use `apicup` to accept the license. License acceptance is stored in `apiconnect-up-v10.yml`. Each accepted `License ID` is passed into subsystem CRs.

```
apicup licenses accept <License_ID>
```

For example:

```
apicup licenses accept I-EMZJ-MQ4M24
```

- Use `apicup licenses list` displays licenses available for current version. Also shows all accepted licenses, including prior versions. `apicup licenses list` has a `-o yaml|json` flag to make script based usage easier.
- If an invalid value is passed to `apicup licenses accept`, an error is displayed showing the valid values:

```
Error: Must run `apicup licenses accept ID` with one of [L-GVEN-GFUPVE, L-BYRR-EEASJ3, .....]
```
- If you run other `apicup` commands, such as `apicup subsys get <subsystem_name>` from within a project directory, without first accepting a license, those commands will fail. Once you accept the license, the commands will succeed.

You accept the license during [First steps for deploying in a VMware environment](#).

API Connect 10.0.5 licenses

For API Connect 10.0.5.3 and later, the licenses in Table 1 will be used as the master mod-level license for all Fix Pack and security roll-up releases in this stream. There are no changes to license terms, only updates to open-source notices documented in the notes for each.

Table 1. API Connect 10.0.5 licenses

License ID	Program Name	URL
L-VQYA-YNM22H	IBM API Connect Enterprise V10.0.5.3	https://ibm.biz/BdPGTL
L-SLCD-D9MBTA	IBM API Connect Enterprise Add-on for IBM Products V10.0.5.3	https://ibm.biz/BdPGTQ
L-XSJQ-UMJP6P	IBM API Connect Professional V10.0.5.3	https://ibm.biz/BdPGTC

Table 2. API Connect 10.0.5.2 licenses

License ID	Program Name	URL
L-GVEN-GFUPVE	IBM API Connect Enterprise V10.0.5.2	https://ibm.biz/BdPPmt
L-BYRR-EEASJ3	IBM API Connect Enterprise Add-on for IBM Products V10.0.5.2	https://ibm.biz/BdPPm6
L-EMZJ-MQ4M24	IBM API Connect Professional V10.0.5.2	https://ibm.biz/BdPPmU

Table 3. API Connect 10.0.5.0 and 10.0.5.1 licenses

License ID	Program Name	URL
L-RJON-CEBLEH	IBM API Connect Enterprise PVU V10.0.5	https://ibm.biz/BdPEpN
L-RJON-CEBLCF	IBM API Connect Enterprise PVU Add-on for IBM Products V10.0.5	https://ibm.biz/BdPEpW
L-RJON-CEBL97	IBM API Connect Professional PVU V10.0.5	https://ibm.biz/BdPF8B

What's new for v10 installation

Summary of installation changes for API Connect v10 on VMware.

- Changes to `apicup` settings:
 - `license-use`. Values changed: `Production` is now `production`. `Nonproduction` is now `nonproduction`.
 - `licenses accept` added for setting Program license. See [API Connect licenses](#)
 - `mode` is deprecated and replaced by `deployment-profile`. Each subsystem (Management, Analytics, Portal) has separate values for one replica profiles and three replica profiles.
 - v2018 settings that are deprecated:
 - `az-name` - no longer used with the Management subsystem
 - `cross-az-peers` - no longer used with the Management subsystem
 - `cassandra-max-memory-gb` - no longer used with the Management subsystem
 - `es-memory-gb` - no longer used with the Analytics subsystem.
 - All `cassandra-backup-*` settings are no longer used with the Management subsystem. The Cassandra database is deprecated and replaced by Postgres.
 - `cassandra-backup-auth-pass`
 - `cassandra-backup-auth-user`
 - `cassandra-backup-host`
 - `cassandra-backup-path`
 - `cassandra-backup-port`
 - `cassandra-backup-protocol`
 - `cassandra-backup-schedule`
- The minimum size data disk for the Management system increases from 150 GB in v2018 to 200 GB in v10. When combined with the 100 GB requirement for the root disk (unchanged), you need 300 GB for the Management subsystem.
- Upon reboot, any extra disk that was added to the VM is picked up and added to the secure storage (data disk).

First steps for deploying in a VMware environment

The first steps in deploying in a VMware environment are to obtain the API Connect distribution files and to create a project directory.

Before you begin

- Review [Requirements for initial deployment on VMware](#).
- See [What's new for v10 installation](#)
- See also [Configuring API Connect subsystems in a cluster](#).

About this task

In these First Steps, you will use the `apicup` command to create a project directory that contains the configuration file `apiconnect-up-v10.yml`. When you configure the first subsystem, such as the Management Service, the subsystem configuration settings are placed in the file.

When you want to configure a second subsystem, it is important that you reuse the same project directory. This means that you only need to download `apicup` once, and create a project directory once. The configuration settings for the second subsystem are added to the existing `apiconnect-up-v10.yml`. In this way, the second subsystem, such as Developer Portal, can access the configuration information needed to interact with the first subsystem.

After completing these First Steps, follow the links to instructions for configuring your subsystem. You will specify configuration settings, create an ISO of the subsystem configuration, and then use VMware to deploy the distribution file (.ova file) for the subsystem with your ISO. Note that you create a separate ISO for each subsystem.

Installation and configuration of DataPower® Gateway on an appliance (physical or virtual) is completed after you install the API Connect subsystems. For the gateway service in a VMware environment, use the instructions in [Deploying DataPower Gateway virtual appliance](#).

Note:

- For upgrades, do not use the procedures on this page. See [Upgrading API Connect](#).
- Some `apicup` commands have changed from previous versions of API Connect. See [What's new for v10 installation](#).
- When maintaining API Connect, do not use `kubect1 exec` commands to access API Connect pods unless advised by IBM. Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

Procedure

1. Obtain the API Connect files.

The following files are used for initial deployment on VMware:

IBM® API Connect <version> Management for VMware
Management subsystem files

IBM® API Connect <version> Developer Portal for VMware
Developer Portal subsystem files

IBM® API Connect <version> Analytics for VMware
Analytics subsystem files

IBM® API Connect <version> Install Assist (apicup) for <operating_system_type>
The apicup installation utility. Required for all installations on VMware.

IBM® API Connect <version> Toolkit for <operating_system_type>

Toolkit command line utility. Packaged standalone, or with API Designer or Loopback:

- IBM® API Connect <version> Toolkit for <operating_system_type>
- IBM® API Connect <version> Toolkit with Loopback for <operating_system_type>
- IBM® API Connect <version> Toolkit Designer with Loopback for <operating_system_type>

Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See [Installing the toolkit](#).

IBM® API Connect <version> Local Test Environment

Optional test environment. See [Testing an API with the Local Test Environment](#)

IBM® API Connect <version> Security Signature Bundle File
Checksum files that you can use to verify the integrity of your downloads.

Note: The Fix Pack page contains two copies of the files for each subsystem. One copy is for new installations and one is for upgrades of existing installations. For new installations, do not use files with *Upgrade* in the file name.

2. Select one of the following actions:

- If you are configuring your first subsystem, go to step [3](#).
- If you have already configured a subsystem, go to step [5](#).

3. Install the installation utility.

- a. Locate the apicup installation utility file for your operating system, and download it:
- b. Rename the file for your OS type to `apicup`. Note that the instructions in this documentation refer to `apicup`.
- c. OSX and Linux® only: Make the apicup file an executable file by entering the following command:

```
chmod +x apicup
```

- d. Set your path to the location of your apicup file.

- For the OSX and Linux operating systems:

```
export PATH=$PATH:/Users/your_path/
```

- For the Windows operating system:

```
set PATH=c:\your_path;%PATH%
```

4. Create a project called *myProject* and copy the `apicup` executable into the project directory:

- a. Create a project:

```
apicup init myProject
```

- b. Copy the `apicup` executable into the *myProject* directory or folder created by the `apicup init` command.

- c. From within your project directory, specify the API Connect license:

```
apicup licenses accept <License_ID>
```

The <License_ID> is specific to the API Connect Program Name you purchased. To view the supported license IDs, see [API Connect licenses](#).

Important:

Use a single APICUP project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.

The original project directory created with APICUP during the initial product installation (for example, *myProject*) is required to both restore the database and to upgrade your deployment. You cannot restore the database or perform an upgrade without the initial project directory because it contains pertinent information about the cluster. Note that the endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored or upgraded system. A good practice is to backup the original project directory to a location from where it can always be retrieved.

Endpoints for the components cannot change between deployments. However, the endpoints for the VMware hosts can be modified for the new deployment.

The `apiconnect-up-v10.yml` file is created in that directory.

Important: The `apiconnect-up-v10.yml` file must be in a secure and permanent location. The file contains password information and other information that is exposed in text format. Ensure that the project directory is secure.

5. Continue with the configuration steps for your subsystem:

- [Deploying the Management virtual appliance](#)
- [Deploying the Analytics subsystem](#)
- [Deploying the Developer Portal virtual appliance](#)

Signature verification by using PGP

You can verify the integrity of files to ensure that they originated from IBM and are not modified.

About this task

You can use code signatures to verify that a downloaded file was created by IBM and that no bits in the file were changed. The signature files that are used are `*.asc`. The key/cert file is `PRD0003216key.pub.pgp`.

Procedure

1. Import the public key.

```
$ gpg --import PRD0003216key.pub.pgp
gpg: key 020ED6B5DBE65F3B: public key "APIConnect <psirt@us.ibm.com>" imported
gpg: Total number processed: 1
gpg:          imported: 1

$ gpg --list-key --fingerprint APIConnect
pub  rsa4096 2023-02-28 [SCE]
    39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
uid          [ unknown] APIConnect <psirt@us.ibm.com>
```

When the key is imported, it does not need to be imported again. It is not signed, but you should make a note of the fingerprint so you can compare to make sure that the key is IBM's:

```
39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
```

2. Verify the files.

```
$ $ gpg --verify helper_files.zip.asc
gpg: assuming signed data in 'helper_files.zip'
gpg: Signature made Mon 28 Sep 17:35:17 2020 PDT
gpg:          using RSA key 39ED16345FCDEDB5D6EDE860020ED6B5DBE65F3B
gpg: Good signature from "APIConnect <psirt@us.ibm.com>" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: 39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
```

The verification shows that the key matches the signature and that shows the fingerprint of the key, which should match the import:

```
39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
```

Deploying the Management virtual appliance

You can create a virtual server by deploying the relevant IBM® API Connect OVA file on a VMware virtual server. Create all of the virtual servers that you want to use in your cloud.

Before you begin

Before you deploy:

- Review the [Deployment requirements on VMware](#).
- Review the [API Connect configuration on VMware](#).
- Review [What's new for v10 installation](#)
- For information on deploying a cluster, see [Configuring API Connect subsystems in a cluster](#)
- If you are upgrading from a previous version, see [Upgrading API Connect](#).

About this task

You must deploy the API Connect OVA template to create each Management virtual server that you want in your cloud.

Attention: The following settings apply to features that are currently not supported, and should not be modified:

- Subsystem settings: test-and-monitor-enabled
- Certificate settings: hub, turnstile

Procedure

Complete each of the following tasks in order:

1. [Configuring the Management subsystem](#)
2. [Deploying the Management subsystem OVA file](#)
3. [Verify installation of the Management subsystem](#)

What to do next

If you want to deploy an API Connect Analytics OVA file, continue with [Deploying the Analytics subsystem](#).

If you want to deploy an API Connect Developer Portal OVA file, continue with [Deploying the Developer Portal virtual appliance](#).

Identify the DataPower® appliances to be used as gateway servers in the API Connect cloud and obtain the IP addresses.

- [Configuring the Management subsystem](#)
Specify configuration properties for your management subsystem, and create an ISO.
- [Deploying the Management subsystem OVA file](#)
After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.
- [Verify installation of the Management subsystem](#)
Verify that deployment of the management subsystem OVA file succeeded.

Configuring the Management subsystem

Specify configuration properties for your management subsystem, and create an ISO.

Before you begin

Review [Deploying the Management virtual appliance](#)

About this task

Use the `apicup` installation utility to specify configuration settings for your management subsystem.

Procedure

1. Ensure that you obtained the distribution file and have a project directory, as described in [First steps for deploying in a VMware environment](#).
2. Change to the project directory.

```
cd myProject
```

3. Create a management subsystem.

```
apicup subsys create mgmt management
```

Where:

- `mgmt` is the name of your management server that you are creating. You can assign it any name, as long as the identifier consists of lowercase alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character.
- `management` indicates that you are creating a management microservice.

The API Connect Helm charts are deployed into the default namespace. You do not need to specify a namespace.

Tip: At any time, you can view the current management subsystem values in the `apiconnect-up-v10.yml` by running the `apicup subsys get` command:

```
apicup subsys get mgmt
```

If you have not yet configured the subsystem, the command might return errors. Also, if you have not updated the value, a default value is listed, if there is one that is available.

After configuration is complete, you can view output similar to the following sample:

Appliance settings

```
=====
```

Name	Value
Description	-----

additional-cloud-init-file	
(Optional) Path to additional cloud-init yml file	
data-device	sdb
VM disk device (usually `sdb` for SCSI or `vdb` for VirtIO)	
default-password	
`\${rounds}=4096\${vtcqp}AVK\${dzqr}OeYP33WTvTug38Q4Rld518TmdQgezzTnkX/PFwkzTiZ2S0CqNRr1S4b08tOc4p.OEg4BtzBe/r8RAk.gw/	
(Optional) Console login password for `apicadm` user, password must be pre-hashed	
dns-servers	[8.8.8.8]

```

List of DNS servers
extra-values-file
(Optional) Path to additional configuration yml file
k8s-pod-network      172.16.0.0/16
(Optional) CIDR for pods within the appliance
k8s-service-network 172.17.0.0/16
(Optional) CIDR for services within the appliance
public-iface         eth0
Device for API/UI traffic (Eg: eth0)
search-domain        [subnet1.example.com]
List for DNS search domains
ssh-keyfiles          [/home/vsphere/.ssh/id_rsa.pub]
List of SSH public keys files
traffic-iface         eth0
Device for cluster traffic (Eg: eth0)

```

Subsystem settings

```
=====
```

Name	Value
Description	-----

deployment-profile	n1xc4.m16
Description	Deployment profile (n1xc2.m16/n3xc4.m16) for analytics, (n1xc4.m16/n3xc4.m16) for management, (n1xc2.m8/n3xc4.m8) for portal
license-use	production
Description	License use (production/nonproduction)
multi-site-ha-enabled	false
Description	Multi site HA enabled
multi-site-ha-mode	active
Description	Multi site HA mode (active/passive)
replication-peer-fqdn	
Description	Replication peer fully qualified name (replication endpoint of active mode site)
site-name	
Description	Site name, used in k8s resource names
test-and-monitor-enabled	false
Description	Test and Monitor enabled

Endpoints

```
=====
```

Name	Value
Description	-----

api-manager-ui	api-manager-ui.testsrv0231.subnet1.example.com
Description	FQDN of API manager UI endpoint
cloud-admin-ui	cloud-admin-ui.testsrv0231.subnet1.example.com
Description	FQDN of Cloud admin endpoint
consumer-api	consumer-api.testsrv0231.subnet1.example.com
Description	FQDN of consumer API endpoint
hub	
Description	FQDN of Test and Monitor hub endpoint, only required if Test and Monitor is enabled
management-replication	
Description	FQDN of Management replication endpoint, only required if HA is enabled
platform-api	platform-api.testsrv0231.subnet1.example.com
Description	FQDN of platform API endpoint
turnstile	
Description	FQDN of Test and Monitor turnstile endpoint, only required if Test and Monitor is enabled

- Specify your deployment profile, the available profiles are described here: [Planning your deployment topology and profiles](#).

```
apicup subsys set mgmt deployment-profile=n1xc4.m16
```

Note: The deployment profiles that are shown in the **Description** column of the `apicup get` output are not correct. The available profiles are documented in [Planning your deployment topology and profiles](#).

- Specify the API Connect license information:

- Specify the license ID:

```
apicup licenses accept <License_ID>
```

The `<License_ID>` is specific to the API Connect Program Name you purchased. To view the supported license IDs, see [API Connect licenses](#).

- Specify the license type:

```
apicup subsys set mgmt
license-use=<license_type>
```

The `license_type` must be either `production` or `nonproduction`. If not specified, the default value is `nonproduction`.

- Optional: Configure backups of the subsystem. Note that once you set up scheduled backups, you can also run backups on-demand. Follow the instructions in [Configure your Management subsystem backup](#).

Important: It is highly recommend that you configure backups and also take additional steps to ensure that your configuration and data can be restored in the event of a disaster event. See [Disaster recovery of the management subsystem on VMware](#).

- Optional: Configure your logging.

Logging can be configured at a later time, but you must enable it before installation to capture the log events from the installation.

- Complete the procedure at [Configuring remote logging for a VMware deployment](#).

- Enter the following command to create the log file:

```
apicup subsys set mgmt additional-cloud-init-file=config_file.yml
```

8. Enter the following commands to update the apiconnect-up-v10.yml with the information for your environment:

a. Set your search domain. Multiple search domains should be separated by commas.

```
apicup subsys set mgmt search-domain=your_search_domain
```

Where *your_search_domain* is the domain of your servers, entered in all lowercase. Setting this value ensures that your searches also append these values, which are based on your company's DNS resolution, at the end of the search value. A sample search domain is *mycompany.example.com*.

Ensure that the value for *your_search_domain* is resolved in the system's */etc/resolv.conf* file to avoid "502" errors when accessing the Cloud Manager web site. For example:

```
# Generated by resolvconf
search your_search_domain ibm.com other.domain.com
```

b. Set your domain name servers (DNS).

Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

```
apicup subsys set mgmt dns-servers=ip_address_of_dns_server[,ip_address_of_another_dns_server_if_necessary]
```

c. Use **apicup** to set your endpoints.

You can use wildcard aliases or host aliases with your endpoints.

Optionally, you can specify all endpoints with one **apicup** command.

Note: You cannot specify the underscore character "_" in domain names that are used in endpoints. See [API Connect configuration on VMware](#).

Table 1. Management subsystem endpoints

Setting	Endpoint host description
platform-api	Platform API endpoint. The host where your platform API calls are routed. <code>apicup subsys set mgmt platform-api=platform-api.hostname.domain</code>
consumer-api	Consumer API endpoint. The host where your consumer API calls are routed. <code>apicup subsys set mgmt consumer-api=consumer-api.hostname.domain</code>
cloud-admin-ui	Cloud admin user interface API endpoint. The host where your cloud administrator user-interface API calls are routed. <code>apicup subsys set mgmt cloud-admin-ui=cloud-admin-ui.hostname.domain</code>
api-manager-ui	API Manager user interface endpoint. The host where your API Manager API calls are routed. <code>apicup subsys set mgmt api-manager-ui=api-manager-ui.hostname.domain</code>
hub	The core microservice components for the Automated API behavior testing capability. This is an optional component and can be left unset if not used. <code>apicup subsys set mgmt hub hub.hostname.domain</code> Note: Automated API behavior testing is not supported in two data center disaster recovery configurations.
turnstile	Allows for communication between the Test pods and the API Management subsystem. This is part of the Automated API behavior testing capability. This is an optional component and can be left unset if not used. <code>apicup subsys set mgmt turnstile turnstile.hostname.domain</code> Note: Automated API behavior testing is not supported in two data center disaster recovery configurations.

9. Set a Public key.

```
apicup subsys set mgmt ssh-keyfiles=path_to_public_ssh_keyfile
```

Setting this key enables you to use **ssh** with this key to log in to the virtual machine to check the status of the installation. You will perform this check in later in [Deploying the Management subsystem OVA file](#).

10. Set the password that you enter to log into your Management appliance for the first time.

a. **Important:** Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).

b. If you do not have a password hashing utility, install one.

Operating system	Command
Ubuntu, Debian, OSX	If the mkpasswd command utility is not available, download and install it. (You can also use a different password hashing utility.) On OSX, use the command: <code>gem install mkpasswd</code>
Windows, Red Hat	If necessary, a password hashing utility for the Windows operating system, like OpenSSL

c. Create a hashed password

Operating system	Command
Ubuntu, Debian, OSX	<code>mkpasswd --method=sha-512 --rounds=4096 password</code>
Windows, Red Hat	For example, using OpenSSL: <code>openssl passwd -1 password</code> . Note that you might need to add your password hashing utility to your path; for example, on Windows: <code>set PATH=c:\cygwin64\bin;%PATH%</code>

d. Set the hashed password for your subsystem:

```
apicup subsys set mgmt default-password='hashed_password'
```

11. Optional: If the default IP ranges for the API Connect Kubernetes pod and the service networks conflict with IP addresses that must be used by other processes in your deployment, modify the API Connect values.

You can change the IP ranges of the Kubernetes pod and the service networks from the default values of 172.16.0.0/16 and 172.17.0.0/16, respectively. In the case that a /16 subnet overlaps with existing IPs on the network, a Classless Inter-Domain Routing (CIDR) as small as /22 is acceptable. You can modify these ranges during initial installation and configuration only. You cannot modify them once an appliance has been deployed. See [API Connect configuration on VMware](#).

- a. Update the IP range for the Kubernetes pod

```
apicup subsys set mgmt k8s-pod-network='new_pod_range'
```

Where *new_pod_range* is the new value for the range.

- b. Update the IP range for Service networks.

```
apicup subsys set mgmt k8s-service-network='new_service_range'
```

Where *new_service_range* is the new value for the range.

12. Add your hosts.

```
apicup hosts create mgmt hostname.domainname hd_password
```

Where the following are true:

- *hostname.domainname* is the fully qualified name of the server where you are hosting your Management service, including the domain information.
- *hd_password* is the password that the Linux Unified Key Setup uses to encrypt the storage for your Management service. This password is hashed when it is stored on the server or in the ISO. Note that the password is base64 encoded when stored in `apiconnect-up-v10.yml`.

Repeat this command for each host that you want to add.

Note: Host names cannot be changed on a cluster after the initial installation.

13. Create your interfaces.

```
apicup iface create mgmt hostname.domainname physical_network_id host_ip_address/subnet_mask network_gateway_ip_address
```

Where *physical_network_id* is the network interface ID of your physical server. The value is most often `eth0`. The value can also be `ethx`, where *x* is a number identifier.

The format is similar to this example: `apicup iface create mgmt myHostname.domain eth0 192.0.2.10/255.255.255.0 192.0.2.1`.

Note: The *network_gateway_ip_address* is the network gateway (not a DataPower Gateway). If you are creating multiple network interfaces, each one must be on a different subnet with a different gateway.

14. Optional: Use `apicup` to view the configured hosts:

```
apicup hosts list mgmt
testsrv0231.subnet1.example.com
  Device  IP/Mask  Gateway
  eth0    1.2.152.231/255.255.254.0  1.2.152.1
```

Note: This command might return the following messages, which you can ignore:

```
* host is missing traffic interface
* host is missing public interface
```

Note: If you are configuring two data center deployment, continue with the installation instructions in [Installing a two data center deployment on VMware](#).

15. Optional: Verify that the configuration settings are valid.

```
apicup subsys get mgmt --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting. See the following sample output.

```

```

16. Create your ISO file.

```
apicup subsys install mgmt --out mgmtplan-out
```

The `--out` parameter and value are required.

In this example, the ISO file is created in the `myProject/mgmtplan-out` directory.

If the system cannot find the path to your software that creates ISO files, create a path setting to that software by running a command similar to the following command:

Operating system	Command
Ubuntu, Debian, OSX	<code>export PATH=\$PATH:/Users/your_path/</code>
Windows, Red Hat	<code>set PATH="c:\Program Files (x86)\cdrtools";%PATH%</code>

17. Deploy the subsystem ISO. Continue with [Deploying the Management subsystem OVA file](#).

Deploying the Management subsystem OVA file

After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.

Before you begin

You must have completed the configuration of the project file entries for the management subsystem, in [Configuring the Management subsystem](#).

About this task

Procedure

1. Log into the VMware vSphere Web Client.
2. Using the vSphere Navigator, navigate to the directory where you are deploying the OVA file.
3. Right-click the directory and select Deploy OVF Template.
4. Complete the Deploy OVF Template wizard.
 - a. Select the Management subsystem .OVA file template by navigating to the location where you downloaded the file in [First steps for deploying in a VMware environment](#).
 - b. Enter a name and location for your file.
 - c. Select a resource for your template.
 - d. Review the details for your template.
 - e. Select the size of your configuration.
 - f. Select the storage settings.

Important: Select at least 200 GB for the data disk size. Note that the boot disk needs 100 GB, so you need a total of 300 GB for the API Connect management subsystem.
 - g. Select the networks.
 - h. Customize the Template, if necessary.
 - i. Review the details to ensure that they are correct.
 - j. Select Finish to deploy the virtual machine.

Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See [Requirements for initial deployment on VMware](#).

The template creation appears in your Recent Tasks list.

5. Select the Storage tab in the Navigator.
6. Navigate to your datastore.
7. Upload your ISO file.
 - a. Select the Navigate to the datastore file browser icon in the icon menu.
 - b. Select the Upload a file to the Datastore icon in the icon menu.
 - c. Navigate to the ISO file that you created in your project.
It is the `myProject/mgmtplan-out`
 - d. Upload the ISO file to the datastore.
8. Leave the datastore by selecting the VMs and Templates icon in the Navigator.
9. Locate and select your virtual machine.
10. Select the Configure tab in the main window.
11. Select Edit....
 - a. On the Virtual Hardware tab, select CD/DVD Drive 1.
 - b. For the Client Device, select Datastore ISO File.
 - c. Find and select your datastore in the Datastores category.
 - d. Find and select your ISO file in the Contents category.
 - e. Select OK to commit your selection and exit the Select File window.
 - f. Ensure that the Connect At Power On check box is selected.

Tip:

 - Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
 - Note that VMware related issues with ISO mounting at boot may occur if Connect At Power On
 - g. Select OK to commit your selection and close the window.
12. Start the virtual machine by selecting the play button on the icon bar.
The installation might take several minutes to complete, depending on the availability of the system and the download speed.
13. Verify the API Connect installation. Continue with [Verify installation of the Management subsystem](#)

Verify installation of the Management subsystem

Verify that deployment of the management subsystem OVA file succeeded.

Before you begin

You must have completed [Deploying the Management subsystem OVA file](#).

About this task

After you configure an ISO and deploy it with the management subsystem ova, as described in [Deploying the Management subsystem OVA file](#), verify that the subsystem installed correctly and is functional.

Procedure

1. Log in to the virtual machine by using an SSH tool to check the status of the installation:
 - a. Enter the following command to connect to `mgmt` using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of `apicadm`, which is the API Connect ID that has administrator privileges.

- b. Select Yes to continue connecting.
Your host names are automatically added to your list of hosts.
- c. Run the `apic status` command to verify that the installation completed and the system is running correctly.
Note that after installation completes, it can take several minutes for all servers to start. If you see the error message `Subsystems not running`, wait a few minutes, try the command again, and review the output in the `Status` column.

The command output for a correctly running Management system is similar to the following lines:

```
apicadm@testsys0181:~$ sudo apic status

2. Ensure that you have saved all the necessary artifacts to enable you to restore the management subsystem in case of a disaster event. See [Preparing the management subsystem for disaster recovery on VMware](#).
3. Verify you can access the API Connect Cloud Manager. Enter the URL in your browser. The syntax is `https://<hostname.domain>/admin`. For example:

```
https://cloud-admin-ui.testsrv0231.subnet1.example.com/admin
```

The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. See [Accessing the Cloud Manager user interface](#).

4. If you configured an S3 backup during installation, verify that the configuration succeeded. See [Verify configuration for s3 backup](#).

Deploying the Analytics virtual appliance

Install the IBM® API Connect Analytics subsystem.

Before you begin

Review the section on [Planning your Analytics deployment](#) to ensure that you understand the choices for configuring the topology, disk space, and other elements of the Analytics subsystem. It is important to follow these steps in sequence, finishing with *Deploying the Analytics subsystem*.

- [Creating the analytics-extra-values file](#)
Create the installation extra-values file for API Connect Analytics so that you can configure additional features.
- [Enabling additional analytics features](#)
Update the `analytics-extra-values.yaml` file to enable and configure additional features of your API Connect Analytics deployment.
- [Deploying the Analytics subsystem](#)
Define your analytics subsystem, create an ISO file for each analytics node, and deploy the analytics nodes using the Analytics OVA file on a VMware virtual server.

Creating the analytics-extra-values file

Create the installation extra-values file for API Connect Analytics so that you can configure additional features.

Before you begin

Create the `analytics-extra-values.yaml` file if you plan to use features such as persistent queue, data offloading to third-party systems, modifying incoming data, or disabling internal storage. For information on the available configuration options, see [Planning your Analytics deployment](#). This file can be created and features configured or reconfigured after installation, except for disabling internal storage, which must be set before installation and cannot be changed afterward.

About this task

To apply configuration options to the Analytics subsystem during installation, create an extra-values file where you can specify your settings. Use the `analytics-extra-values.yaml` file to apply configuration settings when you install, upgrade, and update the configuration of your Analytics subsystem.

Procedure

1. Create a file called `analytics-extra-values.yaml` and open it for editing.
2. For the first line in the file, add:

```
spec:
```

All of your configuration options must follow this line, and must be indented with 2 spaces (or more for nested values).

3. Save the file.

What to do next

Add configuration options to the `analytics-extra-values.yaml` file as explained in [Enabling additional analytics features](#). If you do not want to configure additional analytics features, continue to [Deploying the Analytics subsystem](#).

- [Reference: Fields in analytics-extra-values](#)
Use the table of `analytics-extra-values.yaml` file settings to configure the analytics features you require.

Reference: Fields in analytics-extra-values

Use the table of `analytics-extra-values.yaml` file settings to configure the analytics features you require.

Table 1. Fields that you can set in the `analytics-extra-values` file

Field	Type	Description	Comments
<code>external: offload: filter</code>	String	Filter configuration for external offload.	See Offloading data to a third-party system .
<code>external: offload: enabled</code>	Boolean	Enables analytics offload feature.	See Offloading data to a third-party system .
<code>external: offload: output</code>	String	Output configuration for external offload.	See Offloading data to a third-party system .
<code>external: offload: passwordSecretName</code>	String	The name of the secret that has the password to access the certificate keystore.	See Offloading data to a third-party system .

Field	Type	Description	Comments
<code>external:offload:secretName</code>	String	The name of the secret that contains the certificates used for connecting to the offload target.	See Offloading data to a third-party system .
<code>ingestion:filter</code>	String	Filter to modify API event data that is stored internally (not offloaded).	See Modifying your analytics data .
<code>ingestion:queue</code>	Object	Persistent queue settings. Must be set to <code>persisted</code> if present.	See Analytics persistent queue .
<code>ingestion:queue:volumeClaimTemplate:volumeSize</code>	String	Storage size for your persistent queue.	See Analytics persistent queue .
<code>ingestion:queue:volumeClaimTemplate:storageClassName</code>	String	Storage class name for your persistent storage. Must be set to <code>local-storage</code> .	See Analytics persistent queue .
<code>ingestion:pipelineWorkers</code>	4 <= integer <= 128	Number of pipeline workers.	More workers mean more CPU and memory requirements, but gives you the benefit of extra threads to pull data off the ingestion http interface and process it for storage. This has diminishing returns as the size increases, and should usually be multiple of the number of cores on your hardware. Adjust with caution.
<code>ingestion:pipelineBatchSize</code>	10 <= integer <= 10000	Batch size of a pipeline worker.	Pulling more or less data off the http interface per worker can have benefits. Recommended values are <code>125</code> , <code>250</code> , and <code>500</code> . Increasing the value requires more memory.
<code>ingestion:pipelineBatchDelay</code>	10 <= integer <= 5000	Batch delay of a pipeline worker.	How long to wait for the batch size to fill before leaving the http interface to process for storage. Having threads wait too long causes idle threads in your system; however, setting this value too low decreases performance. Adjust with caution.
<code>ingestion:configReloadAutomatic</code>	Boolean	Whether to automatically reload the pipeline on configuration changes.	Typically, when the underlying files for the pipeline are modified, the pipeline process automatically reloads and picks up the changes. However, in Kubernetes environments where the pipeline is mapped to configmaps, this is unreliable. Ingestion microservice restarts are usually required.
<code>ingestion:pipelineUnsafeShutdown</code>	Boolean	Whether to allow unsafe shutdown of the pipeline.	Typically, the pipeline attempts to empty all workers' batches before shutdown to prevent data loss. You might need to enable this setting if the pipeline is badly configured and refuses to respond to shut down requests (uncommon). Adjust with caution.
<code>storage:enabled</code>	Boolean	Set false to disable internal storage.	See Disabling internal storage .

Enabling additional analytics features

Update the `analytics-extra-values.yaml` file to enable and configure additional features of your API Connect Analytics deployment.

About this task

Based on the planning decisions you made [Planning your Analytics deployment](#), configure your deployment options by completing the steps in the following topics to enable the persistent queue, configure data offloading, disable internal storage, and add ingestion filters.

- [Analytics persistent queue](#)
For enhanced reliability in your analytics data pipeline, enable the persistent queue feature.
- [Offloading data to a third-party system](#)
Update the `analytics-extra-values.yaml` file to configure data offloading from your API Connect Analytics deployment to a third-party system.
- [Disabling internal storage](#)
Update the `analytics-extra-values.yaml` file to offload all data and disable local storage in your API Connect analytics deployment.
- [Modifying your analytics data](#)
Update the `analytics-extra-values.yaml` file to customize data in your API Connect Analytics deployment.

Analytics persistent queue

For enhanced reliability in your analytics data pipeline, enable the persistent queue feature.

About this task

The Logstash persistent queue is an optional feature that provides enhanced reliability in the data pipeline. With the persistent queue enabled, the ingestion pod buffers incoming API event data to persistent storage so that no events are lost if the downstream API Connect services become unavailable.

For example, if the analytics storage service is restarted, any incoming API events are kept in persistent storage and sent on to the storage service when it is available again. If the persistent queue is not enabled, then the ingestion pod rejects further API event data coming from the gateway.

The persistent queue feature does not replay previously sent API events (if you change offload settings for example).

Another benefit of this feature is better handling of unexpected traffic spikes. The only disadvantages are higher CPU and persistent storage requirements.

Procedure

1. Open the `analytics-extra-values.yaml` file for editing.
Remember: All additions to the file must appear after the `spec:` statement.
2. Add the following section to the file:

```
ingestion:
  queue:
    type: persisted
    volumeClaimTemplate:
      storageClassName: local-storage
      volumeSize: <storage size>
```

Where:

- `<storage size>` is the maximum size for your persistent queue. For example, `30Gi`.

3. Save the file.

What to do next

If you do not want to add any more configuration options, skip to the topic [Deploying the Analytics subsystem](#).

Otherwise, continue adding configuration options to the file as explained in the following topics.

Offloading data to a third-party system

Update the `analytics-extra-values.yaml` file to configure data offloading from your API Connect Analytics deployment to a third-party system.

About this task

For information about offloading data from your Analytics deployment, see [Planning to offload data to a third-party system](#).

Procedure

1. Open the `analytics-extra-values.yaml` file for editing.
Remember: All additions to the file must appear after the `spec:` statement.
2. Add the following section to the file:

```
spec:
  external:
    offload:
      enabled: true
      output: |
        $EXTERNAL_OFFLOAD_OUTPUT
```

where `$EXTERNAL_OFFLOAD_OUTPUT` is the plugin output for the target third-party system.

For example, the following example enables offloading to HTTP:

```
spec:
  external:
    offload:
      enabled: true
      output: |
        http {
          url => "example.com"
          http_method => "post"
          codec => "json"
          content_type => "application/json"
          headers => {
            "x-acme-index" => "8"
            "x-acme-key" => "0d5d259f-b8c5-4398-9e58-77b05be67037"
          }
          id => "offload_http"
        }
```

For examples of output plugins, see [Sample output plugins for offloading data](#).

3. Optional: Modify the output plugin to include certificates for connecting to a secure endpoint.
Important: Certificates can only be applied after the Analytics subsystem is deployed. If you want to configure an output plugin that references a certificate, you must install the Analytics subsystem first, then create a secret and apply it to the Analytics deployment, configure the output plugin, and re-install Analytics. For instructions on the correct procedure for applying a certificate to the Analytics deployment, see [Providing a custom certificate for Analytics offload](#).
If your third-party endpoint requires a particular certificate, you can configure the certificate and then reference it in the offload plugin. Include the `secretName` as well as the `cacert`, `client_cert`, and `client_key` settings.

For example, the following output plugin enables offloading to HTTP and provides information on the certificate that is needed for authenticating with the endpoint:

```
spec:
  external:
    offload:
      secretName: offload-certificates
      enabled: true
      output: |
        http {
          url => "https://example.com:443"
          http_method => "post"
          codec => "json"
          content_type => "application/json"
          headers => {
            "x-acme-index" => "8"
            "x-acme-key" => "0d5d259f-b8c5-4398-9e58-77b05be67037"
          }
          id => "offload_http"
          cacert => "/etc/velox/external_certs/offload/cacert.pem"
          client_cert => "/etc/velox/external_certs/offload/client.pem"
          client_key => "/etc/velox/external_certs/offload/client.key"
        }
    }
```

The secret and its defined files are mounted to the `/etc/velox/external_certs/offload` directory.

- Optional: Add a `filter` after the output plugin to modify data prior to offloading it. The following example filter removes the `query_string` field:

```
spec:
  external:
    offload:
      enabled: true
      output: |
        http {
          url => "example.com"
          http_method => "post"
          codec => "json"
          content_type => "application/json"
          headers => {
            "x-acme-index" => "8"
            "x-acme-key" => "0d5d259f-b8c5-4398-9e58-77b05be67037"
          }
          id => "offload_http"
        }
      filter: |
        ruby {
          remove_field => ["query_string"]
        }
    }
```

For information about modifying offloaded data, see [Planning to modify your analytics data](#).

- Save the file.

What to do next

If you do not want to add any more configuration options, skip to the topic on [Deploying the Analytics subsystem](#).

Otherwise, continue adding configuration options to the file as explained in the following topics.

Attention: The third-party endpoint must be available at all times to prevent the loss of analytics data.

- [Sample output plugins for offloading data](#)
Review sample output plugins to see how to code your own plugins for offloading data from API Connect Analytics.
- [Providing a custom certificate for Analytics offload](#)
Prepare a private or self-signed certificate for offloading data.

Sample output plugins for offloading data

Review sample output plugins to see how to code your own plugins for offloading data from API Connect Analytics.

Configure output plugins that direct analytics data to your third-party systems. An output plugin specifies where analytics data is offloaded, plus any information required to access that system, such as certificate information. The output plugin for displaying analytics data in the Analytics user interface is configured by default.

Referencing a certificate in an output plugin

If your third-party system requires a private or self-signed certificate, you can include a reference to the certificate in your output plugin. See the second HTTP output plugin for an example showing how to reference the certificate.

Important: Analytics must be deployed before you attempt to use the certificate. If you want to configure an output plugin that references a certificate, you must install the Analytics subsystem first, then create a secret and apply it to the Analytics deployment, configure the output plugin, and re-install Analytics. For instructions on the correct procedure for applying a certificate to the Analytics deployment, see [Providing a custom certificate for Analytics offload](#).

HTTP

To configure data offload to an HTTP server, you must provide the server URL. You can optionally add standardized or custom HTTP headers to define additional operating parameters.

The following example configures an HTTP output plugin.

```
http {
  url => "example.com"
  http_method => "post"
  codec => "json"
  content_type => "application/json"
  headers => {
    "x-acme-index" => "8"
    "x-acme-key" => "0d5d259f-b8c5-4398-9e58-77b05be67037"
  }
  id => "offload_http"
}
```

The following example configures an HTTP output plugin that references a custom certificate for accessing the third-party endpoint.

```
http {
  url => "https://example.com:443"
  http_method => "post"
  codec => "json"
  content_type => "application/json"
  headers => {
    "x-acme-index" => "8"
    "x-acme-key" => "0d5d259f-b8c5-4398-9e58-77b05be67037"
  }
  id => "offload_http"
  cacert => "/etc/velox/external_certs/offload/cacert.pem"
  client_cert => "/etc/velox/external_certs/offload/client.pem"
  client_key => "/etc/velox/external_certs/offload/client.key"
}
```

For more information on offloading to HTTP, refer to the Logstash documentation on configuring the [HTTP output plugin](#).

Elasticsearch

To configure data offload to an Elasticsearch cluster, you must provide one or more server URLs, define how indices should be created by specifying a dynamically configured name, specify the number of primary shards for storing the indexed documents, and specify a number of replica shards for redundancy. You can optionally specify server authentication credentials.

The naming syntax that you specify for your indices determines how many indices are created and how they are characterized. For example, you can define indices that are created based on a date pattern (for example, daily or weekly), or indices that are created to store data by provider organization or by API name.

The following example configures an Elasticsearch output plugin.

```
elasticsearch {
  hosts => "https://example.com:443"
  index => "apiconnect"
  ssl => true
  cacert => "/etc/pki/tls/cert.pem"
}
```

For more information on offloading to Elasticsearch, refer to the Elasticsearch documentation on the [Elasticsearch output plugin](#).

Apache Kafka

To configure data offload to a Kafka cluster, you must provide host and port connection details for one or more servers, and the name of the Kafka topic to which you want to publish the offloaded data. For logging and monitoring purposes within Kafka, you can optionally specify a string identifier by which API Connect can be uniquely identified.

The following example configures a Kafka output plugin.

```
kafka {
  topic_id => "test"
  bootstrap_servers => "example.com:9093"
  codec => "json"
  id => "kafka_offload"
  ssl_truststore_location => "/usr/lib/jvm/jre/lib/security/cacerts"
  ssl_truststore_password => "changeit"
  ssl_truststore_type => "JKS"
  security_protocol => SSL
}
```

For more information on offloading to Apache Kafka, refer to the Logstash documentation on the [Kafka output plugin](#).

Syslog

To configure data offload to Syslog, you must provide host and port connection details for the server.

Restriction: Syslog does not support the use of chained client certificates for TLS profiles.

The following example configures a Syslog output plugin.

```
syslog {
  host => "example.com"
  port => 601
  protocol => "ssl-tcp"
  id => "offload_syslog"
}
```

```

appname => "apiconnect"
msgid => "%{org_id}"
facility => "log_audit"
severity => "informational"
codec => "json"
ssl_cacert => "/etc/pki/tls/cert.pem"
}

```

Attention: Due to a third-party issue with Logstash, most of the facility values are not set correctly on the offload server. As a temporary workaround, set the facility to "user-level" to ensure that the corresponding value is correctly sent to the offload server. When Logstash corrects this problem, you must update the offload configuration to change the value to a more appropriate setting.
For more information on offloading to Syslog, refer to the Logstash documentation on the [Syslog output plugin](#).

OpenSearch

To configure data offload to OpenSearch: <https://opensearch.org/docs/latest/clients/logstash/ship-to-opensearch/>

Providing a custom certificate for Analytics offload

Prepare a private or self-signed certificate for offloading data.

Before you begin

Install the Analytics subsystem on VMware as explained in [Deploying the Analytics subsystem](#). Analytics must be deployed before you attempt to use the certificate.

When you re-install Analytics after applying the certificate, you can upload the analytics-extra-values.yaml file to include additional configuration options.

You must have the certificate in either of these formats:

- Base64 encoded pem file format.
- JKS file.

Procedure

1. Login to your analytics VM.
 - a. SSH to your analytics VM, or one of the VMs if you have a three replica deployment.

```
ssh apicadm@<analytics VM FQDN>
```

- b. Switch to root user:

```
sudo -i
```

- c. If you are using a JKS file, create a file to contain your certificate.

```
echo "<certificate>" > <certificate filename>
```

2. If you are using a JKS file, encode the contents in base64.

```
cat <certificate filename> | base64
```

Copy the output so that you can paste it into the secret in the next step.

3. Create a Kubernetes secret to contain the certificate.
 - a. Create a file called analytics_certs.yaml.
The method for defining the certificate in the secret depends on whether you are using a PEM file or JKS file.

- JKS file: In the **data** section of the secret, paste the encoded output from step 2 as shown:

```

apiVersion: v1
kind: Secret
metadata:
  name: offload-certificates
data:
  keystore.jks: "<encoded JKS string>"

```

- PEM file: In the **stringData** section of the secret, type a name for the key or certificate (you can choose the name), and paste the contents of the PEM file.

```

apiVersion: v1
kind: Secret
metadata:
  name: offload-certificates
stringData:
  cacert.pem: |-
    -----BEGIN CERTIFICATE-----
    MIIDIDCCAomgAwIBAgIENd70zzANBgkqhkiG9w0BAQUFADBOMQswCQYDVQGEwJVUzEQMA4GA1UE

BIZCe/zuf6IWUrVnZ9NA2zsmWLIodz2uFHdh1voqZiegDfqnclzqcPGUIWVEX/z87yloqaKHee95
70+sB3c4
-----END CERTIFICATE-----

```

You can add multiple certificates, and can set the names to what you want.

Note: Kubernetes, OpenShift, and Cloud Pak for Integration users: For each key included in `analytics_certs.yaml`, a file based on the corresponding key name is created in the ingestion pod container at `/etc/velox/external_certs/offload`. The examples here would result in the files `keystore.jks` and `cacert.pem`.

b. Save the file.

4. Optional: Create a password secret.

If you have sensitive data such as a certificate password that must be available in text format, you can store it in another secret.

If your password is not sensitive (such as the JKS default password), then you can supply it directly in the Logstash configuration, and skip this step.

a. Create a file called `offload_env_var.yaml`.

b. In the `stringData` section, set the property `jks_password.txt` to your password (in plain text):

```

apiVersion: v1
kind: Secret
metadata:
  name: offload-jks-password
stringData:
  jks_password.txt: <password>

```

c. Run the following command:

```
kubectl apply -f offload_env_var.yaml -n <namespace>
```

VMware users can omit the `-n <namespace>`.

5. Apply the secret to the cluster where the analytics subsystem is installed.

Run the following command to update the cluster:

```
kubectl apply -f analytics_certs.yaml -n <namespace>
```

VMware users can omit the `-n <namespace>`.

6. Add the secret (and password secret if you created one) to the offload section in your `analytics-extra-values.yaml`

a. Edit the `analytics-extra-values.yaml` file, and add the secrets:

```

offload:
  enabled: true
  output: |
    kafka {
      ...
    }
  secretName: offload-certificates
  passwordSecretName: offload-jks-password

```

b. Ensure that your `extra-values-file` property is set to point to your `analytics-extra-values.yaml` file:

```
apicup subsys set <analytics subsystem> extra-values-file analytics-extra-values.yaml
```

c. Apply the `analytics-extra-values.yaml` to your analytics subsystem:

```
apicup subsys install <analytics subsystem>
```

Disabling internal storage

Update the `analytics-extra-values.yaml` file to offload all data and disable local storage in your API Connect analytics deployment.

About this task

For information about disabling internal storage in your Analytics deployment, see [Planning to disable internal storage](#).

Warning: It is not possible to enable internal storage after installation. If you install with internal storage disabled and then decide you want to enable it, you will need to reinstall the analytics subsystem.

Procedure

1. Required: Configure data offloading as explained in [Offloading data to a third-party system](#). The analytics subsystem will not start if storage is disabled and offloading not configured.
2. Open the `analytics-extra-values.yaml` file for editing.
3. Add the `storage` section as shown in the following example:

```

storage:
  enabled: false

```

4. Save the file.

What to do next

If you do not want to add any more configuration options, skip to the topic on [Deploying the Analytics subsystem](#).

Otherwise, continue adding configuration options to the file as explained in the following topics.

Modifying your analytics data

Update the `analytics-extra-values.yaml` file to customize data in your API Connect Analytics deployment.

Before you begin

Review the use of filters for modifying analytics data, and make sure that you understand the restrictions. For information about customizing data, see [Planning to modify your incoming analytics data](#).

About this task

You can define filters that add, modify, or remove fields from incoming API event records.

Procedure

1. Open the `analytics-extra-values.yaml` file for editing.

Remember: All additions to the file must appear after the `spec:` statement.

2. Add a `filter` definition.

Filters for API events that are offloaded to an external system are defined in the `external.offload` section. Filters for API events that are stored in the API Connect OpenSearch database are defined in the `ingestion` section. See the following examples:

Ingestion filters - for API event data stored by API Connect

Add the filter definition to the `ingestion` section:

```
spec:
  ingestion:
    ...
    filter: |
      mutate {
        remove_field => ["query_string"]
      }
```

Offload filters - for API event data that is sent to a third-party system.

Add the filter definition to the `external.offload` section:

```
spec:
  external:
    offload:
      filter: |
        mutate {
          remove_field => ["query_string"]
        }
```

For more example filters, see [Sample filters for modifying analytics data](#).

3. Optional: Include geoIP fields in your analytics data, for both stored and offloaded data, by inserting `geoIPEnabled: true` in the ingestion section:

```
ingestion:
  ...
  geoIPEnabled: true
```

By default the `client_geoip` and `gateway_geoip` fields are not included in the analytics data. You do not need to add `geoIPEnabled` to the `external.offload` section. Enabling geoIP in the `ingestion` section enables it for both data routes.

Note: To ensure the value in the `client_geoip` field is accurate, the gateway must receive the `X-Forwarded-For` header in all API calls. Check with the administrator of your deployment environment to ensure that the `X-Forwarded-For` header is passed to your gateways. For example, in a Kubernetes environment where NINGX ingresses are used, configure the NGINX ingress that is used by your gateway to use the `X-Forwarded-For` header: [NGINX Configuration "use-forwarded-headers"](#).

4. Save the file.

What to do next

If there are no more features you want to configure in the extra-values file, proceed to deployment of the OVA: [Deploying the Analytics subsystem](#).

- [Sample filters for modifying analytics data](#)

Review sample filters to see how to code your own filters for refining API Connect Analytics data by adding fields, removing fields, or modifying field contents.

Sample filters for modifying analytics data

Review sample filters to see how to code your own filters for refining API Connect Analytics data by adding fields, removing fields, or modifying field contents.

You can use these sample filters in the `ingestion.filter` and the `external.offload.filter` configurations.

Adding a new field

You can add custom data to API event data by adding a field to the logging document. For example, if you want to search or visualize data that is stored in request and response headers, you can add fields to a filter to include that information.

To avoid naming conflicts with future or current analytics fields, include a prefix that ensures your new field name is unique. For example, instead of naming the field `employee_num` you might name it `x_mycompany_employee_num`.

The following example copies the contents of the `X-Employee-Num` field from the request header and adds it to the `x_mycompany_employee_num` field in the event data. Adding the field to the event data enables you to use the information in visualizations.

```
if [request_http_headers] {
  ruby {
    code => "event.get(['request_http_headers']).collect {|i| event.set(['x_mycompany_employee_num'], i['X-Employee-Num']) if i.has_key?('X-Employee-Num')}"
  }
}
```

Modifying an existing field

Sometimes you don't want to remove a field entirely from your data, you just want to redact sensitive information such as IDs to prevent them from being exposed in visualizations. You can modify the contents of a field and replace information with a symbols or a message.

Remember: The following fields should not be modified if the data is being written to internal analytics storage: `org_id`, `catalog_id`, `space_id`, `developer_org_id`, `datetime`, and `@timestamp`.

The following example replaces sensitive information in the `X-Employee-Name` and `X-Employee-ID` request headers with the string: `*****sanitized*****`.

```
if [request_http_headers] {
  ruby {
    code => "headers=['X-Employee-Name', 'X-Employee-ID']; newHeaders = event.get(['request_http_headers']).collect {|i| headers.each {|header| i[header] = '*****sanitized*****' if i.has_key?(header)}; i}; event.set(['request_http_headers'], newHeaders)"
  }
}
```

Removing an existing field

Use the mutate `remove_field` operation to delete a field from the Analytics data. To remove multiple fields, delimit the field names with commas.

The following example removes multiple fields (`request_http_headers`, `response_http_headers`, `request_body`, `response_body`, and `query_string`) from the Analytics data:

```
mutate {
  remove_field => ["request_http_headers", "response_http_headers", "request_body", "response_body", "query_string"]
}
```

Filter and output plugin for splunk

When you create a filter for use with splunk, you must also create an output plugin for it.

Filter:

```
if "apicapievent" in [tags] {
  ruby {
    code => "event.set(['@metadata][newevent]', event.to_json)"
  }
}
```

Output plugin:

```
http {
  url => "http://your-domain/services/collector/event"
  http_method => "post"
  codec => "json"
  content_type => "application/json"
  id => "offload_http"
  format => "message"
  message => '{"event": "%{[@metadata][newevent]}", "index": "applications-int-ms", "sourcetype": "json:apimlogs"}'
  headers => ["Authorization", "Splunk XXXX"]
}
```

Deploying the Analytics subsystem

Define your analytics subsystem, create an ISO file for each analytics node, and deploy the analytics nodes using the Analytics OVA file on a VMware virtual server.

Before you begin

Before you deploy:

- Review the [Deployment requirements on VMware](#).
- Review the [API Connect configuration on VMware](#).
- Review [What's new for v10 installation](#)
- For information on deploying a cluster, see [Configuring API Connect subsystems in a cluster](#)
- If you are upgrading from a previous version, see [Upgrading API Connect](#).

About this task

You must deploy the API Connect OVA template to create each Analytics virtual server that you want in your cloud.

- [Configuring the Analytics subsystem](#)
Specify configuration properties for your Analytics subsystem, and create the ISO files.
- [Deploying the Analytics subsystem OVA file](#)
After you have specified configuration settings and created your ISO files, deploy the subsystem OVA into an appliance VM.
- [Verifying deployment of the Analytics subsystem](#)
Verify that deployment of the Analytics OVA file succeeded.

Configuring the Analytics subsystem

Specify configuration properties for your Analytics subsystem, and create the ISO files.

Before you begin

Review the requirements. See [Deploying the Analytics subsystem](#).

About this task

Use the `apicup` installation utility to specify configuration settings for your Analytics subsystem.

Procedure

1. Ensure that you obtained the distribution file and have a project directory, as described in [First steps for deploying in a VMware environment](#).
2. Change to the project directory.

```
cd myProject
```

3. Create an analytics subsystem.

```
apicup subsys create analyt analytics
```

Where:

- `analyt` is the name of the analytics server that you are creating. You can assign it any name, as long as the identifier consists of lowercase alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character.
- `analytics` indicates that you want it to create an Analytics subsystem.

The `apiconnect-up-v10.yml` file that is in that directory is updated to add the analytics-related entries.

Tip: At any time, you can view the current analytics subsystem values in the `apiconnect-up-v10.yml` by running the `apicup get` command:

```
apicup subsys get analyt
```

If you have not updated the value, a default value is listed, if there is one that is available.

Sample output from `apicup subsys`

get:

```
Appliance settings
=====
Name          Value          Description
----          -
additional-cloud-init-file
data-device   sdb            (Optional) Path to additional cloud-init yml file
default-password
must be pre-hashed
dns-servers   []            (Optional) Path to additional configuration yml file
extra-values-file
k8s-pod-network 172.16.0.0/16 (Optional) CIDR for pods within the appliance
k8s-service-network 172.17.0.0/16 (Optional) CIDR for services within the appliance
public-iface  eth0          Device for API/UI traffic (Eg: eth0)
search-domain []            List for DNS search domains
ssh-keyfiles  []            List of SSH public keys files
traffic-iface eth0          Device for cluster traffic (Eg: eth0)

Subsystem settings
=====
Name          Value          Description
----          -
analytics-backup-auth-pass (Optional) Server password for analytics backups
analytics-backup-auth-user (Optional) Server username for analytics backups
analytics-backup-certs (Optional) Backup certs which are used for TLS communication
between APIC and backup server. Currently only supported for s3 backups.
analytics-backup-chunk-size 1GB          analytics-backup-chunk-size
analytics-backup-host (Optional) FQDN for analytics backups server
analytics-backup-path (Optional) path for analytics backups server
analytics-backup-schedule 0 0 * * * (Optional) Cron schedule for analytics backups
analytics-enable-compression true          (Optional) Determines whether metadata files are stored in
compressed format
analytics-enable-server-side-encryption false        (Optional) Determines whether files are encrypted. When set to
true, files are encrypted on the server side using AES256
```

deployment-profile (n1xc2.m16/n1xc4.m16/n3xc2.m16/n3xc4.m16) license-use	n1xc2.m16 nonproduction	Deployment profile (n1xc2.m16/n3xc4.m16) for analytics, (n1xc2.m8/n1xc4.m16/n1xc8.m16/n3xc4.m8/n3xc8.m16) for portal License use (production/nonproduction)
--	----------------------------	---

Endpoints
=====

Name	Value	Description
analytics-ingestion		FQDN of Analytics ingestion endpoint

4. Specify your **deployment-profile**.

```
apicup subsys set analyt deployment-profile=profile_type
```

Use one of the following values for the **profile_type**, based on the decision you made while [Planning the Analytics deployment profile](#).

For example, to deploy with a three replica profile, run the following command:

```
apicup subsys set analyt deployment-profile=n3xc4.m16
```

Note: The deployment profiles that are shown in the **Description** column of the **apicup get** output are not correct. The available profiles are documented in [Planning your deployment topology and profiles](#).

5. Specify the license use that you purchased.

```
apicup subsys set analyt license-use=license_type
```

The **license_type** must be either **production** or **nonproduction**. If not specified, the default value is **nonproduction**.

6. Optional: Configure backups of the subsystem. Follow the instructions in [Backing up and restoring the Analytics database on VMware](#).

Important: It is highly recommend that you configure backups and also take additional steps to ensure that your configuration and data can be restored in the event of a disaster event. See [Preparing the Analytics subsystem for disaster recovery on VMware](#).

7. Optional: Configure your logging.

Logging can be configured at a later time, but you must enable it before installation to capture the log events from the installation.

- Complete the procedure at [Configuring remote logging for a VMware deployment](#).
- Enter the following command to create the log file:

```
apicup subsys set analyt additional-cloud-init-file=config_file.yml
```

8. Set your ingestion endpoint.

```
apicup subsys set analyt analytics-ingestion=unique_hostname.domain
```

The ingestion endpoint must be a unique host name that points to the IP address of the OVA (single node deployment), or to the IP of a load balancer configured in front of the OVA nodes. You will use the ingestion endpoint when registering the analytics service in the Cloud Manager UI.

9. Set your search domain. Multiple search domains should be separated by commas.

```
apicup subsys set analyt search-domain=your_search_domain
```

Where *your_search_domain* is the domain of your servers, entered in all lowercase. Setting this value ensures that your searches also append these values, which are based on your company's DNS resolution, at the end of the search value. A sample search domain is *mycompany.example.com*.

Ensure that the value for *your_search_domain* is resolved in the system's */etc/resolv.conf* file to avoid "502" errors when accessing the Cloud Manager web site. For example:

```
# Generated by resolvconf
search your_search_domain ibm.com other.domain.com
```

10. Set your domain name servers (DNS).

Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

```
apicup subsys set analyt dns-servers=ip_address_of_dns_server
```

DNS entries may not be changed on a cluster after the initial installation.

11. Set a Public key.

```
apicup subsys set analyt ssh-keyfiles=path_to_public_ssh_keyfile
```

Setting this key enables you to use **ssh** with this key to log in to the virtual machine to check the status of the installation. You will perform this check later in [Verifying deployment of the Analytics subsystem](#).

12. You can set the password that you enter to log into your Analytics server for the first time.

- Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).
- If you do not have a password hashing utility, install one.

Operating system	Command
Ubuntu, Debian, OSX	If the mkpasswd command utility is not available, download and install it. (You can also use a different password hashing utility.) On OSX, use the command: gem install mkpasswd .
Windows, Red Hat	If necessary, a password hashing utility for the Windows operating system, like OpenSSL

c. Create a hashed password

Operating system	Command
Ubuntu, Debian, OSX	mkpasswd --method=sha-512 --rounds=4096 password

Operating system	Command
Windows, Red Hat	For example, using OpenSSL: <code>openssl passwd -1 password</code> . Note that you might need to add your password hashing utility to your path; for example, on Windows: <code>set PATH=c:\cygwin64\bin;%PATH%</code>

d. Set the hashed password for your subsystem:

```
apicup subsys set analyt default-password='hashed_password'
```

Notes:

- The password is hashed. If it is in plain text, you cannot log into the VMWare console.
- Note that the password can only be used to login through the VMware console. You cannot use it to SSH into the Appliance as an alternative to using the `ssh-keyfiles`.
- On Linux or OSX, use single quotes around `hashed_password`. For Windows, use double quotes.
- If you are using a non-English keyboard, understand the limitations with using the remote VMWare console. See [Requirements for initial deployment on VMWare](#).

13. Optional: If the default IP ranges for the API Connect Kubernetes pod and the service networks conflict with IP addresses that must be used by other processes in your deployment, modify the API Connect values.

You can change the IP ranges of the Kubernetes pod and the service networks from the default values of 172.16.0.0/16 and 172.17.0.0/16, respectively. In the case that a /16 subnet overlaps with existing IPs on the network, a Classless Inter-Domain Routing (CIDR) as small as /22 is acceptable. You can modify these ranges during initial installation and configuration only. You cannot modify them once an appliance has been deployed. See [API Connect configuration on VMWare](#).

a. Update the IP range for the Kubernetes pod

```
apicup subsys set analyt k8s-pod-network='new_pod_range'
```

Where `new_pod_range` is the new value for the range.

b. Update the IP range for Service networks.

```
apicup subsys set analyt k8s-service-network='new_service_range'
```

Where `new_service_range` is the new value for the range.

14. Define the hostname for each subsystem node you are deploying:

```
apicup hosts create analyt hostname.domainname hd_password
```

Where the following are true:

- `hostname.domainname` is the fully qualified name of the server where you are hosting your Analytics service, including the domain information.
- `hd_password` is the password of the Linux Unified Key Setup uses to encrypt the storage for your Analytics service. This password is hashed when it is stored on the server or in the ISO. Note that the password is base64 encoded when stored in `apiconnect-up-v10.yml`.

Repeat this command for each subsystem VM in your deployment. For example, if you are deploying a single node one replica profile then do this once, for a three replica profile you will define three VMs.

Note: Host names and DNS entries may not be changed on a cluster after the initial installation.

15. Define the network interface for each subsystem node you are deploying:

```
apicup iface create analyt hostname.domainname physical_network_id host_ip_address/subnet_mask gateway_ip_address
```

Where `physical_network_id` is the network interface ID of your physical server. The value is most often `eth0`. The value can also be `ethx`, where `x` is a number identifier.

The format is similar to this example: `apicup iface create analyt myHostname.domain eth0 192.0.2.1/255.255.1.1 192.0.2.1`

Repeat this command for each subsystem VM in your deployment. For example, if you are deploying a single node one replica profile then do this once, for a three replica profile you will define three VMs.

16. Optional: Use `apicup` to view the configured hosts:

```
apicup hosts list analyt
testsrv0233.subnet1.example.com
  Device IP/Mask Gateway
  eth0 1.2.152.233/255.255.254.0 1.2.152.1
```

17. Optional: Enable JWT security instead of mTLS for communication from management and gateway to your analytics subsystem.

JWT security provides application layer security and can be used instead of mTLS when there are load-balancers located between subsystems that require TLS termination. For more information about JWT security, see [Enable JWT instead of mTLS](#).

To enable JWT and disable mTLS, first identify the JWKS URL from the management subsystem:

```
apicup subsys get <management subsystem>
...
jwks-url https://appliance1.apic.acme.com/api/cloud/oauth2/certs JWKS URL for Portal and Analytics subsystems to
validate JWT -- this is unsettable and is generated based on the platform-api endpoint
...
```

Disable mTLS and enable JWT by setting the `jwks-url` with `apicup`:

```
apicup subsys set analyt mtls-validate-client=false
apicup subsys set analyt jwks-url=https://appliance1.apic.acme.com/api/cloud/oauth2/certs
```

JWT for gateway to analytics communication requires an additional step during gateway registration. Enable the Use JWT switch when you register the gateway in the Cloud Manager UI.

Note: Do not disable mTLS without enabling JWT.

18. Verify that the configuration settings are valid.

```
apicup subsys get analyt --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting. See the following sample output.

```
apicup subsys get analyt --validate
```

Appliance settings

```

19. If you configured additional deployment options in an extra-values file, run the following command to make the file available during installation:

```
apicup subsys set analyt extra-values-file path/analytcs-extra-values.yaml
```

where `analytics-extra-values.yaml` is the name of the file containing your deployment settings.

20. Create your ISO files:

```
apicup subsys install analyt --out analytplan-out
```

The `--out` parameter and value are required. In this example, the ISO files are created in the `myProject/analytplan-out` directory.

There will be one ISO file for each VM host you defined in step 14.

If the system cannot find the path to your software that creates ISO files, create a path setting to that software by running a command similar to the following command:

Operating system	Command
Ubuntu, Debian, OSX	<code>export PATH=\$PATH:/Users/your_path/</code>
Windows, Red Hat	<code>set PATH="c:\Program Files (x86)\cdrtools";%PATH%</code>

21. Continue with [Deploying the Analytics subsystem OVA file](#).

Deploying the Analytics subsystem OVA file

After you have specified configuration settings and created your ISO files, deploy the subsystem OVA into an appliance VM.

About this task

Repeat this procedure for each analytics VM you are deploying. Use the ISO files created in [Configuring the Analytics subsystem](#).

Procedure

- Log into the VMWare vSphere Web Client.
- Using the VSphere Navigator, navigate to the directory where you are deploying the OVA file.
- Right-click the directory and select Deploy OVF Template.
- Complete the Deploy OVF Template wizard.
 - Select the Analytics subsystem .OVA file template by navigating to the location where you downloaded the file in [First steps for deploying in a VMware environment](#).

- b. Enter a name and location for your file.
- c. Select a resource for your template.
- d. Review the details for your template.
- e. Select the size of your configuration.
- f. Select the storage settings.

Note: Ensure you specify a storage size large enough for your estimated analytics data usage: [Estimating internal storage space](#)

- g. Select the networks.
- h. Customize the Template, if necessary.
- i. Review the details to ensure that they are correct.
- j. Select Finish to deploy the virtual machine.

Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See [Requirements for initial deployment on VMware](#).

The template creation appears in your Recent Tasks list.

5. Select the Storage tab in the Navigator.
6. Navigate to your datastore.
7. Upload your ISO file.
 - a. Select the Navigate to the datastore file browser icon in the icon menu.
 - b. Select the Upload a file to the Datastore icon in the icon menu.
 - c. Navigate to the ISO file that you created in your project.
It is the myProject/*analytplan-out*
 - d. Upload the ISO file to the datastore.
8. Leave the datastore by selecting the VMs and Templates icon in the Navigator.
9. Locate and select your virtual machine.
10. Select the Configure tab in the main window.
11. Select Edit....
 - a. On the Virtual Hardware tab, select CD/DVD Drive 1.
 - b. For the Client Device, select Datastore ISO File.
 - c. Find and select your datastore in the Datastores category.
 - d. Find and select your ISO file in the Contents category.
 - e. Select OK to commit your selection and exit the Select File window.
 - f. Ensure that the Connect At Power On check box is selected.

Tip:

- Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
- Note that VMware related issues with ISO mounting at boot may occur if Connect At Power On

- g. Select OK to commit your selection and close the window.

12. Start the virtual machine by selecting the play button on the icon bar.

The installation might take several minutes to complete, depending on the availability of the system and the download speed.

13. Next, verify the deployment. Continue with [Verifying deployment of the Analytics subsystem](#).

Verifying deployment of the Analytics subsystem

Verify that deployment of the Analytics OVA file succeeded.

Before you begin

You must have completed [Deploying the Analytics subsystem OVA file](#).

About this task

After you configure an ISO and deploy it with the Analytics subsystem OVA, as described in [Deploying the Analytics subsystem OVA file](#), verify that the subsystem installed correctly and is functional.

Procedure

1. Log in to the virtual machine by using an SSH tool to check the status of the installation:
 - a. Enter the following command to connect to *analyt* using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.

- b. Select Yes to continue connecting.
Your host names are automatically added to your list of hosts.
- c. Run the **apic status** command to verify that the installation completed and the system is running correctly.
The command output for a correctly running Analytics system is similar to the following:

```
#sudo apic status
INFO[0000] Log level: info

Cluster members:
- apimdev0239.subnet1.example.com (9.20.152.239)

2. If you have now installed all subsystems, continue to [Post-deployment steps](#).

Deploying the Developer Portal virtual appliance

You create a Developer Portal node by deploying the Developer Portal OVA template. After you deploy the Developer Portal OVA template, you can install the Developer Portal.

Before you begin

Before you deploy:

- Review the [Deployment requirements on VMware](#).
- Review the [API Connect configuration on VMware](#).
- Review [What's new for v10 installation](#)
- For information on deploying a cluster, see [Configuring API Connect subsystems in a cluster](#)
- If you are upgrading from a previous version, see [Upgrading API Connect](#).

Note:

Ensure that your kernel or Kubernetes node has the value of its `inotify` watches set high enough so that the Developer Portal can monitor and maintain the files for each Developer Portal site. If set too low, the Developer Portal containers might fail to start or go into a `non-ready` state when this limit is reached. If you have many Developer Portal sites, or if your sites contain a lot of content, for example, many custom modules and themes, then a larger number of `inotify` watches are required. You can start with a value of 65,000, but for large deployments, this value might need to go up as high as 1,000,000. The Developer Portal containers take `inotify` watches only when they need them. The full number is not reserved or held, so it is acceptable to set this value high.

About this task

You must deploy the Developer Portal OVA template to create each Developer Portal node that you want in your cloud. Each node has a separate CLI password account that is required to log in through a Secure Shell (SSH) to complete specific administrative actions for only that node.

Important deployment information for Developer Portal:

- You must deploy the Developer Portal OVA template by using a version of the VMware vSphere Client that supports the SHA-512 Cryptographic Hash Algorithm.
- The Developer Portal node is initially configured with a default password of `7iron-hide`, with the user name of `admin`. For security reasons, change the default password by completing one of the following actions:
 - During deployment, if the feature is available in your VMware instance, enter a new password. If you specify a password during deployment, the password for the Developer Portal command line interface (CLI) is modified. Use the new password when you log into the CLI. You cannot modify the admin user name for the CLI.
 - After deployment, log in to the CLI for each virtual appliance and run the command to change the default password for that specific node. The CLI command is `passwd`.

Note that this console uses a US keyboard configuration, in which the @ symbol can be in a different place to other keyboard configurations. If you are not using a US keyboard, ensure that you typed the password correctly.

- Only static IP addresses that are specified during the **apicup** project configuration before the installation of the OVAs are supported.
- To enable effective high availability for your Portal service, you need a latency that is less than 50ms between all OVAs to avoid the risk of performance degradation. Servers with uniform specifications are required, as any write actions occur at the speed of the slowest OVA, as the write actions are synchronous across the cluster of OVAs. It is recommended that there are three servers in each cluster of OVAs for the high availability configuration. The three servers can be situated in the same data center, or across three data centers to ensure the best availability. However, you can configure high availability with two data centers.

Procedure

Complete the following steps in order:

Note: The following steps apply to VMware only. Depending on the VMware version that you are using, some of the steps might vary. For example, you might not be able to change the user name and password during deployment.

1. Specify configuration settings for the Developer Portal subsystem and create an ISO. See [Configuring the Developer Portal subsystem](#)
2. Deploy the subsystem OVA into an appliance VM. See [Deploying the Developer Portal subsystem OVA file](#).
3. Verify the deployment. See [Verifying deployment of the Developer Portal subsystem](#)
4. Optional: Define multiple Developer Portal endpoints. See [Defining multiple portal endpoints for a VMware environment](#)

What to do next

If you want to deploy an API Connect Analytics OVA file, continue with [Deploying the Analytics subsystem](#).

If you did not specify a new password during deployment in VMware, then after deployment, log in to the command-line interface (CLI) for each appliance and run the command **passwd** to change the password.

- [Configuring the Developer Portal subsystem](#)
Specify configuration properties for your Developer Portal subsystem, and create an ISO.
- [Deploying the Developer Portal subsystem OVA file](#)
After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.
- [Verifying deployment of the Developer Portal subsystem](#)
Verify that deployment of the Developer Portal OVA file succeeded.
- [Configuring two NICs on the Developer Portal](#)
Configure the Developer Portal to use two network interface cards.
- [Specifying a range of allowable client IP addresses for Developer Portal](#)
Specify the range of client IP addresses to be allowed in a deployment of the Developer Portal
- [Defining multiple portal endpoints for a VMware environment](#)
Multiple public facing endpoints (**portal-*www***) can be defined for the Developer Portal.

Configuring the Developer Portal subsystem

Specify configuration properties for your Developer Portal subsystem, and create an ISO.

Before you begin

Review the requirements and important deployment information for Developer Portal. See [Deploying the Developer Portal virtual appliance](#).

About this task

Use the **apicup** installation utility to specify configuration settings for your Developer Portal subsystem.

Procedure

1. Ensure that you obtained the distribution file and have a project directory, as described in [First steps for deploying in a VMware environment](#).
2. Change to the project directory.

```
cd myProject
```

3. Create a portal subsystem.

```
apicup subsys create port portal
```

Where:

- *port* is the name of the Developer Portal server that you are creating. You can assign it any name, as long as the identifier consists of lowercase alphanumeric characters or '-', with no spaces, starts with an alphabetic character, and ends with an alphanumeric character.
- **portal** indicates that you want it to create a Developer Portal microservice.

Note: Unless you are installing a two data center deployment, leave **multi-site-ha-enabled** as false, and ignore **multi-site-ha-mode**, **replication-peer-fqdn**, **site-name**, and the **portal-replication** endpoint, as these options are all related to that feature. For more information, see [Installing a two data center deployment on VMware](#).

The apiconnect-up-v10.yml file that is in that directory is updated to add the portal-related entries.

Tip: At any time, you can view the current developer portal subsystem values in the apiconnect-up-v10.yml by running the **apicup get** command:

```
apicup subsys get port
```

If you have not yet configured the subsystem, the command might return errors. Also, if you have not updated the value, a default value is listed, if there is one that is available.

After configuration is complete, you can view output similar to the following sample:

Appliance settings

=====

Name	Value
Description	
-----	-----

additional-cloud-init-file	
(Optional) Path to additional cloud-init yml file	
data-device	sdb
VM disk device (usually `sdb` for SCSI or `vdb` for VirtIO)	
default-password	\$6\$rounds=4096\$vtcqpAVK\$dzqrOeYP33WTvTug38Q4Rld518TmdQgezzTnkX/PFwkzTiZ2S0CqNRr1S4b08tOc4p.OEg4BtzBe/r8RAk.gW/
(Optional) Console login password for `apicadm` user, password must be pre-hashed	
dns-servers	[192.168.1.201]
List of DNS servers	
extra-values-file	
(Optional) Path to additional configuration yml file	
k8s-pod-network	172.16.0.0/16
(Optional) CIDR for pods within the appliance	
k8s-service-network	172.17.0.0/16
(Optional) CIDR for services within the appliance	
public-iface	eth0
Device for API/UI traffic (Eg: eth0)	
search-domain	[subnet1.example.com]
List for DNS search domains	
ssh-keyfiles	[/home/vsphere/.ssh/id_rsa.pub]
List of SSH public keys files	
traffic-iface	eth0
Device for cluster traffic (Eg: eth0)	

Subsystem settings

=====

Name	Value
Description	
-----	-----

deployment-profile	n1xc2.m8
Deployment profile (n1xc2.m16/n3xc4.m16) for analytics, (n1xc4.m16/n3xc4.m16) for management, (n1xc2.m8/n3xc4.m8) for portal	
license-use	nonproduction
License use (production/nonproduction)	
multi-site-ha-enabled	false
Multi site HA enabled	
multi-site-ha-mode	active
Multi site HA mode (active/passive)	
replication-peer-fqdn	
Replication peer fully qualified name (replication endpoint of active mode site)	
site-name	
Site name, used in k8s resource names	

Endpoints

=====

Name	Value
Description	
-----	-----

portal-admin	portal-api.example.com
FQDN of Portal admin endpoint	
portal-replication	
FQDN of Portal replication endpoint, only required if HA is enabled	
portal-www	portal-www.example.com
FQDN of Portal web endpoint	

4. Specify deployment-profile.

```
apicup subsys set port deployment-profile=n3xc4.m8
```

The `deployment-profile` parameter indicates that you are deploying a three replica or one replica environment. For more information, see [Planning your deployment topology and profiles](#).

Note: The deployment profiles that are shown in the `Description` column of the `apicup get` output are not correct. The available profiles are documented in [Planning your deployment topology and profiles](#).

5. Specify the license version you purchased.

```
apicup subsys set port  
license-use=<license_type>
```

The `license_type` must be either `production` or `nonproduction`. If not specified, the default value is `nonproduction`.

6. Optional: Configure scheduled backups of the subsystem. This step is optional but is recommended.

Refer to the instructions in [Backing up and restoring the Developer Portal](#).

7. Optional: Configure your logging.

Logging can be configured at a later time, but you must enable it before installation to capture the log events from the installation.

- Complete the procedure at [Configuring remote logging for a VMware deployment](#).
- Enter the following command to create the log file:

```
apicup subsys set port additional-cloud-init-file=config_file.yml
```

8. Enter the following commands to update the apiconnect-up-v10.yml with the information for your environment:

- a. Use **apicup** to set your endpoints.
You can use wildcard aliases or host aliases with your endpoints.
Optionally, you can specify all endpoints with one **apicup** command.

Note: You cannot specify the underscore character "_" in domain names that are used in endpoints. See [API Connect configuration on VMware](#).
The endpoints must be unique hostnames which both point to the IP address of the OVA (single node deployment), or to the IP of a load balancer configured in front of the OVA nodes. See examples in the sample output in step 3.

Setting	Endpoint host description
portal-admin	This is the <i>unique_hostname</i> for communication between your Cloud Manager and API Manager, and your Developer Portal. The values for the portal-admin and portal-www must be different. <code>apicup subsys set port portal-admin=<i>unique_hostname.domain</i></code>
portal-www	This is the <i>unique_hostname</i> for the Developer Portal Internet site that is created for the Developer Portal. Multiple portal-www endpoints may be configured, as described here: Defining multiple portal endpoints for a VMware environment . <code>apicup subsys set port portal-www=<i>unique_hostname.domain</i></code>

- b. Set your search domain. Multiple search domains should be separated by commas.

```
apicup subsys set port search-domain=your_search_domain
```

Where *your_search_domain* is the domain of your servers, entered in all lowercase. Setting this value ensures that your searches also append these values, which are based on your company's DNS resolution, at the end of the search value. A sample search domain is *mycompany.example.com*.

Ensure that the value for *your_search_domain* is resolved in the system's /etc/resolv.conf file to avoid "502" errors when accessing the Cloud Manager web site. For example:

```
# Generated by resolvconf
search your_search_domain ibm.com other.domain.com
```

- c. Set your domain name servers (DNS).

Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

```
apicup subsys set port dns-servers=ip_address_of_dns_server[,ip_address_of_another_dns_server_if_necessary]
```

DNS entries may not be changed on a cluster after the initial installation.

9. Set a Public key.

```
apicup subsys set port ssh-keyfiles=path_to_public_ssh_keyfile
```

Setting this key enables you to use **ssh** with this key to log in to the virtual machine to check the status of the installation. You will perform this check in [Verifying deployment of the Developer Portal subsystem](#).

- 10. If there are multiple Management subsystems in the same project, set the Portal subsystem's **platform-api** and **consumer-api** certificates to match those used by the appropriate Management subsystem to ensure that the Portal subsystem is correctly associated with that Management subsystem. This step only applies if you installed more than one Management subsystem into a single project.

A Portal subsystem can be associated with only one Management subsystem. To associate the new Portal subsystem with the appropriate Management subsystem, manually set the **mgmt-platform-api** and **mgmt-consumer-api** certificates to match the ones used by the Management subsystem.

- a. Run the following commands to get the certificates from the Management subsystem:

```
apicup certs get mgmt-subsystem-name platform-api -t cert > platform-api.crt
apicup certs get mgmt-subsystem-name platform-api -t key > platform-api.key
apicup certs get mgmt-subsystem-name platform-api -t ca > platform-api-ca.crt

apicup certs get mgmt-subsystem-name consumer-api -t cert > consumer-api.crt
apicup certs get mgmt-subsystem-name consumer-api -t key > consumer-api.key
apicup certs get mgmt-subsystem-name consumer-api -t ca > consumer-api-ca.crt
```

where *mgmt-subsystem-name* is the name of the specific Management subsystem that you want to associate the new Portal subsystem with.

- b. Run the following commands to set the Portal's certificates to match those used by the Management subsystem:

```
apicup certs set ptl-subsystem-name mgmt-platform-api Cert_file_path Key_file_path CA_file_path
apicup certs set ptl-subsystem-name mgmt-consumer-api Cert_file_path Key_file_path CA_file_path
```

For more information on **apicup** certificate commands, see [Command reference](#).

11. You can set a hashed password that you enter to log in to your Developer Portal server for the first time.

- a. **Important:** Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).
- b. If you do not have a password hashing utility, install one.

Operating system	Command
Ubuntu, Debian, OSX	If the mkpasswd command utility is not available, download and install it. (You can also use a different password hashing utility.) On OSX, use the command: gem install mkpasswd .
Windows, Red Hat	If necessary, a password hashing utility for the Windows operating system, like OpenSSL

- c. Create a hashed password

Operating system	Command
Ubuntu, Debian, OSX	mkpasswd --method=sha-512 --rounds=4096 <i>password</i>

Operating system	Command
Windows, Red Hat	For example, using OpenSSL: <code>openssl passwd -1 password</code> . Note that you might need to add your password hashing utility to your path; for example, on Windows: <code>set PATH=c:\cygwin64\bin;%PATH%</code>

d. Set the hashed password for your subsystem:

```
apicup subsys set port default-password="hashed_password"
```

Notes:

- The password is hashed. If it is in plain text, you cannot log into the VMWare console.
- Note that the password can only be used to login through the VMware console. You cannot use it to SSH into the Appliance as an alternative to using the `ssh-keyfiles`.
- On Linux or OSX, use single quotes around `hashed_password`. For Windows, use double quotes.
- If you are using a non-English keyboard, understand the limitations with using the remote VMware console. See [Requirements for initial deployment on VMware](#).

12. Optional: If the default IP ranges for the API Connect Kubernetes pod and the service networks conflict with IP addresses that must be used by other processes in your deployment, modify the API Connect values.

You can change the IP ranges of the Kubernetes pod and the service networks from the default values of 172.16.0.0/16 and 172.17.0.0/16, respectively. In the case that a /16 subnet overlaps with existing IPs on the network, a Classless Inter-Domain Routing (CIDR) as small as /22 is acceptable. You can modify these ranges during initial installation and configuration only. You cannot modify them once an appliance has been deployed. See [API Connect configuration on VMware](#).

a. Update the IP range for the Kubernetes pod

```
apicup subsys set port k8s-pod-network='new_pod_range'
```

Where `new_pod_range` is the new value for the range.

b. Update the IP range for Service networks.

```
apicup subsys set port k8s-service-network='new_service_range'
```

Where `new_service_range` is the new value for the range.

13. Add your hosts.

```
apicup hosts create port hostname.domainname hd_password
```

Where the following are true:

- `hostname.domainname` is the fully qualified name of the server where you are hosting your Developer Portal, including the domain information.
- `hd_password` is the password of the Linux Unified Key Setup uses to encrypt the storage for your Developer Portal. This password is hashed when it is stored on the server or in the ISO. Note that the password is base64 encoded when stored in `apiconnect-up-v10.yml`. Repeat this command for each host that you want to add.

Note: Host names and DNS entries may not be changed on a cluster after the initial installation.

14. Create your interfaces.

```
apicup iface create port hostname.domainname physical_network_id host_ip_address/subnet_mask gateway_ip_address
```

Where `physical_network_id` is the network interface ID of your physical server. The value is most often `eth0`. The value can also be `ethx`, where `x` is a number identifier.

The format is similar to this example: `apicup iface create port myHostname.domain eth0 192.0.2.1/255.255.1.1 192.0.2.1`

Note: You can optionally configure a second network interface (NIC) card for use with Developer Portal. In this scenario, one NIC is used for internal traffic between the Portal and APIM, and the second is used as a public interface. If you are creating multiple network interfaces, each one must be on a different subnet with a different gateway. For information on configuring two NICs for Developer Portal, see [Configuring two NICs on the Developer Portal](#).

15. Optional: You can specify a range of allowable client IP addresses.

You can optionally restrict which IP addresses can access any of the ingresses by creating an allowlist annotation, which then will only allow the specified IP addresses to access the ingress and will deny all other source IP addresses. See [Specifying a range of allowable client IP addresses for Developer Portal](#).

Note: One usage of this restriction is the scenario where you split traffic between your private and public networks in 2 NIC configuration.

16. Optional: Use `apicup` to view the configured hosts:

```
apicup hosts list port
apimdev0232.hursley.ibm.com
Device IP/Mask Gateway
eth0 1.2.152.232/255.255.254.0 1.2.152.1
```

Note: If you are configuring a two data center deployment, continue with the installation instructions in [Installing a two data center deployment on VMware](#).

17. Optional: Enable JWT security instead of mTLS for communication from management to your portal subsystem.

JWT security provides application layer security and can be used instead of mTLS when there are load-balancers located between subsystems that require TLS termination. For more information about JWT security, see [Enable JWT instead of mTLS](#). To enable JWT and disable mTLS, first identify the JWKS URL from the management subsystem:

```
apicup subsys get <management subsystem>
```

```
...
jwks-url https://appliance1.apic.acme.com/api/cloud/oauth2/certs JWKS URL for Portal and Analytics subsystems to
validate JWT -- this is unsettable and is generated based on the platform-api endpoint
...
```

Disable mTLS and enable JWT by setting the `jwks-url` with `apicup`:

```
apicup subsys set port mtls-validate-client=false
apicup subsys set port jwks-url=https://appliance1.apic.acme.com/api/cloud/oauth2/certs
```

Note: Do not disable mTLS without enabling JWT.

18. Leave `multi-site-ha-enabled` set to `false`.
19. Optional: Verify that the configuration settings are valid.

```
apicup subsys get port --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting. See the following sample output.

Appliance settings

20. Create your ISO file.

```
apicup subsys install port --out portplan-out
```

The `--out` parameter and value are required. In this example, the ISO file is created in the `myProject/portplan-out` directory.

If the system cannot find the path to your software that creates ISO files, create a path setting to that software by running a command similar to the following command:

Operating system	Command
Ubuntu, Debian, OSX	<code>export PATH=\$PATH:/Users/your_path/</code>
Windows, Red Hat	<code>set PATH="c:\Program Files (x86)\cdrtools";%PATH%</code>

21. Next, use the ISO to deploy the subsystem OVA. Continue with [Deploying the Developer Portal subsystem OVA file](#).

Deploying the Developer Portal subsystem OVA file

After you have specified configuration settings and created an ISO, deploy the subsystem OVA into an appliance VM.

Before you begin

You must have completed the configuration of the project file entries for the Developer Portal subsystem, in [Configuring the Developer Portal subsystem](#).

Procedure

1. Log into the VMWare vSphere Web Client.
2. Using the VSphere Navigator, navigate to the directory where you are deploying the OVA file.
3. Right-click the directory and select Deploy OVF Template.
4. Complete the Deploy OVF Template wizard.
 - a. Select the Portal subsystem .OVA file template by navigating to the location where you downloaded the file in [First steps for deploying in a VMware environment](#).
 - b. Enter a name and location for your file.
 - c. Select a resource for your template.
 - d. Review the details for your template.
 - e. Select the size of your configuration.
 - f. Select the storage settings.Note that the number of Central Processing Units, RAM, and size of disk that you need for the Developer Portal varies depending on the number of sites that are hosted and the number of concurrent users you expect your site to have:

Table 1. Developer Portal hardware requirements

Number of sites	Number of concurrent users	Number of CPUs	Amount of RAM (GB)	Data Disk Size (GB)++
1	1	2**	4	50
20	5	4	16	70
100	20	8	32	100
100	100	16	64	500

Important:

- ++The data disk size is extra to the main disk of the OVA. The main disk of the OVA is sized at 100GB, and should not be changed. Therefore, the total disk size of the OVA is 100GB plus the data disk size. The default data disk size is 200GB. If you want to select a different value, then you need to do this by using the OVF Tool, or the VMware GUI, before you power on the VM. Note that certain versions of the VMware GUI may not allow you to resize the data disk, and in this case you should use the OVF Tool.
- **The requirement of 2 CPUs is suitable only for proof-of-concept work, and non-high availability deployments. For example, this configuration is suitable for the demo mode of the apicup installation, which is set by using the command `apicup subsys set port deployment-profile=n1xc2.m8`.
- It's not recommended to have more than 100 sites per Developer Portal service. Note that it's not necessary to have a Portal site for every Catalog, for example Catalogs that are only for API Developers don't need a Portal site, as the APIs can be tested by using credentials from the API Manager. If more than 100 sites are required, you should configure additional Developer Portal services; see [Registering a Portal service](#).

- g. Select the networks.
- h. Customize the Template, if necessary.
- i. Review the details to ensure that they are correct.
- j. Select Finish to deploy the virtual machine.

Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See [Requirements for initial deployment on VMware](#).

The template creation appears in your Recent Tasks list.

5. Select the Storage tab in the Navigator.
6. Navigate to your datastore.
7. Upload your ISO file.
 - a. Select the Navigate to the datastore file browser icon in the icon menu.
 - b. Select the Upload a file to the Datastore icon in the icon menu.
 - c. Navigate to the ISO file that you created in your project.

It is the myProject/portplan-out
 - d. Upload the ISO file to the datastore.
8. Leave the datastore by selecting the VMs and Templates icon in the Navigator.
9. Locate and select your virtual machine.
10. Select the Configure tab in the main window.
11. Select Edit...
 - a. On the Virtual Hardware tab, select CD/DVD Drive 1.
 - b. For the Client Device, select Datastore ISO File.
 - c. Find and select your datastore in the Datastores category.
 - d. Find and select your ISO file in the Contents category.
 - e. Select OK to commit your selection and exit the Select File window.
 - f. Ensure that the Connect At Power On check box is selected.Tip:
 - Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
 - Note that VMware related issues with ISO mounting at boot may occur if Connect At Power On
- g. Select OK to commit your selection and close the window.
12. Start the virtual machine by selecting the play button on the icon bar.

The installation might take several minutes to complete, depending on the availability of the system and the download speed.
13. Continue with [Verifying deployment of the Developer Portal subsystem](#).

Verifying deployment of the Developer Portal subsystem

Verify that deployment of the Developer Portal OVA file succeeded.

Before you begin

You must have completed [Deploying the Developer Portal subsystem OVA file](#).

About this task

After you configure an ISO and deploy it with the Developer Portal subsystem OVA, as described in [Deploying the Developer Portal subsystem OVA file](#), verify that the subsystem installed correctly and is functional.

Procedure

1. Log in to the virtual machine by using an SSH tool to check the status of the installation:

- a. Enter the following command to connect to *port* using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.

- b. Select Yes to continue connecting.
Your host names are automatically added to your list of hosts.
- c. Run the **apic status** command to verify that the installation completed and the system is running correctly.
The command output for a correctly running Developer Portal system is similar to the following lines:

```
$ sudo apic status
INFO[0000] Log level: info

Cluster members:
- testsrv1251.subnet1.example.com (1.2.3.4)
  Type: BOOTSTRAP_MASTER
  Install stage: DONE
  Upgrade stage: NONE
  Docker status:
    Systemd unit: running
  Kubernetes status:
    Systemd unit: running
    Kubelet version: testsrv1251 (4.4.0-137-generic) [Kubelet v1.10.6, Proxy v1.10.6]
  Etcd status: pod etcd-testsrv1251 in namespace kube-system has status Running
  Addons: calico, dns, helm, kube-proxy, metrics-server, nginx-ingress,
Etcd cluster state:

Running	kube-system	metrics-server-6fbfb84cdd-hkztz	1/1
Running	kube-system	tiller-deploy-84f4c8bb78-v6k95	1/1
Running			

2. Optional: Define multiple Developer Portal endpoints. See [Defining multiple portal endpoints for a VMware environment](#).
3. If you have now installed all subsystems, continue to [Post-deployment steps](#).

Note:

When you create or register a Developer Portal service, the Portal subsystem checks that the Portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the **portal-www** pod, admin container logs, if the endpoint cannot be reached:

An error occurred contacting the provided portal web endpoint: example.com
The provided Portal web endpoint example.com returned HTTP status code 504

In this instance, you can disable the Portal web endpoint check so that the Developer Portal service can be created successfully.
To disable the endpoint check, complete the following update:

On VMware

In your `apicup` project, create a file called `ptl-extra-values.yaml` (or edit the file if one already exists), and add the following section:

```
spec:
  template:
    - containers:
      - env:
        - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
          value: "true"
        name: admin
      name: www
```

Run the following commands:

```
apicup subsys set <ptl_subsys> extra-values-file <path-to-ptl-extra-values-yaml-file>
apicup subsys install <ptl_subsys>
```

Configuring two NICs on the Developer Portal

Configure the Developer Portal to use two network interface cards.

About this task

When deploying the Developer Portal, you can optionally separate network traffic such that the portal has network interface in your private network, where the communications to the APIM manager take places, and another network interface in your public network, where the end users can access the Portal web sites.

You can do this by using the iface on `eth0` for your traffic and defining an extra iface definition (`eth1`) for your public interface. Do this as part of the initial configuration of the Developer Portal. Note the following requirements:

- iface `eth0` and `eth1` must have different subnets. This means that you cannot test the configuration by using two IP addresses on the same subnet, due to the routing table produced by the OVA at bootstrap.
- The hostname of the machine must be reachable via `eth0` and you must use `eth0` as the traffic (private interface) and `eth1` as the public interface.

Procedure

1. Verify that you have created a first interface, by following the instructions in [Step 13 of Configuring the Developer Portal subsystem](#).
2. Use `apicup` to add an extra iface definition as follows for your public interface:

```
apicup iface create test-stack-portal test0094.test.example.com eth1 1.2.3.232/255.255.254.0 1.2.3.1
```

3. Set the hostname of your portal-www ingress to the hostname that is associated with the IP address given on `eth1`.

```
apicup subsys set my-portal portal-www portal.myhost0232.company.com
```

4. When configuring the second NIC during initial installation, return to [Step 14 of Configuring the Developer Portal subsystem](#). Follow the remaining steps in the configuration instructions, and then create the Portal OVA and deploy it as usual.

Notes:

- If you are creating multiple network interfaces, each one must be on a different subnet with a different gateway.
- Before powering on the Portal, use the VMware GUI to add a second network card to the VM, with the correct settings for your public network.

Specifying a range of allowable client IP addresses for Developer Portal

Specify the range of client IP addresses to be allowed in a deployment of the Developer Portal

About this task

Use an extra-values-file, which serves as a portal CR override, to provide an allowable addresses annotation.

Procedure

In your `apicup` project, create a file called `ptl-extra-values.yaml` with the necessary content. For example:

```
spec:
  portalUIEndpoint:
    annotations:
      ingress.kubernetes.io/whitelist-source-range: 1.2.88.0/24
```

In this example, `1.2.88.0/24` is the acceptable range of client IP addresses.

Note: Depending on your network configuration for the forwarding of client IP addresses, you might need to run several test iterations to work out which client IP addresses to include in the list.

Defining multiple portal endpoints for a VMware environment

Multiple public facing endpoints (`portal-www`) can be defined for the Developer Portal.

About this task

You can override the single endpoint definition for `portal-www`, and the associated `portal-www-ingress` TLS certificate, to support multiple `portal-www` endpoints.

For information about the endpoints for the Developer Portal, see [Configuring the Developer Portal subsystem](#).

The task requires accessing your portal virtual appliance and creating Kubernetes secrets. Two methods are available for creating Kubernetes secrets:

- The recommended method uses a tool that exists on the portal appliance VM called cert-manager. To use the cert-manager method, skip step [5](#).
- If you do not want to use the cert-manager method, you can create your Kubernetes secrets manually. Follow step [5](#) instead of steps [3](#) and [4](#).

Procedure

Create `portal-www` endpoint certificates with cert-manager.

1. Log in to your portal virtual appliance with an SSH client, as `apicadm` user

```
ssh apicadm@<subsystem hostname>
```

2. Switch to the root user: `sudo -i`

3. Create a file called `ingress-issuer.yaml` and paste in the following content:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: ingress-ca
spec:
  secretName: ingress-ca
  commonName: "ingress-ca"
  usages:
    - digital signature
    - key encipherment
    - cert sign
  isCA: true
  duration: 87600h # 10 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
  issuerRef:
    name: selfsigning-issuer
    kind: Issuer
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: ingress-issuer
spec:
  ca:
    secretName: ingress-ca
```

Run `kubectl apply -f ingress-issuer.yaml`.

4. Create cert-manager certificate objects for each `portal-www` endpoint.

- a. Create a file called `portal-web-certs.yaml`, and paste in a `Certificate` entry for each `portal-www` endpoint. In this example, two endpoints are created, so the example file contains two certificates:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  labels:
    app.kubernetes.io/instance: portal
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: web-endpoint
  name: portal-web-host1
  namespace: default
spec:
  dnsNames:
    - <FQDN of portal web endpoint 1>
  duration: 17520h0m0s
  issuerRef:
    group: cert-manager.io
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: portal-web-host1
  usages:
    - digital signature
    - key encipherment
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
```

```

labels:
  app.kubernetes.io/instance: portal
  app.kubernetes.io/managed-by: ibm-apiconnect
  app.kubernetes.io/name: web-endpoint
name: portal-web-host2
namespace: default
spec:
  dnsNames:
  - <FQDN of portal web endpoint 2>
  duration: 17520h0m0s
  issuerRef:
    group: cert-manager.io
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: portal-web-host2
  usages:
  - digital signature
  - key encipherment
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  labels:
    app.kubernetes.io/instance: portal
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: web-endpoint
  name: portal-web-host3
  namespace: default
spec:
  dnsNames:
  - <FQDN of portal web endpoint 3>
  duration: 17520h0m0s
  issuerRef:
    group: cert-manager.io
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: portal-web-host3
  usages:
  - digital signature
  - key encipherment

```

b. Apply the file:

```
kubectl apply -f portal-web-certs.yaml
```

Create `portal-www` without cert-manager.

5. Create Kubernetes secrets with OpenSSL. Follow this step instead of steps 3 and 4.

To create the secrets and certificates for each `portal-www` endpoint, complete the following steps:

a. If you are using self-signed certificates, create the TLS secrets for each `portal-www` endpoint by generating the certificates. The following example shows how to generate certificates for each `portal-www` endpoint by using OpenSSL:

```

openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host1-tls.key -out ptl.host1-tls.crt -subj
"/CN=ptl.host1.example.com"
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host2-tls.key -out ptl.host2-tls.crt -subj
"/CN=ptl.host2.example.com"
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host3-tls.key -out ptl.host3-tls.crt -subj
"/CN=ptl.host3.example.com"

```

b. Store the SSL certificates in a secret:

i. Copy the certificates to the Portal virtual appliance, for example:

```
scp ptl.host1-tls.key ptl.host1-tls.crt ptl.host2-tls.key ptl.host2-tls.crt ptl.host3-tls.key ptl.host3-tls.crt
apicadm@portal-vm-address
```

ii. Log in to your portal virtual appliance with an SSH client, as `apicadm` user

iii. Switch to the root user: `sudo -i`

iv. Create the Kubernetes secrets:

```

kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls portal-web-host1 --key ptl.host1-tls.key --
cert ptl.host1-tls.crt
kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls portal-web-host2 --key ptl.host2-tls.key --
cert ptl.host2-tls.crt
kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls portal-web-host3 --key ptl.host3-tls.key --
cert ptl.host3-tls.crt

```

Add `portal-www` endpoints and secrets to your `ptl-extra-values.yaml` file.

6. Exit from the portal VM, and in your `apicup` project directory, create a file called `ptl-extra-values.yaml` with the content:

```

spec:
  portalUIEndpoint:
    annotations: # Remove if cert-manager not used
      cert-manager.io/issuer: ingress-issuer # Remove if cert-manager not used
    hosts:
      - name: ptl.host1.example.com
        secretName: portal-web-host1

```

```
- name: ptl.host2.example.com
  secretName: portal-web-host2
- name: ptl.host3.example.com
  secretName: portal-web-host3
```

Note: If you followed step 5 and did not use cert-manager to create your secrets, then delete the `annotations` section, so your `ptl-extra-values.yaml` contains:

```
spec:
  portalUIEndpoint:
    hosts:
      - name: ptl.host1.example.com
        secretName: portal-web-host1
      - name: ptl.host2.example.com
        secretName: portal-web-host2
      - name: ptl.host3.example.com
        secretName: portal-web-host3
```

Run the commands:

```
apicup subsys set <ptl_subsys> extra-values-file <path-to-ptl-extra-values-yaml-file>
```

```
apicup subsys install <ptl_subsys>
```

7. SSH back into your portal virtual appliance, and confirm that multiple hosts exist for your `ptl-portal-web` ingress:

```
sudo kubectl get ingress
NAME                                HOSTS                                                                 ADDRESS      PORTS      AGE
ptl-portal-director                 api.ptl.example.com                                                 80, 443     25m
ptl-portal-web                       ptl.host1.example.com,ptl.host2.example.com,ptl.host3.example.com  80, 443     25m
```

Deploying DataPower Gateway virtual appliance

API Connect uses IBM® DataPower® Gateway to provide the gateway service.

The instructions in this section describe how to deploy IBM DataPower Gateway from files obtained from [Passport Advantage®](#), and apply to the following API Connect scenarios:

- API Connect deployments for the VMware environment
- API Connect deployments for Kubernetes, with a DataPower Gateway in a *non-Kubernetes* environment.

For these scenarios, continue with [Installing DataPower Gateway](#).

Note: Do not use these instructions if you are deploying API Connect deployments for Kubernetes, with DataPower Gateway in a *Kubernetes* environment. In this case, you can use DataPower Gateway files that are packaged with API Connect, on the API Connect section of Fix Central, and configured by using the API Connect `apicup` commands. Follow the instructions in [Obtaining product files](#).

- [Installing DataPower Gateway](#)
Install and configure IBM DataPower Gateway in a non-Kubernetes environment for use with API Connect.
- [Configuring DataPower Gateway for API Connect](#)
You can configure the IBM DataPower Gateway to prepare for a registration with the API Connect Management server.
- [Sample configuration for multiple peering objects on gateway services external to Kubernetes](#)
Sample for reconfiguring the API Connect domain configuration for your gateway services to include multiple peering objects.

Installing DataPower Gateway

Install and configure IBM® DataPower® Gateway in a non-Kubernetes environment for use with API Connect.

Before you begin

Do not use these instructions for either of the following deployment scenarios:

- Both API Connect and DataPower Gateway in a Kubernetes environment.
In this scenario, use the instructions in [Obtaining product files](#).
- An existing DataPower Gateway in a non-Kubernetes environment, and you want to install a newer Fix Pack.
In this scenario, complete an *upgrade* rather than a new installation. See [Upgrading DataPower Gateway Service](#).

To review the installation and configuration scenarios, see [Deploying DataPower Gateway virtual appliance](#).

Procedure

1. Ensure that DataPower Gateway firmware version you plan to install is compatible with the API Connect Management server version.

Note:

You can use any combination of API Connect 10.0.5.x with DataPower Gateway 10.5.0.x or DataPower API Gateway 10.5.0.x.

Before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in [IBM API Connect Version 10 software product compatibility requirements](#) to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software, Integration Middleware, and view the list of compatible DataPower Gateway versions.

2. Obtain your DataPower files from IBM [Passport Advantage](#).
Note that the DataPower files from [Passport Advantage](#) have entitled services for API Connect users.

See also [Download the firmware image from Passport Advantage](#).
3. Follow the DataPower Gateway installation information: <https://www.ibm.com/docs/en/datapower-gateway>.
Note: Set the timezone to UTC on all DataPower installations for use with API Connect.
4. Continue with [Configuring DataPower Gateway for API Connect](#).

Configuring DataPower Gateway for API Connect

You can configure the IBM® DataPower® Gateway to prepare for a registration with the API Connect Management server.

About this task

API Connect and DataPower supports two different types of gateway configurations. The DataPower Gateway (v5 compatible) provides the same support as the gateway support that was available with API Connect version 5.x. The DataPower API Gateway is an enhanced gateway that is performance-focused. See [API Connect gateway types](#) for more information about the differences between the gateway types.

Continue with the instructions for the type of Gateway Service you are configuring:

- [Configuring DataPower API Gateway](#)
Configure the DataPower API Gateway to prepare for registration with the API Connect Management server.
- [Configuring DataPower Gateway \(v5 compatible\)](#)
You can configure the DataPower Gateway (v5 compatible) to prepare for a registration with the API Connect Management server.

Configuring DataPower API Gateway

Configure the DataPower® API Gateway to prepare for registration with the API Connect Management server.

Before you begin

- These instructions are for DataPower API Gateway deployments in a non-Kubernetes environment. Do not use these instructions if you installed API Connect on Kubernetes, with your DataPower API Gateway Service also in the Kubernetes environment. To review deployment scenarios, see [Deploying DataPower Gateway virtual appliance](#).
- Ensure you have installed a version of DataPower API Gateway that is compatible with the version of the API Connect Management server. See [Installing DataPower Gateway](#).
- A shared certificate and private key is used for securing the communication between the API Connect Management server and the gateway. See *Generating keys and certificates* in the appropriate version of the [DataPower documentation](#) for instructions on how to create them with the DataPower tools.
- Ensure that the time zone for the DataPower API Gateway is set to UTC.

About this task

- These instructions provide the basic steps for configuring a gateway service with a single gateway server. The lowest-level configuration objects are created first, then used in other configuration objects.
- Adding gateways to configure a peering environment is similar to creating the first gateway, and is recommended for resiliency in a production environment. A minimum of three gateway servers in a gateway service is recommended for high availability. See *Gateway peering* in the [DataPower documentation](#) for more information about configuring additional gateways for peering. See *Providing the gateway service to API Connect* in the [DataPower documentation](#) for more details about the DataPower settings and procedures.

Procedure

To configure a DataPower API Gateway to communicate with API Connect, complete the following steps:

Note: Use these instructions only for DataPower API Gateway . If you are configuring DataPower Gateway (v5 compatible) see [Configuring DataPower Gateway \(v5 compatible\)](#).

1. Open the DataPower WebGUI interface.
Most of the configuration procedure is done in the DataPower WebGUI interface, not in the Blueprint Console.
2. Optional: Enable the XML management interface in the default domain.
The XML management interface is optional for DataPower API Gateway. If enabled, this interface allows you to send status and configuration requests to the DataPower appliance through a standard SOAP interface, using SOAP messages.
 - a. Search for XML management interface in the navigation search bar, and select it.
 - b. Set the Administrative state to enabled.
 - c. You can specify a different port number if you do not want to use the default of **5550**.
 - d. Select Apply to make the changes
 - e. Save changes to the default domain by selecting Save Configuration.
3. Optional: Enable the REST management interface in the default domain.
The REST management interface is required if you want to enable to the Trace feature in the assembly Test tab in the API Manager.
 - a. Search for REST management interface in the navigation search bar, and select it.
 - b. Set the Administrative state to enabled.
 - c. You can specify a different port number if you do not want to use the default of **5554**.

- d. Select Apply to make the changes
 - e. Save changes to the default domain by selecting Save Configuration.
4. Create an application domain.
- This domain receives your traffic. The name of the DataPower domain where you configure the API Connect Gateway Service must be the same on each DataPower Gateway.
- a. Search for Application domain in the navigation search bar, and select it.
 - b. Select Add to create the application domain.
 - c. Enter a unique name for your domain.
 - d. Ensure that enabled is selected for the Administrative state.
 - e. Ensure that the default domain is listed in the Visible application domain list.
 - f. Select Apply.
 - g. Change to your new application domain by selecting Domain in the menu bar, and selecting the domain that you created.
 - h. Select Save changes and switch domains.
- All of the remaining steps on the DataPower gateway must be done in the application domain that you created.
- i. Save changes to the domain by selecting Save Configuration.
5. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.
See *Managing the NTP service* in the [DataPower documentation](#).
6. Ensure that you have set a unique **System Identifier** for each v10 DataPower gateway. See *Initializing the DataPower Gateway* in the [DataPower documentation](#).
7. Create a self-signed certificate and private key to be used to protect the traffic between the management server and the API gateway service process. You can generate a certificate and private key using DataPower or by using other tools, such as **OpenSSL**. See *Generating keys and certificates* in the appropriate version of the [DataPower documentation](#) for instructions on how to create a crypto key with the DataPower tools.
8. Upload your private crypto key file to the domain.
- a. Search for Crypto key in the navigation search bar, and select it.
 - b. Select Add to create a key object.
 - c. Create a unique name for the key object in the Name field.
 - d. Select Upload....
 - e. Browse for the key file (which must be a .pem or .p12 file) and select it.
 - f. If you want to rename it, enter a new name for the file.
 - g. Select Upload to move it to the server in the cert:// folder.
 - h. Select Apply to save the changes.
9. Upload your crypto certificate file to the domain.
- Note: If your certificate is signed by an Intermediate CA, you must include the entire chain in a single key file (either .pem or .p12) for uploading.
- a. Search for Crypto certificate in the navigation search bar, and select it.
 - b. Select Add to create a certificate object.
 - c. Create a unique name for the certificate object in the Name field.
 - d. Select Upload....
 - e. Browse for the key file (which must be a .pem or .p12 file) and select it.
 - f. If you want to rename it, enter a new name for the file.
 - g. Select Upload to move it to the server in the cert:// folder.
 - h. Select Apply to save the changes.
10. Associate the Crypto key with the Crypto certificate by setting the Identification credential.
- a. Search for Crypto Identification Credentials in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a name for your credential.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. In the Crypto Key field, select the name of the key object that you created from the drop-down menu.
 - f. In the Certificate object field, select the name of the certificate object that you created from the drop-down menu.
 - g. Select Apply to commit your changes.
11. Create your TLS Client profile.
- a. Search for TLS Client profile in the navigation search bar, and select it.
 - b. Select Add to create a client profile.
 - c. Create a unique name for the profile in the Name field.
 - d. Select your Identification credential from the drop-down list.
 - e. Ensure that the value of Validate server certificate is set to off.
 - f. Ensure that the value of Use SNI is set to on.
 - g. Select Apply to save the changes.
12. Create your TLS Server profile.
- a. Search for TLS Server Profile in the navigation search bar, and select it.
 - b. Select Add to create a server profile.
 - c. Create a unique name for the profile in the Name field.
 - d. Select your Identification credential from the drop-down list.
 - e. Ensure that the value of Request client authentication is set to off.
- Disabling the request for client authentication for the TLS client profile and the validation of server certificates for the TLS server profile disables security for the ease of configuring the gateway. To enable the secure communication using mutual TLS between IBM API Connect and Gateway, see [Binding a TLS server profile to a gateway service](#).
- If mTLS is disabled it is recommended to use JWT application layer security instead. See [Enable JWT instead of mTLS](#).
- f. Select Apply to save the changes.
13. Define a configuration sequence.
- The configuration sequence specifies how DataPower implements the APIs that are defined in API Connect.
- a. Search for Configuration sequence in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a name for your configuration sequence.
- The name **apic-config** is not allowed because it is already used internally.
- d. Ensure that the Administrative state has a value of enabled.
 - e. Ensure that the value in the Location profiles field is set to local:///
- This is the default value, so you might not need to change it.

- f. Select the Access profile.
For instructions on creating access profiles, see *Configuring the access profile for a configuration sequence* in the appropriate version of the [DataPower documentation](#).
 - g. Change the value of the Configuration execution interval field to 3000.
The other fields can retain their default settings.
 - h. Select Apply to commit your changes.
14. Configure your gateway peering object for the API Connect Gateway Service.
This step is required when you set up a peer group of gateways, even if there is only a single gateway server in the gateway service.
- a. Search for Gateway peering in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a unique name for your gateway peering object.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. Select a local address for the communications among the members of the peer group.
 - f. Select a local port for the communication.
You can use the default value of 16380.
 - g. Select a monitor port for the communication.
You can use the default value of 26380.
 - h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
 - i. Clear the Enable TLS check box. TLS is not needed for a single peer.
 - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
 - k. Select Apply to commit your changes.
15. Configure your gateway peering object for rate limit information.
- a. Search for Gateway peering in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a unique name for your gateway peering object.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. Select a local address for the communications among the members of the peer group.
 - f. Select a local port for the communication.
Use a unique port, different than the ports used for communication by other gateway peering objects.
 - g. Select a monitor port for the communication.
Use a unique port, different than the ports used for monitoring by other gateway peering objects.
 - h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
 - i. Clear the Enable TLS check box. TLS is not needed for a single peer.
 - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
 - k. Select Apply to commit your changes.
16. Optional: If you are using the ratelimit module described in the [DataPower documentation](#), configure your gateway peering object for GatewayScript rate limiting information.
- a. Search for Gateway peering in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a unique name for your gateway peering object.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. Select a local address for the communications among the members of the peer group.
 - f. Select a local port for the communication.
Use a unique port, different than the ports used for communication by other gateway peering objects.
 - g. Select a monitor port for the communication.
Use a unique port, different than the ports used for monitoring by other gateway peering objects.
 - h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
 - i. Clear the Enable TLS check box. TLS is not needed for a single peer.
 - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
 - k. Select Apply to commit your changes.
17. Configure your gateway peering object for subscription information.
- a. Search for Gateway peering in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a unique name for your gateway peering object.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. Select a local address for the communications among the members of the peer group.
 - f. Select a local port for the communication.
Use a unique port, different than the ports used for communication by other gateway peering objects.
 - g. Select a monitor port for the communication.
Use a unique port, different than the ports used for monitoring by other gateway peering objects.
 - h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
 - i. Clear the Enable TLS check box. TLS is not needed for a single peer.
 - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
 - k. Select Apply to commit your changes.
18. Configure the gateway peering object for the API probe.
In order for API Connect to receive trace data in the Test tab's debugger, the DataPower API Gateway must be configured to support the API probe.
- a. Search for Gateway peering in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a unique name for your gateway peering object.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. Select a local address for the communications among the members of the peer group.
 - f. Select a local port for the communication.
Use a unique port, different than the ports used for communication by other gateway peering objects.
 - g. Select a monitor port for the communication.
Use a unique port, different than the ports used for monitoring by other gateway peering objects.
 - h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
 - i. Clear the Enable TLS check box. TLS is not needed for a single peer.
 - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.

- k. Select Apply to commit your changes.
19. Configure the gateway peering manager.
 - a. Search for Gateway Peering Manager in the navigation search bar, and select it.
 - b. Set the Administrative state to enabled.
 - c. In the pull-down menu next to API Connect Gateway Service, select the gateway peering object configured in Step 14 for the API Connect Gateway Service.
 - d. In the pull-down menu next to Rate Limit, select the gateway peering object configured in Step 15 for rate limit information.
 - e. In the pull-down menu next to Subscription, select the gateway peering object configured in Step 17 for subscription.
 - f. In the pull-down menu next to API Probe, select the gateway peering object that you configured in Step 18 for the API probe.
 - g. If you are using the ratelimit module described in the [DataPower documentation](#), then for Gateway rate limiting, select the gateway peering object that you configured in Step 16 for rate limit information.
 - h. Select Apply to commit your changes.
20. Configure the API probe settings object.
 - a. Search for API probe settings in the navigation search bar, and select it.
 - b. Set the Administrative state to enabled.
 - c. Set the maximum number of records to 1000.
 - d. Set the expiration to 60 minutes.
 - e. In the pull-down menu next to Gateway Peering, select the gateway peering object that you configured in Step 18 for the API probe.
 - f. Select Apply to commit your changes.
21. Set the API Connect Gateway service to define the communication interface with the API Connect Management server and for API transactions.
 - a. Search for API Connect Gateway service in the navigation search bar, and select it.
 - b. Ensure that the Administrative state is set to enabled.
 - c. In the Local address field, enter the IP address of the DataPower gateway to which you want the traffic from the API Connect Management server to be sent.
 - d. Specify a value for Local port. You can use the default value of 3000, or specify a different port value.
 Note: The Local port specifies the port through which API Connect connects to manage the API Connect Gateway Service. Use this port when you configure a Gateway Service on API Connect. Beyond this port, the gateway service uses two additional consecutive ports after the defined local port to bind to a loopback address. Therefore, you must ensure that there are no conflicts on all three consecutive ports that start from the defined local port.
 - e. In the TLS client field drop-down list, select the name of the TLS client profile that you created.
 - f. In the TLS server field drop-down list, select the name of the TLS server profile that you created.
 - g. In the API gateway address field, enter the IP address for the DataPower gateway to which you want the API traffic sent.
 - h. Use the default port value of 9443 for the API gateway port.
 If the port is not being used by another service, you can also change it to port 443 if you want API transactions to be sent to the default port for HTTPS.
 - i. For DataPower API Gateway, set the Gateway Peering to **(none)**.
 When no gateway peering object is configured for the DataPower API Gateway, the peering configuration defined in the Gateway Peering Manager configuration is used.
 - j. Select whether you want the DataPower Gateway (v5 compatible) or the DataPower API Gateway.
 When the option is selected, it enables the registration of a DataPower Gateway (v5 compatible) gateway. Clear it to enable a DataPower API Gateway.
22. Optional: Enable JWT security instead of mTLS for communication from management to gateway. JWT security provides application layer security and can be used instead of mTLS when load-balancers are located between subsystems that require TLS termination. For more information about JWT security, see [Enable JWT instead of mTLS](#).
 To enable JWT and disable mTLS on the gateway appliance, see *Configuring the API Connect gateway service* in the [DataPower documentation](#). The JWKS URL required to enable JWT security can be found in the management subsystem settings:

```
apicup subsys get <management subsystem>
```

```
...
```

```

jwtks-url      https://appliance1.apic.acme.com/api/cloud/oauth2/certs JWKS URL for Portal and Analytics subsystems to
validate JWT -- this is unsettingtable and is generated based on the platform-api endpoint
...

```
23. Register the gateway service in the API Connect Cloud Manager console:
 - a. Open the API Connect Cloud Manager console.
 - b. Navigate to Configure Topology.
 - c. Select Register Service.
 - d. Select DataPower API Gateway for the DataPower API Gateway.
 - e. Add a title, name, and summary for the gateway connection.
 - f. Optional: Configure the OAuth Shared Secret.
 This setting allows OAuth tokens to be shared across multiple gateway services.
 - g. Enter one of the following values in the API Invocation Endpoint field:
 - IP address of the load balancer for the API transactions
 - IP address or host name of one of the gateways
 For example: `https://192.0.2.0:9443/`
 - h. Enter the one of the following values in the Management Endpoint field:
 - IP address of the load balancer for the management server traffic set to port 3000
 - IP address or hostname of one of the gateways
 For example: `https://192.0.2.0:3000/`
24. Select the default TLS Client Profile
25. Optional: Configure Server Name Indication (SNI) profiles.
 SNI profiles allow different TLS certificates to be used for API transaction requests from different host names.
26. Enable logging for the gateway.
 - a. Use the CLI to configure the following log target in the API Connect application domain:

```

switch domain <apiconnect_domain>
configure terminal
logging target gwd-log
type file
format text
timestamp zulu
size 50000
local-file logtemp:///gwd-log.log
event apic-gw-service debug
exit
apic-gw-service;admin-state disabled;exit
apic-gw-service;admin-state enabled;exit
          
```

```
write mem
exit
```

b. Repeat this set for every gateway server in the cluster.

Configuring DataPower Gateway (v5 compatible)

You can configure the DataPower® Gateway (v5 compatible) to prepare for a registration with the API Connect Management server.

Before you begin

- These instructions are for DataPower API Gateway deployments in a non-Kubernetes environment. Do not use these instructions if you installed API Connect on Kubernetes, with your DataPower API Gateway Service also in the Kubernetes environment. To review deployment scenarios, see [Deploying DataPower Gateway virtual appliance](#).
- Ensure you have installed a version of DataPower API Gateway that is compatible with the version of the API Connect Management server. See [Installing DataPower Gateway](#).
- A shared certificate and private key is used for securing the communication between the API Connect Management server and the gateway. See *Generating keys and certificates* in the appropriate version of the [DataPower documentation](#) for instructions on how to create them with the DataPower tools.
- Ensure that the time zone for the DataPower API Gateway is set to UTC.

About this task

- These instructions provide the basic steps for configuring a gateway service with a single gateway server. The lowest-level configuration objects are created first, then used in other configuration objects.
- Adding gateways to configure a peering environment is similar to creating the first gateway, and is recommended for resiliency in a production environment. A minimum of three gateway servers in a gateway service is recommended for high availability. See *Gateway peering* in the [DataPower documentation](#) for more information about configuring additional gateways for peering. See *Providing the gateway service to API Connect* in the [DataPower documentation](#) for more details about the DataPower settings and procedures.

Procedure

To configure a DataPower gateway to communicate with API Connect, complete the following steps:

Note: Use these instructions only for DataPower Gateway (v5 compatible). If you are configuring DataPower API Gateway, see [Configuring DataPower API Gateway](#).

1. Open the DataPower WebGUI interface.
Most of the configuration procedure is done in the DataPower WebGUI interface, not in the Blueprint Console.
2. Enable the XML management interface in the **default** domain, if required. The XML management interface is required for DataPower Gateway (v5 compatible). The XML management interface is optional for DataPower API Gateway.
 - a. Search for **XML management interface** in the navigation search bar, and select it.
 - b. Set the Administrative state to enabled.
 - c. You can specify a different port number if you do not want to use the default of **5550**.
 - d. Select Apply to make the changes
 - e. Save changes to the default domain by selecting Save Configuration.
3. Create an application domain.
This domain receives your traffic. The name of the DataPower domain where you configure the API Connect Gateway Service must be the same on each DataPower Gateway.
 - a. Search for Application domain in the navigation search bar, and select it.
 - b. Select Add to create the application domain.
 - c. Enter a unique name for your domain.
 - d. Ensure that enabled is selected for the Administrative state.
 - e. Ensure that the default domain is listed in the Visible application domain list.
 - f. Select Apply.
 - g. Change to your new application domain by selecting Domain in the menu bar, and selecting the domain that you created.
 - h. Select Save changes and switch domains.
All of the remaining steps on the DataPower gateway must be done in the application domain that you created.
 - i. Save changes to the domain by selecting Save Configuration.
4. For the DataPower Gateway (v5 compatible) only: Enable statistics in the domain you created for **API Connect**.
 - a. Search for and select Statistics settings in the navigation search.
 - b. Select enabled for the Administrative state.
 - c. Select Apply.
5. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.
See [Managing the NTP service](#).
6. Ensure that you have set a unique **System Identifier** for each v10 DataPower gateway. See [Initializing the DataPower Gateway](#).
7. Create a self-signed certificate and private key to be used to protect the traffic between the management server and the API gateway service process. You can generate a certificate and private key using DataPower or by using other tools, such as **OpenSSL**. See *Generating keys and certificates* in the appropriate version of the [DataPower documentation](#) for instructions on how to create a crypto key with the DataPower tools.
8. Upload your private crypto key file to the domain.
 - a. Search for Crypto key in the navigation search bar, and select it.
 - b. Select Add to create a key object.
 - c. Create a unique name for the key object in the Name field.
 - d. Select Upload...
 - e. Browse for the key file (which must be a .pem or .p12 file) and select it.
 - f. If you want to rename it, enter a new name for the file.
 - g. Select Upload to move it to the server in the cert:// folder.
 - h. Select Apply to save the changes.

9. Upload your crypto certificate file to the domain.

Note: If your certificate is signed by an Intermediate CA, you must include the entire chain in a single key file (either .pem or .p12) for uploading.

 - a. Search for Crypto certificate in the navigation search bar, and select it.
 - b. Select Add to create a certificate object.
 - c. Create a unique name for the certificate object in the Name field.
 - d. Select Upload....
 - e. Browse for the key file (which must be a .pem or .p12 file) and select it.
 - f. If you want to rename it, enter a new name for the file.
 - g. Select Upload to move it to the server in the cert:// folder.
 - h. Select Apply to save the changes.
10. Associate the Crypto key with the Crypto certificate by setting the Identification credential.
 - a. Search for Crypto Identification Credentials in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a name for your credential.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. In the Crypto Key field, select the name of the key object that you created from the drop-down menu.
 - f. In the Certificate object field, select the name of the certificate object that you created from the drop-down menu.
 - g. Select Apply to commit your changes.
11. Create your TLS Client profile.
 - a. Search for TLS Client profile in the navigation search bar, and select it.
 - b. Select Add to create a client profile.
 - c. Create a unique name for the profile in the Name field.
 - d. Select your Identification credential from the drop-down list.
 - e. Ensure that the value of Validate server certificate is set to off.
 - f. Ensure that the value of Use SNI is set to on.
 - g. Select Apply to save the changes.
12. Create your TLS Server profile.
 - a. Search for TLS Server Profile in the navigation search bar, and select it.
 - b. Select Add to create a server profile.
 - c. Create a unique name for the profile in the Name field.
 - d. Select your Identification credential from the drop-down list.
 - e. Ensure that the value of Request client authentication is set to off.

Disabling the request for client authentication for the TLS client profile and the validation of server certificates for the TLS server profile disables security for the ease of configuring the gateway. To enable the secure communication using mutual TLS between IBM API Connect and Gateway, see [Binding a TLS server profile to a gateway service](#).

If mTLS is disabled it is recommended to use JWT application layer security instead. See [Enable JWT instead of mTLS](#).
 - f. Select Apply to save the changes.
13. Configure your gateway peering object for the API Connect Gateway Service.

This step is required when you set up a peer group of gateways, even if there is only a single gateway server in the gateway service.

 - a. Search for Gateway peering in the navigation search bar, and select it.
 - b. Select Add.
 - c. Enter a unique name for your gateway peering object.
 - d. Ensure that the Administrative state has a value of enabled.
 - e. Select a local address for the communications among the members of the peer group.
 - f. Select a local port for the communication.

You can use the default value of 16380.
 - g. Select a monitor port for the communication.

You can use the default value of 26380.
 - h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
 - i. Clear the Enable TLS check box. TLS is not needed for a single peer.
 - j. Set the Persistence location value to **Memory** for either physical DataPower appliance or virtual DataPower appliance.
 - k. Select Apply to commit your changes.
14. Set the API Connect Gateway service to define the communication interface with the API Connect Management server and for API transactions.
 - a. Search for API Connect Gateway service in the navigation search bar, and select it.
 - b. Ensure that the Administrative state is set to enabled.
 - c. In the Local address field, enter the IP address of the DataPower gateway to which you want the traffic from the API Connect Management server to be sent.
 - d. Use the default port value of 3000 for the Local port.
 - e. In the TLS client field drop-down list, select the name of the TLS client profile that you created.
 - f. In the TLS server field drop-down list, select the name of the TLS server profile that you created.
 - g. In the API gateway address field, enter the IP address for the DataPower gateway to which you want the API traffic sent.
 - h. Use the default port value of 9443 for the API gateway port.

If the port is not being used by another service, you can also change it to port 443 if you want API transactions to be sent to the default port for HTTPS.
 - i. For DataPower Gateway (v5 compatible), select the gateway peering object that you created in Step 13.
 - j. Select whether you want the DataPower Gateway (v5 compatible) or the DataPower API Gateway.

When the option is selected, it enables the registration of a DataPower Gateway (v5 compatible) gateway.
15. Optional: Enable JWT security instead of mTLS for communication from management to gateway. JWT security provides application layer security and can be used instead of mTLS when load-balancers are located between subsystems that require TLS termination. For more information about JWT security, see [Enable JWT instead of mTLS](#).

To enable JWT and disable mTLS on the gateway appliance, see *Configuring the API Connect gateway service* in the [DataPower documentation](#). The JWKS URL required to enable JWT security can be found in the management subsystem settings:

```
apicup subsys get <management subsystem>
...
jwks-url https://appliance1.apic.acme.com/api/cloud/oauth2/certs JWKS URL for Portal and Analytics subsystems to
validate JWT -- this is unsettable and is generated based on the platform-api endpoint
...
```
16. Register the gateway service in the API Connect Cloud Manager console:
 - a. Open the API Connect Cloud Manager console.

- b. Navigate to Configure Topology.
- c. Select Register Service.
- d. Select DataPower Gateway (v5 compatible) for the gateway that was available in version 5.
- e. Add a title, name, and summary for the gateway connection.
- f. Optional: Configure the OAuth Shared Secret.
This setting allows OAuth tokens to be shared across multiple gateway services.
- g. Enter one of the following values in the API Invocation Endpoint field:
 - IP address of the load balancer for the API transactions
 - IP address or host name of one of the gateways
 For example: `https://192.0.2.0:9443/`
- h. Enter the one of the following values in the Management Endpoint field:
 - IP address of the load balancer for the management server traffic set to port 3000
 - IP address or hostname of one of the gateways
 For example: `https://192.0.2.0:3000/`
- 17. Select the default TLS Client Profile
- 18. Optional: Configure Server Name Indication (SNI) profiles.
SNI profiles allow different TLS certificates to be used for API transaction requests from different host names.
- 19. Enable logging for the gateway.
 - a. Use the CLI to configure the following log target in the API Connect application domain:

```
switch domain <apiconnect_domain>
configure terminal
logging target gwd-log
type file
format text
timestamp zulu
size 50000
local-file logtemp:///gwd-log.log
event apic-gw-service debug
exit
apic-gw-service;admin-state disabled;exit
apic-gw-service;admin-state enabled;exit
write mem
exit
```

- b. Repeat this set for every gateway server in the cluster.

Sample configuration for multiple peering objects on gateway services external to Kubernetes

Sample for reconfiguring the API Connect domain configuration for your gateway services to include multiple peering objects.

- This reference shows how to configure API Connect domain configuration with gateway-peering configuration. To review domain configuration settings, see [Configuring DataPower Gateway for API Connect](#).
- This sample applies only to gateway services that are deployed external to Kubernetes, on either a physical or virtual appliance. This sample does not apply to gateway services that are deployed on Kubernetes.

The following examples show sample configuration for 3 different gateways, listed here with sample IP addresses of 1.1.1.1, 2.2.2.2, and 3.3.3.3. Note the following:

- The priority should be set differently on each of the three gateways. Set the lowest priority for the gateway that will run as primary.
- **persistence** should be set to **memory** for all configured peering objects.
- Optionally, add SSL configuration.

Configuration on gateway 1 (1.1.1.1)

```
top; configure terminal;
domain apiconnect; visible default; exit;

sw apiconnect;

loglevel debug;
logging target gwd-log
type file
format text
timestamp syslog
size 50000
local-file logtemp:///gwd-log
event apic-gw-service debug
exit

config-sequence "apiconnect"
location "local:/// "
watch "on"
delete-unused "on"
match "(.*)\.cfg$"

```

Post-deployment steps

When all subsystems are deployed, use the admin account to access the Cloud Manager administrative console and begin configuration. Optionally, take VMware snapshots of the VMs.

About this task

When you have deployed all required API Connect components, and all subsystems are running, complete the following:

Procedure

1. If you have not previously accessed the Cloud Manager, verify you can access the API Connect Cloud Manager. Enter the URL in your browser. The syntax is `https://<hostname.domain>/admin`. For example:

```
https://cloud-admin-ui.testsrv0231.subnet1.example.com/admin
```

The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. See [Accessing the Cloud Manager user interface](#).

2. Define your API Connect configuration by using the API Connect Cloud Manager. See [Cloud Manager configuration checklist](#).

- Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVAs and restoring from normal backups. Important: VM snapshots are not an alternative to the standard API Connect backups. You should have completed an API Connect backup of each subsystem when verifying initial deployment, as advised in:
 - [Verify installation of the Management subsystem](#)
 - [Verifying deployment of the Developer Portal subsystem](#)
 - [Verifying deployment of the Analytics subsystem](#)

Installing a two data center deployment on VMware

How to install a two data center disaster recovery (2DCDR) deployment on VMware.

Before you begin

Ensure that you understand the concepts of a 2DCDR deployment in API Connect. For more information, see [A two data center deployment strategy on VMware](#).

Review the information in [Requirements for initial deployment on VMware](#) and, if appropriate, [What's new for v10 installation from previous versions](#).

Familiarize yourself with the instructions in [First steps for deploying in a VMware environment](#). Complete these instructions with the additional steps in this topic that are specific to installing a 2DCDR deployment.

Restriction: It is not possible to use the Automated API behavior testing application ([Installing the Automated API behavior testing application](#)) in a 2DCDR configuration.

About this task

Installing API Connect as a 2DCDR deployment is similar to a single installation. The deployment in each data center is effectively an instance of the same API Connect deployment. The following endpoints must be the same on both data centers:

Management subsystem endpoints

- `platform-api`
- `consumer-api`
- `cloud-admin-ui`
- `api-manager-ui`

Portal subsystem endpoints

- `portal-admin`
- `portal-www`

To install a 2DCDR deployment, you follow the normal stand-alone API Connect installation steps, but before you generate the ISO files you must set some additional 2DCDR properties.

The 2DCDR properties are described in the following table.

Table 1. 2DCDR properties

Setting	Description
<code>multi-site-ha-enabled</code>	Indicates whether 2DCDR deployment is enabled. Set to <code>true</code> to enable 2DCDR. Set to <code>false</code> to disable 2DCDR. The default value is <code>false</code> .
<code>multi-site-ha-mode</code>	The 2DCDR mode of the data center. Possible values are: <ul style="list-style-type: none"> • <code>active</code> - indicates the primary data center. • <code>passive</code> - indicates the warm-standby data center.
<code>management-replication</code>	Required only for the management subsystem. The external ingress name for the management subsystem in the current data center in the 2DCDR deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
<code>portal-replication</code>	Required only for the portal subsystem. The external ingress name for the portal subsystem in the current data center in the 2DCDR deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
<code>replication-peer-fqdn</code>	The ingress hostname for the other data center in the 2DCDR deployment. This information is required so that the two data centers can communicate with each other.
<code>siteName</code>	Unique descriptive name for the API Connect data center. Must be different in each data center. This name is used in the hostnames, and so can contain only <code>a-z</code> and <code>0-9</code> characters. You can set a <code>siteName</code> only when the subsystems are first deployed, and you cannot change the name after deployment. If you don't set <code>siteName</code> at first deployment, the <code>siteName</code> is autogenerated.

Important:

- Use a single APICUP project for all subsystems so that the API Connect deployments in both data centers have the same certificate chains. If network access to both data centers from the same APICUP project location is not possible, you can copy the project directory across to the other data center. If you are copying the project directory to your other data center, ensure that you keep backups of both project directories.
- The original project directory that is created with APICUP during the initial product installation is required to both restore the database and to upgrade your deployment. You cannot restore the database or complete an upgrade without the initial project directory because it contains pertinent information about the cluster.
- Subsystem endpoints for the components cannot be changed.
- The subsystem name of the management and portal subsystems must consist of lowercase alphanumeric characters or '-', contain no spaces, start with an alphabetic character, and end with an alphanumeric character.

Procedure

• Installing on the active data center

The following example shows how to configure the 2DCDR settings for deploying on the active data center (DC). In this example, the active data center is called **dallas** (DC1), and the warm-standby data center is called **raleigh** (DC2).

1. Complete the steps in [Configuring the Management subsystem](#) up to and including step [14](#) to configure the standard (non-2DCDR) settings for the management subsystem in Dallas (DC1).
2. Configure the 2DCDR values to set Dallas to be active for the management subsystem in DC1.

Run the following commands:

```
apicup subsys set mgmt_dallas multi-site-ha-enabled=true
apicup subsys set mgmt_dallas multi-site-ha-mode=active
apicup certs set mgmt_dallas management-replication-ingress --clear
apicup subsys set mgmt_dallas management-replication=mgrreplicationdallas.cluster1.example.com
apicup subsys set mgmt_dallas replication-peer-fqdn=mgrreplicationraleigh.cluster2.example.com
apicup subsys set mgmt_dallas site-name=dallas
```

where

- **mgmt_dallas** is the name of the management subsystem that you are configuring.
 - **mgrreplicationdallas.cluster1.example.com** is the ingress hostname for the current data center in the two data center deployment.
 - **mgrreplicationraleigh.cluster2.example.com** is the ingress hostname for the other data center in the two data center deployment.
 - **dallas** is the name of the site in the current data center.
3. Complete the remainder of the steps in [Configuring the Management subsystem](#) from step [15](#) to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
 4. Complete the steps in [Configuring the Developer Portal subsystem](#) up to and including step [16](#) to configure the standard (non-2DCDR) settings for the portal subsystem in Dallas (DC1).
 5. Configure the 2DCDR values to set Dallas to be active for the portal subsystem in DC1.

Run the following commands:

```
apicup subsys set port_dallas multi-site-ha-enabled=true
apicup subsys set port_dallas multi-site-ha-mode=active
apicup certs set port_dallas portal-replication-ingress --clear
apicup subsys set port_dallas portal-replication=ptlreplicationdallas.cluster1.example.com
apicup subsys set port_dallas replication-peer-fqdn=ptlreplicationraleigh.cluster2.example.com
apicup subsys set port_dallas site-name=dallas
```

where

- **port_dallas** is the name of the portal subsystem that you are configuring.
 - **ptlreplicationdallas.cluster1.example.com** is the ingress hostname for the current data center in the two data center deployment.
 - **ptlreplicationraleigh.cluster2.example.com** is the ingress hostname for the other data center in the two data center deployment.
 - **dallas** is the name of the site in the current data center.
6. Complete the remainder of the steps in [Configuring the Developer Portal subsystem](#) from step [19](#) to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
 7. Log in to the virtual machine subsystems on DC1 by using an SSH tool, and check the status of the installation by running the **apic status** command.
 8. Set your dynamic router to direct all traffic to DC1. The endpoints that must be directed to DC1 are:

Management subsystem endpoints

- **platform-api**
- **consumer-api**
- **cloud-admin-ui**
- **api-manager-ui**

Portal subsystem endpoints

- **portal-admin**
- **portal-www**

• Installing on the warm-standby data center

The following example shows how to set the 2DCDR values for the remote data center called **raleigh** (DC2), which is being installed as the warm-standby location.

Important: Remember to use the same APICUP project directory as for the active data center. If you cannot use the same project directory because its location does not have network access to both data centers, you can copy the project directory over. Ensure that backups are kept of both project directories in each data center.

1. Complete the steps in [Configuring the Management subsystem](#) up to and including step [14](#) to configure the standard (non-2DCDR) settings for the management subsystem in Raleigh (DC2).
2. Configure the 2DCDR values to set the management subsystem to be the warm-standby in the Raleigh (DC2) data center.

Run the following commands:

```
apicup subsys set mgmt_raleigh multi-site-ha-enabled=true
apicup subsys set mgmt_raleigh multi-site-ha-mode=passive
apicup certs set mgmt_raleigh management-replication-ingress --clear
apicup subsys set mgmt_raleigh management-replication=mgrreplicationraleigh.cluster2.example.com
apicup subsys set mgmt_raleigh replication-peer-fqdn=mgrreplicationdallas.cluster1.example.com
apicup subsys set mgmt_raleigh site-name=raleigh
```

where

- `mgmt_raleigh` is the name of the management subsystem that you are configuring.
- `mgrreplicationraleigh.cluster2.example.com` is the ingress hostname for the current data center in the two data center deployment.
- `mgrreplicationdallas.cluster1.example.com` is the ingress hostname for the other data center in the two data center deployment.
- `raleigh` is the name of the site in the current data center.

3. Set the encryption key manually for Raleigh (DC2) by copying it from Dallas (DC1).

Run the following commands:

```
apicup certs get mgmt_dallas encryption-secret -t key > mgmt-encryption-secret
```

```
apicup certs set mgmt_raleigh encryption-secret mgmt-encryption-secret
```

4. Check that the management encryption key is set the same on both DC1 and DC2.

Run the following commands, and verify that the outputs match:

```
apicup certs get mgmt_dallas encryption-secret -t key
```

```
apicup certs get mgmt_raleigh encryption-secret -t key
```

5. Complete the remainder of the steps in [Configuring the Management subsystem](#) from step 15 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.

6. Complete the steps in [Configuring the Developer Portal subsystem](#) up to and including step 16 to configure the standard (non-2DCDR) settings for the portal subsystem in Raleigh (DC2).

7. Configure the 2DCDR values to set Raleigh to be warm-standby for the portal subsystem on DC2.

Run the following commands:

```
apicup subsys set port_raleigh multi-site-ha-enabled=true
```

```
apicup subsys set port_raleigh multi-site-ha-mode=passive
```

```
apicup certs set port_raleigh portal-replication-ingress --clear
```

```
apicup subsys set port_raleigh portal-replication=ptlreplicationraleigh.cluster2.example.com
```

```
apicup subsys set port_raleigh replication-peer-fqdn=ptlreplicationdallas.cluster1.example.com
```

```
apicup subsys set port_raleigh site-name=raleigh
```

where

- `port_raleigh` is the name of the portal subsystem that you are configuring.
- `ptlreplicationraleigh.cluster2.example.com` is the ingress hostname for the current data center in the two data center deployment.
- `ptlreplicationdallas.cluster1.example.com` is the ingress hostname for the other data center in the two data center deployment.
- `raleigh` is the name of the site in the current data center.

8. Copy the encryption key for the portal subsystem on DC1 over to the portal subsystem on DC2.

Run the following command to get the encryption key for the portal subsystem on DC1, and put it into a file that is called `port-encryption-secret`:

```
apicup certs get port_dallas encryption-secret -t key > port-encryption-secret
```

Run the following command to use the `port-encryption-secret` file to set the same encryption key on DC2:

```
apicup certs set port_raleigh encryption-secret port-encryption-secret
```

Where `port_dallas` is the name of the portal subsystem on DC1, and `port_raleigh` is the name of the portal subsystem on DC2.

To check that the encryption key is set the same on both DC1 and DC2, you can run the following commands and verify that the outputs match:

```
apicup certs get port_dallas encryption-secret -t key
```

```
apicup certs get port_raleigh encryption-secret -t key
```

9. Complete the remainder of the steps in [Configuring the Developer Portal subsystem](#) from step 19 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.

10. Log in to the virtual machine subsystems on DC2 by using an SSH tool, and check the status of the installation by running the `apic status` command.

• Converting a single data center deployment to two data centers

Important:

- Use the existing deployment as the active site. The new site must be set to warm-standby. If you set your existing deployment to warm-standby then all your management and portal data is erased.
- The ingress endpoint values from the existing deployment become the global ingress endpoints for the two center deployment. The following endpoints must be set the same on your new deployment, as they are on your existing deployment:

Management subsystem endpoints

- `platform-api`
- `consumer-api`
- `cloud-admin-ui`
- `api-manager-ui`

Portal subsystem endpoints

- `portal-admin`
- `portal-www`

- Configure your network to be able to route the endpoints to either data center, depending on which is the active.
- You cannot configure a `site-name` for the existing management or portal cluster because the `site-name` property can be configured only at first deployment.

The following example shows how to update the 2DCDR values to make the existing data center `Dallas` the active, and for installing and setting the new remote data center `Raleigh` as warm-standby.

1. Configure the 2DCDR values to set Dallas to be active for the API Manager subsystem on DC1.

Run the following commands:

```
apicup subsys set mgmt_dallas multi-site-ha-enabled=true
```

```
apicup subsys set mgmt_dallas multi-site-ha-mode=active
```

```

apicup certs set mgmt_dallas management-replication-ingress --clear
apicup subsys set mgmt_dallas management-replication=mgrreplicationdallas.cluster1.example.com
apicup subsys set mgmt_dallas replication-peer-fqdn=mgrreplicationraleigh.cluster2.example.com

```

where

- `mgmt_dallas` is the name of the management subsystem that you are configuring.
- `mgrreplicationdallas.cluster1.example.com` is the ingress hostname for the current data center in the two data center deployment.
- `mgrreplicationraleigh.cluster2.example.com` is the ingress hostname for the other data center in the two data center deployment.

Note: As the API Manager subsystem already exists, you cannot set the `site-name` property.

2. Configure the 2DCDR values to set Dallas to be active for the portal subsystem on DC1.

Run the following commands:

```

apicup subsys set port_dallas multi-site-ha-enabled=true
apicup subsys set port_dallas multi-site-ha-mode=active
apicup certs set port_dallas portal-replication-ingress --clear
apicup subsys set port_dallas portal-replication=ptlreplicationdallas.cluster1.example.com
apicup subsys set port_dallas replication-peer-fqdn=ptlreplicationraleigh.cluster2.example.com

```

where

- `port_dallas` is the name of the portal subsystem that you are configuring.
- `ptlreplicationdallas.cluster1.example.com` is the ingress hostname for the current data center in the two data center deployment.
- `ptlreplicationraleigh.cluster2.example.com` is the ingress hostname for the other data center in the two data center deployment.

Note: As the portal subsystem already exists, you cannot set the `site-name` property.

3. Run `apicup` to update the settings in each subsystem, for example:

```
apicup subsys install subsystem_name
```

where `subsystem_name` is the name of the management or portal subsystem that you want to update, for example `mgmt_dallas`.

4. Log in to the virtual machine subsystems on DC1 by using an SSH tool, and check the status of the installation by running the `apic status` command.
5. Add the new DC, Raleigh (DC2) by completing the steps in [Configuring the Management subsystem](#) up to and including step [14](#) to create a management subsystem in Raleigh (DC2).

Note:

- Remember to use the same APICUP project directory as for the active data center.
- Remember to set the same endpoints as for DC1:

Management subsystem endpoints

- `platform-api`
- `consumer-api`
- `cloud-admin-ui`
- `api-manager-ui`

Portal subsystem endpoints

- `portal-admin`
- `portal-www`

6. Configure the 2DCDR values to set Raleigh to be warm-standby for the API Manager subsystem on DC2.

Run the following commands:

```

apicup subsys set mgmt_raleigh multi-site-ha-enabled=true
apicup subsys set mgmt_raleigh multi-site-ha-mode=passive
apicup certs set mgmt_raleigh management-replication-ingress --clear
apicup subsys set mgmt_raleigh management-replication=mgrreplicationraleigh.cluster2.example.com
apicup subsys set mgmt_raleigh replication-peer-fqdn=mgrreplicationdallas.cluster1.example.com
apicup subsys set mgmt_raleigh site-name=raleigh

```

where

- `mgmt_raleigh` is the name of the management subsystem that you are configuring.
- `mgrreplicationraleigh.cluster2.example.com` is the ingress hostname for the current data center in the two data center deployment.
- `mgrreplicationdallas.cluster1.example.com` is the ingress hostname for the other data center in the two data center deployment.
- `raleigh` is the name of the site in the current data center.

Note: As this is a new deployment of the API Manager subsystem, you can set the `site-name` property.

7. Set the encryption key manually for Raleigh (DC2) by copying it from Dallas (DC1).

Run the following commands:

```

apicup certs get mgmt_dallas encryption-secret -t key > mgmt-encryption-secret
apicup certs set mgmt_raleigh encryption-secret mgmt-encryption-secret

```

8. Check that the management encryption key is set the same on both DC1 and DC2.

Run the following commands, and verify that the outputs match:

```

apicup certs get mgmt_dallas encryption-secret -t key
apicup certs get mgmt_raleigh encryption-secret -t key

```

9. Complete the remainder of the steps in [Configuring the Management subsystem](#) from step [15](#) to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
10. Complete the steps in [Configuring the Developer Portal subsystem](#) up to and including step [16](#) to create a portal subsystem in Raleigh (DC2).
11. Configure the 2DCDR values to set Raleigh to be warm-standby for the portal subsystem on DC2.

Run the following commands:

```
apicup subsys set port_raleigh multi-site-ha-enabled=true
apicup subsys set port_raleigh multi-site-ha-mode=passive
apicup certs set port_raleigh portal-replication-ingress --clear
apicup subsys set port_raleigh portal-replication=ptlreplicationraleigh.cluster2.example.com
apicup subsys set port_raleigh replication-peer-fqdn=ptlreplicationdallas.cluster1.example.com
apicup subsys set port_raleigh site-name=raleigh
```

where

- `port_raleigh` is the name of the portal subsystem that you are configuring.
- `ptlreplicationraleigh.cluster2.example.com` is the ingress hostname for the current data center in the two data center deployment.
- `ptlreplicationdallas.cluster1.example.com` is the ingress hostname for the other data center in the two data center deployment.
- `raleigh` is the name of the site in the current data center.

12. Run the following command to generate the default portal certificates on the warm-standby site:

```
apicup certs generate port_raleigh
```

13. Copy the encryption key for the portal subsystem on DC1 over to the portal subsystem on DC2.

Run the following command to get the encryption key for the portal subsystem on DC1, and put it into a file that is called `port-encryption-secret`:

```
apicup certs get port_dallas encryption-secret -t key > port-encryption-secret
```

Run the following command to use the `port-encryption-secret` file to set the same encryption key on DC2:

```
apicup certs set port_raleigh encryption-secret port-encryption-secret
```

Where `port_dallas` is the name of the portal subsystem on DC1, and `port_raleigh` is the name of the portal subsystem on DC2.

To check that the encryption key is set the same on both DC1 and DC2, you can run the following commands and verify that the outputs match:

```
apicup certs get port_dallas encryption-secret -t key
```

```
apicup certs get port_raleigh encryption-secret -t key
```

14. Complete the remainder of the steps in [Configuring the Developer Portal subsystem](#) from step 19 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.

15. Log in to the virtual machine subsystems on DC2 by using an SSH tool, and check the status of the installation by running the `apic status` command.

16. Set your dynamic router to direct all traffic to DC1. The endpoints that must be directed to DC1 are:

Management subsystem endpoints

- `platform-api`
- `consumer-api`
- `cloud-admin-ui`
- `api-manager-ui`

Portal subsystem endpoints

- `portal-admin`
- `portal-www`

- **Validating your two data center deployment**

Use the `apicup health-check` command to confirm that the management subsystems are ready and synchronized:

```
apicup subsys health-check <management subsystem>
```

If the management subsystem is healthy, the `health-check` command returns silently with no output.

Create test data on both management and portal subsystems, and complete a test failover:

1. Create some test data, for example, on management create a local user registry: [Configuring a local user registry](#).
2. Complete a failover: [Failure handling of a two data center deployment](#).
3. Verify that the test data created on the original active site, exists on the new active site. For example, login to the Cloud Manager UI on the new active site and confirm the presence of the test local user registry.
4. Delete the test data.
5. Complete another failover to return to your original active and warm-standby configuration.

Example

Example of the management subsystem values that you can view by running the `apicup subsys get mgmt_name` command:

```
apicup subsys get mgmt_dallas
```

```

Upgrading API Connect

Upgrade API Connect on VMware to a newer version.

After reviewing the overview, use the procedures in this section to upgrade API Connect on VMware.

Note:

- For upgrading from v5, see [Migrating a Version 5 deployment](#).
- For information about how to maintain a two data center deployment, including upgrade considerations, see [Maintaining a two data center deployment](#).
- [Upgrade considerations on VMware](#)
Before upgrading API Connect on VMware, ensure that your deployment meets all the upgrade requirements.
- [Preparing to upgrade on VMware](#)
Prepare your VMware deployment for upgrading to the new version of API Connect 10.0.5.x.
- [Upgrading to the latest release on VMware](#)
You can upgrade API Connect on VMware.
- [Upgrading DataPower Gateway Service](#)
Use these instructions when upgrading DataPower Gateway Service in a non-Kubernetes environment, during upgrade of API Connect.
- [Upgrading from 2018 to 10.0.5.4 on VMware](#)
Upgrade API Connect 2018 FP24 and higher directly to 10.0.5.4 on VMware.
- [Enabling Analytics after upgrading](#)
After the upgrade successfully completes, re-enable Analytics data collection.
- [Troubleshooting upgrades on VMware](#)
Review the following troubleshooting guidance if you encounter a problem while upgrading API Connect on VMware.

Upgrade considerations on VMware

Before upgrading API Connect on VMware, ensure that your deployment meets all the upgrade requirements.

Tip: After upgrade, clear your browser cache, and open a new browser window. This action avoids stale cache issues in your browser, that can result in unexpected behavior in the Cloud Manager and API Manager UIs.

Supported upgrade paths

Table 1 lists the releases of IBM® API Connect v10 that can be upgraded to the newest version.

Table 1. Supported upgrade paths

Upgrade from:	How to upgrade to 10.0.5.6:
<ul style="list-style-type: none"> 10.0.5.5 10.0.5.4 10.0.5.3 10.0.5.2 10.0.5.1 10.0.4.0 and iFixes 10.0.3.0 and iFixes 10.0.1.15-eus 10.0.1.12-eus 10.0.1.11-eus 10.0.1.9-eus 10.0.1.6-ifix1-eus 	See Upgrading to the latest release on VMware Note: Version 10.0.5.0 did not support VMware.
<ul style="list-style-type: none"> 10.0.1.6-eus 	Complete 2 upgrades: <ol style="list-style-type: none"> 1. First, apply iFix 1 to your 10.0.1.6-eus deployment. 2. Then, upgrade to the latest version as explained in Upgrading to the latest release on VMware in this documentation.
<ul style="list-style-type: none"> 10.0.1.8-eus 10.0.1.7-eus 10.0.1.5-eus and iFixes 10.0.1.4-eus and iFixes 10.0.1.2-eus and iFixes 	Complete 2 upgrades: <ol style="list-style-type: none"> 1. Upgrade to 10.0.1.9-eus as explained in Upgrading to 10.0.1.9-eus on VMware in the API Connect 10.0.1.x-eus documentation. 2. Then, upgrade to the latest version as explained in Upgrading to the latest release on VMware in this documentation.
Older versions of 10.0.x: <ul style="list-style-type: none"> 10.0.2.0 10.0.1.1 10.0.1.0 10.0.0.0 	Complete 3 upgrades: <ol style="list-style-type: none"> 1. First, upgrade to 10.0.1.2-ifix1-eus as explained in Upgrading from Version 10 to 10.0.1.2-ifix1-eus in the API Connect 10.0.1.x-eus documentation. To upgrade to 10.0.1.2-ifix1-eus, you must deploy a fresh cluster and restore existing data into it. This procedure is required to deploy VMs with Ubuntu 20.4. 2. Then, upgrade to 10.0.1.9-eus as explained in Upgrading to 10.0.1.9-eus on VMware in the API Connect 10.0.1.x-eus documentation. 3. Finally, upgrade to the latest version as explained in Upgrading to the latest release on VMware in this documentation.
2018 FP24	Complete 2 upgrades: <ol style="list-style-type: none"> 1. First, upgrade to 10.0.5.4 as explained in Upgrading from 2018 to 10.0.5.4 on VMware. 2. Then, upgrade to 10.0.5.6 as explained in Preparing to upgrade on VMware.

Upgrade requirements

- API Connect is not supported on a FIPS-enabled environment.
- The instructions for upgrading apply to the latest version of API Connect.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order:
 1. Management
 2. Portal
 3. Analytics
 4. Gateway

Gateway must be upgraded after Management, because upgrading the Management service before the Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
- When maintaining API Connect, do not use `kubect1 exec` commands to access API Connect pods unless advised by IBM.
Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

Validating an API definition file with the API Dev Tools Swagger Parser

From IBM API Connect Version 10.0.3.0 or later, SwaggerDoc (OpenAPI 2.0) and OpenAPI 3.0 documents that form API definition files are now validated at stage or publish time by the API Dev Tools Swagger Parser. Before upgrading, you should ensure that your existing API definition files can be parsed and are considered valid by the Swagger Parser tool. Note that any API definitions that are already staged or published are not impacted, but would undergo Swagger Parser validation again should they be re-staged or re-published in the future.

You can use either of the following techniques to ensure that existing API definition files are can be parsed and considered valid by the Swagger Parser:

- Download and install the `swagger-parser-cli` tool (see <https://www.npmjs.com/package/swagger-cli>). This tool includes a `validate` command that can validate local API definition files against the SwaggerDoc (OpenAPI 2.0) and OpenAPI 3.0 schemas, in both JSON and YAML formats.
- Use the browser-based Swagger Parser Validator available at <https://apitools.dev/swagger-parser/online/>; this accepts a URL to existing files available online, or can accept text copied and pasted into the tool, in both JSON and YAML formats. It can likewise validate against the SwaggerDoc (OpenAPI 2.0) and OpenAPI 3.0

schemas.

Note: Staging or publishing an API in API Connect results in additional syntactic validation of IBM extensions to SwaggerDoc (OpenAPI 2.0) and OpenAPI 3.0, as well as semantic validation to make sure that policies and other resources that the API refers to are valid within the context of the staging or publishing operation. Any errors associated with this additional validation will not be caught by the local or online Swagger Parser tool, nor will they be caught by the `apic validate` toolkit CLI command.

The Swagger Parser tool will report an invalid OpenAPI document. For example, if a document is missing a mandatory section such as `info` or `paths`, the following error is reported:

```
[object Object] is not a valid Swagger API definition
```

If a required property is missing from a given section, a specific error is reported. For example, if the `info` section is missing the required `version` property, the following error is reported:

```
Swagger schema validation failed.  
Missing required property: version at #/info
```

```
JSON_OBJECT_VALIDATION_FAILED
```

Additionally, if the document contains any local references (that is, values of `$ref` properties) that do not resolve to an existing reference within the document (known as de-referencing), this is also be flagged as an error. For example, if a document contains the following as a reference:

```
schema:  
  $ref: '#/definitions/Pet'
```

then the definition of `Pet` (that is, `#/definitions/Pet`) **must** exist in the same document, at the given path (`definitions` section in this example), similar to the following:

```
definitions:  
  Pet:  
    type: object  
    required:  
    - name  
    properties:  
      id:  
        type: integer  
        format: int64
```

If the local reference is not found within the document, the following de-referencing error is reported:

```
Token "Pet" does not exist.
```

- [Additional considerations for upgrading analytics from a version prior to v10.0.5.0](#)

API Connect v10.0.5.0 introduced a new architecture for the Analytics subsystem, so some additional steps are required before and after upgrading from API Connect 10.0.4-ifix3 or 10.0.1.x.

Additional considerations for upgrading analytics from a version prior to v10.0.5.0

API Connect v10.0.5.0 introduced a new architecture for the Analytics subsystem, so some additional steps are required before and after upgrading from API Connect 10.0.4-ifix3 or 10.0.1.x.

The key changes to the Analytics subsystem are highlighted in [What's new in Version 10.0.5](#).

The most important consideration is that existing analytics data is deleted during the upgrade from 10.0.4-ifix3, and from 10.0.1.7-eus (or higher), and cannot be restored. After upgrading to v10.0.5.0 or later, you will have an empty analytics database. If you want to keep your existing analytics data on an external system, there are three options:

- [Exporting analytics data from the UI](#)
Before upgrading to v10.0.5, export any analytics data that you wish to keep using the UI.
- [Exporting analytics with the REST API](#)
Before upgrading to v10.0.5, export any analytics data that you want to keep by using the REST API.
- [Offloading analytics data](#)
An alternative to exporting your analytics data before upgrading to v10.0.5 is to enable analytics offload. However, when enabled this feature only offloads new analytics data. But if your upgrade is not planned for a few days or weeks, you can enable this feature now and avoid the need to export any new analytics data.
- [Update the analytics extra-values file](#)
Review all extra-values file settings and ensure that the file contains only valid v10.0.5 settings.

Exporting analytics data from the UI

Before upgrading to v10.0.5, export any analytics data that you wish to keep using the UI.

About this task

Note: This page refers to analytics features that existed in pre-v10.0.5 releases, for the purposes of exporting analytics data before upgrade. Exporting analytics data from v10.0.5 is described here [Exporting analytics from v10.0.5](#)

Use the Analytics Discover tab to search for event data and then export the *hits* (the records in the search results) to a file. Each hit represents one API invocation in the Gateway server. When you view the hits in the UI, the display is limited to 500 records. To view the entire set of hits, export the data to a CSV or JSON Lines file.

Procedure

1. Navigate to the Analytics page and click Discover.
2. Run a search.

Select a predefined search to run, or click  to define your own search, and then run it. Optionally apply filters to refine the results. The export option is only available when a search returns at least one hit.

3. Click Export (this option displays before the search results).
4. In the "Export Hits" panel, select the Filetype for the exported data. There are two options for the file's type:

- a. JSON Lines (.txt): Exports data to a .txt file that contains a complete JSON record for each hit.
- b. Comma-separated Values (.csv): Exports to a .csv file that can be viewed either in a text editor, a spreadsheet, or some other CSV viewer. If you intend to view the .csv file in a viewer that does not support special characters, select the following options as needed to ensure compatibility with your viewer:
 - i. Escape double quotes: Insert an additional quotation mark (") as an escape character before each " that is already included in the file.
 - ii. Escape special characters: Insert a quotation mark (") as an escape character before each of the following characters: = _ + % @

The content of the API event records in the CSV file depends on the logging policy that is set for the operation. If the logging policy includes the HTTP headers and the payload, then these details are included in the API event record. Where the payload is large, it might take longer to complete the export of the analytics data. For more information, see [activity-log_policy](#). For information about the fields that are included in the CSV file, see [API event records](#).

5. In the panel, click Export to start the export operation.
6. When the "The export has completed successfully." message displays, click Download to save the file, or click Another one? to run a new export operation. (Remember to save the current export results before running a new export).

Attention:

- If your browser is configured to block pop-ups, the download might be blocked. The precise behavior varies across browsers, but if you see a notification about "blocked pop-ups", reconfigure the browser to always allow pop-ups for the API Manager host address. Then check the "Export Hits" panel for the Download option, which completes the operation. If you do not see a Download option, repeat the export operation.
- If you navigate away from the Analytics interface before the exported file is downloaded, the download operation is suspended. If you return to Analytics before any other export operation begins and before the file expires, you might see a Download option that allows you to finish downloading the file. Otherwise, you must repeat the entire export operation.
- Each downloaded file is saved to the download location that is configured for your browser, using a randomly generated file name. If you intend to export more than once, and you are exporting to the same location each time, you might want to rename each file with a meaningful name.

Exporting analytics with the REST API

Before upgrading to v10.0.5, export any analytics data that you want to keep by using the REST API.

Before you begin

API Connect REST API calls are authenticated by using a bearer token in the authorization header. Use the toolkit credentials to request a bearer token. Toolkit credentials can be found in the API Manager UI:

1. Log in to the API Manager UI.
2. From the home page, click the Download toolkit tile.
3. Download the Toolkit credentials.
4. Open the downloaded `credentials.json` file, example:

```
...
"toolkit": {
  "endpoint": "https://mgmt.api.example.com/api",
  "client_id": "7409693f-f726-48b4-8909-7c0d26f13e81",
  "client_secret": "5feeb0be-17f8-41a4-96d6-d40f33d69ef6"
},
...
```

Take note of the `toolkit.client_id`, `toolkit.client_secret`, and `toolkit.endpoint` from this file. You will use these to get your bearer token.

About this task

The Analytics REST API is documented in the [API Connect v10.0.5LATEST](#) API Explorer. You can export the data catalog-by-catalog using `/analytics/catalogs/{org}/{catalog}/analytics-services/{analytics-service}/events`

Procedure

1. Use your provider organization credentials and client_id/secret to request a bearer token:

```
curl -v -k -X POST -d '{"username": "<username>", "password": "<password>", "realm": "<realm>", "client_id": "<client_id>", "client_secret": "<client_secret>", "grant_type": "password"}' -H 'Content-Type: application/json' -H 'Accept: application/json' https://<management server platform api endpoint>/token
```

Where:

- `<username>` is the provider org owner.
- `<password>` is the password for the specified `<username>`.
- `<realm>` is the user registry realm for the specified `<username>`. The default provider organization user registry realm is `provider/default-idp-2`.
- `<client_id>` is the client ID from the "toolkit" section of the `credentials.json` file, or as provided by your API Connect cloud administrator.
- `<client_secret>` is the client secret from the "toolkit" section of the `credentials.json` file, or as provided by your API Connect cloud administrator.
- `<management server platform api endpoint>` is the platform API endpoint from the "toolkit" section of the `credentials.json` file, or as provided by your API Connect cloud administrator.

The bearer token is returned in the `access_token` property:

```
{
  "access_token": "<bearer token>",
  "token_type": "Bearer",
  "expires_in": 28800
}
```

Note the `expires_in` value, which is the number of seconds before the token expires. After expiry you need to request a new bearer token.

2. Use the returned bearer token to call the analytics REST API:

```
curl -v -k -H 'Accept: application/json' -H 'Authorization: Bearer <bearer token>' -X GET --url 'https://<management server platform api endpoint>/analytics/catalogs/<provider org name>/<catalog name>/analytics-services/<analytics service name>/events?after=now-7d'
```

Where:

- `<management server platform api endpoint>` is the `toolkit.endpoint`, but with the `/api` at the end replaced with `/analytics` to access the analytics APIs.

In this example, the REST API call returns the last 7 days (note the `?after=now-7d` at end of the URL) of event data for the specified catalog:

```
{ "total": 2, "found": true, "events": [ { "id": "AYGplP_4umraqLKQkId3", "event": { "immediate_client_ip": "9.145.95.209", "developer_org_name": "", "resource_id": ":GET:/hola-mundo", "developer_org_id": "", "log_policy": "activity" ...
```

Note: For large data sets it might be necessary to make the REST call repeatedly, specifying a different time range for each call. For example, to capture events logged during a specific 30-minute interval, use: `?after=2022-06-28T09:00:00&before=2022-06-28T09:30:00`

3. Additional filters can be used as described in the REST API documentation for the call to GET `/analytics/catalogs/{org}/{catalog}/analytics-services/{analytics-service}/events`

Offloading analytics data

An alternative to exporting your analytics data before upgrading to v10.0.5 is to enable analytics offload. However, when enabled this feature only offloads new analytics data. But if your upgrade is not planned for a few days or weeks, you can enable this feature now and avoid the need to export any new analytics data.

The steps for configuring analytics offload are covered in the v10.0.1 documentation:

https://www.ibm.com/docs/en/SSMNE1 v10/com.ibm.apic.install.doc/analytics_install_offload_vm.html.

Update the analytics extra-values file

Review all extra-values file settings and ensure that the file contains only valid v10.0.5 settings.

The features and settings that are configured with the extra-values file are different in v10.0.5 from previous releases. Review the contents of your analytics extra-values file, and ensure that it contains only settings applicable to v10.0.5: [Reference: Fields in analytics-extra-values](#).

Important: If your extra-values file contains a `template:` section, this must be removed completely. If you have analytics memory overrides configured in a `template:` section, then review the available [development profiles](#) for v10.0.5, and update your deployment profile to match your memory requirements: [Changing deployment profiles on VMware](#).

Preparing to upgrade on VMware

Prepare your VMware deployment for upgrading to the new version of API Connect 10.0.5.x.

Before you begin

Review the [Upgrade considerations on VMware](#) to ensure that you are following a supported upgrade path and that you understand important changes that might affect your deployment.

About this task

Complete the following steps to prepare your deployment for upgrading to the newest version of API Connect.

Procedure

1. Upgrading from 10.0.1.8-eus or earlier, or from 10.0.4.0-ifix3 or earlier: Run the following command to retain the source version images for the upgrade:
 - Target version 10.0.5.1 or 10.0.5.2:

```
cp -R /var/lib/apiconnect-subsystem/registry/* /var/lib/apiconnect/side-registry/
```

- Target version 10.0.5.3 or later:

```
cp -R /var/lib/apiconnect-subsystem/registry/* /usr/local/lib/appliance-side-registry
```

2. Remove obsolete files to ensure a clean upgrade.

Attention: If you do not remove the obsolete files, the upgrade might fail.

- a. SSH into the node:

- i. Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```

- ii. When prompted, select Yes to continue connecting.
- iii. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

- b. Check the `/etc/apt/sources.list.d` directory for files of the format: `repo-<subsystem>-<version>-<appliance version>.list`
- c. Delete all files with names that match the format in substep b.
Run the following command for each file to delete it:

```
rm <file_path>
```

3. If you are upgrading from a release earlier than 10.0.5.1, preserve your analytics data and review your analytics extra-values file.
If upgrading from v10.0.4-ifix3, or upgrading from v10.0.1.6-eus (or higher): Upgrading to 10.0.5.x results in the deletion of existing analytics data. If you want to retain your analytics data, then you must export it before upgrade. Some of the settings in the extra-values file are not compatible with 10.0.5, so they must be reviewed before upgrade is started. For more information, see [Additional considerations for upgrading analytics from a version prior to v10.0.5.0](#).
4. If you are upgrading from 10.0.5.1, check the version of `containerd` used in your deployment.
There is a known issue where upgrades from 10.0.1.7-eus or 10.0.1.8-eus to 10.0.5.1 incorrectly upgraded the `containerd` version. This did not cause a problem in later 10.0.1.x versions or in 10.0.5.1, but might cause problems in newer versions of API Connect. Correct the problem now to ensure clean upgrades in the future.

On each node, complete the following steps to determine the version of `containerd` and if necessary, downgrade it to the correct version:

- a. Run the following command to check the version of `containerd` used in your deployment:

```
kubectl get nodes -o wide
```

The response looks like the following example:

```
NAME          STATUS  ROLES  AGE  VERSION  INTERNAL-IP  EXTERNAL-IP  OS-IMAGE          KERNEL-VERSION  CONTAINER-RUNTIME
s2toiaapi05101 Ready  master  352d  v1.23.5  10.98.128.7 <none>        Ubuntu 20.04.5 LTS  5.4.0-125-generic
containerd://1.6.6
```

- If the response shows `containerd://1.5.11` for the CONTAINER-RUNTIME, skip to the next step because you are already using the correct version of `containerd`.
 - If the response shows `containerd://1.6.6` for the CONTAINER-RUNTIME, complete this step to downgrade it to version 1.5.1.11.
- b. Run the following command on the node and verify that it returns successfully:

```
apic health-check
```

For more information on the health check, see [Checking cluster health on VMware](#).

- c. Run the following set of commands on the healthy node to downgrade the version of `containerd`:

```
systemctl stop appliance-manager
systemctl stop kubelet
systemctl stop containerd
apt-get --allow-downgrades upgrade -y containerd.io
sed -i 's/KillMode=process/KillMode=mixed/g' /lib/systemd/system/containerd.service
systemctl daemon-reload
systemctl restart containerd
apic lock
apic unlock
```

- d. Run the following command to verify that `containerd` now displays `containerd://1.5.11` for the CONTAINER-RUNTIME:

```
kubectl get nodes -o wide
```

Remember to complete these steps on every node.

5. If you did not need to run a health check in the previous step, run it now.

```
apic health-check
```

A health check is run automatically during the upgrade, but you might want to run it now to ensure that you are backing up a healthy deployment in the next step. For more information on the health check, see [Checking cluster health on VMware](#).

6. Back up the API Connect deployment.

This manual backup ensures that any data changes that occurred after the most recent scheduled backup are captured.

For details on creating a backup, see the appropriate documentation for the version of API Connect that you are upgrading from:

- 10.0.5.x: [Backing up and restoring on VMware](#)
- 10.0.1.x: [Backing up and restoring](#)
- 10.0.4-ifix3: [Backing up and restoring on VMware](#)

7. If you are upgrading from 10.0.5.1 and there is a Helm instance of the fluent-bit service running, uninstall the service by running the following command:

```
helm uninstall fluent-bit
```

In new versions of API Connect, fluent-bit is installed as part of the upgrade process.

8. [Configuring remote logging for a VMware deployment](#).

If not already configured, send your deployment logs to a remote server. The upgrade process terminates pods, and the logs will be lost if not stored remotely.

9. Ensure that port 9178 is open between the Analytics, Management, and Portal subsystems, and that the deployment is running `apicup`.

An i/o timeout error can occur if the firewall rejects traffic to the appliance. Example error message:

```
apicup subsys install test-analytics upgrade_analytics_lts_v10.0.1.0.tgz
INFO[0000] Preparing update
INFO[0010] Sending update packet to cluster (connected to testsrv0192.subnet1.example.com)
Error: failed to install the subsystem: unable to open file send stream:
rpc error: code = Unavailable desc = all SubConns are in TransientFailure,
```

```
latest connection error: connection error:
desc = "transport: Error while dialing dial tcp 1.2.3.4:9178: i/o timeout"
```

If you receive the error, make sure port 9178 is open and try again.

10. Download the `apicup` command executable from the same URL where you downloaded files for the new version of API Connect.

You must use the latest `apicup` with the latest product version.

11. Ensure that the original project directory (created with the `apicup` installer during the initial product installation) is available for use during the upgrade.

The original project directory is required to upgrade your deployment. You cannot perform an upgrade without the initial project directory because it contains pertinent information about the cluster.

The original project directory contains the `apiconnect-up-v10.yml` file. An upgrade using the same project directory as the one used for installation will transfer the `encryption-secret` and all other certificates for the project to the upgraded version.

12. Block all external traffic to the management server.

Upgrading API Connect requires down-time while files are transferred and updated. All external traffic to the management server from all sources (Cloud Manager UI, API Manager UI, CLI, and REST API) must be blocked. As a result, the Cloud Manager and API Manager UIs cannot be used during the upgrade. In addition, the Developer Portal cannot be used to create, update, or delete any applications, subscriptions, memberships, or consumer organizations during the upgrade.

13. Review the [Guidelines on upgrading your Developer Portal from Drupal 9 to Drupal 10](#) to ensure that any customizations to the Developer Portal are compatible with Drupal 10.

In API Connect 10.0.5.3, the Developer Portal moved from Drupal 9 to Drupal 10 (this upgrade also requires PHP 8.1). The upgrade tooling will update your Developer Portal sites; however, if you have any custom modules or themes, it is your responsibility to ensure their compatibility with Drupal 10 and PHP 8.1 before starting the upgrade.

Note: If you are upgrading to 10.0.5.3 from 10.0.1.7 or earlier, or from 10.0.5.0 or earlier, your Developer Portal sites will first be upgraded to Drupal 9.5 and then to Drupal 10. When you are planning your the upgrade to 10.0.5.3, consider the extended time frame. To shorten your upgrade window, consider removing the Developer Portal sites that you do not need.

Upgrading a two data center deployment

How to upgrade a two data center disaster recovery (DR) deployment on VMware.

To upgrade a two data center disaster recovery deployment, follow the [Upgrading to the latest release on VMware procedures](#) along with the additional procedures that are described in this topic.

Key points for two data center disaster recovery upgrade on VMware:

- Both data centers must be using the same version of API Connect, including down to the specific fix pack and interim fix level. Therefore, both data centers must be upgraded in the same maintenance window.
- Do not reboot any of the management or portal virtual machines until the end of the upgrade, even if you're instructed to do so by the `apicup subsys health-check` command during the upgrade process.
- 2DCDR is disabled on the management subsystems during the upgrade process. Keep a note of which data center had the active management subsystems when you start the upgrade process; set this same data center as the active at the end of the process.
- For the portal subsystems, 2DCDR is not disabled during upgrade, and the warm-standby data center must be upgraded first.

Upgrade the subsystems in the following order:

1. Review the [Upgrade considerations on VMware](#).
2. Complete the [Preparing to upgrade on VMware](#) steps.
3. Complete the pre-upgrade verification of your 2DCDR deployment, following the [Upgrade on VMware](#) steps, but stop before you run step [10.a](#).
4. If you are upgrading to v10.0.5.5 or later, follow [Management subsystem two data center upgrade to v10.0.5.5 and later](#).
5. If you are upgrading to v10.0.5.4 or earlier, follow [Management subsystem two data center upgrade to v10.0.5.4 and previous](#).
6. To upgrade the portal subsystem, follow the steps in [Upgrade on VMware](#), but ensure that the warm-standby is upgraded first.
7. Upgrade analytics and gateway subsystems as described in [Upgrade on VMware](#).

How to upgrade when one data center is down

If you cannot get your failed data center back online and want to upgrade, you can convert your active data center to a stand-alone and upgrade it:

1. Ensure that the network links to the failed data center are removed, so that if the failed data center recovers unexpectedly, it cannot interfere with your active data center.
2. Convert the active data center to a stand-alone data center: [Removing a two data center deployment](#).
3. Upgrade your active data center with the standard upgrade steps: [Upgrade on VMware](#).

To restore 2DCDR, replace the API Connect deployment in your failed data center with a new installation at the same fix pack level as your upgraded active data center. Follow the steps in [Installing a two data center deployment on VMware](#) to configure 2DCDR between the data centers.

Management subsystem two data center upgrade to v10.0.5.5 and later

About this task

Follow the steps in this topic, along with the steps documented in [Upgrading to the latest release on VMware](#).

Some steps in the upgrade process are run from the project directory with the **apicup** command. Other steps require you to login to the management VMs as root user. To login as root, follow these steps:

- Use SSH to login to the VM as the **apicadm** user:

```
ssh apicadm@<hostname>
```

- Switch to the root user with **sudo**:

```
sudo -i
```

Procedure

1. Review the [Upgrade considerations on VMware](#).
2. Complete the [Preparing to upgrade on VMware](#) steps.
3. Run the upgrade command on both sites with the **--skip-operand-update** flag:

```
apicup subsys install <subsystem name> <subsystem upgrade tar archive> --skip-operand-update
```

Note: If any Control Plane files are needed for your upgrade, you must append the files to the **install** command. For example:

```
apicup subsys install <subsystem name> <subsystem upgrade tar archive> <path to control plane file 1> <path to control plane file 2> --skip-operand-update
```

The **--skip-operand-update** flag tells the subsystem to update only the API Connect operator on the VMs, and not the management software on the VM (the operand).

4. Login to the VMs on both sites and monitor the status. Verify that the subsystem status reaches the **Running** state.

```
kubectl get mgmt
```

NAME	READY	STATUS	VERSION	RECONCILED	VERSION	AGE
management	n/n	Running	<current version>	<current version>	<current version>	5h2m

The **RECONCILED VERSION/VERSION** should still show your current version, not the version you are upgrading to.

5. Disable 2DCDR on the **warm-standby** management subsystem:

```
apicup subsys set <warm-standby management subsystem> multi-site-ha-enabled=false
apicup subsys install <warm-standby management subsystem>
```

Conversion from warm-standby to a stand-alone management subsystem can take some time. Run the health check to ensure that the deployment is in a good state before proceeding:

```
apicup subsys health-check <warm-standby management subsystem>
```

an empty response means no detected problems.

6. Disable 2DCDR on the active management subsystem.

```
apicup subsys set <active management subsystem> multi-site-ha-enabled=false
apicup subsys install <active management subsystem>
```

Conversion from active to a stand-alone management subsystem can take some time. Run the health check to ensure that the deployment is in a good state before proceeding:

```
apicup subsys health-check <active management subsystem>
```

an empty response means no detected problems.

7. Run the upgrade command on both sites without the **--skip-operand-update** flag:

```
apicup subsys install <subsystem name> <subsystem upgrade tar archive>
```

8. Continue following the standard management subsystem upgrade steps, from step [10.a](#) on [Upgrading to the latest release on VMware](#).
9. After the upgrades on both sites are complete, re-enable 2DCDR on the previously **active** management subsystem.

```
apicup subsys set <active management subsystem> multi-site-ha-enabled=true
apicup subsys install <active management subsystem>
```

Login to the active VM to verify that the subsystem status reaches the **Running** state.

```
kubectl get mgmt
```

NAME	READY	STATUS	VERSION	RECONCILED	VERSION	AGE
management	n/n	Running	<new version>	<new version>	<new version>	5h2m

10. Enable 2DCDR on the previously warm-standby management subsystem.

```
apicup subsys set <warm-standby management subsystem> multi-site-ha-enabled=true
apicup subsys install <warm-standby management subsystem>
```

Login to the warm-standby VM to verify that the subsystem status reaches the **Running** state.

```
kubectl get mgmt
```

NAME	READY	STATUS	VERSION	RECONCILED	VERSION AGE
management	n/n	Running	<new version>	<new version>	5h2m

Management subsystem two data center upgrade to v10.0.5.4 and previous

How to upgrade your management subsystem in a two data center deployment.

About this task

If you are upgrading to v10.0.5.5 or later, then do not use this page, instead refer to: [Management subsystem two data center upgrade to v10.0.5.5 and later](#).

Follow the steps in this topic, along with the steps documented in [Upgrading to the latest release on VMware](#).

The steps in this topic involve running command-line operations from several locations:

- **apicup** operations are run from your API Connect project directory.
Note: The **apicup** command is a binary file that is included with each API Connect release. Unless stated otherwise, all operations in this topic that use the **apicup** command must use the **apicup** binary from the target release (the release that you want to upgrade to). Be careful not to use the **apicup** command from your source release.
- **apic** and **kubectl** operations are run from within your management appliance, as the root user. Login to your management virtual appliance with an SSH client and the username **apicadm**, then switch to the root user with **sudo -i**.

Procedure

1. Determine the current version and license of API Connect (the version that you are upgrading from). You will need to specify the correct version number and license in the next step.
 - a. To get the current version, from within the management appliance run the following command:

```
apic version
```

In the response, the `- subsystem-<subsystem-name>` statement displays the installed version. In the following example, the response indicates that the installed version is 10.0.5.2:

```
apic version

INFO[0000] Log level: info
Control plane: 1.26.0
Appliance base 4.6.0
GitCommitSha:10.0.5.2-55-gb784ac7
Packages:
- appliance-base:4.6.0
- appliance-runtime-4.6.0:1.0.0
- appliance-setup-4.6.0:1.0.0
- subsystem-management:1:10.0.5.2
```

Important: If you are upgrading from a source version of 10.0.1.x, you must append `-eus` to the end of all references to that version number; for example 10.0.1.2-ifix2-eus.

- b. To get the current license, run the following **apicup** command in your project directory:

```
apicup licenses list
```

in the response, the `ID` statement displays the installed license, for example:

```
Accepted licenses:
ID: <source_license>
Product Version: <source_version>
URL: <license_url>
```

Note: If there are multiple accepted licenses, refer only to the `<source_license>` that aligns with the `<source_version>` of your system (that is the `<source_version>` that matches the version that you obtained in step [1.a](#)).

2. Add source license and version to your `extra-values.yaml` file.
Note: If you do not have an `extra-values.yaml` file, then create one in a directory that the **apicup** command can access.
Add the source lines that you identified in step [1.b](#) to your `extra-values.yaml` as shown:

```
spec:
  version: "<source_version>"
  license:
    license: <source_license>
  imageRegistry: 127.0.0.1:8675/<source_version>
```

3. Apply the `extra-values.yaml` file.
Run the following **apicup** command to set the `extra-values` file for both the `active` and `warm-standby` sites:

```
apicup subsys set <mgmt> extra-values-file=<extra-values-file-path>
```

where `<mgmt>` is the name of your management subsystem, which you can get with:

```
apicup subsys list
```

If you want to validate your `<extra-values-file-path>`, and the other subsystem settings, before proceeding, you can run:

```
apicup subsys get <mgmt> --validate
```

4. Start the upgrade process on both active and warm-standby management subsystems.

```
apicup subsys install <mgmt> <mgmt_upgrade_tar_archive>
```

Note: If any Control Plane files are needed for your upgrade, you must append the files to the `install` command.

5. Wait for the management subsystem status to become **Running** on both sites.

To determine the status, login to the management appliances on both sites as root user and run:

```
kubectl get mgmt
```

NAME	READY	STATUS	VERSION	RECONCILED	VERSION	AGE
management	n/n	Running	10.0.5.2	10.0.5.2-100	5h2m	

The **RECONCILED**

VERSION/VERSION should be the `source_version` that you retrieved in step 1.

6. Disable 2DCDR on the `warm-standby` management subsystem:

```
apicup subsys set <warm-standby management subsystem> multi-site-ha-enabled=false
apicup subsys install <warm-standby management subsystem>
```

Conversion from warm-standby to a stand-alone management subsystem can take some time. Run the health check to ensure that the deployment is in a good state before proceeding:

```
apicup subsys health-check <warm-standby management subsystem>
```

an empty response means no detected problems.

7. Disable 2DCDR on the active management subsystem.

```
apicup subsys set <active management subsystem> multi-site-ha-enabled=false
apicup subsys install <active management subsystem>
```

Conversion from active to a stand-alone management subsystem can take some time. Run the health check to ensure that the deployment is in a good state before proceeding:

```
apicup subsys health-check <active management subsystem>
```

an empty response means no detected problems.

8. Wait for the management subsystem status to become **Running** on both sites.

To determine the status, login to the management appliances on both sites as root user and run:

```
kubectl get mgmt
```

NAME	READY	STATUS	VERSION	RECONCILED	VERSION	AGE
management	n/n	Running	10.0.5.2	10.0.5.2-100	5h2m	

The **RECONCILED**

VERSION/VERSION should be the `source_version` that you retrieved in step 1.

9. Remove the source license and version from your extra-values.yaml file.

Delete the `version`, `license`, and `imageRegistry` lines that you added to your extra-values.yaml file in step 2.

Apply this change to both sites by running:

```
apicup subsys install <mgmt>
```

10. Wait for the management subsystems status to become **Running** on both sites.

```
kubectl get mgmt
```

NAME	READY	STATUS	VERSION	RECONCILED	VERSION	AGE
management	16/16	Running	10.0.5.3	10.0.5.3-100	5h2m	

The **RECONCILED** **VERSION/VERSION** should now be the target release that you are upgrading to.

11. Run the health check on both clusters to ensure that the upgrade completed.

```
apicup subsys health-check <mgmt>
```

an empty response means no detected problems.

12. Enable 2DCDR on the previously `active` management subsystem.

```
apicup subsys set <active management subsystem> multi-site-ha-enabled=true
apicup subsys install <active management subsystem>
```

13. Wait for the management subsystem status to become **Running** on the active site.

```
kubectl get mgmt
```

NAME	READY	STATUS	VERSION	RECONCILED	VERSION	AGE
management	16/16	Running	10.0.5.3	10.0.5.3-100	5h2m	

The **RECONCILED** **VERSION/VERSION** should now be the target release that you are upgrading to.

14. Enable 2DCDR on the previously `warm-standby` management subsystem.

```
apicup subsys set <warm-standby management subsystem> multi-site-ha-enabled=true
apicup subsys install <warm-standby management subsystem>
```

15. Wait for the management subsystem status to become **Running** on the warm-standby site.

```
kubectl get mgmt
```

NAME	READY	STATUS	VERSION	RECONCILED	VERSION	AGE
management	16/16	Running	10.0.5.3	10.0.5.3-100	5h2m	

The **RECONCILED** **VERSION/VERSION** should now be the target release that you are upgrading to.

16. Verify that 2DCDR replication is working.

To validate that your two data center deployment is replicating data, login to your active management appliance as root user, run `kubectl get mgmt`:

```
kubectl get mgmt
```

NAME	READY	STATUS	VERSION	RECONCILED	VERSION	MESSAGE	AGE
management	n/n	Running	10.0.5.3-0	10.0.5.3-100		Management is ready.	8m59s

If you see **HA Status Warning** in the **MESSAGE** column, then check the status details with `kubectl describe mgmt`:

```
status:
  haStatus:
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
    }
}
```

Notes:

- It takes time for the **warm-standby** site to sync with the **active** site.
- When **STATUS** shows **Running**, you can reboot (if `apicup subsys health-check` advises you to do so).

Upgrading to the latest release on VMware

You can upgrade API Connect on VMware.

Before you begin

- Before starting an upgrade, review the supported upgrade paths from prior versions: [Upgrade considerations on VMware](#).
- Enable keep-alive in your SSH configuration to avoid problems during the upgrade. For information, consult the documentation for your version of SSH.

Attention: Upgrading to v10.0.5.x from v10.0.4-ifix3, or from 10.0.1.6-ifix1-eus (or higher):

- Upgrading to v10.0.5.x results in the deletion of existing analytics data. If you want to retain your analytics data then you must export it before upgrading. For instructions on exporting the data, see [Additional considerations for upgrading analytics from a version prior to v10.0.5.0](#). When you upgrade subsystems in this scenario, you must include the `--accept-data-loss` parameter on all `apicup install` commands that result in an upgrade from the older releases. Since you upgrade the Management subsystem first, including the parameter at that point commits you to the loss of data, and the operation cannot be reversed.
- Delete any `template` section from your analytics CR before upgrading. For instructions, see [Update the analytics extra-values file](#).

About this task

You can upgrade the Management subsystem, Developer Portal subsystem, and Analytics subsystem. The Gateway subsystem remains available during the upgrade of the other subsystems.

For the optional components API Connect Toolkit and API Connect Local Test Environment, you do not need to upgrade. For these components, install the new version of each after you upgrade the subsystems.

Important notes:

- When installing the new files, be sure to use the new `apicup` installer.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order: (1) Management, (2) Portal, (3) Analytics, (4) Gateway. Management must be upgraded first. Gateway must be upgraded after Management because upgrading the Management service before the Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.
- When you run the install, the program sends the compressed tar file, which contains the upgrade images, to all cluster members. The compressed tar file is about 2 GB, and transfer can take some time. When the install command exits, the compressed tar file has arrived at each member. The upgrade process is now underway, and might continue for some time depending on factors such as the size of your deployment, your network speed, and so on.
- The `apicup subsys install` command automatically runs `apicup health-check` prior to attempting the upgrade. An error is displayed if a problem is found that will prevent successful upgrade. When troubleshooting a problem with an upgrade, you can optionally suppress the health check. See [Skipping health check when re-running upgrade](#).
- The certificate and `manager` was upgraded in earlier versions of API Connect. If you are upgrading from an earlier release, then after you trigger the upgrade from the `apim`, `lur`, and `taskmanager` pods will be in a CrashLoopBackoff state due to Postgres requiring a certificate refresh. Correct the problem by completing the following steps:
 1. SSH into the server:
 - a. Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```
 - b. When prompted, select Yes to continue connecting.
 - c. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

2. Run the following command to delete the Postgres pods, which refreshes the new certificate:

```
kubectl get pod --no-headers=true | grep postgres | grep -v backup | awk '{print $1}' | xargs kubectl delete pod
```

Procedure

Attention: If you encounter an issue while performing the upgrade, see [Troubleshooting upgrades on VMware](#).

1. Complete the prerequisites:
 - a. Ensure that your deployment meets the upgrade requirements. See [Upgrade considerations on VMware](#).
 - b. Complete the steps in [Preparing to upgrade on VMware](#) to ensure that your environment is ready for the upgrade.
 - c. Verify the API Connect deployment is healthy and fully operational. See [Checking cluster health on VMware](#)
 - d. Remove any stale upgrade files:

```
apic clean-upgrade-files
```

- e. Verify sufficient free disk space.
For each appliance node that you are planning to upgrade:

- i. SSH into the appliance, and switch to user `root`.
- ii. Check disk space in `/data/secure`:

```
df -h /data/secure
```

Make sure the disk usage shown is below 70%. If it is not, add disk capacity. See [Adding disk space to a VMware appliance](#).

- iii. Check free disk space in `/`:

```
df -h /
```

Make sure usage is below 70%. If it is not, consider deleting or offloading older `/var/log/syslog*` files.

- f. Complete a manual backup of the API Connect subsystems as explained in [Backing up and restoring on VMware](#).

Notes:

- Do not start an upgrade if a backup is scheduled to run within a few hours.
- Do not perform maintenance tasks such as rotating key-certificates, restoring from a backup, or starting a new backup, at any time while the upgrade process is running.

2. Back up the Postgres images on one of the Management Server VMs.

Follow the steps for the version of API Connect that you are upgrading from:

- 10.0.1.9 or later, and 10.0.5.1 or later:

```
SSH to one of the Management Server VMs:
ssh <ip_address of management vm> -l apicadm
Sudo to root:
sudo -i
```

Run the following commands:

```
postgres_operator=$(kubectl get pod -l app.kubernetes.io/name=postgres-operator -o name)

ctr --namespace k8s.io images pull --plain-http=true `kubectl get $postgres_operator -o
jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_PGO_RMDATA")].value}'`
ctr --namespace k8s.io images export rmdata.tar `kubectl get $postgres_operator -o
jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_PGO_RMDATA")].value}'`
ctr --namespace k8s.io images export backrestrepo.tar `kubectl get $postgres_operator -o
jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_PGO_BACKREST_REPO")].value}'`
ctr --namespace k8s.io images export pgbouncer.tar `kubectl get $postgres_operator -o
jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_CRUNCHY_PGBOUNCER")].value}'`
ctr --namespace k8s.io images export postgres-ha.tar `kubectl get $postgres_operator -o
jsonpath='{.spec.containers[].env[?(@.name=="RELATED_IMAGE_CRUNCHY_POSTGRES_HA")].value}'`

postgres_pod=$(kubectl get pod -l role=master -o name)
ctr --namespace k8s.io images export k8s-init.tar `kubectl get $postgres_pod -o
jsonpath='{.spec.initContainers[].image}'`
```

- 10.0.1.8 or earlier, and 10.0.4.0-ifix3 or earlier:

```
SSH to one of the Management Server VMs:
ssh <ip_address of management vm> -l apicadm
Sudo to root:
sudo -i
```

Run the following commands:

```
postgres_operator=$(kubectl get pod -l app.kubernetes.io/name=postgres-operator -o name)

docker pull `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?
(@.name=="RELATED_IMAGE_PGO_RMDATA")].value}'`
docker pull `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?
(@.name=="RELATED_IMAGE_PGO_BACKREST_REPO")].value}'`
docker pull `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?
(@.name=="RELATED_IMAGE_CRUNCHY_PGBOUNCER")].value}'`
docker pull `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?
(@.name=="RELATED_IMAGE_CRUNCHY_POSTGRES_HA")].value}'`
docker save `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?
(@.name=="RELATED_IMAGE_PGO_RMDATA")].value}'` -o rmdata.tar
docker save `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?
(@.name=="RELATED_IMAGE_PGO_BACKREST_REPO")].value}'` -o backrestrepo.tar
docker save `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?
(@.name=="RELATED_IMAGE_CRUNCHY_PGBOUNCER")].value}'` -o pgbouncer.tar
docker save `kubectl get $postgres_operator -o jsonpath='{.spec.containers[].env[?
(@.name=="RELATED_IMAGE_CRUNCHY_POSTGRES_HA")].value}'` -o postgres-ha.tar
```

```
postgres_pod=$(kubectl get pod -l role=master -o name)
docker save `kubectl get $postgres_pod -o jsonpath='{.spec.initContainers[].image}` -o k8s-init.tar
```

Note: After performing the upgrade, if you see that the Postgres pods are in the `imagePullBackOff` state, correct the issue by following steps 2 and 3 in [Management subsystem upgrade imagePullBackOff issue](#) to import each of the images you saved in this step.

3. Run the pre-upgrade health check:

Attention: This is a required step. Failure to run this check before upgrading could result in problems during the upgrade.

a. Run the health check on the Management subsystem:

Note: If you have a 2DCDR deployment, run this check only on the active management subsystem.

i. SSH into the server:

1. Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```

2. When prompted, select Yes to continue connecting.

3. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

ii. Verify that the `apicops` utility is installed by running the following command to check the current version of the utility:

```
apicops --version
```

If the response indicates that `apicops` is not available, install it now. See [The API Connect operations tool: apicops](#) in the API Connect documentation.

iii. Run the version-check script and verify that there are no errors:

```
apicops version:pre-upgrade
```

iv. Run the appliance health check and verify that there are no errors:

```
apicops appliance-checks:appliance-pre-upgrade
```

b. Run the health check on the Portal subsystem:

i. SSH into the server.

ii. Verify that the `apicops` utility is installed by running the following command to check the current version of the utility:

```
apicops --version
```

If the response indicates that `apicops` is not available, install it now. See [The API Connect operations tool: apicops](#) in the API Connect documentation.

iii. Run the following command to check the system status, and verify that there are no errors:

```
apicops upgrade:check-subsystem-status
```

iv. Run the appliance health check and verify that there are no errors:

```
apicops appliance-checks:appliance-pre-upgrade
```

c. Run the health check on the Analytics subsystem:

i. SSH into the server.

ii. Verify that the `apicops` utility is installed by running the following command to check the current version of the utility:

```
apicops --version
```

If the response indicates that `apicops` is not available, install it now. See [The API Connect operations tool: apicops](#) in the API Connect documentation.

iii. Run the following command to check the system status, and verify that there are no errors:

```
apicops upgrade:check-subsystem-status
```

iv. Run the appliance health check and verify that there are no errors:

```
apicops appliance-checks:appliance-pre-upgrade
```

4. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVA's and restoring from normal backups.

Important: VM snapshots are not an alternative to the standard API Connect backups that are described in the previous steps. You must complete the API Connect backups in order to use the API Connect restore feature.

5. Obtain the API Connect files:

You can access the latest files from [IBM Fix Central](#) by searching for the API Connect product and your installed version.

The following files are used during upgrade on VMware:

IBM API Connect <version> Management Upgrade File for VMware

Management subsystem files for upgrade

IBM API Connect <version> Developer Portal Upgrade File for VMware

Developer Portal subsystem files for upgrade

IBM API Connect <version> Analytics Upgrade File for VMware

Analytics subsystem files for upgrade

IBM API Connect <version> Install Assist for <operating_system_type>

The apicup installation utility. Required for all installations on VMware.

The following files are not used during upgrade, but can be installed as new installations used to replace prior versions

IBM API Connect <version> Toolkit for <operating_system_type>

Toolkit command line utility. Packaged standalone, or with API Designer or Loopback:

- IBM API Connect <version> Toolkit for <operating_system_type>
- IBM API Connect <version> Toolkit with Loopback for <operating_system_type>
- IBM API Connect <version> Toolkit Designer with Loopback for <operating_system_type>

Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See [Installing the toolkit](#).

IBM API Connect <version> Local Test Environment

Optional test environment. See [Testing an API with the Local Test Environment](#)

IBM API Connect <version> Security Signature Bundle File

Checksum files that you can use to verify the integrity of your downloads.

6. If necessary, download (from the same Fix Pack page) any Control Plane files that are needed.

Control Plane files provide support for specific Kubernetes versions. The IBM API Connect <version> Management Upgrade File for VMware file contains the latest Control Plane file. An upgrade from the most recent API Connect version to the current version does not need a separate Control Plane file. However, when upgrading from older versions of API Connect, you must install one or more control plane files to ensure that all current Kubernetes versions are supported.

Consult the following table to see if your deployment needs one or more separate Control Plane files.

Table 1. Control Plane files needed for upgrade

Version to upgrade from	Instructions for upgrading to 10.0.5.6
<ul style="list-style-type: none">• 10.0.5.5• 10.0.5.4• 10.0.5.3• 10.0.1.15-eus• 10.0.1.12-eus	No control-plane file needed.

On the Fix Central page, type "control-plane" in the Filter fix details field to only show the list of control plane files in the results table. Then, click the Description header to sort the results so you can easily locate the control plane files that you need.

For information on the Control Plane files used with older releases, see [Control Plane files for earlier releases](#).

7. Verify that the subsystem upgrade files are not corrupted.

a. Run the following command separately for the Management, the Developer Portal, and the Analytics upgrade files:

- Mac or Linux:

```
sha256sum <upgrade-file-name>
```

Example:

```
sha256sum upgrade_management_v10.0.5.6
```

- Windows:

```
C:\> certUtil -hashfile C:\<upgrade-file-name> SHA256
```

Example:

```
C:\> certUtil -hashfile C:\upgrade_management_v10.0.5.6 SHA256
```

b. Compare the result with the checksum values to verify that the files are not corrupted.

If the checksum does not match the value for the corresponding version and subsystem, then the upgrade file is corrupted. Delete it and download a new copy of the upgrade file. The following list shows the checksum values for the current release.

Checksum values:

```
10.0.5.6 analytics : dfaa21ab9daac33bbd0b28eac8c01cff9b5bea1f31ef0a8c38c45664571810a0
10.0.5.6 management : 9fcf6927a4846c6049ebef920972d4056c1d30f015949e98043293f91775737e
10.0.5.6 portal : b94b46331ef9b1f949c637b86ab7943142ef9c2ce514d9da2650960a66e9d7b1
```

For information on the checksum files used with older releases, see [Checksum values for earlier releases](#).

8. Install the installation utility.

a. Locate the apicup installation utility file for your operating system, and place it in your project directory

b. Rename the file for your OS type to **apicup**. Note that the instructions in this documentation refer to **apicup**.

c. OSX and Linux® only: Make the apicup file an executable file by entering **chmod +x apicup**.

d. Set your path to the location of your apicup file.

OSX and Linux	export PATH=\$PATH:/Users/your_path/
Windows	set PATH=c:\your_path;%PATH%

e. From within your project directory, specify the API Connect license:

```
apicup licenses accept <License_ID>
```

The <License_ID> is specific to the API Connect Program Name you purchased. To view the supported license IDs, see [API Connect licenses](#).

9. **If upgrading from v10.0.4-ifix3, or upgrading from v10.0.1.7-eus (or higher):** Disassociate and delete your Analytics services.

Important: Upgrading to v10.0.5.x from v10.0.4-ifix3, or from v10.0.1.6-eus (or higher) will result in the deletion of existing analytics data. If you want to retain your analytics data then you must export it before upgrade. For instructions on exporting see [Additional considerations for upgrading analytics from a version prior to v10.0.5.0](#).

a. In Cloud Manager UI, click Topology.

b. In the section for the Availability Zone that contains the Analytics service, locate the Gateway service that the Analytics service is associated with.

c. Click the actions menu, and select Unassociate analytics service.

Remember to disassociate each Analytics service from all Gateways.

d. In the section for the Availability Zone that contains the Analytics services, locate each Analytics service and click Delete.

10. Upgrade the Management subsystem:

a. Run the upgrade on the Management subsystem:

i. Install the Management subsystem files.

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive>
```

Notes:

- If you are adding one or more control plane files, specify each path and file name on the command line:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file_1> <path_to_control_plane_file_n>
```

- If you are upgrading to v10.0.5.x from v10.0.4-ifix3, or upgrading from v10.0.1.7-eus (or higher), add the argument `--accept-data-loss` to the command to indicate that you accept the loss of the Analytics data:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> --accept-data-loss
```

Remember, when you include this parameter for the Management subsystem upgrade, you commit to the loss of data and the operation cannot be undone.

ii. Verify that the upgrade was successful by running a health check with the following command:

```
apicup subsys health-check <subsystem_name>
```

iii. If upgrading to 10.0.5.6, verify that the health check did not return a false-positive response.

Note: This step only applies if you upgraded to API Connect 10.0.5.6 and is due to a known issue that will be corrected in a later release.

Run the following command to get the current version of API Connect on the upgraded subsystem:

```
kubectl get apic
```

If the health check indicates a successful upgrade but the subsystem is still running the older version of API Connect, skip the remaining steps in this procedure and see [False positive result from health check after upgrading to 10.0.5.6](#) for troubleshooting instructions.

If the subsystem is running the newer version of API Connect then the upgrade was successful; continue with the remaining steps in this procedure.

iv. If the health check indicates that a reboot is needed, run the following command:

```
systemctl reboot
```

b. Use `apicops` to validate the certificates.

For information on the `apicops` tool, see [The API Connect operations tool: apicops](#).

i. Run the following command:

```
apicops upgrade:stale-certs -n <namespace>
```

ii. Delete any stale certificates that are managed by cert-manager.

If a certificate failed the validation and it is managed by cert-manager, you can delete the stale certificate secret, and let cert-manager regenerate it.

Run the following command:

```
kubectl delete secret <stale-secret> -n <namespace>
```

iii. Restart the corresponding pod so that it can pick up the new secret.

To determine which pod to restart, see the following topics:

- [List of ingress certificates](#)
- [List of intra-subsystem certificates](#)

c. Restart all nats-server pods.

i. Run the following command to connect as the API Connect administrator, replacing `<ip_address>` with the appropriate IP address:

```
ssh <ip_address> -l apicadm
```

ii. When prompted, select Yes to continue connecting.

iii. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

iv. Restart all nats-server pods by running the following command:

```
kubectl -n <namespace> delete po -l app.kubernetes.io/name=natscluster
```

d. If needed, delete old Postgres client certificates.

If you are upgrading from 10.0.1.x or 10.0.4.0-ifix1, or if you previously installed any of those versions before upgrading to 10.0.5.x, there might be old Postgres client certificates. To verify, run the following command:

```
kubectl -n <namespace> get certs | grep db-client
```

For example, if you see that both `-db-client-apicuser` and `apicuser` exist, `apicuser` is no longer in use. Remove the old certificates by running one of the following commands, depending on how many old certifications left in your system:

```
kubectl -n <namespace> delete certs apicuser pgbouncer primaryuser postgres replicator
```

or:

```
kubectl -n <namespace> delete certs apicuser pgbouncer postgres replicator
```

11. If there are multiple Management subsystems in the same project, set the Portal subsystem's `platform-api` and `consumer-api` certificates to match those used by the appropriate Management subsystem to ensure that the Portal subsystem is correctly associated with that Management subsystem. This step only applies if you installed more than one Management subsystem into a single project.

A Portal subsystem can be associated with only one Management subsystem. To associate the upgraded Portal subsystem with the appropriate Management subsystem, manually set the `mgmt-platform-api` and `mgmt-consumer-api` certificates to match the ones used by the Management subsystem.

- a. Run the following commands to get the certificates from the Management subsystem:

```
apicup certs get mgmt-subsystem-name platform-api -t cert > platform-api.crt
apicup certs get mgmt-subsystem-name platform-api -t key > platform-api.key
apicup certs get mgmt-subsystem-name platform-api -t ca > platform-api-ca.crt

apicup certs get mgmt-subsystem-name consumer-api -t cert > consumer-api.crt
apicup certs get mgmt-subsystem-name consumer-api -t key > consumer-api.key
apicup certs get mgmt-subsystem-name consumer-api -t ca > consumer-api-ca.crt
```

where *mgmt-subsystem-name* is the name of the specific Management subsystem that you want to associate the new Portal subsystem with.

- b. Run the following commands to set the Portal's certificates to match those used by the Management subsystem:

```
apicup certs set ptl-subsystem-name platform-api Cert_file_path Key_file_path CA_file_path
apicup certs set ptl-subsystem-name consumer-api Cert_file_path Key_file_path CA_file_path
```

For more information on `apicup` certificate commands, see [Command reference](#).

12. Upgrade the Portal subsystem.

- a. If you did not verify that your Portal customizations are compatible with Drupal 10, do that now.

In API Connect 10.0.5.3, the Developer Portal moved from Drupal 9 to Drupal 10 (this upgrade also requires PHP 8.1). The upgrade tooling will update your Developer Portal sites; however, if you have any custom modules or themes, it is your responsibility to ensure their compatibility with Drupal 10 and PHP 8.1 before starting the upgrade. Review the [Guidelines on upgrading your Developer Portal from Drupal 9 to Drupal 10](#) to ensure that any customizations to the Developer Portal are compatible with Drupal 10 and PHP 8.1.

- b. Install the Portal subsystem files:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive>
```

Notes:

- If you are adding one or more control plane files, specify each path and file name on the command line:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file_1>
<path_to_control_plane_file_n>
```

- If you are upgrading to v10.0.5.x from v10.0.4-ifix3, or upgrading from v10.0.1.7-eus (or higher), add the argument `--accept-data-loss` to the command to indicate that you accept the loss of the Analytics data:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> --accept-data-loss
```

- c. Verify that the upgrade was successful by running a health check with the following command:

```
apicup subsys health-check <subsystem_name>
```

Important: If the health check indicates that a reboot is required, first complete the upgrade for all Portal sites and verify that all sites were upgraded before running the reboot command at the end of this step.

- d. If upgrading to 10.0.5.6, verify that the health check did not return a false-positive response.

Note: This step only applies if you upgraded to API Connect 10.0.5.6 and is due to a known issue that will be corrected in a later release.

Run the following command to get the current version of API Connect on the upgraded subsystem:

```
kubectl get apic
```

If the health check indicates a successful upgrade but the subsystem is still running the older version of API Connect, skip the remaining steps in this procedure and see [False positive result from health check after upgrading to 10.0.5.6](#) for troubleshooting instructions.

If the subsystem is running the newer version of API Connect then the upgrade was successful; continue with the remaining steps in this procedure.

- e. Run the following toolkit commands to ensure that the Portal site upgrades are complete:

- i. Log in as an admin user:

```
apic login -s <server_name> --realm admin/default-idp-1 --username admin --password <password>
```

- ii. Get the portal service ID and endpoint:

```
apic portal-services:get -o admin -s <management_server_endpoint> \
--availability-zone availability-zone-default <portal-service-name> \
--output - --format json
```

- iii. List the sites:

```
apic --mode portaladmin sites:list -s <management_server_endpoint> \
--portal_service_name <portal-service-name> \
--format json
```

Any sites currently upgrading display the **UPGRADING** status; any site that completed its upgrade displays the **INSTALLED** status and the new platform version. Verify that all sites display the **INSTALLED** status before proceeding.

For more information on the `sites` command, see [apic sites:list](#) and [Using the sites commands](#).

- iv. After all sites are in **INSTALLED** state and have the new platform listed, run:

```
apic --mode portaladmin platforms:list -s <server_name> --portal_service_name <portal_service_name>
```

Verify that the new version of the platform is the only platform listed.

For more information on the `platforms` command, see [apic platforms:list](#) and [Using the platforms commands](#).

- f. If all Portal sites are upgraded and the health check indicates that a reboot is needed, then run the following command:

```
systemctl reboot
```

13. Upgrade the Analytics subsystem

Important: Upgrading to v10.0.5.x from v10.0.4-ifix3, or from v10.0.1.6-eus (or higher) will result in the deletion of existing analytics data. If you want to retain your analytics data then you must export it before upgrade. For instructions on exporting see [Additional considerations for upgrading analytics from a version prior to v10.0.5.0](#).

a. Install the Analytics subsystem files:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive>
```

Notes:

- If you are adding one or more control plane files, specify each path and file name on the command line:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file_1> <path_to_control_plane_file_n>
```

- If you are upgrading to v10.0.5.x from v10.0.4-ifix3, or upgrading from v10.0.1.7-eus (or higher), add the argument `--accept-data-loss` to the command to indicate that you accept the loss of the Analytics data:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> --accept-data-loss
```

b. Verify that the upgrade was successful by running a health check with the following command:

```
apicup subsys health-check <subsystem_name>
```

c. If upgrading to 10.0.5.6, verify that the health check did not return a false-positive response.

Note: This step only applies if you upgraded to API Connect 10.0.5.6 and is due to a known issue that will be corrected in a later release.

Run the following command to get the current version of API Connect on the upgraded subsystem:

```
kubectl get apic
```

If the health check indicates a successful upgrade but the subsystem is still running the older version of API Connect, skip the remaining steps in this procedure and see [False positive result from health check after upgrading to 10.0.5.6](#) for troubleshooting instructions.

If the subsystem is running the newer version of API Connect then the upgrade was successful; continue with the remaining steps in this procedure.

d. If the health check indicates that a reboot is needed, run the following command:

```
systemctl reboot
```

14. If you are upgrading from v10.0.4-ifix3, or upgrading from v10.0.1.6-eus (or higher): Enable the analytics service as explained in [Enabling Analytics after upgrading](#).

15. If you are upgrading from a release earlier than v10.0.5.3: If you want to use JWT security instead of mTLS, enable this feature as explained in [Use JWT security instead of mTLS between subsystems](#).

16. Complete a manual backup of the upgraded API Connect subsystems; see [Backing up and restoring on VMware](#).

17. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action requires a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully.

18. Complete the disaster preparation steps to ensure recovery of API Connect from a disaster event. See [Preparing for a disaster](#).

What to do next

When you have upgraded all of the API Connect subsystems, upgrade your DataPower Gateway Service. See [Upgrading DataPower Gateway Service](#).

- [Control Plane files for earlier releases](#)

If you are upgrading to an earlier version than 10.0.5.6, refer to the following tables to determine which Control Plane files are required.

- [Checksum values for earlier releases](#)

If you are upgrading to an earlier version than 10.0.5.6, use the corresponding checksum values to verify your downloaded upgrade files.

Control Plane files for earlier releases

If you are upgrading to an earlier version than 10.0.5.6, refer to the following tables to determine which Control Plane files are required.

Attention: Upgrading directly to the latest release from releases earlier than 10.0.1.6-ifix1-eus might run into problems. For best results, first upgrade to 10.0.1.6-ifix1eus and make a full set of backups before proceeding to upgrade to the latest release.

Control planes for upgrading to 10.0.5.6

Installs with `appliance-control-plane-1.27.x.tgz`

Table 1. Control Plane files needed for upgrading to 10.0.5.6

Checksum values for earlier releases

If you are upgrading to an earlier version than 10.0.5.6, use the corresponding checksum values to verify your downloaded upgrade files.

Attention: Upgrading directly to the latest release from releases earlier than 10.0.1.6-ifix1-eus might run into problems. For best results, first upgrade to 10.0.1.6-ifix1eus and make a full set of backups before proceeding to upgrade to the latest release.

Version 10.0.5.0 did not support VMware so there are no checksum values for that release.

```

Upgrading DataPower Gateway Service

Use these instructions when upgrading DataPower Gateway Service in a non-Kubernetes environment, during upgrade of API Connect.

Before you begin

Ensure you have completed the upgrade of the API Connect subsystems (Management service, Developer Portal, Analytics) before upgrading DataPower Gateway. Upgrading the Management service before the DataPower Gateway ensures that any new policies and capabilities will be available to a previously registered Gateway service.

About this task

- The DataPower Gateway Service in a non-Kubernetes environment can be on either a physical appliance or in a virtual DataPower deployment.
- The upgrade of DataPower Gateway Service in a non-Kubernetes environment, for use in API Connect deployments in a VMware environment, does not use the `apicup` command. Use DataPower Gateway instructions in the following steps.

Note: To upgrade the DataPower Gateway Service in a Kubernetes environment, do not use this procedure. Instead, see [Upgrading Gateway subsystem on native Kubernetes](#).

Procedure

- Ensure that DataPower Gateway firmware version you plan to install is compatible with the API Connect Management server version.

Note:

You can use any combination of API Connect 10.0.5.x with DataPower Gateway 10.5.0.x or DataPower API Gateway 10.5.0.x.

Before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in [IBM API Connect Version 10 software product compatibility requirements](#) to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software, Integration Middleware, and view the list of compatible DataPower Gateway versions.

2. When upgrading a high-availability cluster, ensure that you meet the requirements:

- Gateways must be updated one at a time.
- Before starting the upgrade, a single gateway must be running as primary for all gateway-peering definitions.
- When upgrading multiple gateways, the primary gateway must be upgraded last.

To determine which gateway is running as primary, use either the `show`

`gateway-peering-status` command in the DataPower CLI, or use the Gateway Peering Status display in the Web GUI in the API Connect application domain. To move the primary to the DataPower on which you're currently working, you can issue the `gateway-peering-switch-primary <peering-object-name>` command.

3. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.

See [Managing the NTP service](#).

4. Ensure that you have set a unique `System Identifier` for each v10 DataPower gateway. See [Initializing the DataPower Gateway](#).

5. Follow the upgrade instructions on the DataPower Gateway documentation. See [Installation operations](#).

Note:

- If upgrading a cluster (high-availability) deployment, ensure that you have identified which gateway is running a primary in gateway-peering definitions, and that you upgrade that gateway last.
- For troubleshooting help with DataPower operator deployments, see [IBM DataPower Operator documentation](#).

Upgrading from 2018 to 10.0.5.4 on VMware

Upgrade API Connect 2018 FP24 and higher directly to 10.0.5.4 on VMware.

Attention: Beginning with version 10.0.5.5, a direct upgrade from version 2018 is not supported. To upgrade from version 2018, first upgrade to 10.0.5.4, and then perform the upgrade to the newest release.

Complete the API Connect upgrade from 2018 to 10.0.5.4 by performing the following tasks:

Note: When installing version 10.0.5.4, select the appropriate license from [Table 1. API Connect 10.0.5.3 and later licenses](#).

- [Upgrade from v2018: overview and considerations](#)
Review the upgrade overview, requirements, and limitations before upgrading your API Connect 2018 deployment to v10 on VMware.
- [Preparing the 2018 deployment for upgrade](#)
Prepare your 2018 deployment for upgrade to the latest v10 on VMware.
- [Upgrading v2018 subsystems to v10](#)
Install the new v10 system and configure each subsystem with configuration information from 2018.

Upgrade from v2018: overview and considerations

Review the upgrade overview, requirements, and limitations before upgrading your API Connect 2018 deployment to v10 on VMware.

- [Overview of upgrade procedure](#)
- [Planning a v10 deployment](#)
- [Required backups of 2018 subsystems](#)
- [Required disk space for extraction of 2018 management subsystem data](#)
- [Automatic shortening of subsystem names with greater than 63 characters](#)
- [Upgrade Limitations](#)
- [Getting started with the upgrade procedure](#)

Overview of upgrade procedure

The upgrade from v2018 to the latest release of v10 is a fresh install of the v10 subsystems, followed by restoration of saved 2018 data and configuration.

For the management subsystem, you will use custom scripts to extract management database configuration from 2018, and then load it onto a fresh install of v10. The scripts complete the necessary conversion of the Management database information from Cassandra format to Postgres format. The scripts are provided as part of the latest API Connect 10 distribution files on Fix Central.

For the Developer Portal, you will perform a fresh install of the subsystem and then restore data from the 2018 backups.

For Analytics, you will perform a fresh install of the subsystem but you cannot restore data from the 2018 backups due to changes in the v10 Analytics subsystem.

When all subsystem upgrades are complete, you can upgrade DataPower Gateway.

Gateways can continue to run during this process so API traffic is not impacted.

Summary of the upgrade task flow:

1. On the 2018 deployment:
 - a. Backup each 2018 subsystem.
 - b. For the management subsystem, use the provided script to extract the 2018 database.
 - c. Power off the 2018 cluster.

2. On a new v10 installation:
 - a. Create a new v10 cluster using the 2018 project directory, the v10 installation utility (`apicup`) and the v10 distribution images (`.ova`).
 - b. Install the management subsystem. Start the v10 system using the newly created ISO.
 - c. Use a provided script to load the extracted v2018 database info into the new v10 database.
 - d. Install the Developer Portal subsystem and run a restore to load the 2018 backup data.
 - e. Install the Analytics subsystem and run a restore to load the 2018 backup data.
 - f. Upgrade the DataPower Gateway.

Planning a v10 deployment

Before you move from 2018 to v10, plan your v10 deployment by reviewing requirements and features:

- [IBM API Connect Version 10 software product compatibility requirements](#)
- [Requirements for initial deployment on VMware](#)
- [Planning your deployment](#)
- [What's New in the latest release](#) and [What's new for v10 installation](#).
- [Version 10 known limitations](#)

Required backups of 2018 subsystems

Subsystems on 2018 must be backed up in the following order:

1. Management subsystem
2. Developer Portal subsystem
3. Analytics subsystem

Ensure that your archives are valid.

Note: You cannot use a VMware snapshot to skip the preparation steps for the upgrade. VMware snapshots do not provide the necessary API Connect data and backups in a form that can be applied to a new API Connect v10 deployment in a VM.

Required disk space for extraction of 2018 management subsystem data

The upgrade from 2018 to v10 includes extraction of management database data. Prior to running the extract job, ensure that your virtual machine has sufficient disk space to hold a file containing this data.

The amount of disk space required scales with the amount of data on your system. As a minimum, ensure you have 3 times the size of the backup file for your 2018 Cassandra database.

To locate the backup file for your 2018 Cassandra database, see Step 3 in [Restoring the management database in a Kubernetes environment](#).

Automatic shortening of subsystem names with greater than 63 characters

Version 10 imposes a length restriction of 63 characters for subsystem names. Version 2018 did not impose the restriction. If your v2018 subsystem names are greater than 63 characters in length, you must shorten them prior to upgrading. If you do not shorten them, the upgrade will programmatically shorten them for you. You will then want to check `apiconnect-up-v10.yaml` to determine the new shortened name.

The new value is found in `spec.subsystems[n].metadata.name`. For example, for a management subsystem, see the `name: abcde-management` entry below:

```
apiVersion: v1
kind: apic.ibm.com/APICConnectCluster
metadata:
  creationTimestamp: "2021-03-04T13:52:50Z"
  name: abcde
spec:
  secret-name: abcde-my-secret
  subsystems:
  - apiVersion: v1
    kind: apic.ibm.com/ManagementSubsystem
    metadata:
      creationTimestamp: "2021-03-04T13:52:50Z"
      name: abcde-management
    spec:
      ApplianceProperties:
        data-device: sdb
```

Upgrade Limitations

The upgrade is designed to bring your 2018 configuration and data onto a new v10 deployment. Note the following limitations:

- The location of the v10 backups for the management subsystem must be different from the location of the 2018 backups of the management subsystem. Note that for v10, the management database changes from Cassandra to Postgres, so a new backup configuration is required.
- The upgrade does not capture customizations to your 2018 configuration that you made with an extra-values file. If you created an extra-values file on 2018, you must modify it for the v10 deployment, as follows:
 - For the management subsystem, the upgrade process uses a temporary extra-values file to configure upgrade settings, and then removes the temporary file upon successful completion of the upgrade. You can then recreate your extra-values file. See also [Upgrading Management subsystem from 2018 to v10](#)
 - For the Developer Portal subsystem and the Analytics subsystem, if you have an extra-values file on Version 2018, you must convert the file format for Version 10, prior to deploying the Version 10 subsystem. See the instructions in [Upgrading Developer Portal from 2018 to v10](#) and [Upgrading Analytics from 2018 to v10](#)
- Version 10.0.5.0 and later use a new version of the Analytics subsystem, which has the following impacts on your upgrade process:
 - If you want to preserve your v2018 analytics data, export it to a backup location before upgrading as explained in [Preparing the 2018 deployment for upgrade](#).

- Disable analytics before upgrading as explained in [Preparing the 2018 deployment for upgrade](#).
- During the upgrade, the v2018 Analytics subsystem cannot work with v10 Management subsystem, so you must upgrade the new Analytics subsystem immediately. If there is an upgrade failure with Analytics, resolve it as soon as possible and run the upgrade again.

x-ibm-gateway-cors-allow-credentials-when-no-cors-policy API property is deprecated

In 2018, when cross-origin resource sharing (CORS) is enabled for an API, every response to a CORS request contains the header:

```
Access-Control-Allow-Credentials: true
```

Inclusion of Access-Control-Allow-Credentials (ACAC) does not provide optimal security, so starting with 2018.4.1.17, an API property can be set to prevent this header from being returned:

```
Name: x-ibm-gateway-cors-allow-credentials-when-no-cors-policy
Collection: *
Value (string): off
```

The `Collection` setting refers to a specific Catalog to which a property value applies. The "*" value means the value applies to all catalogs. You can either specify * or a Catalog (collection) name.

The property can also be set by using the DataPower CLI:

```
api-definition myAPI
  property x-ibm-gateway-cors-allow-credentials-when-no-cors-policy * off
exit
```

Important: The value of this property must be exactly the string `off` (case-sensitive) in order to remove the header.

It is only possible to turn off this header, or leave it on, for an entire API. In order to have more control, such as returning the header for some origins and not others, you must upgrade to v10 and use the CORS policy feature. For more info, see:

- [Enabling CORS support for an API](#)
- OpenAPI 3.0 editor: [Setting API properties](#)
- OpenAPI 2.0 editor: [Setting API properties](#)

In API Connect 10.0.1.4-ifix1-eus or later, the `x-ibm-gateway-cors-allow-credentials-when-no-cors-policy` property works, but only for API definitions which do NOT contain a cors-policy. You cannot define both this property and a CORS Policy on the same API definition.

This property is deprecated in v10: a warning will be written to the log for every CORS request received by an API whose definition contains this property.

For version 10, the recommended way to ensure the ACAC header does not appear in CORS responses is to add a CORS policy to the API definition. In version 10, any API definition which has a cors-policy defined will NOT return the ACAC header by default. Note that it is possible in the CORS policy rules to explicitly return the ACAC header for some or all origins.

If you move your configuration from 2018 to 10.0.1.4-ifix1-eus or later, and have this custom property defined in your API definitions, you will not see any change in behavior, other than new warnings in the log. This property will remove the ACAC header for any API definition where it appears.

If, when you move your configuration from 2018 to 10, you want to have the ACAC header present in the CORS responses, you can leave the API definitions as-is (without the new property defined) and the ACAC header will be returned, as long as a cors-policy is not added to the API definition. Note also that even with a CORS policy defined for an API, the ACAC header can be returned if desired by explicitly allowing it in the rules of the CORS policy.

Note that the `x-ibm-gateway-cors-allow-credentials-when-no-cors-policy` property in an API definition:

- Will cause a commit-time error in version 10 if a cors-policy is also present in the same API definition
- Will NOT work in 10 or 2018 to turn ON the ACAC header; it can ONLY be used to turn OFF the header. Explanation:
 - In 2018, ACAC is on by default
 - In 10 without cors-policy, ACAC is on by default
 - In 10 with cors-policy, ACAC can be turned on for specific origins via rules in cors-policy

Getting started with the upgrade procedure

The first task in the upgrade procedure is to prepare your 2018 deployment for upgrade. To get started, go to [Preparing the 2018 deployment for upgrade](#)

Preparing the 2018 deployment for upgrade

Prepare your 2018 deployment for upgrade to the latest v10 on VMware.

Before you begin

Before you move from 2018 to v10, ensure that you have reviewed [Upgrade from v2018: overview and considerations](#)

Attention: Review the IBM Support page [API Connect: v2018 to v10 upgrade paths](#) to determine whether your Version 2018 deployment can be directly upgraded to the latest release of API Connect.

About this task

On your v2018 deployment, gather the API Connect information that is needed to restore the 2018 configuration onto a new v10 deployment.

Procedure

1. Ensure that the management subsystem is on a 2018 version that is supported for upgrading to the target version, as listed in [Upgrade from v2018: overview and considerations](#).

To view the version, ssh to the VM and run `sudo -i`. Use `apic version`. For example:

```
# apic version
INFO[0000] Log level: info
.
.
.
Packages:
.
.
.
- subsystem-management:<version_number>
```

2. Make sure the API Connect cluster is healthy. For each subsystem (Management, Developer Portal, and Analytics) run the following command:

```
apic health-check
```

If the cluster is healthy, the health-check command returns silently with a 0 return code.

3. Remove any stale upgrade files:

```
apic clean-upgrade-files
```

4. Complete a full backup for the API Connect v2018 Management, Portal, and Analytics subsystems. See [Backing up and restoring](#).

Tip: Ensure your backup archives are valid. For example:

```
$ tar -tzf <FILENAME>.tar.gz >/dev/null
```

On success, the command returns to the command line prompt with no output. If there is a problem with the file, an error similar to the following would be reported:

```
tar: 0511-169 A directory checksum error on media; -559038737 not equal to 67008.
```

5. On the v2018 management subsystem deployment, use the `apicops` utility to ensure the v2018 management database is consistent:

Note that `apicops` is distinct from `apicup`.

Important: Upgrade will fail if the `apicops` command is not successfully completed within 2 hours of starting the management upgrade. If the management upgrade must be run more than once, you must run the command in fix mode each time within 2 hours of starting the management upgrade.

- a. Obtain the latest v2018 release of `apicops` from <https://github.com/ibm-apiconnect/apicops#latest-v2018-release>.
- b. Download the `apicops` binary to one of the Management cluster servers, and make it executable:

```
chmod +x apicops
```

See also `apicops` set up requirements: <https://github.com/ibm-apiconnect/apicops#requirements>

- c. Run `apicops` as root:

```
# sudo -i
# apicops preupgrade -m fix --upgrade_to v10 -l <outputLogFileName>
```

- The `-m` option runs the utility in fix mode. Running the utility in fix mode resolves most problems. If the utility identifies a problem it cannot resolve, contact IBM Support.
- Set the `-l` option to send output to a log file.

- d. Confirm from the logs that all issues are fixed.

6. Take a backup of the Management subsystem. This backup is in addition to the backup taken in 4. The `apicops preupgrade` operation modifies the Management database and so it is recommended to have backups from before and after.

7. Make sure cluster is healthy before proceeding:

```
apic health-check
```

If the cluster is healthy, the health-check command returns silently with a 0 return code.

8. Obtain the needed upgrade script and supporting files.

- a. Go to the [What's New in the latest version](#) information page.
- b. Locate the Note: *You can access the latest files from <URL link>*. Select the *<URL link>* to go directly to the Announce page on Fix Central, where you can download files for the latest version of API Connect.
- c. Download **IBM® API Connect <version> scripts and assets required for v2018 > <v10.0.1.x_version> side-by-side upgrades** from API Connect Fix Central.
- d. Decompress the tar file and copy (`scp`) the `dr-upgrade` directory to the v2018 management system. The directory contains `dr-upgrade-extract.py`, which you will use to extract v2018 configuration.

9. Ensure that traffic to the management endpoints is stopped before running the python script.

For example, a load balancer might need to mark the backends as down so that no incoming traffic is accepted.

10. Disassociate and delete your v2018 Analytics services.

Note: Upgrading to v10 will result in the deletion of existing analytics data. For instructions on exporting data from v2018, see the v2018 documentation: <https://www.ibm.com/docs/en/api-connect/2018.x?topic=analytics-exporting-api-event-data>. Also, you can set up analytics offload so that all new analytics data is sent to a third-party system for storage: <https://www.ibm.com/docs/en/api-connect/2018.x?topic=cloud-configuring-analytics-offload-api-connect>.

- a. In Cloud Manager UI, click Topology.
- b. In the section for the Availability Zone that contains the Analytics service, locate the Gateway service that the Analytics service is associated with.
- c. Click the actions menu, and select Unassociate analytics service. Remember to disassociate each Analytics service from all Gateways.
- d. In the section for the Availability Zone that contains the Analytics services, locate each Analytics service and click Delete.

11. Extract the v2018 data that is needed for upgrade. Change directory to the `dr-upgrade` directory and run the python extract script as `root`:

```
# sudo -i
# python3 dr-upgrade-extract.py
```

Tip: You can optionally run the script in the background:

```
nohup python3 dr-upgrade-extract.py &> extract.log &
tail -f extract.log
```

- The script creates `2018-extracted-data.zip`. Example output:

```
.
.
.
Extract job is in Running state.
Extract job is complete
Time elapsed: 0:06:17.397687
Zipped 2018 extracted data and logs under '2018-extracted-data.zip'
```

The amount of time required for the extraction is a function of the amount of data in the v2018 database.

The file `2018-extracted-data.zip` contains your application data in an unencrypted format. This data should be kept secure. The data is required to successfully upgrade to v10.

- If the extract script encounters an error:

- Run the cleanup script:

```
python3 dr-upgrade-cleanup.py
```

- Resolve the errors.
- Re-run the extract script:

```
python3 dr-upgrade-extract.py
```

12. Save the following files to a location where you can access them later, while installing the v10 system:

- `2018-extracted-data.zip`
- The `apicup` project directory. You must use this project directory on your v10 system.

13. Power off the virtual machine with the 2018 system.

14. Continue with [Upgrading v2018 subsystems to v10](#).

Upgrading v2018 subsystems to v10

Install the new v10 system and configure each subsystem with configuration information from 2018.

Before you begin

You must have completed [Preparing the 2018 deployment for upgrade](#).

About this task

To upgrade the Management subsystem from 2018 to the latest v10 version, you will do a fresh install of v10, and then run a script to load management data from 2018. For the Developer Portal subsystem and the Analytics subsystem, you will do a fresh install of each subsystem; for Portal only, you will then restore data from the 2018 backup.

When all subsystem upgrades are complete, you can upgrade DataPower Gateway. Optionally, you can then install the API Connect toolkit and the Lightweight Test Environment.

Procedure

1. Obtain the API Connect files from IBM Fix Central.

Note: When upgrading from 2018 to the latest v10 version, you will use the same Fix Central files as are used for a **new** API Connect installation. Do not use the separate product distribution files for **upgrade** of each subsystem on VMware.

The following files are used for upgrading from 2018 on VMware:

IBM® API Connect <version> Management for VMware
Management subsystem files

IBM® API Connect <version> Developer Portal for VMware
Developer Portal subsystem files

IBM® API Connect <version> Analytics for VMware
Analytics subsystem files

IBM® API Connect <version> Install Assist for <operating_system_type>
The apicup installation utility. Required for all installations on VMware.

2. Install the installation utility.

- Locate the apicup installation utility file for your operating system.
- Rename the file for your OS type to `apicup`. Note that the instructions in this documentation refer to `apicup`.
- Make `apicup` accessible on your operating system:

Operating system	Configuration
------------------	---------------

Operating system	Configuration
OSX and Linux®	i. Make the apicup file an executable file: <code>chmod +x apicup</code> ii. Set your path to the location of your apicup file: <code>export PATH=\$PATH:/Users/your_path/</code>
Windows:	Set your path to the location of your apicup file: <code>set PATH=c:\your_path;%PATH%</code>

- Use the following links to upgrade the subsystems, in the specified order:
 - [Upgrading Management subsystem from 2018 to v10](#)
 - [Upgrading Developer Portal from 2018 to v10](#)
 - [Upgrading Analytics from 2018 to v10](#)
- Upgrade the DataPower Gateway. See [Upgrading DataPower Gateway Service](#). DataPower Gateways requires a firmware upgrade from 2018 to 10 after the upgrade of the other API Connect subsystems is complete.
- Optionally, install new versions of other API Connect packages:
For each of the following distribution packages there is no upgrade process. You replace the existing tools or binaries with the new versions for the latest version of v10.

IBM® API Connect <version> Toolkit for <operating_system_type>
Toolkit command line utility. Packaged standalone, or with API Designer or Loopback:

 - IBM® API Connect <version> Toolkit for <operating_system_type>
 - IBM® API Connect <version> Toolkit with Loopback for <operating_system_type>
 - IBM® API Connect <version> Toolkit Designer with Loopback for <operating_system_type>

Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See [Installing the toolkit](#).

IBM® API Connect <version> Local Test Environment
Optional test environment. See [Testing an API with the Local Test Environment](#)

IBM® API Connect <version> Security Signature Bundle File
Checksum files that you can use to verify the integrity of your downloads.
- When you complete the installation and configuration, best practice is to immediately take backups of the new v10 deployment. See:
 - [Backing up the management subsystem](#)
 - [Backing up the Developer Portal subsystem](#)
 - [Running a backup of the Analytics database](#)
 - [Upgrading Management subsystem from 2018 to v10](#)
Upgrade the management subsystem to v10 by installing the latest v10 management subsystem and loading the management database information from 2018.
 - [Upgrading Developer Portal from 2018 to v10](#)
Upgrade the Developer Portal by installing the latest v10 with the 2018 configuration and restoring the subsystem from backups.
 - [Upgrading Analytics from 2018 to v10](#)
Upgrade the Analytics subsystem by installing the v10 subsystem.

Upgrading Management subsystem from 2018 to v10

Upgrade the management subsystem to v10 by installing the latest v10 management subsystem and loading the management database information from 2018.

Before you begin

You should have previously completed the following steps in [Upgrading v2018 subsystems to v10](#):

- Download **IBM® API Connect <version> scripts and assets required for v2018 > <Latest_v10_version> side-by-side upgrades** and **IBM® API Connect <version> Management for VMware** from Fix Central.
- Install **apicup** installation utility.

About this task

Install the latest v10 management subsystem, load the 2018 management database information, and run a cleanup script after the load completes.

Procedure

- Use the v10 version of **apicup** to map your 2018 configuration settings from **apiconnect-up.yml** to the v10 configuration file **apiconnect-up-v10.yaml**:

```
apicup subsys get <subsystem_name>
```

Note: If your subsystem name on 2018 was greater than 63 characters, and you did not manually shorten it prior to upgrading, the upgrade shortened it automatically. To view the new subsystem name:

```
apicup subsys list
```

For more information, see [Automatic shortening of subsystem names with greater than 63 characters](#)

- Review the output from the command. Note the following:
 - Some settings will be automatically converted from their 2018 values, but you should review all values to ensure they are still valid.
- Update the license value by running the following command:

```
apicup licenses accept <License_ID>
```

The <License_ID> is specific to the API Connect program name that you purchased. To view the supported license IDs, see [API Connect licenses](#).

c. Use **apicup** to provide a completely new backup location for the management subsystem in v10. See [Reconfiguring backup settings for the management subsystem](#).

Important:

- For the management subsystem, you cannot use the same backup locations as were used for 2018.
 - For s3 backups you must specify a different s3 bucket for the version 10 deployment, to avoid having version 2018 backups mixed with version 10 backups for the management server.
 - For SFTP backups, create a different folder for version 10 backups, or move the 2018 backups to another location.
- For v10, there is a new (additional) setting **database-backup-s3provider**. This settings is used with S3 backups. This value must be set before install, if S3 backups are being used. The management subsystem might not come online without this parameter being set.

2. Set a temporary configuration to support loading the v2018 data:

a. Place the following text in to a new yaml file, with a name of your choosing:

```
spec:
  template:
  - name: apim
    enabled: false
  - name: apim-schema
    enabled: false
  - name: apim-data
    enabled: false
  - name: taskmanager
    enabled: false
  - name: lur
    enabled: false
  - name: lur-schema
    enabled: false
  - name: lur-data
    enabled: false
  - name: analytics-proxy
    enabled: false
  - name: portal-proxy
    enabled: false
  - name: billing
    enabled: false
  - name: juhu
    enabled: false
  - name: websocket-proxy
    enabled: false
  - name: ui
    enabled: false
```

b. Set the new yaml file as an extra-values configuration file:

```
apicup subsys set <management_subsystem_name> extra-values-file=<path-to-extra-values-file>/<your_extra_values_file>.yaml
```

3. Create your ISO file

```
apicup subsys install mgmt --out mgmtplan-out
```

The **--out** parameter and value are required.

In this example, the ISO file is created in the `myProject/mgmtplan-out` directory.

4. Deploy the ISO and **IBM® API Connect <version> Management for VMware** ova file. Go to [Deploying the Management subsystem OVA file](#).

Note: Wait for the cluster to form - this can take some time.

5. Verify the installation:

```
apicup subsys health-check <management_subsystem_name>
```

Note: This is not a standard install. Some services are disabled during this process, so there will be some pods missing. As a result, you cannot use the Cloud Manager UI to verify the management subsystem until the data from v2018 is loaded.

6. Copy (**scp**) the entire **dr-upgrade** .tgz to the v10 management system VM. Uncompress the file (**tar -xzf**). Verify that the directory contains these files:

- **dr-upgrade-load.py**
A script to load the v2018 data.
- **dr-upgrade-cleanup.py**
A script to cleanup after load of the v2018 data
- **2018-extracted-data.zip**
The data from your v2018 deployment

The directory contains other template files that are used by the scripts.

7. Now load 2018 data into v10 database.

a. ssh into the appliance as **root**.

b. Change directory to the **dr-upgrade** directory

The **dr-upgrade-load.py** script requires **2018-extracted-data.zip** to be in the same directory

c. Run the python script **dr-upgrade-load.py**:

```
# sudo -i
# python3 dr-upgrade-load.py
```

Tip: You can optionally run the script in the background:

```
nohup python3 dr-upgrade-load.py &> load.log &
tail -f load.log
```

- The length of time needed for the load script to complete scales with the size of the data in your system. The upgrade-load job creates a Kubernetes pod named `apiconnect-v10-upgrade-load-<xxxxxx>`. You can follow the Kubernetes logs if you want to track the progress of the script.
- The python script outputs the location (*volume_path*) of the data/logs directories to backup.
- Once `dr-upgrade-load.py` returns successfully the load is complete.

Note: If `dr-upgrade-load.py` encounters an error:

- `ssh` into the appliance as root, and gather the upgrade logs. Check pod logs and PV logs (*volume_path*). To create a zip file with the contents of directories with the logs:

```
zip -r upgrade-pvc.zip {{volume_path}}
```

- Contact IBM Support for guidance on how to resolve the errors.
- After the errors are resolved, run the clean up script:

```
python3 dr-upgrade-cleanup.py --load-error
```

Be sure to include the required parameter `--load-error`. Note that the health-check will fail until the load script is run again in the next step.

- Re-run `dr-upgrade-load.py`

```
python3 dr-upgrade-load.py --rerun
```

Be sure to include the required parameter `--rerun`.

8. Wait for the completion of the job and then return to your local machine (used for configuration) and use `apicup` to unset the extra-values file To unset:

```
apicup subsys set <management_subsystem_name> extra-values-file=
```

9. Set an extra-values file if needed for your customizations:

```
apicup subsys set <management_subsystem_name> extra-values-file=<your_extra-values-file>
```

For example, see [Setting rate limits for public APIs on the management service](#).

10. Install the subsystem:

```
apicup subsys install <management_subsystem_name>
```

11. Verify all management resources have come up

```
apicup subsys health-check <management_subsystem_name>
```

If the subsystem is healthy, the health-check command returns silently with a 0 return code.

If an error is encountered, see [Upgrade Limitations](#).

Your load of v2018 data is now complete.

12. When the `dr-upgrade-load` job has succeeded, backup the PVC data and logs from the `dr-upgrade-load` job:

- a. `ssh` into the appliance as root.
- b. Find the path to the volume:

```
kubectl get pv | grep 'pv-claim-apiconnect-v10-upgrade' | awk '{print $1}' | xargs kubectl get pv -ojsonpath='{.spec.local.path}'
```

- c. Zip up the directory:

```
zip -r upgrade-pvc.zip {{volume_path}}
```

- d. Run the cleanup script:

```
python3 dr-upgrade-cleanup.py
```

This script cleans up the following:

- Load job `apiconnect-v10-upgrade-load`
- Load PVC `pv-claim-apiconnect-v10-upgrade`
- `2018-extracted-data.zip`
- Unpacked `2018-extracted-data.zip` from the PV

13. Restart all `nats-server` pods.

- a. SSH into the server:

- i. Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```

- ii. When prompted, select Yes to continue connecting.

- iii. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

- b. Restart all `nats-server` pods by running the following command:

```
kubectl -n <namespace> delete po -l app.kubernetes.io/name=natscluster
```

14. Next, upgrade the other subsystems. Return to [Upgrading v2018 subsystems to v10](#).

Upgrading Developer Portal from 2018 to v10

Upgrade the Developer Portal by installing the latest v10 with the 2018 configuration and restoring the subsystem from backups.

About this task

You will verify your configuration, create an ISO, deploy the v10 OVA file into the VM, and restore your Developer Portal data from backup.

You do not have to specify configuration settings because the Portal configuration is defined in the 2018 project directory, which you will continue to use for v10. However, you must review the backups settings.

Procedure

1. Obtain **IBM® API Connect <version> Developer Portal for VMware** from Fix Central, as described in [Upgrading v2018 subsystems to v10](#).
2. Use the version 10 release of `apicup` to map your 2018 configuration settings from `apiconnect-up.yml` to the v10 configuration file `apiconnect-up-v10.yml`:

```
apicup subsys get <subsystem_name>
```

- a. Review the output from the command, and ensure backup settings from 2018 have been set or migrated to the configuration for version 10. See [Configuring backup settings for the Developer Portal subsystem](#).
- b. If your 2018 deployment included an extra-values-file, you must first convert the format of the file for v10. For example, if you had an extra-values-file to support multiple Portal endpoints, review the new format in the version 10 documentation. See [Defining multiple portal endpoints for a VMware environment](#).

Note: If your subsystem name on 2018 was greater than 63 characters, and you did not manually shorten it prior to upgrading, the upgrade shortened it automatically. To view the new subsystem name:

```
apicup subsys list
```

For more information, see [Automatic shortening of subsystem names with greater than 63 characters](#)

- c. Update the license value by running the following command:

```
apicup licenses accept <License_ID>
```

The `<License_ID>` is specific to the API Connect program name that you purchased. To view the supported license IDs, see [API Connect licenses](#).

3. Create your ISO file.

```
apicup subsys install port --out portplan-out
```

The `--out` parameter and value are required. In this example, the ISO file is created in the `myProject/portplan-out` directory.

4. Deploy the file into the VM. See [Deploying the Developer Portal subsystem OVA file](#).
5. Verify the deployment: See [Verifying deployment of the Developer Portal subsystem](#).
6. Restore Portal using the backup taken on 2018. See [Restoring the Developer Portal subsystem](#).
7. Confirm the restore has completed successfully:

```
apicup subsys health-check <portal_subsystem_name>
```

When no problems are detected, the health-check commands returns silently with a 0 return code.

Important: If the health check command states that a reboot is required, you must ensure that all Portal sites have been upgraded first before performing the reboot. To check that the Portal sites have upgraded, inspect the `platform` and `state` values for each site. The sites should all be in **INSTALLED** state, and have `platform` equal to the new platform that you can identify with `platforms: list`. Note that there will be two platforms present in the list while the site upgrades are happening. There should be only one `platform` after they have completed. To check that the Portal sites were upgraded:

- a. Obtain the portal service id and endpoint:

```
apic portal-services:get -o admin -s <management_server_endpoint> \
  --availability-zone availability-zone-default <portal-service-name> \
  --output - --format json
```

- b. List the sites:

```
apic --mode portaladmin sites:list -s <management_server_endpoint> \
  --portal_service_name <portal_service_name_from_above_command> \
  --format json
```

Any sites currently upgrading will be listed as **UPGRADING**. Once all sites have finished upgrading they should have the **INSTALLED** status and the new platform version listed.

See also: [apic sites:list](#) and [Using the sites commands](#).

- c. After all sites are in **INSTALLED** state and have the new platform listed, run:

```
apic --mode portaladmin platforms:list -s <management_server_endpoint> \
  --portal_service_name <portal_service_name_from_above_command> \
  --format json
```

The new version of the platform should be the only platform listed.

See also: [apic platforms:list](#) and [Using the platforms commands](#).

If an error is encountered, see [Upgrade Limitations](#).

8. Return to [Upgrading v2018 subsystems to v10](#).

Upgrading Analytics from 2018 to v10

Upgrade the Analytics subsystem by installing the v10 subsystem.

About this task

You will verify your configuration, create an ISO, and deploy the v10 OVA file into the VM. Due to changes in the v10 Analytics subsystem, you cannot restore your Analytics data from backup. You can configure Analytics settings after the upgrade is complete.

Procedure

1. Obtain **IBM® API Connect <version> Analytics for VMware** from Fix Central, as described in [Upgrading v2018 subsystems to v10](#).
2. Use the v10 version of **apicup** to map your 2018 configuration settings from **apiconnect-up.yml** to the v10 configuration file **apiconnect-up-v10.yaml**:

```
apicup subsys get <subsystem_name>
```

Note: If your subsystem name on 2018 was greater than 63 characters, and you did not manually shorten it prior to upgrading, the upgrade shortened it automatically. To view the new subsystem name:

```
apicup subsys list
```

For more information, see [Automatic shortening of subsystem names with greater than 63 characters](#)

Complete the following steps:

- a. Review the output from the command.
- b. Specify backup settings for v10. You cannot use the settings from 2018. See [Configuring backup settings for Analytics](#).
- c. If your 2018 deployment included an extra-values-file, you must first convert the format of the file for v10. To review creation of extra-values files for v10, see [Creating the analytics-extra-values file](#).
- d. Update the license value by running the following command:

```
apicup licenses accept <License_ID>
```

The **<License_ID>** is specific to the API Connect program name that you purchased. To view the supported license IDs, see [API Connect licenses](#).

3. Create your ISO file.

```
apicup subsys install analyt --out analytplan-out
```

The **--out** parameter and value are required. In this example, the ISO file is created in the **myProject/analytplan-out/node-config** directory.

4. Deploy the file into the VM. See [Deploying the Analytics subsystem OVA file](#)
5. Verify the deployment. See [Verifying deployment of the Analytics subsystem](#)
6. Confirm the restore has completed successfully:

```
apicup subsys health-check <analytics_subsystem_name>
```

When no problems are detected, the health-check commands returns silently with a 0 return code.

If an error is encountered, see [Upgrade Limitations](#).

7. Configure the Analytics settings as explained in [Enabling additional analytics features](#).
8. Return to [Upgrading v2018 subsystems to v10](#).

Enabling Analytics after upgrading

After the upgrade successfully completes, re-enable Analytics data collection.

Before you begin

Skip this task if you are upgrading from v10.0.5.1 or later, or migrating from v2018 to v10.

Procedure

1. Delete your pre-10.0.5.x analytics storage allocation. If you skip this step then your previous analytics data, although not extractable, continues to occupy disk space.
 - a. SSH to each of your Analytics VMs as the user 'apicadm', for example: **ssh apicadm@analytics1.example.com**.
 - b. Sudo to the root user: **sudo -i**.
 - c. Identify the pre-10.0.5.x analytics storage allocation (known as PVCs) by running:

```
kubectl get pvc
```

NAME	STATUS	VOLUME	CAPACITY	ACCESS MODES	STORAGECLASS	AGE
data-ger2-analytics-storage-0	Bound	local-pv-8735e017	250Gi	RWO	local-storage	3h29m
data-ger2-analytics-storage-1	Bound	local-pv-2d14de06	250Gi	RWO	local-storage	3h29m
data-ger2-analytics-storage-2	Bound	local-pv-b2a8a5d	250Gi	RWO	local-storage	3h29m
data-ger2-analytics-storage-shared-0	Bound	local-pv-30aac7ed	250Gi	RWO	local-storage	227d
data-ger2-analytics-storage-shared-1	Bound	local-pv-e4a82f28	250Gi	RWO	local-storage	227d
data-ger2-analytics-storage-shared-2	Bound	local-pv-82018f91	250Gi	RWO	local-storage	227d

- d. Delete all PVCs with 'storage' in their name that date back to before you started your upgrade. In this example these are the PVCs that are 227 days old.

```
kubectl delete pvc <pvc name>
```

2. Add the new analytics:view permission to the Administrator role in the Cloud Manager UI.

- a. Click , then select Roles
- b. Click  on the Administrator role and select Edit
- c. Select the checkbox next to the analytics permission and click save:

Analytics

View

3. Register new analytics services: [Registering an analytics service](#)

4. Associate your new analytics services with your gateways [Associating an analytics service with a gateway service](#)

Troubleshooting upgrades on VMware

Review the following troubleshooting guidance if you encounter a problem while upgrading API Connect on VMware.

Locating your product version

In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

False positive result from health check after upgrading to 10.0.5.6

Sometimes an upgrade to API Connect 10.0.5.6 appears to complete successfully and the health-check reports that the upgraded subsystem is healthy, but the older version is still installed. A false positive response from the health check indicates a problem with the upgrade.

Note: This step only applies if you upgraded to API Connect 10.0.5.6 and is due to a known issue that will be corrected in a later release. Complete the following steps to resolve the issue:

1. If you did not do so already, run the follow command on each subsystem to determine what version of API Connect is deployed:

```
kubectl get apic
```

If the new version of API Connect is deployed on a subsystem, then the upgrade was successful for that subsystem.

2. If the older version of API Connect is still deployed on a subsystem, run the following command to check the status of that subsystem in case there is a message about the underlying problem:

```
apic status
```

Sometimes the status indicates the problem and you can correct it before upgrading that subsystem again.

3. If you do not see any messages indicating the source of the problem, contact IBM Support for assistance.

Appliance upgrade from 10.0.4.x to 10.0.5.3 and 10.0.5.4 fails

A direct upgrade from 10.0.4.x to 10.0.5.3 or to 10.0.5.4 on an appliance might fail with a message similar to the following example:

```
Error: failed to install the subsystem: unable to close stream to remote server: rpc error: code = DeadlineExceeded desc = context deadline exceeded
```

Correct the problem by completing the following steps:

1. Restore the content of the `/usr/lib/python3/dist-packages/cloudinit/config/cc_apiconnect.py` file to the original 10.0.4.x definition as shown in the following example:

```
from cloudinit.settings import PER_ALWAYS
from yaml import dump
from subprocess import call
import time

frequency = PER_ALWAYS

UNLOCK_ATTEMPT_MAX_COUNT = 50
UNLOCK_ATTEMPT_DELAY = 10

def handle(name, _cfg, _cloud, log, _args):
    if (name == 'apiconnect'):
        f = open('/var/lib/cloud/instance/apiconnect.yml', 'w')
        f.write(dump(_cfg["apiconnect"]))
        f.close()

    for i in range(1, UNLOCK_ATTEMPT_MAX_COUNT):
        rc = call(['/usr/bin/apic', "unlock", "--prompt=false"])
        if rc == 0:
            return
        log.warning("apic unlock attempt %s of %s failed", i, UNLOCK_ATTEMPT_MAX_COUNT)
        time.sleep(UNLOCK_ATTEMPT_DELAY)
    log.warning("Use apic unlock to mount the secure partition and start the node")
```

2. Reboot the appliance.

The original primary PVC is not attached to any pods in this namespace

If the `apicops version:pre-upgrade` check reports

The original primary PVC is not attached to any pods in this namespace

and you have not started the upgrade yet (you have not run the `apicup subsys install` command) then follow these steps:

1. Take a backup of your management subsystem: [Backing up and restoring the Management subsystem](#).
2. Restore the new backup: [Restoring the management subsystem](#).

The action of taking and restoring a management backup fixes the problem that causes the error message. If you see this error after starting upgrade, see [Original PostgreSQL primary not found](#).

Original PostgreSQL primary not found

If you ran the `apicup subsys install <tar file>` command to start an upgrade, the upgrade does not complete, and the `apicup health-check` command returns:

```
apicup subsys health-check management
Error: Cluster not in good health:
expect member apicdev.ibm.com 'Install stage' to be 'Done' (actual: SETUP_SUBSYSTEM) | Detail: reconcile.go#apply subsystem not ready
```

then SSH into the management appliance and switch to root user to get more details of the error:

```
ssh apicadm@<management appliance>
sudo -i
```

Run `kubectl describe mgmt`, and check the output for the following message:

```
Original PostgreSQL primary not found. Upgrade is blocked. Set apiconnect-operator/db-primary-not-found-allow-upgrade: true annotation to unblock the upgrade. A warning will be issued after the upgrade with further steps
```

To fix this problem, complete the following steps:

1. Create an extra-values.yaml file and set the annotation:

```
metadata:
  annotations:
    apiconnect-operator/db-primary-not-found-allow-upgrade: "true"
```

Note: If you already have an extra-values.yaml file, update the existing file with above annotation.

2. Set the extra-values-file property on your management subsystem with `apicup`:

```
apicup subsys set <management subsystem name> extra-values-file=<extra values filename>
```

3. Restart the upgrade, with the `--skip-health-check` flag:

```
apicup subsys install <management subsystem name> <upgrade tar file> <control plane file - if required> --skip-health-check
```

4. When upgrade is complete:

- a. Remove the annotation from your extra-values.yaml file.
- b. Take a backup of your management subsystem: [Backing up and restoring the Management subsystem](#).
- c. Restore the new backup: [Restoring the management subsystem](#). The action of taking and restoring a management backup fixes the problem that causes the error message **The original primary PVC is not attached to any pods in this namespace**. Be careful to restore from the backup that is taken after the upgrade, and not from a backup taken before upgrade.

The cloud-final.service fails during upgrade

Sometimes during upgrade, there is an issue with the `cloud-final.service` and a node, and the appliance-manager enters a bad state.

To determine whether your upgrade encountered this problem, complete the following steps:

1. Check the output of `apic health-check` command for a result similar to the following example:

```
# apic health-check
INFO[0000] Log level: info
FATA[0000] Unable to cluster status: rpc error: code = Unavailable desc = connection error: desc = "transport: Error while dialing dial tcp 9.20.153.38:9178: connect: connection refuse"
```

2. Check the response to the `journalctl -u appliance-manager | grep cloud-final` command and see if it looks like the following example:

```
# journalctl -u appliance-manager | grep cloud-final
Nov 21 19:41:58 apimdev1040 apic[2569]: Job for cloud-final.service failed because the control process exited with error code.
Nov 21 19:41:58 apimdev1040 apic[2569]: See "systemctl status cloud-final.service" and "journalctl -xe" for details.
```

If you determined that this was the problem, you can correct it by running each of the following commands on every node:

1. `systemctl restart cloud-final.service`
2. `apic lock`
3. `apic unlock`

Upgrade to API Connect 10.0.5.3 fails to start because management subsystem fails the health check

This issue might be caused by a corrupt compliance entry in the pgbouncer.ini file. When the operator is upgraded to v10.0.5.3 but the ManagementCluster CR is not yet upgraded, the operator might update the pgbouncer.ini file in the PGBouncer secret with the older ManagementCluster CR's profile file, which does not contain any value for the `compliance pool_size`. As a result, the value gets incorrectly set to the string `<no value>`.

When this issue occurs, then the health check does not report the management subsystem as healthy so the upgrade will not start.

The following example shows what the error looks like in the pgbouncer logs:

```
Wed May 17 09:00:02 UTC 2023 INFO: Starting pgBouncer..
2023-05-17 09:00:02.897 UTC [24] ERROR syntax error in connection string
2023-05-17 09:00:02.897 UTC [24] ERROR invalid value "host=mgmt-a516d013-postgres port=5432 dbname=compliance pool_size=<no value>" for parameter compliance in configuration (/pgconf/pgbouncer.ini:7)
2023-05-17 09:00:02.897 UTC [24] FATAL cannot load config file
```

Resolve the issue by completing the following steps:

1. SSH to the root user:

```
ssh apicadm@<vm-hostname>
sudo -i
```

2. Run the commands in the following script:

```
NAMESPACE=<mgmt-namespace>
BOUNCER_SECRET=<management-prefix>-postgres-pgbouncer-secret
TEMP_FILE=/tmp/pgbouncer.ini

**Step 1 - Common: Get the existing pgbouncer.ini file**
kubectl get secret -n $NAMESPACE $BOUNCER_SECRET -o jsonpath='{.data.pgbouncer\.ini}' | base64 -d > $TEMP_FILE

**Step 2 - Linux version: Update the file and use it to patch the Secret on the cluster**
sed 's/<no value>/20/' $TEMP_FILE | base64 -w0 | xargs -I{} kubectl patch secret -n $NAMESPACE $BOUNCER_SECRET --
type='json' -p="{['op' : 'replace' , 'path' : '/data/pgbouncer.ini' , 'value' : {} ]}"

**Step 2 - Mac version: Update the file and use it to patch the Secret on the cluster**
sed 's/<no value>/20/' $TEMP_FILE | base64 -b0 | xargs -S2000 -I{} kubectl patch secret -n $NAMESPACE $BOUNCER_SECRET --
type='json' -p="{['op' : 'replace' , 'path' : '/data/pgbouncer.ini' , 'value' : {} ]}"

# Step 3 - Common: Restart pgbouncer to pick up the updated Secret configuration
kubectl delete pod <bouncer_pod_name> -n $NAMESPACE
```

Postgres replica fails to start due to permissions issue

Symptom:

```
2023-04-11 11:31:40,535 INFO: Lock owner: v10-0-5-up-ce0f24dc-sitel-postgres-iszz-c5d9c4f5c-9d9fj; I am v10-0-5-up-ce0f24dc-sitel-postgres-75845474bd-kzcjl
2023-04-11 11:31:40,537 INFO: starting as a secondary
2023-04-11 11:31:41.032 UTC [151610][FATAL: data directory "/pgdata/v10-0-5-up-ce0f24dc-sitel-postgres" has invalid permissions
2023-04-11 11:31:41.032 UTC [151610][DETAIL: Permissions should be u=rwx (0700) or u=rwx,g=rx (0750) .
2023-04-11 11:31:41,055 INFO: postmaster pid=151610
/tmp:5432 - no response
2023-04-11 11:31:41,091 INFO: Lock owner: v10-0-5-up-ce0f24dc-sitel-postgres-iszz-c5d9c4f5c-9d9fj; I am v10-0-5-up-ce0f24dc-sitel-postgres-75845474bd-kzcjl
2023-04-11 11:31:41,092 INFO: failed to start postgres
```

Resolve the issue by completing the following steps to correct the permissions and restart the replica pod:

1. Run the following command to exec into the pod:

```
k exec -it <pg-primary-pod> -- bash
```

2. Run the following command to reset the permissions:

```
chmod 0700 /pgdata/<pg-cluster-name>
```

3. Restart the failed pod.

Upgrade stuck with "Unable to upgrade appliance-base: exit status 100" message

This error can occur when the deployment is using an incorrect version of `containerd`. There is a known issue where upgrades from 10.0.1.7-eus or 10.0.1.8-eus to 10.0.5.1 incorrectly upgraded the `containerd` version.

On each node, complete the following steps to determine the version of `containerd` and if necessary, downgrade it to the correct version:

1. Run the following set of commands on the healthy node to downgrade the version of `containerd`:

```
systemctl stop appliance-manager
systemctl stop kubelet
systemctl stop containerd
apt-get --allow-downgrades upgrade -y containerd.io
sed -i 's/KillMode=process/KillMode=mixed/g' /lib/systemd/system/containerd.service
systemctl daemon-reload
systemctl restart containerd
```

```
apic lock
apic unlock
```

2. Run the following command to verify that `containerd` now displays `containerd://1.5.11` for the CONTAINER-RUNTIME:

```
kubectl get nodes -o wide
```

Remember to complete these steps on every node.

Some containers in the `kube-system` namespace show a status of `ErrImageNeverPull`

When upgrading, some of the containers in the `kube-system` namespace might show a status of `ErrImageNeverPull`. This happens due to Docker not successfully loading all images from the upgrade .tgz file. To resolve this issue and enable the upgrade to proceed, complete the following steps:

1. Run the following command to determine which node is missing the control plane files:

```
kubectl -n kube-system get pods -owide
```

This command returns the names of the nodes containing pods with the `ErrImageNeverPull` status, which indicates missing control plane files.

2. On the node that is missing the control plane files, run the following command to determine which versions of the control plane are missing:

```
cat /var/lib/apiconnect/appliance-control-plane-current
```

3. For each missing control plane, run the following command on the same node to add it, replacing `<version>` with the version of the control plane:

```
docker load < /usr/local/lib/appliance-control-plane/<version>/kubernetes.tgz
```

Pod stuck in Pending status during upgrade

When upgrading, the scheduler might deploy a subset of the same microservice pods on the same node. This can prevent other pods with `requiredDuringSchedulingIgnoredDuringExecution` affinity rules from being deployed due to a lack of resources on a subset of nodes. To allow the pending containers to be deployed successfully, identify any pods of the same type that are scheduled on the same node and delete one of them. This will free up space and cause the deleted pod to get rescheduled. To identify pods that are eligible to be deleted, and then delete the pods, complete the following steps:

1. Run the following command and check for any pods of the same type that are on the same node:

```
kubectl get po -o=custom-columns='name:.metadata.name, node:.spec.nodeName,
antiaffinity:.spec.affinity.podAntiAffinity.preferredDuringSchedulingIgnoredDuringExecution' | grep -v '<none>' | awk
'{print $1" "$2}'
```

In the following example snippet, one of the two `apim` pods on the node `test0186` should be deleted:

```
stv3-management-analytics-proxy-56848c8c69-phpdh test0186
stv3-management-analytics-proxy-56848c8c69-sc45f test0187
stv3-management-analytics-proxy-56848c8c69-scf6g test0188
stv3-management-apim-5574796948-6lnwj test0186
stv3-management-apim-5574796948-h9dgx test0186
stv3-management-apim-5574796948-tsb4g test0188
```

2. Run the following command to delete a pod:

```
kubectl delete po <pod_name>
```

Database replica pods stuck in Unknown or Pending state

In certain scenarios, a postgres replica pod may not recover to a healthy state when a restore completes, a node outage occurs, or after a fresh install or upgrade. In these cases, a postgres pod remains in a `Unknown` or a `Pending` state after a number of minutes. The pod fail to get into a `Running` state.

This situation occurs when the replicas do not initialize properly. You can use the `patronictl reinit` command to reinitialize the replica. Note that this command syncs the replica's volume data from the current Primary pod.

Use the following steps to get the pod back into a working state:

1. SSH into the VM as root.
2. Exec onto the failing pod:

```
kubectl exec -it <postgres_replica_pod_name> -n <namespace> -- bash
```

3. List the cluster members:

```
patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+-----+
|                               Member                               | Host   | Role   | State   | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| fxpk-management-01191b80-postgres-586f899fdf-6s25b             | 172.16.172.244 |        | start failed |    |          |
| fxpk-management-01191b80-postgres-rkw-795665698f-4rh4s         | 172.16.148.51 | Leader | running   | 3 |          |
| fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m         | 172.16.53.68  |        | running   | 3 |          |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
```

In the example shown above `fxpk-management-01191b80-postgres-586f899fdf-6s25b` is not in running state.

Note the `clusterName` and `replicaName` which are not up:

- `clusterName` - `fxpk-management-01191b80-postgres`
- `replicaName` - `fxpk-management-01191b80-postgres-586f899fdf-6s25b`

4. Run:

```
patronictl reinit <clusterName> <replicaName-which-is-not-running>
```

Example:

```
patronictl reinit fxpk-management-01191b80-postgres fxpk-management-01191b80-postgres-586f899fdf-6s25b
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+
| Member | Host | Role | State | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+
| fxpk-management-01191b80-postgres-586f899fdf-6s25b | 172.16.172.244 | | start failed | | unknown |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51 | Leader | running | 3 | |
| fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m | 172.16.53.68 | | running | 3 | 0 |
+-----+-----+-----+-----+-----+-----+
Are you sure you want to reinitialize members fxpk-management-01191b80-postgres-586f899fdf-6s25b? [y/N]: y
Success: reinitialize for member fxpk-management-01191b80-postgres-586f899fdf-6s25b
```

5. Run `patronictl list` again.

You may also observe that the replica is on a different Timeline (TL) and possibly have a Lag in MB. It may take a few minutes for the pod to switch onto the same TL as the others and the Lag should slowly go to 0.

For example:

```
bash-4.2$ patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+
| Member | Host | Role | State | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+
| fxpk-management-01191b80-postgres-586f899fdf-6s25b | 172.16.172.244 | | running | 1 | 23360 |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51 | Leader | running | 3 | |
| fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m | 172.16.53.68 | | running | 3 | 0 |
+-----+-----+-----+-----+-----+-----+
```

6. The pod that previously was in an `Unknown` or `Pending` state or `(0/1) Running` state is now in `(1/1) Running` state.

etcd pod stuck in Terminating state

During an upgrade, you might see a health-check reporting the upgrade is stuck in `ETCD` stage and that an `etcd` pod is stuck in the `Terminating` state.

Verify the issue by completing the following steps:

1. SSH into the VM as root.
2. Run the following command and verify that the upgrade stage is `ETCD`:

```
apic status
```
3. Run the following command to determine whether an `etcd` pod is stuck in the `Terminating` state:

```
kubectl get pods -n namespace | grep etcd
```

Resolve the issue by completing the following steps:

1. Run the following command to retrieve the names of the `etcd` pods:

```
kubectl get pods -n namespace -o wide | grep etcd
```

2. On the pod that is stuck, SSH into the VM as root.
3. Run the following command to restart the pod:

```
systemctl restart kubelet
```

Management subsystem upgrade imagePullBackOff issue

When upgrading the management subsystem, for example from `v10.0.4.0-ifix3` to `v10.0.5.1`, the postgres pods might run into an `imagePullBackOff` issue, where the postgres pods are looking for the `v10.0.4.0-ifix3` images that exist in the Docker registry, but the images haven't been loaded into the `Containerd` registry. To work around this issue, complete the following steps to manually move each image from the Docker registry to the `Containerd` registry:

1. Save the following Docker images, `ibm-apiconnect-management-k8s-init`, `crunchy-pgbackrest-repo`, `crunchy-pgbackrest`, `crunchy-pgbouncer`, and `crunchy-postgres-ha`, into a `.tar` file and keep in a secure location. For example, from `v10.0.4.0-ifix3`:

```
docker save 127.0.0.1:8675/10.0.4.0-ifix3/ibm-apiconnect-management-pgo-scheduler > pgo-scheduler.tar
```

2. Import each saved image into the `Containerd` registry. For example:

```
ctr --namespace k8s.io image import pgo-scheduler.tar --digests=true
```

3. Re-tag the `import-<timestamp>@sha256:nnn` images to their appropriate `ifix2` tags and digests. For example:

```
ctr --namespace k8s.io image tag <source> <target>
```

where:

- `<source>` is the string that is returned in step 2.
- `<target>` is the missing image; you can determine it by describing the pod that is in the `ImagePullBackFailure` state.

Postgres pods fail to start after upgrade

Note: This topic applies only to upgrading the management subsystem from `v10.0.2.0` or later to a newer version of `v10.0.x`. This problem does not occur when upgrading from `v10.0.1.2-ifix2` to `v10.0.3.0` or later.

When upgrading the management subsystem from `v10.0.2.0` or later, as part of [Upgrading to the latest release on VMware](#), you might encounter an error message when checking the subsystem health upon completion of the upgrade. For example:

```

apic health-check
INFO[0000] Log level: info
FATA[0006] Cluster not in good health:
ManagementCluster (current ha mode: active) is not ready | State: 15/16 Phase: Pending

```

To troubleshoot when a message like this occurs:

1. Check the state of postgres pods:

```
kubectl get pods | grep postgres
```

For example:

```

root@apimdev1146:~# kubectl get pods | grep postgres
fxpk-management-fd8b0b1f-postgres-577594c7f-k54pk      0/1      Init:CrashLoopBackOff   17      22h
fxpk-management-fd8b0b1f-postgres-backrest-shared-repo-7fctp88w  1/1      Running                  2       22h
fxpk-management-fd8b0b1f-postgres-elbx-698f445649-rlc2g    0/1      Init:CrashLoopBackOff   16      22h
fxpk-management-fd8b0b1f-postgres-pgbouncer-64f57b7cc7-52bk8  1/1      Running                  2       22h
fxpk-management-fd8b0b1f-postgres-pgbouncer-64f57b7cc7-jjjvb  1/1      Running                  1       22h
fxpk-management-fd8b0b1f-postgres-pgbouncer-64f57b7cc7-qp4zh  1/1      Running                  2       22h
fxpk-management-fd8b0b1f-postgres-stanza-create-6pt6c      0/1      Completed                0       22h
fxpk-management-fd8b0b1f-postgres-ubba-79cdd5cc6-kj4zx    0/1      Init:CrashLoopBackOff   17      22h
postgres-operator-85fb96db4b-gk8k8                       4/4      Running                  8       22h

```

2. If any pods show `Init:CrashLoopBackOff` status, restart the pods. To force a restart, delete the pods:

```
kubectl delete pod <name_of_postgres_pod>
```

For example:

```

kubectl delete pod fxpk-management-fd8b0b1f-postgres-577594c7f-k54pk
kubectl delete pod fxpk-management-fd8b0b1f-postgres-elbx-698f445649-rlc2g
kubectl delete pod fxpk-management-fd8b0b1f-postgres-ubba-79cdd5cc6-kj4zx

```

When pods are deleted, the deployment automatically restarts them.

3. Re-run the health check. For example:

```
apicup subsys health-check <subsys_name>
```

4. When health check is successful, return to the next upgrade step in [Upgrading to the latest release on VMware](#).

Upgrading a 3 node profile to IBM API Connect 10.0.3.0 or later might result in some portal-db/www pods being stuck in the Pending state

IBM® API Connect 10.0.3.0 introduces the pod anti-affinity required rule, meaning that in a 3 node profile deployment, all 3 db and www pods can run only if there are at least 3 running worker nodes. This rule can cause some upgrades to version 10.0.3.0 or later to become stuck in the **Pending** state, in which case some extra steps are needed during the upgrade to workaround the issue. See the following example for detailed information about the issue, and how to continue with the upgrade.

Important: You must have a backup of your current deployment before starting the upgrade.

To run the commands that are needed to workaround this issue, you must log in to the virtual machine portal subsystem by using an SSH tool.

1. Run the following command to log in as `apicadm`, which is the API Connect ID that has administrator privileges:

```
ssh portal_ip_address -l apicadm
```

Where `portal_ip_address` is the IP address of the portal subsystem.

2. Then get a root shell by running the following command:

```
sudo -i
```

In the following example, the VMware stack has 3 VMs (worker nodes):

```

$ kubectl get nodes
NAME          STATUS    ROLES    AGE   VERSION
apimdev0103   Ready    worker   42m   v1.20.0
apimdev0129   Ready    worker   45m   v1.20.0
apimdev1066   Ready    worker   39m   v1.20.0

```

The pods have been scheduled across only 2 of the 3 worker nodes due to a transient problem with `apimdev1066`, as shown in the following pod list. Pods without persistent storage, such as `nginx-X`, can be rescheduled to `apimdev1066` as soon as they are restarted, but any pods with persistent local storage, such as `db-X` and `www-X`, have to be rescheduled onto the same worker node as that is where their files live.

```

$ kubectl get po -o wide
NAME          READY    STATUS    RESTARTS   AGE   IP          NODE          NOMINATED NODE
READINESS GATES

```

The upgrade to version 10.0.3.0 is started and the following pod list is observed:

```

$ kubectl get po -o wide
NAME          READY    STATUS    RESTARTS   AGE   IP          NODE          NOMINATED NODE
READINESS GATES

```

ejs-portal-nginx-84f57ffd8c-hbf66	1/1	Running	0	10m	888.16.109.208	apimdev0103	<none>	<none>
ejs-portal-nginx-84f57ffd8c-mvq96	1/1	Running	0	10m	888.16.142.215	apimdev0129	<none>	<none>
ejs-portal-nginx-84f57ffd8c-vpmtl	1/1	Running	0	10m	888.16.142.214	apimdev0129	<none>	<none>
ejs-portal-sitel-db-0	2/2	Running	0	10m	888.16.109.209	apimdev0103	<none>	<none>
ejs-portal-sitel-db-1	0/2	Pending	0	91s	<none>	<none>	<none>	<none>
ejs-portal-sitel-db-2	2/2	Running	0	2m41s	888.16.142.218	apimdev0129	<none>	<none>
ejs-portal-sitel-www-0	2/2	Running	0	9m51s	888.16.109.210	apimdev0103	<none>	<none>
ejs-portal-sitel-www-1	2/2	Running	0	12m	888.16.142.213	apimdev0129	<none>	<none>
ejs-portal-sitel-www-2	0/2	Pending	0	111s	<none>	<none>	<none>	<none>
ibm-apiconnect-75b47f9f87-p25dd	1/1	Running	0	10m	888.16.109.207	apimdev0103	<none>	<none>

The pod list shows that `db-2` has restarted, and has been rescheduled to `apimdev0129` as there were no other db pods running on that node. However, `db-1` and `www-2` are both stuck in `Pending` state, as there is already a pod of the same type running on the worker node that is hosting the local storage that they are bound to. If you run a `describe` command of either pod you will see the following output:

Events:

Type	Reason	Age	From	Message
Warning	FailedScheduling	10s (x4 over 2m59s)	default-scheduler	0/3 nodes are available: 1 node(s) didn't match pod affinity/anti-affinity, 1 node(s) didn't match pod anti-affinity rules, 2 node(s) had volume node affinity conflict.

To resolve this situation you need to delete the PVCs for each pod, and then delete the pod itself, so that Kubernetes will regenerate the PVCs and schedule the pod on the worker node that does not have the anti-affinity conflict.

Therefore, for the `db-1` pod the following commands must be run:

```
$ kubectl get pvc | grep ejb-portal-sitel-db-1
db-ejs-portal-sitel-db-1          Bound          local-pv-fa445e30    250Gi        RWO          local-storage    15m
dblogs-ejs-portal-sitel-db-1    Bound          local-pv-d57910e7   250Gi        RWO          local-storage    15m
```

```
$ kubectl delete pvc db-ejs-portal-sitel-db-1 dblogs-ejs-portal-sitel-db-1
persistentvolumeclaim "db-ejs-portal-sitel-db-1" deleted
persistentvolumeclaim "dblogs-ejs-portal-sitel-db-1" deleted
```

```
$ kubectl delete po ejb-portal-sitel-db-1
pod "ejb-portal-sitel-db-1" deleted
```

For the `www-2` pod the following commands must be run:

```
$ kubectl get pvc | grep ejb-portal-sitel-www-2
admin-ejs-portal-sitel-www-2    Bound          local-pv-48799536   245Gi        RWO          local-storage    51m
backup-ejs-portal-sitel-www-2   Bound          local-pv-a93f5607   245Gi        RWO          local-storage    51m
web-ejs-portal-sitel-www-2      Bound          local-pv-facd4489   245Gi        RWO          local-storage    51m
```

```
$ kubectl delete pvc admin-ejs-portal-sitel-www-2 backup-ejs-portal-sitel-www-2 web-ejs-portal-sitel-www-2
persistentvolumeclaim "admin-ejs-portal-sitel-www-2" deleted
persistentvolumeclaim "backup-ejs-portal-sitel-www-2" deleted
persistentvolumeclaim "web-ejs-portal-sitel-www-2" deleted
```

```
$ kubectl delete po ejb-portal-sitel-www-2
pod "ejb-portal-sitel-www-2" deleted
```

If the PVC has `persistentVolumeReclaimPolicy: Delete` set on it, as is the case for the OVA deployments, then no cleanup is necessary as the old data will have been deleted on the worker node that is no longer running the `db-1` and `www-2` pods.

Kubernetes can now reschedule the pods. All pods with persistent storage are now spread across the available worker nodes, and the pods whose PVCs were deleted will get a full copy of the data from the existing running pods. The following pod list is now observed in our example:

```
$ kubectl get po -o wide
```

Issues when installing Drupal 8 based custom modules or sub-themes into the Drupal 9 based Developer Portal

From IBM API Connect 10.0.3.0, the Developer Portal is based on the Drupal 9 content management system. If you want to install Drupal 8 custom modules or sub-themes into the Drupal 9 based Developer Portal, you must ensure that they are compatible with Drupal 9, including any custom code that they contain, and not using any deprecated APIs, for example. There are tools available for checking your custom code, such as [Drupal check](#) on GitHub, which checks Drupal code for deprecations.

For example, any Developer Portal sites that contain modules or sub-themes that don't contain a Drupal 9 version declaration will fail to upgrade, and errors like the following output will be seen in the `admin` logs:

```
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: Checking theme: emeraldgreen
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: Incompatible
core_version_requirement ' ' found for emeraldgreen
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: Checking theme: rubyred
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '8.x' found for rubyred
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: Found themes incompatible with
Drupal 9: emeraldgreen rubyred
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: /tmp/restore_site.355ec8 is NOT
```

```

Drupal 9 compatible
...
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: Checking module: custom_mod_1
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '' found for custom_mod_1
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: Checking module: custom_mod_2
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '8.x' found for custom_mod_2
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Found modules incompatible with
Drupal 9: emeraldgreen rubyzed
[ queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: site1.com is NOT Drupal 9
compatible

```

To fix version compatibility errors, all custom modules and sub-themes should declare a `core_version_requirement` key in their `*.info.yml` file that indicates Drupal 9 compatibility. For example:

```

name: Example module
type: module
description: Purely an example
core: 8.x
core_version_requirement: '^8 || ^9'
package: Example module

```

```

# Information added by Drupal.org packaging script on 2020-05-31
version: '8.x-1.3'
project: 'example_module'
datestamp: 1590905415

```

This example specifies that the module is compatible with all versions of Drupal 8 and 9. For more information, see [Let Drupal know about your module with an .info.yml file](#) on the drupal.org website.

If you have a backup of a site that you need to restore, and are getting the version compatibility error, but the module or theme `*.info.yml` file cannot be changed easily, then you have two options. Either:

- Add an environment variable into the portal CR for the `www` pod of the `admin` container stating `SKIP_D9_COMPAT_CHECK: "true"`. However, if you choose this method, you must be positive that all of the custom modules and themes for your sites are Drupal 9 compatible, as otherwise the sites may end up inaccessible after the upgrade or restore.
 1. On VMware, create an extra values file to contain the environment variable, as follows:

```

spec:
  template:
    - containers:
      - env:
        - name: SKIP_D9_COMPAT_CHECK
          value: "true"
        name: admin
      name: www

```

2. Save the file as `d9compat.yaml`, and run the following command:

```
apicup subsys set <portal_subsystem_name> extra-values-file d9compat.yaml
```

3. Then, update the portal VMware with the updated setting by running the following command:

```
apicup subsys install <portal_subsystem_name>
```

Or:

- Extract the site backup, edit the relevant files inside it, and then tar the backup file again. Note that this procedure will overwrite the original backup file, so ensure that you keep a separate copy of the original file before you start the extraction. For example:
 1. `mkdir /tmp/backup`
 2. `cd /tmp/backup`
 3. `tar xzf path_to_backup.tar.gz`
 4. Edit the custom module and theme files to make them Drupal 9 compatible, and add the correct `core_version_requirement` setting.
 5. `rm -f path_to_backup.tar.gz`
 6. `tar cfz path_to_backup.tar.gz`
 7. `cd /`
 8. `rm -rf /tmp/backup`

Skipping health check when re-running upgrade

The `apicup subsys install` command automatically runs `apicup health-check` prior to attempting the upgrade. An error is displayed if a problem is found that will prevent successful upgrade.

In some scenarios, if you encounter an upgrade failure, an attempt to rerun `apicup subsys install` is blocked by errors found by `apicup health-check`. Even when you have fixed the error (such as reconfiguration of an incorrect upgrade CR), the failed upgrade can continue to cause the health check to fail.

You can work around the problem by adding the `--skip-health-check` flag to suppress the health check:

```
apicup subsys install <subsystem_name> --skip-health-check
```

In this case, use of `--skip-health-check` allows the upgrade to rerun successfully.

Maintaining API Connect

You can use utilities to complete maintenance tasks such as backup, restore, and certificate management in a VMware environment.

Note: When maintaining API Connect, do not use `kubectl exec` commands to access API Connect pods unless advised by IBM.

Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

- [Advanced installation on VMware](#)
Optionally install additional software.

Advanced installation on VMware

Optionally install additional software.

See:

- [Installing the IBM License Metric Tool on VMware](#)
The IBM® License Metric Tool (ILMT) helps you determine whether your IBM API Connect deployment is compliant with licensing requirements.
- [Installing the toolkit](#)
- [Installing the Automated API behavior testing application](#)
Install the Automated API behavior testing application in your IBM API Connect deployment on VMware.

Installing the IBM License Metric Tool on VMware

The IBM® License Metric Tool (ILMT) helps you determine whether your IBM API Connect deployment is compliant with licensing requirements.

About this task

ILMT provides useful features for managing virtualized environments and measuring license utilization. ILMT discovers the software that is installed in your infrastructure, helps you to analyze the consumption data, and allows you to generate audit reports. Each report provides you with different information about your infrastructure; for example the computer groups, software installations, and the content of your software catalog.

By default, every ILMT audit report presents data from the previous 90 days. You can customize the type and amount of information displayed in a report by using filters, and save your personal settings for future use. You can also export the reports to .csv or .pdf format, and schedule report emails so that specified recipients are notified when important events occur.

To deploy the ILMT with API Connect, complete the following steps for the Management, Developer Portal, and Analytics OVAs. The instructions refer to topics in the ILMT documentation:

Procedure

1. Add a disconnected data source to your ILMT deployment as explained in [Adding a data source](#).
2. Download the scanner installer as explained in [Downloading the disconnected scanner package \(disconnected scenario\)](#).
3. Install the scanner and run scans as explained in [Installing the disconnected scanner and gathering scan results \(disconnected scenario\)](#).
4. Set up daily transfer of scan results to ILMT as explained in [Setting up daily transfer of scan results to the License Metric Tool server \(disconnected scenario\)](#).

Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + LoopBack + Designer: provides a command line environment for working with IBM API Connect, including LoopBack® support, and the API Designer application.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + LoopBack + Designer option, an executable file for launching the API Designer application.

You can download the toolkit from one of the following locations:

- From IBM Fix Central.
- From the Cloud Manager or API Manager user interface.

Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.

- To download the toolkit from IBM Fix Central, complete the following steps:
 - Open the [IBM Fix Central site](#) in your browser.
 - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
 - Select your Installed Version and click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
 - In the Text field, enter `toolkit`, then click Continue.
 - Select the toolkit file that you want to download.
 - Click Continue, then follow the instructions to complete the download operation.
- To download the toolkit from Cloud Manager or API Manager user interface, complete the following steps:
 - Open the Cloud Manager or API Manager user interface.
 - On the welcome page, click the Download Toolkit tile. The two toolkit options are listed.
 - Click your platform alongside either the CLI option or the CLI + LoopBack + Designer option as required, then save the associated compressed file to your local file system.
 - To download the API Designer credentials (Client ID and Client Secret), click Download alongside API Designer Credentials, then save the `designer_credentials.json` file to your local file system. A command is provided for installing the credentials, as described in detail in [step 6](#).
 - To download the toolkit credentials (Client ID and Client Secret), click Download alongside Credential, then save the `credentials.json` file to your local file system. A command is provided for installing the credentials, as described in detail in [step 5](#).
 - Close the Install API Connect Toolkit window.

2. Extract the contents of the toolkit compressed file to a folder of your choice.

The contents of the file depend on the your chosen toolkit option and platform, as follows:

- The `apic-slim` or `apic-slim.exe` file is the CLI for IBM API Connect.
- The `apic` or `apic.exe` file is the CLI for IBM API Connect including LoopBack support.
 - Tip: If you are using the CLI option, then if you rename the `apic-slim` file to `apic`, or the `apic-slim.exe` file to `apic.exe`, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + LoopBack + Designer option.
- The `api_designer-platform` file is the API Designer user interface application for the specified platform.

3. Optional: Delete the `$HOME/.apiconnect/node_cli` directory.

You need to do this only if you replaced a version of `apic` or `apic.exe` and are using the `apic lb4` command. You need to delete the directory `get apic` to unpack the new loopback.

On Windows, `$HOME` is defined by environment `USERPROFILE`.

4. Run the CLI.

- For the Mac OSX or Linux® platforms, complete the following steps:
 - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
 - Make the CLI file an executable file by entering the following command:

```
chmod +x download_name
```

Where `download_name` is the name of the toolkit file that you downloaded, either `apic` or `apic-slim`.

- Run CLI commands as follows:

```
./apic command_name_and_parameters
```

or

```
./apic-slim command_name_and_parameters
```

For details of the CLI commands, see [apic](#).

- For the Windows platform, complete the following steps:
 - Open a command prompt and navigate to the folder where you extracted the contents of the toolkit compressed file.
 - Run CLI commands as follows:

```
apic command_name_and_parameters
```

or

```
apic-slim command_name_and_parameters
```

For details of the CLI commands, see [apic](#).

Tip: Add the folder location of your CLI file to your `PATH` variable so that you can run CLI commands from anywhere in your file system.

5. Install the toolkit credentials.

If you do not install the toolkit credentials that are provided for download, as detailed previously in the [toolkit credentials download instructions](#), API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the credentials into your local toolkit, run the following command:

```
apic client-creds:set toolkit_credentials_file_path/credentials.json
```

where `credentials_file_path` is the location to which you downloaded the toolkit credentials JSON file. After you have run this command, your toolkit uses these new credentials to authenticate with the management server.

Note: At any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.

To revert to the default toolkit credentials for all login operations from the toolkit CLI, use the following command:

```
apic client-creds:clear
```

For increased security, an administrator can remove the default credentials from the management server by completing the following steps:

- a. Log in to the management server as an administrator; see [Logging in to a management server](#).
- b. Delete the default credentials by running the following commands:

```
apic registrations:delete toolkit --server mgmt_endpoint_url
apic registrations:delete consumer-toolkit --server mgmt_endpoint_url
```

6. Install the API Designer credentials.

If you do not install the API Designer credentials that are provided for download, as detailed previously in the [API Designer credentials download instructions](#), API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the custom credentials into your local API Designer, set the `APIC_DESIGNER_CREDENTIALS` environment variable to the credentials download location, using the mechanism appropriate for your operating system.

After you have set the `APIC_DESIGNER_CREDENTIALS` environment variable, your API Designer uses the new credentials to authenticate with the management server.

• Windows:

If you are using Windows, create an environment variable using one of the following methods:

- Create a permanent environment variable so that you can start API Designer from any location on your computer:
 - Open the Environment Variables page: Click Start, Settings, System and in the "Related Settings" section of the page, click Advanced System Settings.
 - On the Advanced tab of the System Properties dialog box, click Environment Variables.
 - In the "User variables" section, click New and create an environment variables with the following settings:
 - Variable: `APIC_DESIGNER_CREDENTIALS`
 - Value: `<designer_credentials_file_path>\designer_credentials.json` where `<designer_credentials_file_path>` is the location where you stored the `designer_credentials.json` file.
 - Click OK to save the new environment variable, and then exit the dialog box.
- If you don't have the required permissions to create a permanent environment variable, you can create a temporary one that will only be used while you are running the API Designer application. The following steps must be performed every time you start API Designer:
 - Open the Windows command prompt.
 - Run the following command to set the temporary environment variable:

```
set APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>\designer_credentials.json
```

where `<designer_credentials_file_path>` is the location where you stored the `designer_credentials.json` file.

Note: Leave the command prompt open for the next step. You must set the temporary variable and start the API Designer within the same Windows command session.

- Now run the following command to start API Designer:

```
C:\>"Program Files\API Designer\API Designer.exe"
```

By default, API Designer is installed in the `C:\Program Files\API Designer` folder as shown in the example. If you installed it into a different location, use your own location in the command. Note that the path and file name are enclosed in quotation marks because they contain spaces.

• Mac:

If you are using Mac OS X, create an environment variable using one of the following methods:

- Run the following command to set the global environment variable:

```
launchctl setenv APIC_DESIGNER_CREDENTIALS <designer_credentials_file_path>/designer_credentials.json
```

where `<designer_credentials_file_path>` is the location where you stored the API Designer credentials JSON file.

- Pass in the environment variable while starting API Designer from the command line. With this method, you must run the following command every time you start API Designer:

```
APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>/designer_credentials.json open <designer_application_file_path>/'API Designer.app'
```

where:

- `<designer_credentials_file_path>` is the location to which you downloaded the API Designer credentials JSON file.
- `<designer_application_file_path>` is the location to which you downloaded and uncompressed the API Designer application.

7. Start the API Designer application from the location to where you stored the extracted file.

Note:

- To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
 - In Windows File Explorer, navigate to the `USER_HOME\AppData\Local\Programs\api-designer` folder.
 - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
- To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see [Developing your APIs and applications](#).

Installing the Automated API behavior testing application

Install the Automated API behavior testing application in your IBM® API Connect deployment on VMware.

About this task

Use the following steps to install the Automated API behavior testing application as part of your initial deployment, or to add it in later.

Note: It is not possible to use the Automated API behavior testing application with a two data center disaster recovery configuration ([A two data center deployment strategy on VMware](#)).

Procedure

1. Run the following **apicup** commands to install or update your deployment with the the Automated API behavior testing application:

```
apicup subsys set mgmt test-and-monitor-enabled true
apicup certs set mgmt hub --clear
apicup certs set mgmt turnstile --clear
apicup subsys set mgmt hub hub-endpoint
apicup subsys set mgmt turnstile turnstile-endpoint
apicup subsys install mgmt
```

where:

- **mgmt** is the name of your Management server (which you are either installing or updating).
- **hub-endpoint** is an endpoint on the ingress subdomain for the API Connect stack; for example: hub.testsrv0231.subnet1.example.com.
- **turnstile-endpoint** is an endpoint on the ingress subdomain for the API Connect stack; for example: turnstile.testsrv0231.subnet1.example.com.

Attention: The hub and turnstile endpoints should be distinct and must not overlap with any of the 4 management endpoints.

2. Verify that the application deployed properly by completing the following steps:
 - a. Log in to API Manager.
 - b. On the Home page, click the Test APIs tile.
 - c. Verify that the Automated API behavior testing opens.

Advanced configuration on VMware

Perform configuration tasks on your API Connect deployment on VMware.

See:

- [Adding a static route on a virtual machine](#)
You can add a static route to the routing table when deploying API Connect on a VMware virtual machine.
- [Adding disk space to a VMware appliance](#)
Increase disk space on the VMware appliance.
- [Appliance boot mode configuration](#)
Configure the boot mode for the appliance VMs.
- [Running commands at boot with iso-ignored boot mode](#)
When **iso-ignored** boot mode is configured, complete the following steps on each appliance that should run commands at boot.
- [Changing deployment profiles on VMware](#)
You can change an API Connect installation to use a different deployment profile.
- [Changing the DNS server configuration on appliances](#)
Complete this task only if you must change the DNS addresses after the initial boot of the VM.
- [Configuring API Connect subsystems in a cluster](#)
This topic describes how to configure a cluster of API Connect subsystems (management server, analytics, and Developer Portal) with three VMs for each subsystem, for use with a load balancer, to support a high availability (HA) environment.
- [Configuring SSHD to limit access to your deployment](#)
How to configure SSHD in order to limit host access to your VMware deployment, or to change the SSHD cipher level.
- [Enabling Developer Portal feature flags on VMware](#)
Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.
- [Managing an appliance data disk](#)
You can use **apic** commands to manage appliance data disks in your VMware deployment.
- [Replica override for microservices on VMware](#)
Modify the replica count for microservices by using template overrides for Custom Resources.
- [Testing a new configuration against a current cluster](#)
You can use the **apicup** utility to test the validity of a new configuration before you install it.
- [TLS certificate concepts and operations](#)
Information about internal API Connect certificates, renewing expired certificates, exporting certificates, and other certificate maintenance operations.
- [Use JWT security instead of mTLS between subsystems](#)
If your network requires TLS termination on load-balancers located between your API Connect subsystems, then disable mTLS and enable JWT to provide application layer security.
- [Credentials and encryption secrets reference](#)
API Connect user credentials and database encryption secrets that are managed with the **apicup certs** command.

Adding a static route on a virtual machine

You can add a static route to the routing table when deploying API Connect on a VMware virtual machine.

About this task

Add commands to your additional `cloud-init` file. You can do this for the Management, Analytics, and Portal subsystems.

Procedure

1. Specify an additional cloud-init file:

```
apicup subsys set <subsys> additional-cloud-init-file <path-to-cloud-init-file>
```

2. Add lines to your cloud-init file.

Syntax:

```
bootcmd:  
- ip route add <destination>/<mask> via <gateway> dev eth<n>
```

Example:

```
bootcmd:  
- ip route add 172.27.218.0/24 via 172.27.218.1 dev eth1  
- ip route add 172.26.203.0/24 via 172.27.218.1 dev eth1
```

3. Regenerate the ISO file.

```
apicup subsys install <subsys> --out <plan-directory>
```

4. Restart the ISO, and ensure that the node(s) have this updated ISO attached at startup.

Adding disk space to a VMware appliance

Increase disk space on the VMware appliance.

About this task

For multi-node deployment of the appliance, only one VM at a time should have its disk space augmented. The subsystem should be in good health before proceeding to the next node. Health of the subsystem can be checked with `apicup subsys health-check <subsystem-name>`.

Restriction:

The increased disk capacity of a VMware appliance won't be reflected in the storage size of the PVCs that are hosted on the appliance, as those PVCs are immutable. This restriction doesn't impact the Portal and Analytics subsystems, as the PVC storage size isn't used to enforce any disk usage limit, so the subsystems can use all of the additional disk space. However, for the Management subsystem the PVC storage size is used in the database storage utilization computation, and that might trigger disk usage warnings.

The most common reason for the Management subsystem database to run out of disk space, is due to Write Ahead Log (WAL) file accumulation in relation to an incorrectly configured backup, or an unavailable backup server. If this type of condition arises, adding disk space might help with the health of the appliance control plane, but it won't increase the disk space that's available to the database, so you must resolve the WAL file accumulation condition. If the disk space that's available to the Management database must be increased, you should carry out a disaster recovery operation of the Management subsystem, using a larger data disk size for the new installation, so that adding disk space after the install won't be needed.

Procedure

1. Shutdown the virtual machine, either by issuing a shutdown command as root from the VM, or by using the VMware console or command line interface. For example, use the VMware console user interface and click the red rectangle.
2. Use either the VMware console or command line interface to add a new device to the VM, of type Hard Disk and of the desired size to be added to the appliance. For example, on the VMware console:
 - a. Click Edit settings.
 - b. Click Add new device. From the drop-down menu, select Hard Disk.
 - c. Enter size in GB and click OK.
3. Use either the VMware console or the command line interface to power on the VM. As the VM starts it should detect the newly added disk and use it to augment the available capacity for the `/data/secure` mount point.
4. Optionally you may verify that a new disk `sdc` was added (or `sdd` if you already added one disk, and so on). Log in to the server and observe the new disk. For example:

```
root@apimdev1139:~# lsblk  
NAME                MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT  
sda                  8:0    0  100G  0 disk  
├─sda1                8:1    0  99.9G  0 part  /  
├─sda14               8:14   0    4M    0 part  
└─sda15               8:15   0  106M  0 part  /boot/efi  
sdb                  8:16   0  250G  0 disk  
├─apiconnect-data    252:0   0  260G  0 lvm  
├─apicSecureDisk     252:1   0  260G  0 crypt /data/secure  
sdc                  8:32   0   10G  0 disk  
├─apiconnect-data    252:0   0  260G  0 lvm  
├─apicSecureDisk     252:1   0  260G  0 crypt /data/secure  
sr0                 11:0    1   44K  0 rom
```

Appliance boot mode configuration

Configure the boot mode for the appliance VMs.

By default every appliance node requires the presence of an ISO file attached at boot.

Version 10.0.4.0 or later: You can configure individual VMs so that they can be booted and rebooted without an ISO being attached. Each appliance VM (node) is configured individually.

You can:

- [Check the current boot mode of an appliance](#)
- [Configure an appliance for iso-ignored boot mode](#)
- [Configure an appliance for iso-required boot mode](#)
- [Revert back to iso-required boot mode by booting the appliance in rescue mode](#)

Check the current boot mode of an appliance

The default boot mode for all appliances is `iso-required`. To check the current boot mode:

1. Connect to the target appliance via SSH then switch to the root user:

```
ssh apicadm@{ova appliance hostname}
sudo -i
```

2. Use `apic boot-mode` to check the current boot mode of the appliance. For example:

```
root@ip-192-168-122-241:~# apic boot-mode
INFO[0000] Log level: info
INFO[0000] current boot mode is: iso-required
```

Configure an appliance for `iso-ignored` boot mode

An appliance can be configured to use the `iso-ignored` boot mode instead of the default `iso-required`. Prerequisite: The appliance must have first booted with its configuration ISO attached and in `iso-required` boot mode (default) before the boot mode can be changed to `iso-ignored`.

You can configure an appliance to use the `iso-ignored` boot mode instead of the default `iso-required`.

Prerequisite: The appliance must have first booted with its configuration ISO attached and in `iso-required` boot mode (default), before you can change the boot mode to `iso-ignored`.

Note: If you added a static route to the routing table, as documented in [Adding a static route on a virtual machine](#), and if you are relying on a `bootcmd` from the ISO, then using the `iso-ignored` boot mode causes the `bootcmd` section being ignored or ineffective.

1. Connect to the target appliance via SSH then switch to the root user:

```
ssh apicadm@{ova appliance hostname}
sudo -i
```

2. Edit the file `/etc/default/grub.d/50-cloudimg-settings.cfg` to ensure that the `GRUB_TIMEOUT` and `GRUB_RECORDFAIL_TIMEOUT` are set to the value 5. Then run the command `update-grub`. For example:

```
root@ip-192-168-122-241:~# update-grub
Sourcing file `/etc/default/grub'
Sourcing file `/etc/default/grub.d/50-cloudimg-settings.cfg'
Sourcing file `/etc/default/grub.d/init-select.cfg'
Generating grub configuration file ...
Found linux image: /boot/vmlinuz-5.4.0-84-generic
Found initrd image: /boot/initrd.img-5.4.0-84-generic
done
```

3. Set the appliance boot mode to `iso-ignored` with the command `apic boot-mode iso-ignored`. For example:

```
root@ip-192-168-122-241:~# apic boot-mode iso-ignored
INFO[0000] Log level: info
INFO[0000] current boot mode is: iso-ignored
```

4. Shutdown the VM, and remove the CD/DVD device from the VM configuration through VSphere. For any subsequent boot of the appliance while it remains in `iso-ignored` boot mode, any ISO file attached will be ignored, and the boot will proceed as normal, whether an ISO file is attached or not.

Warning: If the appliance was booted in `iso-ignored` boot mode, it is possible to change its boot mode to `iso-required`. However, as stated in the prerequisites, it is not possible to immediately switch back to `iso-ignored`, and the next boot of the appliance must happen with the configuration ISO attached and boot mode `iso-required`.

Configure an appliance for `iso-required` boot mode

The mode `iso-required` is the default boot mode for all appliances. If the appliance boot mode was changed to `iso-ignored` you can revert back to `iso-required` boot mode.

Warning:

If the appliance was booted in `iso-ignored` boot mode, it is possible to change its boot mode to `iso-required`. However, you cannot immediately switch back to `iso-ignored`, and the next boot of the appliance must happen with the configuration ISO attached and boot mode `iso-required`. After the appliance is booted with ISO

attached in `iso-required` boot mode, the boot mode can then be switched to `iso-ignored` if needed.

1. Connect to the target appliance via SSH then switch to the root user:

```
ssh apicadm@{ova appliance hostname}
sudo -i
```

2. Set the appliance boot mode to `iso-required` with the command `apic boot-mode iso-required`. For example:

```
root@ip-192-168-122-241:~# apic boot-mode iso-required
INFO[0000] Log level: info
INFO[0000] current boot mode is: iso-required
```

Important: For any subsequent boot of the appliance while it remains in `iso-required` boot mode, the configuration ISO file must be connected at boot and for every boot.

Revert back to `iso-required` boot mode by booting the appliance in rescue mode

When an appliance is configured with the `iso-ignored` boot mode, the boot sequence ignores any attached ISO. This means that it is not possible to influence the appliance configuration during its boot. In case the appliance is not booting properly and the boot mode needs to be reverted back to `iso-required`, proceed as follows:

1. Access to the VMware console for the Appliance, and after causing it to reboot, bring up a console to the appliance. You can give focus to the window by clicking the mouse into it. Press the `Esc` key to access the Linux grub boot menu. For example:

```
GNU GRUB version 2.04
```

```
*Ubuntu
Advanced options for Ubuntu
```

2. Press `e` and navigate using arrow keys to the line starting with `linux` to append `systemd.unit=rescue.target`

```
GNU GRUB version 2.04
.
.
.
insmod_part_gpt
insmod_ext2
if [ x$feature_platform_search_hint = xy ]; then
  search --no-floppy --fs-uuid --set=root e46dalb8-55ao-4df9-842e-\
8d80c3a22ffc
else
  search --no-floppy --fs-uuid --set=root e46dalb8-55ao-4df9-842e-8\
d80c3a22ffc
fi
linux /boot/vmlinuz-5.4.0-84-generic root=LABEL=cloudimg-roc\
tfs ro console=tty1 console=ttyS0 net.ifnames=0 biosdevname=0 systemd.unit\
=rescue.target
initrd /boot/initrd.img-5.4.0-84-generic
```

3. Press `Ctrl+x` to boot.
4. Press `Enter` to enter maintenance mode. Run the commands:

```
rm -f /etc/cloud/cloud-init.disabled
```

and

```
echo -n "iso-required" > /usr/local/lib/appliance-config/boot-mode
```

```
[ 3.442687] systemd[1]: Mounted Kernel Debug Filesystem

root#ip-192-168-122-241:~#
```

5. Reboot the appliance with correct configuration ISO attached.

Running commands at boot with `iso-ignored` boot mode

When `iso-ignored` boot mode is configured, complete the following steps on each appliance that should run commands at boot.

About this task

If you configured the appliance to boot in `iso-ignored` mode as documented in [Appliance boot mode configuration](#), the `bootcmd` lines will be ignored. For each appliance node that should run commands at boot, complete the following steps.

Procedure

1. SSH into the appliance as root.
2. Create the `/usr/local/bin/appliance-boot-commands.sh` script to be executed at boot; for example:

```
cat << EOF > /usr/local/bin/appliance-boot-commands.sh
#!/bin/bash

ip route add 172.27.218.0/24 via 192.168.122.1 dev eth0
ip route add 172.26.203.0/24 via 192.168.122.1 dev eth0
EOF
```

This step takes the same example, and essentially achieves the same result, as the procedure in [Adding a static route on a virtual machine](#).

3. Make the script executable by running the following command:

```
chmod +x /usr/local/bin/appliance-boot-commands.sh
```

4. Create the following systemd service file `/lib/systemd/system/appliance-boot-commands.service`:

```
cat << EOF > /lib/systemd/system/appliance-boot-commands.service
[Unit]
After=network-online.target

[Service]
Type=oneshot
ExecStart=/usr/local/bin/appliance-boot-commands.sh
RemainAfterExit=false
StandardOutput=journal

[Install]
WantedBy=multi-user.target
EOF
```

5. Enable the systemd service by running the following command:

```
systemctl enable appliance-boot-commands
```

Upon subsequent boots, the `/usr/local/bin/appliance-boot-command.sh` script will be executed.

Changing deployment profiles on VMware

You can change an API Connect installation to use a different deployment profile.

For information on the available deployment profiles, see [Planning your deployment topology and profiles](#). The steps for changing deployment profile after installation depend on whether you want to change to a profile that has a different number of VMs and whether additional CPU and memory resources are required for the profile you move to.

Note: The procedures to change deployment profile that are described in this topic do not permit the endpoints to be changed. The API Connect endpoints are listed here: [Deployment overview for endpoints](#). If you want to change a one replica deployment to a three replica deployment, and you used your VM hostnames in your endpoints, then you must configure load-balancers and logical DNS records so that your original VM hostnames route to your new VMs. Alternatively, you can change endpoints by following the form factor migration procedure: [Migrating from v10 to v10 on a different form factor](#).

Moving to a profile that has the same number of VMs

If you are moving to a profile that requires greater CPU and memory resources, follow these steps:

1. Complete the disaster recovery preparation steps for your subsystems: [Preparing for a disaster](#).
2. Shutdown your API Connect VMs.
3. Update the CPU and memory resources for your API Connect VMs in your VMware console, as required for your new profile.
4. Restart your VMs.
5. In your project directory, update your deployment profile:

```
apicup subsys set <subsystem_name> deployment-profile=<new profile>
```

6. Apply the new profile:

```
apicup subsys install <subsystem_name>
```

If you are moving to a profile that requires lower CPU and memory resources, follow these steps:

1. Complete the disaster recovery preparation steps for your subsystems: [Preparing for a disaster](#).
2. In your project directory, update your deployment profile:

```
apicup subsys set <subsystem_name> deployment-profile=<new profile>
```

3. Apply the new profile:

```
apicup subsys install <subsystem_name>
```

4. Shutdown your API Connect VMs.
5. Update the CPU and memory resources for your API Connect VMs in your VMware console, as required for your new profile.
6. Restart your VMs.

If for any reason you are not able to change the CPU or memory on your VMs, redeploy them following the disaster recovery process: [Recovering from a disaster](#).

Moving from a one replica to a three replica deployment profile

1. Complete the disaster recovery preparation steps for your subsystems: [Preparing for a disaster](#).
Note: You do not need to take VMware snapshots, since your existing VMs are deleted and replaced when you change deployment profile.
2. In your project directory, update your deployment profile:

```
apicup subsys set <subsystem_name> deployment-profile=<three replica profile>
```

3. Define the hostname and network interfaces for the two new VMs in each of your subsystems. Use the `apicup hosts create` and `apicup iface create` commands. For more information, see the hosts and interface create steps in the installation instructions for each subsystem:
 - [Configuring the Management subsystem](#).
 - [Configuring the Analytics subsystem](#).
 - [Configuring the Developer Portal subsystem](#).
4. Shutdown your existing API Connect VMs.
Note: To minimize downtime, you can delay shutting down your existing deployment until you are about to deploy their replacement VMs in the next step.
5. Follow the disaster recovery steps for each subsystem: [Recovering from a disaster](#), but note that you must create new ISO files. Do not attempt to reuse the previous ISO file for one of the VMs in your new three replica deployment.

Moving from a three replica to a one replica deployment profile

1. Complete the disaster recovery preparation steps for your subsystems: [Preparing for a disaster](#).
Note: You do not need to take VMware snapshots, since your existing VMs are deleted and replaced when you change deployment profile.
2. In your project directory, update your deployment profile:

```
apicup subsys set <subsystem_name> deployment-profile=<one replica profile>
```

3. Delete two of your three VMs from your configuration with the `apicup hosts delete` command.
4. Shutdown your existing API Connect VMs.
Note: To minimize downtime, you can delay shutting down your existing deployment until you are about to deploy their replacement VMs in the next step.
5. Follow the disaster recovery steps for each subsystem: [Recovering from a disaster](#), but note that you must create new ISO files. Do not attempt to reuse any previous ISO files for your new one replica deployment.

Changing the DNS server configuration on appliances

Complete this task only if you must change the DNS addresses after the initial boot of the VM.

Before you begin

Verify that you have VMware console access to the VM, as well as the correct password. If you cannot `ssh` into the appliance, you can use the VMware console interactive login instead (use the `apicadm` login and the password configured as `default-password` in the `apicup` project).

About this task

This task is only valid for making changes to DNS resolution. The IP address of the VM cannot be changed at any time after the initial boot.

Procedure

1. Edit the `/etc/netplan/50-cloud-init.yaml` file and update the list of nameserver addresses.
Attention: Typically, you do not edit this file manually. You should only make direct changes to the `/etc/netplan/50-cloud-init.yaml` file when you need to update the nameserver addresses.
The following example shows what the list of nameserver addresses looks like in the file:

```
network:
  ethernets:
    eth0:
      addresses:
        - 192.168.122.242/24
      nameservers:
        addresses:
          - 1.1.1.1
          - 1.0.0.1
          - 8.8.8.8
        search:
          - nip.io
      routes:
        - metric: 10
          to: 0.0.0.0/0
          via: 192.168.122.1
  version: 2
```

2. Run the following command to apply the changes:

```
sudo netplan apply
```

3. Run the following command to verify the changes:

```
cat /run/systemd/resolve/resolv.conf
```

4. Attach an updated ISO to the VM to ensure all artifacts are up-to-date in case a disaster recovery is needed.
 - a. Update the **apicup** project configuration with the correct DNS values.
 - b. Generate a new ISO based on the updated project.
 - c. Attach the new ISO to the VM.

Configuring API Connect subsystems in a cluster

This topic describes how to configure a cluster of API Connect subsystems (management server, analytics, and Developer Portal) with three VMs for each subsystem, for use with a load balancer, to support a high availability (HA) environment.

Before you begin

To create a cluster of hosts for each API Connect subsystem, use **apicup** to create a subsystem with all the required parameters, and to add as many hosts as needed to the configuration file. The configuration file is a .yml file in the project directory.

For each host of a subsystem added in the .yml file, a separate ISO file is created for the cluster member VM. Note that the ISO files for each VM must stay attached during the whole lifetime of the VM.

In an API Connect cluster in a VMware environment, the first three nodes are master nodes. Additional nodes are worker nodes.

Note: To add a new host to an existing cluster, you can create the host, regenerate the ISO and attach it to the new virtual machine, and it will automatically join the cluster.

To use these instructions, you should first review:

- [Requirements for initial deployment on VMware](#)
- [Load balancer configuration in a VMware deployment](#)
- [Deployment overview for endpoints](#)
- [Firewall requirements on VMware](#)
- [Firewall enabled ports for clustered OVA deployments](#)
- Important: For best performance it is recommended that the network latency between any 2 nodes be as low as possible. Do not configure nodes from the same subsystem cluster across multiple data centers with a high latency network. A high latency network is one that experiences more than 30ms latency between nodes.

About this task

This page presents a concise step-by-step flow, with sample commands, for the configuration of each subsystem. As you step through the flow, you might want to refer back to the detailed configuration steps for each subsystem. The detailed instructions provide additional considerations for each step, and include optional configuration tasks for backups, logging, message queues (analytics), and password hashing. Each of the subsystem pages describe how to use the VMware console to deploy the ISOs that you create here.

Detailed configuration steps:

- [Deploying the Management virtual appliance](#)
- [Deploying the Analytics subsystem](#)
- [Deploying the Developer Portal virtual appliance](#)

The example commands uses the following values for DNS server, internet gateway, host names and IP addresses:

Component	Host names and IP addresses
DNS Name Server	IP: 192.168.1.1
Internet gateway	IP: 192.168.1.2
Manager on VM1	Hostname: manager1.sample.example.com IP: 192.168.1.101
Manager on VM2	Hostname: manager2.sample.example.com IP: 192.168.1.102
Manager on VM3	Hostname: manager3.sample.example.com IP: 192.168.1.103
Analytics on VM4	Hostname: analytics1.sample.example.com IP: 192.168.1.104
Analytics on VM5	Hostname: analytics2.sample.example.com IP: 192.168.1.105
Analytics on VM6	Hostname: analytics3.sample.example.com IP: 192.168.1.106
Developer Portal on VM7	Hostname: portal1.sample.example.com IP: 192.168.1.107
Developer Portal on VM8	Hostname: portal2.sample.example.com IP: 192.168.1.108
Developer Portal on VM9	Hostname: portal3.sample.example.com IP: 192.168.1.109

Procedure

1. Create the Management subsystems
 - a. Create the Management subsystem.

```
apicup subsys create mgmt management
```

- b. Set deployment-profile to `n3xc4.m16`.

```
apicup subsys set mgmt deployment-profile=n3xc4.m16
```

If you omit this step, the deployment-profile defaults to `n1xc4.16`, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

- c. Specify the license version you purchased.

```
apicup subsys set mgmt
license-use=<license_type>
```

The `license_type` must be either `production` or `nonproduction`. If not specified, the default value is `nonproduction`.

- d. Set management endpoints

Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following values point to a sample load balancer URL.

Component	Command
Management REST API URL	<code>apicup subsys set mgmt platform-api platform-api.sample.example.com</code>
Consumer (Portal) REST API URL	<code>apicup subsys set mgmt consumer-api consumer-api.sample.example.com</code>
Cloud Manager UI	<code>apicup subsys set mgmt cloud-admin-ui cloud-admin-ui.sample.example.com</code>
API Manager UI	<code>apicup subsys set mgmt api-manager-ui api-manager-ui.sample.example.com</code>

- e. Set the search domain for the VM.

```
apicup subsys set mgmt search-domain sample.example.com
```

- f. Set the DNS Name Server for the VM to look up endpoints.

```
apicup subsys set mgmt dns-servers 192.168.1.1
```

- g. Set a Public Keyfile.

This is the public key of the user account that you want to use to `ssh` from, to the appliance.

```
apicup subsys set mgmt ssh-keyfiles "id_rsa.pub"
```

- h. Create the hosts for the subsystem.

You must specify a password to use to encrypt the disks that the appliance uses. Replace the example password in the previous example with a strong password that meets your security requirements.

```
apicup hosts create mgmt manager1.sample.example.com password123
apicup hosts create mgmt manager2.sample.example.com password123
apicup hosts create mgmt manager3.sample.example.com password123
```

- i. Set the network interface. Note that the last parameter is the Internet Gateway.

```
apicup iface create mgmt manager1.sample.example.com eth0 192.168.1.101/255.255.255.0 192.168.1.2
apicup iface create mgmt manager2.sample.example.com eth0 192.168.1.102/255.255.255.0 192.168.1.2
apicup iface create mgmt manager3.sample.example.com eth0 192.168.1.103/255.255.255.0 192.168.1.2
```

- j. Set the network traffic interfaces.

```
apicup subsys set mgmt traffic-iface eth0
apicup subsys set mgmt public-iface eth0
```

- k. Verify the host configuration.

```
apicup hosts list mgmt
```

Note: This command might return the following messages, which you can ignore:

```
* host is missing traffic interface
* host is missing public interface
```

- l. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use `apicup` to set the hashed password for your subsystem:

```
apicup subsys set mgmt default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiU.8ctr0'
```

Important: Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).

- m. Validate the installation.

```
apicup subsys get mgmt --validate
```

- n. Create an ISO file in a plan folder. For example, `mgmtplan-out`.

```
apicup subsys install mgmt --out mgmtplan-out
```

If you have multiple nodes listed for the hosts, when you run the `--out` command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

- o. To deploy the management ISOs on VMware, see [Deploying the Management subsystem OVA file](#).

2. Create the analytics subsystems

- a. Create the subsystem:

```
apicup subsys create analyt analytics
```

- b. Set deployment-profile to `n3xc4.m16`.

```
apicup subsys set analyt deployment-profile=n3xc4.m16
```

If you omit this step, the deployment-profile defaults to `n1xc2.16`, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

- c. Specify the license version you purchased.

```
apicup subsys set analyt
license-use=<license_type>
```

The `license_type` must be either `production` or `nonproduction`. If not specified, the default value is `nonproduction`.

- d. Set analytics ingestion endpoint

Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following value points to a sample load balancer URL.

Component	Command
analytics-ingestion	<code>apicup subsys set analyt analytics-ingestion=analytics-ingestion.sample.example.com</code>

- e. Set the search domain for the VM.

```
apicup subsys set analyt search-domain sample.example.com
```

- f. Set the DNS Name server for the VM to look up endpoints.

```
apicup subsys set analyt dns-servers 192.168.1.1
```

- g. Set a Public Keyfile.

This is the public key of the user account that you want to use to `ssh` from, to the appliance

```
apicup subsys set analyt ssh-keyfiles "id_rsa.pub"
```

- h. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use `apicup` to set the hashed password for your subsystem:

```
apicup subsys set analyt default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
```

Important: Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).

- i. Create the hosts for the subsystem. You must specify a password to use to encrypt the disks that the appliance uses. Replace the example password in the following password with a strong password that meets your security requirements.

```
apicup hosts create analyt analytics1.sample.example.com password123
apicup hosts create analyt analytics2.sample.example.com password123
apicup hosts create analyt analytics3.sample.example.com password123
```

- j. Set the network interface.

Note that the last parameter is the Internet Gateway.

```
apicup iface create analyt analytics1.sample.example.com eth0 192.168.1.104/255.255.255.0 192.168.1.2
apicup iface create analyt analytics2.sample.example.com eth0 192.168.1.105/255.255.255.0 192.168.1.2
apicup iface create analyt analytics3.sample.example.com eth0 192.168.1.106/255.255.255.0 192.168.1.2
```

- k. Check the host configuration for problems.

```
apicup hosts list analyt
```

- l. Validate the installation.

```
apicup subsys get analyt --validate
```

- m. Create an ISO file in a plan folder. For example, `analytplan-out`.

```
apicup subsys install analyt --out analytplan-out
```

If you have multiple nodes listed for the hosts, when you run the `--out` command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

- n. To deploy the ISOs, see [Deploying the Analytics subsystem OVA file](#).

3. Create the portal subsystems

- a. Create the portal.

```
apicup subsys create port portal
```

- b. For three replica environments, set deployment-profile to `n3xc4.m8`.

```
apicup subsys set port deployment-profile=n3xc4.m8
```

If you omit this step, the deployment-profile defaults to `n1xc4.m8`, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

- c. Specify the license version you purchased.

```
apicup subsys set port
license-use=<license_type>
```

The `license_type` must be either `production` or `nonproduction`. If not specified, the default value is `nonproduction`.

- d. Set the portal endpoints.

Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following values point to a sample load balancer URL.

Component	Command
portal-admin	<code>apicup subsys set port portal-admin=portal-admin.sample.example.com</code>
portal-www	<code>apicup subsys set port portal-www=portal-www.sample.example.com</code>

- e. Set the search domain for the VM.

```
apicup subsys set port search-domain sample.example.com
```

- f. Set the DNS Name server for the VM to look up endpoints.

```
apicup subsys set port dns-servers 192.168.1.1
```

- g. Set a Public Keyfile.

This is the public key of the user account that you want to use to **ssh** from, to the appliance

```
apicup subsys set port ssh-keyfiles "id_rsa.pub"
```

- h. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use **apicup** to set the hashed password for your subsystem:

```
apicup subsys set port default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
```

Important: Review the requirements for creating and using a hashed password. See [Setting and using a hashed default password](#).

- i. Create the hosts for the subsystem. You must specify a password to use to encrypt the disks that the appliance uses.

```
apicup hosts create port portal1.sample.example.com password123
apicup hosts create port portal2.sample.example.com password123
apicup hosts create port portal3.sample.example.com password123
```

Replace the example password in the previous example with a strong password that meets your security requirements.

- j. Set the network interface.

Note that the last parameter is the Internet Gateway.

```
apicup iface create port portal1.sample.example.com eth0 192.168.1.107/255.255.255.0 192.168.1.2
apicup iface create port portal2.sample.example.com eth0 192.168.1.108/255.255.255.0 192.168.1.2
apicup iface create port portal3.sample.example.com eth0 192.168.1.109/255.255.255.0 192.168.1.2
```

- k. Check the host configuration for problems.

```
apicup hosts list port
```

- l. Validate the installation.

```
apicup subsys get port --validate
```

- m. Create an ISO file in a plan folder. For example, **portplan-out**.

```
apicup subsys install port --out portplan-out
```

If you have multiple nodes listed for the hosts, when you run the **--out** command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

- n. To deploy the ISOs, see [Deploying the Developer Portal subsystem OVA file](#).

Configuring SSHD to limit access to your deployment

How to configure SSHD in order to limit host access to your VMware deployment, or to change the SSHD cipher level.

About this task

The following instructions show how to configure SSHD in order to limit VMware access to a certain set of IP addresses, and how to change the SSHD cipher level.

Attention:

- SSHD configuration settings are not included in the IBM® API Connect backups. However, the settings are kept when you upgrade to a new fix pack.
- If you change the SSHD cipher level, and encounter issues with the new configuration, you must revert your cipher changes and retest. If after the retest with the original cipher level that came with IBM API Connect you still have issues, contact IBM Support.

Procedure

- The following instructions show you how to configure SSHD in order to limit VMware access to a certain set of IP addresses.
 1. Log in to the target virtual machine by using an SSH tool, and switch to the root user. For example, to log in to the Management subsystem, run the following commands:

```
ssh ip_address -l apicadm
sudo -i
```

2. Move to the following folder:

```
/etc/ssh/sshd_config.d
```

3. Create a new configuration file with the extension **.conf** that contains the IP address of the host that you want to allow to access your deployment. For example, to create the file run the following command:

```
vi filename.conf
```

Then, edit the file by using the following format, which in this example is allowing users from IP address **123.135.1.2**:

```
AllowUsers *@123.135.1.2
```

Additional hosts can be added by separating the IP address patterns with a space. For example:

```
AllowUsers *@123.135.1.2 *@135.168.1.2
```

- Restart the SSHD service by running the following command:

```
systemctl restart sshd.service
```

- The following instructions show you how to configure SSHD to change the cipher level.
 - Log in to the target virtual machine by using an SSH tool, and switch to the root user. For example, to log in to the Management subsystem, run the following commands:

```
ssh ip_address -l apicadm  
sudo -i
```

- Move to the following folder:

```
/etc/ssh/sshd_config.d
```

- Create a new configuration file with the extension .conf that contains the list of ciphers that you want to support. For example, if you want to remove the 128 bit UMAC cipher from the following list of currently supported ciphers:

```
MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,umac-128-etm@openssh.com,hmac-sha2-512,hmac-sha2-256,umac-128@openssh.com
```

Create the .conf file by running the following command:

```
vi filename.conf
```

Then, remove that cipher from the list by adding the following line to the file:

```
MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,hmac-sha2-512,hmac-sha2-256
```

- Restart the SSHD service by running the following command:

```
systemctl restart sshd.service
```

Results

Your SSHD configuration is updated to limit access to your VMware to a certain set of IP addresses, or to change the cipher level.

Enabling Developer Portal feature flags on VMware

Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.

About this task

You can add a template override to the Developer Portal subsystem CR to change the default behavior of the Portal subsystem, or to turn specific features on and off. Table 1 describes the available feature flags.

Table 1. List of available feature flags for the Developer Portal

Feature flag name	Default value	Pod	Container	Description
DISABLE_MEMCACHE	false	www	admin	Controls whether the distributed in-memory cache is disabled. From IBM® API Connect 10.0.5.6 Portal web sites use a distributed in-memory cache by default, instead of using cache tables in the main site database. This update provides better performance for web site operations, but does mean that the cache needs to be repopulated when any of the Portal pods or virtual machines are restarted, for example, during an upgrade. While the cache is being repopulated, there is a reduction in performance. You can set the DISABLE_MEMCACHE flag to true to disable the distributed in-memory cache for all Portal sites, both existing and new.

Feature flag name	Default value	Pod	Container	Description
<code>ENABLE_TRUSTED_REVERSE_PROXY</code>	false	www	admin	<p>Controls whether the Drupal <code>trusted_reverse_proxy</code> module can manage the reverse proxies list.</p> <p>If you have multiple load balancers and reverse proxies in your upstream network, and the perimeter module is triggered, the incorrect IP address might be banned rather than the intended client IP address. However, you can manage which IP addresses are banned by using the Drupal <code>trusted_reverse_proxy</code> module, and setting this feature flag to <code>true</code>.</p> <p>The Drupal module inspects the <code>x-forwarded-for</code> headers to identify the reverse proxies, and trusts that the first IP address found in the list is the client IP. For example, in <code>X-Forwarded-For: <client>, <proxy1>, <proxy2></code>, the client IP <code><client></code> will be banned. For more information about this module, see https://www.drupal.org/project/trusted_reverse_proxy.</p> <p>To use this module, you must ensure that all of the proxies in your upstream network, including the ingress controller, are configured correctly so that the <code>x-forwarded-for</code> header is passed through to the <code>portal-www</code> pod. For example, the default behavior of the <code>nginx-ingress-controller</code> is to ignore the inbound <code>x-forwarded-for</code> header, and create a new one. To change this behavior, update the <code>nginx-ingress-controller configmap</code> with the following information:</p> <pre>data: compute-full-forwarded-for: "true" use-forwarded-headers: "true"</pre> <p>Warning: Enable this feature flag only if you trust your upstream reverse proxies, as it is possible to trick the <code>x-forwarded-for</code> header.</p>
<code>MEMCACHE_MEMORY_LIMIT</code>	"128" or "256"	www	admin	<p>Controls the amount of memory that the distributed in-memory cache can use, before space is freed up by removing the least used entries.</p> <p>The default memory limit value depends on your deployment profile, for example:</p> <ul style="list-style-type: none"> 8 GB profiles have 128 MB per <code>portal-www</code> pod. 16 GB profiles have 256 MB per <code>portal-www</code> pod. <p>If you think that performance is consistently worse when using the in-memory cache, you can either disable it by using the <code>DISABLE_MEMCACHE</code> setting, or change the memory limit by setting a specific <code>MEMCACHE_MEMORY_LIMIT</code> value. Note that the value is always in MB, and is always set as a number enclosed in quotes, for example "512".</p> <p>Note:</p> <ul style="list-style-type: none"> The cache is distributed across the pods, so an n1 8 GB profile has only 128 MB of in-memory cache storage, but an n3 8 GB profile has 3 x 128 MB of in-memory cache storage. An empty site consumes about 3 MB of the memory cache. A site with around 6000 objects (spread across APIs, Products, Apps, Consumer Organizations, and so on) can consume about 87 MB of in-memory cache when every object is cached. However, this consumption is not usually the case unless every single page in your site is accessed. You don't need to be able to fit the entire cache of every single site into memory, as the less often used cache entries will be evicted, and their space reused for new cache entries.
<code>PORTAL_SKIP_WEB_ENDPOINT_VALIDATION</code>	false	www	admin	<p>Controls whether the Portal subsystem checks whether the Portal web endpoint is accessible.</p> <p>Sometimes, the endpoint cannot be reached, for example due to the complexity of the networks. In which case the following type of error can be seen in the <code>portal-www</code> pod, and <code>admin</code> container logs:</p> <pre>An error occurred contacting the provided portal web endpoint: example.com The provided Portal web endpoint example.com returned HTTP status code 504</pre> <p>You can disable the check by setting this flag to <code>true</code>.</p>

Procedure

1. Create an `extra-values.yaml` file, or open an existing `extra-values.yaml` file.
2. In the file, append the feature flag definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file. The following example enables the `trusted_reverse_proxy` feature on all possible UI pages.

```
spec:
  template:
    - containers:
      - env:
        - name: ENABLE_TRUSTED_REVERSE_PROXY
          value: "true"
        name: container
      name: pod
```

Where:

- `container` is the name of the portal container.

- `pod` is the name of the portal pod.

Note: You can add multiple feature flags to the file.

3. Save the file.

4. Run the following command to set the `extra-values.yaml` file:

```
apicup subsys set <portal_subsystem> extra-values-file <path_to_portal_extra-values.yaml_file>
```

5. Apply the overrides to the portal subsystem by running the following command:

```
apicup subsys install <SUBSYSTEM_NAME>
```

The Developer Portal subsystem is updated to enable or disable features as specified.

Managing an appliance data disk

You can use `apic` commands to manage appliance data disks in your VMware deployment.

The API Connect deployment on VMware uses 2 partitions. The first contains the base operating system, while the second is encrypted so that any customer data that is stored on disk uses the encrypted volume. Encryption is done with Linux Unified Key Setup (LUKS) disk encryption.

During installation of each API Connect subsystem, you specify a password `HD-PASSWD` when configuring the host:

```
apicup hosts create <SUBSYS> <HOSTNAME> <HD-PASSWD>
```

If you want to force a restart of processes, without requiring a full restart of the virtual machine, you can use the command `apic lock` to stop the Kubernetes node on the virtual machine and lock the secured storage. When you are ready to restart processes, you can use `apic unlock` to restart the Kubernetes node. The command `apic unlock` uses the password to unlock the partition so that files can be read from it and written to it. The unlock command also starts the `apic` daemon, also known as the `appliance-manager` service.

You can check that status of this service with:

```
sudo systemctl status appliance-manager
```

One `appliance-manager` daemon runs on each node, where it manages the Kubernetes cluster, processes update and upgrade requests, and gathers logs.

apic command	Description
<code>lock</code>	Shut down appliance services and lock the secured storage
<code>logs</code>	Retrieve logs from all nodes in the cluster
<code>status</code>	Report on cluster status
<code>unlock</code>	Unlock the secure storage and start the appliance
<code>version</code>	Get the API Connect appliance base version

Replica override for microservices on VMware

Modify the replica count for microservices by using template overrides for Custom Resources.

When API Connect is deployed, the deployment profile you select drives the number of replicas to be used for most deployment. For one replica profiles, specified by `n1x` . . . , the replica count is 1. For three replica profiles, specified by `n3x` . . . , the replica count is 3.

You can override the replica count for individual deployments by using template overrides.

- Template overrides are a piece of yaml that should be added to the Kubernetes custom resource. The examples provided in this topic show only that the `template:` element should be under the main `spec:` element of a CR. The rest of the CR is not shown.
- When applying overrides for Appliance deployments (virtual machines), the yaml sample provided as example must be added in an `extra-values-file` for the subsystem. To view an example of documenting a template override for an Appliance, see [Setting rate limits for public APIs on the management service](#)

Management subsystem

For a Management CR in Kubernetes or OpenShift, the following override specifies 5 replicas for the `apim` deployment:

```
spec:
  template:
    - name: apim
      replicaCount: 5
```

You can also configure replicate count through a similar template override for:

- `juhu`
- `ldap`
- `lur`

Analytics subsystem

The Analytics microservices that can be scaled using template override are:

- `ingestion`
- `mtls-gw`

- **storage-shared**

Note that this microservice cannot be scaled below 2 replicas when using a three replica deployment profile.

Testing a new configuration against a current cluster

You can use the **apicup** utility to test the validity of a new configuration before you install it.

The **apicup** utility is used to set configuration properties for subsystems on API Connect on VMware appliances. The utility can be used for installation, upgrade, and maintenance activities such as backup and restore.

The usage pattern is to set values for each parameter you need for a subsystem, and then deploy the new values with the **apicup subsys install** command.

You can use the **--dry-run** option to test the validity of your values prior to deploying them to an existing cluster:

```
apicup subsys install <subsystem_name> --dry-run
```

Important: You cannot use **apicup subsys install <SUBSYS> --dry-run** for a fresh install or an upgrade. The **--dry-run** feature is for testing proposed configuration changes on an existing cluster.

For example, if you want to configure S3 backups for you management subsystem, the command flow is:

1. Follow the instructions for configuring S3 backups [Reconfiguring backup settings for the management subsystem](#) by issuing the required **apicup subsys set** commands:

```
apicup subsys set mgmt <setting>=<value>
apicup subsys set mgmt <second_setting>=<value>
apicup subsys set mgmt <third_setting>=<value>
.
.
```

2. Do a dry run of the install command:

```
apicup subsys install mgmt --dry-run
```

Example message on success:

```
managementcluster.management.apiconnect.ibm.com/management configured (server dry run)
```

Example message on failure:

```
Error: Failed to execute dry-run:....
```

The error message also contains details about the error.

3. When dry run returns success, deploy:

```
apicup subsys install mgmt
```

TLS certificate concepts and operations

Information about internal API Connect certificates, renewing expired certificates, exporting certificates, and other certificate maintenance operations.

This topic covers advanced certificate configuration procedures that are not required in day-to-day API Connect operations. For best practices relating to API Connect certificates, see [API Connect TLS certificate best practices](#).

API Connect certificate types

All TLS certificates that are generated and used by API Connect fall into one of the following categories:

- CA certificates - API Connect creates self-signed CA certificates to sign all the API Connect end-entity certificates. The CA certificates are:
 - **ingress-ca** - used by the ingress-issuer. The ingress-ca signs all user-facing and inter-subsystem certificates.
 - **root-ca** - a self-signed root certificate that signs the **ingress-ca** certificate.
 - **management-ca** - signs all the management intra-subsystem certificates.
 - **portal-ca** - signs all the portal intra-subsystem certificates.
 - **analytics-ca** - signs all the analytics intra-subsystem certificates.CA certificates have a default duration of 10 years.
Do not customize CA certificates. The only scenarios when CA certificates require updating are:
 - Expiry, after 10 years.
 - Synchronizing the **ingress-ca** certificate between data centers in multiple data center deployments.
- Ingress certificates - Ingress certificates are end-entity certificates that are signed by the **ingress-ca** certificate and secure the API Connect endpoints. Ingress certificates are divided into two types:
 - Inter-subsystem certificates - certificates that are used to secure the communication between API Connect subsystems, for example between the management subsystem and gateway. By default, communication between most subsystems uses mTLS. It is possible to use JWT instead of mTLS: [Using JWT instead of mTLS on OVA](#).
Do not customize inter-subsystem certificates.
 - User-facing certificates - certificates that API Connect users see when they interact with the API Connect UIs and REST API.
You can customize your user-facing certificates: [Customizing your user-facing certificates](#)

All the ingress certificates have a duration of 2 years.

- Intra-subsystem certificates - certificates that are used between software components in the same subsystem. Intra-subsystem certificates are signed by a subsystem specific CA certificate: **management-ca**, **portal-ca**, **analytics-ca**. The gateway subsystem is a single pod, and has no intra-subsystem certificates. Do not customize intra-subsystem certificates.

Note: The inter and intra-subsystem certificates use of a self-signed root CA presents no security risk. For internal communications with a limited number of predefined endpoints, use of locally generated self-signed CA certificates can be more secure than external CA certificates, as certificates are only ever issued for the known components and the domain of trust is kept as small as possible.

- [Certificate validation reference](#)
Certificates validation errors reference table.

Certificate reference VMware

Details of all API Connect TLS certificates on VMware.

The **apicup certs list** command returns all the API Connect TLS certificates that can be configured with the **apicup** command.

Note: The **apicup certs list** command also returns credentials and encryption secrets that are used by API Connect. For information about these secrets and credentials, see [Credentials and encryption secrets reference](#).

Common certificates

Common certificates exist in all subsystems of an API Connect deployment, and must be identical in each subsystem to enable them to communicate with each other.

Because you deploy your API Connect subsystems from a single project directory, these certificates are automatically set to be the same on all subsystems.

Do not customize any of the common certificates.

Table 1. Common certificates

Certificate name	Description
root-ca	CA certificate that is the root of the certificate chain for all other API Connect certificates. Do not update this certificate.
ingress-ca	Intermediate CA certificate used to generate all API Connect ingress certificates . Do not customize this certificate. If the certificate expires (duration is 10 years), see: Renewing ingress-ca . If you have multiple data centers that are managed from different project directories, you can synchronize this certificate, see: Synchronizing the ingress-ca certificate .
appliance-client	A client certificate that is used by the apicup command to communicate with the API Connect subsystem appliances. Requires EKU clientAuth . Do not update this certificate.
k8s-ca	CA certificate that forms the root of the certificate chain for the Kubernetes cluster components that run in the API Connect subsystem appliance. Do not update this certificate.

Management certificates

The following table lists the certificates that exist on the management subsystem, in addition to the [common certificates](#).

Table 2. Management subsystem certificates

Certificate name	Description
portal-client	The portal-client certificate is an inter-subsystem ingress certificate that is presented to the developer portal subsystem during portal service registration. For successful portal registration the portal-client certificate must meet these requirements: <ul style="list-style-type: none"> • Specify EKU clientAuth. • Signed by the same CA (ingress-ca) as the portal-admin-ingress certificate that secures the admin endpoint on the developer portal. • The subject name must match the adminClientSubjectDN in the portal subsystem. If you have a multiple data center deployment, both data centers must use an identical subject name. Do not update this certificate.
analytics-client-client	A legacy certificate, it is not used from v10.0.5 onwards.

Certificate name	Description
analytics-ingestion-client	<p>The analytics-ingestion-client certificate is an inter-subsystem ingress certificate that is presented to the analytics subsystem during analytics service registration.</p> <p>For successful analytics registration the analytics-ingestion-client certificate must meet these requirements:</p> <ul style="list-style-type: none"> Specify EKU clientAuth. Signed by the same CA (ingress-ca) as the analytics-ingestion-ingress certificate that secures the ingestion endpoint on the analytics subsystem. The subject name must match the clientSubjectDN in the analytics subsystem. <p>analytics-ingestion-client is also used by the gateway subsystem to authenticate with the analytics ingestion endpoint, for the transmission of API event data.</p> <p>For multiple data center deployments, both data centers must have an identical subject name.</p> <p>Do not update this certificate.</p>
platform-api	<p>The platform-api certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at cloud scope.</p> <p>The endpoint in the management subsystem configuration uses the same name: platform-api</p> <p>The hostnames for which the certificate is valid must include the platform-api endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <i>store.acme.com</i>, the certificate can be one that is valid for hostnames that match <i>*.acme.com</i>.</p> <p>Requires EKU serverAuth.</p>
consumer-api	<p>The consumer-api certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at organization scope.</p> <p>The endpoint in the management subsystem configuration uses the same name: consumer-api</p> <p>The hostnames for which the certificate is valid must include the consumer-api endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <i>store.acme.com</i>, the certificate can be one that is valid for hostnames that match <i>*.acme.com</i>.</p> <p>Requires EKU serverAuth.</p>
api-manager-ui	<p>The api-manager-ui certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Manager UI.</p> <p>The endpoint in the management subsystem configuration uses the same name: api-manager-ui.</p> <p>The hostnames for which the certificate is valid must include the api-manager-ui endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <i>store.acme.com</i>, the certificate can be one that is valid for hostnames that match <i>*.acme.com</i>.</p> <p>Requires EKU serverAuth.</p>
cloud-admin-ui	<p>The cloud-admin-ui certificate is a user-facing ingress certificate that is returned to users when they attempt to access the Cloud Manager UI.</p> <p>The endpoint in the management subsystem configuration uses the same name: cloud-admin-ui.</p> <p>The hostnames for which the certificate is valid must include the cloud-admin-ui endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <i>store.acme.com</i>, the certificate can be one that is valid for hostnames that match <i>*.acme.com</i>.</p> <p>Requires EKU serverAuth.</p>
hub	Used by the Automated API behavior testing application. User-facing ingress certificate for the hub-endpoint .
turnstile	Used by the Automated API behavior testing application. User-facing ingress certificate for the turnstile-endpoint .
management-replication-client	<p>Used in 2DCDR deployments only.</p> <p>The management-replication-client certificate is an inter-subsystem ingress client certificate that is used when connecting to the management-replication endpoint in the other data center.</p> <p>Requires EKU clientAuth.</p>
management-replication-ingress	<p>Used in 2DCDR deployments only.</p> <p>The management-replication-ingress certificate is an inter-subsystem ingress server certificate that is used to secure the management-replication endpoint.</p> <p>management-replication-ingress must be valid for the endpoint defined by</p> <pre>apicup subsys set <subsystem> management-replication=<endpoint></pre> <p>Requires EKU serverAuth.</p>

Portal subsystem certificates

The following table lists the certificates that exist on the management subsystem, in addition to the [common certificates](#).

Table 3. Portal subsystem certificates

Certificate name	Description
------------------	-------------

Certificate name	Description
<code>mgmt-consumer-api</code>	<p>The <code>mgmt-consumer-api</code> certificate is an inter-subsystem ingress certificate that secures the consumer API endpoint on the management subsystem. The portal has a copy of this certificate so it can verify that it is communicating with the management subsystem.</p> <p>This certificate must be identical to the <code>consumer-api</code> certificate in the management subsystem.</p> <p>Do not update this certificate.</p>
<code>mgmt-platform-api</code>	<p>The <code>mgmt-platform-api</code> certificate is an inter-subsystem ingress certificate that secures the platform API endpoint on the management subsystem. The portal has a copy of this certificate so it can verify that it is communicating with the management subsystem.</p> <p>This certificate must be identical to the <code>platform-api</code> certificate in the management subsystem.</p> <p>Do not update this certificate.</p>
<code>portal-admin-ingress</code>	<p>The <code>portal-admin-ingress</code> certificate is an inter-subsystem ingress certificate that is used to secure the portal administration endpoint. The management subsystem communicates with this endpoint to register the portal and to send portal configuration updates.</p> <p>Do not update this certificate.</p>
<code>portal-replication-client</code>	<p>Used in 2DCDR deployments only.</p> <p>The <code>portal-replication-client</code> certificate is an inter-subsystem ingress client certificate that is used when connecting to the <code>portal-replication</code> endpoint in the other data center.</p> <p>Requires EKU <code>clientAuth</code>.</p>
<code>portal-replication-ingress</code>	<p>Used in 2DCDR deployments only.</p> <p>The <code>portal-replication-ingress</code> certificate is an inter-subsystem ingress server certificate that is used to secure the <code>portal-replication</code> endpoint.</p> <p><code>portal-replication-ingress</code> must be valid for the endpoint defined by</p> <pre>apicup subsys set <subsystem> portal-replication=<endpoint></pre> <p>Requires EKU <code>serverAuth</code>.</p>
<code>portal-wwv-ingress</code>	<p>The <code>portal-wwv-ingress</code> certificate is a user-facing ingress certificate that is returned to users when they attempt to access developer portal sites.</p> <p>The endpoint is called <code>portal-wwv</code> in the portal subsystem configuration.</p>

Analytics subsystem certificates

The following table lists the certificates that exist on the management subsystem, in addition to the [common certificates](#).

Table 4. Analytics subsystem certificates

Certificate name	Description
<code>analytics-ca</code>	<p>Internal certificate used for communication between analytics subsystem components.</p> <p>Do not update this certificate.</p>
<code>analytics-ingestion-ingress</code>	<p>The <code>analytics-ingestion-ingress</code> certificate is an inter-subsystem ingress certificate that is used to secure the analytics ingestion endpoint, which is used for the following:</p> <ul style="list-style-type: none"> Receiving API event data from associated gateways. Configuration and analytics queries from the management subsystem. <p>Do not update this certificate.</p>
<code>service-client</code>	<p>Internal certificate used for communication between analytics subsystem components.</p> <p>Do not update this certificate.</p>
<code>service-server</code>	<p>Internal certificate used for communication between analytics subsystem components.</p> <p>Do not update this certificate.</p>

Ingress certificates

The following table lists all the certificates across all subsystems that are signed by the `ingress-ca`. If you renew your `ingress-ca` certificate, then you must also renew all the ingress end-entity certificates that are listed in this table. For steps on renewing the `ingress-ca`, see [Renewing ingress-ca](#).

Table 5. Certificates signed by `ingress-ca`

Certificate name	Description
<code>portal-client</code>	<p>The <code>portal-client</code> certificate is an inter-subsystem ingress certificate that is presented to the developer portal subsystem during portal service registration.</p> <p>For successful portal registration the <code>portal-client</code> certificate must meet these requirements:</p> <ul style="list-style-type: none"> Specify EKU <code>clientAuth</code>. Signed by the same CA (<code>ingress-ca</code>) as the <code>portal-admin-ingress</code> certificate that secures the admin endpoint on the developer portal. The subject name must match the <code>adminClientSubjectDN</code> in the portal subsystem. <p>If you have a multiple data center deployment, both data centers must use an identical subject name.</p> <p>Do not update this certificate.</p>
<code>analytics-client-client</code>	<p>A legacy certificate, it is not used from v10.0.5 onwards.</p>

Certificate name	Description
analytics-ingestion-client	<p>The analytics-ingestion-client certificate is an inter-subsystem ingress certificate that is presented to the analytics subsystem during analytics service registration.</p> <p>For successful analytics registration the analytics-ingestion-client certificate must meet these requirements:</p> <ul style="list-style-type: none"> Specify EKU clientAuth. Signed by the same CA (ingress-ca) as the analytics-ingestion-ingress certificate that secures the ingestion endpoint on the analytics subsystem. The subject name must match the clientSubjectDN in the analytics subsystem. <p>analytics-ingestion-client is also used by the gateway subsystem to authenticate with the analytics ingestion endpoint, for the transmission of API event data.</p> <p>For multiple data center deployments, both data centers must have an identical subject name.</p> <p>Do not update this certificate.</p>
platform-api	<p>The platform-api certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at cloud scope.</p> <p>The endpoint in the management subsystem configuration uses the same name: platform-api</p> <p>The hostnames for which the certificate is valid must include the platform-api endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <i>store.acme.com</i>, the certificate can be one that is valid for hostnames that match <i>*.acme.com</i>.</p> <p>Requires EKU serverAuth.</p>
consumer-api	<p>The consumer-api certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at organization scope.</p> <p>The endpoint in the management subsystem configuration uses the same name: consumer-api</p> <p>The hostnames for which the certificate is valid must include the consumer-api endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <i>store.acme.com</i>, the certificate can be one that is valid for hostnames that match <i>*.acme.com</i>.</p> <p>Requires EKU serverAuth.</p>
api-manager-ui	<p>The api-manager-ui certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Manager UI.</p> <p>The endpoint in the management subsystem configuration uses the same name: api-manager-ui.</p> <p>The hostnames for which the certificate is valid must include the api-manager-ui endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <i>store.acme.com</i>, the certificate can be one that is valid for hostnames that match <i>*.acme.com</i>.</p> <p>Requires EKU serverAuth.</p>
cloud-admin-ui	<p>The cloud-admin-ui certificate is a user-facing ingress certificate that is returned to users when they attempt to access the Cloud Manager UI.</p> <p>The endpoint in the management subsystem configuration uses the same name: cloud-admin-ui.</p> <p>The hostnames for which the certificate is valid must include the cloud-admin-ui endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <i>store.acme.com</i>, the certificate can be one that is valid for hostnames that match <i>*.acme.com</i>.</p> <p>Requires EKU serverAuth.</p>
hub	Used by the Automated API behavior testing application. User-facing ingress certificate for the hub-endpoint .
turnstile	Used by the Automated API behavior testing application. User-facing ingress certificate for the turnstile-endpoint .
portal-admin-ingress	<p>The portal-admin-ingress certificate is an inter-subsystem ingress certificate that is used to secure the portal administration endpoint. The management subsystem communicates with this endpoint to register the portal and to send portal configuration updates.</p> <p>Do not update this certificate.</p>
portal-www-ingress	<p>The portal-www-ingress certificate is a user-facing ingress certificate that is returned to users when they attempt to access developer portal sites.</p> <p>The endpoint is called portal-www in the portal subsystem configuration.</p>
analytics-ingestion-ingress	<p>The analytics-ingestion-ingress certificate is an inter-subsystem ingress certificate that is used to secure the analytics ingestion endpoint, which is used for the following:</p> <ul style="list-style-type: none"> Receiving API event data from associated gateways. Configuration and analytics queries from the management subsystem. <p>Do not update this certificate.</p>
management-replication-client	<p>Used in 2DCDR deployments only.</p> <p>The management-replication-client certificate is an inter-subsystem ingress client certificate that is used when connecting to the management-replication endpoint in the other data center.</p> <p>Requires EKU clientAuth.</p>

Certificate name	Description
<code>management-replication-ingress</code>	Used in 2DCDR deployments only. The <code>management-replication-ingress</code> certificate is an inter-subsystem ingress server certificate that is used to secure the <code>management-replication</code> endpoint. <code>management-replication-ingress</code> must be valid for the endpoint defined by <code>apicup subsys set <subsystem> management-replication=<endpoint></code> Requires EKU <code>serverAuth</code> .
<code>mgmt-consumer-api</code>	The <code>mgmt-consumer-api</code> certificate is an inter-subsystem ingress certificate that secures the consumer API endpoint on the management subsystem. The portal has a copy of this certificate so it can verify that it is communicating with the management subsystem. This certificate must be identical to the <code>consumer-api</code> certificate in the management subsystem. Do not update this certificate.
<code>mgmt-platform-api</code>	The <code>mgmt-platform-api</code> certificate is an inter-subsystem ingress certificate that secures the platform API endpoint on the management subsystem. The portal has a copy of this certificate so it can verify that it is communicating with the management subsystem. This certificate must be identical to the <code>platform-api</code> certificate in the management subsystem. Do not update this certificate.
<code>portal-replication-client</code>	Used in 2DCDR deployments only. The <code>portal-replication-client</code> certificate is an inter-subsystem ingress client certificate that is used when connecting to the <code>portal-replication</code> endpoint in the other data center. Requires EKU <code>clientAuth</code> .
<code>portal-replication-ingress</code>	Used in 2DCDR deployments only. The <code>portal-replication-ingress</code> certificate is an inter-subsystem ingress server certificate that is used to secure the <code>portal-replication</code> endpoint. <code>portal-replication-ingress</code> must be valid for the endpoint defined by <code>apicup subsys set <subsystem> portal-replication=<endpoint></code> Requires EKU <code>serverAuth</code> .

User-facing certificates

The following table lists all the certificates that are used for user-facing endpoints.

Table 6. User-facing endpoint certificates.

Certificate name	Description
<code>portal-www-ingress</code>	The <code>portal-www-ingress</code> certificate is a user-facing ingress certificate that is returned to users when they attempt to access developer portal sites. The endpoint is called <code>portal-www</code> in the portal subsystem configuration.
<code>api-manager-ui</code>	The <code>api-manager-ui</code> certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Manager UI. The endpoint in the management subsystem configuration uses the same name: <code>api-manager-ui</code> . The hostnames for which the certificate is valid must include the <code>api-manager-ui</code> endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <code>store.acme.com</code> , the certificate can be one that is valid for hostnames that match <code>*acme.com</code> . Requires EKU <code>serverAuth</code> .
<code>cloud-admin-ui</code>	The <code>cloud-admin-ui</code> certificate is a user-facing ingress certificate that is returned to users when they attempt to access the Cloud Manager UI. The endpoint in the management subsystem configuration uses the same name: <code>cloud-admin-ui</code> . The hostnames for which the certificate is valid must include the <code>cloud-admin-ui</code> endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <code>store.acme.com</code> , the certificate can be one that is valid for hostnames that match <code>*acme.com</code> . Requires EKU <code>serverAuth</code> .
<code>consumer-api</code>	The <code>consumer-api</code> certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at organization scope. The endpoint in the management subsystem configuration uses the same name: <code>consumer-api</code> . The hostnames for which the certificate is valid must include the <code>consumer-api</code> endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <code>store.acme.com</code> , the certificate can be one that is valid for hostnames that match <code>*acme.com</code> . Requires EKU <code>serverAuth</code> .
<code>platform-api</code>	The <code>platform-api</code> certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at cloud scope. The endpoint in the management subsystem configuration uses the same name: <code>platform-api</code> . The hostnames for which the certificate is valid must include the <code>platform-api</code> endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: <code>store.acme.com</code> , the certificate can be one that is valid for hostnames that match <code>*acme.com</code> . Requires EKU <code>serverAuth</code> .
<code>hub</code>	Used by the Automated API behavior testing application. User-facing ingress certificate for the <code>hub-endpoint</code> .

Certificate name	Description
turnstile	Used by the Automated API behavior testing application. User-facing ingress certificate for the <code>turnstile-endpoint</code> .

Customizing user-facing certificates

How to set the user-facing endpoints of API Connect to use your own TLS server certificates.

Before you begin

Identify the user-facing certificates that you want to customize: [Table 6](#).

Ensure that you have certificate, key, and CA PEM files for each certificate you want to customize. The PEM files must not be password-protected.

For example, to customize the certificate that secures the Cloud Manager UI, you must have the following PEM files: `cloud-admin-ui-cert.pem`, `cloud-admin-ui-key.pem`, `cloud-admin-ui-ca.pem`

User-facing certificates must meet the following requirements:

- Specify Extended Key Usage (EKU) of `serverAuth`.
- Include the Subject Alternative Name (SAN) of the endpoint that they secure.
- If the certificate is signed by an intermediate CA, then the `ca.pem` file must contain the full chain to root CA.

About this task

You update the user-facing certificates with the `apicup` command.

You can set custom user-facing certificates during installation, or you can update them after installation, replacing the default certificates that are generated.

Procedure

1. If you are updating a user-facing certificate after installation, you must first clear the default certificate that was created:

```
apicup certs set <subsystem name> <certificate name> --clear
```

For example, to clear the certificate that secures the Cloud Manager UI:

```
apicup certs set mgmt cloud-admin-ui --clear
```

2. Set the user-facing certificate with the `apicup certs set` command, supplying the PEM files for your new certificate:

```
apicup certs set <subsystem name> <certificate name> <cert file> <key file> <ca file>
```

For example:

```
apicup certs set mgmt cloud-admin-ui cert.pem key.pem ca.pem
```

3. If you are updating the certificate after installation, then apply the update with `apicup subsys install`

```
apicup subsys install <subsystem name>
```

4. You can verify that the certificate is updated with `apicup certs list`:

```
apicup certs list <subsystem name>
```

Example output:

```
Common certificates
```

```
=====
```

Name	Summary	Validation errors
----	-----	-----
...		

```
Subsystem def-management certificates
```

```
=====
```

Name	Summary	Validation errors
----	-----	-----
...		
cloud-admin-ui	CN: cloud-admin-ui SubjectKeyId: 9E:8B:FA:7E:92:70:EC:86:2F:C3:3A:20:E8:13:EA:F4 AuthorityKeyId: E4:AB:09:FF:A9:7D:D3:70:DD:AD:69:C4:A4:34:8D:96	
...		

Note: Along with the user-facing certificates, the `apicup certs list` command outputs details of other internal API Connect certificates and secrets that you should not update.

Certificate expiry and renewal

How to renew and replace TLS certificates in your VMware deployment.

The instructions in this topic apply only to the management, portal, and analytics subsystems. For gateway appliance-specific instructions, see *Configuring the API Connect Gateway Service* in the appropriate version of the [DataPower documentation](#).

All [ingress certificates](#) in API Connect have a duration of 2 years. To avoid an outage when they expire, they must be manually renewed before expiration.

The `ingress-ca` [CA certificate](#) has a duration of 10 years and also requires manual steps to renew it before expiry.

[Intra-subsystem certificates](#) are renewed automatically.

Identifying expired certificates

1. Login to each subsystem VM:

```
ssh apicadm@<subsystem hostname>
```

Note: If you have a three replica deployment, login to only one of the VMs of each subsystem.

2. Switch to the root user:

```
sudo -i
```

3. Install the **apicops** tool: [The API Connect operations tool: apicops](#):

- a. Download the latest **apicops-v10-linux** executable file:

```
wget <URL of latest apicops-v10-linux>
```

For example:

```
wget https://github.com/ibm-apiconnect/apicops/releases/download/<latest version>/apicops-v10-linux
```

- b. Add execute permissions to **apicops-v10-linux**:

```
chmod a+x apicops-v10-linux
```

4. Run the **apicops certs:validate** command:

```
./apicops-v10-linux certs:validate -s <subsystem>
```

where *<subsystem>* is the subsystem you are running the command on, either: Management, portal, or analytics.

The **apicops** command reports any certificates that are expired or within 60 days of expiry.

You can ignore the message:

```
Cannot check who signed the certificate returned by ... as no ingress issuer was provided
```

this is expected on VMware deployments.

5. Renew any certificates that are expired or approaching expiry, except for the certificates that are listed under the heading **Validating subsystem**

certificates for <subsystem name>, these are intra-subsystem certificates that are renewed automatically.

```
Validating subsystem certificates for abc-management
Good certificate: <subsystem name>-ca
Good certificate: <subsystem name>-client
Good certificate: <subsystem name>-server
```

Follow the step in [Renewing certificates](#) to renew expired or nearly expired certificates.

Renewing certificates

Use the **apicup** command to renew certificates.

Warning: Use these steps to renew only end-entity ingress certificates as defined here: [ingress certificates](#). If you want to renew the `ingress-ca` certificate, then see [Renewing ingress-ca](#).

1. Clear the existing certificate with the **apicup certs clear** command:

```
apicup certs set --clear <subsystem> <certificate name>
```

Repeat for all ingress certificates that you want to renew.

2. Generate new certificates for all the certificates that you cleared in step 1:

```
apicup certs generate <subsystem>
```

You do not need to specify the certificates with the **apicup certs generate**, the command identifies all empty (cleared) certificates in the subsystem and generates new ones.

3. Apply the updated certificates to the subsystem:

```
apicup subsys install <subsystem>
```

Renewing ingress-ca

Use the **apicup** command to renew `ingress-ca`, and then renew all the end-entity certificates the are signed by `ingress-ca`.

1. Clear the `ingress-ca` certificate:

```
apicup certs set --clear <management subsystem> ingress-ca
```

Although this command specifies *<management subsystem>*, because `ingress-ca` is a common certificate, it is cleared for all subsystems. You do not need to repeat this command for every portal or analytics subsystem that is managed from the same project directory.

2. Generate a new `ingress-ca`:

```
apicup certs generate <subsystem>
```

The `generate` command creates certificates for all previously cleared certificates, you do not need to specify `ingress-ca` in this command.

3. Clear all the ingress end-entity certificates that are signed by `ingress-ca`:

```
apicup certs set --clear <subsystem> <certificate name>
```

For a list of the ingress certificates, see [Ingress certificates](#).

4. Generate new ingress end-entity certificates for each subsystem:

```
apicup certs generate <subsystem>
```

5. Apply the updated certificates to all subsystems:

```
apicup subsystem install <subsystem>
```

Extracting and copying certificates

How to extract certificate contents and apply them to API Connect subsystems in other environments.

If you have a two data center disaster recovery deployment, or have API Connect subsystems in different data centers that are managed by different project directories, then it is necessary to manually synchronize the TLS certificates between the environments.

Synchronizing the `ingress-ca` certificate

To export the `ingress-ca` certificate from your target environment, follow these steps:

1. Extract the `ingress-ca` public certificate to a file called `ingress-ca-cert.pem`

```
apicup certs get <subsystem> ingress-ca > ingress-ca-cert.pem
```

2. Extract the `ingress-ca` private key to a file called `ingress-ca-key.pem`

```
apicup certs get <subsystem> ingress-ca -t key > ingress-ca-key.pem
```

3. Extract the `ingress-ca` CA to a file called `ingress-ca-CA.pem`

```
apicup certs get <subsystem> ingress-ca -t ca > ingress-ca-CA.pem
```

Note: The `ingress-ca` certificate is the same for all subsystems that are managed from the same project directory, so you can specify any subsystem in the `apicup certs get` command.

To apply the exported `ingress-ca` certificate to another environment, follow these steps:

1. Apply the exported certificate files to the `ingress-ca`:

```
apicup certs set <subsystem> ingress-ca ingress-ca-cert.pem ingress-ca-key.pem ingress-ca-CA.pem
```

Note: The `ingress-ca` certificate is the same for all subsystems that are managed from the same project directory, so you can specify any subsystem in the `apicup certs set` command.

2. Clear all the ingress end-entity certificates that are signed by `ingress-ca`:

```
apicup certs set --clear <subsystem> <certificate name>
```

For a list of the ingress certificates, see [Ingress certificates](#).

3. Generate new ingress end-entity certificates for each subsystem:

```
apicup certs generate <subsystem>
```

4. Apply the updated certificates to all subsystems:

```
apicup subsystem install <subsystem>
```

Apicup certs command reference

Documentation of the `apicup certs` command you use to manage API Connect TLS certificates and secrets.

The `apicup certs` command is used to set, clear, and generate the TLS certificates that are used by API Connect. The `apicup certs` command is also used to manage some of the secrets used by API Connect, such as remote backup server credentials and database encryption secrets.

After you modify certificates with the `apicup certs` command, you must apply the changes to your subsystems with:

```
apicup subsys install <subsystem name>
```

Setting and clearing certificates

Run the `apicup certs set` command:

Table 1. `apicup certs set`

Command	Values	Result
---------	--------	--------

Command	Values	Result
<code>apicup certs set</code> <code>SUBSYS CERT_NAME</code> <code>[CERT_FILE</code> <code>KEY_FILE CA_FILE]</code> <code>[flags]</code>	Parameters are: <ul style="list-style-type: none"> SUBSYS - name of the subsystem to which the certificate applies CERT_NAME - name of the certificate; see Certificate reference VMware for a list of certificates that can be set for each subsystem. CERT_FILE - Path to the certificate file in PEM format. KEY_FILE - Path to the private key file in PEM format. CA_FILE - Path to the certificate authority (CA) file. The contents of the file might be the concatenation of an intermediate CA and the root CA (in that order). Note: When you set the <code>root-ca</code> certificate, omit the <code>CA_FILE</code> parameter. 	Sets the specified certificate to be applied when <code>apicup subsys install</code> is run.
<code>apicup certs set</code> <code>SUBSYS CERT_NAME</code> <code>[KEY_FILE]</code> <code>[flags]</code>	<code>KEY_FILE</code> - The file that contains the encryption-secret for field level encryption in the management database. Applies only to the management subsystem . The certificate name is <code>encryption-secret</code> . The type is secure random bytes with a length of 128 bytes. For example, <code>apicup certs set mgmt1 encryption-secret /path/to/encryption-secret.bin</code> . Note: Do not specify any of the <code>[CERT_FILE KEY_FILE CA_FILE]</code> parameters when you set the <code>encryption-secret</code> .	Applies the <code>encryption-secret</code> when the management subsystem is installed.
<code>flags</code> <ul style="list-style-type: none"> <code>--clear</code> <code>--help</code> 	Flags are: <ul style="list-style-type: none"> <code>--clear</code> - Clears the specified certificate. For example, <code>apicup certs set mgmt1 encryption-secret --clear</code> <code>--help</code> - Displays help for the command. 	The specified certificate is cleared. When you make configuration changes such as changing endpoints, the corresponding certificate must be cleared so that a new certificate can be set.

Viewing details of a certificate

Run the `apicup certs get` command:

Table 2. `apicup certs get`

Command	Values	Result
<code>apicup certs get</code> <code>SUBSYS CERT_NAME</code> <code>[flags]</code>	Parameters are: <ul style="list-style-type: none"> SUBSYS - name of the subsystem to which the certificate applies CERT_NAME - name of the certificate to retrieve; see Certificate reference VMware for a list of certificates 	Returns the specified certificate for the specified subsystem.
<code>flags</code> <ul style="list-style-type: none"> <code>--output string</code> <code>--type string</code> <code>--help</code> 	Flags are: <ul style="list-style-type: none"> <code>--output string</code> - Specify a file for the retrieved values, or specify "-" to send to stdout. The default is "-" to send to stdout. For example, <code>apicup certs get mgmt1 --output myCertsFile</code> <code>--type string</code> - Returns only the specified type. If not specified, the type is cert. For example, <code>apicup certs get mgmt1 --type ca</code> <code>--help</code> - Displays help for the command. 	<ul style="list-style-type: none"> For <code>--output</code>: The specified certificate is retrieved and sent to stdout or saved to the specified file For <code>--type</code>: Certificates are retrieved that match the type specified.

List the certificates for a subsystem

Run the command `apicup certs list`:

Table 3. `apicup certs list`

Command	Values	Result
<code>apicup certs list SUBSYS</code> <code>[flags]</code>	Parameters are: <ul style="list-style-type: none"> SUBSYS - name of the subsystem for which you want to list certificates 	Returns a list of certificates that are configured for the subsystem.
<code>flags</code> <ul style="list-style-type: none"> <code>--help</code> 	Flags are: <ul style="list-style-type: none"> <code>--help</code> - Displays help for the command. 	Help text is displayed.

Generate certificates

The `apicup certs generate` command generates and sets default certificates. The `generate` command generates and sets a certificate only if it is not already set.

Note: The `apicup subsys install` operation also generates and sets any unset certificates, but use the `apicup certs generate` command so that you can set them and review them before you install.

Table 4. `apicup certs generate`

Command	Values	Result
<code>apicup certs generate</code> <code>SUBSYS [flags]</code>	Parameters are: <ul style="list-style-type: none"> SUBSYS - name of the subsystem for which you want to generate certificates 	Generates certificates that are currently not set for the subsystem. Generates self-signed certificates.
<code>flags</code> <ul style="list-style-type: none"> <code>--help</code> 	Flags are: <ul style="list-style-type: none"> <code>--help</code> - Displays help for the command. 	Help text is displayed.

Certificate validation reference

Certificates validation errors reference table.

The following table lists the certificate validation errors that the **apicup certs** command might report.

Validation	Messages	Error	Action to take
Verify that the certificate is set properly.	certificate <cert> not set	The certificate is not set.	
	unable to load cert <cert>	The certificate is set but cannot be read.	
Verify certificate key usage (Extended Key Usage).	unable to verify cert <cert>: missing key usage <n>	The certificate is missing the required key usage.	Check Certificate reference VMware to confirm the EKU required for the certificate.
Verify the certificate signing CA. If available, the CA file is loaded. Then the certificate is verified against the provided CA file, including enforcement of Extended Key Usage.	unable to parse CA to verify cert <cert>	The CA file could not be parsed and loaded.	
	unable to verify cert <cert>	The certificate failed verification against the provided CA file.	One possible reason for receiving this error is that the correct EKU is missing.
Verify certificate hosts.	unable to verify cert <cert>: missing <host>	The certificate is not valid for the required host.	See Certificate reference VMware for the required hosts.
Verify that a certificate that is being used as a CA is a CA certificate.	unable to verify cert <cert>: certificate is not a CA	The certificate is not a valid CA.	
Verify client certificate match. The portal-client, and analytics-ingestion-client certificates are verified against the CA of portal-admin-ingress, and analytics-ingestion-ingress.	a CA certificate must be provided for this certificate	The CA certificate is missing for one of the portal-admin-ingress, and analytics-ingestion-ingress.	The common certificates portal-client, and analytics-ingestion-client must be set before you set any custom certificates.
	client cert cannot be verified against provided CA certificate	The verification failed.	

Use JWT security instead of mTLS between subsystems

If your network requires TLS termination on load-balancers located between your API Connect subsystems, then disable mTLS and enable JWT to provide application layer security.

JWT security provides application layer security and can be used instead of mTLS when there are load-balancers located between subsystems that require TLS termination. For more information about JWT security, see [Enable JWT instead of mTLS](#).

1. To enable JWT and disable mTLS, first identify the JWKS URL from the management subsystem:

```
apicup subsys get <management subsystem>
...
jwks-url https://appliance1.apic.acme.com/api/cloud/oauth2/certs JWKS URL for Portal and Analytics subsystems to validate JWT -- this is unsettable and is generated based on the platform-api endpoint
...
```

2. Disable mTLS and enable JWT on portal and analytics by setting the mtls-validate-client and jwks-url values with **apicup**:

```
apicup subsys set <portal> mtls-validate-client=false
apicup subsys set <portal> jwks-url=appliance1.apic.acme.com/api/cloud/oauth2/certs

apicup subsys set <analytics> mtls-validate-client=false
apicup subsys set <analytics> jwks-url=appliance1.apic.acme.com/api/cloud/oauth2/certs
```

3. Apply the change to portal and analytics with **apicup subsys install**:

```
apicup subsys install <subsystem_name>
```

4. To enable JWT and disable mTLS on the gateway appliance, see *Configuring the API Connect gateway service* in the [DataPower documentation](#).

Note: Do not disable mTLS without enabling JWT.

Credentials and encryption secrets reference

API Connect user credentials and database encryption secrets that are managed with the **apicup certs** command.

The **apicup certs** command is used to manage various credentials and encryption secrets that are used by API Connect management and portal subsystems.

Note: For details of the TLS certificates that you can manage with the **apicup certs** command, see [Certificate reference VMware](#).

Management subsystem credentials and secrets

The following table lists all the secrets and credentials that are returned from the **apicup certs list <management subsystem>** command:

Table 1. Management subsystem credentials and secrets

Secret or credential name	Description
<code>atm-credential</code>	Credential used in internal API Connect communication. Do not modify this credential.
<code>consumer-toolkit-credential</code>	Credential used in internal API Connect communication. Do not modify this credential.
<code>consumer-ui-credential</code>	Credential used in internal API Connect communication. Do not modify this credential.
<code>database-backup-auth-ssh-key</code>	SSH key for authentication with a remote SFTP backup server.
<code>designer-credential</code>	Credential used in internal API Connect communication. Do not modify this credential.
<code>encryption-secret</code>	A 128-bytes long encryption secret that is used to do field level encryption in the management subsystem database.
<code>juhu-credential</code>	Credential used in internal API Connect communication. Do not modify this credential.
<code>toolkit-credential</code>	Credential used in internal API Connect communication. Do not modify this credential.
<code>ui-credential</code>	Credential used in internal API Connect communication. Do not modify this credential.

Portal subsystem credentials and secrets

The following table lists all the secrets and credentials that are returned from the `apicup certs list <portal subsystem>` command:

Table 2. Portal subsystem credentials and secrets

Secret or credential name	Description
<code>encryption-secret</code>	A 128-bytes long encryption secret that is used to do field level encryption in the portal subsystem database.
<code>original-encryption-secret</code>	A copy of the encryption-secret that was first used to generate the Kubernetes secret name. Do not modify this secret.
<code>site-backup-auth-ssh-key</code>	Authentication key for your remote portal backup SFTP server.

Advanced configuration for management subsystem

Specify advanced configuration for the management subsystem.

Note: VMware deployments include subsystem settings that cannot be reconfigured without a complete deployment. For example, for the Management Service these settings include hosts, endpoints, interfaces (`public-iface`, `traffic-iface`), IP ranges of the Kubernetes pod and the service networks (`k8s-pod-network`, `k8s-service-network`). Before reconfiguring, review the installation instructions for your subsystem to determine which settings are optional during initial installation and thus able to be updated later.

See:

- [Setting rate limits for public APIs on the management service](#)
Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.
- [Configuring maximum size of client requests to the Management subsystem on VMware](#)
You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.
- [Configuring monetization on VMware](#)
You can optionally configure monetization in API Connect on a VMware virtual machine by enabling the billing microservice.
- [Configuring use of an external NTP server](#)
You can optionally configure an external NTP server for use by API Connect when deploying on a VMware virtual machine.
- [Overriding resources for Postgres components on VMware](#)
In 10.0.4.0 and greater, you can optionally override the CPU and Memory resources used by postgres database components.
- [Enabling UI feature flags on VMware](#)
Use a template override to update the installation CR with settings that control UI features.

Setting rate limits for public APIs on the management service

Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.

Before you begin

These instructions assume you have the kubectl command-line tool installed. For more information, see <https://kubernetes.io>.

About this task

Rate limits can be set for public APIs on the management service. Rate limits on APIs help provide protection from DDoS (distributed denial of service) attacks. Without a rate limit, API calls from public APIs are unlimited.

The rate limit configuration requires that the header contains the actual client IP address. Any load balancer or proxy (for example, HAProxy) that is installed in front of the management service must be configured to pass the actual client IP address.

This procedure must be performed on a running API Connect deployment.

Rate limits are calculated as requests per seconds per client.

Note: If the rate limit has been reached on the management subsystem, the client will get an HTTP error: **429 Too Many Requests**.

Procedure

- Set a rate limit:
 1. Add the following entries to the extra-values-file:

```
spec:
  template:
    - name: juhu
      containers:
        - name: juhu
          env:
            - name: RATE_LIMIT_PER_CLIENT
              value: "10"
            - name: LIMIT_REQUEST_OPTION
              value: "burst=10 nodelay"
```

In this example, the first option sets the rate to 10 requests per second (10r/s). The second option allows 10 requests boosted without delay within < 1 second. You can customize as needed.

The `rateLimitPerClient` property sets `rate`, and `limitRequestOption` sets `[burst=number] [nodelay | delay=number]` in the following nginx configuration:

```
limit_req_zone key zone=name:size rate=rate;
limit_req zone=name [burst=number] [nodelay | delay=number];
```

Note that `zone` has been pre-defined and can't be configured. For more details, see the nginx doc http://nginx.org/en/docs/http/nginx_limit_req_module.html.

2. Save the extra-values file with a filename of your choice, but it must have a .yaml or .yml extension.
3. Use `apicup` to update the VMware `extra-values-file` attribute to point to the new or updated management subsystem extra-values file:

```
apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
```

Where:

- `<mgmt_subsystem_name>` is the name of the management subsystem that you are configuring.
- `<extra_values_file_path_and_name>` is the fully qualified path and name of your extra-values file.

For example:

```
apicup subsys set ds10-management extra-values-file /workspace/v10012/my_extra_values.yaml
```

4. Verify that the configuration settings are valid in the `apiconnect-up-v10.yaml` by running the following command:

```
apicup subsys get <mgmt_subsystem_name> --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.

5. Run `apicup` to update the settings in the deployed Management subsystem.

```
apicup subsys install <management-subsystem>
```

6. Enter the following command to connect to the management subsystem using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of `apicadm`, which is the API Connect ID that has administrator privileges.

7. Select Yes to continue connecting, and once connected:

```
sudo -i
```

8. Validate that the juhu pod has restarted by listing the pods:

```
kubectl get pods grep juhu
```

9. Check the AGE column to ensure a new juhu pod has started.
10. If the older juhu pod is still running, delete it with the following command:

```
kubectl delete pods <old-juhu-pod>
```

- Disable a rate limit:
 1. Remove the values from the extra-values-file.
 2. Run `apicup` to update the settings in the deployed Management subsystem.

```
apicup subsys install <management-subsystem>
```

3. Enter the following command to connect to the management subsystem using SSH:

```
ssh ip_address -l apicadm
```

You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.

4. Select Yes to continue connecting, and once connected:

```
sudo -i
```

5. Validate that the juhu pod has restarted by listing the pods:

```
kubectl get pods grep juhu
```

6. Check the AGE column to ensure a new juhu pod has started.
7. If the older juhu pod is still running, delete it with the following command:

```
kubectl delete pods <old-juhu-pod>
```

Configuring maximum size of client requests to the Management subsystem on VMware

You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.

About this task

The default maximum size is 8 megabytes. You can increase this value.

Increasing the setting can be useful if you get errors when using the CLI to import a large API. Example error:

```
HTTP/1.1 413 Request Entity Too Large
```

Note:

- These instructions apply only to VMware installations. For Kubernetes installations, see [Configuring maximum size of client requests to the Management subsystem](#).
- These instructions use an extra-values file. This file can be used to define CR overrides. Note that extra-values files for a CR can contain more than one override. If you already use an extra-values file, you can add the new override to it.
- All of the commands must be run in the **apicup** management project directory.

Procedure

1. Create, or edit if one already exists, a management subsystem extra-values file in the **apicup** management project directory, and enter the following configuration details:

```
spec:
  template:
  - name: juhu
    containers:
    - name: juhu
      env:
      - name: CLIENT_MAX_BODY_SIZE
        value: "12m"
```

2. Save the extra-values file with a filename of your choice, but it must have a .yaml or .yml extension.
3. Use **apicup** to update the VMware **extra-values-file** attribute to point to the new or updated management subsystem extra-values file:

```
apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
```

Where:

- **<mgmt_subsystem_name>** is the name of the management subsystem that you are configuring.
- **<extra_values_file_path_and_name>** is the fully qualified path and name of your extra-values file.

For example:

```
apicup subsys set ds10-management extra-values-file /workspace/v10011/my_extra_values.yaml
```

4. Verify that the configuration settings are valid in the apiconnect-up.yaml by running the following command:

```
apicup subsys get <mgmt_subsystem_name> --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.

5. Update the management VMware with the updated setting.

```
apicup subsys install <mgmt_subsystem_name>
```

6. Monitor the health-check output until the management subsystem is healthy by running the following command:

```
apicup subsys health-check <mgmt_subsystem_name>
```

If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of 1. The following output is an example of unhealthy output while the install is running:

```
Error: Cluster not in good health:
ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
```

When all of the health criteria are successfully met, the command displays no output, and exits with a status of 0.

Configuring monetization on VMware

You can optionally configure monetization in API Connect on a VMware virtual machine by enabling the billing microservice.

Before you begin

Important: If the optional billing microservice is enabled, you must increase the memory for the API Manager for VMware component by 0.5 GB.

About this task

API Connect includes a subscription billing microservice that allows API providers to define pricing plans in their API Products, and monetize their API offerings. If a Product contains a pricing plan, API Consumers must enter their payment information into the Developer Portal before they can subscribe to that plan. API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.

Note:

- These instructions apply only to VMware installations. For Kubernetes installations, see [Configuring monetization on Kubernetes](#).
- To use Stripe as your credit card processing vendor, you must have port 443 open to HTTPS communication between the Stripe API and your Developer Portal management and the Management cluster servers. See [Firewall requirements on Kubernetes](#) and [Firewall requirements on VMware](#) for more information about this requirement.
- Provider organizations cannot add any billing integrations until the billing microservice is enabled.
- After provider organizations have added billing integrations, the billing microservice must not be disabled.
- All of the commands must be run in the `apicup` management project directory.

To enable or disable the billing microservice, you must configure a management subsystem extra-values file. See the following instructions:

- [Enabling the billing microservice](#)
- [Disabling the billing microservice](#)

Procedure

• Enabling the billing microservice

1. Create, or edit if one already exists, a management subsystem extra-values file in the `apicup` management project directory, and enter the following configuration details:

```
spec:
  billing:
    enabled: true
```

2. Save the extra-values file with a filename of your choice, but it must have a `.yaml` or `.yml` extension.
3. Update the VMware `extra-values-file` attribute to point to the new or updated management subsystem extra-values file. Run the following `apicup` command to insert the location of the extra-values file:

```
apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
```

Where:

- `<mgmt_subsystem_name>` is the name of the management subsystem that you are configuring.
- `<extra_values_file_path_and_name>` is the fully qualified path and name of your extra-values file.

For example:

```
apicup subsys set ds10-management extra-values-file /workspace/v10011/monetization.yaml
```

4. Verify that the configuration settings are valid in the `apiconnect-up.yaml` by running the following command:

```
apicup subsys get <mgmt_subsystem_name> --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.

5. Update the management VMware with the updated billing value. Install the new setting for the billing microservice by running the following command:

```
apicup subsys install <mgmt_subsystem_name> --debug
```

Including the `--debug` option enables the debug output for the command.

6. Monitor the health-check output until the management subsystem is healthy by running the following command:

```
apicup subsys health-check <mgmt_subsystem_name>
```

If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

```
Error: Cluster not in good health:
ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
```

When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.

The billing microservice is now enabled, and provider organization owners can create billing integration resources for API providers in the API Manager UI. For more information, see [Monetizing your Products](#).

• Disabling the billing microservice

Important: After provider organizations have added billing integrations, the billing microservice must not be disabled.

1. Edit the management subsystem extra-values file in the `apicup` management project directory, and change the `enabled` configuration option to `false`:

```
spec:
  billing:
    enabled: false
```

2. Save the changed extra-values file.
3. Verify that the configuration settings are valid in the `apiconnect-up.yaml` by running the following command:

```
apicup subsys get <mgmt_subsystem_name> --validate
```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.

4. Update the management VMware with the altered billing value.
Install the updated setting for the billing microservice by running the following command:

```
apicup subsys install <mgmt_subsystem_name> --debug
```

Including the `--debug` option enables the debug output for the command.

5. Monitor the health-check output until the management subsystem is healthy by running the following command:

```
apicup subsys health-check <mgmt_subsystem_name>
```

If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

```
Error: Cluster not in good health:
ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
```

When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.
The billing microservice is now disabled.

Configuring use of an external NTP server

You can optionally configure an external NTP server for use by API Connect when deploying on a VMware virtual machine.

About this task

Secure communication between API Connect subsystems relies on the system time being in sync on all hosts. For example, time stamps are checked to ensure that certificates are valid. When API Connect is deployed behind a firewall that blocks access to the internet, the API Connect subsystems cannot by default access a Network Time Protocol (NTP) server.

You can use an additional cloud-init file to manually specify an NTP server for use by the subsystems. Complete the following steps.

Procedure

1. Create the cloud-init file extra values file, and enter the configuration details that you want to overwrite. For example:

```
ntp:
  enabled: true
  ntp_client: systemd-timesyncd
  servers:
    - time.google.com
```

2. Use `apicup` to specify the cloud-init file.

Syntax:

```
apicup subsys set <subsys> additional-cloud-init-file <path-to-cloud-init-file>
```

Example:

```
apicup subsys set mgmt additional-cloud-init-file myCloudInitFile.yaml
```

3. Install the subsystem. Note that the output directory must be empty:

```
apicup subsys install mgmt --out mgmtplan-out
```

4. Deploy the VMware image (.ova) with the ISO file that is generated.
To review the deployment steps, see [Deploying the Management virtual appliance](#).

5. Verify that the correct NTP server is being used:

```
journalctl -u systemd-timesyncd
```

Example output for the NTP server that was set in Step [1](#):

```
Nov 05 21:09:24 h-apicdev-4 systemd[1]: Starting Network Time Synchronization...
Nov 05 21:09:24 h-apicdev-4 systemd[1]: Started Network Time Synchronization.
Nov 05 21:09:24 h-apicdev-4 systemd-timesyncd[1697]: Synchronized to time server 216.239.35.8:123 (time.google.com).
```

Overriding resources for Postgres components on VMware

In 10.0.4.0 and greater, you can optionally override the CPU and Memory resources used by postgres database components.

About this task

There are three postgres components:

- **postgres**
- **pgBouncer**
- **pgBackRest**

The default resources used in **postgres**, **pgBouncer** and **pgBackRest** components are:

Table 1. Postgres component default resources

Resource	Postgres DB	pgBouncer	pgBackRest
Memory Request	512Mi	24Mi	48Mi
Memory Limit	8Gi	128Mi	128Mi
CPU Request	600m	80m	80m
CPU Limit	1500m	200m	200m

Procedure

To override resources, complete the following procedure

1. Create an extra-values yaml file, or add values to an existing extra-values file.
 - Ensure that you specify the name of the container for the resource you want to override. Names:
 - **postgres**
 - **pgBouncer**
 - **pgBackRest**
 - You can override multiple postgres components in parallel. Adding one container section under **mgmt-pgcluster** template.
 - You can override just a single value, such as CPU limit.

Examples:

- Example yaml, to replace all **postgres** resources:

```
spec:
  template:
  - name: mgmt-pgcluster
    containers:
    - name: postgres
      resources:
        requests:
          cpu: 1500m
          memory: 8Gi
        limits:
          cpu: 600m
          memory: 512Mi
```

- Example yaml, to replace all **pgBouncer** resources:

```
spec:
  template:
  - name: mgmt-pgcluster
    containers:
    - name: pgBouncer
      resources:
        requests:
          cpu: 200m
          memory: 128Mi
        limits:
          cpu: 300m
          memory: 256Mi
```

- Example yaml, to replace CPU limit of **postgres** database:

```
spec:
  template:
  - name: mgmt-pgcluster
    containers:
    - name: postgres
      resources:
        limits:
          cpu: 1000m
```

- Example yaml, to replace CPU limits of **postgres** database and **pgBouncer**:

```
spec:
  template:
  - name: mgmt-pgcluster
```

```

containers:
- name: postgres
  resources:
    limits:
      cpu: 1000m
- name: pgBouncer
  resources:
    limits:
      cpu: 1000m

```

2. Set the extra values file:

```
apicup subsys set <SUBSYSTEM_NAME> extra-values-file=<PATH_TO_EXTRA_VALUES_FILE>
```

3. Apply the overrides:

```
apicup subsys install <SUBSYSTEM_NAME>
```

4. Check health of cluster:

```
apicup subsys health-check <SUBSYSTEM_NAME>
```

Results

The postgres components will restart with updated values.

Enabling UI feature flags on VMware

Use a template override to update the installation CR with settings that control UI features.

About this task

You can add a template override to the Management subsystem CR and use it to control whether specific features are available in the UI. Some features can be optionally disabled by users (by disabling them in the browser) provided you have enabled the feature for the cluster as a whole. Table 1 describes the available feature flags.

Table 1. Flags and settings for controlling UI features

Feature ID	Default Value	Partial Override For	Description
ffAdvancedPublish	true		Enable advanced publish option (deprecated)
allOmniSearch	true		Enables OmniSearch for all lists. This flag is used in conjunction with other flags.
draftsOmniSearch	true	allOmniSearch	Enable OmniSearch for drafts list
catalogProductsOmniSearch	true	allOmniSearch	Enable OmniSearch for catalog
orgsOmniSearch	true	allOmniSearch	Enable OmniSearch for org lists
appsOmniSearch	true	allOmniSearch	Enable OmniSearch for apps
subscriptionsOmniSearch	true	allOmniSearch	Enable OmniSearch for subscriptions, if disabled, subscription lists will be removed from catalog list
requestedApprovalsOmniSearch	true	allOmniSearch	Enable OmniSearch for requested approvals
approvalTasksOmniSearch	true	allOmniSearch	Enable OmniSearch for approvals
productApisOmniSearch	true	allOmniSearch	Enable OmniSearch for apis within products
membersOmniSearch	true	allOmniSearch	Enable OmniSearch for member lists

Procedure

1. Add the template override to the `management-extra-values.yaml` file.
2. In the file, append the feature-flag definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file. The following example enables the OmniSearch feature on all possible UI pages.

```

spec:
  template:
    - name: ui
      containers:
        - name: ui
          env:
            - name: APIC_UI_FEATURES
              value: allOmniSearch=always

```

`APIC_UI_FEATURES` is a URL-encoded string. Each parameter is formed as `featureId=$featureValue`, and you can list multiple parameters with the `&` delimiter (`featureId=$featureValue&featureId=$featureValue`).

Use the `featureId` values from Table 1. For each feature, specify one of the following `featureValue` settings:

- **true** - On by default, but can be overridden by the user, for their browser alone
- **false** - Off by default, but can be overridden by the user, for their browser alone
- **never** - Off regardless of browser setting, disabled in feature flag page
- **always** - On regardless of browser setting, disabled in feature flag page

3. Save the file.
4. Run the following command to update the deployment:

```
apicup subsys set <management_subsystem> extra-values-file <path_to_management-extra-values.yaml_file>
```

The cluster is updated to enable or disable features as specified.

Backing up and restoring on VMware

Backup and restore API Connect on VMware.

Backups are for recovery of the API Connect subsystems in the same environment that the backups were taken. If you want to move your API Connect deployment to a different environment and change the form factor or modify your API Connect endpoints, then see [Migrating from v10 to v10 on a different form factor](#).

Note: For information about how to maintain a two data center deployment, including backup and restore considerations, see [Maintaining a two data center deployment](#).

- **Backing up and restoring the Management subsystem**
You can back up and restore your Management subsystem in your VMware environment.
- **Backing up and restoring the Developer Portal**
You can backup and restore a Developer Portal in a VMware environment.
- **Backing up and restoring the Analytics database on VMware**
The IBM® API Connect Analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required; for example, IBM Cloud Object Storage.

Backing up and restoring the Management subsystem

You can back up and restore your Management subsystem in your VMware environment.

About this task

- You use the `apicup` utility to configure backup settings for the management subsystem.
- Database backups can be used to restore the database for disaster recovery.
- Backups can be scheduled or generated manually (on-demand). You can then list what backups are available and then use one to restore your Management subsystem if required.
- Postgres replica pods depend on a successful completed backup. If backup configuration is not correct, replica pods won't come up.
- Restoring a backup restores the registration credentials (`client_ID`, `client_secret`) that were in use at the time that the selected backup was created. For information on the registration credentials, see [Changing the registration client_id and client_secret for applications](#).

Note: You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.

Types of backups supported:

- Cloud-based S3 storage
 - IBM Cloud Object Storage
 - AWS S3
 - **v10.0.2.0 or later:** Any custom S3, such as minIO
- SFTP
- Local Backups
- **Configuring backup settings during initial installation of the management subsystem**
You can use the `apicup` utility to configure backup settings during initial installation of the management subsystem
- **Verify configuration for s3 backup**
Verify that the configuration for s3 backups succeeded.
- **Reconfiguring backup settings for the management subsystem**
You can use the `apicup` utility to add or reconfigure backup settings for the management subsystem, after completion of initial installation.
- **Backing up the management subsystem**
Use `apicup` to create a manual backup of the management subsystem
- **Restoring the management subsystem**
Use `apicup` to list backups and restore a selected backup of the management subsystem
- **Troubleshooting management subsystem backups on VMware**
You can troubleshoot failures of the management subsystem backups.

Configuring backup settings during initial installation of the management subsystem

You can use the `apicup` utility to configure backup settings during initial installation of the management subsystem

Before you begin

Review [Backing up and restoring the Management subsystem](#).

Note: You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.

About this task

- During an initial installation, use these steps to configure the backup settings prior to creating the initial management ISO.
- You can configure scheduled backups, or generate manual (on-demand) backups.

- Changing backup settings results in database downtime, unless `database-backup-protocol=sftp`.
- Backup to S3 providers of type `custom` is supported in v10.0.2.0 or greater. For `custom` S3, provide values for `database-backup-certs` and `database-backup-s3-uri-style`.
- OpenSSH key authentication for SFTP is supported.
- When you specify a filepath in a backup setting, be sure to escape any blank spaces in the path.

Important: For S3 backups of the management subsystem, do not use retention features provided by Cloud-based S3 storage providers. Use of such features can result in periodic deletion of archived backups, which can cause backup corruptions that can cause database restores to fail.

Procedure

1. Use `apicup` to specify backup settings:

- For most settings, use `apicup subsys`:

```
apicup subsys set <subsystem_name> <setting>=<value>
```

- When configuring ssh-key authentication for SFTP, use `apicup certs`:

```
apicup certs set <subsystem_name> database-backup-auth-ssh-key <ssh-key-file-path>
```

Table 1. Configuration settings for backup of management subsystem

Parameter	Description
<code>database-backup-protocol</code>	<p>The type of the backup. Supported types:</p> <ul style="list-style-type: none"> • <code>objstore</code> <pre>apicup subsys set mgmt database-backup-protocol=objstore</pre> <ul style="list-style-type: none"> • <code>sftp</code> <pre>apicup subsys set mgmt database-backup-protocol=sftp</pre> <p>The default value is <code>sftp</code>.</p> <ul style="list-style-type: none"> • <code>local</code> - Local storage backups <pre>apicup subsys set mgmt database-backup-protocol=local</pre> <p>Note:</p> <ul style="list-style-type: none"> • The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: <code>x509: certificate signed by unknown authority</code>.
<code>database-backup-auth-pass</code>	<p>The password for the server specified in <code>database-backup-host</code>. If using object store, this would be the S3 Secret Access Key parameter. The password will be stored in Base64 encoded format.</p> <p>For example:</p> <pre>apicup subsys set mgmt database-backup-auth-pass '<password>'</pre> <p>Note that you cannot use the <code>`</code> sign to assign the password to <code>database-backup-auth-pass</code>.</p>
<code>database-backup-auth-user</code>	<p>The username for the server specified in <code>database-backup-host</code>. If using object store, this would be the S3 Secret Key ID.</p> <pre>apicup subsys set mgmt database-backup-auth-user <user_name></pre>
<code>database-backup-auth-ssh-key</code>	<p>Optional: OpenSSH private key for DB backups using SFTP only. Changing this value will restart the DB.</p> <p>Important:</p> <ul style="list-style-type: none"> • Use <code>apicup certs</code> to set this value. Do not use <code>apicup subsys</code>. • Only OpenSSH keys are supported.¹ <pre>apicup certs set mgmt database-backup-auth-ssh-key <ssh private key filepath></pre>
<code>database-backup-s3provider</code>	<p>When using <code>objstore</code> type backup, specify the name of the S3 provider to use. Specify one of the supported values:</p> <ul style="list-style-type: none"> • <code>ibm</code> • <code>aws</code> • <code>custom - v10.0.2.0 or later</code> <p>Not required for local backups or SFTP backups.</p> <pre>apicup subsys set mgmt database-backup-s3provider=ibm</pre>
<code>database-backup-host</code>	<p>The backups host:</p> <ul style="list-style-type: none"> • For <code>objstore</code> type backup, specify S3 endpoint with the corresponding S3 region in the format <code><S3endpoint>/<S3region></code> <pre>apicup subsys set mgmt database-backup-host=s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard</pre> <ul style="list-style-type: none"> • For <code>sftp</code> type, the SFTP server hostname <pre>apicup subsys set mgmt database-backup-host=my.sftp.backup.domain.example.com</pre> <ul style="list-style-type: none"> • Not required for local storage backups

Parameter	Description
<code>database-backup-path</code>	<p>The path to the location of the backup:</p> <ul style="list-style-type: none"> For <code>objstore</code> backups, the name of your S3 bucket to store backup data. For example, <code>bucket-name/folder</code>. The use of subdirectories in the bucket name is not supported. <pre>apicup subsys set mgmt database-backup-path=apic-backup</pre> <p>Note: When your deployment includes a management subsystem in two different clusters (with active databases), the two management subsystems cannot use the same s3 bucket name in the database backup configurations. Each management subsystem must use a unique s3 bucket name.</p> <p>Ensure that <code>bucket-name/folder</code> is empty. If the folder was previously used for backups, the folder will not be empty, and stanza create might encounter an error.</p> <ul style="list-style-type: none"> Explanation: Once a folder is used, <code>archive.info</code> and <code>backup.info</code> files are created. During stanza creation, the process compares the database version and database system id between the two info files and the current Postgres database cluster. Stanza creation fails if there is a mismatch. To prevent this possibility, remove all files from the folder before configuring. <ul style="list-style-type: none"> For <code>sftp</code> type, the full absolute path of the folder on the SFTP server, beginning with <code>/</code>. <pre>apicup subsys set mgmt database-backup-path=<folder_name></pre> <ul style="list-style-type: none"> Not required for local storage backups
<code>database-backup-port</code>	<p>The port for the protocol to connect to the <code>database-backup-host</code>. The backup port is not required for object storage. Default: 22</p> <pre>apicup subsys set mgmt database-backup-port=<port_number></pre>
<code>database-backup-retries</code>	<p>For <code>sftp</code> type backups, the number of times the <code>ibm-apiconnect</code> Operator attempts backups in the event of a failed SFTP backup.</p> <pre>apicup subsys set mgmt database-backup-retries=3</pre> <p>Default value: 0.</p> <p>Not used for <code>objstore</code> or local storage backup.</p>
<code>database-backup-schedule</code>	<p>Cron like schedule for performing automatic backups. The format for the schedule is:</p> <ul style="list-style-type: none"> <code>*****</code> <code>-----</code> <code> </code> <code> +-----</code> day of week (0 - 6) (Sunday=0) <code> +-----</code> month (1 - 12) <code> +-----</code> day of month (1 - 31) <code> +-----</code> hour (0 - 23) <code>+-----</code> min (0 - 59) <p>The backup schedule defaults to <code>0 0 * * *</code>. This means a backup is run every day at midnight and minute zero.</p> <p>The timezone for backups is UTC.</p> <p>For local backups, the default is 01:00 UTC.</p> <p>When you configure a host, if you do not specify a value for <code>database-backup-schedule</code>, the default backup schedule is automatically set. Note that the default backup schedule is not set, and scheduled backups not enabled, until host configuration is completed.</p> <pre>apicup subsys set mgmt database-backup-schedule="0 0 * * *"</pre>
<code>database-backup-certs</code>	<p>Custom certificate. Used only when <code>s3Provider</code> is set to <code>custom</code>. Most of the custom S3 providers are created based on custom CA certificate.</p> <p>This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be <code>ca.crt</code> and value should be base64 encoded value of CA certificate.</p> <p>The API Connect management subsystem validates the custom S3 certificate against the customer-provided CA certificate.</p> <p>Sample bash script to create the Kubernetes secret:</p> <pre>cat >customs3ca.yaml <<EOF apiVersion: v1 data: ca.crt: \$(base64 <path-to-ca-certificate> tr -d '\n') kind: Secret metadata: name: custom-server-ca type: generic EOF kubectl apply -f customs3ca.yaml -n <namespace></pre> <p>For example:</p> <pre>apicup subsys set mgmt database-backup-certs=my-custom-s3-ca-cert</pre>
<code>database-backup-s3-uri-style</code>	<p>Valid values: <code>host</code> and <code>path</code>. Default value: <code>host</code></p> <p>Only allowed if <code>s3Provider</code> is set to <code>custom</code>.</p> <p>Some custom S3 providers require URI style to be set to <code>path</code>. For example, minIO supports both <code>host</code> and <code>path</code> style setup. You can create a minIO S3 server to only accept <code>path</code> style client communications.</p> <p>Important: Contact your custom S3 administrator before configuring this field. If not properly configured, upstream custom S3 can reject connections from the client, such as API Connect management subsystem.</p> <pre>apicup subsys set mgmt database-backup-s3-uri-style='<host path>'</pre>

Parameter	Description
<code>database-backup-repo-retention-full</code>	<p>The number of full S3 or local backups to retain. Not supported for SFTP.</p> <p>When the next full backup successfully completes, and the specified number of retained backups is reached, the oldest full backup is deleted. All incremental backups and archives associated with the oldest full backup also expire. Incremental backups are not counted for this setting.</p> <p>Applies to both manual backups and scheduled backups.</p> <p>Minimum value: 1</p> <p>Maximum value: 9999999</p> <p>Default: none (S3 backups), 14 (local backups).</p>

2. Verify that your settings are valid:

- To view all subsystem settings except `database-backup-auth-ssh-key`:

```
apicup subsys get <subsystem_name> --validate
```

- To view `database-backup-auth-ssh-key`:

```
apicup certs get <subsystem_name> database-backup-auth-ssh-key --type key
```

3. Return to the instructions for installing the management subsystem: [Deploying the Management virtual appliance](#).

Note that the configuration settings for backups will be installed when you run `apicup`

`subsys install <subsystem_name>` after all configuration settings are complete.

4. **S3 backups only:** After you complete the deployment of the Management subsystem in the previous step, continue to [Verify configuration for s3 backup](#).

¹ PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see <https://www.puttygen.com/>.

Verify configuration for s3 backup

Verify that the configuration for s3 backups succeeded.

About this task

When you configure Management subsystem backups, the operator runs a `stanza-create` job. This job creates the stanza (Postgres cluster configuration) on the upstream S3 server, which is used for backup and archive procedures. The job also brings up the necessary pod.

Procedure

- SSH into the management appliance.
- Check the status of the `stanza-create` job:

```
kubectl get jobs -n <namespace> | grep stanza
```

- On success:

- The `stanza-create` job status is 1/1:

```
kubectl get jobs | grep stanza
m1-b722e361-postgres-stanza-create      1/1      5s      127m
```

- The `stanza-create` job shows `status: "True"` and `type: Complete`:

```
kubectl get job m1-b722e361-postgres-stanza-create -o yaml
```

```
status:
  completionTime: "2021-04-13T18:38:50Z"
  conditions:
  - lastProbeTime: "2021-04-13T18:38:50Z"
    lastTransitionTime: "2021-04-13T18:38:50Z"
    status: "True"
    type: Complete
  startTime: "2021-04-13T18:38:45Z"
  succeeded: 1
```

- The `stanza-create` pod is in `Completed` state:

```
kubectl get pods | grep stanza
m1-b722e361-postgres-stanza-create-q4fvp      0/1      Completed      0      127m
```

- Exec into the pod:

```
kubectl exec -it <backrest-shared-repo-pod> -- bash
```

- The `pgbackrest` command returns the S3 contents in valid JSON:

```
pgbackrest info --output json --repol-type s3
{"backup":{"held":false},"message":"ok"}} [pgbackrest@m1-b722e361-postgres-backrest-shared-repo-69cdfd5-rs882
/
```

- On failure:

- `stanza-create` pods fail, and job status is 0/1:

```
kubectl get jobs | grep stanza
m1-3bfe12ac-postgres-stanza-create 0/1 32m 32m
```

- Listing all pods brought up by `stanza-create` job shows multiple pods because a job tries `backoffLimit` times to complete the job. By default, there will be 7 pods in error state:

```
kubectl get pods | grep stanza
m1-3bfe12ac-postgres-stanza-create-726z4 0/1 Error 0 11m
m1-3bfe12ac-postgres-stanza-create-9vq4n 0/1 Error 0 22m
m1-3bfe12ac-postgres-stanza-create-gbtgb 0/1 Error 0 30m
m1-3bfe12ac-postgres-stanza-create-g15g5 0/1 Error 0 17m
m1-3bfe12ac-postgres-stanza-create-q8qhw 0/1 Error 0 26m
m1-3bfe12ac-postgres-stanza-create-t84zs 0/1 Error 0 8m54s
m1-3bfe12ac-postgres-stanza-create-z8tfs 0/1 Error 0 12m
```

Note: In some cases, the pods are cleaned by Kubernetes and the logs of these pods can be lost.

- Pod log errors show a reason for the failure. For example, when a hostname is not valid:

```
kubectl logs m1-3bfe12ac-postgres-stanza-create-gbtgb

time="2021-04-13T20:01:19Z" level=info msg="pgo-backrest starts"
time="2021-04-13T20:01:19Z" level=info msg="debug flag set to false"
time="2021-04-13T20:01:19Z" level=info msg="backrest stanza-create command requested"
time="2021-04-13T20:01:19Z" level=info msg="s3 flag enabled for backrest command"
time="2021-04-13T20:01:19Z" level=info msg="command to execute is [pgbackrest stanza-create --db-host=192.1.2.3 --db-path=/pgdata/m1-3bfe12ac-postgres --repo1-type=s3]"
time="2021-04-13T20:01:19Z" level=info msg="command is pgbackrest stanza-create --db-host=192.1.2.3 --db-path=/pgdata/m1-3bfe12ac-postgres --repo1-type=s3 "
time="2021-04-13T20:05:21Z" level=error msg="command terminated with exit code 49"
time="2021-04-13T20:05:21Z" level=info msg="output=[]"
```

- Job status is set to `type: Failed` and `status: "True"`, with `reason: BackoffLimitExceeded`:

```
kubectl get job m1-3bfe12ac-postgres-stanza-create -o yaml

status:
  conditions:
  - lastProbeTime: "2021-04-13T20:28:03Z"
    lastTransitionTime: "2021-04-13T20:28:03Z"
    message: Job has reached the specified backoff limit
    reason: BackoffLimitExceeded
    status: "True"
    type: Failed
    failed: 7
  startTime: "2021-04-13T20:01:18Z"
```

- If pod logs are lost, you can execute a command inside the `backrest-shared-repo` pod:
 - Obtain the `backrest-shared-repo` pod name:

```
kubectl get pods -n <namespace> | grep backrest-shared-repo
```

For example:

```
kubectl get pods | grep backrest-shared-repo
m1-eb8edc18-postgres-backrest-shared-repo-98dd46cc6-tw195 1/1 Running
```

- Exec into the pod:

```
kubectl exec -it <backrest-shared-repo-pod> -- bash
```

- Run:

```
pgbackrest info --output json --repo1-type s3
```

For example, for invalid hostname:

```
ERROR: [049]: unable to get address for 'test1-v10-backup.s3.exampleaws.com': [-2] Name or service not knownCopy
```

The exact **ERROR**: will vary depending on the misconfiguration. Common errors:

```
Invalid access key
Invalid access key secret
Invalid bucket region
Invalid bucket or folder path
```

- To fix the incorrect settings, see [Reconfiguring backup settings for the management subsystem](#).

Reconfiguring backup settings for the management subsystem

You can use the `apicup` utility to add or reconfigure backup settings for the management subsystem, after completion of initial installation.

About this task

Warning: If you use the S3 backup protocol, changes to the backup settings result in a short period of database downtime.

- After initial installation, use these steps to add or reconfigure the backup settings.
- When you add or reconfigure backups after completion of the initial installation, the steps are the same as configuring during the initial installation, with the addition of using **apicup** to install (activate) the new settings immediately after adjusting the settings. During initial configuration, you typically wait to use **apicup** to activate settings until all other subsystem settings (unrelated to backup) are complete.
- You can add or reconfigure scheduled backups, or generate manual (on-demand) backups.
- When you specify a filepath in a backup setting, be sure to escape any blank spaces in the path.

Note: You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.

Procedure

1. Use **apicup** to specify backup settings:

```
apicup subsys set <subsystem_name> <setting>=<value>
```

Table 1. Configuration settings for backup of management subsystem

Parameter	Description
database-backup-protocol	<p>The type of the backup. Supported types:</p> <ul style="list-style-type: none"> • objstore <pre>apicup subsys set mgmt database-backup-protocol=objstore</pre> <ul style="list-style-type: none"> • sftp <pre>apicup subsys set mgmt database-backup-protocol=sftp</pre> <p>The default value is sftp.</p> <ul style="list-style-type: none"> • local - Local storage backups <pre>apicup subsys set mgmt database-backup-protocol=local</pre> <p>Note:</p> <ul style="list-style-type: none"> • The public certificate on the S3 storage provider must be signed by a known certificate authority that is trusted by API Connect. Use of an untrusted authority can cause the following error during backup upload: x509: certificate signed by unknown authority.
database-backup-auth-pass	<p>The password for the server specified in database-backup-host. If using object store, this would be the S3 Secret Access Key parameter. The password will be stored in Base64 encoded format.</p> <p>For example:</p> <pre>apicup subsys set mgmt database-backup-auth-pass '<password>'</pre> <p>Note that you cannot use the '=' sign to assign the password to database-backup-auth-pass.</p>
database-backup-auth-user	<p>The username for the server specified in database-backup-host. If using object store, this would be the S3 Secret Key ID.</p> <pre>apicup subsys set mgmt database-backup-auth-user <user_name></pre>
database-backup-auth-ssh-key	<p>Version 10.0.3.0 or later: Optional: OpenSSH private key for DB backups using SFTP only. Changing this value will restart the DB.</p> <p>Important:</p> <ul style="list-style-type: none"> • Use apicup certs to set this value. Do not use apicup subsys. • Only OpenSSH keys are supported.¹ <pre>apicup certs set mgmt database-backup-auth-ssh-key <ssh private key filepath></pre>
database-backup-s3provider	<p>When using objstore type backup, specify the name of the S3 provider to use. Specify one of the supported values:</p> <ul style="list-style-type: none"> • ibm • aws • custom <p>Not required for local backups or SFTP backups.</p> <pre>apicup subsys set mgmt database-backup-s3provider=ibm</pre>
database-backup-host	<p>The backups host:</p> <ul style="list-style-type: none"> • For objstore type backup, specify S3 endpoint with the corresponding S3 region in the format <S3endpoint>/<S3region> <pre>apicup subsys set mgmt database-backup-host=s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard</pre> <ul style="list-style-type: none"> • For sftp type, the SFTP server hostname <pre>apicup subsys set mgmt database-backup-host=my.sftp.backup.domain.example.com</pre> <ul style="list-style-type: none"> • Not required for local storage backups

Parameter	Description
<code>database-backup-path</code>	<p>The path to the location of the backup:</p> <ul style="list-style-type: none"> For <code>objstore</code> backups, the name of your S3 bucket to store backup data. For example, <code>bucket-name/folder</code>. The use of subdirectories in the bucket name is not supported. <pre>apicup subsys set mgmt database-backup-path=apic-backup</pre> <p>Note: When your deployment includes a management subsystem in two different clusters (with active databases), the two management subsystems cannot use the same s3 bucket name in the database backup configurations. Each management subsystem must use a unique s3 bucket name.</p> <p>Ensure that <code>bucket-name/folder</code> is empty. If the folder was previously used for backups, the folder will not be empty, and stanza creation might encounter an error.</p> <ul style="list-style-type: none"> Explanation: Once a folder is used, <code>archive.info</code> and <code>backup.info</code> files are created. During stanza creation, the process compares the database version and database system id between the two info files and the current Postgres database cluster. Stanza creation fails if there is a mismatch. To prevent this possibility, remove all files from the folder before configuring. <ul style="list-style-type: none"> For <code>sftp</code> type, the folder name on the SFTP server <pre>apicup subsys set mgmt database-backup-path=<folder_name></pre> <ul style="list-style-type: none"> Not required for local storage backups

<code>database-backup-retries</code>	<p>For <code>sftp</code> type backups, the number of times the <code>ibm-apiconnect</code> Operator attempts backups in the event of a failed SFTP backup.</p> <pre>apicup subsys set mgmt database-backup-retries=3</pre> <p>Default value: 0.</p> <p>Not used for <code>objstore</code> or local storage backup.</p>
<code>database-backup-schedule</code>	<p>Cron like schedule for performing automatic backups. The format for the schedule is:</p> <ul style="list-style-type: none"> * * * * * - - - - - +----- day of week (0 - 6) (Sunday=0) +----- month (1 - 12) +----- day of month (1 - 31) +----- hour (0 - 23) +----- min (0 - 59) <p>The backup schedule defaults to <code>0 0 * * *</code>. This means a backup is run every day at midnight and minute zero.</p> <p>The timezone for backups is UTC.</p> <p>When you configure a host, if you do not specify a value for <code>database-backup-schedule</code>, the default backup schedule is automatically set. Note that the default backup schedule is not set, and scheduled backups not enabled, until host configuration is completed.</p> <pre>apicup subsys set mgmt database-backup-schedule="0 0 * * *"</pre>
<code>backup-certs</code>	<p>Optional. Backup certificates to use for TLS communication between API Connect and the backup server. Supported for custom s3 backups only. Use this setting when you have set <code>database-backup-s3provider=custom</code></p> <p>For example:</p> <pre>apicup subsys set mgmt backup-certs=<certificate_name></pre>
<code>database-backup-s3-uri-style</code>	<p>Optional: Specifies whether the URI is in the form of <code>host</code> or <code>path</code>. Used only with custom s3providers. Use this setting when you have set <code>database-backup-s3provider=custom</code>.</p> <pre>apicup subsys set mgmt database-backup-s3-uri-style='<host path>'</pre> <p>Supported values:</p> <ul style="list-style-type: none"> <code>host</code> <code>path</code>
<code>database-backup-repo-retention-full</code>	<p>The number of full S3 or local backups to retain. Not supported for SFTP.</p> <p>When the next full backup successfully completes, and the specified number of retained backups is reached, the oldest full backup is deleted. All incremental backups and archives associated with the oldest full backup also expire. Incremental backups are not counted for this setting.</p> <p>Applies to both manual backups and scheduled backups.</p> <p>Minimum value: 1</p> <p>Maximum value: 9999999</p> <p>Default: none (S3 backups), 14 (local backups).</p>

Note: To view all subsystem settings for the management subsystem:

```
apicup subsys get <subsystem_name> --validate
```

2. Apply the settings:

```
apicup subsys install <subsystem_name>
```

Note: The `apicup subsys install` command automatically runs `apicup health-check` prior to installing the new configuration. An error is displayed if a problem is found that will prevent successful reconfiguration.

In some scenarios, after you fix the problem, the health check might continue to fail. In this case, you can use the `--skip-health-check` flag to suppress the automatic health check:

```
apicup subsys install <subsystem_name> --skip-health-check
```

3. Ensure that the changes were applied successfully:

```
apicup subsys health-check <subsystem_name>
```

¹ PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see <https://www.puttygen.com/>.

Backing up the management subsystem

Use `apicup` to create a manual backup of the management subsystem

Before you begin

You must have configured backups for the subsystem. See [Configuring backup settings during initial installation of the management subsystem](#)

About this task

Use this task to create an on-demand, or manual, backup of the management system.

To set up scheduled backups, see the `schedule` option in [Configuring backup settings during initial installation of the management subsystem](#).

Procedure

1. Ensure that there are no Management subsystem backups in Running state before creating a new Management backup.
2. Ensure your system is healthy:

```
apicup subsys health-check [subsystem_name]
```

When successful, the command returns silently with an exit code of 0.

3. Make sure that the management cluster status is Running and the READY condition displays the same value before and after the "/>. SSH into the appliance and run `kubectl`:

```
kubectl get mgmt
NAME   READY   STATUS    VERSION   RECONCILED VERSION   AGE
mgmt   16/16   Running   10.0.2.0   10.0.2.0               19h
```

Note: Be sure **READY** status is 16/16. If you have just configured or reconfigured the backup settings, there is a period of time when the postgres pods are taken offline and brought back up with the new configuration. During this time, the `kubectl get mgmt` command will show 11/11 instead of 16/16. If you start a backup before the Management cluster is on 16/16, the backup attempt might stall indefinitely.

4. Create a backup:

```
apicup subsys backup [subsystem_name] [flags]
```

Decide which of the two types of manual backups you want to do:

- **full**: backs up the entire Management subsystem database.

```
apicup subsys backup management --type full
```

- **incr**: backs up any data that has not been backed up since the last **full** or **incr** backup.

```
apicup subsys backup management --type incr
```

To view additional flags, use

```
-h:
```

```
./apicup subsys backup management -h
Backup management subsystem
Usage:
  backup SUBSYS [flags]Flags:
  --debug           Enable debug logging
  -h, --help       help for backup
  --type string    Type of backup to take ['incr' (backup data starting from last backup), 'full' (complete backup)] (default "full")
  --wait           Wait for the operation to complete or fail.
  --wait-timeout duration Command timeout in seconds. (default 40s)
```

Restoring the management subsystem

Use `apicup` to list backups and restore a selected backup of the management subsystem

Before you begin

- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.

- When restoring, the Management, Analytics, and Developer Portal subsystems must be at the same version and fix pack level.
- Restoring the Management Service requires database downtime and is a destructive process that deletes current data and copies backup data. During the restoration process, external traffic must be stopped.
- In a Disaster Recovery scenario, do not log in to the administration UI or attempt to configure or change any settings prior to restoring the backup. Restore the backup immediately after installing the subsystem.
- To restore the management database, you must use the original project directory that was created with `apicup` during the initial product installation. You cannot restore the database without the initial project directory because it contains pertinent information about the cluster. The endpoints and certificates cannot change; the same endpoints and certificates will be used in the restored system. Successful restoration depends on use of a *single apicup* project for all subsystems, even those in a different cluster. Multiple projects will result in multiple certificate chains which will not match.
- Endpoints for the components cannot change between deployments. However, the endpoints for the VMware hosts can be modified for the new deployment.
- Map the DNS entries from the source cluster to the corresponding IP addresses on the target cluster. Record the DNS entries for each endpoint before starting the restore.
- When restoring the management database, the endpoints (on the new cluster which is the target for the restoration) have to be the same as those on the old cluster (the source of the backup).

About this task

Restoring a backup restores the registration credentials (client_ID, client_secret) that were in use at the time that the selected backup was created. For information on the registration credentials, see [Changing the registration client_id and client_secret for applications](#).

Note: There is a known issue where sometimes a restore from the Management subsystem's SFTP backup succeeds but the data is not restored. If this happens, run the restore again.

Procedure

1. To list the available backups:

```
apicup subsys list-backups [subsystem_name] [flags]
```

Example:

```
# apicup subsys list-backups mgmt
NAME                STATUS  ID                CLUSTER  TYPE  CR TYPE  AGE
management-3aa3bebf Ready  20200929-152150F management full record 10h
management-3c4ca8df Ready  20200929-115520F management full record 20h
management-5tbxj    Ready  20200929-224349F management full create 17h
management-f10af337 Ready  20200925-133703F management full record 5d2h
management-jtlcd    Ready  20200929-224349F management full create 25h
management-zxjtz    Ready  20200929-224349F management full create 28h
```

Optional flags:

```
./apicup subsys list-backups -h
List backups of the subsystem
Usage:
  apicup subsys list-backups SUBSYS [flags]
Flags:
  -h, --help                help for list-backups
  --timeout duration        Command timeout in seconds. (default 40s)
Global Flags:
  --accept-license          Accept the license for API Connect
  --debug                   Enable debug logging
```

Attention: You can restore the Management subsystem from any backup where the STATUS is Ready; however, you should avoid restoring to the initial system backup. During installation, the Management database is used for an initial system backup before certain database schema jobs are complete. Restoring to this backup will result in an unstable system.

2. To restore a selected backup:

```
apicup subsys restore [subsystem_name] --name <backup_name> [flags]
```

Example, where `management-zxjtz` is the value of `<backup_name>`, chosen from the backup NAMES listed by `apicup subsys list-backups` in Step 1:

```
apicup subsys restore mgmt --name management-zxjtz
```

Optional flags:

```
apicup subsys restore management -h
Restore management subsystem
Usage:
  restore SUBSYS_NAME [flags]
Flags:
  --debug                   Enable debug logging
  -h, --help                help for restore
  --name string              Name of the backup to restore
  --wait                    Wait for the operation to complete or fail.
  --wait-timeout duration   Command timeout in seconds. (default 40s)
```

3. You can list your restores and their statuses.

```
apicup subsys list-restores [subsystem_name] [flags]
```

To view the optional flags, use `-h`:

```
apicup subsys list-restores -h
List restores of the subsystem
Usage:
```

```
apicup subsys list-restores SUBSYS [flags]
```

Flags:

```
-h, --help                help for list-restores
--timeout duration        Command timeout in seconds. (default 40s)
```

Global Flags:

```
--accept-license        Accept the license for API Connect
--debug                 Enable debug logging
```

Troubleshooting management subsystem backups on VMware

You can troubleshoot failures of the management subsystem backups.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

See:

- [Troubleshooting resiliency issues](#)
Resolve resiliency issues with API Connect management system backups.
- [Troubleshooting stanza-create job for S3 backup configuration](#)
Troubleshoot configuration of s3 backups when the stanza-create job fails.

Troubleshooting resiliency issues

Resolve resiliency issues with API Connect management system backups.

pgbackrest-shared-repo resiliency problems

If the Kubernetes node hosting pgbackrest-shared-repo pod is down and the PVC attached to the pod has strict zone requirements (for example, in AWS or other clouds) or if the storage class is set to `local-storage`, then pgbackrest-shared-repo pod will not get rescheduled to another Kubernetes node.

As a result, there is a single point of failure and the following conditions might occur:

- Backups of the management database fails
- Disk space fills with accumulated Postgres wal (Write-Ahead Logging) files

To avoid this problem, monitor the disk usage: [Monitoring Postgres disk usage on VMware](#).

When the Kubernetes node comes back up, the pod is scheduled and all the processes should resume properly.

Troubleshooting stanza-create job for S3 backup configuration

Troubleshoot configuration of s3 backups when the stanza-create job fails.

When you configure Management subsystem backups for s3 providers, the operator runs a `stanza-create` job. This job creates the stanza (Postgres cluster configuration) on the upstream S3 server, which is used for backup and archive procedures. The job also brings up the necessary pod.

SSH into the appliance VM, and check the status of the `stanza-create` job:

```
kubectl get jobs -n <namespace> | grep stanza
```

On failure:

- `stanza-create` pods fail, and job status is 0/1:

```
kubectl get jobs | grep stanza
m1-3bfe12ac-postgres-stanza-create      0/1      32m      32m
```

- Listing all pods brought up by `stanza-create` job shows multiple pods because a job tries `backoffLimit` times to complete the job. By default, there will be 7 pods in error state:

```
kubectl get pods | grep stanza
m1-3bfe12ac-postgres-stanza-create-726z4      0/1      Error    0      11m
m1-3bfe12ac-postgres-stanza-create-9vq4n      0/1      Error    0      22m
m1-3bfe12ac-postgres-stanza-create-gbtgb      0/1      Error    0      30m
m1-3bfe12ac-postgres-stanza-create-g15g5      0/1      Error    0      17m
m1-3bfe12ac-postgres-stanza-create-q8qhw      0/1      Error    0      26m
m1-3bfe12ac-postgres-stanza-create-t84zs      0/1      Error    0      8m54s
m1-3bfe12ac-postgres-stanza-create-z8tfs      0/1      Error    0      12m
```

Note: In some cases, the pods are cleaned by Kubernetes and the logs of these pods can be lost.

- Pod log errors show a reason for the failure. For example, when a hostname is not valid:

```
kubectl logs m1-3bfe12ac-postgres-stanza-create-gbtgb
```

```

time="2021-04-13T20:01:19Z" level=info msg="pgo-backrest starts"
time="2021-04-13T20:01:19Z" level=info msg="debug flag set to false"
time="2021-04-13T20:01:19Z" level=info msg="backrest stanza-create command requested"
time="2021-04-13T20:01:19Z" level=info msg="s3 flag enabled for backrest command"
time="2021-04-13T20:01:19Z" level=info msg="command to execute is [pgbackrest stanza-create --db-host=192.1.2.3 --db-path=/pgdata/m1-3bfel2ac-postgres --repol-type=s3]"
time="2021-04-13T20:01:19Z" level=info msg="command is pgbackrest stanza-create --db-host=192.1.2.3 --db-path=/pgdata/m1-3bfel2ac-postgres --repol-type=s3"
time="2021-04-13T20:05:21Z" level=error msg="command terminated with exit code 49"
time="2021-04-13T20:05:21Z" level=info msg="output=[]"

```

- Job status is set to `type: Failed` and `status: "True"`, with reason: `BackoffLimitExceeded`:

```

kubect1 get job m1-3bfel2ac-postgres-stanza-create -o yaml

status:
  conditions:
  - lastProbeTime: "2021-04-13T20:28:03Z"
    lastTransitionTime: "2021-04-13T20:28:03Z"
    message: Job has reached the specified backoff limit
    reason: BackoffLimitExceeded
    status: "True"
    type: Failed
    failed: 7
  startTime: "2021-04-13T20:01:18Z"

```

- If pod logs are lost, you can execute a command inside the `backrest-shared-repo` pod:
 1. Obtain the `backrest-shared-repo` pod name:

```
kubect1 get pods -n <namespace> | grep backrest-shared-repo
```

For example:

```
kubect1 get pods | grep backrest-shared-repo
m1-eb8edc18-postgres-backrest-shared-repo-98dd46cc6-tw195 1/1 Running
```

2. Exec into the pod:

```
kubect1 exec -it <backrest-shared-repo-pod> -- bash
```

3. Run:

```
pgbackrest info --output json --repol-type s3
```

For example, for invalid hostname:

```
ERROR: [049]: unable to get address for 'test1-v10-backup.s3.exampleaws.com': [-2] Name or service not knownCopy
```

The exact **ERROR**: will vary depending on the misconfiguration. Common errors:

```

Invalid access key
Invalid access key secret
Invalid bucket region
Invalid bucket or folder path

```

- To fix the incorrect settings, see [Reconfiguring backup settings for the management subsystem](#).

Backing up and restoring the Developer Portal

You can backup and restore a Developer Portal in a VMware environment.

About this task

It is strongly recommended that you configure the backup parameters for your portal service during installation. If you did not do so when you installed API Connect in your runtime environment, you must configure the backups for the Developer Portal before performing an upgrade. These backups can then be used to restore the Developer Portal if required. When your Developer Portal subsystem is running, you can also make on-demand backups by using the command line.

Note:

- You must backup both the Management and Portal subsystems at the same time, to ensure synchronicity across the services.
- When restoring, the Management, Analytics, and Developer Portal subsystems must be at the same version and fix pack level.

The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

- To complete a backup and restore of your Portal Subsystem, you must use `apicup` to configure the backup settings.
- Backups can be scheduled or generated manually (on-demand).
- You can then list the available backups are available and select one to restore your Portal Subsystem when necessary.

- Supported backup types:
 - Cloud-based S3 storage
 - IBM Cloud Object Storage
 - AWS S3
 - SFTP
- [Configuring backup settings for the Developer Portal subsystem](#)
You can use the `apicup` utility to configure backup settings for the Developer Portal subsystem
- [Backing up the Developer Portal subsystem](#)
After you have configured backup settings, you can use `apicup` to create a manual backup of the Developer Portal.
- [Restoring the Developer Portal subsystem](#)
You can use `apicup` to restore the Developer Portal subsystem.

Configuring backup settings for the Developer Portal subsystem

You can use the `apicup` utility to configure backup settings for the Developer Portal subsystem

Before you begin

Review [Backing up and restoring the Developer Portal](#).

About this task

- During an initial installation, use these steps to configure the backup settings prior to creating the initial management ISO.
- You can configure scheduled backups, or generate manual (on-demand) backups.
- When you specify a filepath in a backup setting, be sure to escape any blank spaces in the path.
- Version 10.0.3.0 or later:** OpenSSH key authentication for SFTP is supported.

The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

Tip: If you are using remote backups, and there are a large number of rows in your `portalbackup` list that have a `CR TYPE` of `record`, there might be a slow down in system performance, including during Developer Portal upgrades. Although there is no upper limit to how many portal backups you can have, it is recommended that you prune your remote backups so that the number of rows does not become excessively large. One `portalbackup` row of type `record`, corresponds to one backup file on the configured remote backup server. For more information, see [Overview of the Developer Portal backup resources](#).

Procedure

- Open your API Connect installation project directory.
- Run the following commands to set the location and timing of your backups:

```
apicup subsys set <subsystem_name> <setting>=<value>

apicup subsys set pt1 site-backup-host=mybackuphost.com
apicup subsys set pt1 site-backup-port=22
apicup subsys set pt1 site-backup-auth-user=mybackupauthusername
apicup subsys set pt1 site-backup-auth-pass=mybackupauthpassword
apicup subsys set pt1 site-backup-path=/site-backups
apicup subsys set pt1 site-backup-protocol=sftp
apicup subsys set pt1 site-backup-certs=<custom-s3-server-CA-cert>
apicup subsys set pt1 site-backup-s3-uri-style=<host-or-path>
apicup subsys set pt1 site-backup-schedule="0 2 * * *"
apicup subsys set pt1 site-priority-list=portal.a1.example.com/test-1/spacecatalog,portal.a1.example.com/test-4/cat3,portal.a1.example.com/test-3/cat1
```

Use `apicup certs` instead of `apicup subsys` to configure ssh-key authentication for SFTP:

```
apicup certs set pt1 site-backup-auth-ssh-key <ssh-key-file-path>
```

The backup parameters are detailed in the following table.

Table 1. Portal backup parameters

Parameter	Description
<code>site-backup-host</code>	<p>The fully qualified domain name of the backup server, in lowercase only.</p> <ul style="list-style-type: none"> For <code>objstore</code> type backup, specify the S3 endpoint with the corresponding S3 region in the format <code><S3endpoint></code>, or with an optional S3 region in the format <code><S3endpoint>/<S3region></code>. <pre>apicup subsys set pt1 site-backup-host=s3.eu-gb.cloud-object-storage.appdomain.cloud</pre> <ul style="list-style-type: none"> For <code>sftp</code> type, the SFTP server hostname <pre>apicup subsys set pt1 site-backup-host=my.sftp.backup.domain.example.com</pre>

Parameter	Description
<code>site-backup-port</code>	<p>The port for the protocol to connect to the <code>site-backup-host</code>. Defaults to <code>22</code> if not explicitly set. The backup port is not required for object storage but if specified, is typically port <code>443</code>.</p> <pre>apicup subsys set ptl site-backup-port=22</pre>
<code>site-backup-auth-user</code>	<p>The user name for the server specified in <code>site-backup-host</code>. If using object storage, the user name is the S3 Secret Key ID.</p> <pre>apicup subsys set ptl site-backup-auth-user=<user_name></pre>
<code>site-backup-auth-pass</code>	<p>The password for the server specified in <code>site-backup-host</code>. If using object storage, the password is the S3 Secret Access Key parameter. The password is stored in Base64 encoded format, and must not be edited directly in the <code>apiconnect-up.yml</code> file.</p> <pre>apicup subsys set ptl site-backup-auth-pass=password</pre>
<code>site-backup-auth-ssh-key</code>	<p>Version 10.0.3.0 or later: OpenSSH key for database backups by using SFTP. Important:</p> <ul style="list-style-type: none"> Use <code>apicup certs</code> to set this value. Do not use <code>apicup subsys</code>. Only OpenSSH keys are supported.¹ <pre>apicup certs set ptl site-backup-auth-ssh-key=<ssh-key-file-path></pre>
<code>site-backup-path</code>	<p>The location of where the backups are stored:</p> <ul style="list-style-type: none"> S3 - the name of your S3 bucket to store backup data, optionally followed by a <code>/</code> and then any subdirectories inside the bucket. Valid examples: <pre>bucket bucket/path bucket/lots/of/paths</pre> <p>Example:</p> <pre>apicup subsys set ptl site-backup-path=apic-backup</pre> <ul style="list-style-type: none"> SFTP - the full absolute path of the folder on the SFTP server, beginning with <code>/</code>. <pre>apicup subsys set ptl site-backup-path=</folder></pre>
<code>site-backup-protocol</code>	<p>The protocol that is used to communicate with your remote backup endpoint. Specify one of the following values:</p> <ul style="list-style-type: none"> <code>sftp</code> - for secure file transfer protocol <code>local</code> - for local storage <code>objstore</code> - for S3 compatible object storage <p>Starting with v10.0.3.0, the default protocol is <code>local</code> (earlier releases used <code>sftp</code> as the default). For example:</p> <pre>apicup subsys set ptl site-backup-protocol=local</pre>
<code>site-backup-certs</code>	<p>The name of a custom certificate that contains your upstream custom S3 CA certificate. Supported beginning with 10.0.2. This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be <code>ca.crt</code> and the value is the base64-encoded value of the CA certificate.</p> <p>If the server certificate that is presented by your S3/object-store endpoint is signed by a well known CA and includes any intermediate certificates in the chain, then you do not need to provide the CA certificate using this feature because the Portal subsystem already trusts the server certificate. You can test this by configuring the Portal backup to your S3/object-store server without providing the CA certificate.</p> <p>If you do need to provide the CA certificate then you must provide the entire chain in the <code>ca.crt</code> member of the secret, as follows:</p> <pre>intermediate-certificate-1 intermediate-certificate-2 . . intermediate-certificate-n root-certificate</pre> <p>Where the first certificate in the <code>ca.crt</code> member (intermediate-certificate-1) is the issuer of the S3/object-store server certificate, and each subsequent certificate in the <code>ca.crt</code> member is the issuer of the preceding certificate. The root certificate in the <code>ca.crt</code> member must be self-signed.</p> <p>If there are no intermediate certificates involved, then the <code>ca.crt</code> member contains only the root certificate.</p> <p>The following sample bash script creates a Kubernetes secret:</p> <pre>cat >customs3ca.yaml <<EOF apiVersion: v1 data: ca.crt: \$(base64 <path-to-ca-certificate> tr -d '\n') kind: Secret metadata: name: custom-server-ca type: generic EOF</pre> <pre>kubectl apply -f customs3ca.yaml -n <namespace></pre>
<code>site-backup-s3-uri-style</code>	<p>Optional. Indicates whether URIs to your S3 backup should use specify a host or a path value. When not specified, defaults to <code>host</code>. Supported beginning with 10.0.2. Valid values: <code>host</code> and <code>path</code>.</p> <p>Some custom S3 providers require URI style to be set to <code>path</code>. For example, MinIO supports both <code>host</code> and <code>path</code> style setup. You can create a MinIO S3 server to only accept <code>path</code> style client communications.</p> <p>Important: Contact your custom S3 administrator before configuring this field. If not properly configured, an upstream custom S3 can reject connections from the client, such as the API Connect Management subsystem.</p>

Parameter	Description
<code>site-backup-schedule</code>	<p>The schedule for how often automatic Portal backups are run. The format for the schedule is any valid cron string, as follows:</p> <pre>* * * * * - - - - - +----- day of week (0 - 6) (Sunday=0) +----- month (1 - 12) +----- day of month (1 - 31) +----- hour (0 - 23) +----- min (0 - 59)</pre> <p>For example: <code>30 22 * * 1</code> performs backups at 10:30 pm on Mondays. The default backup schedule is <code>0 2 * * *</code> (runs every day at 2 am).</p> <p>The timezone for backups is UTC.</p> <pre>apicup subsys set pt1 site-backup-schedule="0 2 * * *"</pre>
<code>site-priority-list</code>	<p>Optional list of prioritized sites to restore. Default: empty.</p> <pre>apicup subsys set <portal-subsystem-name> site-priority-list <comma-separated-list-of-sites></pre> <p>For example:</p> <pre>apicup subsys set pt1 site-priority-list portal.a1.example.com/e2etest-1/spacecatalog,portal.a1.example.com/e2etest-4/cat3,portal.a1.example.com/e2etest-3/cat1</pre>

3. At any time you can view the current Portal subsystem values:

- For most values:

```
apicup subsys get pt1
```

where `pt1` is the name that you assigned to your Portal service. The output from this command lists all of the subsystem settings, including backup, and indicates whether there are any errors. You must fix any errors before continuing.

- For ssh-key authentication for SFTP:

```
apicup certs get pt1 site-backup-auth-ssh-key
```

4. Activate the backup settings by running the following command:

```
apicup subsys install pt1
```

where `pt1` is the name that you assigned to your Portal service.

Note: The `apicup subsys install` command automatically runs `apicup health-check` prior to installing the new configuration. An error is displayed if a problem is found that will prevent successful reconfiguration.

In some scenarios, after you fix the problem, the health check might continue to fail. In this case, you can use the `--skip-health-check` flag to suppress the automatic health check:

```
apicup subsys install <subsystem_name> --skip-health-check
```

5. Validate the installation with the new backup parameters by running the following command:

```
apicup subsys get pt1 --validate
```

where `pt1` is the name that you assigned to your Portal service. The output from this command lists all of the subsystem settings, including backup, and indicates whether the values are valid or invalid. You must correct any invalid values before continuing.

6. Ensure that the changes were applied successfully:

```
apicup subsys health-check <subsystem_name>
```

- [Overview of the Developer Portal backup resources](#)

How to manage your Developer Portal remote backup resources.

¹ PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see <https://www.puttygen.com/>.

Overview of the Developer Portal backup resources

How to manage your Developer Portal remote backup resources.

Note: This information is relevant only if you're taking remote Developer Portal backups.

The Developer Portal uses two types of portal backup resources. When you run the command `kubect1 get portalbackup`, you see a list of backups, for example:

NAME	ID	TASK ID	STATUS	TYPE	CR TYPE	CLUSTER	AGE	COMMENT
<code>my-backup-f91ms</code>	n/a	20b47fe090f5	Ready	system	create	portal	78m	
<code>portal-record-222cg</code>	20220108.010033		Ready	system	record	portal	94m	
<code>portal-record-222xdc</code>	20220702.010339		Ready	site	record	portal	9m49s	
<code>portal-record-245j7</code>	20221002.010340		Ready	site	record	portal	5m	
<code>portal-record-246hm</code>	20221218.010103		Ready	site	record	portal	32m	
<code>portal-record-24h44</code>	20220509.010037		Ready	site	record	portal	68m	
<code>portal-record-24wb4</code>	20221003.010029		Ready	site	record	portal	60m	
<code>portal-record-264mh</code>	20221119.010453		Ready	system	record	portal	78m	

There are two types of resources listed, and these are denoted by the `CR TYPE` column; `create` or `record` types.

1. **create**: This resource is a representation of a `portalbackup` task that was created manually. See [Backing up and restoring the Developer Portal in a Kubernetes environment](#), [Backing up Developer Portal on OpenShift and Cloud Pak for Integration](#), or [Backing up the Developer Portal subsystem](#) on VMware, for information about how to create a manual portal backup.
2. **record**: This resource is generated by the operator, and it's a representation of a backup file that's stored on the remote backup server. A record listing can be modified only to add a comment to it. You can describe each record to understand which file it is referring to by running the following command:

```
kubectl describe portalbackup portal-record-name
```

For example:

```
kubectl describe portalbackup portal-record-zmmfw
.
.
Name:          portal-record-zmmfw
Namespace:    apic
Labels:       createdBy
.
.
Full Backup Name:  my-portal-s3-hostname@my-porg@catal-20220604.010302.tar.gz
```

Record rows are generated and updated on a schedule, according to the backups that exist on your remote backup server. If you have 10 backup files stored on your remote server, then there will be 10 record rows; one row for each file.

The Developer Portal doesn't have a retention policy for remote backups. Therefore, it's your responsibility to ensure that you're keeping the number of backups that are stored remotely under control. An excessive number of portal backups results in delays administrating and upgrading the Developer Portal. This is due to the operator needing to maintain the excessive number of record rows that correspond to each remote portal backup.

Backing up the Developer Portal subsystem

After you have configured backup settings, you can use `apicup` to create a manual backup of the Developer Portal.

About this task

You can make on-demand backups of your Developer Portal system, sites, and complete service, by running the following `apicup` commands in your API Connect installation project directory.

The default Developer Portal backup schedule is once every 24 hours, but the schedule can be changed in the backup settings. The Developer Portal saves all system and site backups locally, and also saves them remotely based on the configured SFTP and s3 settings.

The local backups are automatically maintained so that the latest three backups of each site and of the system are kept, and older backups are removed. This maintenance means that the Developer Portal retains the latest three backups for each site and for the system however old they are, but there is no deletion of the old backups on the remote server. If a site is deleted, then all of the local backups for that site are also deleted, as otherwise the backup volume might become full of old site backups. For remote backups, you can configure a retention policy on your remote server to remove the old backup files as required.

Tip: If you are using remote backups, and there are a large number of rows in your `portalbackup` list that have a `CR TYPE` of `record`, there might be a slow down in system performance, including during Developer Portal upgrades. Although there is no upper limit to how many portal backups you can have, it is recommended that you prune your remote backups so that the number of rows does not become excessively large. One `portalbackup` row of type `record`, corresponds to one backup file on the configured remote backup server. For more information, see [Overview of the Developer Portal backup resources](#).

Procedure

1. Ensure your system is healthy:

```
apicup subsys health-check [subsystem_name]
```

When successful, the command returns silently with an exit code of 0.

2. Create a backup:

```
apicup subsys backup [subsystem_name] [flags]
```

- To backup the Portal system configuration (and not the sites), run the following command:

```
apicup subsys backup ptl --type system
```

- To backup a specific Portal site or all sites, run the following command:

```
apicup subsys backup ptl --type site --site-name arg
```

where *arg* is a specific site UUID or URL, or to backup all sites use the argument `installed`.

- To backup the entire Portal service (the system and all installed sites), run the following command:

```
apicup subsys backup ptl
```

Where *ptl* is the name that you assigned to your Portal service.

Note: To restore a Developer Portal service, you need backups of both the Portal system and the installed sites.

To view additional flags, use `-h`:

```
apicup subsys backup portal -h
Backup portal subsystem
```

```
Usage:
  backup SUBSYS [flags]
```

```

Flags:
--comment string      Comment to add to the backup CR before creation
--debug              Enable debug logging
-h, --help            help for backup
--site-name string    Site to restore to the remote server if TYPE=site. Accepts site uuid/url or 'installed' to
backup all installed sites.
--type string         Type of backup to take ['system' (backup Portal System), 'site' (backup Portal Site),
'all' (complete backup)] (default "all")
--wait               Wait for the operation to complete or fail.
--wait-timeout duration Command timeout in seconds. (default 40s)

```

3. To view the available backups and their status:

```
apicup subsys list-backups [subsystem_name] [flags]
```

Optional flags:

```

./apicup subsys list-backups -h
List backups of the subsystem
Usage:
  apicup subsys list-backups SUBSYS [flags]
Flags:
  -h, --help            help for list-backups
  --timeout duration    Command timeout in seconds. (default 40s)
Global Flags:
  --accept-license      Accept the license for API Connect
  --debug               Enable debug logging

```

Restoring the Developer Portal subsystem

You can use `apicup` to restore the Developer Portal subsystem.

About this task

You can restore your Developer Portal service by using the backups that exist on your remote server, by running the following `apicup` commands in your API Connect installation project directory. Note that before you can run these commands, you must have configured your remote backup server details, and have valid backups of both the Portal system and the installed sites. See [Configuring backup settings for the Developer Portal subsystem](#) and [Backing up the Developer Portal subsystem](#).

Note:

- If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. The backups of the Management and Portal must be taken at the same time to ensure that the Portal sites are consistent with Management database.
- Restoration requires a functioning Developer Portal. In a disaster recovery scenario, you might need to reinstall the Developer Portal subsystem before you can restore the backed-up data. For disaster recovery, see [Recovering the Developer Portal subsystem on VMware](#).

Procedure

1. To view the available backups and their status:

```
apicup subsys list-backups subsystem_name [flags]
```

Optional flags:

```

./apicup subsys list-backups -h
List backups of the subsystem
Usage:
  apicup subsys list-backups SUBSYS [flags]
Flags:
  -h, --help            help for list-backups
  --timeout duration    Command timeout in seconds. (default 40s)
Global Flags:
  --accept-license      Accept the license for API Connect
  --debug               Enable debug logging

```

2. Review which restore actions will be performed

To see what restore actions are performed when the `apicup subsys restore ptl` command is run, you can use the following command:

```
apicup subsys restore ptl --dry-run --timestamp [now|YYYYMMDD.HHMMSS]
```

where `--timestamp` can be `now`, so the latest backup file that is available is used. Or you can specify a timestamp in the format of `YYYYMMDD.HHMMSS` to retrieve the nearest backup file to a specified time, searching backwards from the timestamp given.

Note:

- From IBM® API Connect Version 10.0.3.0, the timestamp format changed to `YYYYMMDD.HHMMSS`. For Version 10.0.2.0 and earlier, the timestamp format is `YYYY-MM-DD HH:MM:SS`.

- With the `--dry-run` option, the utility runs through the restore steps without executing them. You can use this option to see if the restore from the selected backup will succeed.

The `--dry-run` option starts with the following output message:

```
Starting restore...please check later for completion status of restore
PortalRestore is Running
```

To view the results of the dry-run, you can either look in the portal restore CR for a message of completion (or failure) or you can get a high-level status by entering:

```
apicup subsys list-restores <subsys_name>
```

Status values can be: **Ready**, **Completed**, **Failed** or **Running**.

3. Run the following command, and attach any flags as appropriate.

```
apicup subsys restore [SUBSYS_NAME] [flags]
```

- To restore your Portal service, run the following command:

```
apicup subsys restore ptl --timestamp [now|YYYYMMDD.HHMMSS]
```

where `--timestamp` can be `now`, so the latest backup file that is available is used. Or you can specify a timestamp in the format of `YYYYMMDD.HHMMSS` to retrieve the nearest backup file to a specified time, searching backwards from the timestamp given. This command executes the portal restore process, which downloads the system backup and all of the site backups from the remote server, and installs them within the Portal stack. This process will then restore the system configuration from the found backup, and restore all of the sites. Note that if a backed up site is already installed on the current stack, then the site is reinstalled by using the backup (the site is overwritten by the backup). If there are multiple sites to restore, then these sites are queued for restoring. You can track the restoration process within the Portal `www admin` logs.

- By default the restore is a complete restore. You can optionally include `--type all` on the command line to specify a complete restore, but the flag is not required, as a complete restore is performed by default. Note that a complete restore supports only remote restores. Note that the complete restore uses the `priorityList` configuration setting that you specified in [Configuring backup settings for the Developer Portal subsystem](#).

- To restore just the Portal system configuration, run the following command:

```
apicup subsys restore ptl --type system --system-name arg
```

where `arg` can be a `.tgz` name or also accepts `backup ID` if `TYPE=system` and `CR TYPE=record` from the `list-backups` command.

Note that if Portal system configuration information exists on the current stack, running this command will overwrite that configuration.

- To restore just the Portal sites, run the following command:

```
apicup subsys restore ptl --type site --site-name arg
```

where `arg` can be the site backup `tgz` file name or URL, to restore a particular site by using the specified backup ID (or the latest backup file found if using a URL). Or you can use the argument `all` to restore all of the Portal sites that have backup files on the remote server. Note that if any of the backed up sites are already installed on the current stack, then they are reinstalled by using the backup (the sites are overwritten by the backup).

```
> ./apicup subsys restore <portal> -h
Restore portal subsystem
```

Usage:

```
restore SUBSYS [flags]
```

Flags:

```
--custom-platform-api-hostname string  The custom platform API hostname to override for the portal system when
restoring it. Used only when performing a portal restore system or portal restore all.
--custom-url string                    The custom URL to override for the portal site when restoring it. Used only
when performing a portal site restore.
--debug                                Enable debug logging
--dry-run                               Runs a dry run of the command, returning the actions that will be taken.
-h, --help                             help for restore
--site-name string                     File to restore site from which should exist on the pod's local filesystem
or the remote server. Also accepts backup ID if TYPE=site and CR TYPE=record.
--system-name string                   File to restore system from which should exist on the pod's local filesystem
or the remote server. Also accepts backup ID if TYPE=system and CR TYPE=record.
--timestamp string                     In YYYYMMDD.HHMMSS format, specify a timestamp to retrieve the backup from.
The nearest backup, searching backwards from this timestamp, is used.
--type string                           Type of restore to take ['system' (restore Portal System), 'site' (restore
Portal Site), 'all' (complete restore)] (default "all")
--wait                                  Wait for the operation to complete or fail.
--wait-timeout duration                 Command timeout in seconds. (default 40s)
```

4. To view your restores and their statuses, run:

```
apicup subsys list-restores <subsys_name> <flags>
```

Help output:

```
apicup subsys list-restores -h
List restores of the subsystem
```

Usage:

```
apicup subsys list-restores SUBSYS [flags]
```

Flags:

```
-h, --help                help for list-restores
--timeout duration        Command timeout in seconds. (default 40s)
```

Global Flags:

```
--accept-license  Accept the license for API Connect
--debug           Enable debug logging
```

5. To list the Portal backup sites, use the Portal CLI command. See [Using the sites commands](#).

6. To list the Portal system sites, use the Portal CLI command. See [Using the platforms commands](#).

Backing up and restoring the Analytics database on VMware

The IBM® API Connect Analytics database can be backed up and restored from an S3 repository. S3 compatible object storage is required; for example, IBM Cloud Object Storage.

About this task

Begin by configuring your backup configuration, which optionally includes a schedule if you want to automate your backups. You can run backups manually as needed. To restore a backup, review the set of available backups, and then restore the selected backup.

Note: On a v10.0.5 API Connect deployment, you can restore only analytics backups that were taken from a v10.0.5 analytics deployment. You cannot restore analytics backups that were taken from a deployment that was on v10.0.4 or an earlier release.

- [Configuring backup settings for Analytics](#)
Use the `apicup` utility to configure backup settings for the Analytics database in your VMware environment.
- [Running a backup of the Analytics database](#)
Initiate a backup of the API Connect Analytics database on VMware.
- [Restoring the Analytics database](#)
Restore a selected backup of the IBM API Connect Analytics database on VMware.

Configuring backup settings for Analytics

Use the `apicup` utility to configure backup settings for the Analytics database in your VMware environment.

About this task

The Analytics database can be backed up and restored from an S3 repository. S3-compatible object storage is required; for example, IBM Cloud Object Storage.
Note:

- Only host-style S3 backups are supported. Path-style S3 backups are not supported.
- If you are using a self-managed S3 backup server, check that you have a DNS hostname entry and matching TLS certificate for your S3 backup endpoint.
- When you specify a filepath in a backup setting, be sure to escape any blank spaces in the path.

Procedure

1. Use the `apicup` utility to configure the backup settings.
Configure each setting by running the following command with the key and value from Table 1 that you want to apply:

```
apicup subsys set <analytics_subsystem> <key> <value>
```

Table 1 shows the supported backup settings with the default value (if any) and a description of each setting.

Table 1. Analytics backup settings

Key	Default value	Description
<code>analytics-backup-auth-pass</code>		Server password for Analytics backups.
<code>analytics-backup-auth-user</code>		Server user name for Analytics backups.
<code>analytics-backup-host</code>		The S3 endpoint with the corresponding S3 region in the format: <code>s3.s3region.s3domain</code> For example: <code>s3.eu-gb.cloud-object-storage.appdomain.cloud</code> Attention: A path style host value (formatted as <code>S3endpoint/S3region</code>) is not supported for AWS.

Key	Default value	Description
<code>analytics-backup-certs</code>		<p>The name of a custom certificate that contains your upstream custom S3 CA certificate. This field accepts name of the Kubernetes secret containing your upstream custom S3 CA certificate. The key of the secret must be <code>ca.crt</code> and the value is the base64-encoded value of the CA certificate.</p> <p>If the server certificate that is presented by your S3/object-store endpoint is signed by a well known CA and includes any intermediate certificates in the chain, then you do not need to provide the CA certificate using this feature because the Portal subsystem already trusts the server certificate. You can test this by configuring the Portal backup to your S3/object-store server without providing the CA certificate.</p> <p>If you do need to provide the CA certificate then you must provide the entire chain in the <code>ca.crt</code> member of the secret, as follows:</p> <pre>intermediate-certificate-1 intermediate-certificate-2 . . intermediate-certificate-n root-certificate</pre> <p>Where the first certificate in the <code>ca.crt</code> member (intermediate-certificate-1) is the issuer of the S3/object-store server certificate, and each subsequent certificate in the <code>ca.crt</code> member is the issuer of the preceding certificate. The root certificate in the <code>ca.crt</code> member must be self-signed.</p> <p>If there are no intermediate certificates involved, then the <code>ca.crt</code> member contains only the root certificate.</p> <p>The following sample bash script creates a Kubernetes secret:</p> <pre>cat >customs3ca.yaml <<EOF apiVersion: v1 data: ca.crt: \$(base64 <path-to-ca-certificate> tr -d '\n') kind: Secret metadata: name: custom-server-ca type: generic EOF</pre> <pre>kubectl apply -f customs3ca.yaml -n <namespace></pre>
<code>analytics-backup-path</code>		A combination of the S3 bucket and the base path within the bucket, using the format: <code>bucket_name/path</code>
<code>analytics-backup-chunk-size</code>	1GB	(Optional) Specifies how large files are stored. Large files can be stored as chunks when the snapshot is created. This setting specifies the size of the chunks as GB, MB, or KB.
<code>analytics-backup-schedule</code>	0 2 ***	(Optional) Determines how often backups will be invoked automatically. The format for the schedule is any valid <code>cron</code> string. The timezone for backups is UTC. Backing up once a day is probably sufficient; remember that the more frequently you run backups, the more storage space you need.
<code>analytics-enable-compression</code>	true	(Optional) Determines whether metadata files are stored in compressed format.
<code>analytics-enable-server-side-encryption</code>	false	(Optional) Determines whether files are encrypted. When set to true, files are encrypted on the server side using AES256.

2. Validate the backup settings by running the following command:

```
apicup subsys get <analytics_subsystem> --validate
```

3. Apply the backup settings to the Analytics subsystem by reinstalling with the following command:

```
apicup subsys install <analytics_subsystem>
```

Note: The `apicup subsys install` command automatically runs `apicup health-check` prior to installing the new configuration. An error is displayed if a problem is found that will prevent successful reconfiguration.

In some scenarios, after you fix the problem, the health check might continue to fail. In this case, you can use the `--skip-health-check` flag to suppress the automatic health check:

```
apicup subsys install <subsystem_name> --skip-health-check
```

4. Verify that the backup settings were successfully applied by running the following command:

```
apicup subsys health-check <analytics_subsystem>
```

Running a backup of the Analytics database

Initiate a backup of the API Connect Analytics database on VMware.

About this task

Procedure

1. Perform a health check of your Analytics system by running the following command:

```
apicup subsys health-check <analytics_subsystem>
```

If successful, the command returns silently with exit code 0.

2. Start the backup by running the following command and including the appropriate flags:

```
apicup subsys backup <analytics_subsystem>
```

View the list of supported flags by running the `backup` command with the `-h` (help) flag, as shown in the following example:

```
apicup subsys backup analytics -h
Backup analytics subsystem
```

```
Usage:
  backup SUBSYS [flags]
```

```
Flags:
  --comment string      Comment to add to the backup CR before creation
  --debug              Enable debug logging
  -h, --help           help for backup
  --ignore-unavailable If false, the backup will fail if an index is missing. If true, missing indices will be
skipped and the backup will continue.
  --indices strings    Indice(s) you'd like to backup (all/apievents/ui). It can be set to any combination of
indices (e.g. ui or ui,apievents).
  --wait              Wait for the operation to complete or fail.
  --wait-timeout duration Command timeout in seconds. (default 40s)
```

Note: The `--indices` flag can be set to `all|apievents|ui`, or to the names of individual indexes. `all` includes `apievents` and `ui` indexes. Multiple values can be supplied with a comma-separated list. For example, to backup all UI data and all data from August of 2022:

```
--indices ui, "apic-api-2022.08*"
```

3. Optionally view a list of available backups, and the status of each, by running the following command:

```
apicup subsys list-backups <analytics_subsystem>
```

View the list of supported flags by running the `list-backups` command with the `-h` (help) flag, as shown in the following example:

```
apicup subsys list-backups -h
List backups of the subsystem
```

```
Usage:
  apicup subsys list-backups SUBSYS [flags]
```

```
Flags:
  -h, --help           help for list-backups
  --timeout duration  Command timeout in seconds. (default 40s)
```

```
Global Flags:
  --accept-license  Accept the license for API Connect
  --debug          Enable debug logging
```

Restoring the Analytics database

Restore a selected backup of the IBM® API Connect Analytics database on VMware.

About this task

Use the `apicup` utility to view the list of available backups for the Analytics database, and then restore a selected backup.

Procedure

1. Retrieve a list of available backups, and the status of each, by running the following command:

```
apicup subsys list-backups <analytics_subsystem>
```

View the list of supported flags by running the `list-backups` command with the `-h` (help) flag, as shown in the following example:

```
apicup subsys list-backups -h
List backups of the subsystem
```

```
Usage:
  apicup subsys list-backups SUBSYS [flags]
```

```
Flags:
  -h, --help           help for list-backups
  --timeout duration  Command timeout in seconds. (default 40s)
```

```
Global Flags:
  --accept-license  Accept the license for API Connect
  --debug          Enable debug logging
```

The response includes the unique ID of each backup. Note the ID of the backup that you want to restore, so you can use it in the next step.

2. Restore a backup by running the following command with the appropriate flags:

```
apicup subsys restore <analytics_subsystem>
```

View the complete list of supported flags by running the `restore` command with the `-h` (help) flag, as shown in the following example:

```
apicup subsys restore analytics -h
Restore analytics subsystem
```

Usage:

```
restore SUBSYS [flags]
```

Flags:

```
--debug          Enable debug logging
-h, --help       help for restore
--id string       ID of the backup to restore
--ignore-unavailable If false, the restore will fail if an index is missing. If true, missing indices will be
skipped and the restore will continue.
--indices strings Indice(s) you'd like to restore (all/apievents/ui). It can be set to any combination of
indice(s) (eg. ui or ui,apievents) (default [all])
--override        If set to true, then the restore operation will override existing indices.
--wait            Wait for the operation to complete or fail.
--wait-timeout duration Command timeout in seconds. (default 40s)
```

- `--id` the backup ID provided must be enclosed in double quotes.
- `--indices` can be set to `all|apievents|ui`, or to the names of individual indices. `all` includes `apievents` and `ui` indices. Multiple values can be supplied with a comma-separated list. For example, to restore all UI data and all data from August of 2022:

```
--indices "ui,apic-api-2022.08"
```
- `--override` by default is set to `false` to prevent you from accidentally replacing existing indices. If `--override` is set to `false` and you specify indices that already exist in the database that you are restoring, then the restore fails. The failure prevents you from accidentally replacing or losing data that exists in the current database.

3. Optionally view a list of available restores, and the status of each, by running the following command:

```
apicup subsys list-restores <analytics_subsystem>
```

View the list of supported flags by running the `list-restores` command with the `-h` (help) flag, as shown in the following example:

```
apicup subsys list-restores -h
List restores of the subsystem
```

Usage:

```
apicup subsys list-restores SUBSYS [flags]
```

Flags:

```
-h, --help          help for list-restores
--timeout duration Command timeout in seconds. (default 40s)
```

Global Flags:

```
--accept-license Accept the license for API Connect
--debug           Enable debug logging
```

Important:

For deployment profiles with fewer than 3 storage nodes, the restore process is never marked as **Complete**. The storage cluster status is expected to be yellow and to have more than 0 unassigned shards. In this situation, the restore process is likely to be complete when there are 0 initializing shards.

Disaster recovery

Prepare for disaster events and recover API Connect on VMware if a disaster event occurs.

You must complete preparation steps prior to a disaster in order to recover API Connect on VMware.

The backups that you create for disaster recovery are for recovery of the API Connect subsystems in the same data center that the backups were taken. If you want to restore your backups in a different data center (a cold-standby), it must have the same network configuration and API Connect form factor.

If you want to move your API Connect deployment to a different data center and change the form factor or modify your API Connect endpoints, then see [Migrating from v10 to v10 on a different form factor](#).

- [Preparing for a disaster](#)
Prepare your API Connect deployment for disaster recovery in a VMware environment.
- [Recovering from a disaster](#)
Recover the API Connect subsystems on VMware.
- [Using VM snapshots for infrastructure backup and disaster recovery](#)
You can use VM snapshots to backup and restore the infrastructure used by API Connect on VMware, and also for infrastructure disaster recovery.

Preparing for a disaster

Prepare your API Connect deployment for disaster recovery in a VMware environment.

Important: Successful disaster recovery of API Connect depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery.

- [Preparing the management subsystem for disaster recovery on VMware](#)
Prepare a Management subsystem for disaster recovery by taking specific steps before and after the installation of the subsystem.
- [Preparing the Developer Portal subsystem for disaster recovery on VMware](#)
Prepare a Developer Portal subsystem for disaster recovery by taking specific steps immediately after the installation of the subsystem.

- [Preparing the Analytics subsystem for disaster recovery on VMware](#)
Prepare the API Connect Analytics subsystem for disaster recovery in a VMware environment.

Preparing the management subsystem for disaster recovery on VMware

Prepare a Management subsystem for disaster recovery by taking specific steps before and after the installation of the subsystem.

About this task

- This task must be performed before any disaster event occurs, and also prior to the installation of a replacement Management subsystem during the recovery process. Best practice is to complete these steps immediately after initial configuration of a management subsystem during your original v10 deployment.
- Any **local** backups are presumed to have been lost in the disaster scenario and are non-recoverable in this procedure.

Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

Procedure

1. Make sure that you have a backup that can be used in case of a disaster event:
 - For backup configuration, see [Configuring backup settings during initial installation of the management subsystem](#).
 - If scheduled backups were configured during backup configuration, you should have access to a backup on the specified cloud storage.
 - You can perform a manual backup at any time. See [Backing up the management subsystem](#).
2. Ensure that you have a backup of your project directory.
The original project directory that was created with the `apicup` command during the initial product installation is required for disaster recovery, see: [First steps for deploying in a VMware environment](#). The project directory contains the yaml files that describe your deployment, encryption keys, and deployment ISO files. It is not possible to restore the subsystem databases on a deployment that uses a new or different project directory.
3. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVAs and restoring from normal backups.
Important: VM snapshots are not an alternative to the standard API Connect backups that are described in the previous step. Do not rely solely on VM snapshots for your backups.

What to do next

You should now complete the preparation steps for the Developer Portal subsystem; see [Preparing the Developer Portal subsystem for disaster recovery on VMware](#).

Preparing the Developer Portal subsystem for disaster recovery on VMware

Prepare a Developer Portal subsystem for disaster recovery by taking specific steps immediately after the installation of the subsystem.

About this task

- Perform this task before any disaster event occurs, and also prior to the installation of a replacement Developer Portal subsystem for the recovery process.
- Best practice is to complete these steps immediately after initial configuration of a Developer Portal subsystem during your original v10 deployment.
- Any **local** backups are presumed to have been lost in the disaster scenario and are non-recoverable in this procedure.
- Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. For information about preparing the Management subsystem, see [Preparing the management subsystem for disaster recovery on VMware](#).
If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

Procedure

1. Before the initial installation, configure the Developer Portal subsystem for database backups. See [Configuring backup settings for the Developer Portal subsystem](#).
2. Ensure you create a backup:
 - You can perform a manual backup at any time. See [Backing up the Developer Portal subsystem](#).
 - If you configure scheduled backups as part of [Configuring backup settings for the Developer Portal subsystem](#), backups to the specified cloud storage take place at the configured time.
3. Ensure that you have a backup of your project directory.
The original project directory that was created with the `apicup` command during the initial product installation is required for disaster recovery, see: [First steps for deploying in a VMware environment](#). The project directory contains the yaml files that describe your deployment, encryption keys, and deployment ISO files. It is not possible to restore the subsystem databases on a deployment that uses a new or different project directory.
4. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVAs and restoring from normal backups.
Important: VM snapshots are not an alternative to the standard API Connect backups that are described in the previous step. Do not rely solely on VM snapshots for your backups.

What to do next

To restore the Developer Portal on VMware after a disaster, see [Recovering the Developer Portal subsystem on VMware](#).

Preparing the Analytics subsystem for disaster recovery on VMware

Prepare the API Connect Analytics subsystem for disaster recovery in a VMware environment.

About this task

Preparing for disaster recovery involves backing up analytics data and your project directory.

Procedure

1. [Perform a backup of the Analytics database](#).
Scheduling automatic backups ensures that a recovery includes recent updates. For more information on configuring backups, see [Configuring backup settings for Analytics](#).
2. Ensure that you have a backup of your project directory.
The original project directory that was created with the `apicup` command during the initial product installation is required for disaster recovery, see: [First steps for deploying in a VMware environment](#). The project directory contains the yaml files that describe your deployment, encryption keys, and deployment ISO files. It is not possible to restore the subsystem databases on a deployment that uses a new or different project directory.
3. Ensure that you have a backup of the `analytics-extra-values.yaml` file if you created one: [Creating the analytics-extra-values file](#). This file might be included in the project directory backup if you kept it there.
4. Optional: Take a Virtual Machine (VM) snapshot of all your VMs; see [Using VM snapshots for infrastructure backup and disaster recovery](#) for details. This action does require a brief outage while all of the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVA's and restoring from normal backups.
Important: VM snapshots are not an alternative to the standard API Connect backups that are described in the previous step. Do not rely solely on VM snapshots for your backups.

Recovering from a disaster

Recover the API Connect subsystems on VMware.

- [Recovering the Management subsystem on VMware](#)
Recover the management subsystem from backups after a disaster event.
- [Recovering the Developer Portal subsystem on VMware](#)
Recover the Developer Portal on VMware.
- [Recovering the Analytics subsystem on VMware](#)
Recover the API Connect Analytics subsystem in a VMware environment.

Recovering the Management subsystem on VMware

Recover the management subsystem from backups after a disaster event.

Before you begin

To successfully recover the management subsystem, you must have previously completed the steps in [Preparing the management subsystem for disaster recovery on VMware](#).

You must use the same project directory that you used for your original deployment, or a restore of your project directory backup, to ensure that configuration and secret information is transferred to the replacement deployment.

In a clustered deployment, if any one VM is corrupted then all of the VMs in the cluster must be redeployed. You cannot replace just a single corrupted VM in a cluster.

Important: Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. You must complete preparation steps for both subsystems in order to achieve disaster recovery. If you have to perform a restore, you must complete the restoration of the Management Service first, and then immediately restore the Developer Portal. Therefore, the backups of the Management and Portal must be taken at the same time, to ensure that the Portal sites are consistent with Management database.

Procedure

1. Determine which backup to restore from.
 - a. Obtain a list of the available backups for your backup type:
 - s3 backups
 - For IBM®'s Cloud Object Storage, you can check currently stored backups in the COS console. Select Buckets > Objects. See the Object Names displayed on the `<cos_name>/backup/db` panel. For example:

```
20200605-105429F
20200605-100008F
20200605-11040F
```

- For Amazon's AWS, you can check currently stored backups in the S3 console. For example, under Amazon S3 > *cluster_name* > old cluster > backup > db:

```
20200606-144315F
20200606-145011F
```

- SFTP backups
View the SFTP backups available on your remote storage site:

```
-rw-r--r-- 1 root root 13092333 Aug 26 08:56 20200826-154646F.tgz
-rw-r--r-- 1 root root 18703758 Aug 26 09:10 20200826-160010F.tgz
-rw-r--r-- 1 root root 24318561 Aug 26 09:21 20200826-161301F.tgz
```

b. Select the backup ID of the backup you want to restore. For example, in the sample SFTP backup list, for the Aug 26 09:21 backup, the backup ID is **20200826-161301F**.

Each filename contains the date, time, and type of the backup stored. The format of the backup ID is **YYYYMMDD-HHMMSS<F|I>**. Full backups are denoted with a suffix **F** on the ID. Incremental backups are denoted with a suffix **I** on the ID. For incremental backups, ensure each incremental backup has its prior full backup also present in storage. You can check this by examining the ID **<prior-backup-id>_<backup-id>**.

Note:

During the disaster recovery process, the S3 configuration detail of the older management system is used, but the older management system must be in offline mode. The old subsystem must be offline because you cannot have two management systems simultaneously using the same s3 bucket name in the database backup configurations.

2. Make sure you know the management database cluster name. Use the following steps applicable to your backup type:

Backup type	How to obtain database cluster name
S3	<p>a. Open your IBM Cloud® Object Storage or AWS S3 console and proceed to the bucket location where the old Management subsystem backups are located.</p> <p>b. Download <code>backup/db/<backup-id>/pg_data/postgresql.conf.gz</code>. Open <code>postgresql.conf</code> to view the database cluster name:</p> <ul style="list-style-type: none"> IBM Cloud Object Storage <pre>cluster_name = 'm1-a6287572-postgres'</pre> <ul style="list-style-type: none"> m1 - Management subsystem name a6287572 - site name AWS S3 <pre>cluster_name = 'm1-c91dc0b9-postgres'</pre> <ul style="list-style-type: none"> m1 - Management subsystem name c91dc0b9 - site name
SFTP	<p>a. Recover the Management database cluster name and siteName by examining the SFTP backup tar. Download or move the SFTP backup tar file and decompress (untar) it.</p> <p>b. Open <code><management-subsystem-name>-<siteName>-postgres-backrest-shared-repo/backup/db/<backup-id>/pg_data/postgresql.conf.gz</code> which contains the management subsystem name and siteName. For example:</p> <pre># Do not edit this file manually! # It will be overwritten by Patroni! include 'postgresql.base.conf' archive_command = 'source /opt/cpm/bin/pgbackrest/pgbackrest-set-env.sh && pgbackrest archive-push "%p"' archive_mode = 'True' archive_timeout = '60' autovacuum_vacuum_cost_limit = '1000' autovacuum_vacuum_scale_factor = '0.01' cluster_name = 'm1-f785a3e3-postgres'</pre> <p>In this example:</p> <ul style="list-style-type: none"> <code>cluster_name</code> has both the management subsystem name and siteName m1 - Management subsystem name f785a3e3 - site name

3. Use your prior existing project directory, or a restore of your project directory backup, to install the Management subsystem:

a. Create your ISO files

```
apicup subsys install mgmt --out mgmtplan-out
```

The `--out` parameter and value are required.

In this example, the ISO files are created in the `myProject/mgmtplan-out` directory.

Note: If your original ISO files are still available and you haven't upgraded from the original installation, you can reuse them. However, if you have upgraded your original deployment, you must create new ISO files using the version of **apicup** that corresponds to the version your API Connect installation was on at the time of the disaster. For example, do not attempt to deploy v10.0.5.1 OVAs with ISO files that were created with **apicup** v10.0.4.0.

b. Deploy the files into the replacement VMs. See [Deploying the Management subsystem OVA file](#).

c. Verify the deployment. See [Verify installation of the Management subsystem](#).

Important:

For S3, the recovery remains in an intermediate state until the restore is complete, and Postgres wal files might cause serious disk issues. To avoid this possibility, continue immediately with the next step.

Note that if you delay completion of the restore:

- Health check might fail. In this case, you can still proceed to the next step and perform a restore.
- Postgres wal files might cause problems by consuming all disk space. In this case, you must either:
 - Re-install the system, prepare again for disaster recovery, and perform the restore.
 - Or increase disk space so that the system returns to a stable state, and then proceed with the restore.

- Once your Management subsystem is ready, confirm the backup ID noted in Step 1 is present on the sftp or s3 server.
- After a few moments, confirm there is a **ManagementBackup** of type **record** and its backup ID matches with the backup ID noted in Step 1. You can list the management backups using:

```
apicup subsys list-backups <subsystem_name>
```

For example:

NAME	STATUS	ID	CLUSTER	SUBSYSTEM	TYPE	CR TYPE	AGE
mgmt-backup-8hqgg	Ready	20200826-161301F	management-82b290a2-postgres	management	full	record	40s

- Perform a Management Restore using the name of the backup that has the ID you want to restore. For example, for ID **20200826-161301F** the backup name is **mgmt-backup-8hqgg**.

For instructions on how to restore, see [Restoring the management subsystem](#).

Once the Management Restore has completed and the database is running again, the data of the old Management subsystem will be successfully restored onto the new Management subsystem. Manual and scheduled backups should perform as normal once again.

What to do next

You should now complete the recovery steps for the Developer Portal subsystem on VMware, see [Recovering the Developer Portal subsystem on VMware](#).

Recovering the Developer Portal subsystem on VMware

Recover the Developer Portal on VMware.

Before you begin

Successful disaster recovery depends on recovery of both the Management subsystem and the Developer Portal subsystem. If you must recover a deployment due to a disaster, you must first complete [Recovering the Management subsystem on VMware](#), and then immediately recover the Developer Portal.

Recovery of the Portal subsystem is also dependent on prior completion of the preparation steps: [Preparing the Developer Portal subsystem for disaster recovery on VMware](#)

About this task

- In a disaster recovery scenario, an installation of a new Developer Portal subsystem is required.
- In a clustered deployment, if any one VM is corrupted then all of the VMs in the cluster must be redeployed. You cannot replace just a single corrupted VM in a cluster.
- You must use the same project directory that you used for your original Portal deployment, or a restore of your project directory backup, to ensure that configuration and secret information is transferred to the replacement deployment. The **apiconnect-up-v10.yaml** file contains Portal configuration.

Use the following steps to recover the data from your previous Developer Portal subsystem.

Procedure

- Use your prior existing project directory, or a restore of your project directory backup, to install the replacement Portal subsystem:
 - Create your ISO files.

```
apicup subsys install portal-subsystem-name --out portal-subsystem-nameplan-out
```

The **--out** parameter and value are required.

In this example, the ISO files are created in the `myProject/portal-subsystem-nameplan-out` directory.

Note: If your original ISO files are still available and you haven't upgraded from the original installation, you can reuse them. However, if you have upgraded your original deployment, you must create new ISO files using the version of **apicup** that corresponds to the version your API Connect installation was on at the time of the disaster. For example, do not attempt to deploy v10.0.5.1 OVAs with ISO files that were created with **apicup** v10.0.4.0.

- Deploy the files into the replacement VMs. See [Deploying the Developer Portal subsystem OVA file](#).
 - Verify the deployment. See [Verifying deployment of the Developer Portal subsystem](#).
- View the available backups and their status:

```
apicup subsys list-backups [subsystem_name] [flags]
```

Optional flags:

```
./apicup subsys list-backups -h
List backups of the subsystem
Usage:
  apicup subsys list-backups SUBSYS [flags]
Flags:
  -h, --help                help for list-backups
  --timeout duration        Command timeout in seconds. (default 40s)
Global Flags:
  --accept-license          Accept the license for API Connect
  --debug                   Enable debug logging
```

- Perform a Developer Portal restore. Run the following command, and attach any flags as appropriate.

```
apicup subsys restore [SUBSYS_NAME] [flags]
```

- To restore your Portal service, run the following command:

```
apicup subsys restore ptl --timestamp [now|YYYYMMDD.HHMMSS]
```

where `--timestamp` can be `now`, so the latest backup file that is available is used. Or you can specify a timestamp in the format of `YYYYMMDD.HHMMSS` to retrieve the nearest backup file to a specified time, searching backwards from the timestamp given. This command executes the portal restore process, which downloads the system backup and all of the site backups from the remote server, and installs them within the Portal stack. This process will then restore the system configuration from the found backup, and restore all of the sites. Note that if a backed up site is already installed on the current stack, then the site is reinstalled by using the backup (the site is overwritten by the backup). If there are multiple sites to restore, then these sites are queued for restoring. You can track the restoration process within the Portal `www admin` logs.

Note: From IBM® API Connect Version 10.0.3.0, the timestamp format changed to `YYYYMMDD.HHMMSS`. For Version 10.0.2.0 and earlier, the timestamp format is `YYYY-MM-DD`

`HH:MM:SS`.

- For a disaster recovery scenario, it is advised that you restore all sites and systems. By default the restore is a complete restore. You can optionally include `-type all` on the command line to specify a complete restore, but the flag is not required, as a complete restore is performed by default. Note that the complete restore uses the `priorityList` configuration setting that you specified in [Configuring backup settings for the Developer Portal subsystem](#).
- For more information, see [Restoring the Developer Portal subsystem](#)

Recovering the Analytics subsystem on VMware

Recover the API Connect Analytics subsystem in a VMware environment.

About this task

Recovering the Analytics subsystem involves deploying a new installation of the Analytics subsystem and then restoring the Analytics database from a back-up copy.

You must use the same project directory that you used for your original deployment, or a restore of your project directory backup, to ensure that configuration and secret information is transferred to the replacement deployment.

In a clustered deployment, if any one VM is corrupted then all of the VMs in the cluster must be redeployed. You cannot replace just a single corrupted VM in a cluster.

Procedure

- Use your prior existing project directory, or a restore of your project directory backup, to install the replacement Analytics subsystem:

- Create your ISO files:

```
apicup subsys install install-subsystem-name --out analytplan-out
```

The `--out` parameter and value are required.

In this example, the ISO files are created in the `myProject/analytplan-out` directory.

Note: If your original ISO files are still available and you haven't upgraded from the original installation, you can reuse them. However, if you have upgraded your original deployment, you must create new ISO files using the version of `apicup` that corresponds to the version your API Connect installation was on at the time of the disaster. For example, do not attempt to deploy v10.0.5.1 OVAs with ISO files that were created with `apicup` v10.0.4.0.

- Deploy the files into the replacement VMs. See [Deploying the Analytics subsystem OVA file](#).
- Verify the deployment. See [Verifying deployment of the Analytics subsystem](#).

- Restore the Analytics data from backup, as explained in [Restoring the Analytics database](#).

Using VM snapshots for infrastructure backup and disaster recovery

You can use VM snapshots to backup and restore the infrastructure used by API Connect on VMware, and also for infrastructure disaster recovery.

Backup and restore procedures for the databases used by IBM API Connect on VMware are described in [Backing up and restoring on VMware](#). The procedures back up all of the state required by API Connect but do not include the underlying infrastructure software or other internal state.

In some scenarios, you may want to perform backups and disaster recovery at an infrastructure layer. You can do this by taking snapshots of the virtual machines or underlying storage volumes, providing that you follow the constraints described here.

Note that performing backups at the infrastructure layer differs from the standard approach in that not only is the database state backed up, but also the precise state of the software. This approach can be useful, for example, when testing upgrades of production systems.

VM snapshots should not be used as an alternative to taking normal backups. Ideal times to take VM snapshots are after initial install and configuration, and before and after upgrades. In the event of a disaster, reverting to the last snapshot taken and then restoring the standard daily backup can be faster than redeploying OVAs and restoring the backup.

- Requirements for taking a consistent backup of an API connect system at the infrastructure level
 - An API Connect system can be approximated by the following diagram:

Table 1. API Connect Installation

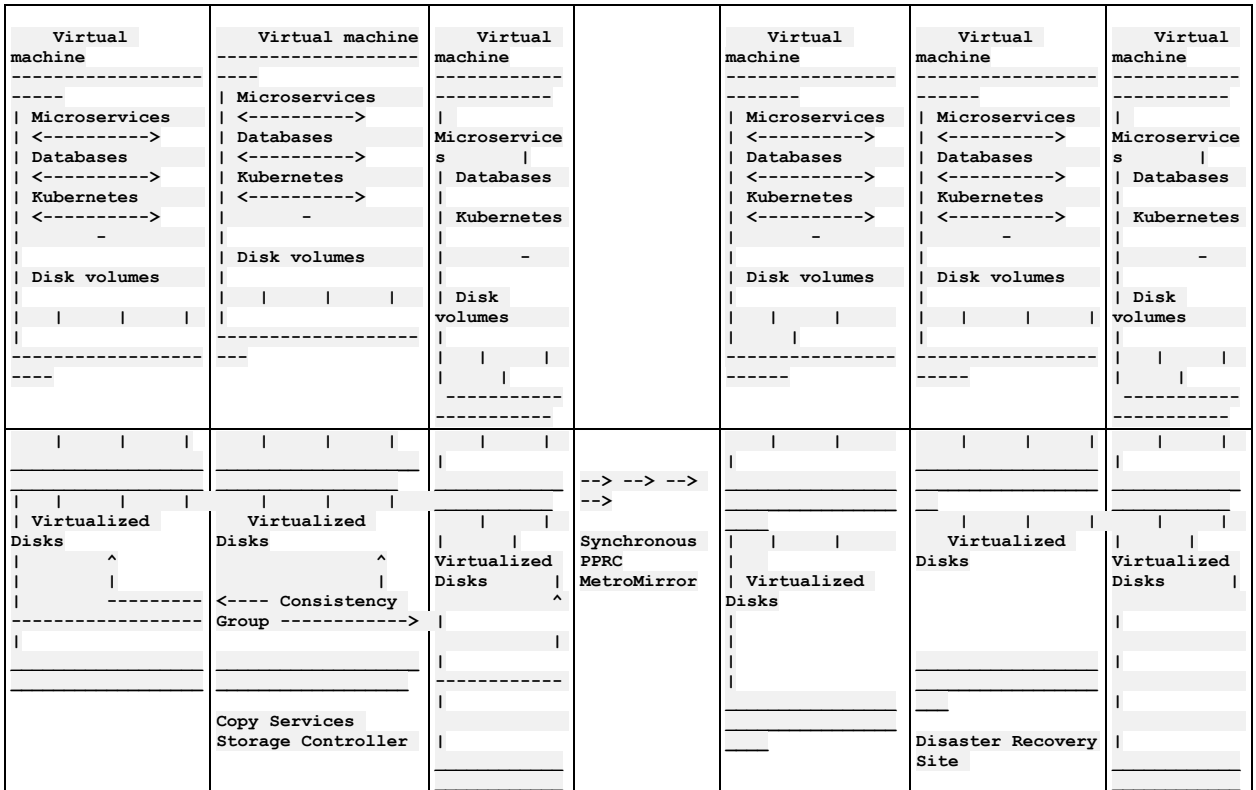

- o The system comprises multiple Virtual Machine images which are running Kubernetes, multiple databases, with the API Connect micro services running on top. There is transactional communication between the virtual machines which is occurring at all levels of this stack. This communication occurs all the time, even if the system is seemingly idle.
- o Within the system there are multiple stateful or database layers on the software that maintain a consistency protocol. For example `etcd` upon which Kubernetes is based uses the [Raft](#) consensus algorithm. These algorithms depend for consistency on the basic assertion that time flows forwards on all systems together. If one or more of the virtual machine's state were to move backwards relative to the others by even the smallest quantum of time then consistency would be lost and the system might behave badly.

Clearly, if Virtual Machine snapshots are taken across multiple virtual machines it is certain that these snapshots will not be taken at precisely the same time. The result will be a backup that contains a system state that contains data from snapshots taken at slightly different times. It is possible that such a backup system may be restored and may appear to work correctly but hidden deep within it there may be undetected inconsistencies that will cause strange unpredictable errors and inconsistencies later. These issues can be extremely difficult to diagnose.

It is also possible that you can test this procedure successfully multiple times and see no apparent problem occurring. Irrespective of the apparent success of tests, corruption can be occurring in the system state. For this reason, taking VM snapshots or clones of a running API Connect system is not supported.

- How to take a consistent backup of an API connect system at the infrastructure level
 - o The only way to take a consistent backup of an API connect system using VM snapshots and clones is to shut down ALL of the virtual machines comprising the system before taking the snapshot or clone.
 - o Once the virtual machines are stopped at the VM level, time is effectively frozen. Then a snapshot can be taken on all the VMs. A clone can be made from the snapshot taken on each VM. This set of clones represent a valid, consistent state that the API Connect system was in when it was shut down.
 - o Once all of the snapshots and clones have been taken the original API Connect system can be restarted.
- Restoring an API Connect System from VM clones
 - o The Cloned VMs represent a valid state of the original API Connect system. They will restart in exactly the same way as the original system restarted.
 - o If the objective is to stand up another instance of the cloned API connect system for testing or DR purposes, the following must be true:
 - The original system and the cloned system must be isolated from one another. The clone will be using the same hostnames and IP addresses as the original and so must be stood up in a separate virtual machine hosting environment with Network Address Translation between itself and any network to which the original system is stood up.
 - The cloned system must be stood up in an identical environment in terms of its hardware, software and network.
- Disaster Recovery approaches using Disk Replication:
 - o A common DR approach used by enterprises is to use disk based replication. In this case, a storage controller such as IBM's San Volume Controller provides [Copy Services](#). You can use Copy Services to create a completely consistent copy of a set of disks. IBM calls this feature *Synchronous Remote Copy* or *MetroMirror*. Other storage vendors have similar features.
 - o If you use Remote Copy to synchronize disk images to a DR site then IBM will support API connect used with these systems so long as the copy at the DR site is completely consistent. Ensuring this consistency is the responsibility of the storage controller and its configuration. It is **critically important** to ensure that ALL of the disk volumes for all of the VMs or nodes in the entire API Connect system are in the same [remote copy consistency group](#) as shown below. This ensures that DR scenarios do not create inconsistent volumes. If the disks are not in the same consistency group then the copy will not be managed consistently and the system will not be supported.

Table 2. API Connect Installation and corresponding Disaster Recovery site

- Infrastructure based backup of API Connect using vSphere
 - o The following procedure outlines steps to clone a VMware instance of API Connect v10, using the following topology:
 - 3 Management Nodes
 - 3 Portal Nodes

- 3 Analytics Nodes
 - 3 Gateways
- Each of these components has a load balancer with its own IP address. The load balancers all sit on a single VM. The cluster is installed and configured on 13 VMs in VMware. In this example, the system was populated with data and APIs. These should first be tested to ensure that all published APIs respond as expected. Once this is done, use vSphere UI to complete the following steps:
 1. Power off VMs

To power off the VMs in sync, schedule a “shutdown guest OS” such that all the VMs shutdown at the same time. Although the shutdown does not occur at exactly the same instant, this does allow the shutdown for every machine to be as close in time as possible.
 2. Take snapshots

Take snapshots of each VM after shutdown. Using the scheduling feature in the UI, schedule a snapshot of all the VMs at the same instant. If cloning should adversely affect the system in any way then the original VMs can be reverted back to these snapshots.
 3. Clone VMs

Use the clone feature of the UI to create a clone of each VM. This VM should sit in the same resource pool as the original cluster. This is simply an exact copy of the disks of the original machine. The clones and originals are in no way coupled.
 4. Power on clones

Schedule the power-on for each clone VM such that all the clone VMs power on simultaneously. Once this is done, test the cluster to ensure that the APIs respond as expected. For the example cluster topology shown earlier on this page, it can take a couple of hours after power-on for all the APIs to respond as expected.

Disabling and re-enabling the Analytics subsystem on VMware

Disable the Analytics subsystem by shutting down the VM that hosts it.

Before you begin

This operation requires the use of the Analytics CLI. [Using the Analytics CLI](#).

About this task

Disabling the Analytics subsystem stops the collection and storage of data as well as making the subsystem unavailable.

When you disable Analytics, there will be no data in either the API Manager Dashboards or third-party offloads.

Procedure

1. Back up your Analytics data as explained in [Backing up and restoring the Analytics database on VMware](#).
2. Disable shard allocation for storage by following these steps:

Disabling shard allocation is optional, but is recommended because it prevents new shards from being created for replication when a node is unavailable, and helps avoid corruption issues in full system restarts.

- a. Create a json file called `analytics_persistent_settings.json` and insert the contents:

```
{"persistent":{"cluster.routing.allocation.enable":"none"}}
```

- b. Run the following Analytics CLI command:

```
apic --mode analytics clustermgmt:putSettings --server <management server platform api endpoint> --analytics-service <analytics service name> --format json analytics_persistent_settings.json
```

where:

- `<management server platform api endpoint>` is the Management server platform api endpoint.
- `<analytics service name>` is the name of Analytics service as configured in the Cloud Manager.

The output from this command should be:

```
{"acknowledged":true,"persistent":{"cluster":{"routing":{"allocation":{"enable":"none"}}},"transient":{}}
```

3. Perform a synced flush of storage by running the following command:

Flushing the storage is optional, but is recommended because it helps to avoid losing the data that was not yet written to disk before you restart pods. This step flushes all current index operations synchronously and attempts to write everything that is in flux to disk.

```
apic --mode analytics clustermgmt:postFlush --server <management server platform api endpoint> --analytics-service <analytics service name> --format json
```

where:

- `<management server platform api endpoint>` is the Management server platform endpoint.
- `<analytics service name>` is the name of Analytics service as configured in the Cloud Manager.

When you flush storage, the response looks like the following example, with the *failed* count set to zero:

```
{
  "_shards": {
    "total": 16,
    "successful": 6,
    "failed": 0
  }
}
```

This operation occasionally fails, but it is safe to rerun it multiple times until it passes and the "failed" count is zero.

4. Shut down the Analytics VMs.
You can shut down the VMs using one of the following methods:
 - Use the VMware console
 - `ssh` into the images and run the `shutdown` command

Re-enabling analytics

5. Start your analytics VMs.
6. Enable shard allocation by following these steps:
Note: If you did not disable shard allocation, skip this step.
 - a. Create a json file called `analytics_persistent_settings.json` and insert the contents:

```
{"persistent": {"cluster.routing.allocation.enable": "all"}}
```

- b. Run the following Analytics CLI command:

```
apic --mode analytics clustermgmt:putSettings --server <management server platform api endpoint> --analytics-service <analytics service name> --format json analytics_persistent_settings.json
```

where:

- `<management server platform api endpoint>` is the Management server platform api endpoint.
- `<analytics service name>` is the name of Analytics service as configured in the Cloud Manager.

When you enable shard allocation, the response looks like the following example:

```
{"acknowledged": true, "persistent": {"cluster": {"routing": {"allocation": {"enable": "all"}}}}, "transient": {}}
```

Maintaining a two data center deployment

How to maintain a two data center disaster recovery (DR) deployment on VMware, including information about normal operation, failure handling, and recovery.

Ensure that you understand the concepts of a 2DCDR deployment in API Connect. For more information, see [A two data center deployment strategy on VMware](#).

See the following topics for information about failure handling, backup, upgrade, and removing a 2DCDR deployment.

- [Backup and restore considerations for a two data center deployment](#)
Points to consider when backing up and restoring a two data center disaster recovery (2DCDR) deployment on VMware.
- [Failure handling of a two data center deployment](#)
How to detect failures, and perform service failover, in a two data center disaster recovery deployment on VMware.
- [Recovering from a failover of a two data center deployment](#)
How to recover a two data center disaster recovery deployment on VMware.
- [Removing a two data center deployment](#)
You can remove your two data center disaster recovery deployment on VMware.

Backup and restore considerations for a two data center deployment

Points to consider when backing up and restoring a two data center disaster recovery (2DCDR) deployment on VMware.

The 2DCDR backup requirements are different for the Portal and Management subsystems.

Management subsystem 2DCDR backup requirements

- Different remote backup locations must be specified for each data center.
- Before you configure S3 backup settings you must first disable 2DCDR on both sites, and then re-enable 2DCDR after reconfiguring your backup settings.
 1. Disable 2DCDR for the management subsystems on both sites:

```
apicup subsys set <management subsystem> multi-site-ha-enabled=false  
apicup subsys install <management subsystem>
```

2. Configure your S3 backup settings.
3. Enable 2DCDR for the management subsystems on both sites:

```
apicup subsys set <management subsystem> multi-site-ha-enabled=true  
apicup subsys install <management subsystem>
```

You do not need to do this for SFTP or local backups.

- Both active and warm-standby Management subsystems run the scheduled backup job.
- Restores must be run on the active data center.

Portal subsystem 2DCDR backup requirements

- The backup settings for both the active and warm-standby portal must be identical.
- Only the active data center portal takes backups. On failover, the backup job of the new warm-standby is disabled, and the backup job of the new active is enabled.
- Portal restores are only done on the active data center.

Configuring backups for 2DCDR deployments

Keeping the different Portal and Management 2DCDR backup requirements in mind, the actual steps for configuring backups for both subsystems are the same as for a single API Connect deployment:

- [Backing up the management subsystem](#)
- [Restoring the management subsystem](#)
- [Backing up and restoring the Developer Portal](#)

Failure handling of a two data center deployment

How to detect failures, and perform service failover, in a two data center disaster recovery deployment on VMware.

Before you begin

Ensure that you understand the concepts of a 2DCDR deployment in API Connect. For more information, see [A two data center deployment strategy on VMware](#).

About this task

Failure handling comprises of two main concepts; failure detection, and failover of services.

Failure detection is about detecting that a failure has happened, and then alerting the relevant administrator for them to take action. Failure detection is different from system monitoring. Failure detection checks are run often and fast (for example, every 5 seconds). As such they are normally more limited in what they check. In API Connect, failure checks detect only whether the database and web server are online, and nothing more. Whereas monitoring checks typically are run less frequently, but are more likely to check for things like CPU, memory, and disk space usage. The results of these checks can then be recorded to perform historical trend analysis to spot memory leaks for example.

If a failure is detected, it's then important to make sure that the cluster or service is definitely offline. So, for example, if data center one (DC1) appears to have an outage, and the plan is to failover to data center two (DC2), then it's important to make sure that the pods in DC1 really are offline. If the DC1 pods are actually still running, then they might continue to send data to DC2, which would lead DC2 to think it wasn't the active deployment, and then that could lead to split-brain. A fast way to ensure that the cluster or service really is offline, is to drop the network link to those pods in your VMware infrastructure, and then delete them.

The failure detection endpoint must be location specific and must be exempt from any traffic routing, so that it's possible to explicitly check the health of each data center regardless of how traffic is being routed.

You can failover a specific service, for example `portal_service_1`, or all of the services that are running in a particular data center. The following sections describe how failover is achieved.

The operational states of an API Manager service:

Operational state	Description
progressing to active	Pods are progressing to the active state, but none are capable of serving traffic.
active	All of the pods are ready and in the correct disaster recovery state for the active data center.
progressing to passive	Pods are progressing to the warm-standby state, but none are capable of serving traffic.
passive	All of the pods are ready and in the correct disaster recovery state for the warm-standby data center.

The operational states of a Developer Portal service:

Operational state	Description
progressing to active	Pods are progressing to the active state, but none are capable of serving traffic.
progressing to active (ready for traffic)	At least one pod of each type is ready for traffic. The dynamic router can be linked to this service.
active	All of the pods are ready and in the correct disaster recovery state for the active data center.
progressing to passive	Pods are progressing to the warm-standby state, but none are capable of serving traffic.
progressing to passive (ready for traffic)	At least one pod of each type is ready for traffic.
passive	All of the pods are ready and in the correct disaster recovery state for the warm-standby data center.
progressing to down	Pods are moving from warm-standby state to down.
down	The multi-site HA mode is deleted from the warm-standby data center.

You can run the following command to check the operational state of a service:

```
kubect1 describe ServiceName
```

Where *ServiceName* is the name of the API Manager or Developer Portal service.

Important:

- If the active data center is offline, do not change the `multi-site-ha-enabled` setting to `false` on the warm-standby data center, as this action deletes all the data from the databases. If you want to revert to a single data center topology, you must change the `multi-site-ha-enabled` setting to `false` on the active data center, and then redeploy the warm-standby data center. If the active data center is offline, you must first change the warm-standby data center to be active, and then change the `multi-site-ha-enabled` setting to `false` on the now active data center.
- If the warm-standby data center is offline for more than 24 hours, there can be issues with the disk space on the active data center so you must revert your deployment to a single data center topology. To revert to a single data center topology, you must change the `multi-site-ha-enabled` setting to `false` on the active data center. When the warm-standby site has been redeployed, the `multi-site-ha-enabled` setting can be reapplied to the active site.

Procedure

• API Manager service failover

To initiate a failover from DC1 to DC2 you first must set DC1 to warm-standby, before making the warm-standby data center active. This action is needed to prevent split-brain, as there cannot be two active services or clusters at the same time. If the failover is being done because the current active data center has had a complete outage, then you should ensure that the network links to that data center are dropped in your VMware infrastructure, in order to avoid the potential for split-brain occurring. The offline data center must be set to warm-standby before the network links are restored. The following instructions show how to failover DC1 to DC2 for the API Manager service.

1. Set DC1 (in this example, located in Dallas) to be warm-standby.

Run `apicup` to change the `multi-site-ha-mode` property to `passive` on the Dallas data center, for example:

```
apicup subsys set mgmt_dallas multi-site-ha-mode=passive
```

where

- `mgmt_dallas` is the name of the management service on DC1.

Note: If DC1 is completely down, and you cannot set it to be warm-standby at this point, you must ensure that the network links to DC1 are removed before continuing to set DC2 to be active. You must then not restore the network links to DC1 until you can set DC1 to be warm-standby.

2. Run `apicup` to update the settings on DC1, for example:

```
apicup subsys install mgmt_dallas
```

3. Log in to the virtual machine management subsystem on DC1 by using an SSH tool, and run the following command to check that the API Manager service is ready for traffic:

```
kubectl describe ServiceName
```

The service is ready for traffic when the `Ha mode` part of the `Status` object is set to `passive`. For example:

```
Status:
...
Ha mode: passive
...
```

4. Set DC2 (in this example, located in Raleigh) to be active.

Run `apicup` to change the `multi-site-ha-mode` property to `active` on the Raleigh data center, for example:

```
apicup subsys set mgmt_raleigh multi-site-ha-mode=active
```

where

- `mgmt_raleigh` is the name of the management service on DC2.

5. Run `apicup` to update the settings on the services on DC2.

For example:

```
apicup subsys install mgmt_raleigh
```

6. Update your dynamic router to redirect all traffic to DC2 instead of DC1. Note that until the DC2 site becomes `active`, the UIs might not be operational.

7. Log in to the virtual machine management subsystem on DC2 by using an SSH tool, and run the following command to check that the API Manager service is ready for traffic:

```
kubectl describe ServiceName
```

The service is ready for traffic when the `Ha mode` part of the `Status` object is set to `active`. For example:

```
Status:
...
Ha mode: active
...
```

• Developer Portal service failover

To initiate a failover for the Developer Portal from DC1 to DC2 you first must ensure that the existing DC1 is warm-standby, before making the warm-standby data center active, in order to prevent split-brain. The following instructions show how to failover DC1 to DC2 for the Developer Portal service. You must repeat these steps for each Developer Portal service that you want to failover.

Note:

- Switching a Developer Portal service to warm-standby mode instantly restarts all of its `portal-db` and `portal-www` pods at the same time. Therefore, if you don't have an active Developer Portal service that is online, there will be an outage of the Developer Portal web sites until the warm-standby data center is ready to accept traffic.
- If you want to monitor the failover process, you can run the following command to check the status of the Portal pods in the `PortalService` CR file:

```
kubectl describe ServiceName
```

For more details about the status information in a `PortalCluster` CR file, see the [Example](#) section.

- Do not edit the `PortalService` CR file during the failover process.

1. Set DC1 (in this example, located in Dallas) to be warm-standby.

Run `apicup` to change the `multi-site-ha-mode` property to `passive` on the Dallas data center, for example:

```
apicup subsys set port_dallas multi-site-ha-mode=passive
```

where

- `port_dallas` is the name of the Portal service on DC1.

Note: If DC1 is completely down, and you cannot set it to be warm-standby at this point, you must ensure that the network links to DC1 are removed before continuing to set DC2 to be active. You must then not restore the network links to DC1 until you can set DC1 to be warm-standby.

2. Run `apicup` to update the settings on DC1, for example:

```
apicup subsys install port_dallas --skip-health-check
```

Important: You must not wait for the active DC `Status` to become `warm-standby`, before failing over the warm-standby DC to become `active`. You should change the DC1 `multi-site-ha-mode` to `passive`, and then run the `kubectl describe ServiceName` command, and as soon as the `haMode` is set to `progressing to passive`, you must change DC2 to be `active`.

3. Set DC2 (in this example, located in Raleigh) to be active.

Run `apicup` to change the `multi-site-ha-mode` property to `active` on the Raleigh data center, for example:

```
apicup subsys set port_raleigh multi-site-ha-mode=active
```

where

- `port_raleigh` is the name of the Portal service on DC2.

4. Run `apicup` to update the settings on the services on DC2.

For example:

```
apicup subsys install port_raleigh --skip-health-check
```

5. Update your dynamic router to redirect all traffic to DC2 instead of DC1.

6. Log in to the virtual machine management subsystem on DC2 by using an SSH tool, and run the following command to check that the Developer Portal service is ready for traffic:

```
kubectl describe ServiceName
```

The service is ready for traffic when the `haMode` part of the `Status` object is set to `active`. For example:

```
Status:
...
haMode: active
...
```

- **Entire data center failover**

To failover an entire datacenter, follow the previous steps to failover the API Manager service, followed by the steps to failover each Developer Portal service in that data center.

How long it takes to complete the failover varies, and depends on hardware speed, network latency, and the size of the databases. However, here are some approximate timings:

For API Manager:

- `warm-standby` to `active` approximately 5 minutes
- `active` to `warm-standby` approximately 15 minutes

For Developer Portal:

- `warm-standby` to `active` 15 - 40 minutes
- `active` to `warm-standby` approximately 10 minutes

Example

Example of the status section of a `PortalCluster` CR file for an active data center that you can view by running the `kubectl describe PortalService` command:

```
status:
  conditions:
  - lastTransitionTime: "2020-04-27T08:00:25Z"
    message: 4/6
    status: "False"
    type: Ready
  customImages: true
  dbCASecret: portal-db-ca
  encryptionSecret: ptl-encryption-key
  endpoints:
    portal-director: https://api.portal.ha-demo.cloud/

versions:
  available:
    channels:
      - name: "10"
      - name: "10.0"
      - name: 10.0.0
      - name: 10.0.0.0
    versions:
      - name: 10.0.0.0-1038
  reconciled: 10.0.0.0-1038

```

Meaning of the **haMode** for the active data center:

- **active** - this is the active data center, or the only data center, and all pods are ready and accepting traffic.
- **progressing to active** - this is the active data center, or the only data center, and there are no pods ready yet.
- **progressing to active (ready for traffic)** - this is the active data center, or the only data center, and there is at least one pod of each type, www, db, and nginx, ready, so the data center is accepting traffic.

Example of the status section of a **PortalCluster** CR file for a warm-standby data center that you can view by running the **kubectl describe PortalService** command:

```

status:
  conditions:
  - lastTransitionTime: "2020-04-21T10:54:54Z"
    message: 6/6
    status: "True"
    type: Ready
  customImages: true
  dbCASecret: portal-db-ca

de.containers.appdomain.cloud/
  localMultiSiteHAPeerConfigHash: VguODE74TkiS3Lcc5ytQiaF8100PXMHUrvBtb+PbKOG=
  haMode: progressing to passive (ready for traffic)
  microServiceSecurity: custom
  multiSiteHA:
    dbPodScale: 3
    remoteSiteDeploymentName: portal
    remoteSiteName: dallas
    replicationPeer: https://ptl-replication.cvs.apic-2ha-dallas-144307-xxxx14539d6e75f74e950db7077951d4-0000.us-
south.containers.appdomain.cloud/
    wwwPodScale: 3
  phase: 0
  serviceCASecret: portal-ca
  serviceClientSecret: portal-client
  serviceServerSecret: portal-server
  services:
    db: portal-frankfurt-db
    db-remote: portal-dallas-db
    nginx: portal-nginx
    tunnel: portal-tunnel
    www: portal-frankfurt-www
    www-remote: portal-dallas-www
  versions:
    available:
      channels:
        - name: "10"
        - name: "10.0"
        - name: 10.0.0
        - name: 10.0.0.0
      versions:
        - name: 10.0.0.0-1038
    reconciled: 10.0.0.0-1038

```

Meaning of the **haMode** for the warm-standby data center:

- **passive** - this is the warm-standby data center, and all pods are ready and accepting traffic.
- **progressing to passive** - this is the warm-standby data center, and there are no pods ready yet.
- **progressing to passive (ready for traffic)** - this is the warm-standby data center, and there is at least one pod of each type, www, db, and nginx, ready, so the data center is accepting traffic.

What to do next

As soon as a failure on a data center has been resolved, the failed data center should be brought back online and re-linked to the currently active data center in order to maintain the highest availability; see [Recovering from a failover of a two data center deployment](#) for more information.

Recovering from a failover of a two data center deployment

How to recover a two data center disaster recovery deployment on VMware.

Before you begin

Ensure that you understand the concepts of a 2DCDR deployment in API Connect. For more information, see [A two data center deployment strategy on VMware](#).

About this task

After a failure has been resolved, the failed data center can be brought back online and re-linked to the currently active data center. It's important to do this as soon as possible, in order to reinstate disaster recovery. Otherwise, if another failure occurred before the failed data center is brought back online, there could be a complete outage.

The failed data center can be brought back online as the new active primary data center, or it can be brought back as a warm-standby secondary data center and the currently active data center kept as the primary one. This decision will be based on your own company policies about recovering from a failure.

The amount of data that is sent when recovering from a failover, will depend on how long the outage lasted, and how much activity there was during that period.

Important:

- If the active data center is offline, do not change the `multi-site-ha-enabled` setting to `false` on the warm-standby data center, as this action deletes all the data from the databases. If you want to revert to a single data center topology, you must change the `multi-site-ha-enabled` setting to `false` on the active data center, and then redeploy the warm-standby data center. If the active data center is offline, you must first change the warm-standby data center to be active, and then change the `multi-site-ha-enabled` setting to `false` on the now active data center.
- If the warm-standby data center is offline for more than 24 hours, there can be issues with the disk space on the active data center so you must revert your deployment to a single data center topology. To revert to a single data center topology, you must change the `multi-site-ha-enabled` setting to `false` on the active data center. When the warm-standby site has been redeployed, the `multi-site-ha-enabled` setting can be reapplied to the active site.

Procedure

- **Recovering from an API Manager failover**

The following instructions show how to bring data center one (DC1) back as the primary (`active`) data center, and assume that DC1 is now online and in the warm-standby state. If you prefer, you can keep DC1 as the secondary data center, and leave data center two (DC2) as the primary (`active`) data center.

1. Set DC2 (in this example, located in Raleigh) to be warm-standby.

Run `apicup` to change the `multi-site-ha-mode` property to `passive` on the Raleigh data center, for example:

```
apicup subsys set mgmt_raleigh multi-site-ha-mode=passive
```

where

- `mgmt_raleigh` is the name of the management service on DC2.

2. Run `apicup` to update the settings on DC2, for example:

```
apicup subsys install mgmt_raleigh
```

3. Log in to the virtual machine management subsystem on DC2 by using an SSH tool, and run the following command to check that the API Manager service is ready for traffic:

```
kubectl describe ServiceName
```

The service is ready for traffic when the `Ha mode` part of the `Status` object is set to `passive`. For example:

```
Status:
...
Ha mode:           passive
...
```

You must also ensure that the database in DC2 has replicated over completely before proceeding.

4. Set DC1 (in this example, located in Dallas) to be active.

Run `apicup` to change the `multi-site-ha-mode` property to `active` on the Dallas data center, for example:

```
apicup subsys set mgmt_dallas multi-site-ha-mode=active
```

where

- `mgmt_dallas` is the name of the management service on DC1.

5. Run `apicup` to update the settings on DC1.

For example:

```
apicup subsys install mgmt_dallas
```

6. Update the dynamic router to redirect all traffic to DC1 instead of DC2. Note that until the DC1 site becomes `active`, the UIs might not be operational.
7. Log in to the virtual machine management subsystem on DC1 by using an SSH tool, and run the following command to check that the API Manager service is ready for traffic:

```
kubectl describe ServiceName
```

The service is ready for traffic when the `Ha mode` part of the `Status` object is set to `active`. For example:

```
Status:
...
Ha mode: active
...
```

- **Recovering from a Developer Portal failover**

When recovering from a Developer Portal failover, how much data is sent from the now warm-standby data center (in this example, DC2) back to the newly recovered active data center (in this example, DC1) varies depending on how much time has passed and how many changes have been made in the meantime.

If possible, the Portal sends an Incremental State Transfer (IST), which is a replay of the transactions that have happened since the failed data center, DC1, became unreachable. The IST can grow to be up to 3 GB in size. If the IST grows larger than 3 GB, then the Portal sends a State Snapshot Transfer (SST) instead, which is basically a full copy of the whole database. How long this process takes depends on how many Portal sites there are, how much content in each of those sites, how active they are (as in number of transactions), and how fast the network speed is between the data centers. However, it is likely to take in the range 5 - 60 minutes.

You can check whether the Developer Portal servers are in sync by running the `status` command in the `portal-www` pod admin container. If all servers show as `primary`, then they are in sync and traffic can be directed wherever needed. For information about running the status command, see [Verifying deployment of the Developer Portal subsystem](#).

Note:

- If you want to monitor the recovery process, you can log in to the virtual machine Portal subsystem by using an SSH tool, and run the following command to check the status of the Portal pods in the `PortalService` CR file:

```
kubectl describe ServiceName
```

For more details about the status information in a `PortalCluster` CR file, see the [Example](#) section.

- Do not edit the `PortalService` CR file during the recovery process.

The following instructions show how to bring DC1 back as the active primary data center, and switch DC2 to be the warm-standby secondary data center. Again, you can keep DC2 as the active primary data center if you prefer, and leave DC1 to be warm-standby.

1. Set DC2 (in this example, located in Raleigh) to be warm-standby.

Run `apicup` to change the `multi-site-ha-mode` property to `passive` on the Raleigh data center, for example:

```
apicup subsys set port_raleigh multi-site-ha-mode=passive
```

where

- `port_raleigh` is the name of the Portal service on DC2.

2. Run `apicup` to update the settings on the services on DC2.

For example:

```
apicup subsys install port_raleigh --skip-health-check
```

Important: You must not wait for the active DC `Status` to become `warm-standby`, before changing the warm-standby DC to become `active`. You should change the DC2 `multi-site-ha-mode` to `passive`, and then run the `kubectl describe ServiceName` command, and as soon as the `haMode` is set to `progressing to passive`, you must change DC1 to be `active`.

3. Set DC1 (in this example, located in Dallas) to be active.

Run `apicup` to change the `multi-site-ha-mode` property to `active` on the Dallas data center, for example:

```
apicup subsys set port_dallas multi-site-ha-mode=active
```

where

- `port_dallas` is the name of the Portal service on DC1.

4. Run `apicup` to update the settings on the services on DC1.

For example:

```
apicup subsys install port_dallas --skip-health-check
```

5. Update the dynamic router to redirect all traffic to DC1 instead of DC2.

6. Log in to the virtual machine Portal subsystem on DC1 by using an SSH tool, and run the following command to check that the Developer Portal service is ready for traffic:

```
kubectl describe ServiceName
```

The service is ready for traffic when the `Ha mode` part of the `Status` object is set to `active`. For example:

```
Status:
...
Ha mode: active
...
```

Removing a two data center deployment

You can remove your two data center disaster recovery deployment on VMware.

Before you begin

Ensure that you understand the concepts of a 2DCDR deployment in API Connect. For more information, see [A two data center deployment strategy on VMware](#).

About this task

If you decide to remove your two data center disaster recovery (DR) deployment, you go from two data centers to one. The active data center remains as the only working system. The warm-standby one loses all data as part of the process.

Warning: If the active data center is offline, do not remove the multi-site HA CR section from the warm-standby data center, as this action deletes all the data from the databases.

As part of the installation, you configured the `multi-site-ha` settings on each data center, as described in the following table:

Table 1. The `multi-site-ha` settings

Setting	Description
<code>multi-site-ha-enabled</code>	Indicates whether two data center DR deployment is enabled. Set to <code>true</code> to enable two data center DR. Set to <code>false</code> to disable two data center DR. The default value is <code>false</code> .
<code>multi-site-ha-mode</code>	The state of the data center in the context of the two data center deployment. Valid values are: <ul style="list-style-type: none"><code>active</code> - indicates the primary data center<code>passive</code> - indicates the warm-standby data center
<code>management-replication</code>	Required only for the Management subsystem. The external ingress name for the Management subsystem in the current data center in the two data center deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
<code>portal-replication</code>	Required only for the Portal subsystem. The external ingress name for the Portal subsystem in the current data center in the two data center deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
<code>replication-peer-fqdn</code>	The ingress hostname for the other data center in the two data center deployment. This information is required so that the two data centers can communicate with each other.

If you want to revert to a single data center topology, or temporarily remove the warm-standby data center from DR, you must disable the `multi-site-ha` configuration on the active data center, and then remove the warm-standby data center. If the active data center is offline, you must first change the warm-standby data center to be active, and then disable the `multi-site-ha` configuration on the now active data center.

Procedure

- Disable the `multi-site-ha` configuration on the Management subsystem of the active data center. For example:

```
apicup subsys set mgmt multi-site-ha-enabled=false
apicup subsys install mgmt
```

- Disable the `multi-site-ha` configuration on the Portal subsystem of the active data center. For example:

```
apicup subsys set ptl multi-site-ha-enabled=false
apicup subsys install ptl
```

- You can now power off and shut down your warm-standby data center.

Monitoring and health checks

Monitor your deployment and complete health checks on subsystems.

See:

- [Checking cluster health on VMware](#)
You can use `apicup` to check the health of the API Connect clusters in your VMware deployment.
- [Monitoring Postgres disk usage on VMware](#)
Monitor disk usage by the Postgres database in the management subsystem, when deployed on VMware.
- [Obtaining simple health check data of Developer Portal sites by using a REST API call](#)
Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.
- [Monitoring the network with SNMP](#)
Presents a table of OID trees that you can poll using SNMP Get.

Checking cluster health on VMware

You can use `apicup` to check the health of the API Connect clusters in your VMware deployment.

The `health-check` command checks a number of criteria to determine the health of their cluster. When all criteria are successfully met, the command displays no output, and exits with a status of 0. When one or more criteria are not met, the command stops processing and displays a message with the failure and exits with a status of 1.

The command takes no arguments. The only option is the `--verbose` flag. If `--verbose` is set the command prints all checks that were performed.

The `health-check` is run against the namespace that is specified in `apiconnect-up.yaml`.

The health check is run on the specified subsystem.

The command verifies that for the specified subsystem:

- The `apicup` version matches the API Connect release version.
- All cluster members are running the same API Connect release version.
- All cluster members have a deployment status of `Done`.
- Docker is running.
- `kubelet` is running
- All Kubernetes-defined nodes are running.
- The Kubernetes Control Plane pods are running:
 - `etcd/kube-apiserver`
 - `kube-system.kube-controller`
 - `kube-scheduler`
 - `kube-apiserver-proxy`
- The add-on Kubernetes Deployments are fulfilled:
 - `coredns`
 - `metrics-server`
- The add-on Kubernetes DaemonSets are fulfilled:
 - `calico-node`
 - `ingress-nginx-ingress-controller`
 - `kube-proxy`

Syntax:

Usage:

```
apicup subsys health-check <SUBSYS> [flags]
```

Flags:

```
-h, --help                help for health-check
--kubeconfig string      (optional) absolute path to the kubeconfig file (default "/Users/<username>/<username>.kube/config")
-v, --verbose            Verbose output
```

Global Flags:

```
--accept-license  Accept the license for API Connect
--debug           Enable debug logging
```

Example usage, for a subsystem named `mgmt`:

```
../apicup subsys health-check mgmt
```

Note:

- The command flag `--kubeconfig string` does not apply to deployments on VMware.
- In a multi-node OVA cluster, the `apicup subsys health-check` command does not return status information if a majority of the nodes are down. To obtain status information, start more nodes. Status is returned only when a quorum is achieved.

Monitoring Postgres disk usage on VMware

Monitor disk usage by the Postgres database in the management subsystem, when deployed on VMware.

Postgres Database is the core database used in Management Subsystem. It is important to monitor the Postgres disk usage.

In v10.0.3.0 and greater, the APICConnect operator tracks the current disk usage of the Postgres components, and regularly updates `apic health-check` command.

APICConnect operator regularly updates the `ManagementCluster` instance status which is reflected in the `apic health-check` command.

`apic health-check` command reports WARNING state when disk utilization reaches 50%.

`apic health-check` command reports ERROR state when disk utilization reaches 70% and Postgres is brought down.

See:

- [Management Cluster disk stats](#)
- [Warning condition is populated at 50% usage](#)
- [Error condition is populated at 70% usage](#)

Management Cluster disk stats

The `ManagementCluster` instance has `.status.postgresDataStats` where the operator prints the current disk usage of Postgres components. Use `kubect1` to view the status.

To use `kubect1`, first ssh into the appliance as `root`.

```
kubectl get mgmt ml -o json | jq .status.postgresDataStats
[

  }
]
```

Warning condition is populated at 50% usage

When one of the Postgres components occupy 50% usage, the operator marks the overall status of the **ManagementCluster** to **Warning** with an appropriate warning message, which is included in the output from **apic health-check** command.

The warning condition explains why the warning condition was set.

To use **apic**, first ssh into the appliance as **root**.

```
apic health-check
```

```
FATA[0007] Cluster not in good health:
ManagementCluster is not Ready or Complete | State: 17/17 Phase:
Warning Message: Current WAL disk usage of nihar-stac-3955b42d-sitel-postgres is 51 percent.
DATABASE SHUTDOWN starts at 70 percent utilization. Please contact IBM Support immediately
```

If you encounter the warning, contact IBM support to fix the root cause.

Error condition is populated at 70% usage

An error condition is populated when the operator brings down Postgres because it is using 70% of available disk space. Postgres is brought down to avoid problems, such as disk corruption, that can occur if the disk becomes completely filled.

To use **apic**, first ssh into the appliance as **root**.

apic health-check

```
FATA[0011] Cluster not in good health:
ManagementCluster is not Ready or Complete | State: 17/17 Phase:
Error Message: Current WAL disk usage of nihar-stac-3955b42d-site1-postgres is more than 70 percent,
initiating DATABASE SHUTDOWN
```

If you encounter the error, contact IBM support to fix the root cause.

Important:

On VMware, because the entire disk is allocated to the worker node, in some cases before the operator reacts to 70% usage, , Kubernetes itself can face disk pressure and starts evicting pods. In these cases, increase the disk allocated to worker node in order to stabilize the worker node. See [Adding disk space to a VMware appliance](#).

Obtaining simple health check data of Developer Portal sites by using a REST API call

Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.

About this task

You can use the site health REST API to determine whether a particular Developer Portal site is running. The site health API returns the current system time of the site if both the database and web server are running. This API is fast and puts no load on the system, so it is ideal for use with load balancers to help them determine where to route traffic.

Procedure

To call the site health REST API, append `/health` to the end of your Developer Portal site URL in your web browser, as follows:

```
site_url/health
```

Where `site_url` is the URL of the Developer Portal site that you want to check.

If both the database and web server of the site are running, the web browser returns the current system time. For example:

```
1511367695
```

If either the database or the web server of the site is not running, the web browser returns an error that the site can't be reached.

If you do get an error from the `/health` endpoint, refer to [Gathering logs for a VMware environment](#) and obtain the `portal-www` web logs, so that you can see more information on the error.

Monitoring the network with SNMP

Presents a table of OID trees that you can poll using SNMP Get.

Simple Network Management Protocol (SNMP) collects information from network devices, such as servers, printers, hubs, switches, and routers on an Internet Protocol (IP). SNMP employs addresses for network devices using a hierarchical numbering system called Object Identifiers (OID). The following table provides OID addresses for polling in SNMP to monitor API Connect servers.

Note:

- Only SNMP v2 and SNMP v3 are supported. However, it is not recommended to enable SNMP v2. Instead, configure SNMPv3 as shown in [Configuring SNMPv3](#), and then enable it as shown in [Enabling SNMP](#).
- If the server has two or more network interfaces, the SNMP request is sent only to the first network interface.
- SNMP is disabled by default for all hosts.
- This information applies to API Connect deployments in VMware environments. It does not apply to Kubernetes deployments.

Each entry in the table represents many individual items. Use `snmpwalk` or another SNMP polling utility to see the complete list. You can poll the following OID trees:

Table 1. Default SNMPv2 configuration

OID	SNMP Name	Notes
.1.3.6.1.2.1.1	SNMPv2-MIB::system	
.1.3.6.1.2.1.2	IF-MIB::interfaces	
.1.3.6.1.2.1.4	IP-MIB::ip	
.1.3.6.1.2.1.5	IP-MIB::icmp.	
.1.3.6.1.2.1.6	TCP-MIB::tcp	
.1.3.6.1.2.1.7	UDP-MIB::udp	
.1.3.6.1.2.1.11	SNMPv2-MIB::snmp	
.1.3.6.1.2.1.25.1	HOST-RESOURCES-MIB::hrSystem	Excluding .1.3.6.1.2.1.25.1.3 HOST-RESOURCES-MIB::hrSystemInitialLoadDevice Excluding .1.3.6.1.2.1.25.1.4 HOST-RESOURCES-MIB::hrSystemInitialLoadParameters
.1.3.6.1.2.1.25.2	HOST-RESOURCES-MIB::hrStorage	
.1.3.6.1.2.1.25.3	HOST-RESOURCES-MIB::hrDevice	
.1.3.6.1.4.1.2021.4	UCD-SNMP-MIB::memory	
.1.3.6.1.4.1.2021.10	UCD-SNMP-MIB::laTable	CPU Load Average
.1.3.6.1.4.1.2021.11	UCD-SNMP-MIB::systemStats	

Configuring SNMPv3

From an OVA shell prompt as root edit the file `/etc/snmp/snmpd.conf` so that its content is:

```
createUser readOnlyUser SHA authpassphrase AES privpassphrase
rouser readOnlyUser
agentAddress udp:161,udp6:[::1]:161
```

- Replace `authpassphrase` with the passphrase to be used for authentication,
- Replace `privpassphrase` with the passphrase to be used for privacy (encryption) of the communications.

Enabling SNMP

It is not recommended to start SNMP without first configuring it for SNMPv3. See [Configuring SNMPv3](#).

Enable SNMP on each individual OVA node with the following commands from an OVA shell prompt as root:

```
systemctl start snmpd
systemctl enable snmpd
```

Sample output:

```
root@mgmt:~# systemctl start snmpd
root@mgmt:~# systemctl enable snmpd
snmpd.service is not a native service, redirecting to systemd-sysv-install
Executing /lib/systemd/systemd-sysv-install enable snmpd
inserv: warning: current start runlevel(s) (empty) of script `snmpd' overrides LSB defaults (2 3 4 5).
inserv: warning: current stop runlevel(s) (0 1 2 3 4 5 6) of script `snmpd' overrides LSB defaults (0 1 6).
```

Disabling SNMP

Disable SNMP on each individual OVA node with the following commands from an OVA shell prompt as root:

```
systemctl stop snmpd
systemctl disable snmpd
```

Sample output:

```
root@mgmt:~# systemctl stop snmpd
root@mgmt:~# systemctl disable snmpd
snmpd.service is not a native service, redirecting to systemd-sysv-install
Executing /lib/systemd/systemd-sysv-install disable snmpd
inserv: warning: current start runlevel(s) (empty) of script `snmpd' overrides LSB defaults (2 3 4 5).
inserv: warning: current stop runlevel(s) (0 1 2 3 4 5 6) of script `snmpd' overrides LSB defaults (0 1 6).
```

Checking SNMP status

Check whether SNMP is enabled on each individual OVA node with the following commands from an OVA shell prompt:

```
systemctl status snmpd
```

Sample output when SNMP is enabled and running:

```
apicadm@mgmt:~$ systemctl status snmpd
snmpd.service - LSB: SNMP agents
  Loaded: loaded (/etc/init.d/snmpd; bad; vendor preset: enabled)
  Active: active (running) since Wed 2019-02-06 03:53:02 UTC; 2 days ago
    Docs: man:systemd-sysv-generator(8)
   Tasks: 1
  Memory: 6.0M
     CPU: 3min 1.641s
  CGroup: /system.slice/snmpd.service
          └─1366 /usr/sbin/snmpd -Lsd -Lf /dev/null -u snmp -g snmp -I -smux mteTrigger mteTriggerConf -p /run/snmpd.pid
...
```

Sample output when SNMP is stopped and disabled:

```
root@mgmt:~# systemctl status snmpd
snmpd.service - LSB: SNMP agents
  Loaded: loaded (/etc/init.d/snmpd; bad; vendor preset: enabled)
  Active: inactive (dead)
    Docs: man:systemd-sysv-generator(8)
...
```

Logging

Configure logging for your deployment on VMware.

See:

- [Configuring remote logging for a VMware deployment](#)
Logging collection is required for IBM Support to assist with troubleshooting. You can configure fluent-bit to collect and forward logs to a remote Syslog server.
- [Gathering logs for a VMware environment](#)
The `generate_postmortem.sh` script gathers all logs for troubleshooting and diagnostics.

- [Changing logging levels](#)
You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

Configuring remote logging for a VMware deployment

Logging collection is required for IBM Support to assist with troubleshooting. You can configure fluent-bit to collect and forward logs to a remote Syslog server.

Before you begin

Beginning in version 10.0.5.1, API Connect uses [fluent-bit](#) to collect log files for appliance-based deployments using OVA and forward the logs to a remote Syslog server.

In API Connect 10.0.5.2 or later, the fluent-bit service is already installed on the appliances and is configured to forward container logs to `/var/log/syslog` on the local machine. For best results, upgrade to API Connect 10.0.5.2 or later so you can take advantage of the included fluent-bit service.

Important: This article refers to third-party software that IBM does not control. As such, the software may change and this information might become outdated. In addition, the fluent-bit service was tested only for simple container log routing to local and remote Syslog servers as configured in the instructions that follow. Any customization of other fluent-bit settings (for example, to set up parsers or filters) is at your own risk and should be performed with caution by referring to the [fluent-bit documentation](#).

About this task

Remote logs created with fluent-bit use the following format:

```
Mar 1 00:38:44 apicdev1147 calico-node-gqbv_42428a8ade169ad3 2023-03-01 00:38:44.684 [INFO][208] felix/int_dataplane.go 1245: Applying dataplane updates
```

Where:

- `Mar 1 00:38:44` is the time the log arrived on the remote server.
- `apicdev1147` is the hostname of the log source.
- `calico-node-gqbv_42428a8ade169ad3` is a portion of the pod name/container_id where the log is coming from.
- `2023-03-01 00:38:44.684` is the timestamp at which the logged event actually took place within the container.
- The rest of the log is the log message itself.

Logs posted to your local server look different, as in this example:

```
Feb 28 23:47:03 apicdev1147 fluent-bit[2332273]: [2] kube.var.log.containers.kqn2-management-portal-proxy-647b96b89f-pkz5w_default_portal-proxy-74a1723512574fdc23fb9c014b80c7e83aff225b9d44d995736251edd18c49b4.log: [1677628023.503190040, {"_p"=>"F", "log"=>"Tue, 28 Feb 2023 23:47:03 GMT express:router expressInit : /healthz", "tag"=>"kqn2-management-74a1723512574fdc", "time"=>"2023-02-28T23:47:03.503190005Z", "stream"=>"stderr"}]
```

On the local log, the whole fluent-bit JSON object is logged, which provides slightly more information (for example, the full file name of the log file) than in the remote log.

To configure remote logging, use the appropriate instructions for your deployed version of API Connect:

- [API Connect 10.0.5.2 and later: Configuring remote logging](#)
- [API Connect 10.0.5.2 and later: Update the remote logging configuration](#)
- [API Connect 10.0.5.1: Installing and configuring remote logging](#)
- [API Connect 10.0.5.1: Update the remote logging configuration](#)

API Connect 10.0.5.2 and later: Configuring remote logging

About this task

The fluent-bit service is already installed on the appliance and is configured to forward container logs to `/var/log/syslog` on the local machine. If you want to change the output destination to a remote Syslog server, complete the following steps:

Procedure

1. Create the `/etc/fluent-bit/append-tag.lua` file.
 - a. Paste the following code into the new file:

```
function append_tag(tag, timestamp, record)
    new_record = record
    local pod_name = string.sub(string.match(tag, "^kube%.var%.log%.containers%. (.+)$"), 1, 16)
    local container_id = string.sub(string.match(tag, "-([^-]+)%.log$"), 1, 16)

    new_record["tag"] = pod_name .. "_" .. container_id
    return 1, timestamp, new_record
end
```

- b. Save and close the file.
2. Create the `/etc/fluent-bit/fluent-bit-override.conf` file.
 - a. Add the following statements to the new file::
Replace the variables in the `[OUTPUT]` section with values for your deployment:

```
[SERVICE]
  Daemon Off
  Flush 1
  Log_Level info
  Parsers_File parsers.conf
  HTTP_Server On
```

```

HTTP_Listen 0.0.0.0
HTTP_Port 2021
Health_Check On

[INPUT]
Name tail
Path /var/log/containers/*.log
multiline.parser docker, cri
Tag kube.*
Mem_Buf_Limit 5MB
Skip_Long_Lines On

[INPUT]
Name systemd
Tag host.*
Systemd_Filter _SYSTEMD_UNIT=kubelet.service
Read_From_Tail On

[FILTER]
Name kubernetes
Match kube.*
Merge_Log On
Keep_Log Off
K8S-Logging.Parser On
K8S-Logging.Exclude On

[FILTER]
Name lua
Match kube.*
Script /etc/fluent-bit/append-tag.lua
call append_tag

[OUTPUT]
Name syslog
Match *
Host <host>
port 514
mode udp
syslog_format rfc5424
syslog_maxsize 2048
syslog_hostname_key hostname
syslog_hostname_preset <hostname of local machine/log source>
syslog_appname_key tag
syslog_message_key log

```

Note: The default values shown in the [OUTPUT] section can be modified as explained in the [fluent-bit documentation](#).
b. Save and close the file.

3. Run the following command to restart the fluent-bit service so it picks up the configuration changes:

```
systemctl restart appliance-manager && systemctl restart fluent-bit
```

API Connect 10.0.5.2 and later: Update the remote logging configuration

To update the fluent-bit configuration, complete the following steps:

Procedure

1. Run the following command to edit the configuration file:
- ```
vim /etc/fluent-bit/fluent-bit-override.conf
```
2. Complete your configuration changes, then save and close the file.
  3. Run the following command to restart the appliance-manager:

```
systemctl restart appliance-manager
```

## API Connect 10.0.5.1: Installing and configuring remote logging

### About this task

Download Debian packages from IBM Fix Central to install fluent-bit by completing the following steps:

### Procedure

1. If you previously performed a Helm installation of fluent-bit, uninstall it by running the following command:  

```
helm uninstall fluent-bit
```
2. Download the following files from IBM Fix Central:
  - [libpq5\\_12.13-0ubuntu0.20.04.1\\_amd64.deb](#)
  - [fluent-bit\\_2.0.6\\_amd64.deb](#)
3. Install libpq5 by running the following command:

```
apt install <path-to-libpq5_12.13-0ubuntu0.20.04.1_amd64.deb>
```

4. Install fluent-bit by running the following command:  
Be sure to install libpq5 first because it is a prerequisite for fluent-bit.

```
apt install <path-to-fluent-bit_2.0.6_amd64.deb>
```

5. Create the /etc/fluent-bit/append-tag.lua file.

- a. Paste the following code into the new file:

```
function append_tag(tag, timestamp, record)
 new_record = record
 local pod_name = string.sub(string.match(tag, "^kubernetes%.(.+)"), 1, 16)
 local container_id = string.sub(string.match(tag, "-([^-]+).log$"), 1, 16)

 new_record["tag"] = pod_name .. "-" .. container_id
 return 1, timestamp, new_record
end
```

- b. Save and close the file.

6. Configure the input and output settings for the configuration file, so that fluent-bit forwards logs to Syslog:

- a. Run the following command to edit the configuration:

```
vim /etc/fluent-bit/fluent-bit.conf
```

- b. Replace the contents of the file with the following information:

- For a local Syslog:

```
[SERVICE]
 flush 1
 daemon Off
 log_level info
 parsers_file parsers.conf
 plugins_file plugins.conf
 http_server Off
 http_listen 0.0.0.0
 http_port 2020
 storage.metrics on

[INPUT]
 Name tail
 Path /var/log/containers/*.log
 Parser cri
 Mem_Buf_Limit 5MB
 Skip_Long_Lines On

[OUTPUT]
 name stdout
 match *
```

- For a remote Syslog:

Replace the variables in the [OUTPUT] section with values for your deployment:

```
[SERVICE]
 Daemon Off
 Flush 1
 Log_Level info
 Parsers_File parsers.conf
 HTTP_Server On
 HTTP_Listen 0.0.0.0
 HTTP_Port 2021
 Health_Check On

[INPUT]
 Name tail
 Path /var/log/containers/*.log
 multiline.parser docker, cri
 Tag kube.*
 Mem_Buf_Limit 5MB
 Skip_Long_Lines On

[INPUT]
 Name systemd
 Tag host.*
 Systemd_Filter _SYSTEMD_UNIT=kubelet.service
 Read_From_Tail On

[FILTER]
 Name kubernetes
 Match kube.*
 Merge_Log On
 Keep_Log Off
 K8S-Logging.Parser On
 K8S-Logging.Exclude On

[FILTER]
 Name lua
 Match *
 Script /etc/fluent-bit/append-tag.lua
 call append_tag

[OUTPUT]
 Name syslog
 Match *
 Host <host>
 port 514
 mode udp
 syslog_format rfc5424
 syslog_maxsize 2048
 syslog_hostname_key hostname
 syslog_hostname_preset <hostname of local machine/log source>
 syslog_appname_key tag
 syslog_message_key log
```

Note: The default values shown in the [OUTPUT] section can be modified as explained in the [fluent-bit documentation](#).  
c. Save and close the file.

7. Run the following commands to start the fluent-bit service:
  - a. Enable fluent-bit to start after a system restart:

```
systemctl enable fluent-bit
```

- b. Start fluent-bit:

```
systemctl start fluent-bit
```

## API Connect 10.0.5.1: Update the remote logging configuration

---

To update the fluent-bit configuration, complete the following steps:

### Procedure

1. Run the following command to edit the configuration file:

```
vim /etc/fluent-bit/fluent-bit.conf
```

2. Complete your configuration changes, then save and close the file.
3. Run the following command to restart the fluent-bit service:

```
systemctl restart fluent-bit
```

---

## Gathering logs for a VMware environment

The `generate_postmortem.sh` script gathers all logs for troubleshooting and diagnostics.

### About this task

---

When you contact IBM Support, logs and VMware environment data are normally required to help diagnosis. Run the `generate_postmortem.sh` script on each API Connect VM to gather all the required logs and data. The data that is gathered by the script includes OS-level information from each VM, so if you have a three replica deployment, it is recommended to run the `generate_postmortem.sh` script on each VM in the cluster.

The logs that are gathered by the `generate_postmortem.sh` script include the logs of the currently running API Connect processes. The logs have a maximum size, and older log messages are not retained when the maximum size is reached. To ensure that the logs gathered cover the time when the problem occurred, it is recommended to reproduce the problem and then immediately gather the logs. Offboarding the logs to an external server is the recommended best practice for long-term storage of log data. See [Configuring remote logging for a VMware deployment](#).

### Procedure

---

1. Connect to the target appliance with SSH:

```
ssh apicadm@<ova_appliance_hostname>
```

2. Switch to the `root` user:

```
sudo -i
```

3. Download the `generate_postmortem.sh` script. Enter the following command:

```
curl -s -o generate_postmortem.sh https://raw.githubusercontent.com/ibm-apiconnect/v10-postmortem/master/generate_postmortem.sh
```

Note: If your API Connect VMs do not have external internet access, download the `generate_postmortem.sh` script to another computer that has internet access, and copy it to your API Connect VMs.

4. Add execute permissions to the `generate_postmortem.sh` script. Enter the following command:

```
chmod +x generate_postmortem.sh
```

5. Run the postmortem tool by using the following command:

```
./generate_postmortem.sh --ova --pull-appliance-logs
```

6. Optional: Specify either management, portal, or analytics for more detailed logs from that subsystem. Specify `--diagnostic-all` for detailed logs of every subsystem:

- Portal:

```
./generate_postmortem.sh --ova --diagnostic-portal --pull-appliance-logs
```

- Management:

- Download an additional file that gathers management database information: `crunchy_gather.py`:

```
wget https://github.com/ibm-apiconnect/v10-postmortem/blob/master/crunchy_gather.py
```

- Run `generate_postmortem.sh` with `--diagnostic-manager`:

```
./generate_postmortem.sh --ova --diagnostic-manager --pull-appliance-logs
```

- Analytics:

```
./generate_postmortem.sh --ova --diagnostic-analytics --pull-appliance-logs
```

Note: The diagnostic level logs generated with the `--diagnostic-<subsystem name>` argument produce a much larger output file.

7. If you see errors when you run the `generate_postmortem.sh` script, run again with `--debug`:

```
./generate_postmortem.sh --ova --debug &>debug.log
```

For more documentation on the script, see <https://github.com/ibm-apiconnect/v10-postmortem>.

---

## Changing logging levels

You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

### About this task

---

For apim-v2 pods, the default logging settings do not include entry and exit trace and logging of large payloads.

Logging of large payloads is typically needed if you are logging `apim:webhookPayload` or other processes that log large variables.

You can also set the debug level without needing to restart the pods.

You can enable the settings through either the APIM deployment YAML file, the toolkit, or the REST APIs. Note, you must use the toolkit or REST API to set the debug level without restarting the pods.

### Procedure

---

- Updating the settings in the APIM deployment YAML file

Note: This action causes a pod restart.

- The DEBUG variable works the same as prior releases.

```
- env:
 - name: DEBUG
 value:
audit,bhendi:error,bhendi:probe,bhendi:flags,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:
*
```

To enable entry and exit trace, add `trace:*` to the start of the debug string:

```
- env:
 - name: DEBUG
 value: trace:*,audit,bhendi:error,bhendi:probe,bhendi:flags,bhendi:webhookAudit,bhendi:cassandra-
transactions,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:*,apim:taskmanager:info
```

- To enable large object logging:

```
- env:
 - name: VELOX_LOG_FULL_PAYLOAD
 value: "true"
```

- Updating the settings by using the toolkit

Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

```
apic log-spec:get
apic log-spec:update LOG_SPEC_FILE
```

Where the spec file contains:

```
{"specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error", "large_objects": true}
```

- Updating the settings by using the REST API

Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

```
GET /cloud/api/log-spec
PUT /cloud/api/log-spec
```

For example, to set debug level and large objects logging:

```
curl -k https://172.16.140.212:3003/api/cloud/log-spec -X PUT -H "Authorization: Bearer $BEARER"
-H "Accept: application/json" -d '{"specification":
"apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error", "large_objects": true}'
-H "Content-Type: application/json"
```

The command responds with:

```
{
 "specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error",
 "large_objects": true,
 "message": "Successfully changed the log specification on all apim-v2 pods. Success on IP(s): 172.16.140.212,
172.16.140.213"
}
```

Note: The response might include the following warning, which can be ignored:

```
WARNING: Could not change the log specification on all apim-v2 pods. Success on IP(s): 4.5.6.7 Failed on IP(s): 1.2.3.4
```

To view the REST APIs for logging, go to [API Connect REST APIs](#), and select IBM API Connect Platform - Cloud Management API 2.0.0 reference\_2\_Resource: Log Spec.

---

## Troubleshooting

Troubleshoot your deployment on VMware.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from. See:

- [Recreating a calico pod that is in the CrashLoopBackOff state](#)  
If you complete an upgrade and find that one or more of the calico pods are in the `CrashLoopBackOff` state, you can delete the pod to recreate it.
- [Running a filesystem check on a VMware root partition](#)  
You can run a filesystem check on the appliance root filesystem at boot time.
- [Troubleshooting the management database](#)  
You can troubleshoot the API Connect management database
- [Increasing the PostgreSQL archive timeout on VMware](#)  
Increase the `archive_timeout` to 3600 (seconds) so that accumulated wal files do not cause a disk-space issue during a network outage.
- [Dynamically re-registering and reconfiguring a Gateway service in a VMware deployment](#)  
In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.
- [Troubleshooting Analytics on VMware](#)  
If your API Connect Analytics subsystem encounters problems, review the following topics for help resolving the issue.

---

## Recreating a calico pod that is in the `CrashLoopBackOff` state

If you complete an upgrade and find that one or more of the calico pods are in the `CrashLoopBackOff` state, you can delete the pod to recreate it.

Complete the following steps:

1. Get the names of the calico pods:

```
kubectl -n kube-system get pods | grep calico
```

2. Recreate each pod by deleting it with the following command:

```
kubectl -n kube-system delete pod <calico_pod_name>
```

---

## Running a filesystem check on a VMware root partition

You can run a filesystem check on the appliance root filesystem at boot time.

---

### About this task

If the appliance root filesystem is mounted read-only because it is corrupt, use the following steps to run `fsck` on root partition:

---

### Procedure

1. Access to the VMware console for the Appliance, and after causing it to reboot, make sure to bring up a console to the appliance (as needed to give focus to the window by clicking the mouse into it), and press the `Esc` key repeatedly. You will see a boot screen similar to the following:

```
GNU GRUB v2.02
.
- Ubuntu
- Advanced options for Ubuntu
.
.
Press Enter to boot the selected OS, 'e' to edit the commands
before booting or 'c' for a command-line
```

2. Press `e` to edit the commands before booting, and add the lines `fsck.mode=force` and `fsck.repair=yes`. For example, the boot screen contents resemble:

```
GNU GRUB v2.02
.
set params 'Ubuntu'
fsck.mode=force
fsck.repair=yes
```

```
Press Ctrl-x or F10 to boot
```

3. Press F10 to boot.
4. The following command should show that **fsck** was run recently:

```
root@ip-230:~# sudo tune2fs -l /dev/sda1 | grep "Last checked"
Last checked: Wed Jul 1 19:32:25 2020
```

## Troubleshooting the management database

You can troubleshoot the API Connect management database

### Database Replica Pods stuck in Unknown or Pending state

In certain scenarios, a postgres replica pod may not recover to a healthy state when a restore completes, a node outage occurs, or after a fresh install or upgrade. In these cases, a postgres pod remains in a **Unknown** or a **Pending** state after a number of minutes. The pod fail to get into a **Running** state.

This situation occurs when the replicas do not initialize properly. You can use the **patronictl reinit** command to reinitialize the replica. Note that this command syncs the replica's volume data from the current Primary pod.

Use the following steps to get the pod back into a working state:

1. SSH into the appliance as **root**.
2. Exec onto the failing pod:

```
kubectrl exec -it <postgres_replica_pod_name> -n <namespace> -- bash
```

3. List the cluster members:

```
patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+-----+-----+
| Member | Host | Role | State | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+
| fxpk-management-01191b80-postgres-586f899fdf-6s25b | 172.16.172.244 | | start failed | | unknown |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51 | Leader | running | 3 | |
| fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m | 172.16.53.68 | | running | 3 | 0 |
+-----+-----+-----+-----+-----+-----+
```

In the example shown above **fxpk-management-01191b80-postgres-586f899fdf-6s25b** is not in running state.

Note the **clusterName** and **replicaName** which are not up:

- **clusterName** - **fxpk-management-01191b80-postgres**
- **replicaName** - **fxpk-management-01191b80-postgres-586f899fdf-6s25b**

4. Run:

```
patronictl reinit <clusterName> <replicaName-which-is-not-running>
```

Example:

```
patronictl reinit fxpk-management-01191b80-postgres fxpk-management-01191b80-postgres-586f899fdf-6s25b
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+-----+-----+
| Member | Host | Role | State | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+
| fxpk-management-01191b80-postgres-586f899fdf-6s25b | 172.16.172.244 | | start failed | | unknown |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51 | Leader | running | 3 | |
| fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m | 172.16.53.68 | | running | 3 | 0 |
+-----+-----+-----+-----+-----+-----+
Are you sure you want to reinitialize members fxpk-management-01191b80-postgres-586f899fdf-6s25b? [y/N]: y
Success: reinitialize for member fxpk-management-01191b80-postgres-586f899fdf-6s25b
```

5. Run **patronictl list** again.

You may also observe that the replica is on a different Timeline (TL) and possibly have a Lag in MB. It may take a few minutes for the pod to switch onto the same TL as the others and the Lag should slowly go to 0.

For example:

```
bash-4.2$ patronictl list
+ Cluster: fxpk-management-01191b80-postgres (6893134118851096752) -----+-----+-----+-----+-----+-----+
| Member | Host | Role | State | TL | Lag in MB |
+-----+-----+-----+-----+-----+-----+
| fxpk-management-01191b80-postgres-586f899fdf-6s25b | 172.16.172.244 | | running | 1 | 23360 |
| fxpk-management-01191b80-postgres-rkww-795665698f-4rh4s | 172.16.148.51 | Leader | running | 3 | |
| fxpk-management-01191b80-postgres-uvag-9475f7c5f-qr84m | 172.16.53.68 | | running | 3 | 0 |
+-----+-----+-----+-----+-----+-----+
```

6. The pod that previously was in an **Unknown** or **Pending** state or (0/1) **Running** state is now in (1/1) **Running** state.

## Increasing the PostgreSQL archive\_timeout on VMware

Increase the `archive_timeout` to 3600 (seconds) so that accumulated wal files do not cause a disk-space issue during a network outage.

## About this task

PostgreSQL sends its wal archives to the backup location (S3 or local PVC) whenever the configured `archive_timeout` period elapses. By default, the `archive_timeout` is set to 60 seconds. During a network outage, the files cannot be transferred and instead accumulate on the current server, and could cause a disk-space issue. Increasing the `archive_timeout` value helps to mitigate this issue by creating archive files less frequently.

For information on tracking the Postgres disk space, see [Monitoring Postgres disk usage on VMware](#).

Complete the following steps to increase the PostgreSQL `archive_timeout` value.

## Procedure

1. SSH into the server by completing the following steps:
  - a. Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```
  - b. When prompted, select Yes to continue connecting.
  - c. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

2. Get the name of the `pgha` config map by running the following command:

```
kubectl -n <namespace> get cm -l pgha-config='true'
```

The response looks like the following example:

| NAME                                            | DATA | AGE |
|-------------------------------------------------|------|-----|
| apis-prod-d18f3f0-0d18f3f0-postgres-pgha-config | 5    | 22d |

3. Edit the config map by running the following command:

```
kubectl -n <namespace> edit configmap <config-map-name>
```

In the command, replace `<config-map-name>` with the `NAME` returned in step 1.

4. Change the `archive_timeout` value to 3600.

The value must be an integer, and represents the number of seconds that must elapse before the archive file is generated.
5. Save the file and exit the editor.

The configuration is updated automatically; archives will be generated and pushed every 3600 seconds.

## Dynamically re-registering and reconfiguring a Gateway service in a VMware deployment

In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.

If a Gateway service is not configured properly for resiliency and is restarted, the gateways in the Gateway service will lose the configuration from the Management server. Configuration data from the Management server is maintained on the gateway service according to the gateway peering configuration on the gateways.

## Preventing the loss of configuration data

For high availability in production environments, use a minimum of three gateways in the Gateway service. In non-production environments, if a single gateway is used, then availability can be improved by ensuring the persistence setting on the gateway peering configuration is set to `local://` or `RAID`; these settings apply to virtual and physical appliances only.

## Forcing re-population of the configuration data

To repopulate the configuration data, complete the steps in the following section to trigger an outage-less DRR.

## Triggering an outage-less DRR

To force a Dynamic Reregistration and Reconfiguration across a peer group from within the gateway service without requiring a restart, complete the following steps using the CLI. This process flushes the primary peering object configured for the `apic-gw-service`. This task can only be performed with CLI, and requires the default admin ID for running the `diag` command.

1. Use `ssh` to connect to gateway service.
2. Switch to the API Connect application:

```
switch <APIC_APP_DOMAIN>
```

3. Show the current gateway-peering-status:

```
show gateway-peering-status
```

4. If the server to which the ssh connection was made is not primary for the `apic-gw-service` gateway-peering object, force this server to become primary:

```
config; gateway-peering-switch-primary <gateway-peering-name-for-apic-gw-service>;
```

5. Flush the apic-gw-service gateway-peering object:

```
diag; gateway-peering-flush <gateway-peering-name-for-apic-gw-service>; exit
```

6. Disable and then re-enable the apic-gw-service object for every member of the gateway service:

```
config; apic-gw-service; admin-state disabled; exit
apic-gw-service; admin-state enabled; exit; exit
```

7. Confirm that the apic-gw-service was flushed and is now waiting for gateway service registration:

Look in the debug log target for the apic-gw-service, located in logtemp:/// and check for a message similar to the following example:

```
20200618T232339.332Z [0x88e000d7][apic-gw-service][notice]
apic-gw-service(default): tid(2653): Waiting for gateway service registration.
```

The DRR will be triggered by the next arrival of a webhook event. The Management server sends a heartbeat to the gateway at five-minute intervals, prompting the gateway to check whether it has lost its configuration and if so, trigger a DRR. In addition, if the Management server has previously marked a Catalog or cloud as being unavailable for a particular gateway service, a successful heartbeat triggers synchronization for that Catalog or cloud on that gateway service.

8. (Optional) Force a BAU webhook event to be sent from API Manager to trigger the DRR:

If you do not want to wait for the Management server to send a heartbeat, you can trigger the DRR manually by completing the following steps:

- a. Open the API Manager.
- b. Open the Catalog.
- c. Click Settings > Edit.
- d. Update the Summary field with some text so that it is modified.
- e. Click Save.

When the event is received, the DRR is initiated.

---

## Troubleshooting Analytics on VMware

If your API Connect Analytics subsystem encounters problems, review the following topics for help resolving the issue.

- [Analytics offload issues on VMware](#)  
If your Analytics offload fails, you can perform checks to help determine the cause. Common causes for an offload failure are connection or security-related issues.
- [Empty Analytics display on VMware](#)  
If your API Connect analytics data doesn't display in the Analytics dashboard, complete the following steps to determine the cause of the problem.
- [Analytics running out of disk space on VMware](#)  
Actions that you can take if your analytics data is using more persistent storage space than you expected.

---

## Analytics offload issues on VMware

If your Analytics offload fails, you can perform checks to help determine the cause. Common causes for an offload failure are connection or security-related issues.

When you save the configuration files, their syntax is first validated to verify that it can be applied. However, this does not confirm that other parts of your analytics collection ecosystem are trouble-free, for example, that your endpoints are running, or that the TLS certificates are validated. Errors in these areas may also result in no data output.

To verify issues you will need to examine the logs of your analytics ingestion pods. (Note that it may take a few minutes for the pods to pick up changes in the configuration files after edits are applied.)

For information on obtaining logs, refer to [Logging](#).

Following are some common checks you can make to troubleshoot the offload:

- Verify that the specified URL or the host and port values for the target system are accurate.
- Verify that the server or cluster of servers in the target system are running and reachable. If applicable, also verify that the connection problems are not caused by firewall settings.
- If you are using Transport Layer Security (TLS) to establish a private and secure communication channel to the target system, investigate whether the issue is caused by SSL certificate errors; for example, untrusted server certificates, certificates that have expired or are not yet valid, or missing intermediate (or chain) certificates. For more information on using TLS, see [Creating a TLS profile](#).
- If offloading to an Elasticsearch or Kafka target, verify that your configuration settings are valid; for example, the user credentials for authenticating to Elasticsearch or the Kafka topic name.

---

## Empty Analytics display on VMware

If your API Connect analytics data doesn't display in the Analytics dashboard, complete the following steps to determine the cause of the problem.

---

## Before you begin

This operation requires the use of the Analytics CLI. [Using the Analytics CLI](#).

## Procedure

1. SSH into the server:
  - a. Run the following command to connect as the API Connect administrator, replacing `ip_address` with the appropriate IP address:

```
ssh ip_address -l apicadm
```

- b. When prompted, select Yes to continue connecting.
- c. When you are connected, run the following command to receive the necessary permissions for working directly on the appliance:

```
sudo -i
```

2. Run the following command to check the logs of the `mtls-gw` pod:

```
kubect1 logs analyt-mtls-gw-7665f5d445-4cx4n -n <APIC_namespace>
```

The response looks like the following example:

```
10.254.6.1 - - [22/Sep/2021:18:05:54 +0000] "POST /x2020/v1/apievent/_bulk HTTP/1.1" 200 2 "-" 2841 0.072 0.070
```

- a. Check the response for any `_bulk` request coming from the gateway, as shown in the example. If there are no `_bulk` requests, then the problem is with the gateway and the `wsm-agent`, which is not sending bulk requests to the Analytics server.
- b. If you see the `_bulk` request., then check the return code in the response. If `_bulk` requests are processed successfully you will see a return code 200 (as in the example), which indicates that the bulk request has been ingested.
- c. If it is any other return code, check the ingestion pod logs for any errors, which will indicate any issues during ingestion:

```
oc logs analyt-ingestion-78d7cff7f7-6pktd
```

3. If everything with the data flow looks fine, and if you are unable to see analytics data, then check the health of analytics using the CLI:

```
apic --mode analytics clustermgmt:getHealth --server <management server platform api endpoint> --analytics-service <analytics service name> --format json
```

where:

- `<management server platform api endpoint>` is the Management server admin endpoint.
- `<analytics service name>` is the name of Analytics service as configured in the Cloud Manager.

When you check the cluster's health, the response for a single node analytics deployment looks like the following example:

```
{
 "cluster_name": "apic-analytics-cluster",
 "status": "yellow",
 "timed_out": false,
 "number_of_nodes": 1,
 "number_of_data_nodes": 1,
 "discovered_master": true,

}
```

Note: Single node analytics clusters never show **green** in the health output. Green indicates that the data is replicated to at least one other node, and since there are no other nodes in a single node cluster it remains as **yellow**.

- a. Check the status of the cluster (red, yellow, green) in the response. In the example, the status is set to yellow.
  - Green indicates all indices are fine.
  - Yellow indicates there are some unassigned shards, which might still be replicating.
  - Red indicates there is a problem with one or more of the indices.
- b. Run the following command to get a list of indices:

```
apic --mode analytics clustermgmt:catIndices --server [SERVER] --analytics-service [ANALYTICS SERVICE]
```

where:

- `SERVER` is the Management server admin endpoint.
- `ANALYTICS SERVICE` is the name of Analytics service as configured in the Cloud Manager.

- c. From the list of indices returned, identify the those with status of 'red'.
- d. Delete each red index by running the following command:

```
apic --mode analytics clustermgmt:deleteIndex --index <index_name> --server [SERVER] --analytics-service [ANALYTICS SERVICE] --format json
```

where:

- `SERVER` is the Management server admin endpoint.
- `ANALYTICS SERVICE` is the name of Analytics service as configured in the Cloud Manager.

---

## Analytics running out of disk space on VMware

Actions that you can take if your analytics data is using more persistent storage space than you expected.

## Reduce retention period

---

The simplest remedy to running out of storage space is to reduce the data retention period.

By default, API event records are retained for 30 days on a one replica deployment, and 90 days on a three replica deployment.

If your analytics subsystem was deployed more recently than your retention period (for example, less than 30 days ago for a default one replica deployment), and you are running out of storage space, then there is a risk that your persistent storage fills up before the retention period is reached. Check in the Cloud Manager UI how many days back your API event data goes, and set the retention period to a lower number. For example, if you see API event records from 15 days ago, reduce your storage requirement by one-third by setting your retention period to 10 days. See [Configuring data retention and index rollover time periods](#).

## Add extra disk

---

You can increase the space available for your analytics data by adding a disk, see: [Adding disk space to a VMware appliance](#).

Warning: Do not attempt to increase the size of the existing data disk. Changing the disk size corrupts your existing analytics data.

## Reduce space used by new API event data

---

To reduce the storage required for new analytics data, update the activity log settings of your APIs. If you have logging set to **payload** when it is not needed, then change logging to **activity**: [Configuring activity logging](#).

Note: If you're not able to update the activity log setting for your APIs, you can disable response payload logging for all APIs with ingestion filters. For example:

```
filter {
 if "apicapievent" in [tags] {
 mutate {
 remove_field => ["response_body"]
 }
 }
}
```

For more information about filters, see: [Planning to modify your analytics data](#).

## What to do if your storage is 100% full

---

If your storage space is 100% full, your analytics subsystem might be unresponsive, so reducing the retention period is not possible. In this scenario, follow the disaster recovery steps: [Disaster recovery](#).

## Migrating from API Connect v5 Public Cloud

---

Prepare to move to API Connect v10 by migrating your existing data from API Connect v5 Public Cloud.

The migration process provides tools to extract v5 data, arrange it for v10 formats, and load it onto a v10 deployment.

## What can I migrate to v10?

---

The resources and assets associated with your v5 Public Cloud instance are included in the migration; for example, TLS profiles, APIs, Catalogs, Products, Consumers, subscriptions, user registries, and developer organizations. In addition, your billing data (Stripe integrations, paid Plans, and consumer payment methods) is migrated from v5 to v10.

Analytics data (including searches, visualizations, and dashboards) cannot be migrated due to changes in the Analytics feature. If you want to preserve your event data, you should export it from v5 Public Cloud using either [CSV files](#) or [REST API calls](#) as explained in the v5 Public Cloud documentation.

Important: The migration utility allows migration from v5 to a v10 v5-compatible gateway or v10 API Gateway. References to conversion of v5-compatible artifacts to v10 API Gateway refer to the v5-compatible artifacts that were initially from a v5 environment and were unpacked by the migration utility.

## How do I migrate to v10?

---

You should be familiar with v5 Public Cloud architecture and requirements, and with the deployment configuration that you want to migrate to v10. The migration process requires you to have administrator-level access to both v5 Public Cloud and to your v10 on-premises deployment. During the migration process you can keep your existing v5 system active while you set up your v10 API Connect deployment.

The migration process involves the following high-level tasks, which are described in the topics that follow:

1. Deploy API Connect v10.
2. In your v5 Public Cloud instance, enable migration and download your data.
3. Install the AMU (API Connect Migration Utility) tool on the computer where you downloaded your data.
4. Unpack the downloaded data, which creates a directory structure containing YAML files where you can modify data for use in v10.
5. Use the AMU tool to upload the modified data to your v10 API Connect deployment.
6. Recreate billing integrations and other customizations as needed.

- [Migration considerations](#)

You can optimize the migration process by reviewing the migration considerations and taking any actions that apply to your deployment.

- [Preparing to migrate from v5 Public Cloud](#)

Plan the migration, deploy API Connect v10, download v5 Public Cloud data, and set up the migration utility.

- [Migrating data and Portal Delegated User Registries](#)  
Complete the following steps to migrate v5 Public Cloud data and Portal Delegated User Registries.
- [Migration troubleshooting](#)  
If you run migration and observe error messages in your log output, you can take troubleshooting steps, and run the migration again.

## Migration considerations

You can optimize the migration process by reviewing the migration considerations and taking any actions that apply to your deployment.

Review the following information:

- [Limitations and workarounds](#)
- [Version 5 data that is not migrated](#)
- [Parity between v5 and v10](#)
- [Customizations to recreate](#)

## Limitations and workarounds

- When migrating catalog spaces in a provider organization that uses a local user registry (LUR), ensure that the LUR is configured with the visibility setting of either Public or Custom. If set to Custom, ensure that the provider organization is selected.
- Migration of the v5 username token policy for authenticating the username token is not supported.
- In v10, you cannot publish a product containing an API with a `regex` Swagger property that includes the ( or ? in the characters for the pattern. You can expect to see an error message similar to the following example:

```
(? The preceding token is not quantifiable
```

- The migration utility validates Products and APIs against the OpenAPI specification (validation is not performed on draft Products and draft APIs). The `archive:unpack` command issues warnings for any Product or API that fails validation. To resolve warnings, fix the Product or API and re-run the `unpack` command. Example warning:

```
WARN[0019] Error validating product cloud/provider-orgs/onlinebanking/catalogs/test/products/clientipfilter-policy-test-api-1.0.0.yml:
Validation errors:
Error validating API cloud/provider-orgs/onlinebanking/catalogs/test/products/api123-1.0.0.api.yml
- Must validate one and only one schema (oneOf) (context: (root).securityDefinitions, line: 36, col: 3)
- securityDefinitions.authorizationUrl Does not match format 'uri' (context: (root).securityDefinitions.authorizationUrl, line: 0, col: 0)
```

- OAuth Provider APIs:
  - To ensure that APIs that use OAuth security definitions are mapped to the corresponding OAuth Provider APIs in v10, make sure that either the Authorization URL or the Token URL defined in OAuth Security Definitions of APIs that use OAuth correctly point to the base path of the OAuth Provider API. Note that the Migration tool uses that logic to map Consumer APIs to Provider APIs, and adds `x-ibm-oauth-provider` in the OAuth Security Definition of the consumer API.
  - To verify whether OAuth Provider APIs are migrated correctly, ensure that all the APIs that use OAuth Security Definition have the new field `x-ibm-oauth-provider` added. Check the value of that field and make sure it points to a correct OAuth Provider resource object that was created and configured in the catalog to which the API is published.
  - In v5, OAuth Providers are a specialized type of API that are published within products. In v10, OAuth Providers are first class objects that are directly published in the provider organization and are not APIs that are published within products. Because of this, it is possible that you may have some v5 products that only contained OAuth Provider APIs. Since these products do not contain any Open API definitions in v10, they will not be published as all products in v10 must contain at least one Open API definition.
- Portal Delegated User Registry migration limitations
  - OIDC: Automated migration is not supported for some v5 PDUR OIDC registries and you will see instructions for providing the `client_id` and `client_secret` while mapping the registries.
  - LDAP: Automated configuration is not supported for LDAP registries and you will see instructions for configuring them manually while mapping the registries.
- The SCIM (System for Cross-domain Identity Management) user registry type was supported in Version 4 but was deprecated for Version 5 and is not supported in v10. If data with a SCIM identity provider type is detected during migration of v5 data, the migration utility logs the following error message:

```
WARN[0614] manual fix required for cloud/provider-orgs/apimteam/user-registries/scimcv/user-registry.yml:
The SCIM user registry type is no longer supported
```

Any v5 data with a SCIM identity provider type must be manually migrated. For v10, you can use OIDC with a back-end user registry that supports SCIM. You must develop custom code to complete the data flow between the OIDC provider and your backend user registry. The API Connect built-in OIDC registry interacts with your OIDC provider.

- Roles limitations

In API Connect v5, it was possible to create a role (and associated permissions) at the organization level and the role was inherited by the catalogs within the organization. With the v5 inheritance model it was possible to modify the inherited role and add or remove permissions.

In API Connect v10 the inheritance model has changed and it is no longer possible to remove permissions from an inherited role. Because of this design change, it becomes difficult to perform a true 1-to-1 migration keeping the original parent-child relationships. For example, in v5 it was possible for an inherited role to contain fewer permissions than its parent role, but this is not supported in v10. To work around this restriction, the parent-child relationship is purposely decoupled during migration, and a new artificial parent role is created for each of the child roles.
- Modifications made to default roles in v5 are not migrated to v10.
- If the v5 settings `server_name_indication` and `limit_renegotiation` are not specified, the value defaults to `true`. However if they are specified with value of `false` that value is changed to `true`. Thus the settings are always `true`.
- Subscriptions on staged products are not automatically migrated because in v10, staged products cannot have subscriptions on them. To save those subscriptions, change the state of the product to either deprecated or published before running the `archive:push` command to upload data to v10. You can do this either in v5 before downloading your data, or in by mapping or editing the downloaded product metadata and to change the state of the product.  
If you have already pushed the staged product, then you can publish the product in your v10 environment and rerun `archive:push` to migrate the subscriptions.

- The migration utility appends `-apigw` to the end of the `x-ibm-name` of APIs to maintain uniqueness from the original v5 artifacts. Therefore, custom backend services that rely on the `x-ibm-name` of the APIs to be matched must be updated to look for `-apigw` in the new API name. Alternatively, the custom backend service can be modified to strip `-apigw` from the API name.
- When migrating default catalog user registries, and migration has completed, you might see more than one catalog User Registry with the same title. Whenever a new catalog is created in v10, API Connect creates a default catalog user registry. When migration takes place, the catalog user registry from v5 is migrated onto the v10 system. Both these registries receive the same Title; however they receive different Names and function as separate user registries (registries are managed by Name, not Title).

Example: If the catalog is called `test`:

- Name of user registry migrated from v5: `test-catalog`
- Name of default user registry created in v10: `test-catalog-0`
- Title of both the user registries: `Test Catalog User Registry`

All the user data is successfully migrated to the user registry coming from v5; manually update the catalog settings to use the migrated v5 user registry as the default. You can optionally clear the default user registry provided by v10 from the list of configured catalog user registries.

If you manually create the catalog and users already exist in the default catalog user registry provided by v10, then both the migrated v5 catalog user registry and the v10 default user registry can coexist, and either of them can be selected as default.

## Version 5 data that is not migrated

- APIs with LTPA policies are not migrated because this policy is not supported in v10.
- Configuration in v5 for gateway type `Microgateway` is not migrated because `Microgateway` is not supported in v10.
- Transient or conflicting configuration data is not migrated:
  - Tasks that are still active are not included in the downloaded v5 data; for example, lifecycle approvals or subscription approvals that have been requested but not granted.
  - Drafts on v5 that are local are not migrated. If you have draft APIs or draft products that you want migrated to v10, use `apic drafts:push` to upload in v5 before you download your v5 data for migration. For more information, see [Working with drafts](#) in the v5 Public Cloud documentation.
  - Pending invitees in user registries are not migrated.
  - Pending invitations for ownership of provider organizations are not migrated; however consumer organizations with pending ownership are migrated. If the v5 provider organization owner received an invitation for ownership but never accepted it, the owner identity is not migrated, which causes the organization to not be migrated. To avoid this issue, check for any unaccepted invitations prior to migration, and ensure they are accepted.
  - Conflicting user names within the same identity provider are not migrated.
  - Conflicting OAuth provider names or base paths are not migrated. If the migration utility encounters conflicting names or base paths for OAuth providers, the provider is not migrated.
- OAuth Shared secret keys are not migrated unless you explicitly [map them in the mapping.yml file for the gateway](#).
- Organizations without an active owner (user identity) are not migrated. One effect of this is that if the original owner of the organization is an identity that was not migrated, the provider organization or consumer organization cannot be migrated. Prevent this issue by verifying that the owner of the organization is a current user.
- Analytics data is not migrated. Analytics data (including searches, visualizations, and dashboards) cannot be migrated due to changes in the Analytics feature. If you want to preserve your event data, you should export it from v5 Public Cloud using either [CSV files](#) or [REST API calls](#) as explained in the v5 Public Cloud documentation.

## Parity between v5 and v10

- The migration utility slugifies (a slug is a human-readable, unique identifier) the names and versions of some elements when migrating from v5 to v10 to ensure that each element in v10 passes Open API schema validation and is uniquely named. The conversion rules differ depending upon which version you are migrating to.
    - **Version 10.0.5.1 and earlier:** For the names of API properties, Catalogs, Provider Organizations, Consumer Organizations, Spaces, and some other elements, any character other than `a-z`, `0-9`, or `-`, is converted to `-` and a unique suffix (based on the checksum of the name or version) is appended. Uppercase letters are changed to lowercase, with `-` added between words. Leading `-` characters are removed, and multiple consecutive `-` characters are reduced to a single `-`. For versions of similar elements, the `.` (period) character is also allowed.
    - **Version 10.0.5.2 and later:** For the names and versions of API properties, Products, Consumer Organizations, Space and some other elements, any character other than `a-z`, `A-Z`, `0-9`, `-`, `_`, or period (`.`), is converted to `-` and a unique suffix (based on the checksum of the name or version) is appended. Catalog and Provider Organization names follow the same rules, except that they do not support the period (`.`) character. Names or versions with uppercase characters are not converted to lowercase, but a unique suffix is appended to them.
- If you are using the latest version 10.0.5.2 or later version of the migration utility, you can use the `--use-old-slugify` parameter with the `apicm archive:unpack` command to unpack the V5 configuration data onto the local filesystem using the version 10.0.5.1 conversion rules. You can use this option in the following scenarios.
- You are starting a new migration to API Connect v10.0.5.1 with version 10.0.5.2-R4 or later of the migration utility.
  - You started the migration using version 10.0.5.1 of the migration utility and have upgraded to version 10.0.5.2-R4 or later.
- For more information, see the migration instructions that apply to your deployment.
- [Migration steps with PDUR](#)
  - [Migration steps without PDUR](#)

Table 1. Example migrated names on v10

| v5 name               | Migrated name on v10.0.5.1 or earlier                                                     | Migrated name on v10.0.5.2 or later                                                       |
|-----------------------|-------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| <code>abc-def</code>  | <code>abc-def</code> (no change)                                                          | <code>abc-def</code> (no change)                                                          |
| <code>Abc</code>      | <code>abc-a2c6</code>                                                                     | <code>Abc-a2c6</code>                                                                     |
| <code>AbcDef</code>   | <code>abc-def-dfc</code>                                                                  | <code>AbcDef-dfc</code>                                                                   |
| <code>Abc Def</code>  | <code>abc-def-1e82</code><br>With <code>slugify-no-checksum</code> : <code>abc-def</code> | <code>Abc-Def-1e82</code><br>With <code>slugify-no-checksum</code> : <code>Abc-Def</code> |
| <code>abc_def</code>  | <code>abc-def-c2bb</code>                                                                 | <code>abc_def</code> (no change)                                                          |
| <code>abc--def</code> | <code>abc-def-813d</code>                                                                 | <code>abc--def</code> (no change)                                                         |
| <code>-abc-def</code> | <code>abc-def-abb</code>                                                                  | <code>-abc-def</code> (no change)                                                         |
| <code>ABC-DEF</code>  | <code>abc-def-d1e</code>                                                                  | <code>ABC-DEF-d1e</code>                                                                  |

Table 2. Example migrated versions on v10

| v5 version | Migrated version on v10.0.5.1 or earlier | Migrated version on v10.0.5.2 or later |
|------------|------------------------------------------|----------------------------------------|
| 1.0.0      | 1.0.0 (no change)                        | 1.0.0 (no change)                      |
| 1.0_2      | 1.0-2-3933                               | 1.0_2 (no change)                      |
| 1.0 2      | 1.0-2-913                                | 1.0-2-913                              |
| 1.0--2     | 1.0-2-5410                               | 1.0--2 (no change)                     |
| -1.0-2     | 1.0-2-26cf                               | -1.0-2 (no change)                     |

You can use `apicm sluggify <string>` to view how a name or version string will be slugged. The following examples are for version v10.0.5.2 or later:

```
$./apicm sluggify Abc
Abc-a2c6
$./apicm sluggify -v 1.0_2
1.0_2
$./apicm sluggify --version '1.0 2'
1.0-2-913
```

- In v10, Spaces are not supported in the Sandbox Catalog. Spaces in Sandbox Catalogs are not migrated from v5 to v10. The names of Spaces found in v5 Sandbox Catalogs are logged in the migration output log. To preserve the Spaces, use a mapping file to rename the Sandbox Catalogs.
- In v10, publishing an API fails if enforced is set to `true`, and phase is set to either `Specified` or `Identified` instead of `Realized`. During migration, the phase will be set to `Realized` to allow the API to be published.
- Enforcement of user subscription to an API is handled differently in v5 and v10. In v5, subscription to a product is not allowed when in the following scenario: An API is created with enforced set to `false`, the API is associated with a product, the product is published, and then a user attempts to subscribe to a Product or Plan from the Developer Portal. In v10, the subscription is allowed for this scenario. This change can affect migration because a v5 Product that could not be subscribed to in v5 can be subscribed to in v10. Note that the change in behavior for v10 accommodates the scenario where Products or Plans have multiple APIs, some of which are enforced and some of which are not enforced. The new behavior allows such Products or Plans to be subscribed to.
- In v10, the API Manager handles all authentication methods. This change eliminates the need for configuration of a catalog with a Portal Delegated User Registry (PDUR), so during migration you will map PDURs to v10 standard user registries (see [Migration steps with PDUR](#)).
- If `OpenAPI.info.contact.email` contains more than one email address, only the first email address is migrated. If the email is not in valid RFC5322 email format then it is removed during migration.
- Provider-side applications:

In API Connect, registered applications are a fundamental concept representing an application identity known to the system. Applications have their own credential sets in the form of client ID and client secret pairs, and access to published API endpoints is governed by subscriptions associated with registered applications. Most commonly, registered applications are created by app developers belonging to a consumer organization in the context of a developer portal.

However, API Connect v5 also provides the ability for provider organizations to register and manage applications, independent of any consumer organization. Provider-owned apps behave in the same way as consumer-owned apps and carry credentials and subscriptions in exactly the same way. Customers use provider-owned applications for API testing or for cases where the app and API are owned and managed directly by the same team.

The API Connect v10 platform API does not support the creation of provider-side apps, so migration of provider-side apps is only possible if they are converted to consumer-side apps. Each provider-side app is migrated as follows by the API Connect migration utility:

- An instance of the app including its credentials (sets of client ID and secret) is created in each catalog belonging to the provider organization.
- The app is owned by a consumer organization which is the existing Sandbox Test Organization (for the provider organization's automatically created sandbox catalog) or a consumer organization named `Catalog-name Test Organization` (for other catalogs).
- The consumer organization's owner is a user named `test-user`. This user name already exists in the context of a provider organization's automatically created sandbox catalog.
- The consumer organization's owning user belongs to a user registry named `catalog-name-test-org`.
- The subscriptions belonging to the original provider-side app are retained.

These definitions are added to the relevant locations subordinate to the `cloud/` directory that is produced by the `apicm archive:unpack` command. When an `apicm archive:push` is performed, the definitions are propagated to the target system as part of the overall configuration.

## Customizations to recreate

Version 5 provides methods to customize some configurations. After you complete the automated migration, manually reapply the following customizations.

- Customized email templates  
Customized email templates are not migrated from Version 5. You can customize email templates in Version 10 with greater flexibility and precision. See [Customizing email templates](#).
- Developer Portal customizations are not migrated to a new Drupal version  
For the Developer Portal, none of the customizations are migrated because the v10 Drupal-9 baseline differs greatly from the v5 Drupal-7 baseline. This means that custom portal themes, custom modules, custom fields, custom blocks, custom pages, and more cannot be migrated. For more information, see [Migrating your Developer Portal from Version 5 to Version 10](#).

## Preparing to migrate from v5 Public Cloud

Plan the migration, deploy API Connect v10, download v5 Public Cloud data, and set up the migration utility.

### Procedure

Complete the following steps:

- Plan your migration:
  - Review all of the migration topics to ensure you understand the requirements, the general process, and important considerations.
  - Plan your new v10 deployment.

When moving from v5 to v10, use the opportunity to review your current resources, such as user registries, provider organizations, and so on. You might want to look at the existing data in v5 Public Cloud and remove or consolidate data before running the extract. This will help ensure only objects that are still needed in v10 will be migrated, and that your data will require less clean-up in the new deployment.

c. Plan to do run several test iterations of migration.

You can use the migration utility's `--dry-run` option to perform iterations of the migration push without actually uploading data to v10. The test runs offer an opportunity to test for errors and warnings that need to be resolved before you perform the actual data push.

d. Prepare a pilot migration of your APIs.

API Connect v10 on-premises supports both a v5-compatible DataPower Gateway and the newer DataPower API Gateway, which has different requirements.

To ensure a smooth migration, convert 10-to-20 of your most commonly used v5 APIs to meet the requirements of the API Gateway. Use one or more test runs to ensure that APIs do not generate errors during migration. Then, migrate the converted APIs and test them in v10 to verify that they can be used in the new environment, and to determine the appropriate migration utility settings before you convert your remaining APIs.

## 2. [Install and configure API Connect v10.](#)

Configure v10 with usage of the incoming v5 data in mind. Before you push your v5 data to v10, your v10 system must be up and running, with all required gateway services, provider organizations, user registries, and so on, ready to receive the data. In particular, ensure that your v10 deployment meets the following requirements for migration:

- Understand the requirements for the Gateway in v10:

API Connect v10 supports two types of gateway services: DataPower Gateway (v5-compatible) and DataPower API Gateway (the DataPower API Gateway type is not available in API Connect v5). When you register your gateway service on your v10 system, you must select a gateway service type (see [API Connect gateway types](#)).

If you select the API Gateway, then you must complete the following tasks:

- Ensure that `xm1-manager` is enabled in the default domain of all gateways.
- Your migration process must include a step to convert the v5 API Definitions from the DataPower Gateway format to the DataPower API Gateway format. For information on converting the v5 APIs, see [Converting APIs to DataPower API Gateway](#).
- Review the OAuth Security Definitions of APIs that use OAuth.  
To ensure that APIs that use OAuth security definitions are mapped to the corresponding OAuth Provider APIs in v10, make sure that either the Authorization URL or the Token URL defined in OAuth Security Definitions of APIs that use OAuth correctly point to the base path of the OAuth Provider API. Note that the migration utility uses logic to map Consumer APIs to Provider APIs, and adds `x-ibm-oauth-provider` in the OAuth Security Definition of the consumer API.

- Prepare a provider organization in v10 that will own the v5 Public Cloud assets:

In v5 public cloud, there is a single provider organization; all of your data migrates to a single provider organization in v10. If the target provider organization in v10 uses the same name as in v5 public cloud, data is migrated automatically. If the names don't match, you can map the names while preparing your data for migration (see [Mapping v5 resource names to v10](#)).

- Prepare user registries in v10:

Configure user registries to match the user registries in v5 Public Cloud. The migration process migrates users and sends email to users about their accounts.

Note: Portal Delegated User Registries are not supported in v10 because they are replaced with equivalent registries that are managed by the Management subsystem. If you used the PDUR feature in v5 Public Cloud, create matching registries in v10 so that you can migrate users to the new registries. For information on mapping a PDUR registry to a v10 registry, see [Mapping v5 PDUR registries to v10](#).

- Create the Portal services that you want to use with the Catalogs that you plan to migrate:

You will configure the catalogs to the Portals after the migration data is pushed to the v10 system.

## 3. Set up the AMU migration utility on a secure computer where you will process the data from V5 Public Cloud before importing it into V10.

The V5 Public Cloud migration archive file must be downloaded to the same computer, so that you can use the AMU to push the V5 Public Cloud data to your v10 deployment.

Note: When running the migration utility commands on Windows, open a command window with Administrator privileges, and omit the `./` from the commands.

a. Install Node 18.19.1 (or greater).

To use the migration utility for converting API definitions for the API Gateway, you must have Node version 18.19.1 (or greater) installed.

b. Download and extract the newest version of the [AMU for API Connect 10.0.5](#) from IBM Fix Central.

Note: If you do not already have entitlement to use IBM Fix Central, contact IBM Support to request access.

Note: When you unpack the data from v5 Public Cloud using the AMU tool `unpack` command, it is stored in a directory called `c1oud` within the same folder structure where the AMU is stored. When you extract the AMU, keep the following considerations in mind:

- Keep the path to the AMU short, especially on Windows.  
Windows has path length limits that can interfere with large extracts. To avoid this issue, keep the path for your extracted data as short as possible (short folder names with as flat a folder structure as you can manage).
- Do not include a folder named `c1oud` in the path where you extract the AMU.  
When you unpack the data from v5 Public Cloud, it is stored in a folder called `c1oud` within the same folder structure where the AMU is stored. If a folder named `c1oud` already exists, the conflict will cause an error during the unpack process.

c. Start the AMU:

i. In the folder where you extracted the AMU, navigate to the appropriate subfolder for your operating system (Mac, Linux, or Windows).

ii. Open a command window where you can run AMU commands.

Note: On Windows: open a command window with Administrator privileges.

iii. Verify that the utility is available by running the `apicm` command to view the list of available commands; for example:

```
./apicm
```

Note: On Windows: omit the `./` from the command.

 Run the "apicm" command to see the full list of commands

Tip: Use the `apicm <command-name> --help` command to review the command options and their purpose. To see the list of commands, run: `apicm help`.

## 4. Get owner access to the v5 Public Cloud provider organization.

Only the provider organization's owner can download the data for migration. If you will migrate data but are not the owner of the provider organization, contact the current owner and have that person complete the following steps to make you the new owner.

Attention: Only the current owner of the provider organization can transfer ownership to another user.

- a. Log in to v5 Public Cloud as the owner of the provider organization.
- b. Click Admin > Members.
- c. In the list of members, locate the row containing the name of the person who will become the new owner of the provider organization.
- d. On the row containing the selected user, click  Actions menu > Transfer Organization Owner.
- e. At the confirmation message, click OK.

Notes:

- The previous owner of the provider organization loses access to the Admin > Members page.
- The previous owner is removed from the provider organization unless they also owned a catalog (limitation in v5). As the new owner, you can add that person as a member of the provider organization.
- Transferring ownership of the provider organization does not transfer ownership of any catalogs or spaces. The previous provider organization owner still retains ownership of all catalogs and spaces that they previously owned.

#### 5. Download your v5 Public Cloud data.

Complete this step on the secure computer where you have the AMU migration utility installed.

- a. Log in to V5 Public Cloud as the owner of the provider organization.  
Only the owner of the provider organization can migrate data.
  - b. Open the Dashboard, locate the "API Connect Public Cloud instances will expire soon" message and click Download.
  - c. At the "Select the type of API Connect environment to which the assets will be migrated" message, select API Connect v10 on-premise installation as your migration target, and click Next.
  - d. At the "Please enter API Connect Service Instance URL from AWS Subscriptions and Services Instances View Details Page" message, type or paste the URL for accessing your instance of API Connect Enterprise as a Service, and click Continue.  
You can obtain the URL from the link to your instance that is provided on the IBM Automation management console's [Subscriptions](#) page.
  - e. At the "Please enter an encryption password then press the download button which will start preparing the data" message, create an encryption password: The encryption password that you create here is required for extracting the downloaded data. If you lose the password you cannot retrieve it; however you can download the data again with a new password.
    - i. In the Encryption Password field, type a new password.
    - ii. In the Re-enter Encryption Password field, type the new password again to confirm it.
  - f. At the "Assets Download" message, click the Download button to start the data extraction from v5 Public Cloud.  
It might take a few minutes for the assets to be prepared and the button to be enabled.
  - g. At the "Downloading is in progress" message, click OK.  
The extracted data is downloaded as an archive file called `<ProviderOrgName>-extract.tgz`. Proceed to the next step to extract the data.

#### 6. Decompress the archive file containing the v5 Public Cloud data.

Run the following command to decompress the `<ProviderOrgName>-extract.tgz` that you downloaded from v5 Public Cloud:

```
tar xvf "<ProviderOrgName>-extract.tgz"
```

The decompress process creates the following files:

- `extract-backup.ecr` contains your v5 Public Cloud data. If you did not use the PDUR (Portal Delegated User Registry) feature in v5, this file also contains your registry information.
- (PDUR only) `pdurexport.ecr` If you used PDUR feature in v5 Public Cloud, then registries were managed by the Portal subsystem and this file contains the registry information from the v5 Developer Portals.

#### 7. Unzip the decompressed files using the encryption password that you created when you downloaded the archive.

- a. Unzip the `extract-backup.ecr` file by running the following command and replacing with your encryption password:

```
unzip -P "<encryption_password>" extract-backup.ecr
```

This step creates the `extract-backup.tgz` file.

- b. If available, unzip the `pdurexport.ecr` file by running the following command and replacing with your encryption password: The `pdurexport.ecr` file is only available if you used the PDUR feature in v5.

```
unzip -P "<encryption_password>" pdurexport.ecr
```

This step creates the `pdurexport.tgz` file.

#### 8. Use the AMU to unpack the `extract-backup.tgz` and `pdurexport.tgz` files.

The AMU must be run in a command window with administrative privileges on Windows. You might prefer to run the migration utility from a Linux VM on your Windows computer.

Run the following command to unpack the files (if you do not have a `pdurexport.tgz` file, omit it from the command):

```
./apicm archive:unpack ./extract-backup.tgz ./pdurexport.tgz
```

The output from this command looks like the following example:

```
INFO[2022-06-20T13:03:16-07:00] Saving copy of: saveErrorLog to: logs/archive-unpack20220620T13-03-16error.log
INFO[2022-06-20T13:03:16-07:00] Saving copy of: saveInfoLog to: logs/archive-unpack20220620T13-03-16info.log
INFO[2022-06-20T13:03:16-07:00] Disabled PDUR errors as no PDUR archive was passed in
INFO[2022-06-20T13:03:16-07:00] unpacking v5 archive ./extract-backup.tgz
INFO[2022-06-20T13:03:23-07:00] Writing unpacked content to /Users/single_porg/osx/cloud
.....
.....
INFO[2022-06-20T13:03:39-07:00] Completed unpacking of provider_org_name organization contents.
INFO[2022-06-20T13:03:39-07:00] Completed unpacking archive ./extract-backup.tgz.
 Admin Org Stats:
 - Availability Zones: 1

 Provider Org Stats:
```

```
- Provider Organizations: 1
.....
```

The unpack process produces YAML files containing your v5 data formatted for use in v10 and stores them in a folder structure stemming from the `cloud` folder.

Example output from the unpacked migration data:

```
cloud
├── provider-orgs
│ └── <providerOrg>
│ ├── catalogs
│ │ ├── develop
│ │ │ ├── catalog-settings.yml
│ │ │ ├── catalog.yml
│ │ │ ├── configured-gateway-services
│ │ │ │ ├── g-w-1-8f82
│ │ │ │ └── configured-gateway-service.yml
│ │ │ ├── members
│ │ │ │ └── testuser2-example-com-b9ed.yml
│ │ │ ├── products
│ │ │ │ ├── account-1.0.0.api.meta.yml
│ │ │ │ └── account-1.0.0.api.yml

```

Troubleshooting:

- Path: The unpack command might return an error message stating that the `cloud` must be empty, as in the following example:

```
ERRO[2022-06-20T13:02:00-07:00] AMUAU000E: The migration tool failed to initialize.
Reason: The cloud directory /Users/single_porg/osx/cloud must be empty to run the unpack command
```

The error indicates that the location where you extracted the files already contained a folder named `cloud`, which caused a conflict. Correct the error by extracting the files to a folder that does not already contain a subfolder named `cloud`.

- Invalid characters: The unpack command ensures that catalog names and API properties contain only valid characters; invalid characters are replaced with "-".
- Validation issues: The unpack command issues warning messages for APIs and Products that fail validation against the OpenAPI specification. Correct the APIs and Products before attempting to migrate them into v10.
- The unpack command might return error messages related to your PDUR archive missing some information, as in the following example:

```
ERRO[3414] PDUR backup data for IDP PortalDelegatedIdentityProvider-123b81f8e4b06de411580e2e
(123b81f8e4b06de411580e2f) not provided: not found
ERRO[3414] PDUR backup data for IDP PortalDelegatedIdentityProvider-123b820de4b06de411580e32
(123b820ee4b06de411580e33) not provided: not found
```

If your v5 Public Cloud instance used the PDUR feature, this error indicates that the AMU could not find all of the specified Portal user registries when it unpacked the `pdurexport.tgz` archive. To resolve this problem, download your data from V5 Public Cloud again, and then re-run the unpack command.

If you are not migrating PDUR data and your command did not include the `pdurexport.tgz` file, this error indicates that you do in fact have a PDUR registry, and that you should have included the `pdurexport.tgz` file in the unpack command. To resolve this problem, download your data from v5 Public Cloud again and re-run the unpack command with the `pdurexport.tgz` file included.

- Any other Warnings or Errors that occur during `archive:unpack` process should be investigated for remediation (see [Migration troubleshooting](#)).

## Migrating data and Portal Delegated User Registries

Complete the following steps to migrate v5 Public Cloud data and Portal Delegated User Registries.

## About this task

Use the migration utility to migrate your API Connect v5 Public Cloud data to a v10 deployment. Your v10 deployment must be up and running, with gateway services, provider organizations, user registries, and so on, ready to receive the migrated data.

## Procedure

1. Optional: Set up a temporary SMTP server to hold automatic emails without sending them during migration.

During migration, if subscription approval is needed to enable an application to subscribe to a plan, notifications are sent to all users within the organization who have subscription approval permission. In some cases, this results in a large number of emails. To avoid sending these emails, set up a temporary email server prior to running the migration, and use it to collect all notifications rather than sending them to users' email accounts.

If subscription approvals are not needed during your migration, you can skip this step.

2. Optional: Set up a temporary LDAP server.

A temporary LDAP server can be needed if you are temporarily working behind a firewall.

- a. Install a server:

```
git clone https://github.com/veo-labs/ldap-server-mock
npm install
```

- b. Creating the configuration files:

- `ldap-server-mock-conf.json`

```
{
 "port": 3004,
 "userLoginAttribute": "cn",
 "searchBase": "dc=test",
 "searchFilter": "(&(objectclass=person)(cn={username}))"
}
```

- `users.json`

```
[
 {
 "dn": "cn=user,dc=test",
 "cn": "user-login"
 }
]
```

- c. Run the LDAP server:

```
node server.js --conf=./ldap-server-mock-conf.json --database=./users.json
```

- d. Modifying a current LDAP provider.

The following file is a dummy user registry file that maps to a read-only test server. The fields in bold font (`admin_dn` and `endpoint`) have been changed to fit the dummy server configuration. Change these on all user registries that need to be fixed.

```
api_version: 2.0.0
configuration:
 admin_dn: cn=user,dc=test
 admin_password: xxxx
 authenticated_bind: "true"
 authentication_method: search_dn
 bind_prefix: ""
 bind_suffix: ""
 protocol_version: "3"
 search_dn_base: ""
 search_dn_filter_prefix: (examplelegacyuid=
 search_dn_filter_suffix:)
 search_dn_scope: sub
endpoint:
 endpoint: ldap://172.20.20.11:3004
 tls_client_profile_url: idurl://.../admin-org/tls-client-profiles/tls-profile-for-ldap-1.0.0.yml
integration_url: file://.../integrations/user_registry/ldap.yml
metadata:
 v5_id: xxxxxx40cf2fc09a9ba0d6c
 v5_scope: ["api"]
 v5_type: ldap
name: xxxxxxxxxxxxxxxx
title: xxxxxxxxxxxxxxxxxxxxxxxx
type: user_registry
```

3. Map v5 resource names to v10 resources names as explained in [Mapping v5 resource names to v10](#).

Most deployments adjust the names or quantities of gateway services, provider organizations, and user registries when setting up a new environment for v10. Be sure to specify any changed v10 destinations for the v5 data in a migration mapping file so that the migration utility can automatically move the data.

4. If you used the PDUR feature in v5 Public Cloud, map your Portal Delegated User Registries to the equivalent registries that you created in v10, as explained in [Mapping v5 PDUR registries to v10](#).

API Connect v10 supports new registries and you no longer need the PDUR feature. Instead, you can configure functionally equivalent registries in v10 that are maintained by the Management subsystem and migrate users to the new registries.

5. Convert the v5 API definitions to formats required by v10 DataPower API Gateway as explained in [Migrating v5 APIs to v10 API Gateway format](#).

Note: If you are migrating your APIs to a DataPower v5-compatible Gateway, skip this step because there is no need to convert your APIs.

6. Remove unneeded configuration objects.

Inspect the set of configuration objects and their attributes, and remove the ones that are not needed. In many cases, some of the configuration objects present in the v5 system are not needed in the new v10 environment. For example, there is no value in preserving inactive users, obsolete apps, obsolete consumer organizations, and so on.

When deleting objects, make sure that you do not delete objects that have other dependent objects, such as products with subscriptions on them or users that are active. If you delete a consumer organization, make sure you also delete all apps and subscriptions associated with that consumer organization. Be aware of any groups or visibility settings that include these consumer organizations.

7. Upload the v5 data to v10.

To upload the v5 data, log in to your v10 deployment with the migration utility and push the data with the migration utility. The admin organization and its data, and then the provider organization and all of its assets, are imported into v10. You can push to v10 as many times as needed to correct errors and provide missing information.

- a. Get the log-in information from your v10 deployment.

Log in to your v10 deployment and note down the `<v10_host_name>` from the URL:

For example, in the following URL, the v10 host name is `apicdev10.acme.com`:

```
https://apicdev10.acme.com/manager/
```

- b. On the computer where your extracted v5 Public Cloud data is stored, use the migration utility to log in to your v10 deployment as an API Connect administrator:

Note: On Windows: open a command window with Administrator privileges, and omit the "/" from the command.

```
./apicm login -s <v10_host_name> -r admin/default-idp-1 -u admin
```

For example:

```
./apicm login -s apicdev10.acme.com -r admin/default-idp-1 -u admin
```

- c. Use the migration utility to push your v5 Public Cloud admin organization data to the v10 deployment:

In the same directory where you ran the `apicm: archive:unpack` command, run the following command where `<v10_host_name>` is the host name:

```
./apicm archive:push <v10_host_name> cloud/admin-org
```

For example:

```
./apicm archive:push apicdev10.acme.com cloud/admin-org
```

The output from this command looks like the following example:

```
INFO[2022-06-22T12:54:25-07:00] Saving copy of: saveErrorLog to: logs/archive-push20220622T12-54-25error.log
INFO[2022-06-22T12:54:25-07:00] Saving copy of: saveInfoLog to: logs/archive-push20220622T12-54-25info.log
.....
INFO[2022-06-22T14:46:35-07:00] archive:push for organization admin completed
```

- d. On the same computer, use the migration utility to log in to your v10 deployment's provider organization:

Log in as an Owner of the provider organization.

```
./apicm login -s <v10_host_name> -r provider/default-idp-2 -u provider_org_owner
```

For example:

```
./apicm login -s apicdev10.acme.com -r provider/default-idp-2 -u example_user
```

- e. Use the migration utility to push your v5 Public Cloud provider organization data to your v10 deployment:

In the same directory where you ran the `apicm: archive:unpack` command, run the following command where `<v10_host_name>` is the host name and `<v10_provider_organization_name>` is the name of the provider organization:

```
./apicm archive:push <v10_host_name> cloud/provider-orgs/<v10_provider_organization_name>/
```

For example:

```
./apicm archive:push apicdev10.acme.com cloud/provider-orgs/my-provider-org/
```

Table 1 describes optional parameters that you can include when you push your v5 Public Cloud provider organization data to your v10 deployment.

Table 1. Optional parameters for the `apicm archive:push` command

| Optional parameter                                | Description                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--catalogs=&lt;cat_1,cat_2,cat_n&gt;</code> | Push data for only the specified Catalogs (if you don't want to push the entire provider organization). When a catalog is mapped, specify the v10 Catalog name.                                                                                                                                                                                                                                      |
| <code>--dry-run</code>                            | Create a test directory similar to <code>cloud</code> (but titled <code>.workdir-&lt;apim_admin_server&gt;</code> ) where you can view how the data will be loaded into your new system. This option also displays the objects that will fail during migration, providing an opportunity to correct errors before actually importing data into v10 (see <a href="#">Migration troubleshooting</a> ). |
| <code>--no-drafts</code>                          | Do not push any draft (unpublished) APIs or Products. This option can optionally be used with the <code>--catalogs</code> parameter. This option cannot be used with the <code>--drafts-only</code> option.                                                                                                                                                                                          |
| <code>--drafts-only</code>                        | Only push draft (unpublished) APIs or Products and do not push any published APIs or Products. This option cannot be used with <code>--catalogs=a,b,c</code> or the <code>--no-drafts</code> option.                                                                                                                                                                                                 |
| <code>--overwrite</code>                          | Overwrite all existing assets in the v10 deployment. Omit this parameter if you want to retain existing data in v10; for example, if you run the migration in iterations.                                                                                                                                                                                                                            |
| <code>--apigw-only</code>                         | Optional flag. Use when migrating to a DataPower API Gateway.                                                                                                                                                                                                                                                                                                                                        |

The output from this command looks like the following example:

```
INFO[2022-06-22T12:54:25-07:00] Saving copy of: saveErrorLog to: logs/archive-push20220622T12-54-25error.log
INFO[2022-06-22T12:54:25-07:00] Saving copy of: saveInfoLog to: logs/archive-push20220622T12-54-25info.log
.....
INFO[2022-06-22T14:46:35-07:00] archive:push for organization <v10_provider_organization_name> completed
```

#### Troubleshooting:

- The `apicm` login token expires after eight hours. If the token expires while `apicm archive:push` is running, `apicm` generates errors due to lack of the necessary access permissions. There are two workarounds:
  - Log in again and re-run `apicm archive:push`. The token is refreshed with each new login.
  - Extend the token expiration time by logging in again with an optional argument: `-expireHours=<number_of_hours>` (see [Token expiration](#)).
- If you observe error messages in your log output, consult the [Migration troubleshooting](#) topic for information on resolving the problems, and then run the migration again. You can push to v10 as many times as needed to correct errors and provide missing information.

#### 8. When migration successfully finishes, complete the following steps:

a. Apply any customized configurations from your v5 deployment (see [Customizations](#)).

b. Optional: Switch the v10 provider organization ownership to the identity that owned it in v5.

This step might be necessary if you created and migrated the provider organization using a different identity (such as administrative account) than the user identity of the v5 provider org. Note that the UI does not provide this function, but you can use the API `/orgs/{org}/transfer-owner` to switch ownership.

c. If Stripe billing integrations were included in your migration, configure the Stripe integrations in your v10 Developer Portal sites; see [Configuring Stripe in the Developer Portal](#) for detailed instructions. For more information about the billing feature in v10, see [Monetizing your Products](#).

#### • [Mapping v5 resource names to v10](#)

Create files to map the name of each v5 Public Cloud resource to the corresponding v10 resource.

#### • [Mapping v5 PDUR registries to v10](#)

Map your Portal Delegated User Registries to equivalent v10 registry types.

#### • [Migrating OAuth providers and OAuth secured APIs](#)

You can migrate v5 OAuth providers and OAuth secured APIs to your v10 API Connect deployment.

#### • [Migrating v5 APIs to v10 API Gateway format](#)

You can convert API Connect v5 APIs to the format required by the DataPower API Gateway in v10.

#### • [Logging in to a management server with an OIDC registry](#)

Logging in with an OIDC registry involves several steps, in which you obtain a temporary token and pass it to the toolkit to ensure it can communicate securely with the management server.

---

## Mapping v5 resource names to v10

Create files to map the name of each v5 Public Cloud resource to the corresponding v10 resource.

---

### About this task

The names of some API Connect resources that you used in v5 Public Cloud might be different in v10. Mapping files allows you to specify the v10 resource that corresponds to a particular v5 resource that uses a different name, ensuring that data associated with the resource can be migrated. You only need to create mapping files for resources that use a different name in the old and new versions of API Connect.

Note: If you used Portal Delegated User Registries in v5 Public Cloud, you will map those registries to v10 registries in a later task.

#### What does a mapping file do?

Mapping files are simple YAML files that you create in the directory structure created by the `apicm archive:unpack` command. Any directory that contains a YAML file describing a configuration object might need a mapping file to specify the name of the corresponding v10 resource.

A mapping file contains the name of the v5 resource file that it is related, to plus one or more **key: value** pairs that specify the v10 values to apply in place of the original v5 configuration values.

#### What kinds of settings can I map?

You can override any values in the YAML configuration files; the most common mappings for v5 migrations are for the Gateway service name and the provider organization name.

#### What does a mapping file contain?

A mapping entry consists of two or more lines:

- The first line in the mapping file specifies the name of the v5 configuration file that you want to override, but without the `.yaml` extension. For example, when overriding a value in `provider-org.yaml`, the first line of the mapping is `provider-org`.
- Additional lines specify **key: value** pairs that override the V5 **key: value** pairs that appear in the V5 file that you are overriding. The most common reason for mapping is to override the resource name; for example, to map a V5 provider organization to a new name in V10.

To override the resource name, include the `name:` setting as the key, and the new V10 resource name as the value. The following example replaces the V5 provider organization name in the V5 `provider-org` file (located in the current folder) with the name `myv10porg` in V10:

```
provider-org:
 name: myv10porg
```

#### Where do I create mapping files?

Create each v10 mapping file in the same folder where the corresponding v5 configuration file is stored, within the cloud folder structure that was created when you unpacked the v5 Public Cloud files. Create one mapping file in each folder, and name every mapping file with the following filename: `mapping.yml`.

In the following steps, you will create 2 mapping files: one for the resources associated with v5 Public Cloud provider organization and one for the resources associated with the v5 Public Cloud Gateway service.

---

## Procedure

Map the provider organization resources:

1. Locate the `provider-org.yaml` in the unpacked cloud folder.
  - a. In the unpacked cloud folder, locate the `provider-orgs` subfolder.
  - b. In the `provider-orgs` folder, locate the folder containing the `provider-org.yml` file.
2. In the same folder as the `provider-org.yml` file, use any text editor to create a new file called `mapping.yml`.

3. Map the name of the v5 Public Cloud provider organization to the v10 Enterprise as a Service provider organization.  
Example mapping.yml file for the provider organization (note the indentation):

```
provider-org:
 name: <v10_provider_organization_name>
```

where `<v10_provider_organization_name>` is the name of the provider organization in v10 that you want to migrate the v5 assets to.

4. Save and close the provider organization `mapping.yml` file.

Map the gateway service resources:

5. Locate the `gateway-service.yml` in the unpacked cloud folder.
  - a. In the unpacked cloud folder, locate the `configured-gateway-services` subfolder.
  - b. In the `configured-gateway-services` folder, locate the folder containing the `gateway-service.yml` file.
6. In the same folder as the `gateway-service.yml` file, use any text editor to create a new file called `mapping.yml`.
7. Map the v5 DataPower Gateway service to the v10 DataPower API Gateway service.
  - a. Add the following content to the `mapping.yml` file to map the v5 Gateway service to the v10 API Gateway service:  
Example mapping.yml file for the Gateway service (note the indentation):

```
gateway-service:
 name: <v10_gateway_service_name>
 gateway-type: datapower-api-gateway
```

where `<v10_gateway_service_name>` is the name (not the Title or ID) of the v10 DataPower API Gateway service. To determine the gateway service name, complete the following steps:

- i. Log in to API Connect v10 API Manager and click  `<catalog_name>` > Catalog settings > Gateway services.
- ii. On the Gateway services page, click  Actions menu icon next to the gateway service and select View status.
- iii. On the Gateway processing status page, choose any item in the "Event" column, locate the "(name: *value*" that follows the event description, and copy the value (shown highlighted in the following image).

The gateway service's name

Leave the `mapping.yml` file open for the next step.

8. Map a migrated OAuth shared secret key.  
Information about migrated OAuth shared secret keys is contained in your `gateway-service.yml` file, so . When you map a v5 gateway to v10, you must ensure that the OAuth shared secret key is associated with the v10 gateway name.

Note: Only migrate one OAuth shared secret key; mapping more than one key to a service will result in an error.

- a. Determine whether the v5 Gateway service has an OAuth shared secret associated with it.  
In the v5 `gateway-service.yml` file, look for a key called `oauth_shared_secret:` . If your file does not contain this key, then no OAuth shared secrets were migrated and you can skip to step [9](#).
- b. If the file does include the key, then add `migrate_oauth_shared_secret:` `true` to the `mapping.yml` file.  
Example mapping.yml file for the Gateway service and OAuth shared secret (note the indentation):

```
gateway-service:
 name: <v10_gateway_service_name>
 gateway-type: datapower-api-gateway
 migrate_oauth_shared_secret: true
```

Leave the `mapping.yml` file open for the next step.

9. Map Server Name Indication (SNI) settings.  
When enabled, SNI settings (which include the host and TLS Server Profile pairs) are included in the migration of gateway services.
  - a. Determine whether the v5 Gateway service has SNI settings to migrate. your `gateway-service.yml` file contains SNI settings to migrate  
In the v5 `gateway-service.yml` file, look for a section called `sni:` containing one or more `host:` keys. If your file does not contain this section, then no SNI settings were migrated and you can skip to step [10](#).
  - b. If the file does include the `sni:` section, then add `migrate_sni: true` to the `mapping.yml` file.  
Example mapping.yml file for the Gateway service, OAuth shared secret, and SNI settings (note the indentation):

```
gateway-service:
 name: <v10_gateway_service_name>
 gateway-type: datapower-api-gateway
 migrate_oauth_shared_secret: true
 migrate_sni: true
```

10. Save and close the gateway service `mapping.yml` file.

---

## Mapping v5 PDUR registries to v10

Map your Portal Delegated User Registries to equivalent v10 registry types.

---

### Before you begin

If you did not use the PDUR (Portal Distributed User Registry) feature in v5 Public Cloud, then skip this task.

If you used the PDUR feature in v5 Public Cloud, create matching registries in v10 so that you can migrate users from the PDUR registries to the new v10 registries.

---

### About this task

If you used the Portal Delegated User Registry (PDUR) feature for a Catalog in API Connect v5 Public Cloud, then the user management for that Catalog was delegated from the Management subsystem to the Developer Portal and the site administrator within the Portal site performed the configuration tasks. The Management subsystem recorded that the delegation had taken place, and stored a record of the users that existed in the catalog; however, the Management subsystem did not maintain information about the configuration of the specific registries or how users mapped to them.

API Connect v10 supports new registries and you no longer need the PDUR feature. Instead, you configure functionally equivalent registries in v10 that are maintained by the Management subsystem. To migrate the PDUR user registries and users, you will use the `pdurexport.tgz` archive (that you previously downloaded and unpacked) to configure the PDUR registries for v10.

Table 1 shows the mapping Portal Delegated User Registries to the v10 equivalents:

Table 1. Registry type mappings

| v5 PDUR Registry | v10 Equivalent Registry | Manual migration required? |
|------------------|-------------------------|----------------------------|
| LDAP             | LDAP                    | Yes                        |
| OIDC             | OIDC                    | Yes                        |
| HybridAuth       | OIDC                    | Yes                        |

## Procedure

1. If you are migrating a PDUR LDAP user registry, complete the following steps.

The user registries that are required in the target v10 deployment are described in the `user-registry.yml` file for each registry. When possible, the configuration for the v10 registries is complete in these files; however, for LDAP the registry cannot be configured automatically due to differences between how the v5 Portal subsystem and the v10 Management subsystem specify the user registry configuration. Instead, the v5 configuration is provided as helpful information in the `metadata.v5_config` property.

- a. Configure the LDAP user registry for v10.

Configure the v10 user registry by modifying the v5 `user-registry.yml` file and adding the required LDAP fields that are described in the `metadata.v5_config` property. Remove the metadata when the changes are complete.

The `user-registry.yml` file is located in the following directory:

```
cloud/provider-orgs/<v5-provider-org>/user-registries/<PDUR_LDAP_User_registry_name>
```

For example:

```
cloud/provider-orgs/test-user1-org1/user-registries/example-5c38556de4b0c5f69db90ee0/user-registry.yml
```

- b. In the same folder, create a mapping file entry for the LDAP user registry.

Create a file called `mapping.yml` and specify the name of the v10 LDAP user registry that will contain the users from your v5 PDUR:

```
user-registry:
 name: <v10_LDAP_user_registry_name>
```

Where `<v10_LDAP_user_registry_name>` is the name of the target v10 registry.

2. If you are migrating a PDUR HybridAuth or PDUR OIDC user registry, complete the following steps.

API Connect v10 supports OAuth 2.0 but does not support OAuth 1.0, so OIDC registries that use OAuth 1.0 with v5 Public Cloud cannot be migrated to v10.

OIDC registries that use OAuth 2.0 must be migrated manually by completing the following steps.

- a. Add the `client_id` and `client_secret` to the OIDC user registry.

If your OIDC registry used a `client_id` and `client_secret` in v5 Public Cloud, the values were not included in the downloaded registry information so you must add them now. If you did not use a `client_id` and `client_secret` for the registry, skip this step.

Edit the v5 `user-registry.yml` file and insert the values into the `client_id` and `client_secret` keys. The `user-registry.yml` file is located in the following folder:

```
cloud/provider-orgs/<v5-provider-org>/user-registries/<PDUR_OIDC_User_registry_name>
```

For example:

```
cloud/provider-orgs/test-user1-org1/user-registries/git-hub-5c5xyz6ee4b0c5f69db94xxxx-a339/user-registry.yml
```

Example `user-registry.yml` file for GitHub:

```
api_version: 2.0.0
configuration:
 client_id: ""
 client_secret: ""
 authorization_endpoint: https://github.com/login/oauth/authorize
 provider_type: github
 token_endpoint:
 endpoint: https://github.com/login/oauth/access_token
 integration_url: file://../../../../integrations/user_registry/oidc.yml
metadata:
 v5_id: 5c5xyz6ee4b0c5f69db94xxxx
 name: git-hub-5c5xyz6ee4b0c5f69db94xxxx-a339
 registry_type: oidc
 title: GitHub
 type: user_registry
```

If your registry requires the `client_id` and `client_secret` but you omit this step, you will see the following errors when you push the OIDC registry to V10 Enterprise as a Service:

```
ERRO[0010] unable to create User registry git-hub-5c5xyz6ee4b0c5f69db94xxxx-a339
ERRO[0010] git-hub-5c5xyz6ee4b0c5f69db94xxxx-a339: The properties client_id, client_secret are required.
```

- b. Create a mapping file for the OIDC user registry.

Create the mapping file in the following folder (if you modified the `user-registry.yml` file, use the same folder):

```
cloud/provider-orgs/<v5-provider-org>/user-registries/<PDUR_OIDC_User_registry_name>
```

Create a file called `mapping.yml` and specify the name of the migration endpoint for the OIDC user registry used with your V5 PDUR:

```
user-registry:
 name: <v10_OIDC_user_registry_name>
```

Where `<v10_OIDC_user_registry_name>` is the name of the target v10 registry.

---

## Migrating OAuth providers and OAuth secured APIs

You can migrate v5 OAuth providers and OAuth secured APIs to your v10 API Connect deployment.

In v5 OAuth providers are a specialized type of API that are published within products. In v10 OAuth providers are first-class objects that are directly published in the provider organization. This is applicable for both DataPower Gateway (v5-compatible) and DataPower API Gateway.

Also, v10 adds tight coupling between the API using OAuth and the OAuth provider object. Hence an API using OAuth security must link to the corresponding OAuth provider object. For a review of how API Connect v10 uses OAuth providers, see [OAuth Provider overview](#).

The API Connect Migration Utility (AMU) migrates all OAuth provider APIs from v5 to the first-class OAuth provider objects on both DataPower Gateway (v5-compatible) and DataPower API Gateway.

In addition, the AMU uses logic to determine which OAuth provider is used by a given API and populates it in the newly added field `x-ibm-configuration` of API security definitions. If the AMU is unable to find a match between an API using OAuth and the OAuth provider, it prints out error messages. See [Error messages and warnings from archive:unpack](#).

- To ensure that APIs that use OAuth security definitions are mapped to the corresponding OAuth provider APIs in v10, make sure that either the Authorization URL or the Token URL defined in OAuth Security Definitions of APIs that use OAuth correctly point to the base path of the OAuth provider API. Note that the AMU uses logic to map consumer APIs to provider APIs, and adds `x-ibm-oauth-provider` in the OAuth Security Definition of the consumer API.
- To verify whether OAuth provider APIs are migrated correctly, ensure that all the APIs that use OAuth Security Definition have the new field `x-ibm-oauth-provider` added. Check the value of that field and make sure that it points to a correct OAuth provider resource object that was created and configured in the catalog to which the API is published.
- As mentioned earlier, in v5 OAuth providers are a specialized type of API that are published within products. In v10 OAuth providers are instead first-class objects that are directly published in the provider organization, and are not APIs that are published within products. Because of this, it is possible that you may have some v5 products that only contained OAuth provider APIs. Since these products do not contain any Open API definitions in v10, they will not be published as all products in v10 must contain at least one Open API definition.
- Because v10 OAuth providers are first-class objects rather than APIs as in v5, the application authentication feature is not available to v10 OAuth providers migrated from v5.

---

## Migrating OAuth token revocation information

In v5, token revocation could be enabled either using native token management system (TMS) or using external TMS. For migration to v10:

- Native TMS migration
  - DataPower Gateway (v5-compatible)  
If you had configured native token revocation, then you would have configured Quota enforcement peering group objects on v5 to synchronize between gateway servers. When migrating to v5-compatible, a QES peering group can contain QES peers from both v5 Multi-Protocol Gateway Service (MPGW) and v10 DataPower Gateway, so the revocation information is retained.  
  
After setting up a v10 DataPower Gateway instance, follow these steps to configure the v10 DataPower Gateway quota enforcement server (QES) to use the same QES on both v5 and v5-compatible. You must configure the QES and verify that it is enabled and functional before migrating from v5 to v10. For more details about configuring the QES, see the DataPower Gateway documentation topic *Configuring the quota enforcement server*.
    1. Log into the graphical interface of the DataPower Gateway instance in the default domain.
    2. Cluster the v5 MPGW QES with the v10 DataPower Gateway QES.
      - a. In DataPower Gateway, navigate to Objects > System Settings > Quota Enforcement Server.
      - b. Specify the password alias, data storage location, and the server and monitor port numbers.  
If your v10 DataPower Gateway is a Docker instance, configure the QES to store data in memory. For more information about RAID and Docker, see the DataPower Gateway documentation topic *RAID and a DataPower Docker image*.
      - c. Enable Peer group mode.
      - d. Specify the IP address of the DataPower Gateway.  
The IP address can be the IP address on any interface of the current appliance and must be accessible by other peers in the peer group.
      - e. Specify the IP addresses of the v5-compatible gateways to add them as peers.  
The appliance connects to each peer in the order in which the peers are added in the list.
      - f. Apply and save the configuration.
    3. As a test, revoke a token on the v5 MPGW server.  
Revocation data will replicate to v10 DataPower Gateway QES.
    4. Migrate the v5 APIs to the v10 DataPower Gateway QES.
    5. Send a request to the v10 DataPower Gateway QES with previously revoked token, which should fail as expected.  
The expected failure indicates that the APIs were migrated and revocation data was replicated.
  - DataPower® API Gateway  
When migrating to DataPower API Gateway, QES is not used for native token management and revocation. Instead, you can migrate token revocation information from a v5 QES to a gateway-peering cache in v10 DataPower API Gateway. For information, see [Migrating token revocation information to DataPower API Gateway](#).

- [Migrating token revocation information to DataPower API Gateway](#)  
You can use the Token Migration Utility (TMU) to migrate token revocation information from a v5 quota enforcement server (QES) to a gateway-peering cache in v10 DataPower API Gateway.
- [Token migration errors](#)  
After you run the Token Migration Utility (TMU), check the log in the logs subdirectory for errors. If it contains any of the following error messages, complete the troubleshooting steps before you run the utility again.

## Migrating v5 APIs to v10 API Gateway format

You can convert API Connect v5 APIs to the format required by the DataPower API Gateway in v10.

### About this task

Converting APIs to the API Gateway format is a two-step process: make a first pass with the migration utility, and then resolve any issues with manual modifications.

Note: If you are migrating your APIs to a DataPower v5-compatible Gateway, skip this step because there is no need to convert your APIs. The migration utility generates an annotated YAML file and logs with information regarding the artifacts that it attempts to convert. Because of differences between the programming models of v5 APIs and v10 API Gateway APIs, the migration utility might not be able to convert all items. In these cases, messages generated by the `apicm archive:port-to-apigw` command provide links to documentation with more details about changes you must make by manually editing the API definitions.

### Procedure

1. Automatically convert the APIs with the migration utility by running the following command, where `c1oud` is the directory where the unpacked v5 Public Cloud data resides:

```
./apicm archive:port-to-apigw /c1oud
```

Note: On Windows: open a command window with Administrator privileges, and omit the `./` from the command.

When you run the command, all artifacts within the `c1oud` folder structure are ported to v10 configuration, including APIs, Products, OAuth providers, custom policies, subscriptions, and so on.

Usage notes:

- Specify migration configuration parameters using either a YAML configuration file or with parameters on the command line, but not both. For information about configuration parameters, see [Configuration parameters for migrating APIs](#).
- By default, all changes that the migration utility makes when rewriting APIs are logged as comments within the API YAML file. You can use the `enable-api-logging` parameter to disable logging of these changes, as in the following example:

```
./apicm archive:port-to-apigw /c1oud --enable-api-logging=false
```

- Multiple runs of the command on the same `c1oud` folder will skip artifacts that have already been converted.
- If you decide to rewrite one API at a time, you can replace `c1oud` with the path to the API definition in the command. With this approach, you cannot use the migration utility to push the API to the v10 deployment. Instead, use the toolkit or the API Manager in v10 to manually import the API definition.

Because of differences between the programming models of v5 APIs and v10 DataPower API Gateway APIs, the migration utility might not be able to convert all items. You might need to port these items to the API Gateway. In these cases, messages generated by the conversion process include links to documentation that provides more details about changes you must make in the next step for these items to be compatible with DataPower API Gateway.

2. Review the conversion results and make any manual changes to the APIs as needed.  
The conversion produces an output YAML file, which you can review for information on API conformance, performance, and errors. Review the log files for messages about any manual actions that might be needed. For information on reviewing the results and modifying the migrated APIs, see [Reviewing and correcting migrated v5 APIs](#).
- [Configuration parameters for migrating v5 APIs](#)  
If you are converting APIs to DataPower API Gateway, you can accept the default migration configuration or specify configuration parameters.
  - [Reviewing and correcting migrated v5 APIs](#)  
The migration utility v5 APIs to the format required by the v10 DataPower API Gateway but sometimes encounters issues that require manual intervention.
  - [Frequently asked questions about migrating APIs to API Gateway](#)  
Answers to some of the most frequently asked questions about migrating APIs to API Gateway.

## Configuration parameters for migrating v5 APIs

If you are converting APIs to DataPower API Gateway, you can accept the default migration configuration or specify configuration parameters.

You can specify migration configuration parameters using either a YAML configuration file or from the command line, but not both. The `config.yml` file must be located in the same directory as the migration utility. You can specify to use this file when the migration utility is invoked using the `apicm` command with the `port-to-apigw` option, as in the following example.

```
./apicm archive:port-to-apigw <path_to_API_definition> --use-config-file=true
```

If use of the configuration file is not specified, the migration utility uses parameters specified on the command line. If no parameters are specified, then the default parameters are used.

Table 1. Migration configuration options

| Parameter | Valid values | Description |
|-----------|--------------|-------------|
|-----------|--------------|-------------|

Specifying <b>invoke_2.0.0</b> can cause migration errors or run-time errors. Use <b>invoke_2.0.0</b> if you are able to review and verify all changes made by the migration utility in the API YAML file.                                                                                                                                                                                                                                                                                                                                                                    |
| <b>no-rename</b>            | <b>true / false</b><br>The default value is <b>false</b> .                                                                                      | Defines whether to append the porting suffix to artifact file versions or names or within artifacts. When set to <b>false</b> , the files are renamed using the porting suffix. When set to <b>true</b> , the original unpacked v5c files are overwritten with the ported API Gateway artifacts.<br><br>A <b>y/n</b> prompt appears when using this option. To bypass this prompt, use the <b>--accept-no-rename-deletion</b> option.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>no-retitle</b>           | <b>true / false</b><br>The default value is <b>false</b> .                                                                                      | Defines whether to append the porting suffix to the <b>title</b> of the migrated API, product, or OAuth provider. Set this option to <b>true</b> if you want the <b>title</b> of the migrated API, product, or OAuth provider to match the original <b>title</b> in the v5-compatible YAML file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>optimize-gws</b>         | <b>true / false</b><br>The default value is <b>false</b> .                                                                                      | When set to <b>true</b> , gatewayscript policies are modified to map v5 functions to API Gateway functions.<br><br>Setting <b>optimize-gws</b> to <b>true</b> is valid only for the <b>gatewayscript_2.0.0</b> policy. If it is set to <b>true</b> for <b>gatewayscript_1.0.0</b> , an error is generated.<br><br>Note: Setting <b>optimize-gws</b> to <b>true</b> can result in performance enhancements. However, the modifications to gatewayscript policies by the migration utility can cause problems. When using this setting, review all gatewayscript policy modifications after migration.                                                                                                                                                                                                                                                              |
| <b>porting-suffix</b>       | A string containing alphanumeric, dash, underscore and dot characters.<br>The default value is <b>-apigw</b> .                                  | Defines the suffix to be used when renaming APIs, Products, OAuth Providers, and other ported artifacts. The suffix is appended to the version on APIs, Products and other ported artifacts that have versions, and onto the name for OAuth Providers and other ported artifacts that do not have versions. If <b>porting-suffix</b> is not specified then a value of <b>-apigw</b> will be used. The porting suffix can contain alphanumeric, dash, underscore and dot characters. Prior to AMU 10.0.5.4 the porting suffix could not be overridden and <b>-apigw</b> was appended to the name for all ported artifacts.                                                                                                                                                                                                                                         |
| <b>proxy-policy</b>         | One of the following values:<br><b>proxy_1.5.0</b> ,<br><b>invoke_2.0.0</b><br>The default value is <b>proxy_1.5.0</b> .                        | Defines which proxy policy the migration utility uses when rewriting the API assembly.<br><br><b>proxy_1.5.0</b> : The migration utility rewrites the existing API to <b>proxy 1.5.0</b> .<br><br><b>invoke_2.0.0</b> : The migration utility converts the proxy policy to invoke 2.0.0. Specifying <b>invoke_2.0.0</b> can cause migration errors or run-time errors. Use <b>invoke_2.0.0</b> if you are able to review and verify all changes made by the migration utility in the API YAML file.                                                                                                                                                                                                                                                                                                                                                               |
| <b>redact-policy</b>        | One of the following values:<br><b>redact_1.5.0</b> ,<br><b>redact_2.0.0</b><br>The default value is <b>redact_1.5.0</b> .                      | Defines which redact policy the migration utility uses when rewriting the API assembly.<br><br><b>redact_1.5.0</b> : The migration utility rewrites the existing API to <b>redact 1.5.0</b> .<br><br><b>redact_2.0.0</b> : The migration utility rewrites the existing API to <b>redact 2.0.0</b> . Specifying <b>redact_2.0.0</b> can cause migration errors or run-time errors, including changes to what is redacted, particularly with redactions meant for JSON payloads. Use <b>redact_2.0.0</b> if you are able to review and verify all changes made by the migration utility in the API YAML file.                                                                                                                                                                                                                                                       |
| <b>repair-wsdl-apis</b>     | <b>true / false</b><br>The default value is <b>true</b> .                                                                                       | If an API ported from V5 is created from WSDL, the WSDL is read and checked for accuracy. If <b>repair-wsdl-apis</b> is set to <b>true</b> , then the API and WSDL are automatically repaired. For example, if the WSDL ZIP file contains unnecessary files, they are automatically removed if <b>repair-wsdl-apis</b> is <b>true</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>return-v5-responses</b>  | <b>true / false</b><br>The default value is <b>false</b> .                                                                                      | When set to <b>true</b> , OAuth-related messages are printed in the v5 response format. When set to <b>false</b> , OAuth-related response messages are printed in API Gateway response format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <code>v5-request-headers</code>             | <code>true / false</code><br>The default value is <code>true</code> .                                                            | When set to <code>true</code> , the following v5-compatible request headers are set: <code>Via</code> , <code>X-Global-Transaction-ID</code> , <code>X-Client-IP</code> . When set to <code>false</code> , these request headers are not set.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>validate-username-token-policy</code> | <code>validate-username-token_1.0.0</code><br>The default value is empty.                                                        | Defines whether or not to use the <code>validate-username-token</code> v5 emulation policy when the migration utility rewrites the API assembly. When empty, the migration utility takes no action on the policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>xslt-policy</code>                    | One of the following values: <code>xslt_1.0.0</code> , <code>xslt_2.0.0</code><br>The default value is <code>xslt_1.0.0</code> . | Defines which gateway script policy the migration utility uses when rewriting the API assembly.<br><br><code>xslt_1.0.0</code> : A user-defined policy created by the migration utility. This policy uses the v5 MPGW processing rule. Use <code>xslt_1.0.0</code> if the xslt policy is dependent on v5 MPGW capabilities, such as load balancer groups or XML Manager settings.<br><br><code>xslt_2.0.0</code> : The migration utility rewrites the existing API to xslt 2.0.0. Specifying <code>xslt_2.0.0</code> can cause migration errors or run-time errors. Use <code>xslt_2.0.0</code> if you are able to review and verify all changes made by the migration utility in the API YAML file. |

## Example migration configurations

The following examples show configuration options using the `config.yml` file or the `apicm` command.

- The following example uses the `config.yml` file to specify the migration configuration.

```

deploy-policies:
- proxy_1.5.0
- redact_1.5.0
- invoke_1.5.0
- xslt_2.0.0
- gatewayscript_1.0.0
- switch_2.0.0
rewrite-apis:
 enable-api-logging: false
 proxy-policy: proxy_1.5.0
 redact-policy: redact_1.5.0
 invoke-policy: invoke_1.5.0
 xslt-policy: xslt_2.0.0
 gatewayscript-policy: gatewayscript_1.0.0
 if-policy: switch_2.0.0
 switch-policy: switch_2.0.0
 optimize-gws: true
 no-retitle: true

```

Use the `use-config-file` parameter when running the `apicm` command to specify that the `config.yml` file is used for migration configuration values.

```
./apicm archive:port-to-apigw <path> --use-config-file=true
```

- The following example uses the `apicm` command to specify the same settings as in the previous example.

```

./apicm archive:port-to-apigw <path> --deploy-
policies="proxy_1.5.0,redact_1.5.0,invoke_1.5.0,xslt_2.0.0,gatewayscript_1.0.0,switch_2.0.0" --enable-api-logging=false --
proxy-policy="proxy_1.5.0" --redact-policy="redact_1.5.0" --invoke-policy="invoke_1.5.0" --xslt-policy="xslt_2.0.0" --
gatewayscript-policy="gatewayscript_1.0.0" --if-policy="switch_2.0.0" --switch-policy="switch_2.0.0" --optimize-gws=true --
no-retitle=true

```

- The following example uses the `apicm` command to specify that the default migration configuration values are used.

```
./apicm archive:port-to-apigw <path>
```

## Reviewing and correcting migrated v5 APIs

The migration utility v5 APIs to the format required by the v10 DataPower API Gateway but sometimes encounters issues that require manual intervention.

### About this task

Review the following topics to understand how your v5 APIs were converted, any problems that were encountered, and whether you need to complete the conversion manually.

- [Messages generated during conversion of APIs to DataPower API Gateway](#)  
Reference information about the messages generated by the migration utility commands `apicm archive:port-to-apigw` and `apicm archive:port-to-apigw-v10`.
- [Parse actions added to the API assembly after migration](#)  
The migration utility `apicm archive:port-to-apigw` and `apicm archive:port-to-apigw-v10` commands add parse actions to the API assembly depending on the policies specified in your migration configuration.
- [Fine-tuning APIs after migration](#)  
After running the migration utility `apicm archive:port-to-apigw` or `apicm archive:port-to-apigw-v10` command, review the converted APIs to determine if any of the changes made by the migration utility can be modified to enhance performance and usability.

## Parse actions added to the API assembly after migration

The migration utility `apicm archive:port-to-apigw` and `apicm archive:port-to-apigw-v10` commands add parse actions to the API assembly depending on the policies specified in your migration configuration.

Review the API assembly to determine if any of the parse actions or other actions added by the migration utility can be removed. For more information, see [Fine-tuning APIs after migration](#).

Parse actions are added to the assembly according to the rules in the following tables.

Table 1. Parse actions added to the API assembly after conversion of policies to 1.0.0 or 2.0.0

| Policy                                                                                           | Where the parse action is added                                                 |
|--------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| If a <b>POST</b> , <b>PUT</b> , <b>DELETE</b> , <b>OPTIONS</b> , or <b>PATCH</b> method is found | As the first action in the assembly                                             |
| invoke 2.0.0                                                                                     | After the invoke action, except when invoke is the last action in the assembly. |
| json-to-xml 2.0.0                                                                                | Before the json-to-xml action                                                   |
| proxy 2.0.0                                                                                      | After the proxy action                                                          |
| validate 2.0.0                                                                                   | Before the validate action                                                      |
| xml-to-json 2.0.0                                                                                | Before the xml-to-json action                                                   |
| xslt 1.0.0 or 2.0.0                                                                              | Before the xslt action                                                          |

Table 2. Parse actions added to the API assembly after conversion of invoke and proxy policies to 1.5.0

| Policy       | Where the parse action is added                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| invoke 1.5.0 | A parse action is added after the invoke if any of the following are true: <ul style="list-style-type: none"><li>• <code>stop-on-error</code> is specified</li><li>• <code>final-action</code> is set to <code>false</code>. This is the default setting.</li><li>• <code>x-ibm-gateway-optimize-invoke</code> is explicitly set to <code>false</code></li></ul> The parse action is added because there can be a subsequent use of the output. |
| proxy 1.5.0  | A parse action is added after the proxy if <code>final-action</code> is set to <code>false</code> .                                                                                                                                                                                                                                                                                                                                             |

## Fine-tuning APIs after migration

After running the migration utility `apicm archive:port-to-apigw` or `apicm archive:port-to-apigw-v10` command, review the converted APIs to determine if any of the changes made by the migration utility can be modified to enhance performance and usability.

If the migration utility makes any of the following changes to your APIs, consider making the suggested changes.

- If the last policy in the assembly has output that is set to a variable that is not used afterward, remove the output set or the entire policy.
- Remove any unnecessary parse actions that the migration utility adds to the assembly. For information about the parse actions added by the migration utility, see [Parse actions added to the API assembly after migration](#).
- If the assembly contains redact policies, verify that these policies are necessary. Delete any unnecessary redact policies.

What is **port-to-apigw**?

**port-to-apigw** is a command in the API Connect migration utility that converts all APIs, products, subscriptions, OAuth providers, and custom policies into v10 native API Gateway artifacts from a v5 system. These newly created artifacts live side-by-side with the original v5-compatible artifacts in the cloud directory, and have **-apigw** appended to the end of the filename. Starting in 10.0.5.4 a porting suffix can be used to override **-apigw**. For more information, see [Converting APIs to DataPower API Gateway](#).

What is **port-to-apigw-v10**?

**port-to-apigw-v10** is a command in the API Connect migration utility that converts all v5-compatible APIs, products, OAuth providers, and custom policies from a v10 system into v10 native API Gateway artifacts. These newly created artifacts live side-by-side with the original v5-compatible artifacts, and have **-apigw** appended to the end of the filename. A porting suffix can be used to override **-apigw**. The subscriptions on the v5-compatible products can optionally be moved to the v10 native API Gateway products using the **push:v10** command. For more information, see [Converting v5-compatible API definitions](#).

When is it necessary to run the **port-to-apigw** command, and how do I use it?

Run this command if you are migrating to a v10 native API Gateway. Follow the migration steps that are appropriate for your v5 environment. For instructions on running the **port-to-apigw** command, see [Migration steps](#). For information on configuring migration options, see [Configuring migration options for DataPower API Gateway](#). For other information to help you optimize migration, see [Migration considerations](#).

Why is the **port-to-apigw** command needed for migrating to v10 API Gateway?

The required fields, properties, settings, and configuration in v10 native API Gateway differs from v5-compatible mode. The **port-to-apigw** step in the migration process is needed to convert the artifacts to conform to the changes.

What is the difference between these terms: "porting to API Gateway", **port-to-apigw**, and "migration"?

"Porting to API Gateway" describes what the **port-to-apigw** command does in the migration utility. "Migration" is the overall purpose of the migration utility. The **port-to-apigw** step is necessary for migrating to a v10 native API Gateway. Migration can be completed without the **port-to-apigw** step if you are migrating to a v10 deployment that uses only the v5-compatible DataPower Gateway.

What is v5 policy emulation and how does it work?

The v5 policy emulation layer allows both custom policies and the 1.0.x policies to run on the native v10 API Gateway. It is deployed automatically by the API Connect migration utility to the `local:///isp` folder of the DataPower appliance when a custom policy is found in the v5 backup, or if you specify a 1.0.x policy in the policy option for the **port-to-apigw** command. The deployment is first staged by the **port-to-apigw** command, and pushed by the **archive:push** command. Follow the steps as outlined in [Migration steps](#). Note that 1.5.x policies do not use v5 policy emulation, and exist only as native wrappers to the 2.0.0 implementation.

What is the purpose of the policy parameter options?

Input options allow you to customize your migration. If you want to use the native policies, such as `invoke_2.0.0` instead of the default `invoke_1.5.0-compatible` option, you can select the appropriate option. However, using these options can result in migration errors that require manual changes to get your APIs up and running. If you want to be up and running quickly, it is best to use the default options for the input. The default options convert APIs in a way that is most backwards compatible with v5.

For more information about the migration configuration options, see [Configuring migration options for DataPower API Gateway](#) for migrating from a v5 deployment, [Configuration parameters for migrating v5 APIs](#) for migration from v5 Public Cloud, or [Converting v5-compatible API definitions](#) for v5c to API Gateway migration. For explanations of errors and other messages generated during migration and suggestions for manual changes to APIs, see [Messages generated during conversion of APIs to DataPower API Gateway](#).

How do the v5 emulated policies `invoke_1.5.0`, `proxy_1.5.0`, `xslt_1.0.0`, and `gatewayscript_1.0.0` work?

When the push step of the migration utility is completed, these policies will exist on the DataPower Gateway as assembly function objects. The 1.0.x policies call the v5 policy emulation layer in order to function as if they were v5 policies. The 1.5.x policies are wrapper policies to the 2.0.0 implementation. They call the 2.0.0 policies and exist only as a compatibility layer between the original v5 policy and the new 2.0.0 policy.

What is the difference between the 1.5.0 and 2.0.0 versions of the `invoke` and `proxy` policies, and the 1.0.0 and 2.0.0 versions of the `gatewayscript` policy? Why isn't the 2.0.0 version the default version?

The 1.5.x policy implementations are native wrappers to the underlying 2.0.0 implementation. They exist only to create a compatibility layer between the v5 policy and the APIGW native policy. The `gatewayscript_1.0.0` policy uses v5 policy emulation to run as if it were on a v5 environment. The performance of the 1.0.x v5 emulation layer policies in API Gateway is the same or slightly better than the v5 and v5-compatible versions. The performance of 1.5.x policies is slightly slower than their corresponding 2.0.0 policies. You can inspect the 1.5.x wrapper implementation in Assembly Functions in DataPower Gateway.

Should I rewrite my GatewayScript policies?

Most GatewayScript policies do not require rewriting, as the native v10 API Gateway contains an enhanced compatibility layer that accepts most of the **apim** functions without modification. In most cases, GatewayScript policies require rewriting when they contain any of the following:

- inline parameters
- `require('service-metadata')` and service variables associated with it
- `require('mgmt')`
- `require('fs')`
- OAuth context variables

What is the `optimize-gws` option?

The `optimize-gws` migration option converts certain v5 gatewayscript functions to the native API Gateway implementation. This setting is optional because the compatibility layer already handles processing of original v5 gatewayscript functions. If set to true, the migration utility makes the following conversions:

- `apim.getvariable()` is converted to `context.get()`
- `apim.setvariable()` is converted to `context.set()`
- `hm.current.remove()` is converted to `context.clear()`

What is the `gateway-extension.zip` file and how does it work?

After running the `port-to-apigw` command, a `gateway-extension.zip` file is located in the `cloud/admin-org/availability-zones/default-availability-zone/gateway-services/<gateway-service>` folder. This file is automatically generated by the migration utility during the processing of the `port-to-apigw` command. It contains a `manifest.json` file, and every custom policy under the gateway service that came from the v5 backup. The `manifest.json` file contains a list of custom policies to push, and backwards-compatible policies to advertise and make available for use by APIs. These backwards-compatible policies include `invoke_1.5.0`, `proxy_1.5.0`, `xslt_1.0.0`, and `gatewayscript_1.0.0`. During the `archive:push` steps of the migration process, this zip file is pushed to the API Manager as a gateway extension.

For more information, see [Gateway extensions manifest](#).

How does the migration utility migrate custom policies?

Custom policies are migrated in multiple steps, depending on whether the `custom-policies-scope` option is set to `global` or `catalog`. Once custom policies are pushed to the DataPower Gateway, they use the v5 `policy emulation` layer that was unpacked into the `local:///isp` folder in order to run on the native v10 API Gateway.

When `port-to-apigw` is run, the following steps are performed depending on the `custom-policies-scope` setting.

- If `custom-policies-scope` is set to `global`, and there are no duplicate custom policies with differing implementations, the custom policies under each gateway service are bundled in a `gateway-extension.zip` file. This zip file contains a `manifest.json` file that describes the contents. The `gateway-extension.zip` file is copied to the `admin-org gateway-service` folder. These steps are performed automatically when `port-to-apigw` is run. Next, you must push the `admin-org` during the `archive:push` step, which pushes the `gateway-extension.zip` bundles (one per gateway) to the API Manager using an internal **APIC Toolkit** `gateway-extensions:create` call. The custom policies within the bundle are advertised on the API Manager. The custom policies and compatible legacy policies are shown in the policy pallet in the API Manager Assemble UI. These custom policies are also in the DataPower filesystem in the `local:///` folder. Note that if duplicate custom policies with the same name, version, and differing underlying implementation are found, the migration utility logs a message and automatically falls back to `catalog` scope to prevent the migration from failing.
- If `custom-policies-scope` is set to `catalog`, the custom policies under each gateway service are bundled in a `gateway-extension.zip` zip file. This zip file contains a `manifest.json` file that describes the contents. The `gateway-extension.zip` file is then copied to the `admin-org gateway-service` folder. The custom policy definition files under each catalog are copied into the `catalog-scoped-staging` folder, where their gateway type is set to `datapower-api-gateway`. Next, you must push the `admin-org` during the `archive:push` step, which pushes the `gateway-extension.zip` bundles (one per gateway) to the API Manager using an internal **APIC Toolkit** `gateway-extensions:create` call. Note that the custom policies and compatible legacy policies are not visible in the policy pallet in the UI. You can see the custom policies in the DataPower filesystem in the `local:///` folder. Before you can publish APIs that use these policies, you must push your `provider-orgs` during the `archive:push` step. The custom policy definitions as described earlier from the `catalog-scoped-staging` folder are then pushed to the API Manager automatically using an internal **APIC Toolkit** `policies:create` call. The APIs containing the newly migrated catalog-scoped custom policies are then published.

Note: The folders and zip files are created automatically, and you should not need to modify them. For instructions on the tasks you must perform, see [Migration steps](#).

Should I set the `custom-policies-scope` option to `global` or `catalog`?

Global scope custom policies are visible to every catalog and org on the gateway. Catalog scope custom policies are visible only to the catalog that they were migrated from. If you plan to migrate to v10 with the intention of custom policy availability the same as it is on v5, then use the default `catalog` setting.

Why are my custom policies not showing up in the Assembly Editor policy palette?

See the following troubleshooting information: [Custom policies not appearing in the policy palette after migration](#)

---

## Logging in to a management server with an OIDC registry

Logging in with an OIDC registry involves several steps, in which you obtain a temporary token and pass it to the toolkit to ensure it can communicate securely with the management server.

Attention: If you want to log in using a non-OIDC registry, see the login steps in [Migration steps without PDUR](#) or [Migration steps with PDUR](#).

To log in, complete the following steps:

1. Enter the following command on the command line:

```
apicm login --server mgmt_endpoint_url --sso
```

where `mgmt_endpoint_url` is the endpoint URL. When you log in with a Cloud admin or Provider organization, specify one of the following URLs:

- platform API endpoint URL
- management API manager URL

These endpoint URLs are configured during the installation of API Connect, as described in [Installing the Management subsystem into a Kubernetes environment](#) and [Deploying the Management subsystem in a VMware environment](#). If you have access to the Cloud Manager user interface, you can view the configured endpoint

URLs as described in [Viewing platform and UI endpoints](#), ignoring any segments at the end of the displayed URLs. If you are not sure of the endpoint URL, ask your administrator.

2. When the toolkit prompts for the context, type **provider**:

```
Context? provider
```

3. The server responds with the following message:

```
Please copy and paste the url https://mgmt_endpoint_url/auth/manager/sign-in/?from=TOOLKIT to a browser to start the authentication process.
Do you want to open the url in default browser? [y/n]: y
```

Take one of the following actions:

- If you want to use your default browser to log in to API Manager, type **y** and press Enter. The API Manager sign-in page opens in a new browser tab.
  - If you don't use to use your default browser, type **n** and press Enter.
    - Copy the URL from the command window.
    - Open a browser, paste the URL, and press Enter. The API Manager sign-in page displays.
4. On the API Manager sign-in page, select the OIDC registry and then log in to API Connect. After you log in, API Connect displays the "You are authenticated!" message and provides a temporary token. Copy the token.
5. Return to the command window. Paste the token at the **API Key?** prompt and press Enter.

When the token is validated and you are successfully logged in to the toolkit, the following message displays:

```
Logged into mgmt_endpoint_url successfully
```

---

## Migration troubleshooting

If you run migration and observe error messages in your log output, you can take troubleshooting steps, and run the migration again.

Refer to the following sections for information on resolving migration issues:

- [apicm command line help](#)
- [Log files for apicm](#)
- [Common errors](#)
- [Error messages and warnings from archive:unpack](#)
- [Error messages and warnings from archive:push](#)
- [Troubleshooting tips](#)
- [Failure to convert API definitions to API Gateway](#)
- [Custom policies not appearing in the policy palette after migration](#)

---

## apicm command line help

You can use command line help to review usage syntax for **apicm**. For example:

```
./apicm --help
API Connect Migration Utility (AMU)
```

```
Usage:
 apicm [command]
```

```
Available Commands:
 archive:apistatus Generate stats about API use
 archive:automation Generate summary of the data
 archive:gwstats Generate stats about gatewayscript cmd use
 archive:port-to-apigw Port artifacts to apigw
 archive:push Push unpacked content to APIConnect server
 archive:unpack Unpack a V5 management/portal archive
 help Help about any command
 login Log in to IBM API Connect
 sluggify Sluggify a name or version string
 version APIConnect migration toolkit version
```

```
Flags:
 --accept-license Accept the license for API Connect
 -h, --help Help for apicm
```

Use "apicm [command] --help" for more information about a command.

Example usage for more information about a command:

```
$./apicm archive:push --help
Push unpacked content to APIConnect server
```

```
Usage:
 apicm archive:push CLOUD_MANAGER_ENDPOINT/API_MANAGER_ENDPOINT ARTIFACT_PATH
```

Locate CLOUD\_MANAGER\_ENDPOINT and API\_MANAGER\_ENDPOINT in the apiconnect-up.yml file used during apic install [flags]

```
Flags:
 --apigw-only Only attempt to push APIGW artifacts
```

|                                                |                                                                                                                                                                                                   |
|------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--catalog strings</code>                 | Provide a comma separated list of catalogs to push (e.g. <code>--catalogs=cat1,cat2</code> )                                                                                                      |
| <code>--dry-run</code>                         | Prepare the working directory but do not push to server                                                                                                                                           |
| <code>-h, --help</code>                        | help for archive:push                                                                                                                                                                             |
| <code>--no-drafts</code>                       | No draft APIs or Products will be pushed to the server                                                                                                                                            |
| <code>-f, --overwrite</code>                   | Overwrite draft APIs and products, published APIs and products, and OAuth providers if they exist on the server                                                                                   |
| <code>--saveDebugLog string=["default"]</code> | Debug logs are saved by default to <code>logs/debug/archive-push&lt;timestamp&gt;debug.log</code><br>This flag saves the file with a custom name (e.g. <code>--saveDebugLog=debugLog.txt</code> ) |
| <code>--saveErrorLog string=["default"]</code> | Error logs are saved by default to <code>logs/archive-push&lt;timestamp&gt;error.log</code><br>This flag saves the file with a custom name (e.g. <code>--saveErrorLog=myLog.txt</code> )          |
| <code>--saveInfoLog string=["default"]</code>  | Info logs are saved by default to <code>logs/archive-push&lt;timestamp&gt;info.log</code><br>This flag saves the file with a custom name (e.g. <code>--saveInfoLog=myLog.txt</code> )             |

**Global flags:**

`--accept-license` Accept the license for API Connect

## Log files for apicm

The `apicm` command creates log files that you can use to review messages produced by the `unpack` and `push` actions. All logs are saved in the `logs` directory. Unique files are saved for each run. All default log names can be overridden via the command line.

### Error log

Includes all warning and error level messages.

Error logs are saved by default to:

- `logs/archive-unpackerror.log/`
- `logs/archive-pusherror.log/`
- `logs/archive-port-to-apigwerror.log/`

You can optionally give the file a different name:

```
apicm --saveErrorLog= '<filename>'
```

For example:

```
apicm archive:unpack apic33-2020-02-19-1650.tar.gz --saveErrorLog= 'unpack.txt'
```

This command creates a file `unpack.txt` in the `logs` directory:

```
~/example/migration-cli/logs/unpack.txt
```

### Info Log

Includes all info, warning and error level messages.

Info logs are saved by default to:

- `logs/archive-unpackinfo.log/`
- `logs/archive-pushinfo.log/`
- `logs/archive-port-to-apigwinfo.log/`

You can optionally give the file a different name:

```
apicm --saveInfoLog= '<filename>'
```

For example:

```
apicm archive:unpack apic33-2020-02-19-1650.tar.gz --saveInfoLog= 'unpack_info.txt'
```

This will create a file `unpack_info.txt` in the `logs` directory:

```
~/example/migration-cli/logs/unpack_info.txt
```

Default path for info logs?

### Debug Log

Includes all info, warning, error and debug level messages. If you encounter errors or limitations that are not documented on this page, access the debug log.

Debug logs are saved by default to:

- `logs/debug/archive-unpackdebug.log`
- `logs/debug/archive-pushdebug.log`
- `logs/debug/archive-port-to-apigwdebug.log`

Contact your IBM representative for help with using the Debug log.

## Common errors

You can use the `--saveErrorLog` flag to specify that all the errors are saved in a file in `logs` folder, as described in [Saving the error log](#). Common errors:

- Long chain of error messages hours into a `push`:  
This scenario typically occurs due to expiration of an authentication token. To resolve this issue, either reauthenticate and or extend the token timeout. See [Token expiration](#).
- Unable to find User Registry when migrating (pushing) a provider-org:  
Occurs when the `admin-org` user registry artifacts are not shared prior to pushing provider organization artifacts. To resolve the issue, use the cloud admin account to change the visibility of the registry to `public`, and `push` the provider organization again.
- Unable to find `xxxx` when migrating (pushing) a provider organization:  
Occurs when `admin-org` artifacts are not pushed prior to pushing provider organization artifacts. Ensure that all of admin org data is pushed without errors, and then `push` your provider organization again.

- Unable to create an identity provider portal-delegated-identity-provider **xxxx** because the PDUR backup data is not provided. This error occurs if certain Portal delegated user registries are missing from the PDUR extract provided. If the missing user registries are not no longer used, they can be skipped. If they are still used, you must create a fresh backup of the PDUR.
- Unable to create product **xxxx**. The OpenAPI definition **<xyz>** requires the policy **<sample-policy>** that is not configured on the gateway-service **<sample-gateway>**: This error occurs when the specified policy is not configured on the gateway for the catalog that contains the product. To resolve this, you must configure, on the v5 system, the specified policy on the gateway for the catalog, and re-extract the data.
- Fixing API Errors  
Example:

```
WARN[2002-01-10T15:06:16-05:00] AMUUAU005W: product oauth-apis:1.0.0 requires updating before it can be pushed to a target system
Reason: product oauth-apis:1.0.0 includes content with validation errors:
Error validating API cloud/provider-orgs/onlinebanking/catalogs/oauthcatalog/products/api050-1.0.0.api.yml
- Must validate one and only one schema (oneOf) (context: (root).securityDefinitions, line: 35, col: 3)
- securityDefinitions.authorizationUrl Does not match format 'url' (context: (root).securityDefinitions.authorizationUrl, line: 0, col:0)
```

For example, where the issue is in the API:

```
securityDefinitions:
 ClientID:
 in: query
 name: client_id
 type: apiKey
 OAuthDef:
 authorizationUrl: ""
 description: ""
```

- v5 emulated policies and custom policies not deployed to gateway. Make sure the following was done during the migration steps:
  - xml-manager is enabled in default domain of all gateways
  - Mapping of gateways was done before the porting step
  - gateway-extension.zip shows up under cloud/admin-org/availability-zones/availability-zone-default/gateway-services/<gw-name>/gateway-extension.zip
  - Ensure push of admin-org is done after all of the above is verified
- Missing Subscriptions  
One of the causes for missing subscriptions could be that the products associated with those subscriptions have not been created successfully. Make sure to check the logs and see if there have been any errors during creation of those products. Please also note in these cases there would be no logs related to those missing subscriptions.

## Error messages and warnings from archive:unpack

"AMUUAU000E": "The migration tool failed to initialize."

The migration utility could not access files or directories needed to establish its working environment. Ensure that file permissions allow write access to the current working directory and that the cloud directory is empty or non-existent.

"AMUUAU001E": "The {{.Type}} {{.Name}} contains content that could not be unpacked and will not be included."

The migration utility is unable to read the API Connect v5 representation of an object in the migration archive. This content is skipped and will not appear in the unpacked migration data.

"AMUUAU002F": "The archive content at {{.DocPath}} cannot be read."

The migration utility is unable to read the internal contents of a collection in the API Connect v5 migration archive. This is likely to indicate a corrupt migration archive file. The archive:unpack operation cannot be completed.

"AMUUAU003E": "The portal delegated user registry file {{.File}} cannot be unpacked and will be skipped."

The migration utility is unable to read a PDUR archive. User information associated with this user registry will not be included in the unpacked migration contents.

"AMUUAU004E": "The archive content at {{.FilePath}} cannot be read and will not be unpacked."

The migration utility is unable to read the internal contents of an individual file in the API Connect v5 migration archive. This is likely to indicate a corrupt migration archive file. This content is skipped and will not appear in the unpacked migration data.

"AMUUAU005W": "{{.Type}} {{.Name}} requires updating before it can be pushed to a target system."

The migration utility has unpacked a configuration object for which modifications are required because the content is incorrect or missing information required by a target API Connect v10 system. The unpacked file must be updated by the user before it can be published successfully to the target system.

"AMUUAU006W": "The {{.Type}} {{.Name}} has been linked to OAuth provider {{.Provider}}. Please update the security definition {{.Security}} if another OAuth Provider should be used instead."

The migration utility has added a reference from an OAuth security definition in the named API to an OAuth provider resource. The migration utility uses the authorization URL, token URL and scope information where possible to determine which OAuth provider resource is to be used with each OAuth-secured API. In some cases, the migration utility cannot accurately determine which OAuth provider is intended for use with a particular API. The OAuth provider reference can be modified if needed by editing the security definition in the unpacked API file and changing the x-ibm-oauth-provider property value to match the intended OAuth provider resource. The reference value is a relative file path that identifies an unpacked OAuth provider resource.

"AMUUAU007W": "The {{.Type}} {{.NameVersion}} could not be linked to an OAuth provider. Please update the security definition {{.Security}} to select an OAuth provider."

The migration utility has been unable to add a reference from an OAuth security definition in the named API to an OAuth provider resource.

The migration utility uses the authorization URL, token URL and scope information where possible to determine which OAuth provider resource is to be used with each OAuth-secured API. In some cases, the migration utility cannot accurately determine which OAuth provider is intended for use with a particular API. The OAuth provider reference can be added by editing the security definition in the unpacked API file and setting the x-ibm-oauth-provider property value to match the intended OAuth provider resource. The reference value is a relative file path that identifies an unpacked OAuth provider resource.

"AMUUAU008W": "{{.Type}} {{.Name}} could not be introspected for OAuth provider API references."

The migration utility has attempted to determine which OAuth providers should be configured in support of an API product, but a reference to an OAuth provider API in the product cannot be correlated with an OAuth provider resource.

"AMUUAU009W": "{{.Type}} {{.Name}} contains invalid content that cannot be unpacked."

The migration utility has encountered an entry in the API Connect v5 migration archive that contains unexpected or corrupt data. This content is skipped and will not appear in the unpacked migration data.

"AMUUAU010E": "{{.Type}} {{.Name}} cannot be unpacked to the local filesystem."

The migration utility has attempted to unpack an entry in the API Connect v5 migration archive that could not be written to the local filesystem during the archive:unpack operation. This may be the result of a local file permissions problem, an unexpectedly long file name resulting from the unpack, or a shortage of space on the local filesystem.

"AMUUAU011E": "{{.Type}} {{.Name}} contains a {{.Target}} reference that cannot be resolved."

The migration utility has encountered a SOAP API entry in the API Connect v5 archive that refers to a WSDL definition that cannot be found in the archive. This entry will not be included in the unpacked content.

"AMUUAU012W": "The {{.Type}} {{.Name}} contains a {{.Target}} reference that cannot be resolved."

The migration utility has encountered an entry in the API Connect v5 archive that refers to another entry that cannot be found in the archive. This entry will not be included in the unpacked content.

"AMUUAU013E": "Portal delegated user registry information could not be loaded for user registry {{.Name}}."

The migration utility has encountered a portal delegated user registry definition in the API Connect v5 archive for which no PDUR file name has been provided as an argument to the archive:unpack command. The user registry contents will not be included in the unpacked content.

"AMUUAU014E": "The migration tool failed to load content for the admin organization."

The migration utility was unable to find the admin organization while unpacking provider organization information in the API Connect v5 archive. This is likely to result in further errors while unpacking the provider organization contents.

"AMUUAU015E": "The migration tool failed to load provider organization contents."

The migration utility was unable to find the load provider organization contents while unpacking the API Connect v5 archive. This message indicates an internal error with the migration utility.

"AMUUAU016E": "The {{.Type}} information belonging to organization {{.Org}} could not be unpacked."

The migration utility was unable to process the provider organization contents while unpacking the API Connect v5 archive. This message indicates an internal error with the migration utility.

"AMUUAU017W": "The settings update for {{.Type}} {{.Name}} could not be completed."

The migration utility was unable to update the settings for a configuration object while unpacking the API Connect v5 archive.

"AMUUAU018E": "Apps belonging to provider organization {{.Org}} could not be converted to consumer apps."

The migration utility was unable to convert registered applications belonging to the provider organization into applications in each catalog. The conversion occurs because the representation of applications differs between API Connect v5 and API Connect v10. This message indicates an internal error in the migration utility.

"AMUUAU019W": "User registry {{.UserRegistryName}} must be migrated to a different user registry type."

The migration utility has encountered a user registry in the API Connect v5 migration archive that is not directly supported in API Connect v10. User entries can be migrated if a mapping file is used to override the user registry name and refer to another user registry that has been created in the target API Connect v10 environment.

"AMUUAU020W": "User {{.User}} in portal delegated user registry {{.Registry}} is not associated with any OIDC provider and will be skipped."

The migration utility has encountered a user entry in the API Connect v5 migration archive that belongs to a portal delegated user registry but cannot be associated with any backing identity provider. This can occur if no PDUR export file has been provided, or if the user entry information is incomplete.

"AMUUAU021W": "The TLS profile {{.Name}} includes an unsupported protocol {{.Protocol}} that will not be included in the configuration."

The migration utility has encountered a TLS profile entry in the API Connect v5 migration archive that uses a protocol that is not supported in the API Connect v10 environment. This protocol will be omitted from the unpacked entry for the TLS profile.

"AMUUAU022W": "User {{.UserName}} ({{.ID}}) will need a password reset"

The migration utility has encountered a user entry in the API Connect v5 migration archive that is associated with a local user registry but does not have a password configured. The user entry will be migrated, but the user's password reset must be reset before logging in. This may occur when user registry mappings are used to migrate users to a local user registry from some other user registry type.

"AMUUAU023W": "Uniqueness of names cannot be guaranteed when using the --slugify-no-checksum option during unpack"

For v10.0.5.1 and earlier: The archive:unpack command has been invoked with an option that could in unusual cases result in duplicate names being used for different unpacked entries. This is likely only for names with near-identical spelling but differ only in their use of upper and lower case letters or symbols that are converted to a hyphen during the unpack process. If duplicate names appear for entries of the same type in the same context, further messages indicating problems with the duplicate will appear.

For v10.0.5.2 and later: If the migration utility is run on Windows or on Mac OS in a case-insensitive partition, additional errors may occur because of duplicate file names such as `name-1.yml` and `Name-1.yml`, which would be considered to be the same file.

"AMUUAU024E": "The stats summary could not be generated"

The migration utility was unable to produce information listing the total numbers of entries of different types that were unpacked from the API Connect v5 migration archive. This message indicates an internal error in the migration utility.

"AMUUAU025I": "{{.Type}} {{.Name}} contains an invalid value that will be removed."

The migration utility has encountered an entry in the API Connect v5 migration archive that contains a value that is not valid for the property in which it appears. The invalid value is automatically removed. This can occur with values such as email or URL properties that contain values that do not match the required format.

"AMUUAU026I": "{{.Type}} {{.Name}} contains an invalid value that will be replaced."

The migration utility has encountered an entry in the API Connect v5 migration archive that contains a value that is not valid for the property in which it appears. The invalid value is automatically corrected. This can occur with values such as email or URL properties that contain values that do not match the required format.

"AMUUAU027W": "The product subscription {{.Name}} cannot be pushed to the target system."

The migration utility has encountered a subscription entry in the API Connect v5 migration archive that refers to a product that is in a state that does not allow subscriptions. The subscription is removed and will not appear in the unpacked data.

"AMUUAU028E": "The migration tool failed to create default roles for {{.Type}} {{.Name}}."

The migration utility has encountered an error while attempting to create the default roles for an organization, catalog, or space. This may be the result of a local file permissions problem or a shortage of space on the local filesystem.

"AMUUAU029W": "The OAuth provider {{.OAuthProvider}} with base path {{.BasePath}} could not be unpacked."

The migration utility has failed to create an OAuth Provider with a particular base path. This can occur if there is an OAuth provider of this name with a different base path that has already been created in this provider organization. In API Connect v5, OAuth providers existed at the catalog level. In API Connect v10, they exist at the provider organization level, which can cause this issue to occur.

## Error messages and warnings from `archive:push`

"AMUAP001E": "The {{.Type}} {{.Name}} contains nested content that cannot be published."

The migration utility is unable to read or load nested configuration content during the archive:push operation. After the migration unpack has been completed, some configuration objects are comprised of a directory with one or more nested files. For example, information about catalogs in their unpacked form consists of a

directory with a name matching the catalog name, and a nested catalog.yml and catalog-settings.yml file. This message indicates that one or more of these files cannot be opened or loaded.

"AMUAP002E": "The {{.Type}} {{.Name}} cannot be published."

The migration utility is unable to read or load configuration content during the archive:push operation. This message indicates that the file representing the named configuration object is unreadable or contains unexpected content.

"AMUAP003W": "Skipping mapping file {{.Name}}."

The migration utility found a mapping file (mapping.yml) with invalid contents. The archive:push operation proceeds as if this mapping file were not present.

"AMUAP004E": "The file {{.Filepath}} could not be loaded and will not be published."

The migration utility is unable to read or load configuration content during the archive:push operation. This message indicates that the file representing a configuration object cannot be read or loaded.

"AMUAP005E": "The file {{.Filepath}} contains references that could not be loaded and will not be published."

The migration utility is unable to read or load configuration content during the archive:push operation. This message indicates that the file representing a configuration object cannot be read or loaded.

"AMUAP006E": "Unable to update reference to {{.Path}} in file {{.File}}."

The migration utility is unable to resolve a reference in the named file to another configuration object. This message indicates that the content in the file refers to other objects that are not found in the unpacked content, or the referenced content is not of the expected format.

"AMUAP007E": "The {{.Type}} {{.Name}} cannot be published because of a missing prerequisite."

The migration utility is unable to publish the named object because it refers to another object that cannot be found in the target API Connect system. This message indicates that the object contains an incorrect reference, or that the referenced object has not been successfully created or has been deleted from the target system.

"AMUAP008W": "The update to the {{.Type}} {{.Name}} could not be verified and may not have been successful."

The archive:push operation has attempted to update an object in the target API Connect system, but the results of the update were not received or indicated an error. This can occur in the event of a network interruption or timeout between the migration utility and the target API Connect system. If this occurs, it is safe to retry the archive:push operation; the same update will be attempted.

"AMUAP009E": "The {{.Type}} {{.Name}} was not published because it could not be checked in the target system."

The migration utility has attempted to check the existence of an object in the target API Connect system, but the check did not complete successfully. The migration utility will not overwrite objects in the target system if it cannot successfully determine whether or not a conflict will occur.

"AMUAP010W": "The creation of the {{.Type}} {{.Name}} could not be verified and may not have been successful."

The migration utility has attempted to create an object in the target API Connect system, but the results of the creation were not received or indicated an error. This can occur in the event of a network interruption or timeout between the migration utility and the target API Connect system. If this occurs, it is safe to retry the archive:push operation; if the named object was created, then it will subsequently be skipped unless the overwrite option is used.

"AMUAP011W": "The deletion of the {{.Type}} {{.Name}} could not be verified and may not have been successful."

The migration utility has attempted to delete an object in the target API Connect system, but the results of the deletion were not received or indicated an error. This can occur in the event of a network interruption or timeout between the migration utility and the target API Connect system. If this occurs, it is safe to retry the archive:push operation.

"AMUAP012W": "The ownership transfer of the {{.Type}} {{.Name}} could not be verified and may not have been successful."

The migration utility has attempted to transfer ownership of an object in the target API Connect system, but the results of the ownership transfer were not received or indicated an error. This can occur in the event of a network interruption or timeout between the migration utility and the target API Connect system. If this occurs, it is safe to retry the archive:push operation.

"AMUAP013E": "The endpoint settings for catalog {{.Name}} could not be updated."

The migration utility has attempted to update the endpoint settings for a catalog in the target API Connect system, but the update was not successful. This can occur if the catalog settings refer to a gateway service for which the configuration cannot be found in the unpacked migration contents.

"AMUAP014E": "The {{.Type}} {{.NameVersion}} could not be {{.Action}} in the target system."

The migration utility has attempted to create or modify an object in the target API Connect system, but the target system returned an error. The reason associated with the message indicates the error returned by the server.

"AMUAP015E": "The gateway extension for the gateway service {{.Name}} could not be published."

The migration utility has attempted to publish a gateway extension zip to the target API Connect system, but the target system returned an error. The reason associated with the message indicates the error returned by the server.

"AMUAP016W": "The {{.Type}} for the gateway service {{.Name}} could not be updated."

The migration utility has attempted to update the OAuth shared secret or SNI items for a gateway service in the target API Connect system, but an OAuth shared secret or SNI items were previously set. The migration utility will not overwrite an OAuth shared secret or SNI items that have already been set.

"AMUAP017W": "The product {{.NameVersion}} could not be validated and may contain errors."

The migration utility has attempted to validate a product before publishing, but the validation operation did not complete successfully. If validation errors are present in the product file, then the publish to the target API Connect system will not be successful.

"AMUAP018W": "The product {{.NameVersion}} contains API {{.APIName}} that could not be validated and may contain errors."

The migration utility has attempted to validate the APIs in a product before publishing, but the validation operation did not complete successfully. If validation errors are present in the API file, then the publish to the target API Connect system will not be successful.

"AMUAP019W": "The product {{.NameVersion}} contains validation errors: {{.Errors}}"

The migration utility has validated the content of a product before publishing, and the validation revealed errors in the product file contents. The product cannot be published to the target API Connect system unless the validation errors in the product file are corrected.

"AMUAP020W": "The product {{.NameVersion}} contains an API {{.APINameVersion}} with validation errors: {{.Errors}}"

The migration utility has validated the content of a product and its associated APIs before publishing, and the validation revealed errors in the API file contents. The product cannot be published to the target API Connect system unless the validation errors in the API file are corrected.

"AMUAP021W": "The product {{.NameVersion}} contains API content that could not be updated."

The migration utility has attempted to update the state of an API in the named product, but the metadata file (\*.api.meta.yml) containing extra API attributes could not be read or contained unexpected content.

"AMUAP022W": "Subscription {{.Name}} will not be published."

The migration utility has encountered a subscription for which the subscribed product cannot be found. The subscription cannot be created in the target API Connect system.

"AMUAP023W": "The user registry {{.Name}} cannot be published."

The migration utility has encountered a user registry object that cannot be published to the target API Connect system. This can occur for user registry types that may appear in an API Connect v5 system but are not directly supported in API Connect v10. A mapping file in the unpacked user registry directory may be used to identify an alternative user registry into which user entries can be migrated.

"AMUAP024I": "Subscriptions for the product {{.NameVersion}} will not be published."

The migration utility has encountered a product that contains no subscribable APIs. This can occur when a product originating in API Connect v5 contains one or more OAuth provider APIs, and no REST or SOAP APIs. OAuth provider APIs are converted to OAuth provider resources by the archive:unpack operation, and do not appear as APIs in API Connect v10. OAuth provider instances in API Connect v10 use subscription information associated with the REST or SOAP APIs that refer to the OAuth provider in a security definition.

"AMUAP025E": "Non-fatal errors were found while running the preflight check: {{.Errors}}"

The migration utility encountered a non-fatal error during its preflight check before the start of `archive:push`. The details of any of these errors will be reported back here and the `archive:unpack` will continue.

## Troubleshooting tips

---

- The migration utility may have issues when running across a VPN. The connection might fail if you use a corporate VPN to attempt to access an API Connect subsystem (API Manager UI) located behind an internet firewall. To workaround this problem, add the IP addresses of the API Connect management server and API manager to your local `/etc/hosts`.
- Token expiration: By default, the `apicm` login token expires after eight hours. If the token expires while `apicm archive:push` is running, `apicm` generates errors due to lack of the necessary access permissions. In this case, log in again and re-run `apicm archive:push`. (The token is refreshed every time you log in.) Optionally, you can extend the token expiration time when logging in as the admin user:

```
apicm login --expireHours=<number_of_hours>
```

The `expireHours` flag overrides the default authentication token expiration of 8 hours. Use this flag when pushing data sets that take longer than 8 hours to complete. Note that the revised value persists after the session ends. Best practice is to revert the value to the default (8 hours) after migration.

- If your prior migration created an incorrect artifact on v10, you may have to manually remove the artifact before re-running migration. If you use the `--overwrite` flag when running additional `archive:push` commands, existing OAuth Providers, draft products, draft APIs, and published products and their APIs will be overwritten.
- When you re-run migration, the utility will not recreate any artifacts that already exist on v10 unless the `--overwrite` flag is used for OAuth Providers, draft products, draft APIs, and published products and their APIs. If a collision occurs for other artifacts or if the `--overwrite` flag was not used, the older artifact takes priority. Also, the utility will not delete any artifacts from v10. Thus, you can re-run migration to cover any gaps in artifact creation on v10 without affecting existing artifacts.
- The steps you need to take depend on whether you need to change the v5 export data. For example, if you need to publish or replace a v5 API, you need to export the v5 data and run `unpack` again. If you do not need to change the v5 data, you can skip those steps.

Example 1: Re-using the v5 export data

For example, your v5 export data is accurate and current, but you migrated a consumer-org that is no longer needed on v10, and you mapped a catalog to an incorrect name. Complete the following steps:

1. Delete the incorrect artifacts from the v10 deployment `/cloud` directory. For this example, delete the unneeded consumer-org and the incorrectly named catalog.
2. Edit the contents of the `/cloud` directory as needed. For example, remove the unneeded consumer-org entry.
3. Edit your mapping entries as needed. For example, remap the catalog name.
4. Run `apicm archive:push <server> <project_directory>`.

Example 2: Revising v5 export data

In this example your v5 export data is not current because you want to publish or replace a v5 API and then migrate it to v10. Complete the following steps:

1. On v5, recreate the export data: `config dbextract sftp <host_name> user <user_name> file <path/name>`
2. On v10, delete the `/cloud` directory.
3. Run `apicm archive:unpack` to create the v10 hierarchy in `/cloud` directory.
4. Recreate any edits you made to the `/cloud` directory.
5. Recreate any mappings.
6. Run `apicm archive:push <server> <project_directory>`.

## Failure to convert API definitions to API Gateway

---

When you change gateway types from DataPower Gateway (v5-compatible) to DataPower API Gateway, you use `./apicm archive:port-to-apigw <path>` to convert API definitions to API Gateway format. The conversion requires Node version 18.19.1 or greater. If Node is not installed, this error is displayed:

```
ERRO[0000] Error getting node version: exec: "node": executable file not found in $PATH
```

If an unsupported version of Node is installed, an error is displayed as in the following example:

```
ERRO[0000] Node version installed must be >=18.19.1. Currently installed version: 4.9.1. Use the --allow-older-node flag to allow the use of an older node 18 version at the users own risk.
```

To resolve the error, install Node and re-run the command. If you are on an older version of node 18 you can re-run the command using the `--allow-older-node` flag but you do this at your own risk.

To view the conversion step, see [Migration steps without PDUR](#) or [Migration steps with PDUR](#). For information about the conversion, see [Reviewing APIs converted to DataPower API Gateway](#).

## Custom policies not appearing in the policy palette after migration

---

If you are migrating to v10.0.1.3 or earlier, or v10.0.2.0 or earlier, follow these steps to have custom policies appear in the policy palette in the API Manager Assembly UI.

1. Open `gateway-extension.zip` in the `cloud/admin-org/.../<gateway-service>` folder that is generated in `admin-org` after `port-to-apigw` is run.
2. Open the `manifest.json` file.
3. Edit the `manifest.json` file to specify the implementation files for the custom policies to push to the sandbox catalog.  
Add entries for the sandbox catalog for all provider-orgs using the format `<provider-org>_<catalog-name>`. The filename can remain the same for each respective provider-org, as it will be the same custom policy. Ensure that the actual file that the filename is pointing to in the `.zip` file exists. The same filename can be re-used multiple times in the `manifest.json` to add the sandbox entries for the custom policy. Only the `manifest.json` must be edited. You do not need to edit any of the `.zip` files in the `gateway-extension.zip` package.
4. Save the `manifest.json` file and zip it.
5. If the `archive:push` was already performed before step 1, then delete the `gateway-extension.zip` file from the gateway using the API Connect toolkit command `apic gateway-extensions:delete`.
6. Push `admin-org`, which pushes the updated `gateway-extension.zip` file.

7. Follow these steps to ensure that the API Manager advertises the custom policy that is being pushed.
  - a. In each of the provider orgs in the cloud folder, navigate to the `catalog-scoped-staging` folder and log in to the API Connect toolkit as a provider-org user.
  - b. Run this command on every .zip file that you want to appear in the policy palette in the v10 UI:

```
apic policies:create -c sandbox --configured-gateway-service -o -s $API_SERVER_URL --scope catalog .zip
```

The `gateway-service` name is under Topology. `$API_SERVER_URL` is the same one you use to log in to the API Connect toolkit. The custom policy zip filename will appear in the `catalog-scoped-staging` folder.

8. Navigate to the API Manager UI and check the assembly policy palette. The custom policies should now appear in the list. You do not need to push the provider orgs.

If you are migrating to v10.0.1.4 or later, v10.0.3.0 or later, follow these steps to have custom policies appear in the policy palette in the API Manager Assembly UI.

1. After the migration of admin-org and provider-orgs has completed, navigate to the API Manager UI.
2. While editing a draft API, click the gear icon next to the offline button. A pop-up should appear.
3. Select the target-catalog to publish the draft API to. The target-catalog must already have the custom policies pushed to it.
4. Select the Application to use for the API.
5. Click Save.
6. Navigate to the Assembly policy palette. The custom policies for that specific target-catalog should now appear. For more details about these steps, see [Specifying the testing preferences for an API](#).

When artifacts such as provider org, space or catalog are mapped, any warning or error messages for artifacts in subdirectories underneath those may have the location incorrect. The location will include the mapped artifact location instead of the original location.

---

## Migrating a Version 5 deployment

Use the Migration Utility to automate the migration of a v5 deployment to a v10 deployment.

### Supported versions

---

- You can migrate API Connect Version 5.0.8.7 or later point release to API Connect Version 10.0.2.0 or later point release. If your Version 5 system is older than the minimum, you must first upgrade it to the minimum version.
- You can migrate API Connect Version 5.0.8.7 or later point release to a Cloud Pak for Integration version 2021.4 or later. The version of Cloud Pak for Integration must use API Connect Version 10.0.4.0 or later.
- The migration utility version must match the API Connect and DataPower version. Observe the following Version 10 API Connect requirements:
  - For Kubernetes, the installation operator version must match the API Connect version.
  - For VMware, the `apicup` utility version must match the API Connect version.

### Obtaining the API Connect Migration Utility

---

Download the API Connect Migration Utility (AMU) from IBM Fix Central. For a link to the latest files on Fix Central, see [What's new in the latest release](#).

- [Migration overview](#)  
The migration process provides tools to extract v5 data, arrange it for v10 formats, and load it onto a v10 system.
- [Migration steps](#)  
Plan the migration, install a new v10 deployment, and move data from v5 to v10.
- [Converting APIs to DataPower API Gateway](#)
- [Migration mapping files](#)  
You can use mapping files to map the name of a v5 object to a corresponding v10 object that has a different name.
- [Migrating OAuth providers and OAuth secured APIs](#)  
You can migrate v5 OAuth providers and OAuth secured APIs to your v10 API Connect deployment.
- [Migrating custom policies](#)  
The migration utility migrates API Connect Version 5 user-defined custom policies to API Connect Version 10. After migration, the v5 custom policies run on a v5-compatible DataPower Gateway or the DataPower API Gateway. Custom policies can be migrated to API Gateway with limitations.
- [Migrating gateway extensions](#)  
Use the appropriate procedure for migrating extensions to either a v10 DataPower® Gateway (v5 compatible) or a v10 DataPower API Gateway.
- [Migration considerations](#)  
You can optimize the migration process by reviewing the migration considerations and taking any actions that apply to your deployment.
- [Migration troubleshooting](#)  
If you run migration and observe error messages in your log output, you can take troubleshooting steps, and run the migration again.

---

## Migration overview

The migration process provides tools to extract v5 data, arrange it for v10 formats, and load it onto a v10 system.

Important: The migration utility allows migration from v5 to a v10 v5-compatible gateway or v10 API Gateway. References to conversion of v5-compatible artifacts to v10 API Gateway refer to the v5-compatible artifacts that were initially from a v5 environment and were unpacked by the migration utility.

The migration model is centered around using tooling to bring the contents of Version 5 catalogs onto a Version 10 deployment that is set up to import them. The tooling migrates provider organization configuration information, including APIs, Catalogs, Products, Consumers, subscriptions, user registries and more.

The migration utility also supports migrating your billing data from v5 to v10:

- All Stripe billing integrations in v5 are migrated to v10 and applied automatically to all Catalogs.
- All products that use paid plans will have the plans migrated.

- Consumer payment methods that exist in the v5 Portal will be automatically created in v10.

After the migration is complete, you must configure the Stripe integrations in the Developer Portal sites; see [Configuring Stripe in the Developer Portal](#) for detailed instructions. For more information about the billing feature in v10, see [Monetizing your Products](#).

You use a v5 extract command to gather the v5 data, and then use a migration unpack command to convert the data into Version 10 format. This extraction will generate a `c1oud` directory where your v5 data will be represented as YAML files. By viewing the contents of the `c1oud` folder, you can see which structures, such as provider organizations, are needed to support your catalog.

The model recognizes that not all v5 data is applicable to a new Version 10 deployment. To optimize your v10 deployment, you may use a text editor to remove unneeded or obsolete v5 configurations from the converted file. When you install and configure your v10 management server, you manually create those structures. You can then use migration tooling to load the v5 data into the prepared v10 system.

During the migration process you can keep your existing v5 system active while you install and configure a parallel (side-by-side) v10 system. You must have system administrator privileges to complete a migration. You should be familiar with IBM API Connect Version 5 architecture and requirements, and with the deployment configuration that you want to migrate.

The migration process supports migrating v5 data to both v10 DataPower Gateway (v5-compatible) and v10 DataPower® API Gateway.

The following sections in this topic review each step in the migration process. See also [Migration considerations](#).

---

## Migration steps

Plan the migration, install a new v10 deployment, and move data from v5 to v10.

### About this task

---

At the highest level, the migration steps are:

- Plan your migration.
- Install and configure a v10 system to best meet current needs and integrate v5 data.
- Backup your v5 data and migrate the data to your new v10 deployment.

### Procedure

---

Complete the following steps:

1. Plan your migration:
  - Read [Migration overview](#).
  - Ensure you have supported versions of the software. See [Supported versions](#).
  - Plan your new v10 deployment. When moving from v5 to v10, use the opportunity to review your topology, user registries, provider organizations, etc. You might want to look at the existing data on the v5 system, and do some cleanup before running the extract. This will help ensure only objects that are required in v10 are migrated over.
  - If you are migrating to DataPower API Gateway, migrate a proof-of-concept deployment before migrating your entire v5 backup. Migrate 10 to 20 of your most commonly used v5 APIs and test them to determine which migration utility settings you may need to convert your APIs to DataPower API Gateway.

2. Install and configure a v10 system.

Install and deploy v10 with usage of the incoming v5 data in mind. Before you push your v5 data to v10, your v10 system must be up and running, with gateway services, provider organizations, user registries, etc, ready to receive the data.

- For the v10 deployment, install the API Connect subsystems. Use the normal installation and configuration processes as shown in the documentation:
  - [Installing and maintaining IBM API Connect](#)
  - [Configuring and managing your server environment](#)

Important:

Verify that you completed the following steps as part of deploying your v10 environment:

- Ensure that you create the same number of API Managers as on the v5 deployment.
- Use the Cloud Manager to configure topology. See [Defining your topology](#).
- If your v10 topology uses identical names and quantities of gateway services as v5, the migration utility automatically maps configuration information. If your v10 configuration uses different names or a different number, you must manually map the v5 gateway services to v10 gateway services. You will be guided to map gateway services in a later step. To review the mapping requirement, see [Mapping a gateway service](#).
- Review Gateway types and configurations:

API Connect v10 supports two types of gateway services: DataPower Gateway (v5-compatible) and DataPower API Gateway. The DataPower API Gateway type is not supported for API Connect v5. When you register your gateway service on your v10 system, you must select the gateway service type. If you select API Gateway, your migration process must include a step to convert (port) the v5 API Definitions from the DataPower Gateway (v5-compatible) format to the DataPower API Gateway format. The migration utility provides an option to do the porting. Command line instructions are provided in a later step.

If migrating to datapower-api-gateway, confirm xml-manager is enabled in default domain of all gateways.

To review gateway types and configuration, see [API Connect gateway types](#) and [Registering a gateway service](#).

- Create the provider organizations. If your v10 configuration for provider organizations uses different names or a different quantity, you must manually map the v5 provider organizations to v10 provider organizations. You will be guided to map provider organizations in a later step. To review the mapping requirement, see [Mapping a provider organization](#).
- When migrating catalog spaces in a provider organization that uses a local user registry (LUR), ensure that the LUR is configured with the visibility setting of either **Public** or **Custom**. If set to Custom, ensure that the provider organization is selected. For information on configuring visibility, see [Setting visibility for a user registry](#).
- Configure user registries such as LDAP, as needed to match the user registries used for v5 users.
- The migration process includes migration of users. Configuration of users into API Connect includes sending email to users to set up their accounts. The recommended way to do this during an automated migration is to set up a temporary SMTP server. One open source option for SMTP is MailHog. See

<https://github.com/mailhog/MailHog>. When the migration process is complete, be sure to replace your temporary SMTP server with the permanent SMTP server for your API Connect v10 deployment.

- Create the Portal services that you want to use with the Catalogs that you plan to migrate. You will configure the catalogs to the Portals after the migration data is pushed to the v10 system.
3. Backup your v5 data and migrate the data to your new v10 deployment.
- a. Download the migration utility. See [Obtaining the API Connect Migration Utility](#).
  - b. Determine if your v5 system contain catalogs that use a Portal Delegated User Registry (PDUR).  
Use of the PDUR was optional in v5. Migration of systems that use PDUR is very similar to migration of systems that do not use PDUR, however a few additional steps are needed. If you are not sure if your v5 catalogs use PDUR, check your v5 registry settings. See [Selecting the Portal Delegated User Registry](#).
  - c. Continue with instructions that apply to your deployment:
    - [Migration steps with PDUR](#)
    - [Migration steps without PDUR](#)
- [Migration steps with PDUR](#)  
Complete the following steps to migrate from v5 to v10 when your v5 catalogs use Portal Delegated User Registries (PDUR).
  - [Migration steps without PDUR](#)  
Complete the following steps to migrate from v5 to v10 when your v5 catalogs do not use Portal Delegated User Registries (PDUR).
  - [Logging in to a management server with an OIDC registry](#)  
Logging in with an OIDC registry involves several steps, in which you obtain a temporary token and pass it to the toolkit to ensure it can communicate securely with the management server.

---

## Migration steps with PDUR

Complete the following steps to migrate from v5 to v10 when your v5 catalogs use Portal Delegated User Registries (PDUR).

---

### Before you begin

Important: If your v5 deployment does **not** use Portal Delegated User Registry (PDUR), do not use these instructions. See [Migration steps without PDUR](#).

- Ensure you planned your migration, obtained the migration utility, and installed a v10 deployment, as described in [Migration steps](#)
- Review [Migration considerations](#).
- Ensure you have system administrator privileges.
- To use `apicm` to convert the API definitions, you must have Node version 18.19.1 (or greater) installed.

---

### About this task

Tip:

To achieve a smooth and successful migration, we recommend these best practices:

- Before you push your v5 data to v10, your v10 system must be up and running, with gateway services, provider organizations, user registries, etc, ready to receive the data.
- Plan to do several test iterations of migration. You can use the `--dry-run` option to do iterations of the migration push, to test for any errors or warnings to address before the actual data push.
- Use the `apicm <command> --help` command to review the command options and their purpose. To see the list of commands you can run: `apicm help`.
- Complete all the steps in this topic in the order listed, unless the step is marked optional and does not apply to your scenario. You can push provider orgs as many times as needed.

The migration of v5 catalogs that use PDUR to a v10 deployment contains all of the steps for migration a non-PDUR v5 deployment to a v10 deployment (as described in [Migration steps without PDUR](#)) plus additional steps that are needed to migrate Portal Delegated User Registry data.

In IBM API Connect Version 5, when Portal Delegated User Registry (PDUR) was selected for a Catalog, the user management was delegated from the management server to the Developer Portal. The site administrator within the Portal site then performed the configuration. The management server recorded that the delegation had taken place, and stored a record of the users which existed in the catalog. However, the management service maintained no information about the configuration of the specific registries or how users mapped to them.

PDUR in IBM API Connect v5 was highly configurable. A single Portal site (catalog) could be configured to use multiple different registry types or different registries of the same type. Details of this configuration, and which users map to which registry, is all stored in the Portal.

However, IBM API Connect Version 10 and later supports new registries, and no longer needs the PDUR. Instead, functionally equivalent registries can be configured in v10 and used. To migrate the PDUR user registries and users from v5 to v10, we must gather configuration information from both the management server and the Portal node.

PDUR supported 4 different types of user registries. The following table shows the mapping of these types to the v10 equivalents:

Table 1. Mapping of Registry types

| v5 PDUR Registry          | v10 Equivalent Registry   |
|---------------------------|---------------------------|
| LDAP                      | LDAP                      |
| OIDC                      | OIDC                      |
| HybridAuth                | OIDC                      |
| Local User Registry (LUR) | Local User Registry (LUR) |

In this scenario, if you want to migrate users from an IBM API Connect V5 Developer Portal to an IBM API Connect v10 Developer Portal, you must export the user information that is stored in the Developer Portal local database. This information can then be used by the migration tooling to migrate the PDUR user registry. You complete this action after you have exported the v5 configuration database for the management server.

## Procedure

1. Log in to the command line interface of the v5 appliance. Use the following command to create a tar.gz export of the v5 configuration database and place it on an **sftp** server:

```
config dbextract sftp <host_name> user <user_name> file <path/name>
```

- Specify a name of your choice for the compressed file to contain the dbextract. For example, `v5mgmt_data.tgz`.
- If you are not familiar with the v5 appliance CLI, see [The Command Line Interface](#). For information on `config dbextract`, see [Configuration commands](#).

2. Log in to Developer Portal CLI to export Portal Delegated User Registry user information for all of the sites on a Developer Portal server. Use the following command to create a `*.tgz` file:

```
pdur_user_export
```

The status of the export is displayed. For example:

```
admin@apimxxx123:~$ pdur_user_export
portal123.company.com/api-provider/production: Exporting pdur users
portal123.company.com/api-provider/preprod: Exporting pdur users
portal123.company.com/api-provider/uat: Exporting pdur users
portal123.company.com/api-provider/development: Skipping as not a pdur enabled site
portal123.company.com/api-provider/sandbox: Skipping as not a pdur enabled site
~/pdurexport ~
5c20b903e4b0485cbbd81775.5c20bf43e4b0485cbbd81795.json
5c20b903e4b0485cbbd81775.5c2cddb4e4b0485cbbd818a0.json
5c20b903e4b0485cbbd81775.5c335211e4b0485cbbd8196e.json
~
Output can be found in /home/admin/pdurexport.tgz
```

Results:

- When the command completes, you can see the output `*pdurexport.tgz` in `/home/admin/pdurexport.tgz`.
  - This compressed file contains all of the JSON user-mapping files for that server. Each `.json` file contains a list of all of the PDUR user information that is stored in the Developer Portal local database. The naming convention used for the individual user-mapping files is `<provider_org_id>.<catalog_id>.json`.
  - The user information for all of the user registration methods that are used in the specific Developer Portal are included in the same file. For example, local user registry, LDAP user registry, third-party authentication, OpenID Connect, and any custom user registration method.
  - If a site doesn't contain any PDUR data, that site is skipped. The example output shows that there was one provider organization on the server, and that organization had five Developer Portal sites, three of which contained PDUR user information. The PDUR user information for all of the sites on the server is exported into a `pdurexport.tgz` file.
3. Optional: Setup a temporary SMTP server.  
During migration, if subscription approval is needed to enable an application to subscribe to a plan, notifications are sent to all users, within the organization, who have subscription approval permission. In some cases, this results in a large number of emails. To avoid the sending of these emails, set up a temporary email server prior to running the migration, and use it to collect all notifications rather than sending them to users' email accounts.

If subscription approvals are not needed during your migration, you can skip this step.

4. Optional: If necessary, set up a temporary LDAP server. This can be needed if you are temporarily behind a firewall.
  - a. Install a server:

```
git clone https://github.com/veo-labs/ldap-server-mock
```

```
npm install
```

- b. Creating the configuration files:

- `ldap-server-mock-conf.json`

```
{
 "port": 3004,
 "userLoginAttribute": "cn",
 "searchBase": "dc=test",
 "searchFilter": "(&(objectclass=person)(cn={{username}}))"
}
```

- `users.json`

```
[
 {
 "dn": "cn=user,dc=test",
 "cn": "user-login"
 }
]
```

- c. Run the LDAP server:

```
node server.js --conf=./ldap-server-mock-conf.json --database=./users.json
```

- d. Modifying a current LDAP provider.

The following file is a dummy user registry file that maps to a read-only test server. The fields in bold font (`admin_dn` and `endpoint`) have been changed to fit the dummy server configuration. Change these on all user registries that need to be fixed.

```
api_version: 2.0.0
configuration:
 admin_dn: cn=user,dc=test
 admin_password: xxxx
 authenticated_bind: "true"
 authentication_method: search_dn
 bind_prefix: ""
 bind_suffix: ""
 protocol_version: "3"
 search_dn_base: ""
```

```

5. Unpack both the v5 management data backup and the PDUR tar file.

Important: Migration on Windows 10

Windows has path length limits that can interfere with large extracts. It is recommended that you keep the initial path for migration on Windows as short as possible. The AMU must be run in a command window with administrative privileges on Windows. Running from a Linux VM on your Windows system may be a better option for doing migration.

- Copy the v5 extract tar file (<v5mgmt\_data>.tgz) and the PDUR extract file (pdurexport.tgz) from the sftp server to the location where you have v10 migration utility installed.
- Run `apicm archive:unpack` command from the directory where you downloaded the v5 extract file. When you invoke `apicm` for the first time, you are prompted to accept the license. Accept the license to continue.

You can optionally limit the unpack to only specific provider orgs. See [Table 2](#).

```
./apicm archive:unpack <v5_extract_file>.tgz pdurexport.tgz
```

Table 2. `apicm archive:unpack` command options

| Parameters         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <v5_extract_file>  | Can be compressed file (.tgz, tar.gz) or uncompressed file (.tar). Use any file name of your choosing. Example:<br><code>v5_DBextract_data.tgz</code>                                                                                                                                                                                                                                                                                                                                                  |
| pdurexport.tgz     | The Portal Delegated User Registry export file generated by the <code>pdur_user_export</code> utility. Example:<br><code>pdurexport.tgz</code>                                                                                                                                                                                                                                                                                                                                                         |
| --provider-orgs    | One or more provider orgs to unpack. This flag is optional. Use it when you want to unpack only specific provider orgs rather than the entire archive. Example:<br><code>./apicm archive:unpack v5_DBextract_data.tgz pdurexport.tgz --provider-orgs=&lt;pOrg1_name&gt;</code><br><br>Use a comma-separated list to specify multiple provider orgs:<br><code>./apicm archive:unpack v5_archive_data.tgz pdurexport.tgz --provider-orgs=&lt;pOrg1_name&gt;,&lt;pOrg2_name&gt;,&lt;pOrg3_name&gt;</code> |
| --use-old-sluggify | Unpack the V5 configuration data onto the local filesystem using the version 10.0.5.1 conversion rules for sluggifying element names and version numbers. For more information about the conversion rules, see <a href="#">Parity between v5 and v10</a> .                                                                                                                                                                                                                                             |

Note:

- You can avoid the license prompt by adding `--accept-license` to the command line.
- The unpack command ensures that catalog names and API properties contain only valid characters. Any invalid characters are mapped to '-'. See [Parity between v5 and v10](#).
- The unpack command issues warning messages for APIs and Products that fail validation against the OpenAPI specification. See the limitations section in [Migration considerations](#).
- For troubleshooting tips, see [Migration troubleshooting](#)
- The unpack command might return error messages related to PDUR, such as:

```

ERRO[3414] PDUR backup data for IDP PortalDelegatedIdentityProvider-123b81fbe4b06de411580e2e
(123b81fbe4b06de411580e2f) not provided: not found
ERRO[3414] PDUR backup data for IDP PortalDelegatedIdentityProvider-123b820de4b06de411580e32
(123b820ee4b06de411580e33) not provided: not found

```

The error means that when the migration utility unpacked `pdurexport.tgz`, it could not find all the specified Portal user registries. To resolve the errors, re-run `pdur_user_export` and re-run the unpack..

When the command completes, the data is unpacked to the `/cloud` directory. The `/cloud` directory is located in the same directory as `apicm`, and populated with yaml files representing the configuration objects in the export. The unpack processes produce output in the format required for v10 configuration.

Note: The unpack directory must be named `/cloud`. Do not rename the directory.

Example output in `/cloud` for provider-org:

```

├─ provider-orgs
│ └─ pOrg1
│ ├── catalogs
│ │ ├── catalog1
│ │ └─ ...
│ └─ user-registries
│ ├── pdur-ldap-5c38c102e4b0485cbbd81a84
│ │ ├── mapping.yml
│ │ ├── user-registry.yml
│ │ └─ users
│ │ ├── gauss.yml
│ │ └─ riemann.yml
│ ├── git-hub-5c38c102e4b0485cbbd81a84-bbfe
│ │ ├── user-registry.yml
│ │ └─ users
│ └─ apicmtestgithub-apicmtestgithub-c646.yml

```

6. If the v5 Developer Portal used LDAP, HybridAuth, or OIDC (such as social login through Google, GitHub, or Slack) user registries, you must manually configure them in v10 before using `apicm archive:push` to migrate PDUR. See the following instructions for your registry type:

- LDAP

- Manually configure LDAP

The user registries which are required in the target v10 system are described in the `user-registry.yml` file. Where possible the configuration for the v10 registries is complete in these files. However, for LDAP the configuration of the registry is not possible due to differences in the way the v5 Portal (Drupal) and v10 API Manager (`apim`) specify user registry configuration.

For LDAP with v10, create a user registry manually, using the same LDAP server and configuration as used with v5. Where it is possible, the v5 configuration is provided as helpful information in the `metadata.v5_config` property. To view the v10 configuration instructions, see [Configuring an LDAP user registry](#).

For example: An `ldap.tar.gz` file, when unpacked, creates the following directory hierarchy, for an LDAP directory **example**:

You can create an LDAP user registry for the PDUR by either modifying `user-registry.yml` or by creating the registry in the UI:

- Modify the `user-registries/example-5c38556de4b0c5f69db90ee0/user-registry.yml` file directly and add the required LDAP fields based on the extracted info provided in the metadata. Remove the metadata after you are done. The modification of `user-registry.yml` is preferred over using the UI. This method enables any APIs that depend on the user registry to be satisfied when the migration command `apicm archive:push` is run in Step [10](#).
    - Create the registry in the UI. The creation of the registry in the UI requires more manual setup of the organization and catalog. In addition, you must provide a mapping file to map from the `example-5c38556de4b0c5f69db90ee0` to the ID of the registry that was created manually.
  - Create a mapping file entry for the LDAP user registry. In the `/cloud` directory, go to `provider-org/<provider-org>/user-registry/<PDUR_LDAP_User_registry>` and create a mapping file to tell migration utility the name of the migration endpoint for the LDAP user registry used with v5 PDUR:

```

user-registry:
 name: <pdur-ldap-v10-name>

```

To determine which name to use for the v10 LDAP registry, go to the management user interface, click on **Resources** -> **User Registries** then use **Name** not **Title**.

For more information on how to create mapping files, see [Migration mapping files](#).

- OIDC

- Manually configure OIDC

- Note that v10 supports OAuth 2.0 but does not support OAuth 1.0. Deployments, such as Twitter, which use OAuth 1.0 with APIC version 5, can not use OAuth 1.0 when migrating to v10.

- Automatic migration is not supported for the OIDC user registries which you use in your v5 Portal. Thus if you are using OIDC OAuth 2.0, e.g., Google, GitHub, or Slack, please complete the following manual steps.
- The OIDC data from the Portal Delegated User registry does not contain the `client_id` and `client_secret` that are needed to migrate a user registry automatically. You must obtain the data and update the user registry manually if you are using `client_id` and `client_secret`.

On the Version 10 system:

- Edit `user-registry.yml`. For example, for GitHub:  
`cloud/provider-orgs/test-user1-org1/user-registries/git-hub-5c5xyz6ee4b0c5f69db94xxxx-a339/user-registry.yml`

```
api_version: 2.0.0
configuration:
 client_id: ""
 client_secret: ""
 authorization_endpoint: https://github.com/login/oauth/authorize
 provider_type: github
 token_endpoint:
 endpoint: https://github.com/login/oauth/access_token
integration_url: file://../../../../integrations/user_registry/oidc.yml
metadata:
 v5_id: 5c5xyz6ee4b0c5f69db94xxxx
 name: git-hub-5c5xyz6ee4b0c5f69db94xxxx-a339
 registry_type: oidc
 title: GitHub
 type: user_registry
```
- Insert the values for `client_id` and `client_secret`. Once the client id and client secrets have been updated in the `user-registry.yml` file just described, the `apimc archive:push` can be successfully executed. Upon creation and configuration of the Developer Portal, you can log in by using, as in this example, an account such as a GitHub account.

To verify that the manual configuration succeeded, view the log file for entries for the users after you run `apim archive:push` in Step [10](#).

- Example success message:

```
INFO[0012] User registry git-hub-5c5xyz6ee4b0c5f69db94xxxx-a339 created
INFO[0013] User test-user1-4d48 created
```

- Example error message:

```
ERRO[0010] unable to create User registry git-hub-5c5xyz6ee4b0c5f69db94xxxx-a339
ERRO[0010] git-hub-5c5xyz6ee4b0c5f69db94xxxx-a339: The properties client_id, client_secret are required.
```

- Create a mapping file entry for the OIDC user registry. In the `/cloud` directory, go to `provider-org/<provider-org>/user-registry/<PDUR_OIDC_User_registry>` and create a mapping file to tell migration utility the name of the migration endpoint for the OIDC user registry used with v5 PDUR:

```
user-registry:
 name: <pdur-OIDC-v10-name>
```

For more information on how to create mapping files, see [Migration mapping files](#).

#### 7. Optional: Remove unneeded configuration objects.

Inspect the set of configuration objects and their attributes, and remove the ones that are not needed. In many cases, some of the configuration objects present in the v5 system are not needed in the new v10 environment. For example, there is no value in preserving inactive users, obsolete apps, obsolete consumer organizations, and so on.

When deleting objects, make sure that you do not delete objects that have other dependent objects, such as products with subscriptions on them or users that are active. If you delete a consumer organization make sure you also delete all apps and subscriptions associated with that consumer org. Be aware of any groups that include these consumer orgs or visibility settings that include the consumer orgs.

#### 8. Map v5 object names to v10 object names.

Most deployments adjust the names or quantities of gateway services, provider organizations, and user registries when setting up a new environment for v10. Be sure to specify any changed v10 destinations for the v5 data in a migration mapping file so that the migration utility can automatically move the data.

Complete the following, as needed. You can skip the steps for any objects that are unchanged from v5 to v10.

- [What is a mapping file?](#)
- [Mapping a gateway service](#)
- [Mapping a provider organization](#)

- 9. Optional: If your v10 deployment uses a **DataPower API Gateway**, convert the v5 API definitions to v10 DataPower® API Gateway. To convert API definitions using the default migration configuration, use the following syntax.

```
./apimc archive:port-to-apigw <path>
```

Important: Ensure that the DataPower Gateway version that you are using with your API Connect v10 deployment is compatible with the version of the migration utility that you are using. For details, see the version compatibility information in [Configuring and managing your server environment](#).

Important: If you are running the migration utility in Windows, Administrator privileges are required to complete this step.

Table 3. Parameter for `archive:port-to-apigw`

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <path>    | <p>Specify the unpacked <code>ccloud</code> directory as input:</p> <pre>./apicm archive:port-to-apigw /ccloud</pre> <p>By specifying <code>/ccloud</code>, <code>apicm</code> ports all artifacts within the directory, including APIs, Products, OAuth providers, custom policies, subscriptions and so on. Running a subsequent <code>archive:push</code> pushes all the artifacts to API Gateway.</p> <p>Running <code>archive:port-to-apigw</code> on any subdirectory within the unpacked <code>/ccloud</code> directory could leave the directory in an inconsistent state, and cause the subsequent <code>archive:push</code> of artifacts to API Gateway to fail. Custom policies and OAuth providers are not migrated if a directory other than <code>/ccloud</code> is specified.</p> <p>Note: However, if you decide to rewrite one API at a time, to migrate them to API Gateway, you can use:</p> <pre>./apicm archive:port-to-apigw &lt;path&gt;</pre> <p>where <code>&lt;path&gt;</code> is a single API file, or a directory that contains only APIs or Products.</p> <p>In this case, you cannot use <code>archive:push</code> to push artifacts to API Gateway. All the ported APIs and Products must be pushed (or imported) into API Manager by either the toolkit or UI.</p> |

Usage notes:

- The conversion produces a draft output YAML file. Review the entire draft output YAML file for conformance, performance, and errors. Review the log files for messages about any manual actions that might be needed. For more information, see [Reviewing APIs converted to DataPower API Gateway](#).
  - By default, all changes that the migration utility makes when rewriting APIs are logged as comments within the API YAML file. You can use the `enable-api-logging` parameter to disable logging of these changes.
- ```
./apicm archive:port-to-apigw <folder> --enable-api-logging=false
```
- You can also specify migration configuration parameters using either a YAML configuration file or from the command line, but not both. For information about configuration options and DataPower requirements for certain configuration parameters, see [Configuring migration options for DataPower API Gateway](#).
 - Multiple runs of `./apicm archive:port-to-apigw` on the same `/ccloud` folder will skip artifacts that have already been converted to DataPower® API Gateway.
 - If your v10 deployment uses DataPower MultiProtocol Gateway (v5-compatible) you do not need to convert the API definitions.
10. Use `apicm` commands to push the Cloud Manager admin organization data onto your v10 Management Server.
- a. Log in to the Cloud Manager on the destination v10 Management Server as an Owner of the admin organization:
- Important: You must be logged in as an Owner of the admin organization to be able to migrate Cloud Manager admin organization data.

- Syntax:

```
./apicm login --server <cloud_manager_endpoint> --realm admin/identity_provider --username admin --password admin_password
```

- Example on API Connect v10 standalone

```
./apicm login --server cloud-admin-ui.mgmt.dev.apic10-stack.example.test --realm admin/default-idp-1 --username admin --password 'myadminpassword'
```

- Example on Cloud Pak for Integration

```
./apicm login --server cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod --realm admin/default-idp-1 --username admin --password 'XXXXXXXXXXXX'
```

The values to supply for the login parameters depend on whether your management server is deployed on API Connect v10 standalone or as part of Cloud Pak for Integration. See [Table 4](#) to review how to obtain each parameter.

Note: If you want to login using an OIDC user registry, see [Logging in to a management server with an OIDC registry](#).

Table 4. `apicm login` command parameters

Parameters	Description
------------	-------------

Parameters	Description						
<pre>--server <cloud_manager_endpoint></pre>	<p>The endpoint on the management server for communication with the Cloud Manager user interface.</p> <p>v10 standalone Example:</p> <pre>cloud-admin-ui.mgmt.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the management subsystem was installed. View the <code>apiconnect_api</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory that you created for initial deployment of v10. Examples:</p> <ul style="list-style-type: none"> VMware: see the <code>cloud-admin-ui</code> endpoint in Deployment overview for endpoints. Kubernetes: see the <code>admin</code> endpoint in Deployment overview for endpoints and certificates. <p>Cloud Pak for Integration Syntax:</p> <pre><cpd-APIC_namespace.your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance></pre> <p>Example:</p> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre> <p>where <code>e2e</code> is <code><APIC_namespace></code> and <code>prod</code> is <code><APIC_instance></code>.</p> <p>Note: How to obtain the server parameter on Cloud Pak for Integration Use the Platform Navigator UI to determine the parameter. Note that you cannot get the endpoint by using <code>oc get routes</code> because Zen modifies the route internally.</p> <ol style="list-style-type: none"> Locate the Platform UI panel with entries for the deployment. Identify the row that has a Type column entry with the description <code>API management administration</code> To display the endpoint, hover over the entry in the Name column for that row. For example, hover over the <code>prod</code> entry, as shown in bold font, and the <code>URL</code> displays at the bottom of the panel. <table border="1"> <thead> <tr> <th>Name</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>prod</td> <td>API management administration</td> </tr> <tr> <td>prod</td> <td>API management</td> </tr> </tbody> </table> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod/admin</pre> <ol style="list-style-type: none"> Remove the trailing <code>/admin</code> from the endpoint, to obtain the parameter for the login command: <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre>	Name	Type	prod	API management administration	prod	API management
Name	Type						
prod	API management administration						
prod	API management						
<pre>--realm admin/default-idp-1</pre>	<p>The <code>apicm login</code> example shows the expected <code>--realm</code> parameter values for a default API Connection administration organization. The default user is <code>admin</code> and the identity provider is <code>default-idp-1</code>. You can determine which identity provider to use in the <code>--realm</code> parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):</p> <pre>apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm</pre> <p>For example:</p> <pre>apic identity-providers:list --scope admin --server myserver.com --fields title,realm total_results: 2 results: - title: Cloud Manager User Registry realm: admin/default-idp-1 - title: Corporate LDAP user registry realm: admin/corporate-ldap</pre> <p>The <code>title</code> value should enable you to determine which identity provider to use; you can then copy the corresponding <code>--realm</code> parameter directly from the displayed <code>realm</code> value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is <code>default-idp-1</code>.</p>						
<pre>--username admin</pre>	Administrative user with permissions to modify API Connect admin-org. The default user is <code>admin</code> .						
<pre>--password myadminpassword</pre>	Administrative user password. Cloud Pak for Integration: When you installed with the top-level CR for CP4I, the password was auto-generated. To obtain the password, see step 3 in Installing API Connect .						

b. Run `/apicm archive:push` to migrate data for the Cloud Manager administrative org (admin-org).

- Syntax

```
./apicm archive:push <cloud_manager_endpoint> <path_to_admin_org> [optional flags]
```

- Example for v10:

```
./apicm archive:push cloud-admin-ui.mgmt.dev.apic10-stack.example.test cloud/admin-org
```

- Example for Cloud Pak for Integration:

```
./apicm archive:push cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod cloud/admin-org
```

See [Table 5](#) to review how to obtain each parameter.

Tip: First run the command with the optional flag `--dry-run` to test for errors or warnings. Review the command parameters, examples and guidance that follow before you run it.

Table 5. `apicm`
`archive:push` command parameters for admin org

Parameters	Description
<code><cloud_manager_endpoint></code>	<p>The endpoint on the management server for communication with the Cloud Manager user interface.</p> <p>v10 standalone Example:</p> <pre>cloud-admin-ui.mgmt.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the management subsystem was installed. View the <code>apiconnect_api</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory that you created for initial deployment of v10. Examples:</p> <ul style="list-style-type: none"> VMware: see the <code>cloud-admin-ui</code> endpoint in Deployment overview for endpoints. Kubernetes: see the <code>admin</code> endpoint in Deployment overview for endpoints and certificates. <p>Cloud Pak for Integration Syntax:</p> <pre><cpd-APIC_namespace.your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance></pre> <p>Example:</p> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre> <p>where <code>e2e</code> is <code><APIC_namespace></code> and <code>prod</code> is <code><APIC_instance></code>.</p> <p>See How to obtain the server parameter for Cloud Pak for Integration.</p>
<code><path_to_admin_org></code>	Must be <code>cloud/admin-org</code> .
<code>--dry-run</code>	<p>Optional flag. You can test the Admin org migration output first view by using the <code>--dry-run</code> option.</p> <pre>./apicm archive:push <cloud_manager_endpoint> <path_to_admin_org> --dry-run</pre> <p>This option creates a project directory similar to <code>cloud</code>, titled <code>.workdir-<apim_admin_server></code> where you can view how the data will be loaded into your new system. The option also displays the objects that will fail due to existing already or missing dependencies. Use this option to view the resolved URLs for where the data will be loaded, without creating resources on the new system. See apicm command line help.</p>
<code>--apigw-only</code>	<p>Optional flag. Use when migrating to a DataPower API Gateway. For example:</p> <pre>./apicm archive:push <cloud_manager_endpoint> <path_to_admin_org> --apigw-only</pre>

Important: Usage notes:

- Run `./apicm archive:push` in the same directory where you ran `./apicm archive:unpack`.
- If you run migration and observe error messages in your log output, you can take troubleshooting steps, and run the migration again. See [Migration troubleshooting](#).
- The `apicm` login obtains a token that expires after eight hours. If the token expires while `apicm archive:push` is running, `apicm` generates errors due to lack of the necessary access permissions. In this case, log in again and re-run `apicm archive:push`. The token is refreshed every time you log in. See also [Token expiration](#) in [Migration troubleshooting](#).
- An alternative method of viewing endpoints is to run `kubectl get ingress` and get the values from the output. For example, see the values in **bold** in the following sample output:

```
r7c221d8a33-apic-portal-director    api.portal.dev.apic10-stack.example.test    80, 443    21h
r7c221d8a33-apic-portal-web        portal.dev.apic10-stack.example.test        80, 443    21h
re314d70920-apiconnect-api         platform.mgmt.dev.apic10-stack.example.test  80, 443    22h
re314d70920-apiconnect-apim-ui     apim.mgmt.dev.apic10-stack.example.test     80, 443    22h
re314d70920-apiconnect-cm-ui       cloud.mgmt.dev.apic10-stack.example.test     80, 443    22h
re314d70920-apiconnect-consumer-api consumer.mgmt.dev.apic10-stack.example.test  80, 443    22h
rfe867a858b-dynamic-gateway-service service.gw.dev.apic10-stack.example.test     80, 443    21h
rfe867a858b-dynamic-gateway-service-gw api.gw.dev.apic10-stack.example.test         80, 443    21h
rfff5043330-analytics-client      ac.dev.apic10-stack.example.test            80, 443    21h
rfff5043330-analytics-ingestion    ai.dev.apic10-stack.example.test            80, 443    21h
```

11. Migrate the API Manager provider organizations.

- If you have not already done so, create the provider organizations on your API Connect v10 deployment.
- Use `apicm` to log in to the API Manager user interface as an Owner or Administrator of the provider organization that you want to migrate. If you want to login using an OIDC user registry, see [Logging in to a management server with an OIDC registry](#).

Important: You cannot migrate a provider organization while you are logged in with the Cloud Manager admin organization. You must be logged in as an Owner or Administrator of the provider organization to be able to migrate that organization's data.

- Syntax:

```
./apicm login --server <api-manager-ui-endpoint> --realm provider/identity_provider --username org_username --password org_password
```

- Example for API Connect v10:

```
./apicm login --server api-manager-ui.dev.apic10-stack.example.test --realm provider/default-idp-2 --username org_username@example.com --password myorgpassword
```

- Example for Cloud Pak for Integration:

```
./apicm login -server cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod --realm provider/default-idp-2 --username org_username@example.com --password myorgpassword
```

Table 6. `apicm login` parameters for logging in to provider orgs on API Connect v10 standalone

Parameters	Description
<pre>--server <api- manager-ui- endpoint></pre>	<p>API Manager URL endpoint on the management server for communication with the API Manager user interface.</p> <p>API Connect v10 standalone</p> <p>For example:</p> <pre>api-manager-ui.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the management subsystem was installed. To verify your endpoint setting you can:</p> <ul style="list-style-type: none"> View the <code>apiconnect-apim-ui</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory. In the Cloud Manager UI, select Settings, Endpoints and view API Manager URL. <p>Cloud Pak for Integration</p> <p>Syntax (line-break is for table formatting only; your value will not include a line-break):</p> <pre><cpd-APIC_namespace.your-company.domain.com>/integration/apis /<APIC_namespace>/<APIC_instance></pre> <p>Example:</p> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre> <p>where <code>e2e</code> is <code><APIC_namespace></code> and <code>prod</code> is <code><APIC_instance></code>.</p> <p>See How to obtain the server parameter for Cloud Pak for Integration.</p>
<pre>--realm provider/ide ntity_provid er</pre>	<p>The <code>apicm login</code> example shows the expected <code>realm</code> parameter values for a default API Connection provider organization. The default user is <code>provider</code> and the identity provider is <code>default-idp-2</code>.</p> <p>You can determine which identity provider to use in the <code>--realm</code> parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):</p> <pre>apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm</pre> <p>For example,</p> <pre>apic identity-providers:list --scope provider --server myserver.com --fields title,realm total_results: 2 results: - title: API Manager Local User Registry realm: provider/default-idp-2 - title: Corporate LDAP user registry realm: provider/corporate-ldap</pre> <p>The <code>title</code> value should enable you to determine which identity provider to use; you can then copy the corresponding <code>--realm</code> parameter directly from the displayed <code>realm</code> value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is <code>default-idp-2</code>.</p>
<pre>--username <org_ usernam e></pre>	<p>A user with permissions to modify the provider organization. Typically this is the owner or administrator of the organization.</p>
<pre>--password <org_passwor d></pre>	<p>Organization owner or administrator password.</p>

c. Run `/apicm archive:push` to migrate data for the Provider organization.

- Syntax:

```
./apicm archive:push <api-manager-ui-endpoint> cloud/provider-orgs/<pOrg_name> [optional flags]
```

- Example on v10:

```
./apicm archive:push api-manager-ui.mgmt.dev.apic10-stack.example.test cloud/provider-orgs/production_Org
```

- Example on Cloud Pak for Integration

```
./apicm archive:push cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod cloud/provider-
orgs/production_Org
```

See [Table 7](#) to review how to obtain each parameter.

Tip: First run the command with the optional flag `--dry-run` to test for errors or warnings.

Table 7. `apicm archive:push` command parameters for Provider orgs

Parameters	Description
------------	-------------

Parameters	Description
<code><api-manager-ui-endpoint></code>	<p>API Manager URL endpoint on the management server for communication with the API Manager user interface.</p> <p>API Connect v10 standalone For example:</p> <pre>api-manager-ui.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the management subsystem was installed. To verify your endpoint setting you can:</p> <ul style="list-style-type: none"> View the <code>apiconnect_api</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory. In the Cloud Manager UI, select Settings > Endpoints and view API Manager URL. <p>Cloud Pak for Integration Syntax (line-break is for table formatting only, your value will not include a line-break).</p> <pre><cpd-APIC_namespace.your-company.domain.com>/integration/apis/APIC_namespace/<APIC_instance></pre> <p>Example:</p> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre> <p>where <code>e2e</code> is <code><APIC_namespace></code> and <code>prod</code> is <code><APIC_instance></code>.</p> <p>See How to obtain the server parameter for Cloud Pak for Integration.</p>
<code>cloud/provider-orgs/<pOrg_name></code>	<p>The location of your Provider org within the <code>/cloud</code> file hierarchy you created when you ran <code>apicm archive:unpack</code>.</p> <pre>cloud/provider-orgs/production_Org</pre>
<code>--catalogs=<name></code>	<p>Optionally, you can push data for only specified Catalogs if you don't want to push the entire Provider organization. Use this flag to specify the name of the Catalog you want to push:</p> <pre>./apicm archive:push <api-manager-ui-endpoint> cloud/provider-orgs/<pOrg_name> --catalogs=<catalog_name></pre> <p>Note: Type the command on a single line. When a catalog is mapped, specify the mapped new catalog name.</p> <p>To specify multiple catalogs, use a comma-separated list:</p> <pre>./apicm archive:push <api-manager-ui-endpoint> cloud/provider-orgs/<pOrg_name> --catalogs=<catalog_name1,catalog_name2,catalog_name3></pre> <p>Note: Type the command on a single line.</p>
<code>--dry-run</code>	<p>You can test the Provider org migration output first view by using the <code>--dry-run</code> option. This will create a project directory similar to <code>cloud</code>, titled <code>.workdir-<capim_admin_server></code> where you can view how the data will be loaded into your new system. The option also displays the objects that will fail due to existing already or missing dependencies. Use this option to view the resolved URLs for where the data will be loaded, without creating resources on the new system. See apicm command line help.</p> <pre>./apicm archive:push <api-manager-ui-endpoint> cloud/provider-orgs/<pOrg_name> --dry-run</pre> <p>Note: Type the command on a single line.</p>
<code>--no-drafts</code>	<p>Do not push any Draft APIs or Products. Draft objects are objects that have not been published.</p> <pre>./apicm archive:push <cloud_manager_endpoint> <path_to_provider_org> --no-drafts</pre> <p>Note: Type the command on a single line. This option can be used with or without <code>--catalogs=a,b,c</code>.</p>
<code>--overwrite</code>	<p>When this option is used, draft products, draft APIs, published products and their APIs, and OAuth Providers that are already on the v10 system will be overwritten. When this option is not used these artifacts will be skipped.</p>

Important: Usage notes

- Run `./apicm archive:push` in the same directory where you ran `./apicm archive:unpack`.
- If you run migration and observe error messages in your log output, you can take troubleshooting steps, and run the migration again. See [Migration troubleshooting](#).
- The `apicm` login obtains a token that expires after eight hours. If the token expires while `apicm archive:push` is running, `apicm` generates errors due to lack of the necessary access permissions. In this case, log in again and re-run `apicm archive:push`. The token is refreshed every time you log in. See also [Token expiration in Migration troubleshooting](#).
- An alternative method of viewing endpoints is to run `kubectl get ingress` and get the values from the output. See [kubectl example](#).

12. When migration finishes, complete the following steps:

- If a user in a Local User Registry is owner of a Consumer Organization, the user must reset their password.
- If applicable, reapply any customized configurations from your v5 deployment. See [Customizations to recreate](#).
- Optional: If necessary, switch the provider organization ownership to the identity that owned it in v5. This step might be necessary if you created and migrated the provider organization using a different identity (such as administrative account) than the user identity of the v5 provider org. Note that the UI does not provide this function, but you can use the API `/orgs/{org}/transfer-owner` to switch ownership.
- If Stripe billing integrations were included in your migration, you must now configure the Stripe integrations in your Developer Portal sites; see [Configuring Stripe in the Developer Portal](#) for detailed instructions. For more information about the billing feature in v10, see [Monetizing your Products](#).

Migration steps without PDUR

Complete the following steps to migrate from v5 to v10 when your v5 catalogs do not use Portal Delegated User Registries (PDUR).

Before you begin

Important: Do not use these instructions if your v5 catalogs use Portal Delegated User Registry. Instead, see [Migration steps with PDUR](#).

- Ensure you planned your migration, obtained the migration utility, and installed a v10 deployment, as described in [Migration steps](#)
- Review [Migration considerations](#).
- Ensure you have system administrator privileges.
- To use `apicm` to convert the API definitions, you must have Node version 18.19.1 (or greater) installed.

About this task

Use the `apicm` utility to migrate your API Connect v5 data to a new API Connect v10 installation.

Tip:

To achieve a smooth and successful migration, we recommend these best practices:

- Before you push your v5 data to v10, your v10 system must be up and running, with gateway services, provider organizations, user registries, etc, ready to receive the data.
- Plan to do several test iterations of migration. You can use the `--dry-run` option to do iterations of the migration push, to test for any errors or warnings to address before the actual data push.
- Use the `apicm <command> --help` command to review the command options and their purpose. To see the list of commands you can run: `apicm help`.
- Complete all the steps in this topic in the order listed, unless the step is marked optional and does not apply to your scenario. You can push provider orgs as many times as needed.

Procedure

1. Log in to the command line interface of the v5 appliance. Use the following command to create a tar.gz export of the v5 configuration database and place it on an `sftp` server:

```
config dbextract sftp <host_name> user <user_name> file <path/name>
```

- Specify a name of your choice for the compressed file to contain the dbextract. For example, `v5mgmt_data.tgz`.
- If you are not familiar with the v5 appliance CLI, see [The Command Line Interface](#). For information on `config dbextract`, see [Configuration commands](#).

2. Optional: Setup a temporary SMTP server.

During migration, if subscription approval is needed to enable an application to subscribe to a plan, notifications are sent to all users, within the organization, who have subscription approval permission. In some cases, this results in a large number of emails. To avoid the sending of these emails, set up a temporary email server prior to running the migration, and use it to collect all notifications rather than sending them to users' email accounts.

If subscription approvals are not needed during your migration, you can skip this step.

3. Optional: If necessary, set up a temporary LDAP server. This can be needed if you are temporarily behind a firewall.
 - a. Install a server:

```
git clone https://github.com/veo-labs/ldap-server-mock
npm install
```

- b. Creating the configuration files:

- `ldap-server-mock-conf.json`

```
{
  "port": 3004,
  "userLoginAttribute": "cn",
  "searchBase": "dc=test",
  "searchFilter": "(&(objectclass=person)(cn={username}))"
}
```

- `users.json`

```
[
  {
    "dn": "cn=user,dc=test",
    "cn": "user-login"
  }
]
```

- c. Run the LDAP server:

```
node server.js --conf=./ldap-server-mock-conf.json --database=./users.json
```

- d. Modifying a current LDAP provider.

The following file is a dummy user registry file that maps to a read-only test server. The fields in bold font (`admin_dn` and `endpoint`) have been changed to fit the dummy server configuration. Change these on all user registries that need to be fixed.

```
api_version: 2.0.0
configuration:
  admin_dn: cn=user,dc=test
  admin_password: xxxx
  authenticated_bind: "true"
```

```

authentication_method: search_dn
bind_prefix: ""
bind_suffix: ""
protocol_version: "3"
search_dn_base: ""
search_dn_filter_prefix: (examplelegacyuid=
search_dn_filter_suffix: )
search_dn_scope: sub
endpoint:
  endpoint: ldap://172.20.20.11:3004
  tls_client_profile_url: idurl://...\\admin-org\tls-client-profiles\tls-profile-for-ldap-1.0.0.yml
integration_url: file://...\\integrations\user_registry\ldap.yml
metadata:
  v5_id: xxxxxx40cf2fc09a9ba0d6c
  v5_scope: '["api"]'
  v5_type: ldap
name: xxxxxxxxxxxxxxxx
title: xxxxxxxxxxxxxxxxxxxxxxxx
type: user_registry

```

4. Unpack the V5 configuration data onto the local filesystem.

Important: Migration on Windows 10

Windows has path length limits that can interfere with large extracts. It is recommended that you keep the initial path for migration on Windows as short as possible. The AMU must be run in a command window with administrative privileges on Windows. Running from a Linux VM on your Windows system may be a better option for doing migration.

- a. Copy the v5 extract tar file from the sftp server to the location where you have v10 migration utility installed.
- b. Run `apicm archive:unpack` command from the directory where you downloaded the v5 extract file.

```
./apicm archive:unpack <v5_extract_file>.tgz
```

When you invoke `apicm` for the first time, you are prompted to accept the license. Accept the license to continue.

You can optionally limit the unpack to only specific provider orgs. See [Table 1](#).

Table 1. `apicm archive:unpack` command options

Parameters	Description
<code><v5_extract_file></code>	Can be compressed file (.tgz, tar.gz) or uncompressed file (.tar). Use any file name of your choosing. Example: <code>./apicm archive:unpack v5_DBextract_data.tgz</code>
<code>--provider-orgs</code>	One or more provider orgs to unpack. This flag is optional. Use it when you want to unpack only specific provider orgs rather than the entire archive. Example: <code>./apicm archive:unpack v5_DBextract_data.tgz --provider-orgs=<pOrg1_name></code> Use a comma-separated list to specify multiple provider orgs: <code>./apicm archive:unpack v5_archive_data.tgz --provider-orgs=<pOrg1_name>,<pOrg2_name>,<pOrg3_name></code>
<code>--use-old-sluggify</code>	Unpack the V5 configuration data onto the local filesystem using the version 10.0.5.1 conversion rules for sluggifying element names and version numbers. For more information about the conversion rules, see Parity between v5 and v10 .

Note:

- **Important:** Any Warnings or Errors that occur during `archive:unpack` should be investigated for remediation. See [Migration troubleshooting](#)
- You can avoid the license prompt by adding `--accept-license` to the command line.
- The unpack command ensures that catalog names and API properties contain only valid characters. Any invalid characters are mapped to '-'. See [Parity between v5 and v10](#).
- The unpack command issues warning messages for APIs and Products that fail validation against the OpenAPI specification. See the limitations section in [Migration considerations](#).
- For troubleshooting tips, see [Migration troubleshooting](#)
- The unpack command might return error messages related to PDUR, such as:

```

ERRO[3414] PDUR backup data for IDP PortalDelegatedIdentityProvider-123b81f8e4b06de411580e2e
(123b81f8e4b06de411580e2f) not provided: not found
ERRO[3414] PDUR backup data for IDP PortalDelegatedIdentityProvider-123b820de4b06de411580e32
(123b820ee4b06de411580e33) not provided: not found

```

If you are not migrating PDUR backup data, and your command did not include a `<pdur_user_export>.tgz`, the error indicates that you do in fact have a PDUR registry, and that you should have included a PDUR backup. Follow the migration instructions in [Migration steps with PDUR](#).

When the command completes, the data is unpacked to the `/cloud` directory. The `/cloud` directory is located in the same directory as `apicm`, and populated with yaml files representing the configuration objects in the export. The unpack processes produce output in the format required for v10 configuration.

Note: The unpack directory must be named `/cloud`. Do not rename the directory.

Example output in `/cloud` for `admin-org`:

```

cloud
├── admin-org
│   ├── availability-zones
│   │   ├── availability-zone-default
│   │   │   ├── availability-zone.yml

```

5. Remove unneeded configuration objects.

Inspect the set of configuration objects and their attributes, and remove the ones that are not needed. In many cases, some of the configuration objects present in the v5 system are not needed in the new v10 environment. For example, there is no value in preserving inactive users, obsolete apps, obsolete consumer organizations, and so on.

When deleting objects, make sure that you do not delete objects that have other dependent objects, such as products with subscriptions on them or users that are active. If you delete a consumer organization make sure you also delete all apps and subscriptions associated with that consumer org. Be aware of any groups that

include these consumer orgs or visibility settings that include the consumer orgs.

6. Map v5 object names to v10 object names.

Most deployments adjust the names or quantities of gateway services, provider organizations, and user registries when setting up a new environment for v10. Be sure to specify any changed v10 destinations for the v5 data in a migration mapping file so that the migration utility can automatically move the data.

Complete the following, as needed. You can skip the steps for any objects that are unchanged from v5 to v10.

- a. [What is a mapping file?](#)
- b. [Mapping a gateway service](#)
- c. [Mapping a provider organization](#)

7. Optional: If your v10 deployment uses a **DataPower API Gateway**, convert the v5 API definitions to v10 DataPower® API Gateway. To convert API definitions using the default migration configuration, use the following syntax.

```
./apicm archive:port-to-apigw <path>
```

Important: Ensure that the DataPower Gateway version that you are using with your API Connect v10 deployment is compatible with the version of the migration utility that you are using. For details, see the version compatibility information in [Configuring and managing your server environment](#).
Important: If you are running the migration utility in Windows, Administrator privileges are required to complete this step.

Table 2. Parameter for archive:port-to-apigw

Parameter	Description
<path>	<p>Specify the unpacked cloud directory as input:</p> <pre>./apicm archive:port-to-apigw /cloud</pre> <p>By specifying /cloud, apicm ports all artifacts within the directory, including APIs, Products, OAuth providers, custom policies, subscriptions and so on. Running a subsequent archive:push pushes all the artifacts to API Gateway.</p> <p>Running archive:port-to-apigw on any subdirectory within the unpacked /cloud directory could leave the directory in an inconsistent state, and cause the subsequent archive:push of artifacts to API Gateway to fail. Custom policies and OAuth providers are not migrated if a directory other than /cloud is specified.</p> <p>Note: However, if you decide to rewrite one API at a time, to migrate them to API Gateway, you can use:</p> <pre>./apicm archive:port-to-apigw <path></pre> <p>where <path> is a single API file, or a directory that contains only APIs or Products. In this case, you cannot use archive:push to push artifacts to API Gateway. All the ported APIs and Products must be pushed (or imported) into API Manager by either the toolkit or UI.</p>

Usage notes:

- The conversion produces a draft output YAML file. Review the entire draft output YAML file for conformance, performance, and errors. Review the log files for messages about any manual actions that might be needed. For more information, see [Reviewing APIs converted to DataPower API Gateway](#).
- By default, all changes that the migration utility makes when rewriting APIs are logged as comments within the API YAML file. You can use the **enable-api-logging** parameter to disable logging of these changes.

```
./apicm archive:port-to-apigw <folder> --enable-api-logging=false
```

- You can also specify migration configuration parameters using either a YAML configuration file or from the command line, but not both. For information about configuration options and DataPower requirements for certain configuration parameters, see [Configuring migration options for DataPower API Gateway](#).
- Multiple runs of **./apicm archive:port-to-apigw** on the same **/cloud** folder will skip artifacts that have already been converted to DataPower® API Gateway.
- If your v10 deployment uses DataPower MultiProtocol Gateway (v5-compatible) you do not need to convert the API definitions.

8. Use **apicm** commands to push the Cloud Manager admin organization data onto your v10 Management Server.

- a. Log in to the Cloud Manager on the destination v10 Management Server as an Owner of the admin organization:

Important: You must be logged in as an Owner of the admin organization to be able to migrate Cloud Manager admin organization data.

- Syntax:

```
./apicm login --server <cloud_manager_endpoint> --realm admin/identity_provider --username admin --password admin_password
```

- Example on API Connect v10 standalone

```
./apicm login --server cloud-admin-ui.mgmt.dev.apic10-stack.example.test --realm admin/default-idp-1 --username admin --password 'myadminpassword'
```

- Example on Cloud Pak for Integration

```
./apicm login --server cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod --realm admin/default-idp-1 --username admin --password 'XXXXXXXXXXXX'
```

The values to supply for the login parameters depend on whether your management server is deployed on API Connect v10 standalone or as part of Cloud Pak for Integration. See [Table 3](#) to review how to obtain each parameter.

Note: If you want to login using an OIDC user registry, see [Logging in to a management server with an OIDC registry](#).

Table 3. **apicm login** command parameters

Parameters	Description
------------	-------------

Parameters	Description						
<pre>--server <cloud_manager_endpoint></pre>	<p>The endpoint on the management server for communication with the Cloud Manager user interface.</p> <p>v10 standalone Example:</p> <pre>cloud-admin-ui.mgmt.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the management subsystem was installed. View the <code>apiconnect_api</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory that you created for initial deployment of v10. Examples:</p> <ul style="list-style-type: none"> VMware: see the <code>cloud-admin-ui</code> endpoint in Deployment overview for endpoints. Kubernetes: see the <code>admin</code> endpoint in Deployment overview for endpoints and certificates. <p>Cloud Pak for Integration Syntax:</p> <pre><cpd-APIC_namespace.your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance></pre> <p>Example:</p> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre> <p>where <code>e2e</code> is <code><APIC_namespace></code> and <code>prod</code> is <code><APIC_instance></code>.</p> <p>Note: How to obtain the server parameter on Cloud Pak for Integration Use the Platform Navigator UI to determine the parameter. Note that you cannot get the endpoint by using <code>oc get routes</code> because Zen modifies the route internally.</p> <ol style="list-style-type: none"> Locate the Platform UI panel with entries for the deployment. Identify the row that has a Type column entry with the description API management administration To display the endpoint, hover over the entry in the Name column for that row. For example, hover over the prod entry, as shown in bold font, and the URL displays at the bottom of the panel. <table border="1"> <thead> <tr> <th>Name</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>prod</td> <td>API management administration</td> </tr> <tr> <td>prod</td> <td>API management</td> </tr> </tbody> </table> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod/admin</pre> <ol style="list-style-type: none"> Remove the trailing <code>/admin</code> from the endpoint, to obtain the parameter for the login command: <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre>	Name	Type	prod	API management administration	prod	API management
Name	Type						
prod	API management administration						
prod	API management						
<pre>--realm admin/default-idp-1</pre>	<p>The <code>apicm login</code> example shows the expected <code>--realm</code> parameter values for a default API Connection administration organization. The default user is <code>admin</code> and the identity provider is <code>default-idp-1</code>.</p> <p>You can determine which identity provider to use in the <code>--realm</code> parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):</p> <pre>apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm</pre> <p>For example:</p> <pre>apic identity-providers:list --scope admin --server myserver.com --fields title,realm total_results: 2 results: - title: Cloud Manager User Registry realm: admin/default-idp-1 - title: Corporate LDAP user registry realm: admin/corporate-ldap</pre> <p>The <code>title</code> value should enable you to determine which identity provider to use; you can then copy the corresponding <code>--realm</code> parameter directly from the displayed <code>realm</code> value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is <code>default-idp-1</code>.</p>						
<pre>--username admin</pre>	<p>Administrative user with permissions to modify API Connect admin-org. The default user is <code>admin</code>.</p>						
<pre>--password myadminpassword</pre>	<p>Administrative user password.</p> <p>Cloud Pak for Integration: When you installed with the top-level CR for CP4I, the password was auto-generated. To obtain the password, see step 3 in Installing API Connect.</p>						

b. Run `/apicm archive:push` to migrate data for the Cloud Manager administrative org (admin-org).

- Syntax

```
./apicm archive:push <cloud_manager_endpoint> <path_to_admin_org> [optional flags]
```

- Example for v10:

```
./apicm archive:push cloud-admin-ui.mgmt.dev.apic10-stack.example.test cloud/admin-org
```

- Example for Cloud Pak for Integration:

```
./apicm archive:push cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod cloud/admin-org
```

See [Table 4](#) to review how to obtain each parameter.

Tip: First run the command with the optional flag `--dry-run` to test for errors or warnings. Review the command parameters, examples and guidance that follow before you run it.

Table 4. `apicm`
`archive:push` command parameters for admin org

Parameters	Description
<code><cloud_manager_endpoint></code>	<p>The endpoint on the management server for communication with the Cloud Manager user interface.</p> <p>v10 standalone Example:</p> <pre>cloud-admin-ui.mgmt.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the management subsystem was installed. View the <code>apiconnect_api</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory that you created for initial deployment of v10. Examples:</p> <ul style="list-style-type: none"> VMware: see the <code>cloud-admin-ui</code> endpoint in Deployment overview for endpoints. Kubernetes: see the <code>admin</code> endpoint in Deployment overview for endpoints and certificates. <p>Cloud Pak for Integration Syntax:</p> <pre><cpd-APIC_namespace.your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance></pre> <p>Example:</p> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre> <p>where <code>e2e</code> is <code><APIC_namespace></code> and <code>prod</code> is <code><APIC_instance></code>.</p> <p>See How to obtain the server parameter for Cloud Pak for Integration.</p>
<code><path_to_admin_org></code>	Must be <code>cloud/admin-org</code> .
<code>--dry-run</code>	<p>Optional flag. You can test the Admin org migration output first view by using the <code>--dry-run</code> option.</p> <pre>./apicm archive:push <cloud_manager_endpoint> <path_to_admin_org> --dry-run</pre> <p>This option creates a project directory similar to <code>cloud</code>, titled <code>.workdir-<apim_admin_server></code> where you can view how the data will be loaded into your new system. The option also displays the objects that will fail due to existing already or missing dependencies. Use this option to view the resolved URLs for where the data will be loaded, without creating resources on the new system. See apicm command line help.</p>
<code>--apigw-only</code>	<p>Optional flag. Use when migrating to a DataPower API Gateway. For example:</p> <pre>./apicm archive:push <cloud_manager_endpoint> <path_to_admin_org> --apigw-only</pre>

Important: Usage notes:

- Run `./apicm archive:push` in the same directory where you ran `./apicm archive:unpack`.
- If you run migration and observe error messages in your log output, you can take troubleshooting steps, and run the migration again. See [Migration troubleshooting](#).
- The `apicm` login obtains a token that expires after eight hours. If the token expires while `apicm archive:push` is running, `apicm` generates errors due to lack of the necessary access permissions. In this case, log in again and re-run `apicm archive:push`. The token is refreshed every time you log in. See also [Token expiration](#) in [Migration troubleshooting](#).
- An alternative method of viewing endpoints is to run `kubectl get ingress` and get the values from the output. For example, see the values in **bold** in the following sample output:

```
r7c221d8a33-apic-portal-director    api.portal.dev.apic10-stack.example.test    80, 443    21h
r7c221d8a33-apic-portal-web        portal.dev.apic10-stack.example.test        80, 443    21h
re314d70920-apiconnect-api         platform.mgmt.dev.apic10-stack.example.test  80, 443    22h

rfe867a858b-dynamic-gateway-service-gw api.gw.dev.apic10-stack.example.test        80, 443    21h
rfff5043330-analytics-client      ac.dev.apic10-stack.example.test            80, 443    21h
rfff5043330-analytics-ingestion   ai.dev.apic10-stack.example.test            80, 443    21h
```

9. Migrate the API Manager provider organizations.

- If you have not already done so, create the provider organizations on your API Connect v10 deployment.
- Use `apicm` to log in to the API Manager user interface as an Owner or Administrator of the provider organization that you want to migrate. If you want to login using an OIDC user registry, see [Logging in to a management server with an OIDC registry](#).

Important: You cannot migrate a provider organization while you are logged in with the Cloud Manager admin organization. You must be logged in as an Owner or Administrator of the provider organization to be able to migrate that organization's data.

- Syntax:

```
./apicm login --server <api-manager-ui-endpoint> --realm provider/identity_provider --username org_username --password org_password
```

- Example for API Connect v10:

```
./apicm login --server api-manager-ui.dev.apic10-stack.example.test --realm provider/default-idp-2 --username org_username@example.com --password myorgpassword
```

- Example for Cloud Pak for Integration:

```
./apicm login -server cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod --realm provider/default-idp-2 --username org_username@example.com --password myorgpassword
```

Table 5. `apicm login` parameters for logging in to provider orgs on API Connect v10 standalone

Parameters	Description
<pre>--server <api- manager-ui- endpoint></pre>	<p>API Manager URL endpoint on the management server for communication with the API Manager user interface.</p> <p>API Connect v10 standalone</p> <p>For example:</p> <pre>api-manager-ui.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the management subsystem was installed. To verify your endpoint setting you can:</p> <ul style="list-style-type: none"> View the <code>apiconnect-apim-ui</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory. In the Cloud Manager UI, select Settings, Endpoints and view API Manager URL. <p>Cloud Pak for Integration</p> <p>Syntax (line-break is for table formatting only; your value will not include a line-break):</p> <pre><cpd-APIC_namespace.your-company.domain.com>/integration/apis /<APIC_namespace>/<APIC_instance></pre> <p>Example:</p> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre> <p>where <code>e2e</code> is <code><APIC_namespace></code> and <code>prod</code> is <code><APIC_instance></code>.</p> <p>See How to obtain the server parameter for Cloud Pak for Integration.</p>
<pre>--realm provider/ide ntity_provid er</pre>	<p>The <code>apicm login</code> example shows the expected <code>realm</code> parameter values for a default API Connection provider organization. The default user is <code>provider</code> and the identity provider is <code>default-idp-2</code>.</p> <p>You can determine which identity provider to use in the <code>--realm</code> parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):</p> <pre>apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm</pre> <p>For example,</p> <pre>apic identity-providers:list --scope provider --server myserver.com --fields title,realm total_results: 2 results: - title: API Manager Local User Registry realm: provider/default-idp-2 - title: Corporate LDAP user registry realm: provider/corporate-ldap</pre> <p>The <code>title</code> value should enable you to determine which identity provider to use; you can then copy the corresponding <code>--realm</code> parameter directly from the displayed <code>realm</code> value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is <code>default-idp-2</code>.</p>
<pre>--username <org_ usernam e></pre>	<p>A user with permissions to modify the provider organization. Typically this is the owner or administrator of the organization.</p>
<pre>--password <org_passwor d></pre>	<p>Organization owner or administrator password.</p>

c. Run `/apicm archive:push` to migrate data for the Provider organization.

- Syntax:

```
./apicm archive:push <api-manager-ui-endpoint> cloud/provider-orgs/<pOrg_name> [optional flags]
```

- Example on v10:

```
./apicm archive:push api-manager-ui.mgmt.dev.apic10-stack.example.test cloud/provider-orgs/production_Org
```

- Example on Cloud Pak for Integration

```
./apicm archive:push cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod cloud/provider-
orgs/production_Org
```

See [Table 6](#) to review how to obtain each parameter.

Tip: First run the command with the optional flag `--dry-run` to test for errors or warnings.

Table 6. `apicm archive:push` command parameters for Provider orgs

Parameters	Description
------------	-------------

Parameters	Description
<code><api-manager-ui-endpoint></code>	<p>API Manager URL endpoint on the management server for communication with the API Manager user interface.</p> <p>API Connect v10 standalone For example:</p> <pre>api-manager-ui.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the management subsystem was installed. To verify your endpoint setting you can:</p> <ul style="list-style-type: none"> View the <code>apiconnect_api</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory. In the Cloud Manager UI, select Settings > Endpoints and view API Manager URL. <p>Cloud Pak for Integration Syntax (line-break is for table formatting only, your value will not include a line-break).</p> <pre><cpd-APIC_namespace.your-company.domain.com>/integration/apis/APIC_namespace/<APIC_instance></pre> <p>Example:</p> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre> <p>where <code>e2e</code> is <code><APIC_namespace></code> and <code>prod</code> is <code><APIC_instance></code>.</p> <p>See How to obtain the server parameter for Cloud Pak for Integration.</p>
<code>cloud/provider-orgs/<pOrg_name></code>	<p>The location of your Provider org within the <code>/cloud</code> file hierarchy you created when you ran <code>apicm archive:unpack</code>.</p> <pre>cloud/provider-orgs/production_Org</pre>
<code>--catalogs=<name></code>	<p>Optionally, you can push data for only specified Catalogs if you don't want to push the entire Provider organization. Use this flag to specify the name of the Catalog you want to push:</p> <pre>./apicm archive:push <api-manager-ui-endpoint> cloud/provider-orgs/<pOrg_name> --catalogs=<catalog_name></pre> <p>Note: Type the command on a single line. When a catalog is mapped, specify the mapped new catalog name.</p> <p>To specify multiple catalogs, use a comma-separated list:</p> <pre>./apicm archive:push <api-manager-ui-endpoint> cloud/provider-orgs/<pOrg_name> --catalogs=<catalog_name1,catalog_name2,catalog_name3></pre> <p>Note: Type the command on a single line.</p>
<code>--dry-run</code>	<p>You can test the Provider org migration output first view by using the <code>--dry-run</code> option. This will create a project directory similar to <code>cloud</code>, titled <code>.workdir-<capim_admin_server></code> where you can view how the data will be loaded into your new system. The option also displays the objects that will fail due to existing already or missing dependencies. Use this option to view the resolved URLs for where the data will be loaded, without creating resources on the new system. See apicm command line help.</p> <pre>./apicm archive:push <api-manager-ui-endpoint> cloud/provider-orgs/<pOrg_name> --dry-run</pre> <p>Note: Type the command on a single line.</p>
<code>--no-drafts</code>	<p>Do not push any Draft APIs or Products. Draft objects are objects that have not been published.</p> <pre>./apicm archive:push <cloud_manager_endpoint> <path_to_provider_org> --no-drafts</pre> <p>Note: Type the command on a single line. This option can be used with or without <code>--catalogs=a,b,c</code>.</p>
<code>--overwrite</code>	<p>When this option is used, draft products, draft APIs, published products and their APIs, and OAuth Providers that are already on the v10 system will be overwritten. When this option is not used these artifacts will be skipped.</p>

Important: Usage notes

- Run `./apicm archive:push` in the same directory where you ran `./apicm archive:unpack`.
- If you run migration and observe error messages in your log output, you can take troubleshooting steps, and run the migration again. See [Migration troubleshooting](#).
- The `apicm` login obtains a token that expires after eight hours. If the token expires while `apicm archive:push` is running, `apicm` generates errors due to lack of the necessary access permissions. In this case, log in again and re-run `apicm archive:push`. The token is refreshed every time you log in. See also [Token expiration in Migration troubleshooting](#).
- An alternative method of viewing endpoints is to run `kubectl get ingress` and get the values from the output. See [kubectl example](#).

10. When migration finishes, complete the following steps:

- If a user in a Local User Registry is owner of a Consumer Organization, the user must reset their password.
- If applicable, reapply any customized configurations from your v5 deployment. See [Customizations to recreate](#).
- Optional: If necessary, switch the provider organization ownership to the identity that owned it in v5. This step might be necessary if you created and migrated the provider organization using a different identity (such as administrative account) than the user identity of the v5 provider org. Note that the UI does not provide this function, but you can use the API `/orgs/{org}/transfer-owner` to switch ownership.
- If Stripe billing integrations were included in your migration, you must now configure the Stripe integrations in your Developer Portal sites; see [Configuring Stripe in the Developer Portal](#) for detailed instructions. For more information about the billing feature in v10, see [Monetizing your Products](#).

Logging in to a management server with an OIDC registry

Logging in with an OIDC registry involves several steps, in which you obtain a temporary token and pass it to the toolkit to ensure it can communicate securely with the management server.

Attention: If you want to log in using a non-OIDC registry, see the login steps in [Migration steps without PDUR](#) or [Migration steps with PDUR](#). To log in, complete the following steps:

1. Enter the following command on the command line:

```
apicm login --server mgmt_endpoint_url --sso
```

where `mgmt_endpoint_url` is the endpoint URL. When you log in with a Cloud admin or Provider organization, specify one of the following URLs:

- platform API endpoint URL
- management API manager URL

These endpoint URLs are configured during the installation of API Connect, as described in [Installing the Management subsystem into a Kubernetes environment](#) and [Deploying the Management subsystem in a VMware environment](#). If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in [Viewing platform and UI endpoints](#), ignoring any segments at the end of the displayed URLs. If you are not sure of the endpoint URL, ask your administrator.

2. When the toolkit prompts for the context, type `provider`:

```
Context? provider
```

3. The server responds with the following message:

```
Please copy and paste the url https://mgmt_endpoint_url/auth/manager/sign-in/?from=TOOLKIT to a browser to start the authentication process.
Do you want to open the url in default browser? [y/n]: y
```

Take one of the following actions:

- If you want to use your default browser to log in to API Manager, type `y` and press Enter. The API Manager sign-in page opens in a new browser tab.
- If you don't use to use your default browser, type `n` and press Enter.
 - Copy the URL from the command window.
 - Open a browser, paste the URL, and press Enter. The API Manager sign-in page displays.

4. On the API Manager sign-in page, select the OIDC registry and then log in to API Connect. After you log in, API Connect displays the "You are authenticated!" message and provides a temporary token. Copy the token.
5. Return to the command window. Paste the token at the `API Key?` prompt and press Enter.

When the token is validated and you are successfully logged in to the toolkit, the following message displays:

```
Logged into mgmt_endpoint_url successfully
```

Converting APIs to DataPower API Gateway

You can convert API Connect v5-compatible APIs to v10 DataPower® API Gateway.

Before you begin

Use the migration utility command `apicm archive:port-to-apigw` to convert v5-compatible APIs to DataPower API Gateway. For instructions on installing the migration utility, see [Installing the migration utility](#).

You can convert your API definitions as part of the migration workflow, or as a separate task. Use these instructions to convert YAML source files separately. For instructions on converting APIs during migration, see [Migration steps without PDUR](#).

The following steps are required before converting v5-compatible APIs to DataPower API Gateway. For detailed instructions on all of these tasks, see [Migration steps without PDUR](#).

- Download the latest IBM API Connect® Migration Utility (AMU) from [IBM® Fix Central](#). The migration utility requires Installer Version 5.0.0 or later. However, if you intend to use it to convert APIs, use Installer Version 7.0.1 or later.
- Ensure that the AMU version that you are using is supported by your versions of DataPower API Gateway and API Connect. For more information, see [Configuring migration options for DataPower API Gateway](#).
- Converting APIs using the migration utility requires Node version 18.19.1. Ensure that you have that version installed.
- Run `archive:unpack` to unpack the V5 dbextract into v5-compatible artifacts.
- Map v5 object names to v10 object names. If the names are preserved exactly between the v5 and v10 environments, this step can be skipped. The gateway service must be mapped to a DataPower API Gateway. For more information, see [Migration mapping files](#).

For information about the differences between gateway types available in API Connect, see [API Connect gateway types](#).

About this task

The migration utility command `apicm archive:port-to-apigw` provides assistance in converting v5-compatible APIs to DataPower API Gateway, rather than full migration. It generates an output API that is supported on API Gateway v10.

The conversion process annotates the YAML file and logs with information regarding the artifacts that it attempts to convert. For cases where additional information is available or further action is required, the YAML input file and logs contain links to documentation.

Because of differences between the programming models of v5-compatible APIs and DataPower API Gateway APIs, the command might not be able to convert all items. You might need to port these items to the API Gateway. In these cases, messages generated by the `apicm archive:port-to-apigw` command provide links to documentation that provides more details about changes you must make for these items to be compatible with DataPower API Gateway.

Procedure

Run the conversion command from the directory where you downloaded the utility.

Command syntax:

```
./apicm archive:port-to-apigw path
```

The path is the full path to the YAML file or directory. You can specify to convert a single YAML file or the contents of an entire directory.

The migration utility produces an output YAML file with the results of the conversion process.

What to do next

Review the output YAML file and make any necessary changes to ensure that your APIs are compatible with DataPower API Gateway. For more information, see [Reviewing APIs converted to DataPower API Gateway](#).

Push the converted YAML files to the v10 deployment. For details, see [Migration steps without PDUR](#).

Configuring migration options for DataPower API Gateway

If you are converting APIs to DataPower API Gateway, you can accept the default migration configuration or specify configuration parameters.

You can specify migration configuration parameters using either a YAML configuration file or from the command line, but not both. The `config.yml` file must be located in the same directory as the migration utility. You can specify to use this file when the migration utility is invoked using the `apicm` command with the `port-to-apigw` option, as in the following example.

```
./apicm archive:port-to-apigw <path> --use-config-file=true
```

If use of the configuration file is not specified, the migration utility uses parameters specified on the command line. If no parameters are specified, then the default parameters are used.

Some of these `port-to-apigw` configuration parameters depend upon a specific DataPower implementation to function. See the information in the following table to ensure that you have the correct version of DataPower for the parameters you want to use.

Table 1. Migration configuration options

Parameter	Valid values	DataPower version required	Description
<code>activity-log-policy</code>	<code>activity-log_1.5.0</code> , <code>set-variable_2.0.0</code>	DP 10.0.4.0+	Defines how to process the v5 activity-log policy when the migration utility rewrites the API assembly. The default value is <code>activity-log_1.5.0</code> , which changes the activity-log version to 1.5.0. When set to <code>set-variable_2.0.0</code> , the migration utility sets context variables based upon the value of the activity-log content and error-content configuration values.
<code>chunked-uploads</code>	<code>true</code> / <code>false</code> The default value is <code>false</code> .	For <code>invoke_1.5.0</code> : 10.0.1.1+, 10.0.2.0+ For <code>invoke_2.0.0</code> : 10.0.0.0+	If an <code>invoke_1.5.0</code> or <code>proxy_1.5.0</code> policy exists in an assembly in the API, then set <code>chunked-uploads</code> to <code>true</code> to enable chunked encoding for HTTP 1.1 requests to the target server. If an <code>invoke_2.0.0</code> policy exists in an assembly after the migration, then set <code>chunked-uploads</code> to <code>false</code> explicitly for the policy, as the default value for <code>chunked-uploads</code> in API Gateway is <code>true</code> .
<code>client-id-header-override</code>	String. The string cannot contain spaces. Follow the guidelines for <code>apiKey name</code> : No default value.	10.0.0.0+	Override the existing <code>X-IBM-Client-Id</code> name value with the new value. In API Gateway, <code>x-key-type</code> makes it possible to define custom naming for <code>client_id</code> and <code>client_secret</code> . Example: <pre>--client-id-header-override="acme-foo"</pre> In this example, the <code>securityDefinitions</code> property is changed from: <pre>foo: type: apiKey name: X-IBM-Client-Id in: header</pre> to the following: <pre>foo: type: apiKey name: acme-foo in: header x-key-type: client_id</pre> Calls to this API must supply <code>acme-foo</code> : <client-id> in the request header instead of the original <code>X-IBM-Client-Id</code> : <client-id>.

Parameter	Valid values	DataPower version required	Description
<code>client-id-query-override</code>	String. The string cannot contain spaces. Follow the guidelines for <code>apiKey name</code> . No default value.	10.0.0.0+	Override the existing <code>client_id</code> name value with the new value. In API Gateway, <code>x-key-type</code> makes it possible to define custom naming for <code>client_id</code> and <code>client_secret</code> . Example: <pre>--client-id-query-override="acme-foo"</pre> In this example, the <code>securityDefinitions</code> property is changed from: <pre>foo: type: apiKey name: client_id in: query</pre> to the following: <pre>foo: type: apiKey name: acme-foo in: query x-key-type: client_id</pre> Calls to this API must supply <code>?acme-foo=<client-id></code> in the query parameter instead of the original <code>?client_id=<client-id></code> .
<code>client-secret-header-override</code>	String. The string cannot contain spaces. Follow the guidelines for <code>apiKey name</code> . No default value.	10.0.0.0+	Override the existing <code>X-IBM-Client-Secret</code> name value with the new value. In API Gateway, <code>x-key-type</code> makes it possible to define custom naming for <code>client_id</code> and <code>client_secret</code> . Example: <pre>--client-secret-header-override="acme-foo"</pre> In this example, the <code>securityDefinitions</code> property is changed from: <pre>foo: type: apiKey name: X-IBM-Client-Secret in: header</pre> to the following: <pre>foo: type: apiKey name: acme-foo in: header x-key-type: client_secret</pre> Calls to this API must supply <code>acme-foo: <client-secret></code> in the request header instead of the original <code>X-IBM-Client-Secret: <client-secret></code> .
<code>client-secret-query-override</code>	String. The string cannot contain spaces. Follow the guidelines for <code>apiKey name</code> . No default value.	10.0.0.0+	Override the existing <code>client_secret</code> name value with the new value. In API Gateway, <code>x-key-type</code> makes it possible to define custom naming for <code>client_id</code> and <code>client_secret</code> . Example: <pre>--client-secret-query-override="acme-foo"</pre> In this example, the <code>securityDefinitions</code> property is changed from: <pre>foo: type: apiKey name: client_secret in: query</pre> to the following: <pre>foo: type: apiKey name: acme-foo in: query x-key-type: client_secret</pre> Calls to this API must supply <code>?acme-foo=<client-secret></code> in the query parameter instead of the original <code>?client_secret=<client-secret></code> .
<code>copy-id-headers-to-message</code>	<code>true</code> / <code>false</code> The default value is <code>false</code> .	10.0.1.1+, 10.0.2.0+	When set to <code>true</code> , the <code>client-id</code> header is copied from <code>request.headers</code> to <code>message.headers</code> to be passed to the backend server. Set this parameter to <code>true</code> if your invoke backend services expect the <code>client-id</code> to be passed through.

Parameter	Valid values	DataPower version required	Description
custom-policies-scope	<code>catalog / global</code> The default value is <code>catalog</code> .	10.0.0.0+	<p>When set to <code>catalog</code>, the original v5 or v5-compatible catalog that contains the custom policy is staged for pushing to the target catalog and organization in API Gateway.</p> <p>When set to <code>global</code>, the custom policy is staged for pushing to API Gateway and is visible to all organizations and catalogs within that gateway.</p> <p><code>archive:port-to-apigw</code> sets up the custom policies for pushing to API Gateway, but does not do the pushing. If <code>global</code> scope is used, <code>archive:push</code> of the admin organization will push all custom policies associated with the configured gateways. If <code>catalog</code> scope is used, then the <code>archive:push</code> of the admin organization will initialize the custom policies on the gateway. A subsequent <code>archive:push</code> of the provider organization is needed to advertise the custom policies in the catalogs contained within the provider organization.</p> <p>Note: Potential conflicts between custom policies of the same name and version are resolved according to the following rules:</p> <ul style="list-style-type: none"> When set to <code>global</code> and two policies under the same gateway service have the same name, version, and md5 hash value, then the duplicates are discarded and a message is generated. When set to <code>global</code> and two policies under the same gateway service have the same name, version, and a differing md5 hash value, then global scope cannot be applied. Catalog scope is used and a warning is generated. When set to <code>catalog</code>, <code><orgname>_<catname></code> is appended to the zip filename to maintain uniqueness.
deploy-policies	Any combination of the following values: <code>gatewayscript_1.0.0</code> , <code>if_1.5.0</code> , <code>invoke_1.5.0</code> , <code>proxy_1.5.0</code> , <code>redact_1.5.0</code> , <code>switch_1.5.0</code> , <code>validate-username-token_1.0.0</code> , <code>xslt_1.0.0</code> The default values are: <code>if_1.5.0</code> , <code>invoke_1.5.0</code> , <code>proxy_1.5.0</code> , <code>redact_1.5.0</code> , <code>switch_1.5.0</code> , <code>validate-username-token_1.0.0</code> , <code>xslt_1.0.0</code>	<p>For <code>invoke_1.5.0</code>, <code>proxy_1.5.0</code>, <code>gatewayscript_1.0.0</code>, and <code>xslt_1.0.0</code>: 10.0.0.0+</p> <p>For <code>if_1.5.0</code> and <code>switch_1.5.0</code>: 10.0.1.1+, 10.0.2.0+</p> <p>For <code>redact_1.5.0</code>: 10.0.3.0+</p> <p>For <code>validate-username-token_1.0.0</code>: 10.0.1.3+, 10.0.2.0+</p>	<p>Defines which backwards-compatible policies should be advertised by DataPower to API Manager.</p> <p>Note: Any legacy policies that are specified in the <code>config.yml</code> file or by using the <code>apicm</code> command must also be specified by using <code>deploy-policies</code>. If these policies are not specified by using <code>deploy-policies</code>, an error is returned.</p>
emulate-v4-plan-rate-limit	<code>true / false</code> The default value is <code>false</code> .	10.0.1.2+, 10.0.2.0+	Determines whether all APIs emulate the v4 plan rate limit. If set to <code>true</code> , then API operations do not share the rate limit. This setting matches the behavior of the <code>x-ibm-gateway-emulate-v4-plan-rate-limit</code> v5 option.
enable-api-logging	<code>true / false</code> The default value is <code>true</code> .	10.0.0.0+	Log all changes that the migration utility makes when rewriting APIs. These changes are logged as comments in the API YAML file.
enforce-required-params	<code>true / false</code> The default value is <code>false</code> .	10.0.1.1+, 10.0.2.0+	When set to <code>true</code> , required parameters are enforced, which is the default behavior in API Gateway. When set to <code>false</code> , required parameters are not enforced, even if the required parameter checkbox selected.
gatewayscript-policy	One of the following values: <code>gatewayscript_1.0.0</code> , <code>gatewayscript_2.0.0</code> The default value is <code>gatewayscript_2.0.0</code> .	10.0.0.0+	<p>Defines which gatewayscript policy the migration utility uses when rewriting the API assembly.</p> <p><code>gatewayscript_1.0.0</code>: A user-defined policy created by the migration utility. This policy uses the v5 MPGW processing rule. Use <code>gatewayscript_1.0.0</code> if the gatewayscript policy is dependent on v5 MPGW capabilities, such as load balancer groups or XML Manager settings.</p> <p><code>gatewayscript_2.0.0</code>: The migration utility rewrites the existing API to gatewayscript 2.0.0. This policy supports the <code>header-metadata</code> module for compatibility with the DataPower® Gateway (v5 compatible).</p> <p>Specifying <code>gatewayscript_2.0.0</code> can cause migration errors or run-time errors. Use <code>gatewayscript_2.0.0</code> if you are able to review and verify all changes made by the migration utility in the API YAML file.</p>
if-policy	One of the following values: <code>if_1.5.0</code> , <code>switch_2.0.0</code> The default value is <code>if_1.5.0</code> .	<p>For <code>if_1.5.0</code>: 10.0.1.1+, 10.0.2.0+</p> <p>For <code>switch_2.0.0</code>: 10.0.0.0+</p>	<p>Defines which <code>if</code> policy the migration utility uses when rewriting the API assembly.</p> <p><code>if_1.5.0</code>: The migration utility rewrites the existing API to <code>if_1.5.0</code>.</p> <p><code>switch_2.0.0</code>: The migration utility rewrites the existing API to <code>switch_2.0.0</code>. Specifying <code>switch_2.0.0</code> can cause migration errors or run-time errors. Use <code>switch_2.0.0</code> if you are able to review and verify all changes made by the migration utility in the API YAML file.</p>

Parameter	Valid values	DataPower version required	Description
<code>invoke-policy</code>	One of the following values: <code>invoke_1.5.0</code> , <code>invoke_2.0.0</code> The default value is <code>invoke_1.5.0</code> .	10.0.0.0+	Defines which invoke policy the migration utility uses when rewriting the API assembly. <code>invoke_1.5.0</code> : The migration utility rewrites the existing API to invoke 1.5.0. <code>invoke_2.0.0</code> : The migration utility rewrites the existing API to invoke 2.0.0. Specifying <code>invoke_2.0.0</code> can cause migration errors or run-time errors. Use <code>invoke_2.0.0</code> if you are able to review and verify all changes made by the migration utility in the API YAML file.
<code>no-rename</code>	<code>true</code> / <code>false</code> The default value is <code>false</code> .	10.0.0.0+	Defines whether to append the porting suffix to artifact file versions or names or within artifacts. When set to <code>false</code> , the files are renamed using the porting suffix. When set to <code>true</code> , the original unpacked v5c files are overwritten with the ported API Gateway artifacts. A <code>y/n</code> prompt appears when using this option. To bypass this prompt, use the <code>--accept-no-rename-deletion</code> option.
<code>no-retitle</code>	<code>true</code> / <code>false</code> The default value is <code>false</code> .	10.0.0.0+	Defines whether to append the porting suffix to the <code>title</code> of the migrated API, product, or OAuth provider. Set this option to <code>true</code> if you want the <code>title</code> of the migrated API, product, or OAuth provider to match the original <code>title</code> in the v5-compatible YAML file.
<code>optimize-gws</code>	<code>true</code> / <code>false</code> The default value is <code>false</code> .	10.0.0.0+	When set to <code>true</code> , gatewayscript policies are modified to map v5 functions to API Gateway functions. Setting <code>optimize-gws</code> to <code>true</code> is valid only for the <code>gatewayscript_2.0.0</code> policy. If it is set to <code>true</code> for <code>gatewayscript_1.0.0</code> , an error is generated. Note: Setting <code>optimize-gws</code> to <code>true</code> can result in performance enhancements. However, the modifications to gatewayscript policies by the migration utility can cause problems. When using this setting, review all gatewayscript policy modifications after migration.
<code>porting-suffix</code>	A string containing alphanumeric, dash, underscore and dot characters. The default value is <code>-apigw</code> .	10.0.0.0+	Defines the suffix to be used when renaming APIs, Products, OAuth Providers, and other ported artifacts. The suffix is appended to the version on APIs, Products and other ported artifacts that have versions, and onto the name for OAuth Providers and other ported artifacts that do not have versions. If <code>porting-suffix</code> is not specified then a value of <code>-apigw</code> will be used. The porting suffix can contain alphanumeric, dash, underscore and dot characters. Prior to AMU 10.0.5.4 the porting suffix could not be overridden and <code>-apigw</code> was appended to the name for all ported artifacts.
<code>proxy-policy</code>	One of the following values: <code>proxy_1.5.0</code> , <code>invoke_2.0.0</code> The default value is <code>proxy_1.5.0</code> .	10.0.0.0+	Defines which proxy policy the migration utility uses when rewriting the API assembly. <code>proxy_1.5.0</code> : The migration utility rewrites the existing API to <code>proxy_1.5.0</code> . <code>invoke_2.0.0</code> : The migration utility converts the proxy policy to invoke 2.0.0. Specifying <code>invoke_2.0.0</code> can cause migration errors or run-time errors. Use <code>invoke_2.0.0</code> if you are able to review and verify all changes made by the migration utility in the API YAML file.
<code>redact-policy</code>	One of the following values: <code>redact_1.5.0</code> , <code>redact_2.0.0</code> The default value is <code>redact_1.5.0</code> .	10.0.3.0+	Defines which redact policy the migration utility uses when rewriting the API assembly. <code>redact_1.5.0</code> : The migration utility rewrites the existing API to <code>redact_1.5.0</code> . <code>redact_2.0.0</code> : The migration utility rewrites the existing API to <code>redact_2.0.0</code> . Specifying <code>redact_2.0.0</code> can cause migration errors or run-time errors, including changes to what is redacted, particularly with redactions meant for JSON payloads. Use <code>redact_2.0.0</code> if you are able to review and verify all changes made by the migration utility in the API YAML file.
<code>repair-wsdl-apis</code>	<code>true</code> / <code>false</code> The default value is <code>true</code> .	10.0.1.1+, 10.0.2.0+	If an API ported from V5 is created from WSDL, the WSDL is read and checked for accuracy. If <code>repair-wsdl-apis</code> is set to <code>true</code> , then the API and WSDL are automatically repaired. For example, if the WSDL ZIP file contains unnecessary files, they are automatically removed if <code>repair-wsdl-apis</code> is <code>true</code> .
<code>return-v5-responses</code>	<code>true</code> / <code>false</code> The default value is <code>false</code> .	10.0.1.1+, 10.0.2.0+	When set to <code>true</code> , OAuth-related messages are printed in the v5 response format. When set to <code>false</code> , OAuth-related response messages are printed in API Gateway response format.
<code>switch-policy</code>	<code>switch_1.5.0</code> , <code>switch_2.0.0</code> The default value is <code>switch_1.5.0</code> .	For <code>switch_1.5.0</code> : 10.0.1.1+, 10.0.2.0+ For <code>switch_2.0.0</code> : 10.0.0.0+	Defines which switch policy the migration utility uses when rewriting the API assembly. <code>switch_1.5.0</code> : The migration utility rewrites the existing API to switch 1.5.0. <code>switch_2.0.0</code> : The migration utility rewrites the existing API to switch 2.0.0. Specifying <code>switch_2.0.0</code> can cause migration errors or run-time errors. Use <code>switch_2.0.0</code> if you are able to review and verify all changes made by the migration utility in the API YAML file.
<code>use-config-file</code>	<code>true</code> / <code>false</code> The default value is <code>false</code> .	10.0.0.0+	Use the <code>config.yml</code> file that is in the same directory as the <code>apicm</code> binary file that is being executed. If this file is used, configuration options cannot be set using the command line. The purpose of the config file is to specify the command inputs given on this page, but in an easy-to-read file format (YAML).
<code>v5-request-headers</code>	<code>true</code> / <code>false</code> The default value is <code>true</code> .	10.0.1.2+, 10.0.2.0+	When set to <code>true</code> , the following v5-compatible request headers are set: <code>Via</code> , <code>X-Global-Transaction-ID</code> , <code>X-Client-IP</code> . When set to <code>false</code> , these request headers are not set.
<code>validate-username-token-policy</code>	<code>validate-username-token_1.0.0</code> The default value is empty.	10.0.1.3+, 10.0.2.0+	Defines whether or not to use the <code>validate-username-token</code> v5 emulation policy when the migration utility rewrites the API assembly. When empty, the migration utility takes no action on the policy.

Parameter	Valid values	DataPower version required	Description
<code>xslt-policy</code>	One of the following values: <code>xslt_1.0.0</code> , <code>xslt_2.0.0</code> The default value is <code>xslt_1.0.0</code> .	10.0.0.0+	Defines which gatewayscript policy the migration utility uses when rewriting the API assembly. <code>xslt_1.0.0</code> : A user-defined policy created by the migration utility. This policy uses the v5 MPGW processing rule. Use <code>xslt_1.0.0</code> if the xslt policy is dependent on v5 MPGW capabilities, such as load balancer groups or XML Manager settings. <code>xslt_2.0.0</code> : The migration utility rewrites the existing API to xslt 2.0.0. Specifying <code>xslt_2.0.0</code> can cause migration errors or run-time errors. Use <code>xslt_2.0.0</code> if you are able to review and verify all changes made by the migration utility in the API YAML file.

Example migration configurations

The following examples show configuration options using the `config.yml` file or the `apicm` command.

- The following example uses the `config.yml` file to specify the migration configuration.

```
custom-policies-scope: global
emulate-v4-plan-rate-limit: false
deploy-policies:
- proxy_1.5.0
- redact_1.5.0
- invoke_1.5.0
- xslt_2.0.0
- gatewayscript_1.0.0
- switch_2.0.0
rewrite-apis:
enable-api-logging: false
proxy-policy: proxy_1.5.0
redact-policy: redact_1.5.0
invoke-policy: invoke_1.5.0
xslt-policy: xslt_2.0.0
gatewayscript-policy: gatewayscript_1.0.0
if-policy: switch_2.0.0
switch-policy: switch_2.0.0
optimize-gws: false
no-retitle: true
```

Use the `use-config-file` parameter when running the `apicm` command to specify that the `config.yml` file is used for migration configuration values.

```
./apicm archive:port-to-apigw <path> --use-config-file=true
```

- The following example uses the `apicm` command to specify the same settings as in the previous example.

```
./apicm archive:port-to-apigw <path> --custom-policies-scope: global --emulate-v4-plan-rate-limit: false --deploy-policies="proxy_1.5.0,redact_1.5.0,invoke_1.5.0,xslt_2.0.0,gatewayscript_1.0.0,switch_2.0.0" --enable-api-logging=false --proxy-policy="proxy_1.5.0" --redact-policy="redact_1.5.0" --invoke-policy="invoke_1.5.0" --xslt-policy="xslt_2.0.0" --gatewayscript-policy="gatewayscript_1.0.0" --if-policy="switch_2.0.0" --switch-policy="switch_2.0.0" --optimize-gws=true --no-retitle=true
```

- The following example uses the `apicm` command to specify that the default migration configuration values are used.

```
./apicm archive:port-to-apigw <path>
```

Reviewing APIs converted to DataPower API Gateway

The migration utility `apicm archive:port-to-apigw` and `apicm`

`archive:port-to-apigw-v10` commands, which assists in the conversion of v5 APIs for use with the v10 DataPower® API Gateway, provides draft output YAML files containing the results of the conversion process.

Procedure

- Review the entire output YAML files for conformance, performance, and errors.

The conversion process annotates the YAML file and logs with information regarding the artifacts that are converted. For cases where additional information is available or further action is required, the YAML file and logs contain links to documentation.

- Make any necessary changes to port APIs to DataPower API Gateway.

- [Messages generated during conversion of APIs to DataPower API Gateway](#)

Reference information about the messages generated by the migration utility commands `apicm archive:port-to-apigw` and `apicm archive:port-to-apigw-v10`.

- [Parse actions added to the API assembly after migration](#)

The migration utility `apicm archive:port-to-apigw` and `apicm archive:port-to-apigw-v10` commands add parse actions to the API assembly depending on the policies specified in your migration configuration.

- [Fine-tuning APIs after migration](#)

After running the migration utility `apicm archive:port-to-apigw` or `apicm archive:port-to-apigw-v10` command, review the converted APIs to determine if any of the changes made by the migration utility can be modified to enhance performance and usability.

- [Frequently asked questions about migrating APIs to API Gateway](#)

Answers to some of the most frequently asked questions about migrating APIs to API Gateway.

Related information

- [Migrating a Version 5 deployment](#)

Messages generated during conversion of APIs to DataPower API Gateway

Reference information about the messages generated by the migration utility commands `apicm archive:port-to-apigw` and `apicm archive:port-to-apigw-v10`.

- [ACT07](#)
- [ACT09](#)

ACT06 `activity-log` policy set to `activity-log_1.5.0`, converting `activity-log` to `activity-log_1.5.0`.

Explanation

See message text.

Severity

info

ACT07 `activity-log` policy set to `set-variable_2.0.0`, converting `activity-log` to `set-variable_2.0.0`.

Explanation

The `activity-log` success and error values are saved into context variables. A subsequent log policy will reference these variables, which will generate the analytics log data based upon the desired log level.

Severity

info

ACT09 For `activity-log` policy set to `set-variable_2.0.0`, added a `switch` policy with `log` policies into the API finally clause to utilize the `activity-log` variables that were set.

Explanation

A `switch` policy determines if the analytics log level should be based upon the success of the API or on error `activity-log` settings. The context variable set in a prior `set-variable` policy is used as the `log` policy log level to gather the appropriate level of data in the analytics log.

API01 The specified API YAML input file is of gateway type `datapower-api-gateway`. This utility accepts only v5-compatible APIs of gateway type `datapower-gateway`.

Explanation

The input API YAML file must be of gateway type `datapower-gateway`. If the gateway type is `datapower-api-gateway`, the API does not need to be converted. Any other gateway type is not supported.

Response

Review your input file to confirm that it is v5 compatible.

Severity

error

API02 Input API policy is already version 2.0.0. This version is reserved for API Gateway policies only. Skipping conversion of this policy.

Explanation

The input API YAML file must be of gateway type `datapower-gateway`. Every policy within that API must be version 1.0.0. Version 2.0.0 policies are reserved for the API Gateway, which should be included only in APIs with gateway type `datapower-api-gateway`. No conversion is performed for this policy.

Severity

error

API04 Added missing `/` to the front of the basepath.

Explanation

A v5 API with a `basepath` property value that does not start with a `/` will have the character `/` added at the beginning of the `basepath` property of the API Gateway.

Severity

info

API05 Trailing slashes (`/`) removed from the basepath to conform to the API Gateway specification.

Explanation

A v5 API with a `basepath` property value that is not a `/` but ends with the `/` character will have the ending `/` character removed in the `basepath` property of the API Gateway.

Response

Calls to the API might need to be updated to conform to the new basepath.

Severity

warn

API06 Changed gateway type to `datapower-api-gateway`.

Explanation

See message text.

Severity

info

API07 Moved `assembly request` into `assembly execute`.

Explanation

Older v5 APIs might include the `execute` property within an `assembly request` property. This `execute` property is moved to the API Gateway `assembly` property.

Severity

info

API08 Moved `assembly implementation` into `assembly execute`.

Explanation

Older v5 APIs might include the `execute` property within an `assembly implementation` property. This `execute` property is moved to the API Gateway `assembly` property.

Severity

info

API09 Moved `assembly response` into `assembly execute`.

Explanation

Older v5 APIs might have the `execute` property within an `assembly response` property. This `execute` property is moved to the API Gateway `assembly` property.

Severity

info

API10 Removed `x-ibm-gateway-invoke-v4-nomap-emulation` API property and replaced it with a `gatewayscript` policy to conform to the API Gateway specification.

Explanation

This v5 API property applies only to the `invoke` policy. In API Gateway, this property has been replaced by a `gatewayscript` policy that will modify the `invoke` policy response in a similar fashion.

Severity

warn

API11 The API property `x-ibm-gateway-sourcecode-resolve-apic-variables` does not exist in the API Gateway. The property has been removed from the YAML file.

Explanation

This v5 API property is not supported by the API gateway and has been removed. If the `x-ibm-gateway-map-resolve-apic-variables` property is not set, then the original value of this property will be set into the map option `mapResolveApicVariables` automatically.

Severity

error

API12 The API property `x-ibm-gateway-reencode-request-params-slash` does not exist in the API Gateway. The property has been removed from the YAML file.

Explanation

This v5 API property only applies to the `invoke` and `proxy` policies. In the API Gateway, the functionality of this property has been implemented as an option in the `invoke` policy.

This change was made for the following reasons.

- The option is now clearly visible in the `invoke` policy, making it easy to identify available options.
- Each use of the `invoke` policy can now have a different setting.

Severity

error

API13 The API property `x-ibm-gateway-framework-legacy-json-encoding` does not exist in the API Gateway. The property has been removed from the YAML file.

Explanation

This v5 API property is not supported by the API gateway and has been removed. If the value of the `x-ibm-gateway-framework-legacy-json-encoding` property is present, it will be used by the migration utility when migrating `xslt`, `gatewayscript`, and `map` policy source code to produce the same result as v5 would have produced based upon the property value.

Severity

error

API14 Converted v5-compatible policies to the API Gateway and updated policy versions to 2.0.0.

Explanation

See message text.

Severity

info

API15 The `x-ibm-gateway-api-enforce-response-limits` API property is enabled. Appended `parse` policy to the end of the assembly to parse the JSON response.

Explanation

The v5 API property `x-ibm-gateway-api-enforce-response-limits` ensures that a JSON response payload is within the defined JSON parser limits. This functionality is emulated in API Gateway by adding a `parse` policy at the end of the assembly.

Severity

info

API16 Removed the `x-ibm-gateway-api-enforce-response-limits` API property and replaced it with a `parse` policy to conform to the API Gateway specification.

Explanation

The v5 API property `x-ibm-gateway-api-enforce-response-limits` ensures that a JSON response payload is within the defined JSON parser limits. This functionality is emulated in API Gateway by replacing it with a `parse` policy.

Severity

info

API17 Setting `x-ibm-soap` to `%s`.

Explanation

The v5 API path does not have a `x-ibm-soap` property with a `soap-action` child property, but the schema referenced by this path is for a SOAP document. The `x-ibm-soap` property is added with a child property of `soap-action` into this path of the API gateway. The `soap-action` property will be determined from the schema encountered.

Severity

info

API18 This `set-variable` policy is used to add the client identification header to the message headers for use by a subsequent `invoke` policy.

Explanation

Typically, the client identification header as defined by the security definition is `X-IBM-Client-Id`. This header will be removed from the message headers at the start of the API. A `set-variable` policy will add this header back into the message headers, as the v5 API specifies not to suppress this header from being sent by subsequent `invoke` policies.

Severity

info

API19 Skipping appending of a `parse` policy for the `x-ibm-gateway-api-enforce-response-limits` API property, as this `parse` policy already exists at the end of the assembly and contains the same `input` and `output` values.

Explanation

See message text.

Severity

info

API20 Added `parse` policy to the beginning of the assembly to parse incoming data.

Explanation

The v5-compatible implementation implicitly parses messages. However, by requiring explicit parsing for every assembly wherever parsing is required, the API Gateway provides greater control over when and how parsing is performed.

The `parse` policy is added in API Gateway for the following purposes.

- To explicitly control when parsing occurs.
- To determine which threat protection settings to apply to a parse.
- To determine which kinds of output to allow.
- To determine how to gather metadata from the parse.

By separating the parsing time from the processing time of the assembly, explicit parsing can also enhance performance.

API Gateway has no implicit parsing. The assembly must explicitly parse when parsing is desired, which ensures that the correct limits and input checks are done.

Response

You should retain the added `parse` policy for any of the following reasons.

- You need non-well-formed XML or JSON documents to abort and call the `catch`.
- The data is still streaming and you need to keep a copy of the data for various reasons.
- You need to use the payload data with another policy.

If you do not need the `parse` policy, remove it. If you retain the `parse` policy, consider the following questions.

- Which threat protection settings do you want to enforce with this `parse` policy?
- Does the use of this `parse` policy remove the need for an additional `parse` policy?
- Do you want to use the metadata from the parse, such as document size and complexity?

Severity

info

API21 Moved catalog specific `x-ibm-gateway-*` API Property: `%s` under catalog: `%s` to API level for further processing.

Explanation

`x-ibm-gateway` catalog-level properties are not supported in API Gateway. The properties have been moved to the top-level properties section in the API for further processing by the migration utility.

Severity

info

API22 Skipped adding ``parse`` policy since an adjacent parse of the same properties was already added.

Explanation

The `invoke` policy might add a `parse` policy next to it in the assembly. If this `parse` policy is detected, another parse is not added because it would result in duplicate parses in the assembly. This prevention of duplicate parses applies only if both parses are found to have the same properties.

Severity

info

API23 Removed redundant ``parse`` policy from end of the assembly.

Explanation

The tool added a duplicate `parse` policy to the end of the assembly. The duplicate policy has been removed as it performs the same action as another `parse` policy in the assembly.

Severity

info

API24 Removed redundant ``parse`` policy from the beginning of the assembly.

Explanation

The tool added a duplicate `parse` policy to the beginning of the assembly. The duplicate policy has been removed as it performs the same action as another `parse` policy in the assembly.

Severity

info

API25 Removed unsupported ``name`` property from the Swagger info property.

Explanation

An empty `name` property under the `info` property is not supported in API Gateway. If an API is published with an empty `name` property, an error is generated. Therefore, the migration utility removes the empty `name` property if it is found.

Severity

info

API26 Removed empty ``description`` property from the Swagger info property.

Explanation

An empty `description` property is not supported in API Gateway. If an API is published with an empty `description` property, an error is generated. Therefore, the migration utility removes the empty `description` property if it is found.

Severity

info

API27 Removed empty ``security`` property from the Swagger file.

Explanation

An empty object `security` property is not supported in API Gateway. If an API is published with an empty object `security` property, an error is generated. Therefore, the migration utility removes the empty object `security` property if it is found.

Severity

info

API28 Moved ``%s`` from API properties to this policy option ``%s`` and set to [%s].

Explanation

In the API Gateway, the functionality of this property has been implemented as a policy option.

Severity

info

API29 Preserved API Property `x-ibm-gateway-policy` in YAML.

Explanation

The API property was preserved because there is a 1.0.0 or 1.5.0 policy that requires it.

Severity

info

API30 Removed API Property `x-ibm-gateway-policy` from YAML.

Explanation

This property is obsolete and has been removed from the YAML file.

Severity

info

API31 The API property `x-ibm-gateway-custom-policy-with-gws-action` does not exist in the API Gateway. The property has been removed from the YAML file.

Explanation

In v10, this property is not required to control the behavior of a custom policy that includes a GatewayScript action, as both `true` and `false` scenarios are handled as expected.

Severity

error

API32 The `x-ibm-gateway-policy` was not found in the swagger.

Explanation

A `$ref` could not be dereferenced because the reference content was not found in the v5 YAML.

Response

Review the v5 file to confirm that the `$ref` references are valid and exist in the YAML.

Severity

warn

API33 Found usage of inline parameters: `x-ibm-gateway-policy` in `x-ibm-gateway-policy` policy.

Explanation

API Gateway does not support inline parameters in the GatewayScript 2.0.0 or XSLT 2.0.0 policies.

Response

Modify the policy to use context variables instead of inline parameters. The following tables show examples of inline parameters in v5 and how they can be rewritten to use context variables in API Gateway.

Table 1. GatewayScript 2.0.0 examples

v5	API Gateway
If <code>test.data</code> is a variable: <code>\$(test.data)</code>	<code>context.get('test.data');</code>
If <code>test.body</code> is a message: <code>\$(test.body)</code>	<code>context.getMessage('test').body;</code>
<code>{test.example}</code>	<code>context.get('request.parameters.test.example')</code>

For more GatewayScript 2.0.0 examples, see [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.](#)

Table 2. XSLT 2.0.0 example

v5	API Gateway
<code>\$(request.parameters.example)</code>	<code>apigw:get-variable('request.parameters.example')</code> Note: Be sure to use the <code>apigw</code> namespace.
<code>{example}</code>	<code>apigw:get-variable('request.parameters.example')</code>

For more XSLT 2.0.0 examples, see [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.](#)

Severity

error

API34 Found `x-ibm-gateway-policy` catalog specific property: `x-ibm-gateway-policy` under catalog section: `x-ibm-gateway-policy`, within an unpublished API.

Explanation

The API was most likely found under the drafts folder of an organization. Because it is not published to a specific catalog, the migration utility cannot determine which API to apply the properties to.

Response

Apply the `x-ibm-gateway-*` properties to the policies of the assembly manually before publishing.

Severity

info

API35 Found `x-ibm-gateway-` catalog specific property: `%s` under catalog section: `%s`. This API is published under catalog: `%s`

Explanation

The API is published to a specific catalog, and other catalog-specific `x-ibm-gateway-*` properties were found under other catalogs.

Response

If you want to move this API to other catalogs, apply these properties manually to the policies in the assembly.

Severity

info

API36 `x-ibm-gateway-` API Property: `%s` found to have invalid value: `%s`.

Explanation

See message text.

Response

Check the API to ensure that the API property has the correct value. For more information on the API property, see the appropriate section of the IBM API Connect Knowledge Center.

Severity

error

API37 JSON Schema contains an invalid reference.

Explanation

See message text.

Response

Confirm that your schema definitions are valid. If you find errors, fix them.

Severity

info

API38 XSD generation ignoring references beyond limit set by property.

Explanation

XSD generation from JSON schema uses the `x-ibm-gateway-schema-definition-reference-limit` property value to determine how many recursions to go in circular references.

Response

Severity

info

API39 An error occurred while generating the XSD for `%s` definition.

Explanation

See message text.

Response

Confirm that your JSON schema is valid before continuing.

Severity

warn

API40 Skipping JSON Schema definition: ` %s ` with multiple roots or not intended for XML data.

Explanation

See message text.

Severity

info

API41 Set ` chunked-uploads ` value to ` false ` to emulate v5 behavior.

Explanation

For information about the Allow chunked uploads property in the Invoke policy, see [Invoke](#).

Severity

info

API42 Input option ` chunked-uploads ` set to ` true `, which is the API Gateway ` chunked-uploads ` default. All invoke and proxy 1.5.0 and 2.0.0 policies will use this default value.

Explanation

For information about the Allow chunked uploads property in the Invoke policy, see [Invoke](#).

Severity

info

API43 Created ` compatibility: ` section for API-wide toggles set by migration utility.

Explanation

The migration utility generates a compatibility section that allows DataPower to read in custom settings to for compatibility between v5 and API Gateway.

Severity

info

API44 Set compatibility toggle ` %s ` to value: ` %s `.

Explanation

See message text.

Severity

info

API45 Compatibility toggle: ` %s ` set to value: ` %s `, which is the same as the API Gateway default.

Explanation

The migration utility input specified to set a compatibility toggle to a value that is already the default. Therefore, no change was made in the API as the default will automatically be used.

Severity

info

API46 Updated ` securityDefinition `: ` %s ` with new name: ` %s ` as specified in toggle input: ` %s `.

Explanation

See message text.

Severity

info

API47 ` application-authentication ` was found to be set, adding ` application-authentication-source ` and ` custom-header-name ` defaults.

Explanation

In v5, `application-authentication-source` does not exist. In API Gateway, it is a new option that must be set if authentication is set. Therefore, the migration utility automatically sets `application-authentication-source` to its most-compatible default, and as a result also sets `custom-header-name`. If `application-authentication` is not set in the v5 API, the migration utility does not set `application-authentication-source` and `custom-header-name`.

Severity

info

API48 `%s` found in API definition `%s`, changing the value to a string null.

Explanation

See message text.

Severity

info

API49 Changed `\$(request.body*)` to `\$(request.parsed_body*)` in: `%s` to use parsed copy of data.

Explanation

In the API Gateway, the `request.body` context is never parsed and cannot be evaluated. The parse policy added to the beginning of the assembly automatically copies `request.body` into `request.parsed_body` and parses that copy. The reference to `request.body` has been changed to use this new context.

Severity

warn

API51 Added missing path parameter definition for path `%s` operation `%s` parameter `%s`.

Explanation

See message text.

Severity

info

API52 Added missing path parameter reference for path `%s` operation `%s` parameter `%s`.

Explanation

See message text.

Severity

info

API53 A path parameter reference `%s` is not a path parameter.

Explanation

See message text.

Severity

warn

API54 A parameter reference `%s` is not defined.

Explanation

See message text.

Severity

warn

API55 Definition: %s is missing property 'Body' or 'properties', this is an invalid SOAP definition.

Explanation

The structure of the SOAP definition is invalid. For example, if the definition contains a SOAP fault that is not within the SOAP body, then the definition is invalid.

Severity

error

API56 Catalog specific API Property found without a corresponding default property: %s for catalog: %s, created empty string default property at the API level.

Explanation

See message text.

Severity

info

API57 Definition reference: %s is incorrect, and should be of form '#/definitions/foo'

Explanation

See message text.

Response

For example, the following reference is invalid:

```
moreDetails:
  $ref: '#definitions/MoreDetails'
```

To make this a valid reference, use the following form:

```
moreDetails:
  $ref: '#/definitions/MoreDetails'
```

Severity

warn

API58 `securityDefinition` property encountered without a `security` property. An empty `security` property is added.

Explanation

See message text.

Severity

info

API59 The missing referenced definition `%s` was added to the swagger.

Explanation

See message text.

Severity

info

API60 The API property name `%s` is invalid and has been removed from the swagger.

Explanation

API properties with an invalid characters such as \$ and parentheses are ignored.

Severity

info

API61 Set buffering property to true.

Explanation

APIs will always have buffering enabled, as v5 did not support streaming.

Severity

info

API62 A query based security definition `%s` was present. A new security definition `%s` was created to match implicit v5 behavior.

Explanation

The security definitions in v5 for an API key that was specified as a query parameter were configured using the key names `client_id` and `client_secret`. However, this behavior implicitly provided the ability to also use query parameters `app_id` and `app_secret`. The specification of `app_id` and `app_secret` must be done explicitly in v10.

Severity

info

API63 A security set was created with security definition references `%s` to match implicit v5 behavior.

Explanation

The security definitions in v5 for an API key that was specified as a query parameter were configured using the key names `client_id` and `client_secret`. However, this behavior implicitly provided the ability to also use query parameters `app_id` and `app_secret`. The specification of `app_id` and `app_secret` must be done explicitly

in v10.

Severity

info

API64 Suffix %s appended to API `version`.

Explanation

See message text.

Severity

info

API65 The referenced definition %s was changed to %s.

Explanation

The referenced definition contained a / character in the name and was not defined in the API. The / character has been removed to allow the API to publish during `archive:push`.

Severity

info

API66 Security has been removed as there are no associated security definitions.

Explanation

The API security is extraneous without associated security definitions.

Severity

info

API67 The API property `x-ibm-gateway-framework-preserve-escaped-reverse-solidus` does not exist in the API Gateway. The property has been removed from the YAML file.

Explanation

This v5 API property is not supported by the API gateway and has been removed. If the `x-ibm-gateway-framework-preserve-escaped-reverse-solidus` API property is present with a `true` value, it will be used by the migration utility when migrating xslt, gatewayscript, and map policy source code to produce the same result as v5 would have produced.

Severity

info

GWS02 This `gatewayscript` policy was added before the newly converted `switch` policy in the assembly to assist with the condition logic.

Explanation

A conditional policy from a v5 API is converted to a `switch` policy in the API Gateway. The v5 API uses GatewayScript for the `if` and `switch` policies, whereas the API Gateway condition syntax is JSONata based. These conditions have been moved into a `gatewayscript` policy that will execute immediately before the `switch` policy.

The switch conditions will use results from the `gatewayscript` policy to execute the correct assembly path.

Response

Review the changes to ensure that the `switch` policy result will be consistent with the v5 API.

Severity

info

GWS04 Found `gatewayscript` policy. Porting might be required.

Explanation

Review the `gatewayscript` policy and make any necessary changes. The following list includes examples of some of the differences between `gatewayscript` code in v5-compatible APIs and API Gateway.

- Calls that reference the `request.parameters` context variable in v5-compatible APIs might not produce the same results in API Gateway. For example, consider the following call in a v5-compatible API.

```
apim.getvariable('request.parameters.org_name')
```

This call is not equivalent to the following call in an API Gateway API.

```
context.get('request.parameters.org_name')
```

The `context.get()` call in API Gateway supports multiple occurrences of the same parameter variable. Therefore, it returns structured JSON for retrieving parameters, as in the following example return.

```
{"locations":["query"], "values":["sandbox-test-org"]}
```

For this example, the `apim.getvariable` call should be changed to the following call in API Gateway.

```
((context.get('request.parameters.org_name') || {}).values || []).slice(-1)[0]
```

- Access to `header-metadata` is not supported in API Gateway. In some cases, the call can be edited to conform to the API Gateway specification. For example, the call `hm.current.remove("Accept-Encoding");` can be replaced in API Gateway with `context.message.header.remove("message.headers.Accept-Encoding")` or `context.clear("message.headers.Accept-Encoding")`. However, if you are using `header-metadata` to set the response message header before the `proxy` policy, you must add a `gatewayscript` policy after the `invoke` policy to set the header on the response message.
- In v5 and in v10 API Gateway, `apim.getvariable()` returns an XML node set if an XML node set was set in the variable being retrieved. In v10 API Gateway, `context.get()` always returns an XML document, even if an xml node set was set in the variable. The API may require modification to work properly.
- In both v5 and v10 API Gateway, using the `apim.getvariable()` function on XML data returns an XML NodeList object. In v10 API Gateway, using the `context.get()` function on XML data returns an XML document. Consider this change before switching to `context.get()` using the `optimize-gws` migration configuration option, as API behavior may change as a result.

Severity

warn

GWS05 Added `require('apim')` function to `gatewayscript` policy to conform to the API Gateway specification.

Explanation

See message text.

Response

Review the changes to ensure that the `gatewayscript` policy result will be consistent with the v5 API.

Severity

info

GWS06 Found `require('header-metadata');` in the `gatewayscript` source.

Explanation

The `header-metadata` module is not supported in the API Gateway. All API context variables in the API Gateway are in the global context module. You can access the context variables directly using `context.set()` or `context.get()`.

For more information about using context variables in `gatewayscript` policies in API Gateway, see [Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway](#).

Response

For better performance, either use the `--optimize-gws=true` toggle when running the migration utility, or use the context module for native API Gateway performance. For more information about `header-metadata`, see [Access to the headers object](#) in the IBM DataPower Gateways documentation.

Severity

info

GWS07 Replaced `require('local:///isp/policy/apim.custom.js')` with `require('apim')` to conform to the API Gateway specification.

Explanation

The v5 `gatewayscript` compatibility module does not exist on the local file system in the API Gateway. The `require` function for this module was present in the `gatewayscript` code and has been changed for API Gateway compatibility.

Severity

info

GWS08 Empty source `gatewayscript` found.

Explanation

See message text.

Response

Consider updating the empty `gatewayscript` policy or remove it from the assembly for better performance.

Severity

warn

GWS09 Found `require('fs')` in the `gatewayscript` source.

Explanation

The `fs` module is supported in the API Gateway. Some API Gateway configuration folders have restricted access.

Severity

info

GWS10 Found `require('service-metadata')` in the `gatewayscript` source.

Explanation

See message text.

Response

The Gatewayscript examples in the following table show how the service variables map to API Gateway metric functions. To obtain the metric data, use the `getMetricData()` API of the `context.metric` object in DataPower API Gateway, as in the following example.

```
var md = context.metric.getMetricData();
```

For more information about the `context.metric` object, see [context.metric object for API Gateway services](#) in the IBM DataPower Gateways documentation.

v5 MPGW service variable	Gatewayscript example	Description
<code>dp:variable('var://service/time-response-complete')</code>	<code>md.filter(n => n.type === 'assembly-invoke').slice(-1).endTime</code>	The end time of the last assembly-invoke metric data.
<code>dp:variable('var://service/time-elapsed')</code>	<code>md.slice(-1).endTime</code>	The end time of the last element in the metric data array.
<code>dp:variable('var://service/time-forwarded')</code>	<code>md.filter(n => n.type === 'assembly-invoke').slice(-1).requestTime</code>	The request time of the last assembly-invoke metric data.
<code>dp:variable('var://service/URL-out')</code>	<code>md.filter(n => n.type === 'assembly-invoke').slice(-1).targetURL</code>	The target URL of the last assembly-invoke metric data.
<code>dp:variable('var://service/mpgw/request-size')</code>	<code>md.filter(n => n.type === 'assembly-invoke').slice(-1).requestSize</code>	The request size of the last assembly-invoke metric data.
<code>dp:variable('var://service/mpgw/response-size')</code>	<code>md.filter(n => n.type === 'assembly-invoke').slice(-1).responseSize</code>	The response size of the last assembly-invoke metric data.

Severity

info

GWS11 Found `require('mgmt')` in the `gatewayscript` source.

Explanation

The `mgmt` module is not supported in the API Gateway.

Response

Remove use of the `mgmt` module from the source code.

Severity

error

GWS12 Found `require('policy/policy-utility')` or `require('policy/policy-utility.js')` in the `gatewayscript` source.

Explanation

`policy-utility` is a DataPower module that is not supported in the API Gateway.

Response

Remove use of the `policy-utility` module from the source code.

Severity

error

GWS18 Found `gatewayscript` containing session function: `%s` and replaced with API Gateway native `%s`

Explanation

See message text.

Severity

info

GWS19 Invalid `gatewayscript` found. The gateway script could not be parsed due to `%s`

Explanation

See message text.

Severity

warn

GWS20 Found `gatewayscript` containing apim function: `%s`. No replacement was performed. The closest match is '%s', but it may not work in all situations.

Explanation

See message text.

Severity

warn

GWS21 Found `gatewayscript` containing session context function: `%s`. No replacement was performed. The closest match is '%s', but it may not work in all situations.

Explanation

See message text.

Severity

warn

GWS22 Found `gatewayscript` containing: `%s` and replaced with API Gateway equivalent context var of: `%s`

Explanation

The following context variable names differ between v5 and v10 API Gateway. The migration utility replaces the v5 variable name with the equivalent v10 API Gateway variable name. For more information, see [API Connect context variables](#).

v5 context variable	v10 API Gateway context variable
<code>env.path</code>	<code>api.catalog.path</code>
<code>env.name</code>	<code>api.catalog.name</code>
<code>client.app.type</code>	<code>client.app.lifecycle-state</code>

Severity

info

GWS24 Found gatewayscript policy containing api.document. Adding a gatewayscript policy to populate the api.document context.

Explanation

The migration utility added a gatewayscript policy before the gatewayscript policy that contains `api.document`. The additional gatewayscript policy is required to populate the `api.document` context.

Severity

info

GWS25 Replaced TLS Profile name `webapi-sslcli-mgmt` or `api-sslcli-all` with default TLS profile name `api-ssl-client-all` to conform to the API Gateway specification.

Explanation

See message text.

Severity

info

GWS26 Removed %s `\\` characters to conform to the API Gateway specification.

Explanation

The processing of v5 API metadata would implicitly remove extraneous \\ characters. The source property of the gatewayscript policy has been changed to removed these characters as they would have been removed in v5.

INV01 Moved `x-ibm-gateway-decode-request-params` from API properties to each `invoke` policy.

Explanation

This v5 API property only applies to the `invoke` and `proxy` policies. In API Gateway, the functionality of this property is implemented as an option in the `invoke` policy. This change was made for the following purposes.

- The option is now clearly visible in the `invoke` policy, making it easy to identify available options.
- Each use of the `invoke` policy can now have a different setting.

Severity

info

INV02 Moved `x-ibm-gateway-invoke-keep-payload` from API properties to the `keep-payload` `invoke` property where applicable.

Explanation

This v5 API property applies only to the `invoke` policy. In API Gateway, the functionality of this property is implemented as an option in the `invoke` policy. This change was made for the following purposes:

- The option is now clearly visible in the `invoke` policy, making it easy to identify available options.
- Each use of the `invoke` policy can now have a different setting.

Severity

warn

INV03 Moved `x-ibm-gateway-queryparam-encode-plus-char` from API properties to each `invoke` policy.

Explanation

This API property only applies to the `Invoke` policy. In API gateway, this property is an option in the `Invoke` policy. This change was made for the following purposes:

- The option is now clearly visible on the invoke policy, making it easy to identify available options.
- Each use of the invoke policy can now have a different setting.

Severity

info

INV04 Added `parse` policy immediately after the `invoke` policy to parse the `invoke` output.

Explanation

The `invoke` policy output context in the API Gateway is not parsed. For compatibility with the v5 API, the `invoke` policy output context will be explicitly parsed by a `parse` policy that has been added to execute immediately after the `invoke` policy.

Severity

info

INV05 Removed `x-ibm-gateway-invoke-suppress-clientid` API property from the YAML file and replaced it with allowlists and blocklists to conform to the API Gateway specification.

Explanation

This v5 API property applies only to the `invoke` policy. In API Gateway, the functionality of this property is implemented as an option in the `invoke` policy. This change was made for the following purposes:

- The option is now clearly visible in the `invoke` policy, making it easy to identify available options.
- Each use of the `invoke` policy can now have a different setting.

Severity

warn

INV06 Found `invoke` policy. Converted to API Gateway `invoke` policy.

Explanation

See message text.

Severity

info

INV07 The API property `x-ibm-gateway-invoke-emulate-v4-soap-error` does not exist in the API Gateway.

Explanation

A `x-ibm-gateway-invoke-emulate-v4-soap-error` property was found. This property does not exist in the API gateway.

Response

Remove the `x-ibm-gateway-invoke-emulate-v4-soap-error` property from the API.

Severity

error

INV08 Incorrect timeout value of `%s` found in `%s` policy, updated to `60` seconds.

Explanation

The `timeout` property of the v5 `invoke` policy is invalid. It must be a numeric data type. It has been set to the default value of `60`.

Response

Correct the timeout value if the default value does not satisfy the requirements of the policy.

Severity

info

INV09 Renamed the `keepPayload` property in the `invoke` policy to `keep-payload`.

Explanation

See message text.

Severity

info

INV10 `X-IBM-Client-Id` HTTP header suppressed using header-control blocklist, as the `x-ibm-gateway-invoke-suppress-clientid` property is undefined or not set in the v5-compatible YAML input file.

Explanation

The v5 default behavior was to not send the `X-IBM-Client-Id` HTTP header to the invoke target. The `x-ibm-gateway-invoke-suppress-clientid` is not provided, so the header will not be sent. The API Gateway accomplishes this behavior by adding the header to the `invoke` policy header-control blocklist.

Severity

info

INV11 `X-IBM-Client-Id` HTTP header suppressed using header-control blocklist, as the `x-ibm-gateway-invoke-suppress-clientid` property is set to `true` in the v5-compatible YAML input file.

Explanation

The v5 default behavior was to not send the `X-IBM-Client-Id` HTTP header to the invoke target. The `x-ibm-gateway-invoke-suppress-clientid` property is provided with a value of `true`, so the header will not be sent. The API Gateway accomplishes this behavior by adding the header to the `invoke` policy header-control blocklist.

Severity

info

INV12 Removed `x-ibm-gateway-optimize-invoke` API property from the YAML file and converted the `invoke` policy to conform to the API Gateway specification.

Explanation

This v5 API property is not supported by the API Gateway.

Severity

info

INV13 Added `set-variable` policy to preserve `X-IBM-Client-Id` HTTP header before the `invoke` policy, as `x-ibm-gateway-invoke-suppress-clientid` is set to `false` in the v5c YAML input file.

Explanation

By default in the API Gateway, the `X-IBM-Client-Id` HTTP header is not copied from the inbound request headers to the message context headers used by the `invoke` policy. This request header will be copied to the message context headers so that it will be available to be sent by the `invoke` policy.

Severity

warn

INV14 Added `gatewayscript` policy for `x-ibm-gateway-invoke-v4-nomap-emulation` as the property is set to `true` in the v5-compatible YAML input file.

Explanation

The v5 `invoke` policy used this property internally, but this behavior is not supported by the API Gateway `invoke` policy. A `gatewayscript` policy that implements the behavior of this v5 API property has been added to execute after the `invoke` policy.

Severity

info

INV15 Invoke `keep-payload` property has been set to the value of the API property `x-ibm-gateway-invoke-keep-payload`.

Explanation

Although not supported by the v5 UI, a `keep-payload` property in the `invoke` policy is always used if present to control this behavior. If not present in the policy, the API property is used instead. The policy property is not present, but the API property is present, therefore the `keep-payload` property in the API Gateway will use the v5 API property.

Severity

info

INV16 Set `keep-payload` setting to `true`.

Explanation

The `keep-payload` setting is set based on the following conditions:

- For an `invoke` policy that meets all of the following criteria, the `keep-payload` property is always set to `true`.

- The policy is at the end of the assembly.
 - The API property `x-ibm-gateway-optimize-invoke` is not set to `false`.
 - The `invoke` policy does not contain a `stop-on-error` property.
- For an `invoke` policy that does not meet the above criteria, the `keep-payload property` is set to one of the following values, in order of precedence.
 - The value of `keepPayload` property, if it is set.
 - The value of the API property `x-ibm-gateway-invoke-keep-payload`, if it is set.
- For an `invoke` policy that meets none of the above criteria, the `keep-payload` property is not set at all.
- For a `proxy` policy, the `keep-payload` property is always set to `true` after it is converted to an `invoke` policy.

Severity

info

INV17 Invoke policy set to `invoke_1.5.0`, converting invoke to `invoke_1.5.0`

Explanation

See message text.

Severity

info

INV18 Set `final-action` parameter on `invoke_1.5.0`

Explanation

If the `invoke_1.5.0` policy is last in the assembly, the migration utility adds the `final-action` parameter, which ensures that the policy sends output to the message context. If `invoke_1.5.0` is not last in the assembly, the policy adds a parse after the wrapper policy to parse the output.

Severity

info

JSON-to-XML policy messages

- [J2X01](#)
- [J2X02](#)

J2X01 Added a `parse` policy to execute before the `json-to-xml` policy.

Explanation

A v5 `json-to-xml` policy must have the current API Gateway context parsed explicitly prior to execution. The `parse` policy has been added to execute before the `json-to-xml` policy.

Severity

info

J2X02 Found `json-to-xml` policy and converted to API Gateway `json-to-xml`.

Explanation

See message text.

Severity

info

JWT-Generate policy messages

- [JTG01](#)
- [JTG02](#)
- [JTG03](#)

JTG01 JWE properties are missing in the `jwt-generate policy`, so encryption has been disabled.

Explanation

If `jwe-enc` or `jwe-alg` is specified, then at least one of `jwe-jwk` and `jwe-crypto` must also be specified.

Severity

warn

JTG02 JWS property is missing in the `jwt-generate policy`, so signing has been disabled.

Explanation

If `jws-a1g` is specified, at least one of `jws-jwk` or `jws-crypto` must also be specified.
A private key must be specified, which can be either a JSON web key or a crypto object.

Severity

warn

JTG03 Converted the `jwt-generate` policy to the API Gateway `jwt-generate` policy .

Explanation

See message text.

Severity

info

LTPA-Generate policy messages

- [LTPA01](#)

LTPA01 Found v5-compatible `ltpa-generate` policy. Because this policy does not exist in the API Gateway, it is unchanged.

Explanation

The `ltpa-generate` policy is not available in the API Gateway.

Response

Remove the `ltpa-generate` policy from the API.

Severity

error

Map policy messages

- [MAP01](#)
- [MAP02](#)
- [MAP03](#)
- [MAP04](#)
- [MAP05](#)
- [MAP06](#)

MAP01 "Moved `%s` from API properties to each `map` policy as map option: `%s`."

Explanation

This v5 API property applies only to the `map` policy. In API Gateway, the functionality of this property is implemented as an option in the `map` policy. This change was made for the following purposes.

- The option is now clearly visible on the `map` policy, making it easy to identify available options.
- Each use of the `map` policy can now have a different setting.

Severity

info

MAP02 Replaced %s with %s to conform to the API Gateway syntax specification.

Explanation

API Connect Version 5 treats a map value property with a string quoted with `\` or `\\` as the same, specifically as a double quote. This is not supported in the API Gateway. The `\\` is converted to a single `\`.

Severity

info

MAP03 Converted `map` to API Gateway `map` for conformance."

Explanation

See message text.

Severity

info

MAP04 Set `map` option of `mapResolveApicVariables` to previous default of `true` for compatibility.

Explanation

If a map policy is found to not have `mapResolveApicVariables` set, the option is set to true to maintain backwards compatibility.

Severity

info

MAP05 Set `map` option of `mapParseXMLOutput` to `true` for compatibility.

Explanation

This property is always set by the migration utility to maintain compatibility with v5. If XML data is output from the `map_2.0.0` policy, then the data is parsed before it reaches `<output>.body`.

Severity

info

MAP06 Removed `%s \\` characters to conform to the API Gateway specification.

Explanation

The processing of v5 API metadata would implicitly remove extraneous `\\` characters. The value properties of the map policy action have been changed to remove these characters as they would have been removed in v5.

Severity

info

Proxy policy messages

- [PRX09](#)
- [PRX10](#)
- [PRX11](#)
- [PRX12](#)
- [PRX13](#)
- [PRX14](#)
- [PRX15](#)

PRX01 Found `proxy` policy and converted to API Gateway `invoke` policy, as `proxy` does not exist in the API Gateway.

Explanation

A `proxy` policy was found. The policy was converted to an `invoke` policy in the API gateway.

Response

Review the changes to ensure that the `invoke` policy result will be consistent with the v5 API. Alternatively, you can specify that the migration utility convert `proxy` policies to `proxy_1.5.0`, which is a backward-compatible policy available in the API Gateway.

Severity

info

PRX02 Removed `x-ibm-gateway-proxy-suppress-clientid` API property from the YAML file and replaced it with allowlists and blocklists to conform to the API Gateway specification.

Explanation

This v5 API property applies only to the `proxy` policy. In the API Gateway, this property is represented by the header control and parameter control options in the `invoke` policy to either allow or restrict the `x-IBM-Client-Id` header or `client_id` parameter being sent to the backend server. This change was made for the following reasons.

- The option is now clearly visible in the `invoke` policy, making it easy to identify available options.
- Each use of the `invoke` policy can now have a different setting.

Severity

warn

PRX03 Set policy `title` to `invoke` as this is now an `invoke` policy.

Explanation

The functionality of the v5 `invoke` and `proxy` policies has been merged into the API Gateway `invoke` policy. The `title` property of the policy was changed to `invoke`.

Severity

info

PRX04 Proxy: Changed `No-Cache` to lowercase `no-cache`.

Explanation

See message text.

Severity

info

PRX05 Proxy: Changed `Time-to-Live` to lowercase `time-to-live`.

Explanation

See message text.

Severity

info

PRX06 Proxy: Changed `Protocol-Based` to lowercase `protocol`.

Explanation

See message text.

Severity

info

PRX07 `client_id` query parameter suppressed using parameter-control blacklist, as `x-ibm-gateway-proxy-suppress-clientid` is set to `true` in the v5-compatible YAML input file.

Explanation

The v5 default behavior is to send the `client_id` query parameter to the proxy target. The `x-ibm-gateway-proxy-suppress-clientid` property was provided with a value of `true`, indicating not to send this query parameter. The API Gateway accomplishes this behavior by adding this query parameter name to the parameter-control blacklist of the policy.

Severity

info

PRX08 `X-IBM-Client-Id` HTTP header suppressed using header-control blacklist, as `x-ibm-gateway-proxy-suppress-clientid` is set to `true` in the v5-compatible YAML input file.

Explanation

The v5 default behavior was to not send the `X-IBM-Client-Id` HTTP header to the proxy target. The `x-ibm-gateway-proxy-suppress-clientid` property was provided with a value of `true`, indicating not to send this HTTP header. The API Gateway accomplishes this behavior by adding this header name to the header-control blacklist of the policy.

Severity

info

PRX09 `X-IBM-Client-Id` HTTP header suppressed using header-control blacklist, as `x-ibm-gateway-proxy-suppress-clientid` is undefined or not set in the v5-compatible YAML input file.

Explanation

The v5 default behavior was to not send the `X-IBM-Client-Id` HTTP header to the proxy target. The `x-ibm-gateway-proxy-suppress-clientid` property was not provided, indicating not to send this HTTP header. The API Gateway accomplishes this behavior by adding this header name to the header-control blacklist of the policy.

Severity

info

PRX10 `client_id` not suppressed in query parameter, as `x-ibm-gateway-proxy-suppress-clientid` is undefined or not set in the v5-compatible YAML input file.

Explanation

The v5 default behavior was to send the `client_id` query parameter to the proxy target. The `x-ibm-gateway-proxy-suppress-clientid` property was not provided, indicating to send this query parameter. No API Gateway `invoke` policy configuration is required to emulate this behavior.

Severity

warn

PRX11 `output` deleted as this policy is the last policy in the assembly flow.

Explanation

The v5 `proxy` API can specify an output context that makes the `proxy` response available for subsequent policies, but that response was also made available as the API response, should a subsequent policy not update the message context. When the `proxy` policy is the last policy in the v5 assembly, this output is removed, which allows the API Gateway `invoke` response to be returned to the client.

Severity

info

PRX12 Added `gatewayscript` policy to copy the proxy policy headers, status, and output to `message` context.

Explanation

A v5 `proxy` policy that specifies an output response context name is not the last policy in the assembly flow. A `gatewayscript` policy has been added after the API Gateway `invoke` policy. The `gatewayscript` policy copies the contents of the response context to the message context to emulate v5 behavior.

Severity

warn

PRX13 Added `set-variable` policy to preserve `X-IBM-Client-Id` HTTP header immediately before the proxy as `x-ibm-gateway-proxy-suppress-clientid` was set to `false` in the V5-compatible YAML input file.

Explanation

By default in the API Gateway, the `X-IBM-Client-Id` HTTP header is not copied from the inbound request headers to the message context headers used by the `invoke` policy. This request header will be copied to the message context headers so that it will be available to be sent by the `invoke` policy.

Severity

info

PRX14 Proxy policy set to `proxy_1.5.0`, converting proxy to `proxy_1.5.0`

Explanation

See message text.

Severity

info

PRX15 Set `final-action` parameter on `proxy_1.5.0`

Explanation

If the `proxy_1.5.0` policy is last in the assembly, the migration utility adds the `final-action` parameter, which ensures that the policy sends output to the message context. If `proxy_1.5.0` is not last in the assembly, the policy adds a parse after the wrapper policy to parse the output.

Severity

info

Redact policy messages

- [RE01](#)
- [RE02](#)
- [RE03](#)
- [RE04](#)
- [RE05](#)
- [RE06](#)
- [RE07](#)
- [RE08](#)
- [RE09](#)
- [RE10](#)

- [RE11](#)
- [RE12](#)
- [RE13](#)
- [RE14](#)

RE01 This API Gateway `redact` policy is added to contain all v5-compatible `redact` paths targeted against the `request`.

Explanation

To redact the request body, an API Gateway `redact` policy is placed at the front of the assembly in order to redact incoming data. All redactions in v5c that are not found within a `switch`, `if`, or `operation-switch` component will be moved to this single `redact` policy.

Response

Review to confirm that this change meets the purpose of the API.

Severity

warn

RE02 API Gateway `redact` policy added to contain all v5-compatible `redact` paths targeted against `response`, `logs`, and `all`.

Explanation

In the API Gateway, `response` and `logs` data must be redacted at the end of the assembly. This API Gateway `redact` policy was added to the end of the assembly to conform to the specification. If `logs` or `all` is the v5-compatible target for the `redact` policy, then a new `log` policy will be added in `gather-only` mode to populate the `log` API context.

The API Gateway emulates the v5-compatible redact on response and logs by adding a redact action at the end of the assembly to redact the response. All redactions in v5c that are not found inside of a `switch`, `if`, or `operation-switch` component will be moved to this single `redact` policy.

Response

Review to confirm that this change meets the purpose of the API.

Severity

warn

RE03 Found v5-compatible `redact` policy. `action:path` pairs from this policy will be sorted into one or both leading and trailing API Gateway `redact` policies to conform to the API Gateway specification.

Explanation

To emulate the v5 redact on `request` and `response`, some of the `redact` policies must be moved to either the end of the assembly or beginning of the assembly. This change is necessary because the `redact` policy now works directly on the API context, so it must be placed in a specific order so that it can redact data either before it enters the assembly or after it exits the assembly.

Response

Review the changes to ensure that the `redact` policy result will be consistent with the v5 API.

Severity

warn

RE04 Found duplicate v5-compatible `redact` path of the same `redact` type. Duplicate item will not be added.

Explanation

Because multiple redactions are consolidated into the leading or trailing `redact` policy, there might be some paths that are duplicates of current paths in the consolidated `redact` policy. These paths are not added as they are redundant.

Response

Review the changes to ensure that the `redact` policy result will be consistent with the v5 API.

Severity

warn

RE05 Redaction on `request` was found in the v5-compatible YAML input file. Added first API Gateway `redact` policy to the front of the assembly after the `parse` policy to perform this redaction.

Explanation

To redact the request body, an API Gateway `redact` policy is placed at the front of the assembly in order to redact incoming data. All redactions in v5c that are not found within a `switch`, `if`, or `operation-switch` component will be moved to this single `redact` policy.

Response

Review to confirm that this change meets the purpose of the API.

Severity

info

RE06 Redact on `response`, `logs`, or `all` was found in the v5-compatible YAML input file. Added second API Gateway `redact` to the end of the assembly to perform this redaction. `log` policy also added if redact on `logs` or `all` was found.

Explanation

In the API Gateway, **response** and **logs** data must be redacted at the end of the assembly. This API Gateway **redact** policy was added to the end of the assembly to conform to the specification. If **logs** or **all** is the v5-compatible target for the **redact** policy, then a new **log** policy will be added in **gather-only** mode to populate the **log** API context.

The API Gateway emulates the v5-compatible redact on response and logs by adding a redact action at the end of the assembly to redact the response. All redactions in v5c that are not found inside of a **switch**, **if**, or **operation-switch** component will be moved to this single **redact** policy.

Response

Review to confirm that this change meets the purpose of the API.

Severity

warn

RE07 Potential JSON v5-compatible `redact` path detected.

Explanation

A v5 **redact** path has been detected that is highly likely to be targeted against JSON data. It has been converted to a JSONata path because the **redact** policy in the API Gateway uses JSONata to specify **path**:

Response

Review to confirm that the path is meant for JSON data and it is formed properly.

Severity

warn

RE08 XML v5-compatible `redact` path detected. Converted to `redact` XPath: `%s` to JSONata: `%s`.

Explanation

A v5-compatible **redact** path has been detected that is highly likely to be targeted against XML data. It has been converted to JSONata to meet the API Gateway specification. The **redact** policy in the API Gateway uses JSONata for **path**:

Response

Review to confirm that the path is meant for XML data and it is formed properly. Note that a malformed XPath may still publish on API Connect v10 API Gateway, but will fail subsequent API calls with a **404 API Not Found** error. The API Definition DataPower object will also be in the **[down]** state because of the invalid XPath. It is also possible for an invalid XPath to work on v5 but fail on API Gateway. For example, the XPath **/test/path/** is invalid because of the trailing slash. However, this XPath will work in v5, and fail with the above scenario in v10 API Gateway.

Severity

warn

RE09 Common `redact` XPath `%s` replaced with JSONata `%s` to adhere to the API Gateway `redact` specification.

Explanation

The **redact** policy in API Gateway uses JSONata to specify the **path**:. All v5-compatible **redact** paths are converted to JSONata.

Response

Review to confirm that the changes conform to the purpose of the **redact** policy.

Severity

info

RE10 Invalid redact action: `%s` found.

Explanation

A v5-compatible **redact** policy was found to contain an invalid **action** type. Valid types include **redact** or **remove**.

Response

Review the `action` type in the `redact` policy and update to either `redact` or `remove`.

Severity

error

RE11 Added `log` policy to populate the `log` API context, because a v5-compatible `redact` policy was found targeted against `logs` or `all`. An API Gateway `redact` policy will be appended after this policy to redact the outgoing `log` data.

Explanation

The API Gateway specification requires a `log` policy in the assembly to populate the `log.request_body` and `log.response_body` context variables. After the `log` policy, the `redact` policy will then redact the contents of `log.request_body` and `log.response_body`.

Severity

warn

RE12 Added `parse` policy before `redact` policy to parse incoming data.

Explanation

The incoming data must be parsed for the `redact` policy to work properly. For example, if the incoming data contains unparsed but well-formed XML data, the `redact` policy does nothing and the data passes through. With this added `parse` policy, the XML data is parsed properly and the redaction works as expected.

Response

Review the changes to ensure that the `redact` policy result will be consistent with the v5 API.

Severity

warn

RE13 Found v5-compatible `redact` policy inside of a `switch` policy. Converted all paths to JSONata.

Explanation

If a v5-compatible `redact` policy is found within a `switch`, `if`, or `operation-switch` component, it will be left in place. If the redaction is on the response and there is an `invoke` policy at the end of the assembly, problems could arise.

Response

Review and confirm that this redaction conforms to the purpose of the API.

Severity

warn

RE14 Invalid `redact` action found: path is empty.

Explanation

The v5-compatible `redact` policy was found to have an empty path. This configuration is invalid

Response

To make the API functional, update the path in the `redact` policy.

Severity

error

Set-Variable policy messages

- [SV01](#)
- [SV02](#)
-
- [SV05](#)
- [SV06](#)
- [SV07](#)
- [SV08](#)

SV01 Found `set-variable` policy and converted to API Gateway `set-variable` policy.

Explanation

See message text.

Severity

info

SV02 Cannot recognize `set-variable` action `'%s'`. It must be `set`, `add`, or `clear` with a valid variable name.

Explanation

The v5 `set-variable` policy contains an action that is not `set`, `add`, or `clear`. The API Gateway `set-variable` policy should be modified to use the correct settings.

Severity

error

SV05 Required property `type` not found. Added `type` of `any` to conform to the API Gateway specification.

Explanation

The v5 `set-variable` policy does not have a `type` property. The type is inherent in the data type of the value. The API Gateway includes this property, which is set to the data type of the value. In conditions where the data type would be determined at runtime (for example, with a variable substitution), the value is set to `any`.

Response

Consider changing the added `type` to a more specific `type`.

Severity

warn

SV06 Required property `type` not found. Added `type` of `'%s'` to conform to the API Gateway specification, and it is consistent with the provided `value`.

Explanation

See message text.

Severity

info

SV07 The set-variable policy has no valid actions and has been removed from the assembly.

Explanation

See message text.

Severity

info

SV08 The set-variable action name '%s' has spaces in the name. Changing the action name to '%s'.

Explanation

See message text.

- [SW05](#)
- [SW06](#)
- [SW07](#)
- [SW08](#)
- [SW09](#)
- [SW10](#)
- [SW11](#)
- [SW12](#)
- [SW13](#)

SW01 Found `operation-switch_1.0.0` and converted to API Gateway `operation-switch_2.0.0`.

Explanation

See message text.

Severity

info

SW03 Found `switch` policy and converted to the API Gateway `switch` policy.

Explanation

A `switch` policy from a v5 API is converted to an API Gateway `switch` policy. The v5 API uses GatewayScript syntax for conditions, whereas the API Gateway uses JSONata syntax. The conditions have been moved to a `gatewayscript` policy that will execute immediately before the `switch` policy. The `switch` conditions will use results from the `gatewayscript` policy to execute the correct assembly path.

Response

Review the changes to ensure that the `switch` policy result will be consistent with the v5 API.

Severity

info

SW04 Found `if` policy and converted to API Gateway `switch` policy.

Explanation

An `if` policy from a v5 API is converted to an API Gateway `switch` policy. The v5 API uses GatewayScript syntax for conditions, whereas the API Gateway uses JSONata syntax. The conditions have been moved to a `gatewayscript` policy that will execute immediately before the `switch` policy. The `switch` conditions will use results from the `gatewayscript` policy to execute the correct assembly path.

Severity

info

SW05 Found `switch` condition: `%s` and converted it to JSONata: `%s` to conform to the API Gateway specification.

Explanation

A v5 `switch` policy condition was converted directly into a JSONata condition. This condition does not require a `gatewayscript` policy that would be executed prior to the switch.

Severity

warn

SW06 `switch` condition: `%s` could not be converted to JSONata. (Error code: `%d`).

Explanation

Cannot convert an `if/switch` condition to JSONata. A GatewayScript policy will be added to handle the Switch logic instead. Changes are needed only if highest performance is desired. See the Response section for more details on performance. This message can appear for the following reasons.

Error code	Explanation
1	The auto-generated JSONata mapping file was not found.
2	The condition was not found in the auto-generated JSONata mapping file.
3	The condition resolved to empty.
4	An unknown error occurred

Response

To improve performance, review the condition in the v5 API and provide the JSONata for this condition.

If an `indexOf()` method is used to determine whether a substring is present in a value, consider using the `$contains()` JSONata string function. If `indexOf()` is used to get a substring before or after the match, consider using the `substringBefore()` or `substringAfter()` JSONata string functions.

For more information about using JSONata to write switch conditions, see [Writing switch condition scripts - DataPower API Gateway](#).

Severity

warn

SW07 `switch` condition: `%s` could not be converted to JSONata or handled by `gatewayscript`.

Explanation

The `if/switch` condition cannot be converted to JSONata. This error can occur for the following reasons:

- A condition contains invalid Javascript.
- The condition contains multiple expressions.

Response

Review the contents of the condition and edit as necessary.

Severity

error

SW08 `switch` policy set to `switch_1.5.0`, converting `switch` to `switch_1.5.0`.

Explanation

See message text.

Severity

VAL01 Found v5-compatible `validate-username-token` policy. This policy does not exist in the API Gateway. No action has been taken.

Explanation

A `validate-username-token` policy was found. This policy does not exist in the api gateway and has been ignored.

Response

Remove the `validate-username-token` policy from the API.

Severity

error

VAL02 Converted `validate` policy into an API Gateway `validate` policy.

Explanation

A `validate` policy was found.

Response

Review the changes to ensure that the `validate` policy result will be consistent with the v5 API.

Severity

info

VAL03 Found `definition: request` and replaced it with `validate-against: body-param`.

Explanation

The `definition` property in the v5 `validate` policy contained a value of `request`. This value has been changed to a value of `body-param` in the `validate-against` property of the API Gateway `validate` policy.

Severity

info

VAL04 Found `definition: response` and replaced it with `validate-against: response-param`.

Explanation

The `definition` property of the v5 `validate` policy contained a value of `request`. This value has been changed to a value of `response-param` in the `validate-against` property of the API Gateway validate policy.`

Severity

info

VAL05 Found `soap-env` `validate` definition and converted it to the API Gateway `xml-schema` property.

Explanation

The `definition` property in the v5 `validate` policy references an OpenAPI definition. The definition referenced is for a SOAP document. This value has been changed to a value of `url` in the `validate-against` property in the API Gateway validate policy. The definition property value has been moved to the xml-schema property.`

Severity

info

VAL06 Set `xml-validation-mode` to `soap-body`.

Explanation

The `definition` property in the v5 `validate` policy references an OpenAPI definition. The definition referenced is for a SOAP document. This value has been changed to a value of `url` in the `validate-against` property in the API Gateway validate policy. The xml-validation-mode property value has been set to soap-body.`

Severity

info

VAL07 Set `validate-against` to `%s`.

Explanation

The **definition** property in the v5 **validate** policy references an OpenAPI definition. This value has been changed to conform to the API Gateway **validate** policy property **validate-against** with a value of **definition** or **url**.

Severity

info

VAL08 Added `parse` policy before `validate` policy.

Explanation

A v5 **validate** policy that is configured to validate the current context payload against a schema definition must have the input of the current API Gateway context parsed explicitly prior to execution. The **parse** policy has been added to execute before the **validate** policy.

XML-to-JSON policy messages

- [X2J01](#)
- [X2J02](#)

X2J01 Added a `parse` policy to execute before the `xml-to-json` policy.

Explanation

A v5 `xml-to-json` policy must have the current API Gateway context parsed explicitly prior to execution. The `parse` policy has been added to execute before the `xml-to-json` policy.

Severity

info

X2J02 Found `xml-to-json` policy and converted to API Gateway `xml-to-json` policy.

Explanation

v5 `xml-to-json` policies are converted to API Gateway `xml-to-json` policies.

Note: When a v5 `xml-to-json` policy that contains the `xml:space="preserve"` attribute is migrated to API Gateway, spaces are not retained after curly braces, commas, and quotes in the JSON.

Response

Review the JSON and edit as necessary.

Severity

info

XSLT policy messages

- [XSLT01](#)
- [XSLT02](#)
- [XSLT03](#)
- [XSLT04](#)
- [XSLT05](#)
- [XSLT06](#)

XSLT01 Replaced `apim.custom`, `apim.setvariable`, and `webapi-util` with `apim.custom.xml` within `xsl import` and `xsl include` statements.

Explanation

The v5 `xslt` policy code that contains an `xsl import` or `xsl include` of v5 framework stylesheets that were found in the local directory of the file system have been changed to use the v5-compatible stylesheet in the store directory of the file system.

Severity

info

XSLT02 Added `parse` policy to execute before the `xslt` policy.

Explanation

A v5 `xslt` policy that is configured to use the current context payload as input to the stylesheet must have the current API Gateway context parsed explicitly prior to execution. The `parse` policy has been added to execute before the `xslt` policy.

Severity

info

XSLT03 Found `xslt` policy. Porting might be required.

Explanation

Review the `xslt` policy and make any changes required for use in API Gateway.

Response

If you want to use v5-compatible XSLT code in API Gateway, use the API Gateway extension elements and functions to ensure compatibility with API Gateway. Depending on the content of your code, you may need to make the following changes.

- Remove the `apim.setvariable-impl.xml` stylesheet from the XSLT code. This stylesheet is not used in API Gateway. Instead, use the API Gateway extension functions to manipulate the assembly context.
- Use API Gateway extension elements to manipulate values in the assembly context. The following example uses the `apigw:set-header` extension element to set the value of the request header.

```
<apigw:set-header name="'request'" value="$request" />
```

- Use of `dp:variable` and `dp:set-variable` functions is not supported in API Gateway. These functions should be changed to `apim:getVariable` and `apim:setVariable`. Access to session, service, and system metadata is restricted.

For more information about the API Gateway extension elements and functions, see the IBM DataPower Gateway documentation.

Severity

warn

XSLT04 `xslt` policy set to `xslt_1.0.0`, converting `xslt` to `xslt_1.0.0`.

Explanation

See message text.

Severity

info

XSLT05 Replaced TLS Profile name `webapi-sslcli-mgmt` or `api-sslcli-all` with default TLS profile name `api-ssl-client-all` to conform to the API Gateway specification.

Explanation

See message text.

Severity

info

XSLT06 Removed `%s` ``` characters to conform to the API Gateway specification.

Explanation

The processing of v5 API metadata would implicitly remove extraneous \\ characters. The source property of the xslt policy has been changed to remove these characters as they would have been removed in v5.

Severity

info

Migration utility messages

- [Catalog property updated with catalog name](#)

Catalog property updated with catalog name Message API: {{.APIFile}}, pOrg: {{.ProviderOrg}}: Updated catalogs: property: {{.OldCatalogName}} with catalog name: {{.NewCatalogName}} based on matching catalog title: {{.FoundCatalogTitle}} since API Gateway requires catalog name instead of catalog title in `catalogs`

Explanation

In v5, the `catalogs:` property uses names based on the Catalog Title. In API Gateway, the Catalog Name must be used. The Migration Utility attempted to find a matching Catalog Title in the same provider-org as the API, and succeeded. The `catalogs:` property that formerly used the Catalog Title has been automatically updated by the Migration Utility to use the Catalog Name of the Catalog instead.

Response

Review your API to confirm that the Catalog Name used in the `catalogs:` property is correct.

Parse actions added to the API assembly after migration

The migration utility `apicm archive:port-to-apigw` and `apicm archive:port-to-apigw-v10` commands add parse actions to the API assembly depending on the policies specified in your migration configuration.

Review the API assembly to determine if any of the parse actions or other actions added by the migration utility can be removed. For more information, see [Fine-tuning APIs after migration](#).

Parse actions are added to the assembly according to the rules in the following tables.

Table 1. Parse actions added to the API assembly after conversion of policies to 1.0.0 or 2.0.0

Policy	Where the parse action is added
If a POST , PUT , DELETE , OPTIONS , or PATCH method is found	As the first action in the assembly
invoke 2.0.0	After the invoke action, except when invoke is the last action in the assembly.
json-to-xml 2.0.0	Before the json-to-xml action
proxy 2.0.0	After the proxy action
validate 2.0.0	Before the validate action
xml-to-json 2.0.0	Before the xml-to-json action
xslt 1.0.0 or 2.0.0	Before the xslt action

Table 2. Parse actions added to the API assembly after conversion of invoke and proxy policies to 1.5.0

Policy	Where the parse action is added
invoke 1.5.0	A parse action is added after the invoke if any of the following are true: <ul style="list-style-type: none">• <code>stop-on-error</code> is specified• <code>final-action</code> is set to <code>false</code>. This is the default setting.• <code>x-ibm-gateway-optimize-invoke</code> is explicitly set to <code>false</code> The parse action is added because there can be a subsequent use of the output.
proxy 1.5.0	A parse action is added after the proxy if <code>final-action</code> is set to <code>false</code> .

Fine-tuning APIs after migration

After running the migration utility `apicm`

`archive:port-to-apigw` or `apicm archive:port-to-apigw-v10` command, review the converted APIs to determine if any of the changes made by the migration utility can be modified to enhance performance and usability.

If the migration utility makes any of the following changes to your APIs, consider making the suggested changes.

- If the last policy in the assembly has output that is set to a variable that is not used afterward, remove the output set or the entire policy.
- Remove any unnecessary parse actions that the migration utility adds to the assembly. For information about the parse actions added by the migration utility, see [Parse actions added to the API assembly after migration](#).
- If the assembly contains redact policies, verify that these policies are necessary. Delete any unnecessary redact policies.

What is **port-to-apigw**?

port-to-apigw is a command in the API Connect migration utility that converts all APIs, products, subscriptions, OAuth providers, and custom policies into v10 native API Gateway artifacts from a v5 system. These newly created artifacts live side-by-side with the original v5-compatible artifacts in the cloud directory, and have **-apigw** appended to the end of the filename. Starting in 10.0.5.4 a porting suffix can be used to override **-apigw**. For more information, see [Converting APIs to DataPower API Gateway](#).

What is **port-to-apigw-v10**?

port-to-apigw-v10 is a command in the API Connect migration utility that converts all v5-compatible APIs, products, OAuth providers, and custom policies from a v10 system into v10 native API Gateway artifacts. These newly created artifacts live side-by-side with the original v5-compatible artifacts, and have **-apigw** appended to the end of the filename. A porting suffix can be used to override **-apigw**. The subscriptions on the v5-compatible products can optionally be moved to the v10 native API Gateway products using the **push:v10** command. For more information, see [Converting v5-compatible API definitions](#).

When is it necessary to run the **port-to-apigw** command, and how do I use it?

Run this command if you are migrating to a v10 native API Gateway. Follow the migration steps that are appropriate for your v5 environment. For instructions on running the **port-to-apigw** command, see [Migration steps](#). For information on configuring migration options, see [Configuring migration options for DataPower API Gateway](#). For other information to help you optimize migration, see [Migration considerations](#).

Why is the **port-to-apigw** command needed for migrating to v10 API Gateway?

The required fields, properties, settings, and configuration in v10 native API Gateway differs from v5-compatible mode. The **port-to-apigw** step in the migration process is needed to convert the artifacts to conform to the changes.

What is the difference between these terms: "porting to API Gateway", **port-to-apigw**, and "migration"?

"Porting to API Gateway" describes what the **port-to-apigw** command does in the migration utility. "Migration" is the overall purpose of the migration utility. The **port-to-apigw** step is necessary for migrating to a v10 native API Gateway. Migration can be completed without the **port-to-apigw** step if you are migrating to a v10 deployment that uses only the v5-compatible DataPower Gateway.

What is v5 policy emulation and how does it work?

The v5 policy emulation layer allows both custom policies and the 1.0.x policies to run on the native v10 API Gateway. It is deployed automatically by the API Connect migration utility to the `local:///isp` folder of the DataPower appliance when a custom policy is found in the v5 backup, or if you specify a 1.0.x policy in the policy option for the **port-to-apigw** command. The deployment is first staged by the **port-to-apigw** command, and pushed by the **archive:push** command. Follow the steps as outlined in [Migration steps](#).

Note that 1.5.x policies do not use v5 policy emulation, and exist only as native wrappers to the 2.0.0 implementation.

What is the purpose of the policy parameter options?

Input options allow you to customize your migration. If you want to use the native policies, such as `invoke_2.0.0` instead of the default `invoke_1.5.0-compatible` option, you can select the appropriate option. However, using these options can result in migration errors that require manual changes to get your APIs up and running. If you want to be up and running quickly, it is best to use the default options for the input. The default options convert APIs in a way that is most backwards compatible with v5.

For more information about the migration configuration options, see [Configuring migration options for DataPower API Gateway](#) for migrating from a v5 deployment, [Configuration parameters for migrating v5 APIs](#) for migration from v5 Public Cloud, or [Converting v5-compatible API definitions](#) for v5c to API Gateway migration.

For explanations of errors and other messages generated during migration and suggestions for manual changes to APIs, see [Messages generated during conversion of APIs to DataPower API Gateway](#).

How do the v5 emulated policies `invoke_1.5.0`, `proxy_1.5.0`, `xslt_1.0.0`, and `gatewayscript_1.0.0` work?

When the push step of the migration utility is completed, these policies will exist on the DataPower Gateway as assembly function objects. The 1.0.x policies call the v5 policy emulation layer in order to function as if they were v5 policies. The 1.5.x policies are wrapper policies to the 2.0.0 implementation. They call the 2.0.0 policies and exist only as a compatibility layer between the original v5 policy and the new 2.0.0 policy.

What is the difference between the 1.5.0 and 2.0.0 versions of the `invoke` and `proxy` policies, and the 1.0.0 and 2.0.0 versions of the `gatewayscript` policy? Why isn't the 2.0.0 version the default version?

The 1.5.x policy implementations are native wrappers to the underlying 2.0.0 implementation. They exist only to create a compatibility layer between the v5 policy and the APiGW native policy. The `gatewayscript_1.0.0` policy uses v5 policy emulation to run as if it were on a v5 environment. The performance of the 1.0.x v5 emulation layer policies in API Gateway is the same or slightly better than the v5 and v5-compatible versions. The performance of 1.5.x policies is slightly slower than their corresponding 2.0.0 policies. You can inspect the 1.5.x wrapper implementation in Assembly Functions in DataPower Gateway.

Should I rewrite my GatewayScript policies?

Most GatewayScript policies do not require rewriting, as the native v10 API Gateway contains an enhanced compatibility layer that accepts most of the **apim** functions without modification. In most cases, GatewayScript policies require rewriting when they contain any of the following:

- inline parameters
- `require('service-metadata')` and service variables associated with it
- `require('mgmt')`
- `require('fs')`
- OAuth context variables

What is the **optimize-gws** option?

The `optimize-gws` migration option converts certain v5 gateway script functions to the native API Gateway implementation. This setting is optional because the compatibility layer already handles processing of original v5 gateway script functions. If set to true, the migration utility makes the following conversions:

- `apim.getvariable()` is converted to `context.get()`
- `apim.setvariable()` is converted to `context.set()`
- `hm.current.remove()` is converted to `context.clear()`

What is the `gateway-extension.zip` file and how does it work?

After running the `port-to-apigw` command, a `gateway-extension.zip` file is located in the `cloud/admin-org/availability-zones/default-availability-zone/gateway-services/<gateway-service>` folder. This file is automatically generated by the migration utility during the processing of the `port-to-apigw` command. It contains a `manifest.json` file, and every custom policy under the gateway service that came from the v5 backup. The `manifest.json` file contains a list of custom policies to push, and backwards-compatible policies to advertise and make available for use by APIs. These backwards-compatible policies include `invoke_1.5.0`, `proxy_1.5.0`, `xslt_1.0.0`, and `gatewayscript_1.0.0`. During the `archive:push` steps of the migration process, this zip file is pushed to the API Manager as a gateway extension. For more information, see [Gateway extensions manifest](#).

How does the migration utility migrate custom policies?

Custom policies are migrated in multiple steps, depending on whether the `custom-policies-scope` option is set to `global` or `catalog`. Once custom policies are pushed to the DataPower Gateway, they use the `v5 policy emulation` layer that was unpacked into the `local:///isp` folder in order to run on the native v10 API Gateway.

When `port-to-apigw` is run, the following steps are performed depending on the `custom-policies-scope` setting.

- If `custom-policies-scope` is set to `global`, and there are no duplicate custom policies with differing implementations, the custom policies under each gateway service are bundled in a `gateway-extension.zip` file. This zip file contains a `manifest.json` file that describes the contents. The `gateway-extension.zip` file is copied to the `admin-org gateway-service` folder. These steps are performed automatically when `port-to-apigw` is run. Next, you must push the `admin-org` during the `archive:push` step, which pushes the `gateway-extension.zip` bundles (one per gateway) to the API Manager using an internal `APIC Toolkit gateway-extensions:create` call. The custom policies within the bundle are advertised on the API Manager. The custom policies and compatible legacy policies are shown in the policy pallet in the API Manager Assemble UI. These custom policies are also in the DataPower filesystem in the `local:///` folder. Note that if duplicate custom policies with the same name, version, and differing underlying implementation are found, the migration utility logs a message and automatically falls back to `catalog` scope to prevent the migration from failing.
- If `custom-policies-scope` is set to `catalog`, the custom policies under each gateway service are bundled in a `gateway-extension.zip` zip file. This zip file contains a `manifest.json` file that describes the contents. The `gateway-extension.zip` file is then copied to the `admin-org gateway-service` folder. The custom policy definition files under each catalog are copied into the `catalog-scoped-staging` folder, where their gateway type is set to `datapower-api-gateway`. Next, you must push the `admin-org` during the `archive:push` step, which pushes the `gateway-extension.zip` bundles (one per gateway) to the API Manager using an internal `APIC Toolkit gateway-extensions:create` call. Note that the custom policies and compatible legacy policies are not visible in the policy pallet in the UI. You can see the custom policies in the DataPower filesystem in the `local:///` folder. Before you can publish APIs that use these policies, you must push your `provider-orgs` during the `archive:push` step. The custom policy definitions as described earlier from the `catalog-scoped-staging` folder are then pushed to the API Manager automatically using an internal `APIC Toolkit policies:create` call. The APIs containing the newly migrated catalog-scoped custom policies are then published.

Note: The folders and zip files are created automatically, and you should not need to modify them. For instructions on the tasks you must perform, see [Migration steps](#).

Should I set the `custom-policies-scope` option to `global` or `catalog`?

Global scope custom policies are visible to every catalog and org on the gateway. Catalog scope custom policies are visible only to the catalog that they were migrated from. If you plan to migrate to v10 with the intention of custom policy availability the same as it is on v5, then use the default `catalog` setting.

Why are my custom policies not showing up in the Assembly Editor policy palette?

See the following troubleshooting information: [Custom policies not appearing in the policy palette after migration](#)

Migration mapping files

You can use mapping files to map the name of a v5 object to a corresponding v10 object that has a different name.

The API Connect migration process allows you to make modifications to the configuration information after it has been extracted from the source v5 system and before it is uploaded to the target v10 system.

The names of some structures may not match exactly between v5 and v10. Since the names of some high-level objects may be intentionally different in the v10 environment, you can substitute values so that references to v5 object names (user registries, gateway services etc.) can be bound to the newly created objects in v10.

Note: If the names are preserved exactly between the v5 and v10 environments, you do not need to map any names.

- [What is a mapping file?](#)
- [Mapping a gateway service](#)
- [Mapping a migrated OAuth shared secret key](#)
- [Mapping SNI settings](#)
- [Mapping a provider organization](#)

What is a mapping file?

What does a mapping file do?

Mapping files are simple yaml files that may be placed at any level in the directory structure produced by the `apim archive:unpack` command where there is a yaml file describing a configuration object. A mapping file contains yaml `key: value` pairs that provide the values to apply in place of the original configuration values.

- You can use mapping files to override any values within the `.yaml` files.

- Common mappings can be specified in `mapping.yml`.
- Server specific mappings can be provided in `mapping.<servername/ip>.yml`. For example: `mapping.hostname.com.yml` for `hostname.com` server.

What kinds of settings can I map?

You can override any values within a `.yml` files. The most common mappings for v5 migrations are:

- Gateway service names
- Provider organization names
- User registry names

What does a mapping file contain?

A mapping entry consists of two or three lines:

- The first line of the mapping entry should be the file name you want to override, without the `.yml` extension. For example, when overriding a value in `provider-org.yml`, the first line of the mapping is `provider-org`.
- Additional lines have `key: value` pairs that override `key: value` pairs found in the main `.yml` file. The most common usage is for overriding the name. To do this include the `name:` setting, followed by the new value for v10. For example, if you have a v5 provider organization `myv5porg`, and you want to map it to `myv10porg`, the second line is `name: myv10porg`.

```
provider-org:
  name: myv10porg
```

- There are a few exceptions for some additional fields with special meaning in the mapping file for gateway services. See [Mapping a gateway service](#).

Where do I create mapping files

Examine the `/cloud` directory hierarchy that you created when you ran `apicm`

`archive:unpack`. Locate the directory that has the `.yml` file with the v5 value you want to overwrite. In that same directory, create a new file named `mapping.yml`. For a detailed example, see the [Mapping tutorial](#).

Mapping a gateway service

You can use a mapping file to tell the migration program the name of the target gateway service in v10 to use when migrating from v5 gateway service data to v10 gateway service data. You might want to map a v5 gateway service name to a v10 gateway service if the names do not match, or if the number of gateway services does not match.

Note: You can map a v5 gateway service to a v10 DataPower API Gateway. In this case, the mapping definition requires a `gateway-type` field. See the [Mapping tutorial](#). After you unpack the v5 data, you can find each of v5 gateway services in `cloud/admin-org/availability-zones/availability-zone-default/gateway-services/`.

For example, the following `cloud/admin-org/availability-zones/availability-zone-default/gateway-services/` hierarchy shows entries for three v5 gateways named: `gateway-2536`, `gateway-2537`, and `gateway-2538`.

Figure 1. Example admin-org with entries for three v5 gateway services

```
admin-org
├── availability-zones
│   ├── availability-zone-default
│   │   ├── availability-zone.yml
│   │   └── gateway-services
│   │       ├── gateway-2536
│   │       │   ├── gateway-service.yml
│   │       │   └── gateway-2537
│   │       ├── gateway-2537
│   │       │   ├── gateway-service.yml
│   │       │   └── gateway-2538
│   │       └── gateway-2538
│   │           ├── gateway-service.yml
```

Mapping a migrated OAuth shared secret key

Information about migrated OAuth shared secret keys is contained in your `gateway-service.yml` file. When you map a gateway to a new name, you must ensure that the OAuth shared secret key is associated with mapped gateway name.

Note: Make sure you only migrate one OAuth shared secret key per gateway service. You will get an error if you attempt to map more than one to the same gateway service.

1. Determine if your `gateway-service.yml` includes information for an OAuth Shared Secret Key (`oauth_shared_secret:`). For example:

```
api_version: 2.0.0
metadata:
  v5_created_at: 2018-12-01 17:43:03.065 +0000 UTC
  v5_created_by: admin
  v5_id: 5c02c827e4b0e816d3874747
  v5_updated_at: 2018-12-04 15:59:03.282 +0000 UTC
  v5_updated_by: admin
name: gw3-cf31
oauth_shared_secret: 0xF2DB3AE67A7988C06FF1EBA5C2B51F04ABC5D3D1192B4C994CA00C79FAB5ADAD
type: gateway_service
```

2. If `oauth_shared_secret:` is found, add `migrate_oauth_shared_secret:` `true` to the mapping `.yml`. For example:

```
gateway-service:
  name: gateway-10-1
  migrate_oauth_shared_secret: true
```

Mapping SNI settings

You can include Server Name Indication (SNI) settings in the mapping file. When enabled, these settings, which include the host and TLS Server Profile pairs, are included in the migration of gateway services.

Note: You can migrate only one set of SNI settings for a v10 gateway service. If you are mapping multiple v5 gateway services to a single v10 gateway service, only the first set of SNI settings is migrated and warnings are generated for the additional mappings.

1. Determine whether your `gateway-service.yml` file contains SNI settings to migrate, as in the following example.

```
api_version: 2.0.0
gateway_service_type: datapower-gateway
metadata:
  v5_created_at: 2022-02-02 20:07:29.566 +0000 UTC
  v5_created_by: admin
  v5_id: 61fae481e4b0b16dad38691a
  v5_updated_at: 2022-02-02 20:07:29.566 +0000 UTC
  v5_updated_by: admin
name: gateway-service6-fabd
oauth_shared_secret: 0x014D004DC0A32EF091C17FEFCF10A621C36A92CE88BCE0F8FC2463B096D72D99
sni:
- host: internal.apic.ibm.com
  tls_server_profile_url: idurl://../../../../../../../../tls-server-profiles/gatewaytlsprofile-1.0.0.yml
- host: partner.apic.ibm.com
  tls_server_profile_url: idurl://../../../../../../../../tls-server-profiles/default-ssl-profile-1.0.0.yml
type: gateway_service
```

2. If SNI settings are found, add `migrate_sni: true` to the `mapping.yml`. For example:

```
gateway-service:
  name: gateway-10-1
  migrate_sni: true
```

Mapping tutorial

You create and bring up a new gateway service in v10 called `gateway-10-1`. You want the data (e.g Catalogs) associated with the v5 gateway `gateway-2536` to be migrated to the v10 gateway named `gateway-10-1`.

1. Go to the `/cloud` hierarchy and locate the `gateway-2536/` directory.

```
|
|  └─ gateway-services
|     └─ gateway-2536
|        └─ gateway-service.yml
```

2. Open the `gateway-service.yml` and verify that the `name:` entry specifies the v5 gateway service that you want to map.

```
api_version: 2.0.0
v5_id: 5c0icef4e45816d32290fb
name: gateway-2536
type: gateway-service
```

3. To map `name: gateway-2536` to a new value, use a text editor to create a **new** file named `mapping.yml`.

- a. On a new line, enter `gateway-service:`.

How do I know what to enter on the first line?

Enter the name of the file that you are overriding, without the `.yml` suffix. In this case, you are overwriting `gateway-service.yml`, so you enter `gateway-service:`.

- b. On the next line, indent two spaces (as required for valid yaml), and enter `name:`
`gateway-10-1`.

```
gateway-service:
  name: gateway-10-1
```

How do I know which name to use when mapping the v10 gateway-service?

In the v10 Cloud Manager UI, go to the Topology page. In the Default Availability Zones table, locate the Service column and click the gateway service entry. On the Edit DataPower Gateway Service page, in the Gateway Details section, locate the value in the **Name** field. Use this value.

Note: Do not use the value in the **Title** field. The value in the **Name** field is slugged to contain only characters that are supported in v10, and thus might differ from the value in the **Title** field.

- c. If the new v10 gateway service `gateway-10-1` is a DataPower API Gateway, add a third line to specify the gateway type:

```
gateway-service:
  name: gateway-10-1
  gateway-type: datapower-api-gateway
```

If the new v10 gateway service `gateway-10-1` is a v5-compatible gateway, do not specify `gateway-type`. When `gateway-type` is not specified, the mapping defaults to v5-compatible.

- d. The mapping is complete. Save the file in the same directory.

The following diagram shows the location of the new `mapping.yml` file in the `c1oud/` hierarchy for `admin-org`. Note that it is in the same directory as the `gateway-service.yml` file for the v5 service it applies to (`gateway-2536`).

Figure 2. Example `admin-org` with `mapping.yml` for `gateway-2536` gateway service entry

When the mapping utility (`apicm archive:push`) runs, it automatically uses the new `name`: value found in `mapping.yml` to overwrite the `v5` value found in `gateway-service.yml`. Note that the gateway service on v10 must be up and running

Do I have to edit the existing `gateway-service.yml`?

No, just create a new `mapping.yml` file and add it to the same directory as `gateway-service.yml`.

What if I want to map several v5 gateway-services to one v10 gateway-service?

If you have several v5 gateway services, and you want to map each of them to the same v10 gateway service, `gateway-10-1`, you can copy your newly edited `mapping.yml` into the directory for each gateway service. Under each gateway entry, place a copy of your new `mapping.yml`.

The following diagram shows the locations of the three copies of `mapping.yml` files (one each for `gateway-2536`, `gateway-2537`, and `gateway-2538`) in the `cloud/` hierarchy for `admin-org`.

Figure 3. Example `admin-org` with `mapping.yml` files for three v5 gateway services

Mapping a provider organization

The `apicm archive:unpack` command produces a directory structure that includes a subdirectory for each provider organization in the original system. A provider organization named `onlinebanking` would be represented by a directory name `cloud/provider-orgs/onlinebanking`, containing a file named `provider-org.yml`:

```

api_version: 2.0.0
name: onlinebanking
org_type: provider
state: enabled
title: OnlineBanking
summary: migrated onlinebanking
metadata:
  v5_id: 5c0ebfdae4b007df531ffe40
  ...

```

To override the organization name (indicated by the `name` property), create a file named `mapping.yml` in the same directory as the `provider-org.yml` file, and include the new name to apply to the organization. Example `mapping.yml`:

```

provider-org:
  name: digitalbanking

```

Here, the result of the override is to cause a provider organization named `digitalbanking` to be used as the target provider organization for the contents originally extracted from the `onlinebanking` organization.

Migrating OAuth providers and OAuth secured APIs

You can migrate v5 OAuth providers and OAuth secured APIs to your v10 API Connect deployment.

In v5 OAuth providers are a specialized type of API that are published within products. In v10 OAuth providers are first-class objects that are directly published in the provider organization. This is applicable for both DataPower Gateway (v5-compatible) and DataPower API Gateway.

Also, v10 adds tight coupling between the API using OAuth and the OAuth provider object. Hence an API using OAuth security must link to the corresponding OAuth provider object. For a review of how API Connect v10 uses OAuth providers, see [OAuth Provider overview](#).

The API Connect Migration Utility (AMU) migrates all OAuth provider APIs from v5 to the first-class OAuth provider objects on both DataPower Gateway (v5-compatible) and DataPower API Gateway.

In addition, the AMU uses logic to determine which OAuth provider is used by a given API and populates it in the newly added field `x-ibm-configuration` of API security definitions. If the AMU is unable to find a match between an API using OAuth and the OAuth provider, it prints out error messages. See [Error messages and warnings from archive:unpack](#).

- To ensure that APIs that use OAuth security definitions are mapped to the corresponding OAuth provider APIs in v10, make sure that either the Authorization URL or the Token URL defined in OAuth Security Definitions of APIs that use OAuth correctly point to the base path of the OAuth provider API. Note that the AMU uses logic to map consumer APIs to provider APIs, and adds `x-ibm-oauth-provider` in the OAuth Security Definition of the consumer API.

- To verify whether OAuth provider APIs are migrated correctly, ensure that all the APIs that use OAuth Security Definition have the new field `x-ibm-oauth-provider` added. Check the value of that field and make sure that it points to a correct OAuth provider resource object that was created and configured in the catalog to which the API is published.
- As mentioned earlier, in v5 OAuth providers are a specialized type of API that are published within products. In v10 OAuth providers are instead first-class objects that are directly published in the provider organization, and are not APIs that are published within products. Because of this, it is possible that you may have some v5 products that only contained OAuth provider APIs. Since these products do not contain any Open API definitions in v10, they will not be published as all products in v10 must contain at least one Open API definition.
- Because v10 OAuth providers are first-class objects rather than APIs as in v5, the application authentication feature is not available to v10 OAuth providers migrated from v5.

Migrating OAuth token revocation information

In v5, token revocation could be enabled either using native token management system (TMS) or using external TMS. For migration to v10:

- Native TMS migration
 - DataPower Gateway (v5-compatible)

If you had configured native token revocation, then you would have configured Quota enforcement peering group objects on v5 to synchronize between gateway servers. When migrating to v5-compatible, a QES peering group can contain QES peers from both v5 Multi-Protocol Gateway Service (MPGW) and v10 DataPower Gateway, so the revocation information is retained.

After setting up a v10 DataPower Gateway instance, follow these steps to configure the v10 DataPower Gateway quota enforcement server (QES) to use the same QES on both v5 and v5-compatible. You must configure the QES and verify that it is enabled and functional before migrating from v5 to v10. For more details about configuring the QES, see the DataPower Gateway documentation topic *Configuring the quota enforcement server*.

 1. Log into the graphical interface of the DataPower Gateway instance in the default domain.
 2. Cluster the v5 MPGW QES with the v10 DataPower Gateway QES.
 - a. In DataPower Gateway, navigate to Objects > System Settings > Quota Enforcement Server.
 - b. Specify the password alias, data storage location, and the server and monitor port numbers.

If your v10 DataPower Gateway is a Docker instance, configure the QES to store data in memory. For more information about RAID and Docker, see the DataPower Gateway documentation topic *RAID and a DataPower Docker image*.
 - c. Enable Peer group mode.
 - d. Specify the IP address of the DataPower Gateway.

The IP address can be the IP address on any interface of the current appliance and must be accessible by other peers in the peer group.
 - e. Specify the IP addresses of the v5-compatible gateways to add them as peers.

The appliance connects to each peer in the order in which the peers are added in the list.
 - f. Apply and save the configuration.
 3. As a test, revoke a token on the v5 MPGW server.

Revocation data will replicate to v10 DataPower Gateway QES.
 4. Migrate the v5 APIs to the v10 DataPower Gateway QES.
 5. Send a request to the v10 DataPower Gateway QES with previously revoked token, which should fail as expected.

The expected failure indicates that the APIs were migrated and revocation data was replicated.
 - DataPower® API Gateway

When migrating to DataPower API Gateway, QES is not used for native token management and revocation. Instead, you can migrate token revocation information from a v5 QES to a gateway-peering cache in v10 DataPower API Gateway. For information, see [Migrating token revocation information to DataPower API Gateway](#).
- [Migrating token revocation information to DataPower API Gateway](#)

You can use the Token Migration Utility (TMU) to migrate token revocation information from a v5 quota enforcement server (QES) to a gateway-peering cache in v10 DataPower API Gateway.
- [Token migration errors](#)

After you run the Token Migration Utility (TMU), check the log in the logs subdirectory for errors. If it contains any of the following error messages, complete the troubleshooting steps before you run the utility again.

Migrating token revocation information to DataPower API Gateway

You can use the Token Migration Utility (TMU) to migrate token revocation information from a v5 quota enforcement server (QES) to a gateway-peering cache in v10 DataPower® API Gateway.

Before you begin

Download the TMU from [IBM Fix Central](#). The TMU includes a container image and a separate configuration file.

The TMU requires the following versions of DataPower Gateway on the source and destination servers.

System	Required DataPower Gateway versions
Source	v10.5.0.0 or higher
	v10.0.4.0sr1 or higher
	v10.0.1.4 or higher
	v2018.4.1.16 or higher
Destination	v10.5.0.4 or higher

About this task

You can use the TMU to migrate revoked access tokens, revoked refresh tokens, resource owner consent, and, optionally, revoked resource owner consent.

Token migration consists of the following stages:

- Export QES data to a JSON file in the local directory.
- Import QES data into v10 DataPower Gateway from the JSON file.
- Configure a deny list in the v10 token cache.

The TMU transforms the data from QES to v10 format. It uses the DataPower Gateway REST management interface to expose the data and import it to the gateway-peering instance. When TLS is enabled in the gateway-peering instance, the TMU creates a TLS proxy and a TLS client profile to import the QES data. When TLS is not enabled, the TMU creates a TCP proxy to import the data.

Attention: Verify that the following requirements are met before you run the TMU.

- Ensure that the DataPower Gateway REST management interface is enabled. For information about enabling the REST management interface and configuring gateway peering for DataPower API Gateway, see [Configuring DataPower API Gateway](#).
- Gateway peering requirements
 - The v10 gateway peering password must be defined.
 - The gateway-peering instance in DataPower Gateway for the internal token store requires that data persists across a restart to prevent data loss. Ensure that this instance is not configured to store data in memory.
- v5 QES configuration requirements
 - Peer group mode must be disabled.
 - The listening server port must use the default value `127.0.0.1:16379`.
 - The v5 QES password must be defined.

Tip:

- The `./tmu` command uses the argument `--stage` or `-s` to indicate the stage of migration to perform.
- Use the `--help` argument to get information about any of the token migration stages.

Procedure

1. Define the following fields in the `config.json` file. All fields must be present and defined unless otherwise noted.

Table 1. Token migration configuration options

Field	Description
<code>v5-gateway-address</code>	v5 DataPower Gateway address
<code>v5-gateway-username</code>	v5 DataPower Gateway username
<code>v5-gateway-password</code>	v5 DataPower Gateway password
<code>v5-qes-password</code>	v5 QES password
<code>v5-cache-proxy-port</code>	The user-defined port on which to expose the v5 QES proxy. Ensure that this port is not in use.
<code>v5-cache-container-port</code>	If DataPower Gateway is deployed in Docker, the port that is exposed on the container that maps to the port defined in <code>v5-cache-proxy-port</code> . If DataPower Gateway is not deployed in Docker, this field can be undefined. When the cache container port is defined, the TMU attempts to connect to these ports, assuming that DataPower Gateway is hosted in a container. When it is not defined, the TMU connects to the cache proxy port.
<code>v5-rest-management-interface-port</code>	REST management interface port. If DataPower Gateway is deployed in Docker, enter the container port.
<code>v10-gateway-address</code>	v10 DataPower Gateway address
<code>v10-gateway-username</code>	v10 DataPower Gateway username
<code>v10-gateway-password</code>	v10 DataPower Gateway password
<code>v10-gwp-password</code>	v10 gateway-peering password
<code>v10-cache-gateway-peering-name</code>	Gateway-peering object name that is mapped to the v10 token cache. If peer group mode is enabled, ensure that the specified gateway-peering object is the primary member, not a replica.
<code>v10-cache-proxy-port</code>	The user-defined port on which to expose the v10 token cache proxy. Ensure that this port is not in use.
<code>v10-cache-container-port</code>	If DataPower Gateway is deployed in Docker, the port that is exposed on the container that maps to the port defined in <code>v10-cache-proxy-port</code> . If DataPower Gateway is not deployed in Docker, this field can be undefined. When the cache container port is defined, the TMU attempts to connect to these ports, assuming that DataPower Gateway is hosted in a container. When it is not defined, the TMU connects to the cache proxy port.
<code>v10-rest-management-interface-port</code>	REST management interface port. If DataPower Gateway is deployed in Docker, enter the container port.
<code>export-file-name</code>	File name for extracted v5 data.
<code>log-file-name</code>	Log file name. After any of the TMU commands are run, a log file is generated in a logs subdirectory of the TMU directory. Log files are named according to the format <code>DATE-TIME %log-file-name%</code> .
<code>log-level</code>	Log level to filter logged messages by severity. Valid values are <code>debug</code> , <code>error</code> , or <code>info</code> .
<code>import-revoked-consent</code>	Whether to import consent revocation entries. Valid values are <code>true</code> or <code>false</code> .

2. Start the TMU container.
3. Copy the edited `config.json` file into the `/home/tmu/ibm` directory of the TMU container.
4. Run the following command to export QES data to a JSON file in the local directory.

```
./tmu --stage v5-export
```

The QES data is exported to a JSON file in the same directory as the TMU. The name of the exported file is specified in the `export-file-name` configuration field. Each exported entry in the file has the following fields.

```
timeExport
  Unix epoch timestamp.
value
```

String value to the key in the QES.
`ttl`
Time to live of the entry in seconds.

Important: Do not modify the entries in the export file.

5. Run the following command to import QES data from the exported JSON file into v10 DataPower Gateway.

```
./tmu --stage v10-import
```

6. Run the following command to configure a deny list in the gateway-peering instance.

```
./tmu --stage token-cache-mode-set-deny
```

Attention: When the gateway-peering token cache mode is set to deny-based caching, it cannot be reset to allow-based caching.

7. Optional: Run the following command at any time to view the cache mode configuration in the v10 token cache.

```
./tmu --stage token-cache-mode-view
```

What to do next

Check the log file in the logs subdirectory for errors. For information about common errors and troubleshooting steps, see [Token migration errors](#).

Token migration errors

After you run the Token Migration Utility (TMU), check the log in the logs subdirectory for errors. If it contains any of the following error messages, complete the troubleshooting steps before you run the utility again.

Cache at {address:port} is not responsive. The proxy may be down or using an incorrect remote port.

The proxy to either the QES or gateway-peering token cache is not responsive. The gateway might be down or the cache might be unreachable.

- Verify that the proxy ports specified in `config.json` are not used by another service.
- If the DataPower Gateway is in a container, verify that the ports specified in `v10-cache-proxy-port`, `v5-cache-proxy-port`, or both, are exposed in the container. The exposed container ports must be specified in `v10-cache-container-port`, `v5-cache-container-port`, or both.
- Verify that the correct host interface (IP address) is selected for the cache proxy at runtime.
- If the v5 QES is unresponsive, check the following settings.
 1. Verify that the v5 QES uses the default address and that it is enabled.
 2. Check the logs in debug mode and search for a line that contains **Making TCP Proxy with URL**. If the log contains this line, check for an error that explains why the TCP proxy was not created. If the error is present, fix the error to allow the proxy to connect to the QES, then run the TMU again.
 3. If the log contains the line **Making TCP Proxy with URL** but there is no error, verify that there is a TCP proxy service configuration called `TMUProxyForMigration`. The remote IP address and remote port must be set to the QES default address and port. If necessary, modify the proxy configuration with correct information to connect to the QES, and then run the TMU again. If `TMUProxyForMigration` does not exist, create it and configure it to connect to the QES, and then run the TMU again.
- If the v10 gateway-peering token cache is unresponsive, check the following configuration settings.
 1. Verify that the gateway-peering object is enabled and specified in `config.json`.
 2. Check the logs in debug mode and search for a line that contains **Gateway peering info**. Verify that the information for the gateway-peering object is correct as specified in `config.json`.
 3. If TLS is disabled, check the logs in debug mode and search for a line that contains **Making TCP Proxy with URL**. If the log contains this line, check for an error that explains why the TCP proxy was not created. If this error is present, fix the error and then run the TMU again.
 4. If the log contains the line **Making TCP Proxy with URL** but there is no error, verify that there is a TCP proxy configuration called `TMUProxyForMigration` in DataPower Gateway. The remote host and port must be set to the local host and port of the gateway-peering object. If necessary, modify the proxy with the correct information to connect to the gateway-peering object, and then run the TMU again. If `TMUProxyForMigration` does not exist, create it and configure it to connect to the gateway-peering object, and then run the TMU again.
 5. If TLS is enabled, check the logs in debug mode and search for lines that contain **Making TLS Client Profile with URL** and **Making TLS Proxy with URL**. If the log contains these lines, check for an error that explains why the TLS client and TLS proxy were not created. Fix the error and run the TMU again.
 6. If the log contains the lines **Making TLS Client Profile with URL** and **Making TLS Proxy with URL** but there is no error, verify that there is a TLS proxy configuration called `TMUProxyForMigration` and a TLS client profile configuration called `TMUProfileForMigration` in DataPower Gateway. The remote host and port of the proxy must be set to the local host and port of the gateway-peering object. If necessary, modify the configurations to connect to the gateway-peering token cache, and then run TMU again. If either the TLS proxy called `TMUProxyForMigration` or the TLS client profile called `TMUProfileForMigration` do not exist, create these objects, configure them to connect to the gateway-peering object, and then run the TMU again.

Failed to establish a connection with {address:port}.

The gateway may be down or the DataPower Gateway REST management interface may be down.

- Verify that the gateway and the REST management interface are up.
- Verify that the port in the message is the port of the REST management interface. If it is not, modify the `v5-rest-management-interface-port` or `v10-rest-management-interface-port` field in `config.json`.
- If the DataPower Gateway is in a container, verify that v5 and v10 REST management interface ports are exposed by the container that is mapped to the DataPower Gateway REST management interface.

Could not get Gateway Peering information.

The DataPower Gateway REST management interface could not retrieve gateway-peering information.

- Verify that the gateway-peering object specified in `config.json` is created and enabled in the chosen DataPower Gateway domain.

Migrating custom policies

The migration utility migrates API Connect Version 5 user-defined custom policies to API Connect Version 10. After migration, the v5 custom policies run on a v5-compatible DataPower Gateway or the DataPower API Gateway. Custom policies can be migrated to API Gateway with limitations.

Overview of the custom policy file format

Review your custom policies in the `/ccloud` hierarchy that is created by the migration upack. The path to custom policies in the `/ccloud` hierarchy structure is:

```
provider-orgs -> <provider-org-name> -> catalogs -> <catalog-name> -> configured-gateway-services -> <gateway-name> -> policies
```

The following example from a `/ccloud` hierarchy shows custom policies for the catalog `policy-and-vendor-ext-test` listed under the gateway service `g-w-1-8f82`:

```
./provider-orgs/onlinebanking/catalogs/policy-and-vendor-ext-test/configured-gateway-services/  
└─ g-w-1-8f82  
  └─ configured-gateway-service.yml  
     └─ policies  
        ├── client-i-p-filter-policy-9d58-1.0.doc.yml  
        ├── client-i-p-filter-policy-9d58-1.0.meta.yml  
        ├── client-i-p-filter-policy-9d58-1.0.zip  
        ├── client-i-p-filter-policy-9d58-2.0.doc.yml  
        ├── client-i-p-filter-policy-9d58-2.0.meta.yml  
        ├── client-i-p-filter-policy-9d58-2.0.zip  
        ├── validate-auto-xsd-jsv-1.0.0.doc.yml  
        ├── validate-auto-xsd-jsv-1.0.0.meta.yml  
        ├── validate-auto-xsd-jsv-1.0.0.zip  
        ├── validate-username-token-5.0.0.doc.yml  
        ├── validate-username-token-5.0.0.meta.yml  
        └── validate-username-token-5.0.0.zip
```

File naming legend:

- `*.doc.yml` - the policy definition files
- `*.meta.yml` - metadata used only by the migration utility.
- `*.zip` - the custom policy zip files

Migrating custom policies to a v5-compatible gateway

A Version 5 custom policy definition is a zip file containing the yaml description of the policy (its name and configuration parameters) and the implementation zip of DataPower configuration that runs on the gateway. The zip file is pushed onto the gateway service used by any catalog that has APIs that make use of the policy. For more information on v5 custom policies, see [User-defined policies in API Connect](#).

The migration utility migrates both the zip file and the yaml description file. After migration, the v5 custom policies run on a v5-compatible DataPower Gateway. Note that the structure of the custom policy zip file is the same in v5-compatible gateway as in v5. The v5-compatible gateway runtime will run any custom policy that a v5 gateway runs.

Migrating custom policies to API Gateway

Important: When migrating custom policies to v10 API Gateway, the v5-emulation layer is used to ease compatibility. For more information, see [v5 policy emulation limitations](#).

You can migrate v5 custom policies to API Gateway using the v5-emulation layer. The migration utility bundles custom policies and groups them by gateway service during the port step. During the push step, the custom policies are pushed to the Gateway Service with instructions for DataPower to enable the v5-emulation layer, along with any v5-emulated or wrapped policies that were specified during the port step, such as `invoke_1.5.0` or `gatewayscript_1.0.0`.

v5 policy emulation is deployed by the API Connect Gateway Service using a Gateway extensions manifest. For more information, see [Gateway extensions manifest](#).

Note: If porting to API Gateway using the `custom-policies-scope=catalog` parameter, and spaces are contained in the v5 backup, then any duplicate custom policies found will be discarded. The final remaining custom policy out of the duplicates when pushed using `archive:push` will be pushed to all spaces within the same catalog. This is the correct behavior of the v10 API migration utility. For more details about pushing custom policies at the catalog (space) scope, see [Importing a user-defined policy into a Catalog](#).

Migrating gateway extensions

Use the appropriate procedure for migrating extensions to either a v10 DataPower® Gateway (v5 compatible) or a v10 DataPower API Gateway.

Migrating gateway extensions to a v10 DataPower Gateway (v5 compatible)

About this task

Follow these steps to migrate gateway extensions to a v10 DataPower Gateway (v5 compatible).

Procedure

Follow all migration utility steps to migrate to a v5-compatible DataPower Gateway. For instructions, see [Migration steps](#).

The gateway extensions are automatically extracted as part of the `archive:unpack` step. No further manual steps are required.

Results

The v5 extension zip file is pushed to the DataPower Gateway (v5 compatible) service.

Note: Only one gateway extension per gateway service can be used.

Migrating gateway extensions to a v10 DataPower API Gateway

Before you begin

Note: When migrating v5 extensions to v10 API Gateway, the v5-emulation layer is used to ease compatibility for any pre-request or post-response global assemblies it contains. For more information, see [v5 policy emulation limitations](#).

The following limitations apply to migrating gateway extensions to a v10 DataPower API Gateway.

- Post-request assemblies are not compatible with the API Gateway and cannot be migrated using this process. Pre-request, post-response, and post-error can be migrated using these steps.
- Any modifications to the DataPower v5 Multiprotocol Gateway cannot be migrated using these steps because the API Gateway does not use a Multiprotocol Gateway. The modifications will still be in the `gateway-extension.zip` that is pushed to API Manager, and the artifacts might still be imported to DataPower. These artifacts can be deleted from the DataPower appliance.
- Any load-balancer modifications cannot be migrated using these steps as the load-balancer DataPower object is not used in the same manner in the API Gateway. These artifacts can be deleted from the DataPower appliance.

About this task

You can migrate pre-request and post-response global assemblies contained within v5 extensions to API Gateway using the v5-emulation layer. The migration utility bundles the entire v5 extension file and groups them by gateway service during the `port` step. During the `push` step, the v5 extensions are pushed to the Gateway Service, and pre-hook and post-hook global assemblies are enabled using global policy files that were generated previously during the `port-to-apigw` step. DataPower object modifications or additions that are not v5 framework changes or load-balancer changes are also automatically imported during this step.

Global assemblies that are pre-request or post-response are utilized through the v5-emulation layer as an Assembly Function. They are referenced by the global policy files auto-generated by the migration utility during the `port-to-apigw` step.

Results

The `gateway-extension.zip` file is pushed to the DataPower API Gateway service.

Note: Only one gateway extension per gateway service can be used at a time. However, the manifest extension allows a vector of multiple extensions contained within the single `gateway-extension.zip` that is pushed to the single gateway service.

Migration considerations

You can optimize the migration process by reviewing the migration considerations and taking any actions that apply to your deployment.

Review the following information:

- [Limitations and workarounds](#)
- [Version 5 data that is not migrated](#)
- [Parity between v5 and v10](#)
- [Customizations to recreate](#)

Limitations and workarounds

- When migrating catalog spaces in a provider organization that uses a local user registry (LUR), ensure that the LUR is configured with the visibility setting of either Public or Custom. If set to Custom, ensure that the provider organization is selected.
- Migration of the v5 username token policy for authenticating the username token is not supported.
- In v10, you cannot publish a product containing an API with a `regex` Swagger property that includes the (or ? in the characters for the pattern. You can expect to see an error message similar to the following example:

```
(? The preceding token is not quantifiable
```

- The migration utility validates Products and APIs against the OpenAPI specification (validation is not performed on draft Products and draft APIs). The `archive:unpack` command issues warnings for any Product or API that fails validation. To resolve warnings, fix the Product or API and re-run the `unpack` command. Example warning:

```
WARN[0019] Error validating product cloud/provider-orgs/onlinebanking/catalogs/test/products/clientipfilter-policy-test-api-1.0.0.yml:
Validation errors:
Error validating API cloud/provider-orgs/onlinebanking/catalogs/test/products/api123-1.0.0.api.yml
- Must validate one and only one schema (oneOf) (context: (root).securityDefinitions, line: 36, col: 3)
- securityDefinitions.authorizationUrl Does not match format 'uri' (context: (root).securityDefinitions.authorizationUrl, line: 0, col: 0)
```

- OAuth Provider APIs:
 - To ensure that APIs that use OAuth security definitions are mapped to the corresponding OAuth Provider APIs in v10, make sure that either the Authorization URL or the Token URL defined in OAuth Security Definitions of APIs that use OAuth correctly point to the base path of the OAuth Provider API. Note that the Migration tool uses that logic to map Consumer APIs to Provider APIs, and adds `x-ibm-oauth-provider` in the OAuth Security Definition of the consumer API.
 - To verify whether OAuth Provider APIs are migrated correctly, ensure that all the APIs that use OAuth Security Definition have the new field `x-ibm-oauth-provider` added. Check the value of that field and make sure it points to a correct OAuth Provider resource object that was created and configured in the catalog to which the API is published.
 - In v5, OAuth Providers are a specialized type of API that are published within products. In v10, OAuth Providers are first class objects that are directly published in the provider organization and are not APIs that are published within products. Because of this, it is possible that you may have some v5 products that only contained OAuth Provider APIs. Since these products do not contain any Open API definitions in v10, they will not be published as all products in v10 must contain at least one Open API definition.
- Portal Delegated User Registry migration limitations
 - OIDC: Automated migration is not supported for some v5 PDUR OIDC registries and you will see instructions for providing the `client_id` and `client_secret` while mapping the registries.

- LDAP: Automated configuration is not supported for LDAP registries and you will see instructions for configuring them manually while mapping the registries.
- The SCIM (System for Cross-domain Identity Management) user registry type was supported in Version 4 but was deprecated for Version 5 and is not supported in v10. If data with a SCIM identity provider type is detected during migration of v5 data, the migration utility logs the following error message:

```
WARN[0614] manual fix required for cloud/provider-orgs/apimteam/user-registries/scimcv/user-registry.yml :
The SCIM user registry type is no longer supported
```

Any v5 data with a SCIM identity provider type must be manually migrated. For v10, you can use OIDC with a back-end user registry that supports SCIM. You must develop custom code to complete the data flow between the OIDC provider and your backend user registry. The API Connect built-in OIDC registry interacts with your OIDC provider.

- Roles limitations

In API Connect v5, it was possible to create a role (and associated permissions) at the organization level and the role was inherited by the catalogs within the organization. With the v5 inheritance model it was possible to modify the inherited role and add or remove permissions.

In API Connect v10 the inheritance model has changed and it is no longer possible to remove permissions from an inherited role. Because of this design change, it becomes difficult to perform a true 1-to-1 migration keeping the original parent-child relationships. For example, in v5 it was possible for an inherited role to contain fewer permissions than its parent role, but this is not supported in v10. To work around this restriction, the parent-child relationship is purposely decoupled during migration, and a new artificial parent role is created for each of the child roles.
- Modifications made to default roles in v5 are not migrated to v10.
- If the v5 settings `server_name_indication` and `limit_renegotiation` are not specified, the value defaults to `true`. However if they are specified with value of `false` that value is changed to `true`. Thus the settings are always `true`.
- Subscriptions on staged products are not automatically migrated because in v10, staged products cannot have subscriptions on them. To save those subscriptions, change the state of the product to either deprecated or published before running the `archive:push` command to upload data to v10. You can do this either in v5 before downloading your data, or in by mapping or editing the downloaded product metadata and to change the state of the product. If you have already pushed the staged product, then you can publish the product in your v10 environment and rerun `archive:push` to migrate the subscriptions.
- The migration utility appends `-apigw` to the end of the `x-ibm-name` of APIs to maintain uniqueness from the original v5 artifacts. Therefore, custom backend services that rely on the `x-ibm-name` of the APIs to be matched must be updated to look for `-apigw` in the new API name. Alternatively, the custom backend service can be modified to strip `-apigw` from the API name.
- When migrating default catalog user registries, and migration has completed, you might see more than one catalog User Registry with the same title. Whenever a new catalog is created in v10, API Connect creates a default catalog user registry. When migration takes place, the catalog user registry from v5 is migrated onto the v10 system. Both these registries receive the same Title; however they receive different Names and function as separate user registries (registries are managed by Name, not Title).

Example: If the catalog is called `test`:

- Name of user registry migrated from v5: `test-catalog`
- Name of default user registry created in v10: `test-catalog-0`
- Title of both the user registries: `Test Catalog User Registry`

All the user data is successfully migrated to the user registry coming from v5; manually update the catalog settings to use the migrated v5 user registry as the default. You can optionally clear the default user registry provided by v10 from the list of configured catalog user registries.

If you manually create the catalog and users already exist in the default catalog user registry provided by v10, then both the migrated v5 catalog user registry and the v10 default user registry can coexist, and either of them can be selected as default.

Version 5 data that is not migrated

- APIs with LTPA policies are not migrated because this policy is not supported in v10.
- Configuration in v5 for gateway type `Microgateway` is not migrated because `Microgateway` is not supported in v10.
- Transient or conflicting configuration data is not migrated:
 - Tasks that are still active are not included in the downloaded v5 data; for example, lifecycle approvals or subscription approvals that have been requested but not granted.
 - Drafts on v5 that are local are not migrated. If you have draft APIs or draft products that you want migrated to v10, use `apic:drafts:push` to upload in v5 before you download your v5 data for migration. For more information, see [Working with drafts](#) in the v5 Public Cloud documentation.
 - Pending invitees in user registries are not migrated.
 - Pending invitations for ownership of provider organizations are not migrated; however consumer organizations with pending ownership are migrated. If the v5 provider organization owner received an invitation for ownership but never accepted it, the owner identity is not migrated, which causes the organization to not be migrated. To avoid this issue, check for any unaccepted invitations prior to migration, and ensure they are accepted.
 - Conflicting user names within the same identity provider are not migrated.
 - Conflicting OAuth provider names or base paths are not migrated. If the migration utility encounters conflicting names or base paths for OAuth providers, the provider is not migrated.
- OAuth Shared secret keys are not migrated unless you explicitly [map them in the mapping.yml file for the gateway](#).
- Organizations without an active owner (user identity) are not migrated. One effect of this is that if the original owner of the organization is an identity that was not migrated, the provider organization or consumer organization cannot be migrated. Prevent this issue by verifying that the owner of the organization is a current user.
- Analytics data is not migrated. Analytics data (including searches, visualizations, and dashboards) cannot be migrated due to changes in the Analytics feature. If you want to preserve your event data, you should export it from v5 Public Cloud using either [CSV files](#) or [REST API calls](#) as explained in the v5 Public Cloud documentation.

Parity between v5 and v10

- The migration utility sluggifies (a slug is a human-readable, unique identifier) the names and versions of some elements when migrating from v5 to v10 to ensure that each element in v10 passes Open API schema validation and is uniquely named. The conversion rules differ depending upon which version you are migrating to.
 - **Version 10.0.5.1 and earlier:** For the names of API properties, Catalogs, Provider Organizations, Consumer Organizations, Spaces, and some other elements, any character other than `a-z`, `0-9`, or `-`, is converted to `-` and a unique suffix (based on the checksum of the name or version) is appended. Uppercase letters are changed to lowercase, with `-` added between words. Leading `-` characters are removed, and multiple consecutive `-` characters are reduced to a single `-`. For versions of similar elements, the `.` (period) character is also allowed.

- **Version 10.0.5.2 and later:** For the names and versions of API properties, Products, Consumer Organizations, Space and some other elements, any character other than **a-z, A-Z, 0-9, -, _,** or period (**.**), is converted to **-** and a unique suffix (based on the checksum of the name or version) is appended. Catalog and Provider Organization names follow the same rules, except that they do not support the period (**.**) character. Names or versions with uppercase characters are not converted to lowercase, but a unique suffix is appended to them.

If you are using the latest version 10.0.5.2 or later version of the migration utility, you can use the `--use-old-sluggify` parameter with the `apicm archive:unpack` command to unpack the V5 configuration data onto the local filesystem using the version 10.0.5.1 conversion rules. You can use this option in the following scenarios.

- You are starting a new migration to API Connect v10.0.5.1 with version 10.0.5.2-R4 or later of the migration utility.
- You started the migration using version 10.0.5.1 of the migration utility and have upgraded to version 10.0.5.2-R4 or later.

For more information, see the migration instructions that apply to your deployment.

- [Migration steps with PDUR](#)
- [Migration steps without PDUR](#)

Table 1. Example migrated names on v10

v5 name	Migrated name on v10.0.5.1 or earlier	Migrated name on v10.0.5.2 or later
abc-def	abc-def (no change)	abc-def (no change)
Abc	abc-a2c6	Abc-a2c6
AbcDef	abc-def-dfc	AbcDef-dfc
Abc Def	abc-def-1e82 With <code>sluggify-no-checksum</code> : abc-def	Abc-Def-1e82 With <code>sluggify-no-checksum</code> : Abc-Def
abc_def	abc-def-c2bb	abc_def (no change)
abc--def	abc-def-813d	abc--def (no change)
-abc-def	abc-def-abb	-abc-def (no change)
ABC-DEF	abc-def-d1e	ABC-DEF-d1e

Table 2. Example migrated versions on v10

v5 version	Migrated version on v10.0.5.1 or earlier	Migrated version on v10.0.5.2 or later
1.0.0	1.0.0 (no change)	1.0.0 (no change)
1.0_2	1.0-2-3933	1.0_2 (no change)
1.0 2	1.0-2-913	1.0-2-913
1.0--2	1.0-2-5410	1.0--2 (no change)
-1.0-2	1.0-2-26cf	-1.0-2 (no change)

You can use `apicm sluggify <string>` to view how a name or version string will be sluggified. The following examples are for version v10.0.5.2 or later:

```
$ ./apicm sluggify Abc
Abc-a2c6
$ ./apicm sluggify -v 1.0_2
1.0_2
$ ./apicm sluggify --version '1.0 2'
1.0-2-913
```

- In v10, Spaces are not supported in the Sandbox Catalog. Spaces in Sandbox Catalogs are not migrated from v5 to v10. The names of Spaces found in v5 Sandbox Catalogs are logged in the migration output log. To preserve the Spaces, use a mapping file to rename the Sandbox Catalogs.
- In v10, publishing an API fails if `enforced` is set to `true`, and `phase` is set to either `Specified` or `Identified` instead of `Realized`. During migration, the `phase` will be set to `Realized` to allow the API to be published.
- Enforcement of user subscription to an API is handled differently in v5 and v10. In v5, subscription to a product is not allowed when in the following scenario: An API is created with `enforced` set to `false`, the API is associated with a product, the product is published, and then a user attempts to subscribe to a Product or Plan from the Developer Portal. In v10, the subscription is allowed for this scenario. This change can affect migration because a v5 Product that could not be subscribed to in v5 can be subscribed to in v10. Note that the change in behavior for v10 accommodates the scenario where Products or Plans have multiple APIs, some of which are enforced and some of which are not enforced. The new behavior allows such Products or Plans to be subscribed to.
- In v10, the API Manager handles all authentication methods. This change eliminates the need for configuration of a catalog with a Portal Delegated User Registry (PDUR), so during migration you will map PDURs to v10 standard user registries (see [Migration steps with PDUR](#).)
- If `OpenAPI.info.contact.email` contains more than one email address, only the first email address is migrated. If the email is not in valid RFC5322 email format then it is removed during migration.
- Provider-side applications:
In API Connect, registered applications are a fundamental concept representing an application identity known to the system. Applications have their own credential sets in the form of client ID and client secret pairs, and access to published API endpoints is governed by subscriptions associated with registered applications. Most commonly, registered applications are created by app developers belonging to a consumer organization in the context of a developer portal.

However, API Connect v5 also provides the ability for provider organizations to register and manage applications, independent of any consumer organization. Provider-owned apps behave in the same way as consumer-owned apps and carry credentials and subscriptions in exactly the same way. Customers use provider-owned applications for API testing or for cases where the app and API are owned and managed directly by the same team.

The API Connect v10 platform API does not support the creation of provider-side apps, so migration of provider-side apps is only possible if they are converted to consumer-side apps. Each provider-side app is migrated as follows by the API Connect migration utility:

- An instance of the app including its credentials (sets of client ID and secret) is created in each catalog belonging to the provider organization.
- The app is owned by a consumer organization which is the existing Sandbox Test Organization (for the provider organization's automatically created sandbox catalog) or a consumer organization named `Catalog-name` Test Organization (for other catalogs).
- The consumer organization's owner is a user named `test-user`. This user name already exists in the context of a provider organization's automatically created sandbox catalog.
- The consumer organization's owning user belongs to a user registry named `catalog-name-test-org`.
- The subscriptions belonging to the original provider-side app are retained.

These definitions are added to the relevant locations subordinate to the `cloud/` directory that is produced by the `apicm archive:unpack` command. When an `apicm archive:push` is performed, the definitions are propagated to the target system as part of the overall configuration.

Customizations to recreate

Version 5 provides methods to customize some configurations. After you complete the automated migration, manually reapply the following customizations.

- Customized email templates
Customized email templates are not migrated from Version 5. You can customize email templates in Version 10 with greater flexibility and precision. See [Customizing email templates](#).
- Developer Portal customizations are not migrated to a new Drupal version
For the Developer Portal, none of the customizations are migrated because the v10 Drupal-9 baseline differs greatly from the v5 Drupal-7 baseline. This means that custom portal themes, custom modules, custom fields, custom blocks, custom pages, and more cannot be migrated. For more information, see [Migrating your Developer Portal from Version 5 to Version 10](#).

Migration troubleshooting

If you run migration and observe error messages in your log output, you can take troubleshooting steps, and run the migration again.

Refer to the following sections for information on resolving migration issues:

- [apicm command line help](#)
- [Log files for apicm](#)
- [Common errors](#)
- [Error messages and warnings from archive:unpack](#)
- [Error messages and warnings from archive:push](#)
- [Troubleshooting tips](#)
- [Failure to convert API definitions to API Gateway](#)
- [Custom policies not appearing in the policy palette after migration](#)

apicm command line help

You can use command line help to review usage syntax for `apicm`. For example:

```
./apicm --help
API Connect Migration Utility (AMU)
```

```
Usage:
  apicm [command]
```

```
Available Commands:
  archive:apistatus  Generate stats about API use
  archive:automation Generate summary of the data
  archive:gstats     Generate stats about gatewayscript cmd use
  archive:port-to-apigw Port artifacts to apigw
  archive:push       Push unpacked content to APIConnect server
  archive:unpack     Unpack a V5 management/portal archive
  help              Help about any command
  login             Log in to IBM API Connect
  sluggify          Sluggify a name or version string
  version           APIConnect migration toolkit version
```

```
Flags:
  --accept-license  Accept the license for API Connect
  -h, --help       Help for apicm
```

Use "`apicm [command] --help`" for more information about a command.

Example usage for more information about a command:

```
$ ./apicm archive:push --help
Push unpacked content to APIConnect server
```

```
Usage:
  apicm archive:push CLOUD_MANAGER_ENDPOINT/API_MANAGER_ENDPOINT ARTIFACT_PATH
```

Locate `CLOUD_MANAGER_ENDPOINT` and `API_MANAGER_ENDPOINT` in the `apiconnect-up.yml` file used during `apic install` [flags]

```
Flags:
  --apigw-only          Only attempt to push APIGW artifacts
  --catalog strings    Provide a comma separated list of catalogs to push (e.g. --catalogs=cat1,cat2)
  --dry-run            Prepare the working directory but do not push to server
  -h, --help          help for archive:push
  --no-drafts         No draft APIs or Products will be pushed to the server
  -f, --overwrite     Overwrite draft APIs and products, published APIs and products,
                     and OAuth providers if they exist on the server
  --saveDebugLog string[="default"] Debug logs are saved by default to logs/debug/archive-push<timestamp>debug.log
  --saveErrorLog string[="default"] This flag saves the file with a custom name (e.g. --saveDebugLog=debugLog.txt)
  --saveInfoLog string[="default"] Error logs are saved by default to logs/archive-push<timestamp>error.log/
  --saveInfoLog string[="default"] This flag saves the file with a custom name (e.g. --saveErrorLog=myLog.txt)
  --saveInfoLog string[="default"] Info logs are saved by default to logs/archive-push<timestamp>info.log
  --saveInfoLog string[="default"] This flag saves the file with a custom name (e.g. --saveInfoLog=myLog.txt)
```

```
Global flags:
  --accept-license  Accept the license for API Connect
```

Log files for apicm

The `apicm` command creates log files that you can use to review messages produced by the `unpack` and `push` actions. All logs are saved in the `logs` directory. Unique files are saved for each run. All default log names can be overridden via the command line.

Error log

Includes all warning and error level messages.
Error logs are saved by default to:

- `logs/archive-unpackerror.log/`
- `logs/archive-pusherror.log/`
- `logs/archive-port-to-apigwerror.log/`

You can optionally give the file a different name:

```
apicm --saveErrorLog= '<filename>'
```

For example:

```
apicm archive:unpack apic33-2020-02-19-1650.tar.gz --saveErrorLog= 'unpack.txt'
```

This command creates a file `unpack.txt` in the logs directory:

```
~/example/migration-cli/logs/unpack.txt
```

Info Log

Includes all info, warning and error level messages.
Info logs are saved by default to:

- `logs/archive-unpackinfo.log/`
- `logs/archive-pushinfo.log/`
- `logs/archive-port-to-apigwinfo.log/`

You can optionally give the file a different name:

```
apicm --saveInfoLog= '<filename>'
```

For example:

```
apicm archive:unpack apic33-2020-02-19-1650.tar.gz --saveInfoLog= 'unpack_info.txt'
```

This will create a file `unpack_info.txt` in the logs directory:

```
~/example/migration-cli/logs/unpack_info.txt
```

Default path for info logs?

Debug Log

Includes all info, warning, error and debug level messages. If you encounter errors or limitations that are not documented on this page, access the debug log.
Debug logs are saved by default to:

- `logs/debug/archive-unpackdebug.log`
- `logs/debug/archive-pushdebug.log`
- `logs/debug/archive-port-to-apigwdebug.log`

Contact your IBM representative for help with using the Debug log.

Common errors

You can use the `--saveErrorLog` flag to specify that all the errors are saved in a file in `logs` folder, as described in [Saving the error log](#). Common errors:

- Long chain of error messages hours into a `push`:
This scenario typically occurs due to expiration of an authentication token. To resolve this issue, either reauthenticate and or extend the token timeout. See [Token expiration](#).
- Unable to find User Registry when migrating (pushing) a provider-org:
Occurs when the `admin-org` user registry artifacts are not shared prior to pushing provider organization artifacts. To resolve the issue, use the cloud admin account to change the visibility of the registry to `public`, and `push` the provider organization again.
- Unable to find `xxxx` when migrating (pushing) a provider organization:
Occurs when `admin-org` artifacts are not pushed prior to pushing provider organization artifacts. Ensure that all of admin org data is pushed without errors, and then `push` your provider organization again.
- Unable to create an identity provider portal-delegated-identity-provider `xxxx` because the PDUR backup data is not provided.
This error occurs if certain Portal delegated user registries are missing from the PDUR extract provided. If the missing user registries are not no longer used, they can be skipped. If they are still used, you must create a fresh backup of the PDUR.
- Unable to create product `xxxx`. The OpenAPI definition `<xyz>` requires the policy `<sample-policy>` that is not configured on the gateway-service `<sample-gateway>`:
This error occurs when the specified policy is not configured on the gateway for the catalog that contains the product. To resolve this, you must configure, on the v5 system, the specified policy on the gateway for the catalog, and re-extract the data.
- Fixing API Errors
Example:

```
WARN[2002-01-10T15:06:16-05:00] AMUUAU005W: product oauth-apis:1.0.0 requires updating before it can be pushed to a target system
Reason: product oauth-apis:1.0.0 includes content with validation errors:
Error validating API cloud/provider-orgs/onlinebanking/catalogs/oauthcatalog/products/api050-1.0.0.api.yml
- Must validate one and only one schema (oneOf) (context: (root).securityDefinitions, line: 35, col: 3)
```

```
- securityDefinitions.authorizationUrl Does not match format 'url' (context:
(root).securityDefinitions.authorizationUrl), line: 0, col:0)
```

For example, where the issue is in the API:

```
securityDefinitions:
  ClientID:
    in: query
    name: client_id
    type: apiKey
  OAuthDef:
    authorizationUrl: ""
    description: ""
```

- v5 emulated policies and custom policies not deployed to gateway. Make sure the following was done during the migration steps:
 - xml-manager is enabled in default domain of all gateways
 - Mapping of gateways was done before the porting step
 - gateway-extension.zip shows up under cloud/admin-org/availability-zones/availability-zone-default/gateway-services/<gw-name>/gateway-extension.zip
 - Ensure push of admin-org is done after all of the above is verified
- Missing Subscriptions
One of the causes for missing subscriptions could be that the products associated with those subscriptions have not been created successfully. Make sure to check the logs and see if there have been any errors during creation of those products. Please also note in these cases there would be no logs related to those missing subscriptions.

Error messages and warnings from archive:unpack

"AMUUAU000E": "The migration tool failed to initialize."

The migration utility could not access files or directories needed to establish its working environment. Ensure that file permissions allow write access to the current working directory and that the cloud directory is empty or non-existent.

"AMUUAU001E": "The {{.Type}} {{.Name}} contains content that could not be unpacked and will not be included."

The migration utility is unable to read the API Connect v5 representation of an object in the migration archive. This content is skipped and will not appear in the unpacked migration data.

"AMUUAU002F": "The archive content at {{.DocPath}} cannot be read."

The migration utility is unable to read the internal contents of a collection in the API Connect v5 migration archive. This is likely to indicate a corrupt migration archive file. The archive:unpack operation cannot be completed.

"AMUUAU003E": "The portal delegated user registry file {{.File}} cannot be unpacked and will be skipped."

The migration utility is unable to read a PDUR archive. User information associated with this user registry will not be included in the unpacked migration contents.

"AMUUAU004E": "The archive content at {{.FilePath}} cannot be read and will not be unpacked."

The migration utility is unable to read the internal contents of an individual file in the API Connect v5 migration archive. This is likely to indicate a corrupt migration archive file. This content is skipped and will not appear in the unpacked migration data.

"AMUUAU005W": "{{.Type}} {{.Name}} requires updating before it can be pushed to a target system."

The migration utility has unpacked a configuration object for which modifications are required because the content is incorrect or missing information required by a target API Connect v10 system. The unpacked file must be updated by the user before it can be published successfully to the target system.

"AMUUAU006W": "The {{.Type}} {{.Name}} has been linked to OAuth provider {{.Provider}}. Please update the security definition {{.Security}} if another OAuth Provider should be used instead."

The migration utility has added a reference from an OAuth security definition in the named API to an OAuth provider resource. The migration utility uses the authorization URL, token URL and scope information where possible to determine which OAuth provider resource is to be used with each OAuth-secured API. In some cases, the migration utility cannot accurately determine which OAuth provider is intended for use with a particular API. The OAuth provider reference can be modified if needed by editing the security definition in the unpacked API file and changing the x-ibm-oauth-provider property value to match the intended OAuth provider resource. The reference value is a relative file path that identifies an unpacked OAuth provider resource.

"AMUUAU007W": "The {{.Type}} {{.NameVersion}} could not be linked to an OAuth provider. Please update the security definition {{.Security}} to select an OAuth provider."

The migration utility has been unable to add a reference from an OAuth security definition in the named API to an OAuth provider resource.

The migration utility uses the authorization URL, token URL and scope information where possible to determine which OAuth provider resource is to be used with each OAuth-secured API. In some cases, the migration utility cannot accurately determine which OAuth provider is intended for use with a particular API. The OAuth provider reference can be added by editing the security definition in the unpacked API file and setting the x-ibm-oauth-provider property value to match the intended OAuth provider resource. The reference value is a relative file path that identifies an unpacked OAuth provider resource.

"AMUUAU008W": "{{.Type}} {{.Name}} could not be introspected for OAuth provider API references."

The migration utility has attempted to determine which OAuth providers should be configured in support of an API product, but a reference to an OAuth provider API in the product cannot be correlated with an OAuth provider resource.

"AMUUAU009W": "{{.Type}} {{.Name}} contains invalid content that cannot be unpacked."

The migration utility has encountered an entry in the API Connect v5 migration archive that contains unexpected or corrupt data. This content is skipped and will not appear in the unpacked migration data.

"AMUUAU010E": "{{.Type}} {{.Name}} cannot be unpacked to the local filesystem."

The migration utility has attempted to unpack an entry in the API Connect v5 migration archive that could not be written to the local filesystem during the archive:unpack operation. This may be the result of a local file permissions problem, an unexpectedly long file name resulting from the unpack, or a shortage of space on the local filesystem.

"AMUUAU011E": "{{.Type}} {{.Name}} contains a {{.Target}} reference that cannot be resolved."

The migration utility has encountered a SOAP API entry in the API Connect v5 archive that refers to a WSDL definition that cannot be found in the archive. This entry will not be included in the unpacked content.

"AMUUAU012W": "The {{.Type}} {{.Name}} contains a {{.Target}} reference that cannot be resolved."

The migration utility has encountered an entry in the API Connect v5 archive that refers to another entry that cannot be found in the archive. This entry will not be included in the unpacked content.

"AMUUAU013E": "Portal delegated user registry information could not be loaded for user registry {{.Name}}.
The migration utility has encountered a portal delegated user registry definition in the API Connect v5 archive for which no PDUR file name has been provided as an argument to the archive:unpack command. The user registry contents will not be included in the unpacked content.

"AMUUAU014E": "The migration tool failed to load content for the admin organization."
The migration utility was unable to find the admin organization while unpacking provider organization information in the API Connect v5 archive. This is likely to result in further errors while unpacking the provider organization contents.

"AMUUAU015E": "The migration tool failed to load provider organization contents."
The migration utility was unable to find the load provider organization contents while unpacking the API Connect v5 archive. This message indicates an internal error with the migration utility.

"AMUUAU016E": "The {{.Type}} information belonging to organization {{.Org}} could not be unpacked."
The migration utility was unable to process the provider organization contents while unpacking the API Connect v5 archive. This message indicates an internal error with the migration utility.

"AMUUAU017W": "The settings update for {{.Type}} {{.Name}} could not be completed."
The migration utility was unable to update the settings for a configuration object while unpacking the API Connect v5 archive.

"AMUUAU018E": "Apps belonging to provider organization {{.Org}} could not be converted to consumer apps."
The migration utility was unable to convert registered applications belonging to the provider organization into applications in each catalog. The conversion occurs because the representation of applications differs between API Connect v5 and API Connect v10. This message indicates an internal error in the migration utility.

"AMUUAU019W": "User registry {{.UserRegistryName}} must be migrated to a different user registry type."
The migration utility has encountered a user registry in the API Connect v5 migration archive that is not directly supported in API Connect v10. User entries can be migrated if a mapping file is used to override the user registry name and refer to another user registry that has been created in the target API Connect v10 environment.

"AMUUAU020W": "User {{.User}} in portal delegated user registry {{.Registry}} is not associated with any OIDC provider and will be skipped."
The migration utility has encountered a user entry in the API Connect v5 migration archive that belongs to a portal delegated user registry but cannot be associated with any backing identity provider. This can occur if no PDUR export file has been provided, or if the user entry information is incomplete.

"AMUUAU021W": "The TLS profile {{.Name}} includes an unsupported protocol {{.Protocol}} that will not be included in the configuration."
The migration utility has encountered a TLS profile entry in the API Connect v5 migration archive that uses a protocol that is not supported in the API Connect v10 environment. This protocol will be omitted from the unpacked entry for the TLS profile.

"AMUUAU022W": "User {{.UserName}} ({{.ID}}) will need a password reset"
The migration utility has encountered a user entry in the API Connect v5 migration archive that is associated with a local user registry but does not have a password configured. The user entry will be migrated, but the user's password reset must be reset before logging in. This may occur when user registry mappings are used to migrate users to a local user registry from some other user registry type.

"AMUUAU023W": "Uniqueness of names cannot be guaranteed when using the --sluggify-no-checksum option during unpack"
For v10.0.5.1 and earlier: The archive:unpack command has been invoked with an option that could in unusual cases result in duplicate names being used for different unpacked entries. This is likely only for names with near-identical spelling but differ only in their use of upper and lower case letters or symbols that are converted to a hyphen during the unpack process. If duplicate names appear for entries of the same type in the same context, further messages indicating problems with the duplicate will appear.
For v10.0.5.2 and later: If the migration utility is run on Windows or on Mac OS in a case-insensitive partition, additional errors may occur because of duplicate file names such as `name-1.yml` and `Name-1.yml`, which would be considered to be the same file.

"AMUUAU024E": "The stats summary could not be generated"
The migration utility was unable to produce information listing the total numbers of entries of different types that were unpacked from the API Connect v5 migration archive. This message indicates an internal error in the migration utility.

"AMUUAU025I": "The {{.Type}} {{.Name}} contains an invalid value that will be removed."
The migration utility has encountered an entry in the API Connect v5 migration archive that contains a value that is not valid for the property in which it appears. The invalid value is automatically removed. This can occur with values such as email or URL properties that contain values that do not match the required format.

"AMUUAU026I": "The {{.Type}} {{.Name}} contains an invalid value that will be replaced."
The migration utility has encountered an entry in the API Connect v5 migration archive that contains a value that is not valid for the property in which it appears. The invalid value is automatically corrected. This can occur with values such as email or URL properties that contain values that do not match the required format.

"AMUUAU027W": "The product subscription {{.Name}} cannot be pushed to the target system."
The migration utility has encountered a subscription entry in the API Connect v5 migration archive that refers to a product that is in a state that does not allow subscriptions. The subscription is removed and will not appear in the unpacked data.

"AMUUAU028E": "The migration tool failed to create default roles for {{.Type}} {{.Name}}."
The migration utility has encountered an error while attempting to create the default roles for an organization, catalog, or space. This may be the result of a local file permissions problem or a shortage of space on the local filesystem.

"AMUUAU029W": "The OAuth provider {{.OAuthProvider}} with base path {{.BasePath}} could not be unpacked."
The migration utility has failed to create an OAuth Provider with a particular base path. This can occur if there is an OAuth provider of this name with a different base path that has already been created in this provider organization. In API Connect v5, OAuth providers existed at the catalog level. In API Connect v10, they exist at the provider organization level, which can cause this issue to occur.

Error messages and warnings from archive:push

"AMUAP001E": "The {{.Type}} {{.Name}} contains nested content that cannot be published."
The migration utility is unable to read or load nested configuration content during the archive:push operation. After the migration unpack has been completed, some configuration objects are comprised of a directory with one or more nested files. For example, information about catalogs in their unpacked form consists of a directory with a name matching the catalog name, and a nested `catalog.yml` and `catalog-settings.yml` file. This message indicates that one or more of these files cannot be opened or loaded.

"AMUAP002E": "The {{.Type}} {{.Name}} cannot be published."
The migration utility is unable to read or load configuration content during the archive:push operation. This message indicates that the file representing the named configuration object is unreadable or contains unexpected content.

"AMUAP003W": "Skipping mapping file {{.Name}}."
The migration utility found a mapping file (`mapping.yml`) with invalid contents. The archive:push operation proceeds as if this mapping file were not present.

"AMUAP004E": "The file {{.Filepath}} could not be loaded and will not be published."
The migration utility is unable to read or load configuration content during the archive:push operation. This message indicates that the file representing a configuration object cannot be read or loaded.

"AMUAP005E": "The file {{.Filepath}} contains references that could not be loaded and will not be published."
The migration utility is unable to read or load configuration content during the archive:push operation. This message indicates that the file representing a configuration object cannot be read or loaded.

"AMUAP006E": "Unable to update reference to {{.Path}} in file {{.File}}."
The migration utility is unable to resolve a reference in the named file to another configuration object. This message indicates that the content in the file refers to other objects that are not found in the unpacked content, or the referenced content is not of the expected format.

"AMUAP007E": "The {{.Type}} {{.Name}} cannot be published because of a missing prerequisite."

The migration utility is unable to publish the named object because it refers to another object that cannot be found in the target API Connect system. This message indicates that the object contains an incorrect reference, or that the referenced object has not been successfully created or has been deleted from the target system.

"AMUAP008W": "The update to the {{.Type}} {{.Name}} could not be verified and may not have been successful."

The archive:push operation has attempted to update an object in the target API Connect system, but the results of the update were not received or indicated an error. This can occur in the event of a network interruption or timeout between the migration utility and the target API Connect system. If this occurs, it is safe to retry the archive:push operation; the same update will be attempted.

"AMUAP009E": "The {{.Type}} {{.Name}} was not published because it could not be checked in the target system."

The migration utility has attempted to check the existence of an object in the target API Connect system, but the check did not complete successfully. The migration utility will not overwrite objects in the target system if it cannot successfully determine whether or not a conflict will occur.

"AMUAP010W": "The creation of the {{.Type}} {{.Name}} could not be verified and may not have been successful."

The migration utility has attempted to create an object in the target API Connect system, but the results of the creation were not received or indicated an error. This can occur in the event of a network interruption or timeout between the migration utility and the target API Connect system. If this occurs, it is safe to retry the archive:push operation; if the named object was created, then it will subsequently be skipped unless the overwrite option is used.

"AMUAP011W": "The deletion of the {{.Type}} {{.Name}} could not be verified and may not have been successful."

The migration utility has attempted to delete an object in the target API Connect system, but the results of the deletion were not received or indicated an error. This can occur in the event of a network interruption or timeout between the migration utility and the target API Connect system. If this occurs, it is safe to retry the archive:push operation.

"AMUAP012W": "The ownership transfer of the {{.Type}} {{.Name}} could not be verified and may not have been successful."

The migration utility has attempted to transfer ownership of an object in the target API Connect system, but the results of the ownership transfer were not received or indicated an error. This can occur in the event of a network interruption or timeout between the migration utility and the target API Connect system. If this occurs, it is safe to retry the archive:push operation.

"AMUAP013E": "The endpoint settings for catalog {{.Name}} could not be updated."

The migration utility has attempted to update the endpoint settings for a catalog in the target API Connect system, but the update was not successful. This can occur if the catalog settings refer to a gateway service for which the configuration cannot be found in the unpacked migration contents.

"AMUAP014E": "The {{.Type}} {{.NameVersion}} could not be {{.Action}} in the target system."

The migration utility has attempted to create or modify an object in the target API Connect system, but the target system returned an error. The reason associated with the message indicates the error returned by the server.

"AMUAP015E": "The gateway extension for the gateway service {{.Name}} could not be published."

The migration utility has attempted to publish a gateway extension zip to the target API Connect system, but the target system returned an error. The reason associated with the message indicates the error returned by the server.

"AMUAP016W": "The {{.Type}} for the gateway service {{.Name}} could not be updated."

The migration utility has attempted to update the OAuth shared secret or SNI items for a gateway service in the target API Connect system, but an OAuth shared secret or SNI items were previously set. The migration utility will not overwrite an OAuth shared secret or SNI items that have already been set.

"AMUAP017W": "The product {{.NameVersion}} could not be validated and may contain errors."

The migration utility has attempted to validate a product before publishing, but the validation operation did not complete successfully. If validation errors are present in the product file, then the publish to the target API Connect system will not be successful.

"AMUAP018W": "The product {{.NameVersion}} contains API {{.APIName}} that could not be validated and may contain errors."

The migration utility has attempted to validate the APIs in a product before publishing, but the validation operation did not complete successfully. If validation errors are present in the API file, then the publish to the target API Connect system will not be successful.

"AMUAP019W": "The product {{.NameVersion}} contains validation errors: {{.Errors}}"

The migration utility has validated the content of a product before publishing, and the validation revealed errors in the product file contents. The product cannot be published to the target API Connect system unless the validation errors in the product file are corrected.

"AMUAP020W": "The product {{.NameVersion}} contains an API {{.APINameVersion}} with validation errors: {{.Errors}}"

The migration utility has validated the content of a product and its associated APIs before publishing, and the validation revealed errors in the API file contents. The product cannot be published to the target API Connect system unless the validation errors in the API file are corrected.

"AMUAP021W": "The product {{.NameVersion}} contains API content that could not be updated."

The migration utility has attempted to update the state of an API in the named product, but the metadata file (*.api.meta.yml) containing extra API attributes could not be read or contained unexpected content.

"AMUAP022W": "Subscription {{.Name}} will not be published."

The migration utility has encountered a subscription for which the subscribed product cannot be found. The subscription cannot be created in the target API Connect system.

"AMUAP023W": "The user registry {{.Name}} cannot be published."

The migration utility has encountered a user registry object that cannot be published to the target API Connect system. This can occur for user registry types that may appear in an API Connect v5 system but are not directly supported in API Connect v10. A mapping file in the unpacked user registry directory may be used to identify an alternative user registry into which user entries can be migrated.

"AMUAP024I": "Subscriptions for the product {{.NameVersion}} will not be published."

The migration utility has encountered a product that contains no subscribable APIs. This can occur when a product originating in API Connect v5 contains one or more OAuth provider APIs, and no REST or SOAP APIs. OAuth provider APIs are converted to OAuth provider resources by the archive:unpack operation, and do not appear as APIs in API Connect v10. OAuth provider instances in API Connect v10 use subscription information associated with the REST or SOAP APIs that refer to the OAuth provider in a security definition.

"AMUAP025E": "Non-fatal errors were found while running the preflight check: {{.Errors}}"

The migration utility encountered a non-fatal error during its preflight check before the start of **archive:push**. The details of any of these errors will be reported back here and the **archive:unpack** will continue.

Troubleshooting tips

- The migration utility may have issues when running across a VPN. The connection might fail if you use a corporate VPN to attempt to access an API Connect subsystem (API Manager UI) located behind an internet firewall. To work around this problem, add the IP addresses of the API Connect management server and API manager to your local /etc/hosts.
- Token expiration: By default, the **apicm** login token expires after eight hours. If the token expires while **apicm archive:push** is running, **apicm** generates errors due to lack of the necessary access permissions. In this case, log in again and re-run **apicm archive:push**. (The token is refreshed every time you log in.) Optionally, you can extend the token expiration time when logging in as the admin user:

```
apicm login --expireHours=<number_of_hours>
```

The **expireHours** flag overrides the default authentication token expiration of 8 hours. Use this flag when pushing data sets that take longer than 8 hours to complete. Note that the revised value persists after the session ends. Best practice is to revert the value to the default (8 hours) after migration.

- If your prior migration created an incorrect artifact on v10, you may have to manually remove the artifact before re-running migration. If you use the `--overwrite` flag when running additional `archive:push` commands, existing OAuth Providers, draft products, draft APIs, and published products and their APIs will be overwritten.
- When you re-run migration, the utility will not recreate any artifacts that already exist on v10 unless the `--overwrite` flag is used for OAuth Providers, draft products, draft APIs, and published products and their APIs. If a collision occurs for other artifacts or if the `--overwrite` flag was not used, the older artifact takes priority. Also, the utility will not delete any artifacts from v10. Thus, you can re-run migration to cover any gaps in artifact creation on v10 without affecting existing artifacts.
- The steps you need to take depend on whether you need to change the v5 export data. For example, if you need to publish or replace a v5 API, you need to export the v5 data and run `unpack` again. If you do not need to change the v5 data, you can skip those steps.

Example 1: Re-using the v5 export data

For example, your v5 export data is accurate and current, but you migrated a consumer-org that is no longer needed on v10, and you mapped a catalog to an incorrect name. Complete the following steps:

1. Delete the incorrect artifacts from the v10 deployment `/cloud` directory. For this example, delete the unneeded consumer-org and the incorrectly named catalog.
2. Edit the contents of the `/cloud` directory as needed. For example, remove the unneeded consumer-org entry.
3. Edit your mapping entries as needed. For example, remap the catalog name.
4. Run `apicm archive:push <server> <project_directory>`.

Example 2: Revising v5 export data

In this example your v5 export data is not current because you want to publish or replace a v5 API and then migrate it to v10. Complete the following steps:

1. On v5, recreate the export data: `config dbextract sftp <host_name> user <user_name> file <path/name>`
2. On v10, delete the `/cloud` directory.
3. Run `apicm archive:unpack` to create the v10 hierarchy in `/cloud` directory.
4. Recreate any edits you made to the `/cloud` directory.
5. Recreate any mappings.
6. Run `apicm archive:push <server> <project_directory>`.

Failure to convert API definitions to API Gateway

When you change gateway types from DataPower Gateway (v5-compatible) to DataPower API Gateway, you use `./apicm archive:port-to-apigw <path>` to convert API definitions to API Gateway format. The conversion requires Node version 18.19.1 or greater. If Node is not installed, this error is displayed:

```
ERRO[0000] Error getting node version: exec: "node": executable file not found in $PATH
```

If an unsupported version of Node is installed, an error is displayed as in the following example:

```
ERRO[0000] Node version installed must be >=18.19.1. Currently installed version: 4.9.1. Use the --allow-older-node flag to allow the use of an older node 18 version at the users own risk.
```

To resolve the error, install Node and re-run the command. If you are on an older version of node 18 you can re-run the command using the `--allow-older-node` flag but you do this at your own risk.

To view the conversion step, see [Migration steps without PDUR](#) or [Migration steps with PDUR](#). For information about the conversion, see [Reviewing APIs converted to DataPower API Gateway](#).

Custom policies not appearing in the policy palette after migration

If you are migrating to v10.0.1.3 or earlier, or v10.0.2.0 or earlier, follow these steps to have custom policies appear in the policy palette in the API Manager Assembly UI.

1. Open `gateway-extension.zip` in the `cloud/admin-org/.../<gateway-service>` folder that is generated in `admin-org` after `port-to-apigw` is run.
2. Open the `manifest.json` file.
3. Edit the `manifest.json` file to specify the implementation files for the custom policies to push to the sandbox catalog. Add entries for the sandbox catalog for all provider-orgs using the format `<provider-org>_<catalog-name>`. The filename can remain the same for each respective provider-org, as it will be the same custom policy. Ensure that the actual file that the filename is pointing to in the `.zip` file exists. The same filename can be re-used multiple times in the `manifest.json` to add the sandbox entries for the custom policy. Only the `manifest.json` must be edited. You do not need to edit any of the `.zip` files in the `gateway-extension.zip` package.
4. Save the `manifest.json` file and zip it.
5. If the `archive:push` was already performed before step 1, then delete the `gateway-extension.zip` file from the gateway using the API Connect toolkit command `apic gateway-extensions:delete`.
6. Push `admin-org`, which pushes the updated `gateway-extension.zip` file.
7. Follow these steps to ensure that the API Manager advertises the custom policy that is being pushed.
 - a. In each of the provider orgs in the cloud folder, navigate to the `catalog-scoped-staging` folder and log in to the API Connect toolkit as a provider-org user.
 - b. Run this command on every `.zip` file that you want to appear in the policy palette in the v10 UI:

```
apic policies:create -c sandbox --configured-gateway-service -o -s $API_SERVER_URL --scope catalog .zip
```

The `gateway-service` name is under Topology. `$API_SERVER_URL` is the same one you use to log in to the API Connect toolkit. The custom policy zip filename will appear in the `catalog-scoped-staging` folder.

8. Navigate to the API Manager UI and check the assembly policy palette. The custom policies should now appear in the list. You do not need to push the provider orgs.

If you are migrating to v10.0.1.4 or later, v10.0.3.0 or later, follow these steps to have custom policies appear in the policy palette in the API Manager Assembly UI.

1. After the migration of `admin-org` and `provider-orgs` has completed, navigate to the API Manager UI.
2. While editing a draft API, click the gear icon next to the offline button. A pop-up should appear.
3. Select the `target-catalog` to publish the draft API to. The `target-catalog` must already have the custom policies pushed to it.
4. Select the Application to use for the API.

5. Click Save.
6. Navigate to the Assembly policy palette. The custom policies for that specific target-catalog should now appear. For more details about these steps, see [Specifying the testing preferences for an API](#).

When artifacts such as provider org, space or catalog are mapped, any warning or error messages for artifacts in subdirectories underneath those may have the location incorrect. The location will include the mapped artifact location instead of the original location.

Migrating v5-compatible APIs to API Gateway

Use the migration utility to automate the migration of v5-compatible APIs to DataPower API Gateway APIs.

About this task

If your deployment includes v5-compatible APIs, they can only be used with the DataPower v5-compatible Gateway (also known as the v5c gateway). To use the v5-compatible APIs with the DataPower API Gateway, you must migrate the APIs to the newer format.

The migration process involves the following tasks:

1. Install and configure the required version of API Connect and migration tools.
 2. Plan and test your migration to ensure all tools work as intended.
 3. Use the API Connect operations tool (**apicops**) to extract API data from your v10.0.5.4 (or later) deployment.
 4. Use the API Connect migration utility (AMU) to unpack the data into YML files for porting to the newer format.
 5. Review the unpacked data and port the v5-compatible APIs to the format required by the DataPower API Gateway.
 6. Use the AMU to load the ported APIs back into your v10.0.5.4 (or later) deployment.
- [Preparing the environment](#)
Install all of the required applications before attempting to migrate v5-compatible APIs to the DataPower API Gateway.
 - [Planning your migration](#)
Plan how you will migrate your v5-compatible APIs and then test the process.
 - [Downloading and extracting the data to migrate](#)
Use **apicops** to download data from API Connect, and then use the AMU to extract the data from the downloaded archive.
 - [Converting v5-compatible API definitions](#)
To convert v5-compatible APIs to the format required by the DataPower API Gateway, you must map all v5-compatible gateway services to DataPower API Gateway services, optionally specify any configuration settings to be used in the conversion, and use the AMU to port the API definitions.
 - [Pushing custom policies and gateway extensions to the DataPower API Gateway](#)
Use the AMU to push the Cloud Manager admin organization's data to the Management server, which pushes custom policies and gateway extensions to your DataPower API Gateway Services.
 - [Pushing provider organization data](#)
Use the AMU to push the provider organization data to the Management server.

Preparing the environment

Install all of the required applications before attempting to migrate v5-compatible APIs to the DataPower API Gateway.

About this task

Migrating v5-compatible APIs to the DataPower API Gateway requires the following applications:

- API Connect v10.0.5.4 or later
- API Connect operations (**apicops**) tool, latest v10 release
- API Connect migration utility (AMU), release v10.0.5.5-R0 or later
- Node version 18.19.1 or later

Complete the following steps to set up your environment with the required applications:

Procedure

1. Upgrade to API Connect v10.0.5.4 or later.
Your API Connect deployment must be at 10.0.5.4, or a later version of 10.0.5.5. Refer to the upgrade instructions in the [Installing and maintaining IBM API Connect](#) section.
2. Download and configure the latest release of the **apicops** tool.
Download the **apicops** binary for your operating system from GitHub at [latest release](#) and rename the file to apicops.

Review the associated [README](#) for requirements and instructions for using the tool.
3. Download the migration utility v10.0.5.5-R0 or later.
The API Connect migration utility (AMU) is available from [IBM Fix Central](#). On Fix Central, set the Install version to 10.0.5.4 (or a later version of 10.0.5.x) and search for the text "migration" to locate the AMU.
4. Install Node version 18.19.1 or later.

What to do next

After you have installed the required applications for your environment, complete the following tasks to migrate your v5c-compatible APIs.

Planning your migration

Plan how you will migrate your v5-compatible APIs and then test the process.

About this task

Plan the migration process, migrate a small set of APIs, and then test the results. You can refine settings and repeat the process as needed.

Procedure

1. Review all of the migration topics to ensure you understand the requirements, the general process, and important considerations.
2. Plan how you will migrate your v5-compatible APIs to the DataPower Gateway.
Make sure you know exactly which APIs you want to migrate, and in which provider organizations and catalogs they are stored.
3. Migrate a proof-of-concept deployment.
Migrate 10 to 20 of your most commonly used v5-compatible APIs to ensure that your migration tools are configured correctly and the migration process works as intended. Plan to run several test iterations of migration.

You can use the migration utility's `--dry-run` option to perform iterations of the migration push without actually uploading data to API Connect. The test runs offer an opportunity to test for errors and warnings that need to be resolved before you perform the actual data push.

You can use the migration utility's `--move-subscriptions` parameter to move subscriptions during the push operation that uploads converted data back into API Connect.

4. Test the APIs that you migrated as proof-of-concept.
Testing the migrated APIs helps you to determine which migration utility settings you need for successfully converting the v5-compatible APIs to DataPower API Gateway. If needed, you can move or delete the results, modify the configuration settings, and run the migration again. When you rerun the migration `port` command using the same target folder for output, the utility skips artifacts that have already been converted to DataPower API Gateway.

Downloading and extracting the data to migrate

Use `apicops` to download data from API Connect, and then use the AMU to extract the data from the downloaded archive.

Procedure

1. Use `apicops` to extract and download data from API Connect as a `.pgdmp` archive file.
Run the following command:

```
apicops postgres:pg_dump -e <archive_name>.pgdmp
```

where `<archive_name>.pgdmp` is a name that you create for the archive file that will contain the downloaded data; for example, `v10_backup.pgdmp`.

2. Copy the `.pgdmp` archive file to the location where you installed the AMU, storing it in the same directory as the AMU.
3. Use the AMU to unpack the archive stored in the `.pgdmp` archive file.
Run the following command in the same directory where you stored the downloaded `.pgdmp` archive file (see Table 1 for available the parameters):

On Windows: open a command window with Administrator privileges, and omit the `./` from the command.

```
./apicm archive:unpack-v10 <archive_name>.pgdmp
```

The first time you use the AMU, you are prompted to accept the license. You must accept the license to continue.

Table 1. AMU `archive:unpack-v10` parameters

Parameter	Description
<code><archive_name>.pgdmp</code>	Required. The <code>.pgdmp</code> archive file created containing the data downloaded from API Connect.
<code>--provider-orgs</code>	Optional. A comma-separated list containing one or more provider organization names. Use this parameter to unpack only the data for the specified provider organizations instead of unpacking the entire archive. Example: <pre>./apicm archive:unpack-v10 <archive_name>.pgdmp --provider-orgs=<pOrg1_name>,<pOrg2_name>,<pOrg3_name></pre>

When the command completes, the data is unpacked to the `/cloud-v10` directory, which is located in the same directory as the AMU, and is populated with YAML files representing the configuration objects in the `.pgdmp` file.

Important: The unpack directory must be named `/cloud-v10`. Do not rename the directory.

Converting v5-compatible API definitions

To convert v5-compatible APIs to the format required by the DataPower API Gateway, you must map all v5-compatible gateway services to DataPower API Gateway services, optionally specify any configuration settings to be used in the conversion, and use the AMU to port the API definitions.

Procedure

1. Map your v5-compatible Gateway Services to DataPower API Gateway services.
You must map your v5-compatible Gateway Services (the v5c gateway) to DataPower API Gateway services so that the AMU command has a target for migrating custom policies and gateway extensions, and can migrate the configured gateway services for each catalog and space.

- a. In the unpacked data, locate the gateway services.
Each of the gateway services is stored in `cloud-v10/admin-org/availability-zones/<az_name>/gateway-services/`.
- b. For each v5-compatible gateway service, create a mapping.yml file that contains the name of the DataPower API Gateway Service you want to map to.
Create the mapping.yml file directly in the directory containing the v5-compatible gateway service. The file must contain 3 statements:
 - The artifact type, which is always `gateway-service`:
 - The name of the DataPower API Gateway service (not the Title or ID)
 - The gateway type for that gateway service, which is always `datapower-api-gateway` for converting to DataPower API Gateway service
 For example, the following mapping.yml file maps the v5-compatible gateway service to the DataPower API Gateway service named "gateway-10-1" and specifies a target gateway of type `datapower-api-gateway`:

```
gateway-service:
  name: gateway-10-1
  gateway-type: datapower-api-gateway
```

If you have several v5-compatible gateway services and you want to map each of them to the same DataPower API Gateway service, copy the mapping.yml file into the directory for each of those v5-compatible gateway services.

Make sure to map all of the v5-compatible gateway services to DataPower API Gateway services before attempting to port the APIs in the next step.

2. Optional: Create a configuration file that defines settings for migrating the v5-compatible APIs.
In the directory where the AMU is stored, create a file called `config.yml` and use it to specify configuration settings (see Table 1 for the configuration settings).

Example `config.yml` file:

```
custom-policies-scope: global
emulate-v4-plan-rate-limit: false
deploy-policies:
  - proxy_1.5.0
  - redact_1.5.0
  - invoke_1.5.0
  - xslt_2.0.0
  - gatewayscript_1.0.0
  - switch_2.0.0
rewrite-apis:
  enable-api-logging: false
  proxy-policy: proxy_1.5.0
  redact-policy: redact_1.5.0
  invoke-policy: invoke_1.5.0
  xslt-policy: xslt_2.0.0
  gatewayscript-policy: gatewayscript_1.0.0
  if-policy: switch_2.0.0
  switch-policy: switch_2.0.0
  optimize-gws: false
  no-retitle: true
```

If you omit the config.yml file, you can optionally specify configuration settings as parameters on the command line when you port the APIs in the next step.

Table 1. Migration configuration settings

Parameter	Valid values	DataPower version required	Description
<code>activity-log-policy</code>	<code>activity-log_1.5.0</code> , <code>set-variable_2.0.0</code>	DP 10.0.4.0+	Defines how to process the v5 activity-log policy when the migration utility rewrites the API assembly. The default value is <code>activity-log_1.5.0</code> , which changes the activity-log version to 1.5.0. When set to <code>set-variable_2.0.0</code> , the migration utility sets context variables based upon the value of the activity-log content and error-content configuration values.
<code>chunked-uploads</code>	<code>true</code> / <code>false</code> The default value is <code>false</code> .	For <code>invoke_1.5.0</code> : 10.0.1.1+, 10.0.2.0+ For <code>invoke_2.0.0</code> : 10.0.0.0+	If an <code>invoke_1.5.0</code> or <code>proxy_1.5.0</code> policy exists in an assembly in the API, then set <code>chunked-uploads</code> to <code>true</code> to enable chunked encoding for HTTP 1.1 requests to the target server. If an <code>invoke_2.0.0</code> policy exists in an assembly after the migration, then set <code>chunked-uploads</code> to <code>false</code> explicitly for the policy, as the default value for <code>chunked-uploads</code> in API Gateway is <code>true</code> .

Parameter	Valid values	DataPower version required	Description
client-id-header-override	String. The string cannot contain spaces. Follow the guidelines for apiKey name :. No default value.	10.0.0.0+	<p>Override the existing X-IBM-Client-Id name value with the new value. In API Gateway, x-key-type makes it possible to define custom naming for client_id and client_secret.</p> <p>Example:</p> <pre>--client-id-header-override="acme-foo"</pre> <p>In this example, the securityDefinitions property is changed from:</p> <pre>foo: type: apiKey name: X-IBM-Client-Id in: header</pre> <p>to the following:</p> <pre>foo: type: apiKey name: acme-foo in: header x-key-type: client_id</pre> <p>Calls to this API must supply acme-foo: <client-id> in the request header instead of the original X-IBM-Client-Id: <client-id>.</p>
client-id-query-override	String. The string cannot contain spaces. Follow the guidelines for apiKey name :. No default value.	10.0.0.0+	<p>Override the existing client_id name value with the new value. In API Gateway, x-key-type makes it possible to define custom naming for client_id and client_secret.</p> <p>Example:</p> <pre>--client-id-query-override="acme-foo"</pre> <p>In this example, the securityDefinitions property is changed from:</p> <pre>foo: type: apiKey name: client_id in: query</pre> <p>to the following:</p> <pre>foo: type: apiKey name: acme-foo in: query x-key-type: client_id</pre> <p>Calls to this API must supply ?acme-foo=<client-id> in the query parameter instead of the original ?client_id=<client-id>.</p>
client-secret-header-override	String. The string cannot contain spaces. Follow the guidelines for apiKey name :. No default value.	10.0.0.0+	<p>Override the existing X-IBM-Client-Secret name value with the new value. In API Gateway, x-key-type makes it possible to define custom naming for client_id and client_secret.</p> <p>Example:</p> <pre>--client-secret-header-override="acme-foo"</pre> <p>In this example, the securityDefinitions property is changed from:</p> <pre>foo: type: apiKey name: X-IBM-Client-Secret in: header</pre> <p>to the following:</p> <pre>foo: type: apiKey name: acme-foo in: header x-key-type: client_secret</pre> <p>Calls to this API must supply acme-foo: <client-secret> in the request header instead of the original X-IBM-Client-Secret: <client-secret>.</p>

Parameter	Valid values	DataPower version required	Description
<code>client-secret-query-override</code>	String. The string cannot contain spaces. Follow the guidelines for <code>apiKey</code> <code>name</code> : No default value.	10.0.0.0+	Override the existing <code>client_secret</code> name value with the new value. In API Gateway, <code>x-key-type</code> makes it possible to define custom naming for <code>client_id</code> and <code>client_secret</code> . Example: <pre>--client-secret-query-override="acme-foo"</pre> In this example, the <code>securityDefinitions</code> property is changed from: <pre>foo: type: apiKey name: client_secret in: query</pre> to the following: <pre>foo: type: apiKey name: acme-foo in: query x-key-type: client_secret</pre> Calls to this API must supply <code>?acme-foo=<client-secret></code> in the query parameter instead of the original <code>?client_secret=<client-secret></code> .
<code>copy-id-headers-to-message</code>	<code>true</code> / <code>false</code> The default value is <code>false</code> .	10.0.1.1+, 10.0.2.0+	When set to <code>true</code> , the <code>client-id</code> header is copied from <code>request.headers</code> to <code>message.headers</code> to be passed to the backend server. Set this parameter to <code>true</code> if your invoke backend services expect the <code>client-id</code> to be passed through.
<code>custom-policies-scope</code>	<code>catalog</code> / <code>global</code> The default value is <code>catalog</code> .	10.0.0.0+	When set to <code>catalog</code> , the original v5 or v5-compatible catalog that contains the custom policy is staged for pushing to the target catalog and organization in API Gateway. When set to <code>global</code> , the custom policy is staged for pushing to API Gateway and is visible to all organizations and catalogs within that gateway. <code>archive:port-to-apigw-v10</code> sets up the custom policies for pushing to API Gateway, but does not do the pushing. If <code>global</code> scope is used, <code>archive:push-v10</code> of the admin organization will push all custom policies associated with the configured gateways. If <code>catalog</code> scope is used, then the <code>archive:push-v10</code> of the admin organization will initialize the custom policies on the gateway. A subsequent <code>archive:push-v10</code> of the provider organization is needed to advertise the custom policies in the catalogs contained within the provider organization. Note: Potential conflicts between custom policies of the same name and version are resolved according to the following rules: <ul style="list-style-type: none"> When set to <code>global</code> and two policies under the same gateway service have the same name, version, and md5 hash value, then the duplicates are discarded and a message is generated. When set to <code>global</code> and two policies under the same gateway service have the same name, version, and a differing md5 hash value, then <code>global</code> scope cannot be applied. <code>catalog</code> scope is used and a warning is generated. When set to <code>catalog</code>, <code><orgname>_<catname></code> is appended to the zip filename to maintain uniqueness.
<code>deploy-policies</code>	Any combination of the following values: <code>gatewayscript_1.0.0</code> , <code>if_1.5.0</code> / <code>invoke_1.5.0</code> , <code>proxy_1.5.0</code> , <code>redact_1.5.0</code> , <code>switch_1.5.0</code> , <code>validate-username-token_1.0.0</code> , <code>xslt_1.0.0</code> The default values are: <code>if_1.5.0</code> , <code>invoke_1.5.0</code> , <code>proxy_1.5.0</code> , <code>redact_1.5.0</code> , <code>switch_1.5.0</code> , <code>validate-username-token_1.0.0</code> , <code>xslt_1.0.0</code>	For <code>invoke_1.5.0</code> , <code>proxy_1.5.0</code> , <code>gatewayscript_1.0.0</code> , and <code>xslt_1.0.0</code> : 10.0.0.0+ For <code>if_1.5.0</code> and <code>switch_1.5.0</code> : 10.0.1.1+, 10.0.2.0+ For <code>redact_1.5.0</code> : 10.0.3.0+ For <code>validate-username-token_1.0.0</code> : 10.0.1.3+, 10.0.2.0+	Defines which backwards-compatible policies should be advertised by DataPower to API Manager. Note: Any legacy policies that are specified in the <code>config.yml</code> file or by using the <code>apicm</code> command must also be specified by using <code>deploy-policies</code> . If these policies are not specified by using <code>deploy-policies</code> , an error is returned.
<code>emulate-v4-plan-rate-limit</code>	<code>true</code> / <code>false</code> The default value is <code>false</code> .	10.0.1.2+, 10.0.2.0+	Determines whether all APIs emulate the v4 plan rate limit. If set to <code>true</code> , then API operations do not share the rate limit. This setting matches the behavior of the <code>x-ibm-gateway-emulate-v4-plan-rate-limit</code> v5 option.
<code>enable-api-logging</code>	<code>true</code> / <code>false</code> The default value is <code>true</code> .	10.0.0.0+	Log all changes that the migration utility makes when rewriting APIs. These changes are logged as comments in the API YAML file.
<code>enforce-required-params</code>	<code>true</code> / <code>false</code> The default value is <code>false</code> .	10.0.1.1+, 10.0.2.0+	When set to <code>true</code> , required parameters are enforced, which is the default behavior in API Gateway. When set to <code>false</code> , required parameters are not enforced, even if the required parameter checkbox selected.

Parameter	Valid values	DataPower version required	Description
gatewayscript-policy	One of the following values: gatewayscript_1.0.0 , gatewayscript_2.0.0 The default value is gatewayscript_2.0.0 .	10.0.0.0+	Defines which gatewayScript policy the migration utility uses when rewriting the API assembly. gatewayscript_1.0.0 : A user-defined policy created by the migration utility. This policy uses the v5 MPGW processing rule. Use gatewayscript_1.0.0 if the gatewayScript policy is dependent on v5 MPGW capabilities, such as load balancer groups or XML Manager settings. gatewayscript_2.0.0 : The migration utility rewrites the existing API to gatewayScript 2.0.0. This policy supports the header-metadata module for compatibility with the v5-compatible gateway. Specifying gatewayscript_2.0.0 can cause migration errors or run-time errors. Use gatewayscript_2.0.0 if you are able to review and verify all changes made by the migration utility in the API YAML file.
if-policy	One of the following values: if_1.5.0 , switch_2.0.0 The default value is if_1.5.0 .	For if_1.5.0 : 10.0.1.1+, 10.0.2.0+ For switch_2.0.0 : 10.0.0.0+	Defines which if policy the migration utility uses when rewriting the API assembly. if_1.5.0 : The migration utility rewrites the existing API to if 1.5.0. switch_2.0.0 : The migration utility rewrites the existing API to switch 2.0.0. Specifying switch_2.0.0 can cause migration errors or run-time errors. Use switch_2.0.0 if you are able to review and verify all changes made by the migration utility in the API YAML file.
invoke-policy	One of the following values: invoke_1.5.0 , invoke_2.0.0 The default value is invoke_1.5.0 .	10.0.0.0+	Defines which invoke policy the migration utility uses when rewriting the API assembly. invoke_1.5.0 : The migration utility rewrites the existing API to invoke 1.5.0. invoke_2.0.0 : The migration utility rewrites the existing API to invoke 2.0.0. Specifying invoke_2.0.0 can cause migration errors or run-time errors. Use invoke_2.0.0 if you are able to review and verify all changes made by the migration utility in the API YAML file.
no-retitle	true / false The default value is false .	10.0.0.0+	Defines whether to append the porting suffix to the title of the migrated API, product, or OAuth provider. Set this option to true if you want the title of the migrated API, product, or OAuth provider to match the original title in the v5-compatible YAML file.
optimize-gws	true / false The default value is false .	10.0.0.0+	When set to true , gatewayScript policies are modified to map v5 functions to API Gateway functions. Setting optimize-gws to true is valid only for the gatewayscript_2.0.0 policy. If it is set to true for gatewayscript_1.0.0 , an error is generated. Note: Setting optimize-gws to true can result in performance enhancements. However, the modifications to gatewayScript policies by the migration utility can cause problems. When using this setting, review all gatewayScript policy modifications after migration.
porting-suffix	A string containing alphanumeric, dash, underscore and dot characters. The default value is -apigw .	10.0.0.0+	Defines the suffix to be used when renaming APIs, Products, OAuth Providers, and other ported artifacts. The suffix is appended to the version on APIs, Products and other ported artifacts that have versions, and onto the name for OAuth Providers and other ported artifacts that do not have versions. If porting-suffix is not specified then a value of -apigw will be used. The porting suffix can contain alphanumeric, dash, underscore and dot characters. Prior to AMU 10.0.5.4 the porting suffix could not be overridden and -apigw was appended to the name for all ported artifacts.
proxy-policy	One of the following values: proxy_1.5.0 , invoke_2.0.0 The default value is proxy_1.5.0 .	10.0.0.0+	Defines which proxy policy the migration utility uses when rewriting the API assembly. proxy_1.5.0 : The migration utility rewrites the existing API to proxy_1.5.0 . invoke_2.0.0 : The migration utility converts the proxy policy to invoke 2.0.0. Specifying invoke_2.0.0 can cause migration errors or run-time errors. Use invoke_2.0.0 if you are able to review and verify all changes made by the migration utility in the API YAML file.
redact-policy	One of the following values: redact_1.5.0 , redact_2.0.0 The default value is redact_1.5.0 .	10.0.3.0+	Defines which redact policy the migration utility uses when rewriting the API assembly. redact_1.5.0 : The migration utility rewrites the existing API to redact_1.5.0 . redact_2.0.0 : The migration utility rewrites the existing API to redact_2.0.0 . Specifying redact_2.0.0 can cause migration errors or run-time errors, including changes to what is redacted, particularly with redactions meant for JSON payloads. Use redact_2.0.0 if you are able to review and verify all changes made by the migration utility in the API YAML file.
repair-wsdl-apis	true / false The default value is true .	10.0.1.1+, 10.0.2.0+	If an API ported from V5 is created from WSDL, the WSDL is read and checked for accuracy. If repair-wsdl-apis is set to true , then the API and WSDL are automatically repaired. For example, if the WSDL ZIP file contains unnecessary files, they are automatically removed if repair-wsdl-apis is true .
return-v5-responses	true / false The default value is false .	10.0.1.1+, 10.0.2.0+	When set to true , OAuth-related messages are printed in the v5 response format. When set to false , OAuth-related response messages are printed in API Gateway response format.
switch-policy	switch_1.5.0 , switch_2.0.0 The default value is switch_1.5.0 .	For switch_1.5.0 : 10.0.1.1+, 10.0.2.0+ For switch_2.0.0 : 10.0.0.0+	Defines which switch policy the migration utility uses when rewriting the API assembly. switch_1.5.0 : The migration utility rewrites the existing API to switch 1.5.0. switch_2.0.0 : The migration utility rewrites the existing API to switch 2.0.0. Specifying switch_2.0.0 can cause migration errors or run-time errors. Use switch_2.0.0 if you are able to review and verify all changes made by the migration utility in the API YAML file.

Parameter	Valid values	DataPower version required	Description
<code>use-config-file</code>	<code>true / false</code> The default value is <code>false</code> .	10.0.0.0+	Use the <code>config.yml</code> file that is in the same directory as the <code>apicm</code> binary file that is being executed. If this file is used, configuration options cannot be set using the command line. The purpose of the config file is to specify the command inputs given on this page, but in an easy-to-read file format (YAML).
<code>v5-request-headers</code>	<code>true / false</code> The default value is <code>true</code> .	10.0.1.2+, 10.0.2.0+	When set to <code>true</code> , the following v5-compatible request headers are set: <code>Via</code> , <code>X-Global-Transaction-ID</code> , <code>X-Client-IP</code> . When set to <code>false</code> , these request headers are not set.
<code>validate-username-token-policy</code>	<code>validate-username-token_1.0.0</code> The default value is empty.	10.0.1.3+, 10.0.2.0+	Defines whether or not to use the <code>validate-username-token</code> v5 emulation policy when the migration utility rewrites the API assembly. When empty, the migration utility takes no action on the policy.
<code>xslt-policy</code>	One of the following values: <code>xslt_1.0.0</code> , <code>xslt_2.0.0</code> The default value is <code>xslt_1.0.0</code> .	10.0.0.0+	Defines which gateway script policy the migration utility uses when rewriting the API assembly. <code>xslt_1.0.0</code> : A user-defined policy created by the migration utility. This policy uses the v5 MPGW processing rule. Use <code>xslt_1.0.0</code> if the xslt policy is dependent on v5 MPGW capabilities, such as load balancer groups or XML Manager settings. <code>xslt_2.0.0</code> : The migration utility rewrites the existing API to xslt 2.0.0. Specifying <code>xslt_2.0.0</code> can cause migration errors or run-time errors. Use <code>xslt_2.0.0</code> if you are able to review and verify all changes made by the migration utility in the API YAML file.

3. Use the `AMU port` command to convert the v5-compatible APIs to the DataPower API Gateway format.

When you run the `port` command with the AMU, there are 3 options for specifying configuration settings for your APIs:

- Store the settings in the `config.yml` migration configuration file.
You must name the configuration file `config.yml`. Specify the `--use-config-file=true` parameter on the command line when you port the APIs.
- Include the configuration settings on the command line (see Table 2 for the configuration settings).
Specify the settings as parameters on the command line. If you also specify a configuration file, any configuration settings specified as parameters directly on the command line are ignored.
- Accept the default configuration settings.
If you don't specify a configuration file and also don't specify any configuration parameters on the command line, the AMU uses the default configuration when porting the APIs.

Before you port the APIs, back up your `/cloud-v10` directory. If you need to rerun the `archive:port-to-apigw-v10` command, first restore the un-ported `/cloud-v10` directory (the `archive:port-to-apigw-v10` command does not overwrite DataPower API Gateway artifacts that were previously created).

To port the APIs, run the following command:

On Windows: open a command window with Administrator privileges, and omit the `./` from the command.

```
./apicm archive:port-to-apigw-v10 <path_to_APIs> --enable-api-logging=false --use-config-file=true
```

where `<path_to_APIs>` represents one of the following locations:

- The top-level `/cloud-v10` directory containing all of the extracted archive:
The AMU ports all artifacts within the directory, including APIs, Products, OAuth providers, and custom policies. Running a subsequent `archive:push-v10` command pushes all of the converted artifacts to the DataPower API Gateway. Custom policies and OAuth providers are not migrated if a directory other than `/cloud-v10` is specified.
Attention: Running the `port` command on any subdirectory within the unpacked `/cloud-v10` directory could leave the directory in an inconsistent state, and cause the subsequent `archive:push-v10` command to fail.
- A single API file, or a directory that contains only APIs or Products:
When you are testing your migration settings, you might want to convert just a few APIs or Products to verify the settings. When you use this approach, you cannot use the high-level `archive:push-v10` command to push the artifacts to the DataPower API Gateway. Instead, you must push the ported artifacts into API Manager using either the toolkit or the user interface.

When testing is complete, you can delete the artifacts from testing and run the `port` command on the top-level `/cloud-v10` directory to convert all of the artifacts in one operation, and then use the `archive:push-v10` command to push them all to the DataPower API Gateway in a second operation.

Table 2. Parameters for the `port` command

Parameter	Description
<code>--enable-api-logging=false</code>	Optional. Disable logging. By default, logging is enabled for the conversion and all changes that the migration utility makes when rewriting APIs are logged as comments within the API's YAML file.
<code>--use-config-file=true</code>	Optional. When converting APIs, apply the configuration settings specified in the <code>config.yml</code> file that is stored in the same directory as the AMU.
Parameters from Table 1, Migration configuration settings.	Optional. Follow the format shown in Table 1, and prefix each parameter with the <code>--</code> symbol and leave a blank space before the next parameter as shown in the example command.

4. Review the ported artifacts.

The API conversion process annotates the YAML file and logs with information regarding the artifacts that it attempts to convert. For cases where additional information is available or further action is required, the YAML input file and logs contain links to documentation.

Review the entire draft output YAML file for conformance, performance, and errors. Review the log files for messages about any manual actions that might be needed. For more information, see [Reviewing APIs converted to DataPower API Gateway](#). By default, all changes that the migration utility makes when rewriting APIs are logged as common.

Because of differences between the programming models of v5-compatible APIs and DataPower API Gateway APIs, the command might not be able to convert all items; you might need to manually convert the failed items. In these cases, messages generated by the `apicm archive:port-to-apigw-v10` command provide links to documentation that provides more details about changes you must make for the items to be compatible with DataPower API Gateway.

Pushing custom policies and gateway extensions to the DataPower API Gateway

Use the AMU to push the Cloud Manager admin organization's data to the Management server, which pushes custom policies and gateway extensions to your DataPower API Gateway Services.

About this task

Custom policies and gateway extensions are stored with the Cloud Manager admin organization data. To push the converted artifacts to the DataPower API Gateway Services, you push the Cloud Manager admin organization to the Management server.

Procedure

1. Log in to the Cloud Manager on the destination v10 Management Server as an Owner of the admin organization.
Important: You must be logged in as an Owner of the admin organization to be able to migrate Cloud Manager admin organization data.
On Windows: open a command window with Administrator privileges, and omit the "/" from the command.

See Table 1 for the login parameters.

Syntax:

```
./apicm login --server <cloud_manager_endpoint> --realm admin/<identity_provider> --username admin --password admin_password
```

Example for standalone deployment:

```
./apicm login --server cloud-admin-ui.mgmt.dev.apic10-stack.example.test --realm admin/default-idp-1 --username admin --password 'myadminpassword'
```

Example for Cloud Pak for Integration:

```
./apicm login --server cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod --realm admin/default-idp-1 --username admin --password 'myadminpassword'
```

Table 1. Login parameters for the Cloud Admin organization

Parameter	Description						
<code>--server <cloud_manager_endpoint></code>	<p>Required. The endpoint on the Management server for communication with the Cloud Manager user interface.</p> <p>Standalone deployment Example: <code>cloud-admin-ui.mgmt.dev.apic10-stack.example.test</code></p> <p>The endpoint was specified when the management subsystem was installed. View the <code>apiconnect_api</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory that you created for initial deployment of v10. Examples:</p> <ul style="list-style-type: none"> • VMware: see the <code>cloud-admin-ui</code> endpoint in Deployment overview for endpoints. • Kubernetes: see the <code>admin</code> endpoint in Deployment overview for endpoints and certificates. <p>Cloud Pak for Integration Syntax: <code>cpd-<APIC_namespace>.<your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance></code></p> <p>Example: <code>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</code></p> <p>where <code>e2e</code> is <code><APIC_namespace></code> and <code>prod</code> is <code><APIC_instance></code>.</p> <p>Note: How to obtain the server URL on Cloud Pak for Integration Use the Platform Navigator UI to determine the parameter. Note that you cannot get the endpoint by using <code>oc get routes</code> because Zen modifies the route internally.</p> <ol style="list-style-type: none"> Locate the Platform UI panel with entries for the deployment. Identify the row that has a Type column entry with the description API management administration. To display the endpoint, hover over the corresponding prod entry in the Name column for that row. The URL displays at the bottom of the panel. <table border="1"> <thead> <tr> <th>Name</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td><code>prod</code></td> <td>API management administration</td> </tr> <tr> <td><code>prod</code></td> <td>API management</td> </tr> </tbody> </table> <p><code>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod/admin</code></p> <ol style="list-style-type: none"> Remove the trailing <code>/admin</code> from the endpoint: <code>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</code> 	Name	Type	<code>prod</code>	API management administration	<code>prod</code>	API management
Name	Type						
<code>prod</code>	API management administration						
<code>prod</code>	API management						

Parameter	Description
<code>--realm</code> <code>admin/default-idp-1</code>	Required. The <code>apicm login</code> example shows the expected <code>--realm</code> parameter values for a default API Connection administration organization. The default user is <code>admin</code> and the identity provider is <code>default-idp-1</code> . You can determine which identity provider to use in the <code>--realm</code> parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command): <code>apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm</code> For example: <pre>apic identity-providers:list --scope admin --server myserver.com --fields title,realm total_results: 2 results: - title: Cloud Manager User Registry realm: admin/default-idp-1 - title: Corporate LDAP user registry realm: admin/corporate-ldap</pre> The <code>title</code> value indicates which identity provider to use; copy the corresponding <code>--realm</code> parameter directly from the displayed <code>realm</code> value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is <code>default-idp-1</code> .
<code>--username</code> <code>admin</code>	Required. Administrative user with permissions to modify API Connect admin-org. The default user is <code>admin</code> .
<code>--password</code> <code>myadminpassword</code>	Required. Administrative user's password. Cloud Pak for Integration: When you installed with the top-level CR for CP4I, the password was auto-generated. To obtain the password, see step 3 in Installing API Connect .

2. Push the ported custom policies and gateway extensions to your DataPower API Gateway services.

In the same directory where you ran the `archive:unpack-v10` command, run the following command to push the ported custom policies and gateway extensions to your DataPower API Gateway services in the Cloud Manager administrative org (admin-org).

See the parameters in Table 2 as well as the usage notes that follow the table:

```
./apicm archive:push-v10 <cloud_manager_endpoint> <path_to_admin_org> [optional flags]
```

Example for standalone deployment (optional flags omitted):

```
./apicm archive:push-v10 cloud-admin-ui.mgmt.dev.apic10-stack.example.test cloud-v10/admin-org
```

Example for Cloud Pak for Integration (optional flags omitted):

```
./apicm archive:push-v10 cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod cloud-v10/admin-org
```

Note: If you observe error messages in your log output, you can take troubleshooting steps, and run the migration again. See [Migration troubleshooting](#).

Table 2. Parameters for the `archive:push-v10` command

Parameter	Description						
<code><cloud_manager_endpoint></code>	Required. The endpoint on the Management server for communication with the Cloud Manager user interface. Standalone deployment Example: <pre>cloud-admin-ui.mgmt.dev.apic10-stack.example.test</pre> The endpoint was specified when the management subsystem was installed. View the <code>apiconnect_api</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect v10 installation project directory that you created for initial deployment of v10. Examples: <ul style="list-style-type: none">VMware: see the <code>cloud-admin-ui</code> endpoint in Deployment overview for endpoints.Kubernetes: see the <code>admin</code> endpoint in Deployment overview for endpoints and certificates. Cloud Pak for Integration Syntax: <pre><cpd-APIC_namespace.your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance></pre> Example: <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre> where <code>e2e</code> is <code><APIC_namespace></code> and <code>prod</code> is <code><APIC_instance></code> . Note: How to obtain the server parameter on Cloud Pak for Integration Use the Platform Navigator UI to determine the parameter. Note that you cannot get the endpoint by using <code>oc get routes</code> because Zen modifies the route internally. a. Locate the Platform UI panel with entries for the deployment. Identify the row that has a Type column entry with the description API management administration b. To display the endpoint, hover over the entry in the Name column for that row. For example, hover over the prod entry, as shown in bold font, and the URL displays at the bottom of the panel. <table border="1"><thead><tr><th>Name</th><th>Type</th></tr></thead><tbody><tr><td>prod</td><td>API management administration</td></tr><tr><td>prod</td><td>API management</td></tr></tbody></table> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod/admin</pre> c. Remove the trailing <code>/admin</code> from the endpoint: <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre>	Name	Type	prod	API management administration	prod	API management
Name	Type						
prod	API management administration						
prod	API management						

Parameter	Description
<code><path_to_admin_org></code>	Required, the only supported value is cloud-v10/admin-org.
<code>--dry-run</code>	Optional. Perform a dry run to test the Admin org migration output. This option creates a project directory similar to cloud-v10, but named <code>.workdir-<apim_admin_server></code> , where you can view how the data will be loaded into your new system. This option also displays the objects that will fail due to pre-existing or missing dependencies. For more information, see the 10.0.5.x Migration Troubleshooting section on apicm command line help .

Usage notes:

- On Windows: open a command window with Administrator privileges, and omit the `"/` from the command.
- Run the `archive:push-v10` command in the same directory where you ran the `archive:unpack-v10` command, and always push the ported data back to the same v10 deployment where you extracted the data.
- The `login` command obtains a token that expires after eight hours. If the token expires while the `archive:push-v10` command is running, the AMU generates errors. In this case, log in again and re-run the `push` command. The token is refreshed every time you log in. For more information, see [Token expiration](#).
- An alternative method of viewing endpoints is to run the `kubectl` `get ingress` and get the values from the output. For example, see the values in **bold** in the following sample output:

```
r7c221d8a33-apic-portal-director api.portal.dev.apic10-stack.example.test 80, 443 21h

```

Pushing provider organization data

Use the AMU to push the provider organization data to the Management server.

About this task

Pushing the provider organization data uploads the ported OAuth Providers, draft APIs, draft products, configured gateway services, and published products to the Management server.

Procedure

1. Log in to the API Manager user interface as an Owner or Administrator of the provider organization that you want to migrate. If you want to login using an OIDC user registry, see [Logging in to a management server with an OIDC registry](#).

Important: You cannot migrate a provider organization while you are logged in with the Cloud Manager admin organization. You must be logged in as the Owner or Administrator of the provider organization whose data you will push.

Syntax:

```
./apicm login --server <api-manager-ui-endpoint> --realm provider/<identity_provider> --username <org_username> --password <org_password>
```

Example for a standalone deployment:

```
./apicm login --server api-manager-ui.dev.apic10-stack.example.test --realm provider/default-idp-2 --username org_username@example.com --password myorgpassword
```

Example for Cloud Pak for Integration:

```
./apicm login --server cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod --realm provider/default-idp-2 --username org_username@ex
```

Table 1. `login` parameters for Provider organizations

Parameters	Description
------------	-------------

Parameters	Description						
<code><api-manager-ui-endpoint></code>	<p>Required. The API Manager URL endpoint on the Management server for communication with the API Manager user interface.</p> <p>Standalone deployment</p> <p>Example:</p> <pre>api-manager-ui.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the Management subsystem was installed. To verify your endpoint setting, do one of the following:</p> <ul style="list-style-type: none"> View the <code>apiconnect-apim-ui</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect installation project directory. In the Cloud Manager UI, select Settings, Endpoints and view API Manager URL. <p>Cloud Pak for Integration</p> <p>Syntax:</p> <pre>cpd-<APIC_namespace>.<your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance></pre> <p>Example:</p> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre> <p>where <code>e2e</code> is <code><APIC_namespace></code> and <code>prod</code> is <code><APIC_instance></code>.</p> <p>Note: How to obtain the server URL on Cloud Pak for Integration</p> <p>Use the Platform Navigator UI to determine the parameter. Note that you cannot get the endpoint by using <code>oc get routes</code> because Zen modifies the route internally.</p> <ol style="list-style-type: none"> Locate the Platform UI panel with entries for the deployment. Identify the row that has a Type column entry with the description API management To display the endpoint, hover over the corresponding prod entry in the Name column for that row. The URL displays at the bottom of the panel. <table border="1"> <thead> <tr> <th>Name</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>prod</td> <td>API management administration</td> </tr> <tr> <td>prod</td> <td>API management</td> </tr> </tbody> </table> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod/manage</pre> <ol style="list-style-type: none"> Remove the trailing <code>/manage</code> from the endpoint: <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre>	Name	Type	prod	API management administration	prod	API management
Name	Type						
prod	API management administration						
prod	API management						
<code>--realm provider/identity_provider</code>	<p>Required.</p> <p>The default <code>identity_provider</code> is <code>default-idp-2</code>. You can determine which identity provider to use in the <code>--realm</code> parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):</p> <pre>apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm</pre> <p>For example,</p> <pre>apic identity-providers:list --scope provider --server myserver.com --fields title,realm total_results: 2 results: - title: Cloud Manager User Registry realm: provider/default-idp-2 - title: Corporate LDAP user registry realm: provider/corporate-ldap</pre> <p>The <code>title</code> value indicates which identity provider to use; copy the corresponding <code>--realm</code> parameter directly from the displayed <code>realm</code> value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is <code>default-idp-2</code>.</p>						
<code>--username <org_username></code>	Required. A user with permissions to modify the provider organization; typically this is the owner or administrator of the organization.						
<code>--password <org_password></code>	Required. The organization owner or administrator password.						

2. Push the data for the provider organization.

In the same directory where you ran the `archive:unpack-v10` command, run the following command to push the ported data to your API Manager. See the parameters in Table 2 as well as the usage notes that follow the table.

Syntax:

```
./apicm archive:push-v10 <api-manager-ui-endpoint> cloud-v10/provider-orgs/<pOrg_name> [optional flags]
```

Example for standalone deployment (optional flags are omitted):

```
./apicm archive:push-v10 api-manager-ui.mgmt.dev.apic10-stack.example.test cloud-v10/provider-orgs/production_Org
```

Example for Cloud Pak for Integration (optional flags are omitted):

```
./apicm archive:push-v10 cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod cloud-v10/provider-orgs/production_Org
```

Table 2. `archive:push-v10` parameters for provider organizations

Parameters	Description						
<code><api-manager-ui-endpoint></code>	<p>Required. The API Manager URL endpoint on the Management server for communication with the API Manager user interface.</p> <p>Standalone deployment</p> <p>Example:</p> <pre>api-manager-ui.dev.apic10-stack.example.test</pre> <p>The endpoint was specified when the Management subsystem was installed. To verify your endpoint setting, do one of the following:</p> <ul style="list-style-type: none"> View the <code>apiconnect-apim-ui</code> definition in the <code>apiconnect-up.yml</code> file in the API Connect installation project directory. In the Cloud Manager UI, select Settings, Endpoints and view API Manager URL. <p>Cloud Pak for Integration</p> <p>Syntax:</p> <pre>cpd-<APIC_namespace>.<your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance></pre> <p>Example:</p> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre> <p>where <code>e2e</code> is <code><APIC_namespace></code> and <code>prod</code> is <code><APIC_instance></code>.</p> <p>Note: How to obtain the server URL on Cloud Pak for Integration</p> <p>Use the Platform Navigator UI to determine the parameter. Note that you cannot get the endpoint by using <code>oc get routes</code> because Zen modifies the route internally.</p> <ol style="list-style-type: none"> Locate the Platform UI panel with entries for the deployment. Identify the row that has a Type column entry with the description API management To display the endpoint, hover over the corresponding prod entry in the Name column for that row. The URL displays at the bottom of the panel. <table border="1"> <thead> <tr> <th>Name</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>prod</td> <td>API management administration</td> </tr> <tr> <td>prod</td> <td>API management</td> </tr> </tbody> </table> <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod/manage</pre> <ol style="list-style-type: none"> Remove the trailing <code>/manage</code> from the endpoint: <pre>cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod</pre>	Name	Type	prod	API management administration	prod	API management
Name	Type						
prod	API management administration						
prod	API management						
<code>cloud-v10/provider-orgs/<pOrg_name></code>	<p>Required. The location of your provider org within the <code>/cloud-v10</code> file hierarchy you created when you ran unpacked the data archive; for example:</p> <pre>cloud-v10/provider-orgs/production_Org</pre>						
<code>--catalogs=<list_of_names></code>	<p>Optional. Push data for only the specified catalogs if you don't want to push the entire provider organization. Use this parameter to specify the names of the catalogs you want to push (to specify multiple catalogs, use a comma-separated list):</p> <pre>./apicm archive:push-v10 <api-manager-ui-endpoint> cloud-v10/provider-orgs/<pOrg_name> --catalogs=<catalog_name1,catalog_name2,catalog_name3></pre>						
<code>--spaces=<list_of_names></code>	<p>Optional. Push data for only the specified spaces if you don't want to push the entire provider organization. The <code>--catalogs</code> parameter must also be specified, and exactly one catalog must be specified. Use this parameter to specify the names of the spaces you want to push (to specify multiple spaces, use a comma-separated list). For example:</p> <pre>./apicm archive:push-v10 <api-manager-ui-endpoint> cloud-v10/provider-orgs/<pOrg_name> --catalogs=<catalog_name> --spaces=<space_name1>,<space_name2>,<space_name3></pre>						
<code>--products=<list_of_name:version_pairs></code>	<p>Optional. Push data for only the specified products if you don't want to push the entire provider organization. The <code>--catalogs</code> parameter must also be specified, and exactly one catalog must be specified. If spaces are enabled on the catalog, then the <code>--spaces</code> parameter must also be specified, and exactly one space must be specified. Use this parameter to specify the names and versions of the products that you want to push (to specify multiple products, use a comma-separated list of name:version pairs as shown in the following examples.</p> <p>Example: catalog with spaces</p> <pre>./apicm archive:push-v10 <api-manager-ui-endpoint> cloud-v10/provider-orgs/<pOrg_name> --catalogs=<catalog_name> --spaces=<space_name> --products=<prod_name1>:<prod_version1>,<prod_name2>:<prod_version2>,<prod_name3>:<prod_version3></pre> <p>Example: catalog without spaces:</p> <pre>./apicm archive:push-v10 <api-manager-ui-endpoint> cloud-v10/provider-orgs/<pOrg_name> --catalogs=<catalog_name> --products=<prod_name1>:<prod_version1>,<prod_name2>:<prod_version2>,<prod_name3>:<prod_version3></pre>						
<code>--dry-run</code>	<p>Optional. Perform a dry run to test the Admin org migration output.</p> <p>This option creates a project directory similar to <code>cloud-v10</code>, but titled <code>.workdir-<api-manager-ui-endpoint></code> where you can view how the data will be loaded into your new system. The option also displays the objects that will fail due to existing already or missing dependencies. Use this option to view the resolved URLs for where the data will be loaded, without creating resources on the new system. See Migration troubleshooting.</p> <pre>./apicm archive:push-v10 <api-manager-ui-endpoint> cloud-v10/provider-orgs/<pOrg_name> --dry-run</pre>						

Parameters	Description
<code>--no-drafts</code>	Optional. Do not push any draft APIs or products (draft objects are objects that have not been published). <pre>./apicm archive:push-v10 <api-manager-ui-endpoint> <path_to_provider_org> --no-drafts</pre> This option can be used with or without the <code>--catalogs</code> parameter.
<code>--drafts-only</code>	Optional. Only push ported draft APIs and products, and do not push any published APIs or products (draft objects are objects that have not been published). <pre>./apicm archive:push-v10 <api-manager-ui-endpoint> <path_to_provider_org> --drafts-only</pre> This option cannot be used with the <code>--catalogs</code> or <code>--no-drafts</code> parameters.
<code>--overwrite</code>	Optional. Overwrite any existing draft products, draft APIs, published products and their APIs, and OAuth Providers that are already on the deployment. If you set this parameter to false, these artifacts will be left intact.
<code>--move-subscriptions</code>	Optional. When this option is used, the subscriptions associated with v5-compatible-API-based products that were ported to API DataPower Gateway-based products and successfully pushed to the API Connect deployment will have their subscriptions moved to the new products, and the original v5-compatible-API-based products will be retired. This option can also be used on subsequent <code>archive:push-v10</code> commands to move the subscriptions even after the migrated products are published. Using the <code>--catalogs</code> , <code>--spaces</code> , and <code>--products</code> parameters with the <code>--move-subscriptions</code> parameters lets you narrow the set of products to have their subscriptions moved.

Usage notes:

- On Windows: open a command window with Administrator privileges, and omit the "/" from the command.
- Run the `archive:push-v10` command in the same directory where you ran the `archive:unpack-v10` command, and always push the ported data back to the same deployment where you extracted the data.
- The `login` command obtains a token that expires after 8 hours. If the token expires while the `archive:push-v10` command is running, the AMU generates errors. In this case, log in again and re-run the `push` command. The token is refreshed every time you log in. For more information, see [migration_troubleshooting.html#migration_troubleshooting_token_expire](#).
- The `archive:push-v10` command only pushes only the following ported objects: OAuth Providers, draft APIs, draft products, configured gateway services, and published products.
- An alternative method of viewing endpoints is to run the `kubectl` `get ingress` and get the values from the output. For example, see the values in **bold** in the following sample output:

```
r7c221d8a33-apic-portal-director api.portal.dev.apic10-stack.example.test 80, 443 21h
r7c221d8a33-apic-portal-web portal.dev.apic10-stack.example.test 80, 443 21h

re314d70920-apiconnect-cm-ui cloud.mgmt.dev.apic10-stack.example.test 80, 443 22h
re314d70920-apiconnect-consumer-api consumer.mgmt.dev.apic10-stack.example.test 80, 443 22h
rfe867a858b-dynamic-gateway-service service.gw.dev.apic10-stack.example.test 80, 443 21h
rfe867a858b-dynamic-gateway-service-gw api.gw.dev.apic10-stack.example.test 80, 443 21h
rfff5043330-analytics-client ac.dev.apic10-stack.example.test 80, 443 21h
rfff5043330-analytics-ingestion ai.dev.apic10-stack.example.test
```

- Test your newly ported products and APIs to make sure they are working as expected. If necessary make changes and push the updates to your API Connect deployment.

Migrating from v10 to v10 on a different form factor

Migrate an API Connect v10 deployment from one form factor to a different form factor.

- [v10 migration overview](#)
Use migration scripts to migrate API Connect to another form factor, or to a different deployment on the same form factor.

Shut down the Postgres database to ensure no changes are made to the database during migration.

v10 migration overview

Use migration scripts to migrate API Connect to another form factor, or to a different deployment on the same form factor.

Scripts are run from a client machine which has access to the Kubernetes or OpenShift cluster. Scripts are supported on Linux and macOS.

It is recommended to review all the documentation before starting a v10 migration.

Overview topics:

- [Migration terminology used in this documentation](#)
- [Location of v10 migration scripts](#)

- [Supported v10 migration paths](#)
- [v10 migration planning](#)

Migration terminology used in this documentation

This documentation uses the following terms for migrations:

- v10 migration

The term **v10 migration** includes:

1. Migration of a v10 API Connect deployment to a v10 API Connect deployment on a different platform.
2. Migration of a v10 API Connect deployment to a v10 API Connect deployment in a different cluster on the same platform.
Applicable to native Kubernetes, OpenShift, and Cloud Pak for Integration.
3. Migration of a v10 API Connect deployment to a Cloud Pak for Integration deployment.
4. Migration of a Cloud Pak for Integration deployment to a Cloud Pak for Integration deployment on a different cluster.
Note that Cloud Pak for Integration is deployed only on the OpenShift platform.

- Form Factor and Form Factor Migration.

The term **Form Factor** is used in v10 migration to characterize a cluster deployment on a particular platform.

Each of the migrations included in the definition for **v10 migration** is a movement of an existing v10 deployment to a different **Form Factor**.

The term **Form**

Factor Migration is another term for **v10 migration**. It refers to different software deployments. Usage of the term **form factor** in this documentation does not refer to any hardware form factors.

- Platform

The term **platform** is used to mean either native Kubernetes, VMware virtual machine, OpenShift Container Platform, or Cloud Pak for Integration.

- Migration

In the v10 API Connect documentation, the term **migration** is also used for scenarios for migrating from API Connect v5 to API Connect v10. Note that migrating from v5 to v10 is unrelated to moving a v10 deployment to a different form factor.

To view instructions for migrating from v5 to v10, see [Migrating a Version 5 deployment](#).

Location of v10 migration scripts

You can obtain the scripts from Fix Central. Obtain the following package:

`apiconnect-operator-release-files_VERSION_NUMBER/helper_files/formFactorMigration`

To access the latest version, see the [What's new in the latest release](#) page. On that page, locate the Note: *You can access the latest files from <URL link>*. Select the *<URL link>* to go directly to the Announce page on Fix Central, where you can download files for the latest version of API Connect.

Supported v10 migration paths

The supported migration paths cover two use cases:

- Migrating from a source system on one form factor to a target system on another form factor.
- Migrating from a source system on one form factor to a target system on the same form factor, when there is a change in hostnames.

Important: The API Connect version on the target system must match the API Connect version on the source system.

Table 1. Supported migration paths for API Connect v10

Source deployment platform of API Connect v10	Target deployment platform, based on API Connect v10
Kubernetes	Cloud Pak for Integration
Kubernetes	OpenShift Container Platform
Kubernetes	Kubernetes, when moving to a different v10 cluster, resulting in hostname changes
VMware	Cloud Pak for Integration
VMware	OpenShift Container Platform
OpenShift Container Platform	Cloud Pak for Integration, using the same hostnames
OpenShift Container Platform	Cloud Pak for Integration, moving to a different cluster, resulting in hostname changes
OpenShift Container Platform	OpenShift Container Platform, moving to a different cluster, resulting in hostname changes
Cloud Pak for Integration	Cloud Pak for Integration, moving to a different cluster, resulting in hostname changes

v10 migration planning

Consider the following information when planning a v10 migration:

- **Data migration**

There are two ways to migrate data:

- Perform complete migration of data:

Before starting migration steps on the target system, have the target system ready with the same or larger topology than what is present in the source system. This means the number of Gateways, Portals, and Analytics subsystems must be same or more than what is present in the source system. Start the

migration process, map the endpoints between source and target systems, and complete the migration process. All data is migrated. The target system must be validated and tested.

If you do not want to migrate data for some subsystems on the source system, skip those endpoints in the mapping. Then, after migration is complete, manually delete the data from Cloud Manager and the API Manager UI on the source system.

- o Perform migration in more than one step

In this scenario, at the time of migration the API Connect target system does not have all the subsystems ready when compared to the total number of subsystems in the source system. Migration is run only for the Gateway and Portal subsystems that are available on the target system. At this point, the target system will still have some stale data related to the subsystems that are not migrated. You can then create additional subsystems (Gateways, Portals, or Analytics) on the target system, and run the necessary migration steps to complete the remaining migration process.

- If additional Gateways or Analytics are added to the source system after completing the initial migration, you must:
 1. Add the new Gateway and Analytics related endpoints in the mapping file.
 2. Register Gateways and Portals on the target system. Complete Step 3 in [Restoring the target system](#).
 3. Update the gateways in the catalog to point to the new Gateway systems. Complete Step 6 in [Restoring the target system](#).
- If additional Portals are added to the source system after completing the initial migration, you must:
 1. Add the new Portal related endpoints in the mapping file.
 2. Register gateways and portals on the target system. Complete Step 3 in [Restoring the target system](#).
 3. Update the portals in the catalog to point to the new portal systems. Complete Step 4 in [Restoring the target system](#).
 4. Restore portal backups for each site on the namespace where the new portal is installed. Complete Step 5 in [Restoring the target system](#).
- The stale data for which migration is not complete will remain on the target system until you install the additional subsystems and complete migration, or until you use the Cloud Manager or API Manager UI to manually delete it.

- Reuse of Gateways from the source system:

1. Export the `ingress-ca` secret from the source system using the `-export_cert` flag in [Preparing the source system](#). The secret is saved to `data/MANAGEMENT_SUBSYSTEM_NAME/ingress-ca_secret.yaml`.
2. Install the `ingress-ca` secret manually on the target cluster. This step must be completed before you begin [Installing the target system](#).
 - If using top-level CR on OpenShift: The top-level CR name you are going to use while installing API Connect must be used while creating the secret name and its contents.
 - The name of the `ingress-ca` secret must be `TOP_CR_NAME-ingress-ca` in case of OpenShift using top-level CR, or CP4I. For Kubernetes or OpenShift using individual subsystems, it must be `ingress-ca`.
 - An example of an `ingress-ca` secret is given in the following example. If top-level CR is used, replace `TOP_CR_NAME` with the top-level CR name you are going to use to install API Connect. For Kubernetes or OpenShift using individual subsystems, all the values will be just `ingress-ca`.
 - After modifying the contents of `ingress-ca` and saving the yaml, create the secret using `oc create -f filename.yaml -n NAMESPACE`.

```
apiVersion: v1
data:
  ca.crt: CA_CERT
  tls.crt: TLS_CERT
  tls.key: TLS_KEY
kind: Secret
metadata:
  annotations:
    cert-manager.io/alt-names: ''
    cert-manager.io/certificate-name: TOP_CR_NAME-ingress-ca
    cert-manager.io/common-name: ingress-ca
    cert-manager.io/ip-sans: ''
    cert-manager.io/issuer-group: ''
    cert-manager.io/issuer-kind: Issuer
    cert-manager.io/issuer-name: TOP_CR_NAME-self-signed
    cert-manager.io/uri-sans: ''
  name: <TOPCR>-ingress-ca
type: kubernetes.io/tls
```

3. Run the migration steps, starting with Step 1 in [Installing the target system](#). Install API Connect, using the same `TOP_CR_NAME` (if using top-level CR), by following the remainder of the steps in [Installing the target system](#).
4. When you complete [Restoring the target system](#), do not map the source system gateways that are to be reused. Just skip them.
5. Once the migration is complete, restart the gateways pods on the source system, wait for few minutes, and run the health check script to check the status of webhooks.
6. Validate the APIs running on the source system gateways.

- Delta changes

Once the migration procedure is started, any delta changes in the source system databases are not handled by the migration scripts. These changes must be handled manually.

- o To avoid delta changes, shut down the Postgres database in the management subsystem. See [Shutting down the Postgres database](#).
- o If there are delta changes to the management database after saving the configuration for the source system, you can optionally take another backup of the Management subsystem, just prior to restoring the Management subsystem. See [Restoring the target system](#).

- Sizing

Before installing the API Connect target system, make sure proper capacity planning is done to handle the production workloads. Ensure you have sufficient memory, CPU, and disk size as needed, based on the deployment profile being installed.

- Expected migration time

The time required to complete migration can depend on the following:

- o The size of the management database. Backup and restore are dependent on this size.
- o Migration of the Portal and Gateway data in all the provider orgs depends on:
 - Number of provider orgs
 - Number of catalogs in these provider orgs
 - Whether Portals are configured for these catalogs
 - Total number of APIs published
- o Creation of Portal sites and restore of Portal backup depends on:
 - Deployment profile (n1, n3 etc) being used
 - Disk performance

- Total number of Portal sites being create or restored
- The amount of customization in a Portal site. Customization plays a role in the time needed to restore.

v10 migration requirements

Ensure your deployment meets the migrations prerequisites and requirements.

Topics:

- [Version prerequisites](#)
- [Subsystem requirements](#)
- [Scripting requirements](#)
- [Credentials requirements](#)
- [How to obtain hostnames](#)
- [How to obtain realm values](#)
- [Backing up subsystems](#)
- [Limitations](#)

Version prerequisites

The API Connect versions on the source and target systems must be the same.

Subsystem requirements

All subsystems must be in a healthy state.

You must manually create storage classes like block storage or file system storage. Applies to all subsystems and, when installing on CP4I, to Platform Navigator.

Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.

- Management subsystem:
 - You must configure Management subsystems with either S3 or SFTP backups.
 - If s3 storage is being used, postgres in the Management subsystem must be stopped on the source system.

Note:
Shutting down postgres is necessary in this scenario because two APIC deployments cannot both use the same S3 backup location. The target API Connect deployment will not start if postgres on the source deployment is up and connecting to the same S3 backup location.

When postgres is stopped, there is no impact on the published APIs in the gateways. However, the Cloud Manager and API Manager UI will not available because the underlying microservices are down. Users are able to browse the APIs in the Portal. But new consumer orgs or applications or users cannot be created.
 - If the Postgres cluster name on the target is different than the source system, restore will fail. For more information on configuring the target system, see [Installing the target system](#).
- Developer Portal subsystem:
 - Developer Portal subsystems must be configured with either S3 or SFTP backups.
 - For Developer Portal subsystem, you must have all the mappings between old and new endpoints and hostnames.
- Gateway subsystem:
 - If a custom gateway image is being used on the source system, the same image must be used on the target system
 - For a Gateway subsystem, you must have all the mappings between old and new endpoints and hostnames.

Scripting requirements

- Python 3 and PyYAML python module must be present on the system where the scripts are run. To install the PyYAML module:

```
pip3 install pyyaml
```
- Do not have any spaces in the complete directory path where the scripts are executed.
- Ensure that the API Connect version of the `apic` toolkit is the same version as for the scripts, and that the toolkit is located in the path where the scripts are executed. Validate toolkit commands to make sure the Cloud Manager and API Manager hostnames are resolved and able to run few commands. Make sure apic toolkit commands are working before trying out the scripts.
- If you are using hostnames, you may need to update the `/etc/hosts` file for the apic toolkit to work.
- When the scripts are run on the target system, the configuration (data directory) saved from the source system must be available in the location where scripts are present.
- Save the output logs for every script being executed.

Credentials requirements

- In all the scripts where the credentials are passed on the command line, these credentials are the admin org (Cloud Manager) credentials.
- You must be able to use `kubect1` (for native Kubernetes) or `oe` (OpenShift) commands to access the source system cluster and the target system cluster.
- To administer the admin org, you must have credentials with administrative role to access Cloud Manager.
- For provider orgs, if you do not use the migration user, and plan to use provider org credentials, you must have the provider org credentials for the API Manager interface.
- You must manually create:
 - Secrets for entitlementment keys to download images from Docker registry.
 - DataPower admin credentials and secret, if the target system is native Kubernetes.

- After migration, the users on the target system will be in the same user registry as in the source system. For example, in CP4I, users from a local user registry (LUR) are not moved to a Zen user registry.

How to obtain hostnames

The hostnames used in the scripts (`--server` or `-s` or `-api_manager_hostname`) and also in the files `gateway_portal_mapping.yaml` or `provider_org_credentials.yaml` can be obtained using the following commands.

The command must be run on the source cluster or target cluster, based on the step for which the hostname is needed.

- Kubernetes:

```
kubectl get ingress -n <NAMESPACE>
```
- OpenShift and Cloud Pak for Integration:

```
oc get routes -n <NAMESPACE>
```

Example output on Kubernetes:

```
kubectl get ingress -n ask1
```

NAME	CLASS	HOSTS	ADDRESS
analytics1-ac-endpoint	<none>	ac1.testuser1-master.fyre.example.com

How to obtain realm values

The value of realm (`--realm` or `-r`) used while running the scripts can be obtained as shown in the following examples. The realm values are for Cloud Manager (admin org) and provider org.

- Example for Cloud Manager (admin org):
The value is passed as a command line option while running the script.

```
apic identity-providers:list --scope admin --fields title,realm --server api.test1-master.fyre.example.com
total_results: 3
results:
- title: Cloud Manager User Registry
  realm: admin/default-idp-1
- title: googleoidc
  realm: admin/googleoidc
- title: ldap1
  realm: admin/ldap1
```

- Example for provider org realm values:
The value is used in `provider_org_credentials.yaml` while updating Portal and Gateway information in the provider orgs, when the default migration user is not used. See Step 4 and Step 6 in [Restoring the target system](#).

```
apic identity-providers:list --scope provider --fields title,realm --server api.testuser1-master.fyre.example.com
total_results: 3
results:
- title: API Manager User Registry
  realm: provider/default-idp-2
- title: googleoidc
  realm: provider/googleoidc
- title: ldap1
  realm: provider/ldap1
```

Backing up subsystems

It is necessary to backup the data in Management and Portal subsystems on the source system. If backup is not configured, you can use the following links to configure backup:

- Management subsystem. Use the directions for your platform:
 - Native Kubernetes: [Backing up and restoring the management subsystem](#)
 - OpenShift and Cloud Pak for Integration: [Backing up and restoring the management subsystem on OpenShift and Cloud Pak for Integration](#)
 - VMware: [Backing up and restoring the Management subsystem](#)

- Developer Portal subsystem. Use the directions for your platform:
 - Native Kubernetes: [Backing up and restoring the Developer Portal in a Kubernetes environment](#)
 - OpenShift and Cloud Pak for Integration: [Backing up and restoring Developer Portal on OpenShift and Cloud Pak for Integration](#)
 - VMware: [Backing up and restoring the Developer Portal](#)

Limitations

1. Analytics service and data is not migrated.
2. If migrating from v10 non-CP4I environment (source apic cluster) to v10 CP4i environment (target apic cluster), make sure the Cloud Manager password for `admin` user is not `7iron-hide` on the source cluster. If default password `7iron-hide` is used, migration will fail after step 3 in [Restoring the target system](#), as configurator job assumes that the install is a fresh installation, and changes the password automatically.

v10 migration steps

Complete the steps that are required for your v10 migration path.

Before you begin

Ensure you have reviewed [v10 migration overview](#) and [v10 migration requirements](#).

Procedure

1. Identify the supported migration path you will use. If necessary, review [Supported v10 migration paths](#) in [v10 migration overview](#).
2. Follow the instructions for your migration path:
 - For all paths except migration from OpenShift top-level CR to Cloud Pak for Integration on the same cluster, complete the following tasks in order:
 - [Preparing the source system](#)
 - [Installing the target system](#)
 - [Restoring the target system](#)
 - [Verifying the target system](#)
 - If migrating from OpenShift top-level CR to Cloud Pak for Integration on the same cluster, complete [Migrating from OpenShift to Cloud Pak for Integration on the same cluster](#).
- [Preparing the source system](#)
Run the `save_v10_source_configuration.py` script to gather the source system configuration.
- [Installing the target system](#)
On the target system, configure a cluster, create the necessary secrets, and install API Connect.
- [Restoring the target system](#)
Restore the saved configuration and backups from the source system onto the target system.
- [Verifying the target system](#)
Verify that the target system is in a healthy state and fully configured.
- [Migrating from OpenShift to Cloud Pak for Integration on the same cluster](#)
Migrate your API Connect v10 deployment from OpenShift to Cloud Pak for Integration, while remaining on the same cluster.

Preparing the source system

Run the `save_v10_source_configuration.py` script to gather the source system configuration.

Before you begin

Review [v10 migration requirements](#).

About this task

The `save_v10_source_configuration.py` script:

- Creates a data directory with all configuration saved in it.
 - Generates two YAML files in the same directory as the script:
 - `gateway_portal_mapping.yaml`
 - `provider_org_credentials.yaml`
- Important:** The YAML files must be filled in:
- `gateway_portal_mapping.yaml` must be filled in if, when restoring onto the target system, you choose to run `register_gateway_portals_in_target.py` in silent mode. See step 3.c in [Restoring the target system](#).
 - `provider_org_credentials.yaml` must be filled in if, when restoring onto the target system, you choose not to use the migration user credentials while updating Portal and Gateway information. See step 4 and step 6 in [Restoring the target system](#).

To view script parameters:

```
python3 save_v10_source_configuration.py --help
```

Procedure

1. Save configuration from the source system. Complete the instructions for the platform type of your source system:

- Kubernetes, or OpenShift, or Cloud Pak for Integration

To save the source system configuration, run `save_v10_source_configuration.py` with the appropriate parameters for your deployment:

- If all subsystems are in the same namespace, and you are using username/password authentication. This command saves configuration of all the installed subsystems in the namespace:

```
python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n NAMESPACE
```

- If a subsystem needs to be skipped so that its configuration is not saved:
 - Skip Portal:

```
python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n NAMESPACE -skip_ptl
```

- Skip Analytics:

```
python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n NAMESPACE -skip_a7s
```

- If all subsystems are in the same namespace, and you are using SSO authentication:

```
python3 save_v10_source_configuration.py --sso -s PLATFORM_API_HOSTNAME -n NAMESPACE
```

- If all subsystems are in different namespace, and you are using username/password authentication:

```
python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -mgmt_ns <mgmt_namespace> -ptl_ns <ptl_namespace> -gw_ns <gw_namespace> -a7s_ns <a7s_namespace>
```

- If the cluster has multiple Gateways, Portals, or Analytics subsystems distributed across namespaces in the cluster, you can save the configuration of the source system using one of the ways shown below. Multiple namespaces need to be separated by "|" symbol. The namespaces used in below example command are `ns1`, `ns2`, `ns3`. Both commands work the same way.

- `python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n "ns1|ns2|ns3"`

- `python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -mgmt_ns "ns1" -ptl_ns "ns1|ns2" -gw_ns "ns1|ns2|ns3" -a7s_ns "ns1|ns2"`

- If ingress-ca certificates must be saved or exported in the configuration, run the previous commands with `-export_cert` flag. Applicable only when you are saving management subsystem configuration.

- VMware

On VMware appliance, save the source configuration by running the `save_v10_source_configuration.py` script on the Management and Portal nodes.

If you have a three replica deployment, run the `save_v10_source_configuration.py` script on just one of the VMs in the cluster.

- Copy the `apic` toolkit and `apicup` installer to the management node.
- Copy the script `save_v10_source_configuration.py` to the management node:
 - If `ingress-ca` and `root-ca` certificates must be saved in the configuration, copy this script to the project directory for this appliance and upload the project directory to the appliance. The script must be run from inside the project directory.
 - If `ingress-ca` and `root-ca` certificates are not needed, just copy this script to the appliance.
- Change to root user (`sudo -i`) and set `PATH` variable to the directory where the `apic` toolkit is present. This directory must be at the beginning of the path.
- Change to the directory where script is located. Check the `PATH` to verify that the `apic` toolkit is present. To validate, use `apic login` and `apicup version`.
- Collect source system configuration. If certificates needed, add the flag `-export_cert` to the command.

```
python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -mgmt_ns default
```

- On the Management node, from the location where the script is run, download the `data` directory, `gateway_portal_mapping.yaml`, and `provider_org_credentials.yaml` files. Copy them to the location where the form factor migration scripts are present.
- Copy the `save_v10_source_configuration.py` script to the Portal node and run the script as root user, using the following command:

```
python3 save_v10_source_configuration.py -ptl_ns default -skip_mgmt
```

On the Portal node, from the location where the script is run, download the `data` directory and merge it with the `data` directory downloaded from the Management node.

If multiple Portal services are configured with the Management subsystem, repeat the same operation for each Portal.

2. Next, begin configuration of the target cluster. Continue with [Installing the target system](#).

Installing the target system

On the target system, configure a cluster, create the necessary secrets, and install API Connect.

Before you begin

- Complete [Preparing the source system](#).
- Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.

About this task

Run the `create_secrets_in_target.py` script to create the necessary secrets. If necessary, shutdown the Postgres database, and then install API Connect, either manually or by running the `install_apic_on_ocp.py` script.

Note: For data migration, you have the option of performing a complete migration at once, or performing migration in more than one step. To review these options, see [v10 migration planning](#).

Procedure

1. Configure a target cluster either Kubernetes or OpenShift or Cloud Pak for Integration, where you intend to migrate the source system data.
 - Note that this configuration is for the cluster only. No API Connect software is installed yet.
 - Make sure `KUBECONFIG` is set to this target cluster, so you can access the cluster using `oc` or `kubectl`.
2. Create the namespaces in the target cluster where you want the API Connect subsystems to run.
 - The namespaces can be different than the source system values.
 - If you have additional subsystems to be installed in different namespaces, create these namespaces also.
3. Run `create_secrets_in_target.py` to create the following secrets:
 - Database backup secrets for Management and Portal subsystems
 - Application credentials
 - Encryption secrets from the source systemUsage examples:
 - If both Management and Portal are in the same namespace, or if Portal is not installed.

```
python3 create_secrets_in_target.py -n NAMESPACE
```
 - If both Management and Portal are in different namespaces:

```
python3 create_secrets_in_target.py -mgmt_ns <MGMT_NAMESPACE> -ptl_ns <PTL_NAMESPACE>
```
 - If you are creating multiple Portal subsystems in the target API Connect system, to match the configuration of the source system, you must run the script more than once for each Portal subsystem from the source system. The script detects that there are two Portal subsystems in the source system, and prompts you to select the subsystem name that matches the target Portal, as shown in the following commands:

- For Management and first Portal on the target system:

```
python3 create_secrets_in_target.py -mgmt_ns <MGMT_NAMESPACE> -ptl_ns <PTL_NAMESPACE1>
```

- For the second Portal on the target system:

```
python3 create_secrets_in_target.py -skip_mgmt -ptl_ns <PTL_NAMESPACE2>
```

4. If applicable to your deployment, shutdown the Postgres database on your source system. You can shutdown the Postgres database now, to ensure that there are no delta changes to your source system while the remainder of the migration process takes place.

Important: If s3 backup is being used for the Management subsystem in the source system, the postgres database MUST be shutdown before launching the target API Connect cluster. If it is not shutdown, the launch of the target apic cluster will fail.

For steps to shutdown Postgres database on Kubernetes or OpenShift, see [Shutting down the Postgres database](#).

5. Launch the target API Connect system.
 - a. Review prerequisites:
 - Have a new OpenShift cluster ready with enough resources (CPU, memory, and disk) as required for the installation profile you will use.
 - As needed, create an entitlement key to download the images related to API Connect.
 - The target system must match the topology (number of Gateways, Portals and Analytics) of the source system to ensure that all the data in the Management database is migrated. If all the data in the Management database is not migrated, the not migrated (stale) data must be manually deleted. Alternatively, you can attempt the remaining migration later after installing the additional Portals and Gateways. See [v10 migration planning](#).Important: If s3 backup is being used for the Management subsystem in the **target** system, once the Management subsystem is ready, you will see that the backup job pods and stanza-create job pods are in **Error** state. This is expected behavior. Once management backup is restored, the error resolves and backups will work. Since the backup will **not** happen until the Management database is restored, it is very important to restore Management subsystem backup on the target system (see step 2 in [Restoring the target system](#)) immediately after installing the target system. Any delay can cause the disk to fill up with write-ahead log (WAL) files.
To review how to monitor Postgres db disk usage, see:

- [Monitoring Postgres disk usage on OpenShift](#)
- [Monitoring Postgres disk usage on VMware](#)
- [Monitoring Postgres disk usage](#) on Kubernetes.

- b. Launch the target API Connect system either manually or by using the `install_apic_on_ocp.py` script:

- To manually launch from the OpenShift cluster UI:

This method is the recommended way to launch the target API Connect system for production systems.

This method is also used for advanced customization or when using custom certificates while launching the target API Connect system.

- Install and launch the target API Connect cluster. See the instructions for your deployment type:
 - API Connect on OpenShift: [Deploying on OpenShift and Cloud Pak for Integration](#)
 - Cloud Pak for Integration: [Installation procedures with IBM Cloud Pak for Integration](#)
- Before creating the top level CR, use the yaml view to add the properties which you saved from the source system configuration. For the Management subsystem, the saved configuration is in `data/config.yaml`. For the Portal subsystem, the saved configuration is in `data/config_portal.yaml`.

Important: If you do not use the configuration from the source system, the migration fails.

- Management subsystem properties:

- encryptionSecret
- Management subsystem name
- site name
- database backup credentials
- custom application credentials
- originalUID
- Portal subsystem properties:
 - encryptionSecret
 - site name
 - database backup credentials
 - originalUID

Note: If target system is Kubernetes, the properties must be in the Management and Portal subsystem CRs.

- The top level CR must look like the following example. The values for this top CR are from the generated artifacts (data/config.yaml and data/config_portal.yaml) after running [Preparing the source system](#). Note that the example shows a value for `spec.management.name`. You can obtain this value from config.yaml.

```

    profile: nlxc7.m48
    storageClassName: rook-ceph-block
    version: 10.0.4.0
```

- You can also use the script `install_apic_on_ocp.py` with `-no_install` flag to generate the top level CR yaml, and use the yaml in the OpenShift UI and customize further.
- To launch using the `install_apic_on_ocp.py` script:

The script is used to launch API Connect on OpenShift or API Connect with Cloud Pak for Integration using a top level CR that specifies one of each subsystem type:

 - Management
 - Developer Portal
 - Analytics
 - API Gateway

Prerequisite:

- The OpenShift cluster must be ready, and accessible using `oc`.
- **Important:** The script is used to launch **ONLY** the specific version of API Connect based on the downloaded version of the artifacts.

Usage:

- Run the script with `--help` option to show additional flags available like `-production` and `-profile`.
- License use is set to `nonproduction` by default unless the flag `-production` is used while running this script.
- The profile defaults to the one replica profile `n1xc7.m48`, to specify a different profile use the `-profile` flag. For details of the available profiles, see [API Connect deployment profiles for OpenShift and Cloud Pak for Integration](#). The one replica profile deploys 1 replica of each pod and is only for light, non-critical workloads such as basic development and testing.
- Optionally, you can use the `-no_install` flag if you want to generate the yaml files (top level CR and other files needed in installation) without installing. In the following example commands, add the `-no_install` flag to the existing command parameters. You can use this top level CR from the OpenShift UI, and create an API Connect cluster.
- Note : If CP4I environment, check if configurator job is completed and also check the output of:

```
oc get apiconnectcluster -n NAMESPACE
```

Example command invocations:

Note: Each of the example commands includes parameters for a three replica profile deployment: `-production -profile n3xc16.m48`. If you have a one replica profile, omit these parameters.

- API Connect on OpenShift:
 - If the apiconnect and DataPower operators must be installed in all namespaces:

```
python3 install_apic_on_ocp.py -license LICENSE_VALUE -n NAMESPACE -name topCRName -storageclass_apic STORAGE_CLASS_NAME -production -profile n3xc16.m48
```

- If the apiconnect and DataPower operators must be installed in a specific namespace:

```
python3 install_apic_on_ocp.py -license LICENSE_VALUE -n NAMESPACE -name topCRName -storageclass_apic STORAGE_CLASS_NAME -operator_in_specific_namespace -production -profile n3xc16.m48
```

- API Connect in Cloud Pak for Integration:

- If operators are in all namespaces:

```
python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic STORAGE_CLASS_NAME1 -cp4i -storageclass_pn STORAGE_CLASS_NAME2 -license_pn LICENSE_VALUE2 -production -profile n3xc16.m48
```

- If operators are in a specific namespace:

```
python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic STORAGE_CLASS_NAME1 -cp4i -storageclass_pn STORAGE_CLASS_NAME2 -license_pn LICENSE_VALUE2 -operator_in_specific_namespace -production -profile n3xc16.m48
```

- If operators are in all namespaces, with additional flags `-production` (for license to be set to production) and `-profile` (using n3 profile in this example):

```
python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic STORAGE_CLASS_NAME1 -cp4i -storageclass_pn STORAGE_CLASS_NAME2 -license_pn LICENSE_VALUE2 -production -profile n3xc16.m48
```

6. Optional: Install any additional Gateways, Developer Portals, or Analytics subsystems that are needed.

- Complete this step now if your target system will have additional Gateways, Developer Portals, or Analytics subsystems to match what is there in the source API Connect system, and you want to complete data migration for all subsystems in one pass through the procedures in [Restoring the target system](#).
- Skip this step now, and proceed to step 7 if either of the following cases are true:
 - If your target system will not need any additional Gateways, Developer Portals, or Analytics subsystems.
 - Your target system will have additional Gateways, Developer Portals, or Analytics subsystems but you want to first complete data migration based on the top CR installation (1 Management, 1 Portal, 1 Gateway, 1 Analytics), before you install any additional subsystems.

Note: To review the data migration choices, see [v10 migration planning](#).

If you choose complete this step now, see:

- [Deploying on OpenShift and Cloud Pak for Integration](#)
- [Installation procedures with IBM Cloud Pak for Integration](#)

7. Next, restore the configuration from the source system. Continue with [Restoring the target system](#).

Restoring the target system

Restore the saved configuration and backups from the source system onto the target system.

Before you begin

- Complete [Installing the target system](#).
- Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.

About this task

Use scripts to:

- Restore the Management subsystem
- Register Gateways and Portals on the target system
- Update Portals in the Catalog to point to new Portal systems
- Restore Portal backups for each site
- Update Gateways in the Catalog to point to new Gateway systems

All scripts run on the target system must be run from a location where the data directory is present so that the source configuration can be used.

Note: You can optionally run scripts in `--silent` mode, particularly for the following scenarios:

- Register Gateways and Portals in the target system. (Step 3)
- Update Portals in the Catalog to point to new Portal systems. (Step 4)
- Update Gateways in the Catalog to point to new Gateway systems. (Step 6)

If there are multiple Portals and Management subsystems present in the data directory (as saved during [Preparing the source system](#)), the restore script prompts you to select the subsystem name to use for migration while running the script. If running in silent mode, that value must be supplied as an additional flag.

Deployments with multiple Portals and Gateways are a common scenario. The saved data can have multiple Management subsystems only if you ran `save_v10_source_configuration.py` against multiple clusters with different Management subsystem names, without cleaning the data directory.

Procedure

1. Before restoring the Management subsystem backup, determine whether there have been any delta changes to your source system since you backed up the Management subsystem database and Portal database.
 - If you shutdown the Postgres database, as instructed in [Installing the target system](#), there are no delta changes. Continue to step 2.
 - If you did not shutdown the Postgres database, there could be some delta changes to the Management database, because the Management subsystem on the source system remains in READY state. In this case, to ensure you capture the latest configuration, repeat [Preparing the source system](#). By doing so, the Management and Portal databases are backed up again. The latest backup will then be used to restore to the target system.
2. Restore a Management subsystem backup onto the target system.
 - a. On the target API Connect system, ensure that the Management subsystem is up and running.
 - b. Run `restore_management_db.py`. Examples:
 - OpenShift or Kubernetes target system:

```
python3 restore_management_db.py -n <mgmt namespace>
```

or:

```
python3 restore_management_db.py -mgmt_ns <mgmt namespace>
```
 - Cloud Pak for Integration target system:

```
python3 restore_management_db.py -n <namespace> -s <platform API hostname>
```
 - If for some reason the management subsystem is not healthy, restore using the command:

```
python3 restore_management_db.py -n <mgmt namespace> -ignore_health_check
```
3. Register Gateways and Portals on the target system.
 - a. Prerequisites:
 - The `register_gateway_portals_in_target.py` script must be run on the target system after the Management database from the source system has been restored.
 - The Gateway and Developer Portal subsystems that need to be registered must be in a healthy state.
 - b. Usage notes:
 - The credentials provided from this step will be same as the credentials used on the source system, because the Management database from the source system is restored.
 - Keep the endpoints ready for the new Gateway and Portal services so that they can be registered by running `register_gateway_portals_in_target.py`. To view endpoints, use `oc get routes`.
 - If you run `register_gateway_portals_in_target.py` for a Cloud Pak for Integration target system, and you see the error `The API Connect Gateway Service is already registered to another API Manager instance`, restart all the gateway pods, wait for them to become healthy, and run `register_gateway_portals_in_target.py` again.
 - Make sure the mapping of old URLs with the new ones are correct. For example, when the source system is a VMware appliance, if wrongly mapped (wrong values provided) communication errors occur during Gateway registration. Example errors messages:
 - `"Error: An error occurred communicating with the gateways subsystem "`
 - `"error: 'Client network socket disconnected before secure TLS connection was established'"`
 - c. Run `register_gateway_portals_in_target.py` in either interactive mode or silent mode:
 - Interactive mode
The `register_gateway_portals_in_target.py` script displays the Portal and Gateway endpoints from the source system, and prompts the user to enter the corresponding values from the target system. Examples:
 - If Management, Portal and Gateway subsystems are in the same namespace:

```
python3 register_gateway_portals_in_target.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -n <namespace>
```
 - If Management, Portal and Gateway subsystems are in different namespaces, use `-mgmt_ns`, `-ptl_ns`, and `-gw_ns` to specify each, for example:

```
python3 register_gateway_portals_in_target.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns <mgmt namespace> -ptl_ns <portal namespace> -gw_ns <gway namespace>
```
 - If you are using SSO authentication, replace:

```
-u <username> -p <password>
```

with:

--sso

- Multiple namespaces can alternatively be specified with "ns1|ns2|ns3" notation. For example:

```
python3 register_gateway_portals_in_target.py -n "ns1|ns2|ns3" -u admin -p <password> -s <platform API hostname> -r admin/default-idp-1 -silent
```

```
python3 register_gateway_portals_in_target.py -s <platform API hostname> -u admin -p <password> -r admin/default-idp-1 -mgmt_ns ns1 -ptl_ns "ns1|ns2" -gw_ns "ns1|ns2|ns3" -silent
```

- Silent mode

The gateway_portal_mapping.yaml file, with mapping between old and new endpoints for Gateway, Portal, and Analytics endpoints, must be located in the same directory as register_gateway_portals_in_target.py.

This gateway_portal_mapping.yaml file is generated when saving the source API Connect system configuration with properties data filled in. For every Gateway, Portal, and Analytics subsystem registered with Management in the source system, the yaml has the endpoint mapping between source and target systems.

Remaining data must be filled to use the yaml in silent mode. All values must begin with https://.

- Example:

```
python3 register_gateway_portals_in_target.py -n <namespace> -u <username> -p <password> -s <platform API hostname> -r <realm name> -silent
```

- Example: If the subsystems are in multiple namespaces.

For example, ns1, ns2, ns3 namespaces contain the subsystems. Both of the following commands work the same way:

```
python3 register_gateway_portals_in_target.py -n "ns1|ns2|ns3" -u <username> -p <password> -s <platform API hostname> -r <realm name> -silent
```

```
python3 register_gateway_portals_in_target.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns ns1 -ptl_ns "ns1|ns2" -gw_ns "ns1|ns2|ns3" -silent
```

- Example gateway_portal_mapping.yaml file with:

- Two Gateways
- One Portal or Analytics subsystem
- All data mapped to the target API Connect system:

```
analytics_mapping:
  registered_analytics_name:
    https://ac.source-apic.example.com: https://a1-a7s-ac-endpoint-apic1.apps.vlxocp-3278.cp.fyre.example.com
gateway_mapping:
  registered_apigw_name:
    https://rgw.source-apic.fyre.example.com: https://a1-gw-gateway-apic1.apps.vlxocp-3278.cp.fyre.example.com
    https://rgwd.source-apic.fyre.example.com: https://a1-gw-gateway-manager-apic1.apps.vlxocp-3278.cp.fyre.example.com
  registered_v5gw_name:
    https://gw.source-apic.fyre.example.com: https://v5gw.gw.apps.vlxocp-3278.cp.fyre.example.com
    https://gwd.source-apic.fyre.example.com: https://v5gw.gwd.apps.vlxocp-3278.cp.fyre.example.com
portal_mapping:
  registered_portal_name:
    https://api.portal.source-apic.fyre.example.com: https://a1-ptl-portal-director-apic1.apps.vlxocp-3278.cp.fyre.example.com
    https://portal.source-apic.fyre.example.com: https://a1-ptl-portal-web-apic1.apps.vlxocp-3278.cp.fyre.example.com
```

- Example gateway_portal_mapping.yaml file with:

- Only two Gateways
- One Portal or Analytics
- One Gateway not mapped

Note that "not mapped" means that the data in the Management subsystem related to this Gateway is not mapped, and the Gateway will not be migrated during this migration phase.

The Gateway could be migrated later; for example, after the second Gateway is created on the target system. Until the data related to the not-migrated Gateway or Portal is migrated or deleted, there will be stale data in the database.

The same behavior can be achieved by leaving the values empty, or removing the entire section (name and mapping).

```
analytics_mapping:
  registered_analytics_name:
    https://ac.source-apic.example.com: https://a1-a7s-ac-endpoint-apic1.apps.vlxocp-3278.cp.fyre.example.com
gateway_mapping:
  registered_apigw_name:
    https://rgw.source-apic.fyre.example.com: https://a1-gw-gateway-apic1.apps.vlxocp-3278.cp.fyre.example.com
    https://rgwd.source-apic.fyre.example.com: https://a1-gw-gateway-manager-apic1.apps.vlxocp-3278.cp.fyre.example.com
  registered_v5gw_name:
    https://gw.source-apic.fyre.example.com: NEW_GATEWAY_API_ENDPOINT_BASE_IN_TARGET_SYSTEM
    https://gwd.source-apic.fyre.example.com: NEW_GATEWAY_ENDPOINT_IN_TARGET_SYSTEM
portal_mapping:
  registered_portal_name:
    https://api.portal.source-apic.fyre.example.com: https://a1-ptl-portal-director-apic1.apps.vlxocp-3278.cp.fyre.example.com
    https://portal.source-apic.fyre.example.com: https://a1-ptl-portal-web-apic1.apps.vlxocp-3278.cp.fyre.example.com
```

4. Use update_to_new_portals.py to update Portals in the catalog to point to new Portal systems.

Note: If there is no Portal subsystem on the source system, skip this step. Also, skip this step if no Portal sites are created in any of the provider orgs. Continue with [6](#).

a. Review prerequisites:

- The Management and Portal subsystems on the target API Connect system must be in a healthy state.
- The `update_to_new_portals.py` script must be run on the target system after the following actions have been completed:
 - The Management database from the source system has been restored.
 - The new Gateway or Portal instance is registered in the Cloud Manager, using script or from the UI.
- The credentials for accessing the admin org (Cloud Manager UI) and, if required, the provider org (API Manager UI) must be available for running the script.

b. Run the `update_to_new_portals.py` script in one of two modes, based on how the Provide Org credentials are available. The modes are:

- Using a common migration user created by the script
- Using credentials provided by the user in a yaml file

Important: The provider org credentials must have administrative access.

Examples:

- Using a common migration user created by the script :

The `update_to_new_portals.py` script runs in this mode by default. This script creates a migration user `muser1` in `migrationur` local user registry, and uses it to migrate Portal information in all the provider orgs. Once the migration is done, the user and user registry are deleted. There is no change in data once the migration is complete.

Examples:

- If the Management and Portal subsystems are in the same namespace

```
python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -n <namespace> -api_manager_hostname <platform API hostname> -silent
```

- If using SSO authentication:

```
python3 update_to_new_portals.py -s <platform API hostname> --sso -n <namespace> -api_manager_hostname API_MANAGER_HOSTNAME -silent
```

- If the Management and Portal subsystems are in different namespaces:

```
python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns <mgmt namespace> -ptl_ns <portal namespace>E -api_manager_hostname <platform API hostname>E -silent
```

- Using credentials provided by the user in a `provider_org_credentials.yaml` file:

The `provider_org_credentials.yaml` file, with some data filled in, is generated by the `save_v10_source_configuration.py` script you ran in [Preparing the source system](#). The yaml file is available in the same directory as the script. The script has to be edited and all details filled in before it can be used.

Examples:

- If Management and Portal subsystems are in the same namespace:

```
python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -n <namespace> -no_migration_user -silent
```

- If using SSO authentication:

```
python3 update_to_new_portals.py -s <platform API hostname> --sso -n <namespace> -no_migration_user -silent
```

- If Management and Portal subsystems are in different namespaces:

```
python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns <mgmt namespace> -ptl_ns <portal namespace> -no_migration_user -silent
```

Example `provider_org_credentials.yaml`:

- With credentials given for every provider org. In this example, only two orgs are present.

```
provider_org_credentials:
  apiManagerHostName: <platform API hostname>
  PORG_NAME_1:
    password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
    realm: provider/default-idp-2
    username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
  PORG_NAME_2:
    password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
    realm: provider/default-idp-2
    username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
  useSameCredentialsForAllProviderOrgs: false
```

- With credentials given for just one provider org. Also requires `useSameCredentialsForAllProviderOrgs` set to true. This method can be used only when the same credentials are used for all provider orgs.

Note: In some cases, there are multiple provider orgs in the Management database.

```
provider_org_credentials:
  apiManagerHostName: <platform API hostname>
  PORG_NAME_1:
    password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
    realm: provider/default-idp-2
    username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
  useSameCredentialsForAllProviderOrgs: true
```

- With SSO credentials and just one provider org:

```
provider_org_credentials:
  apiManagerHostName: <platform API hostname>
  useSameCredentialsForAllProviderOrgs: false
```

```

porg_anme:
#sso authentication
#the key(that can expire in sometime) has to be generated separately using
https://<apiManagerHostname>/auth/manager/sign-in/?from=TOOLKIT
apiKey: some_key

```

5. Restore Portal backups for each site.

Note: If there is no Portal subsystem on the source system, skip this step. Continue with [6](#).

To restore the Portal sites on the target system, you can either use the using script `restore_portal_db.py` or complete a manual restore.

- Restoring through the script:

```
python3 restore_portal_db.py -n PORTAL_SUBSYSTEM_NAMESPACE
```

- Restoring through manual steps:

- Log in to the Portal admin container:

```
oc exec -it <www_pod> -c admin -- bash
```

- List the site backups:

```
remote_transfer_backup -l
```

The list of backups that need to be restored is available in the output logs as a report of [Step 4](#).

- Download each site backup, and run it for all sites:

```
remote_transfer_backup -d <SITE_BACKUP_FILENAME>
```

- Restore each of the site backups:

```
restore_site -f -u <SITE_URL> <SITE_BACKUP_FILENAME>
```

Note: If there are more than one Portal subsystems on the target system, as needed to correspond to the Portal subsystems on the source system, run the script for each of the matching source and target Portal subsystems.

For example, if there are two Portals on the target system, matching what is on the source system, and these Portals are installed in namespaces `target1` (for the top-level CR) and `pt12` (for second portal), then the script will be run twice, as follows:

```
python3 restore_portal_db.py -n target1
```

```
python3 restore_portal_db.py -n pt12
```

6. Run `update_to_new_gateways.py` to update Gateways in the Catalog to point to new Gateway systems.

a. Review prerequisites:

- The Gateway subsystem must be in a healthy state.
- The `update_to_new_gateways.py` script must be run on the target system after the following actions have been completed:
 - The Management database from the source system has been restored.
 - The new Gateway instance is registered in the Cloud Manager, using script or from the UI.
- The credentials for accessing the admin org (Cloud Manager UI) and, if required, the provider org (API Manager UI) must be available for running the script.

b. Run the `update_to_new_gateways.py` script in one of two modes, based on how the Provider Org credentials are available. The modes are:

- Using a common migration user created by the script
- Using credentials provided by the user in a yaml file

Important: The provider org credentials must have administrative access.

- Using a common migration user created by the script:

The `update_to_new_gateways.py` script runs in this mode by default. This script creates a migration user `muser1` in `migrationur` local user registry, and uses it to migrate Portal information in all the provider orgs. Once the migration is done, the user and user registry are deleted. There is no change in data once the migration is complete.

Examples:

- If the Management and Gateway subsystems are in the same namespace:

```
python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -n <namespace> -api_manager_hostname <platform API hostname> -silent
```

- If using SSO authentication:

```
python3 update_to_new_gateways.py -s <platform API hostname> --sso -n <namespace> -api_manager_hostname <platform API hostname> -silent
```

- If the Management and Gateway subsystems are in different namespaces:

```
python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns <mgmt namespace> -pt1_ns <portal namespace> -api_manager_hostname <platform API hostname> -silent
```

- Using credentials provided by the user in a `provider_org_credentials.yaml` file:

The `provider_org_credentials.yaml` file, with some data filled in, is generated by the `save_v10_source_configuration.py` script you ran in [Preparing the source system](#). The yaml file is available in the same directory as the script. The script has to be edited and all details filled in before it can be used.

- If the Management and Gateway subsystems are in the same namespace:

```
python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -n <namespace> -no_migration_user -silent
```

- If using SSO authentication:

```
python3 update_to_new_gateways.py -s <platform API hostname> --sso -n <namespace> -no_migration_user -silent
```

- If the Management and Gateway subsystems are in different namespaces:
Note that if multiple gateway subsystems present across namespaces, you can give multiple namespaces separated by the "|" symbol for `-gw_ns`.

```
python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns <mgmt namespace> -gw_ns GW_NAMESPACE -no_migration_user -silent
```

- Example `provider_org_credentials.yaml`
 - With credentials given for every provider org, and only two orgs present:

```
provider_org_credentials:
  apiManagerHostName: <platform API hostname>
  PORG_NAME 1:
    password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
    realm: provider/default-idp-2
    username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
  PORG_NAME 2:
    password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
    realm: provider/default-idp-2
    username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
  useSameCredentialsForAllProviderOrgs: false
```

- With credentials given for just one provider org, and `useSameCredentialsForAllProviderOrgs` is set to `true`.
This can be used only when same credentials are used for all provider orgs.

Note: There can be multiple provider orgs in the Management database.

```
provider_org_credentials:
  apiManagerHostName: <platform API hostname>
  PORG_NAME 1:
    password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
    realm: provider/default-idp-2
    username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
  useSameCredentialsForAllProviderOrgs: true
```

- With SSO credentials and just one provider org:

```
provider_org_credentials:
  apiManagerHostName: <platform API hostname>
  useSameCredentialsForAllProviderOrgs: false
  org_name:
    #sso authentication
    #the key (that can expire in sometime) has to be generated separately using
    https://<apiManagerHostName>/auth/manager/sign-in/?from=TOOLKIT
  apiKey: some_key
```

7. Continue to [Verifying the target system](#).

Verifying the target system

Verify that the target system is in a healthy state and fully configured.

Before you begin

Complete [Restoring the target system](#).

About this task

Check the health of the target system, complete any optional configuration, and validate data, APIs, and URLs.

Procedure

1. Use the `health_check_post_migration.py` script to health check the target system.

Examples:

- When all the subsystems are in the same namespace, and the deployments uses username/password authentication:

```
python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD -n NAMESPACE
```

- When all the subsystems are in the same namespace, and the deployments uses username/password authentication, with use of the optional flag `-check_portal_site_health` to check the health of Portal sites:

```
python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD -n NAMESPACE -check_portal_site_health
```

- When subsystems are present in different namespaces, and the deployment uses username/password authentication

```
python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD -mgmt_ns NAMESPACE -gw_ns NAMESPACE
```

- When all subsystems are in different namespaces, and the deployment uses username/password authentication:

```
python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD -mgmt_ns NAMESPACE -gw_ns NAMESPACE -ptl_s NAMESPACE -a7s_ns NAMESPACE
```

- When all subsystems are in the same namespace, and the deployment uses SSO authentication:

```
python3 health_check_post_migration.py -n NAMESPACE --sso -s PLATFORM_API_HOSTNAME
```

- When all subsystems are in the same namespace, and the deployment uses SSO authentication silent mode:

```
python3 health_check_post_migration.py -n NAMESPACE --sso -s PLATFORM_API_HOSTNAME -api_key API_KEY_VALUE
```

- When there are multiple subsystems across namespaces:

```
python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD -n "namespace1|namespace2|namespace3"
```

2. Complete any optional configuration steps needed for your deployment:

- a. If necessary, update redirect URLs in the authorization server.

If OIDC or SSO authentication is being used, the redirect URLs must be updated in the authorization server after migration. For example, for Google OIDC, you must add the new redirect URLs in Google Developer Console. The new redirect URLs can be found in the user registry in Cloud Manager.

- b. If necessary, complete configuration for Analytics.

If the Analytics service is present on the target system, backups must be configured. Also, use the Cloud Manager UI to manually associate the Analytics with the Gateways, as needed.

- c. If the target system is Cloud Pak for Integration, you must use the password from the target API Connect system to log in to Platform Navigator.

- d. If necessary, update Portal and Gateway services names in scripts or utilities.

The migrated Portal and Gateway services will have new names (old_name + "new"). Any scripts and utilities written using the apic toolkit must be updated if they are using names as input parameter and not the ids. This is applicable to only Portal and Gateway names.

3. Validate configuration data:

- a. Validate the data in the target API Connect system by logging into Cloud Manager and API Manager UIs.

- b. Validate the APIs published in the Gateways.

- c. Validate the Portal site URLs

- d. If necessary, update the DNS mapping info.

Once all of the APIs are verified, you may need to update the DNS mapping info, to redirect the calls to the new Gateways and Portals.

The v10 migration is now complete.

4. After migration is finished, and verification of the target system is complete, you can uninstall API Connect on the source system.

See [Uninstalling API Connect](#).

Migrating from OpenShift to Cloud Pak for Integration on the same cluster

Migrate your API Connect v10 deployment from OpenShift to Cloud Pak for Integration, while remaining on the same cluster.

Before you begin

Your API Connect instance must use the top-level CR. Direct migration of individual API Connect subsystem installations to Cloud Pak for Integration by the steps described here is not supported. Alternative methods of migration if you are not using the top-level CR are:

- If the same subsystem endpoints can be used, deploy a new top-level CR API Connect and restore disaster recovery backups from your existing installation, see [Disaster recovery on OpenShift and Cloud Pak for Integration](#). The new top-level CR deployment can then be migrated to Cloud Pak for Integration following the steps here.
- If different subsystem endpoints need to be used, migrate your API Connect deployment to a new top-level CR OpenShift cluster first. Follow the form factor migration steps [Migrating from v10 to v10 on a different form factor](#), and then return here to complete the OpenShift top-level CR to Cloud Pak for Integration migration.

About this task

Migration from OpenShift to Cloud Pak for Integration on the same cluster results in changes to the Management subsystem API endpoint URIs, as shown in these examples.

- apiManager endpoint changes from

```
https://topcr-mgmt-api-manager-apic.example.com/manager
```

to

```
https://cpd-apic.example.com/integration/apis/apic/topcr/manager
```

- cloudManager endpoint changes from

```
https://topcr-mgmt-admin-apic.example.com/admin
```

to

```
https://cpd-apic.example.com/integration/apis/apic/topcr/admin
```

- platformAPI endpoint changes from

```
https://topcr-mgmt-platform-api-apic.example.com/
```

to

```
https://cpd-apic.example.com/integration/apis/apic/topcr/api
```

- consumerAPI endpoint changes from

`https://topcr-mgmt-consumer-api-apic.example.com/`

to

`https://cpd-apic.example.com/integration/apis/apic/topcr/consumer-api`

Procedure

1. Update your `<TOP_CR_NAME>-mgmt-admin-pass` secret with your current Cloud Manager admin password:

- a. Check whether the `<TOP_CR_NAME>-mgmt-admin-pass` password already matches your Cloud Manager admin password with:

```
oc get secret -n <APIC-namespace> | grep mgmt-admin-pass
```

```
oc get secret -n <APIC-namespace> <secret_name_from_previous_command> -o jsonpath="{.data.password}" | base64 -d &&
echo ""
```

If the passwords match then skip to [2](#).

- b. From where you run OpenShift CLI commands, use the base64 command to encode your Cloud Manager admin password.

```
echo -n '<password>' | base64
```

Note: If the `base64` command is not available, alternative commands or tools can be used.

- c. Edit the `<TOP_CR_NAME>-mgmt-admin-pass` secret:

```
oc edit secret <TOP_CR_NAME>-mgmt-admin-pass -n <namespace>
```

- d. Replace the `data.password` value with your base64 encoded value from [1.b](#).

```
...
data:
  email: ZXhhbXBsZUBleGFtcGxlLmNvbQ==
  password: <base64 encoded password>
kind: Secret
metadata:
  ...
```

Note: The password in `<TOP_CR_NAME>-mgmt-admin-pass` is only used on API Connect installation, form factor migration, and disaster recovery. It does not need to be kept in sync with the Cloud Manager during normal API Connect usage.

2. Install IBM Cloud Pak Platform UI and create an instance of it.

3. Restart the `apiconnect` operator pod.

The restarted operator pod detects Cloud Pak for Integration and reconciles the subsystems with it. Wait for the subsystems to be healthy.

4. Log in to Cloud Manager and check the services under the topology section.

Known issue: If you see an additional Analytics service with a different name for the same Analytics endpoint, you must delete the newly created Analytics service.

5. Check that the configurator job is complete: :

```
oc get pods -n <namespace>
...
NAME                                READY   STATUS    RESTARTS   AGE
<instance name>-configurator-<random string>  0/1     Completed  0          2h
...
```

Complete the following validation checks:

- Verify you are able to login to the Cloud Pak for Integration Platform UI, and can see your API Connect instance.
- Verify you are able to login to Cloud Manager UI, API Manager UI, and your portal sites.
- Test that your APIs are running, and analytics data is logged.
- Test lifecycle operations such as a product publish or delete, or an app creation.

v10 migration troubleshooting

Troubleshoot problems with v10 migration.

Topics:

- [Script help](#)
- [Restarting migration](#)
- [Factory reset of portal subsystem](#)
- [Avoid error when a gateway is already registered to another API manager](#)

Script help

```
python3 <SCRIPT_FILE_NAME> --help
```

Restarting migration

On the target system, after running `register_gateway_portals_in_target.py` or `update_to_new_portals.py` or `update_to_new_gateways.py` script:

- If you want to restore the Management database and try the steps again:
 - Run the restore Management db (Step [2](#) on [Restoring the target system](#)) with the `-reset_gateway_portal` flag as shown

```
python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
```

If running on a Kubernetes environment, supply the Cloud Manager admin password by using the `-p` flag. After this, continue with next steps of migration.

- If you deleted the data directory after registering Gateways or Portals, but want to use the same target API Connect system which you already installed, then:
 1. Complete [Preparing the source system](#) to create the data directory.
 2. Run the restore management db (Step 2 on [Restoring the target system](#)) with the `-reset_gateway_portal` flag as shown

```
python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
```

If running on a Kubernetes environment, supply the Cloud Manager admin password by using the `-p` flag. After this, continue with next steps of migration.

Factory reset of portal subsystem

You can do a factory reset of the Portal subsystem by either manually or by using a migration script.

- Using migration script
The script will restore the Management database and will factory reset the Portal subsystem, and also delete Gateway pods. The gateway pods will get restarted.

The script will factory reset the Portal subsystem and also delete Gateway pods. When Gateway pods are deleted, they are also restarted.

```
python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
```

If using a Kubernetes environment, you must also supply the Cloud Manager admin password by using the `-p` flag. After this command, you must run the remaining steps of migration, starting with Step 3 in [Restoring the target system](#).

```
python3 register_gateway_portals_in_target.py -n NAMESPACE -u USERNAME -p PASSWORD -s HOSTNAME -r REALM_NAME -reset_gateway_portal
```

- Manual steps

1. Log in to the Portal www pod:

```
kubect1 exec -it PORTAL_WWW_POD_NAME -c admin -n NAMESPACE -- bash
```

2. Run the command :

```
curl -X DELETE -k --cert /etc/nginx/ssl/portal-director-client-both.pem https://localhost:3009/v2/portal/factory-reset
```

3. If any sites are there, use the `list_sites` command to check if all sites are deleted.
4. Check health of the Portal subsystem.

Avoid error when a gateway is already registered to another API manager

Error messages

```
Error: An error occurred communicating with the gateways subsystem at 'some_url' (status: 400, response: '"Unable to perform initial registration for API Management. Error: The API Connect Gateway Service is already registered to another API Manager instance"')
```

You can fix the error condition manually, or use a script:

- Manual step, when Gateway is in a Kubernetes or OpenShift cluster:
Restart all the gateway pods.
- Using the migration script when Gateway is in a Kubernetes or OpenShift cluster:
The script will restore the Management database, factory reset the Portal subsystem, and delete the Gateway pods. Once deleted, Gateway pods get restarted.
 1. Run the following script:

```
python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
```

If using a Kubernetes environment, you must also supply the Cloud Manager admin password by using the `-p` flag.

2. After this command, you must run the remaining steps of migration, starting with Step 3 in [Restoring the target system](#).

- Gateway is on an Appliance
Reboot all the Gateway appliances.

Shutting down the Postgres database

Shut down the Postgres database to ensure no changes are made to the database during migration.

Instructions:

- [Shutting down Postgres database in Management subsystem on Kubernetes or VMware](#)
- [Shutting down Postgres database in Management subsystem on OpenShift](#)

Shutting down Postgres database in Management subsystem on Kubernetes or VMware

When using s3 backup configuration for the Management subsystem, the following steps should be run on the source system, before the target API Connect system is installed.

1. If on a VMware appliance deployment, connect to the Management node and log in as root user (`sudo -i`), so that you can run `kubect1`.
2. Enable pgo client:

```
kubectl set env deploy/ibm-apiconnect ENABLE_PGO_CLIENT="true" -n OPERATOR_NAMESPACE
```

3. Wait for `pgo-client` pod to come up.

4. Bring down the apic operator:

```
kubectl scale deploy ibm-apiconnect --replicas=0 -n OPERATOR_NAMESPACE
```

5. Scale down deployments.

Before scaling down the deployments, make a note of the current replicas:

```
kubectl get deployment -n namespace
```

- Standard deployments :
 - juhu
 - portal-proxy
 - apim
 - lur
 - taskmanager
 - hub (when Test and Monitor is enabled)

a. Scale down:

```
kubectl scale deploy <deployment_name> --replicas=0 -n NAMESPACE
```

b. To get the name of the Postgres cluster:

```
kubectl get pgcluster -n NAMESPACE
```

c. Connect to pgo client pod and run:

```
pgo update cluster PG_CLUSTER_NAME --shutdown -n NAMESPACE
```

Shutting down Postgres database in Management subsystem on OpenShift

When using s3 configuration, the following steps should be run on the source system, before the target API Connect system is installed.

1. Change to operator namespace:

```
oc project "{OPERATOR NS}"
```

2. `oc edit csv ibm-apiconnect.v2.4.0`

a. Search for `APPLIANCE` and add these two lines above it:

```
- name: ENABLE_PGO_CLIENT
  value: "true"
```

b. Save and wait for the `pgo-client` pod to come up.

3. `oc scale deploy ibm-apiconnect --replicas=0`

4. Bring down apiconnect operator pod:

```
oc scale deploy ibm-apiconnect --replicas=0
```

5. Change to the namespace where API Connect is installed:

```
oc project "{APIC NS}"
```

6. Scale down the following deployments: juhu, portal-proxy, apim, lur, taskmanager

```
oc scale deploy JUHU_DEPLOYMENT_NAME --replicas=0
oc scale deploy PORTAL_PROXY_DEPLOYMENT_NAME --replicas=0
oc scale deploy APIM_DEPLOYMENT_NAME --replicas=0
oc scale deploy LUR_DEPLOYMENT_NAME --replicas=0
oc scale deploy TASKMANAGER_DEPLOYMENT_NAME --replicas=0
```

7. To get the name of the pg cluster:

```
oc get pgcluster
```

8. Log in to pgo client pod:

```
oc exec -it $(oc get po|grep pgo|awk '{print $1}') -- bash
```

9. Shutdown Postgres database:

```
pgo update cluster PG_CLUSTER_NAME --shutdown -n NAMESPACE
```

Starting the Postgres database in the Management subsystem on Kubernetes and OVA

Use these steps when you are moving back to the source system because the migration failed, and you want to bring up the Postgres database, if it was shutdown.

1. If on an appliance (VMware), connect to the Management node and log in as root user (`sudo -i`), so that you can run the `kubectl` commands.

2. Get the name of the Postgres cluster:

```
kubectl get pgcluster -n NAMESPACE
```

3. Connect to the pgo client pod and run the command:

```
pgo update cluster PG_CLUSTER_NAME --startup -n NAMESPACE
```

4. Scale up the deployments that use Postgres.

Standard deployments : juhu, portal-proxy, apim, lur, taskmanager, hub (when test and monitor is enabled)

```
kubectl scale deploy DEPLOYMENT_NAME --replicas=N -n NAMESPACE
```

The value of **N** is from the `kubectl get deployment -n namespace` output that you got before shutting down the Postgres database. It is 1 if using n1 profile, and 3 when using n3 profile.

5. Bring up the apic operator:

```
kubectl scale deploy ibm-apiconnect --replicas=1 -n OPERATOR_NAMESPACE
```

6. If s3 backups are used, perform a Management restore with the backup that was taken as part of [Preparing the source system](#).

Note: Any backups that are taken on the target system are not valid for the source system. The backups must not be used during restoration.

7. Ensure that all subsystems are healthy.

Starting postgres database on the Management subsystem on OpenShift

Use these steps when you are moving back to the source system because the migration failed, and you want to bring up the Postgres database, if it was shutdown.

1. Change to the project where the top-level CR (apic) is installed:

```
oc project APIC_NAMESPACE
```

2. Get the name of the Postgres cluster:

```
oc get pgcluster
```

3. Log in to pgo client pod:

```
oc exec -it $(oc get po | grep pgo | awk '{print $1}') -- bash
```

4. Start the postgres database:

```
pgo update cluster PG_CLUSTER_NAME --startup -n NAMESPACE
```

5. Scale up the deployments: juhu, portal-proxy, apim, lur, and taskmanager. Use the following commands, where **N** is the value of replicas. If an n1 profile being used the value is 1, and if an n3 profile is being used the value is 3.

- `oc scale deploy JUHU_DEPLOYMENT_NAME --replicas=N`
- `oc scale deploy PORTAL_PROXY_DEPLOYMENT_NAME --replicas=N`
- `oc scale deploy APIM_DEPLOYMENT_NAME --replicas=N`
- `oc scale deploy LUR_DEPLOYMENT_NAME --replicas=N`
- `oc scale deploy TASKMANAGER_DEPLOYMENT_NAME --replicas=N`

6. Bring down the apiconnect operator pod:

```
oc scale deploy ibm-apiconnect --replicas=1 -n OPERATOR_NAMESPACE
```

7. If s3 backups are used, perform a Management restore with the backup that was taken as part of [Preparing the source system](#).

Note: Any backups that are taken on the target system are not valid for the source system. The backups must not be used during restoration.

8. Ensure that all subsystems are healthy.

Migrating from v2018 to v10 on a different form factor

Migrate an API Connect v2018 deployment to a different form factor on v10. For example, migrate v2018 on Kubernetes to v10 on OpenShift.

Use the v2018 to v10 form factor migration process in the following circumstances:

- You want to change the deployment form factor, for example, moving from v2018 on OVA to v10 on OpenShift.
- You are on an old version of API Connect and are unable or prefer not to upgrade to the latest v2018 fix pack to do in-place upgrade. Form factor migration to v10 is supported for v2018 releases back to v2018.4.1 Fixpack 13.
- You are unable to upgrade your v2018 platform (OpenShift or Kubernetes) source environment to a version that supports v10.
- You want to change your API Connect endpoint URLs, but want to stay on the same form factor, for example, changing the portal web endpoint from `https://portal.v2018inst.example.com` to `https://portal.v10inst.example.com`.

If you do not want to change your deployment form factor and do not want to change your endpoint URLs, then the in-place upgrade is the simplest method to move to v10. See the upgrade documentation corresponding to your platform:

- [Upgrading from 2018 to 10.0.5.4 on Kubernetes.](#)
- [Upgrading from 2018 to 10.0.5.4 on OpenShift.](#)
- [Upgrading from 2018 to 10.0.5.4 on VMware.](#)

Complete the following tasks to migrate your v2018 API Connect deployment to a different form factor on v10:

- [Migration overview](#)
An overview of the migration steps, the supported paths, and the initial planning for a v2018 to v10 form factor migration.
- [Migration preparation](#)
Ensure that you have all the information, scripts, and tools ready to complete the migration.
- [v2018 migration steps](#)
Extract v2018 source data, install v10, load source data into v10 installation.
- [Troubleshooting the form-factor migration from v2018](#)
Troubleshoot problems with migrating from v2018 to v10 on a different form factor.

Migration overview

An overview of the migration steps, the supported paths, and the initial planning for a v2018 to v10 form factor migration.

Restriction: Beginning with version 10.0.5.5, a direct upgrade from version 2018 is not supported using form factor migration. To upgrade from version 2018, upgrade to 10.0.5.4, and then perform the upgrade to the newest release.

What does form factor migration involve?

1. The health of the source v2018 deployment is verified, and any necessary cleanup of the database is completed.
2. Scripts are run against the source deployment to extract Management and Portal data.
3. The v10 target deployment is installed.
4. A mapping file of the API Connect endpoints is generated, mapping your v2018 endpoint URLs to the endpoints of the v10 deployment.
5. Scripts are run against the target deployment to load the data from the v2018 source deployment, applying the endpoint mappings.

The scripts that are used for the migration are in Python and are supported on Linux and MacOS. On Kubernetes and OpenShift the scripts must be run from a client computer that has access to your Kubernetes or OpenShift cluster. On OVA deployments, they are run directly on the Management and Portal VMs.

Supported v2018 to v10 migration paths

The supported migration paths cover two use cases:

- Migrating from a v2018 system on one form factor to a v10 system on another form factor.
- Migrating from a v2018 system on one form factor to a v10 system on the same form factor, when you want to change the API Connect endpoint URLs.

Table 1. Supported migration paths to API Connect v10

Source deployment platform of API Connect v2018	Target deployment platform, based on API Connect v10
Kubernetes	Cloud Pak for Integration
Kubernetes	OpenShift Container Platform
Kubernetes	Kubernetes, when moving to a different cluster, resulting in hostname changes
VMware	Cloud Pak for Integration
VMware	OpenShift Container Platform
VMware	VMware
OpenShift Container Platform	Cloud Pak for Integration, moving to a different cluster, resulting in hostname changes
OpenShift Container Platform	OpenShift Container Platform, moving to a different cluster, resulting in hostname changes
Cloud Pak for Integration	Cloud Pak for Integration, moving to a different cluster, resulting in hostname changes

v10 migration planning

Points for consideration in v2018 to v10 migration planning:

Note: The v2018 deployment is referred to as the 'source' system, and the v10 deployment you are migrating to is referred to as the 'target' system.

- Do you want to migrate all your v2018 source data?
You do not have to migrate all your v2018 Portal and Gateway subsystems. You can start with a v10 target deployment that has one gateway and portal, and migrate your v2018 data to it. Later you can then add more gateway and portal subsystems to your v10 deployment and migrate your remaining v2018 subsystems. This method is called a staged migration.

Other v2018 data such as organizations, products, and APIs that you do not want can be deleted from your v10 Cloud Manager and the API Manager UIs.

- Delta changes
The first step in the migration is extracting the data from your v2018 source deployment. If the v2018 deployment continues in use after the data extraction, then any new changes will not be migrated. You must manually apply any delta changes to your v10 target deployment after the v2018 extracted data is restored.
- Sizing
Ensure that v10 capacity planning is done. Ensure you have sufficient memory, CPU, and disk size, to meet your requirements. See [Planning your deployment](#).
- Time to complete migration.
The time taken to complete migration depends on the size of your Management database and number of portal sites.

Migration preparation

Ensure that you have all the information, scripts, and tools ready to complete the migration.

Decide on your endpoint mappings

Decide on the new endpoints for your v10 deployment. The v2018 endpoints that require mapping for v10 are:

- Management
 - `cloudManagerEndpoint`
 - `apiManagerEndpoint`
 - `platformAPIEndpoint`
 - `consumerAPIEndpoint`
- Portal

- `portalAdminEndpoint`
- `portalUIEndpoint`
- Gateway
 - `gatewayEndpoint`
 - `gatewayManagerEndpoint`
- Analytics
 - `ingestion`

You configure your v10 endpoint URLs when you install v10. You must keep a note of these endpoints and add them to a mapping file that is generated by the v2018 extract script.

Note: It is not a requirement that the endpoints change, in which case you do not need to update the mapping file.

v2018 health checks

Verify that your v2018 deployment is running, APIs operational, and all UIs are accessible.

Ensure that you have recent backups of your Management and Portal subsystems.

v2018 source extraction tools and scripts

The following tools and scripts must be available in your v2018 project directory to run the extract script:

- The form factor migration script: `save_v2018_source_configuration.py`.
- The `apicops` tool.
- The toolkit CLI `apic-slim` command, which must be renamed to `apic`.
- The `apicup` tool.

Follow these steps to download the tools and configure your v2018 project directory:

1. The migration scripts and extract docker image are included in the v10 release and can be obtained from [Passport Advantage](#) or from [IBM Fix Central](#).

- Download `apiconnect-operator-release-files_<version number>.zip`. The migration scripts are in the `helper_files/formFactorMigration` directory.

```
apiconnect-operator-release-files_<version number>/helper_files/formFactorMigration
```

Copy the `save_v2018_source_configuration.py` file contained in this directory to your project directory.

- **OVA users:** Download `v2018_ova_upgrade_files_<version number>.tgz`. The extract docker image is in this compressed file under:

```
build/v2018-dr-upgrade/extract-image.tar.gz
```

Copy the `extract-image.tar.gz` file to your project directory.

Note: Fix Central is intended for users with existing API Connect installations to find updates. For this reason, to find the latest migration scripts on Fix Central select the previous release number in the menu labeled Installed Version*. For example, if the latest v10 release is v10.0.5.2, select v10.0.5.1 in Fix Central.

2. The `apicops` tool is used to verify the health of the v2018 Management subsystem database, see [Installing apicops](#). Ensure you download the latest v2018 version of `apicops`, not the v10 version. Rename the downloaded `apicops-<os_name>` file to just `apicops`, copy it to your project directory, and ensure that it has execute permissions.
3. The migration scripts use the API Connect toolkit CLI, see [Installing the v2018 toolkit](#). The v2018 toolkit CLI `apic-slim` executable file must be renamed to `apic` and be in your `PATH` variable when you run the `save_v2018_source_configuration.py` script.
4. Copy the v2018 `apicup` executable file to your project directory. This `apicup` file is the same as the one that you used to upgrade to your current v2018 release, so it might already be there.

OVA users: Copy your project directory to your Management VM and Portal VMs. If you have a three node deployment, copy the project directory to one VM in each cluster. To access your VMs, SSH to your VM as the `apicadm` user and run `'sudo -i'`. Create a directory called `ffm`, copy your project directory there, and add this directory to your `PATH` variable:

```
ssh apicadm@<VM hostname>
sudo -i
mkdir ffm
scp -r <remote project directory location> /root/ffm
export PATH=/root/ffm/<project dir>:$PATH
```

Warning: `/root/ffm/<project dir>` must be set at the front of the `PATH` variable to prevent a different executable file that is present on OVA and also called `apic` from being run.

Non-OVA users

- Ensure that Python 3 and the PyYAML python module are present and usable from your project directory. To install the PyYAML module run:

```
pip3 install pyyaml
```

- From your project directory, you must be able to run `kubectl` (Kubernetes) or `oc` (OpenShift) commands to access the source system cluster.
- The user that runs the `save_v2018_source_configuration.py` script must have execute permission on the `apicops`, `apicup`, and `apic` commands.
- The user that runs the script must have write access in the project directory, so the exported data can be saved there.
- The full path of your project directory must not contain any space characters.
- Add the project directory to your `PATH` variable:

```
export PATH=<project dir>:$PATH
```

- Load the v10 install images into your image registry, these include the `ibm-apiconnect-management-v2018-to-v10-extract` image that you need to extract your v2018 source data.

The Management subsystem endpoints must be reachable from the location of your project directory.

When your project directory is set up to run the migration, its contents should look like this:

```
ls -l
total 117424
...
-rwxr-xr-x 1 root root 54347564 Jul 1 08:45 apicops
-rwxr-xr-x 1 root root 43742016 Jan 27 2020 apic
-rwxr-xr-x 1 root root 36999168 Oct 21 13:00 apicup
-rw-r--r-- 1 root root 86878 Oct 21 13:27 save_v2018_source_configuration.py
-rw-r----- 1 root root 10682 Oct 24 10:06 apiconnect-up.yml
drwxr-xr-x 3 root root 4096 Oct 24 12:58 build (OVA ONLY - CONTAINS UNPACKED v2018_ova_upgrade_files_<version
number>.tgz)
...

# which apicops
/root/ffm/<project dir>/apicops

# which apic
/root/ffm/<project dir>/apic

# which apicup
/root/ffm/<project dir>/apicup
```

Note: This example is from an OVA deployment. File ownerships can differ on a non-OVA deployment.

Credentials and access requirements

- The migration scripts require the Cloud Manager admin user credentials.
- The computer where you have your project directory must have network access to the Management Platform REST API endpoint.

Backing up v2018 Management and Portal

The migration process checks that backups for Management and Portal subsystems exist. The migration scripts exit if no backups are detected.

- Kubernetes and OpenShift: https://www.ibm.com/docs/en/SSMNED_2018/com.ibm.apic.install.doc/overview_backup_restore.html
- VMware: https://www.ibm.com/docs/en/SSMNED_2018/com.ibm.apic.install.doc/overview_backup_restore_vm.html

Additional requirements and limitations

1. If a custom gateway image is being used on the source system, an equivalent v10 based image must be used on the target system.
2. Analytics data is not migrated.
3. If the target platform is Cloud Pak for Integration, make sure the Cloud Manager password for **admin** user is not **7iron-hide** on the source cluster. If the default password **7iron-hide** is used, migration will fail after step 5 in [Restoring the v2018 data to the v10 target deployment](#), because the configurator job assumes that this is a new installation, and changes the password automatically.
4. Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.

Final readiness checks

Verify that **apicops**, **apic** (renamed from **apic-slim**), **kubectl/oc**, and **apicup** commands all run successfully from your v2018 project directory.

- Verify that the **kubectl** command returns a list of running pods (**oc** command on OpenShift). Example from Management server:

```
# kubectl get pods
NAME                                READY   STATUS    RESTARTS   AGE
apiconnect-analytics-proxy-8d6c595fb-4z6kc  1/1     Running   0           25h
...
```

- Verify that **apicops** can access your Management database by requesting a list of catalogs:

```
# apicops catalogs:list
Current local date/time 10/21/2022, 12:34:24 PM [Current UTC time: 2022-10-21T12:34:24.354Z]
apicops 0.2.215
Pod version is: 2018.4.1.9-ifix1.0 ( apim:2018.4.1.9-ifix1.0-15-fffd5fa )
All catalogs in format (org UUID . catalog UUID => org name . catalog name)
3ac560d2-9d99-43fd-ae9f-dfcc0321044a . 803a3ba3-1903-4b64-8c33-47d236bf1546 => testorg . sandbox
...
```

Note: OVA users: **apicops** is only required on your Management VM, not your Portal VM.

- Verify that you can log in to your Management subsystem with the toolkit CLI. For more information, see [v2018 toolkit CLI login](#):

```
# apic login --server <management server endpoint> --username admin --realm admin/default-idp-1
Enter your API Connect credentials
Password?
Logged into <management server endpoint> successfully
```

Note: OVA users: You need to run the toolkit CLI on your Management VM only.

- Verify that the **apicup** command returns a list of your subsystems:

```
# apicup subsys list
Name                                Type                Target
test-v2018-management               ManagementSubsystem  appliance
test-v2018-portal                   PortalSubsystem     appliance
test-v2018-analytics                AnalyticsSubsystem  appliance
```

v10 target deployment preparation

Non-OVA users: On a computer that has network access to the v10 environment, create a directory that is called `apicv10install`. Ensure the `apicv10install` directory meets the following requirements:

- Python 3 and the PyYAML python module are present and usable from your `apicv10install` directory. To install the PyYAML module run:

```
pip3 install pyyaml
```

- From your `apicv10install` directory, you must be able to run `kubectl` (Kubernetes) or `oc` (OpenShift) commands to access the target deployment environment.
- The full path of your `apicv10install` directory must not contain any space characters.
- The computer where you have your `apicv10install` directory must have network access to the v10 Management REST API endpoints.

OVA users: Create your v10 project directory, as described in [First steps for deploying in a VMware environment](#). You can name the project directory what you want, but this topic assumes it is called `apicv10install`.

All users: From the unpacked `apiconnect-operator-release-files_<version number>.zip`, copy the contents of `helper_files/formFactorMigration` to your `apicv10install` directory.

v2018 migration steps

Extract v2018 source data, install v10, load source data into v10 installation.

Before you begin

Review [Migration overview](#) and complete [Migration preparation](#).

- [Extracting the v2018 source data on Kubernetes and OpenShift](#)
Run the `save_v2018_source_configuration.py` script to gather the source deployment's configuration settings.
- [Extracting the v2018 source data on VMware](#)
Run the `save_v2018_source_configuration.py` script to gather the source deployment's configuration settings.
- [Installing the v10 target on Kubernetes](#)
Prepare your Kubernetes environment, create your API Connect secrets, install v10.
- [Installing the v10 target system on OpenShift and Cloud Pak for Integration](#)
On the target system, configure a cluster, create the necessary secrets, and install API Connect.
- [Installing the v10 target system on VMware](#)
Install your v10 OVA deployments and prepare them for restoring your v2018 data.
- [Restoring the v2018 data to the v10 target deployment](#)
Restore the saved configuration and backups from the source deployment onto the target deployment.
- [Verifying the v10 target deployment](#)
Verify that the target deployment is working correctly. Remove any unwanted v2018 data and subsystems.
- [Migrating additional v2018 subsystems: Staged migration](#)
If you did not migrate all your v2018 portal and gateway subsystems initially, and now want to migrate the remaining ones.

Extracting the v2018 source data on Kubernetes and OpenShift

Run the `save_v2018_source_configuration.py` script to gather the source deployment's configuration settings.

Before you begin

Complete the steps described in [Migration preparation](#).

About this task

Note: It is recommended that you keep the console output of all python scripts that are run. On most MacOS and Linux environments, appending the following to the end of the command saves the output to the specified file:

```
2>&1 | tee <output filename>
```

Procedure

1. Verify and fix any inconsistencies in the Management database by running the `apicops preupgrade` command:

```
apicops preupgrade -m fix --upgrade_to v10 -l apicopsOutput.txt
```

This command checks for known data issues and cleans up the data. The time the command takes to run depends on the size of the management database. `apicops` reports any problems that it is unable to fix at the end of the `apicopsOutput.txt` output file. If `apicops` reports any problems, open a support case and include the `apicopsOutput.txt` file, do not attempt the migration until the case is resolved.

2. Extract the v2018 data by running the `save_v2018_source_configuration.py` script.
Note: The extract script must be run within 2 hours of running the `apicops` health check.
On Kubernetes, if all subsystems are in the same namespace, run:

```
python3 save_v2018_source_configuration.py -n <namespace> -u admin -p <password> -s <platform_api_endpoint> -r admin/default-idp-1 --storage_class <storage class> -registry_secret <image_pull_secret> -extract_image <extract_image_url>
```

On OpenShift, if all subsystems are in the same namespace, run:

```
python3 save_v2018_source_configuration.py -ocp -n <namespace> -u admin -p <password> -s <platform_api_endpoint> -r
admin/default-idp-1 --storage_class <storage_class> -registry_secret <image_pull_secret> -extract_image
<extract_image_url>
```

Where

- `<namespace>` is your v2018 deployment's namespace.
- `<password>` is the Cloud Manager UI admin password.
- `<platform_api_endpoint>` is the FQDN of the platform api endpoint that is defined for your v2018 deployment. To find this run:
 - OpenShift:

```
oc get routes -n <apic namespace> | grep platform-api
```

- Kubernetes:

```
kubectl get ingress -n <apic namespace> | grep platform-api
```

Or get this value from the `apiconnect-up.yml` file in your project directory.

- `<storage_class>` is the name of the storage class your v2018 API Connect deployment is using. Get this value from the `apiconnect-up.yml` file in your project directory.
- `<image_pull_secret>`: Is the secret used to pull the API Connect images. Get this value from the `apiconnect-up.yml` file in your project directory.
- `<extract_image_url>`: is the URL of the API Connect extract load image `ibm-apiconnect-management-v2018-to-v10-extract`. To find the full URL, list all images in your registry. The extract load image URL looks like this:

```
<registry_server>/ibm-apiconnect-management-v2018-to-v10-
extract@sha256:521c4c4a36bf08cd9544084aa69f333f751376c89d0bd51f8e85d27ac00e893f
```

Note: This image is one of the v10 images that you loaded during migration preparation: [Migration preparation](#).

Example (Kubernetes):

```
python3 save_v2018_source_configuration.py -n apicsrc -u admin -p cuISlavSuFImPjwW5cjmMJwLzT -s api.ops-isl.jp-
tok.apiconnect.cloud.ibm.com -r admin/default-idp-1 --storage_class apic-mz-ibmc-block-gold-monthly -registry_secret
apiconnect-image-pull-secret -extract_image apic-dev-docker-local.artifactory.swg-devops.com/ibm-apiconnect-management-
v2018-to-v10-extract@sha256:6ec184f756e03f916b1bb1b22952d8ecc2dff1b445b3c81b9fa943d775ab665a
```

If Management, Portal, and Gateway subsystems are in different namespaces, use `-mgmt_ns`, `-ptl_ns`, and `-gw_ns` to specify each. Example (Kubernetes):

```
python3 save_v2018_source_configuration.py -mgmt_ns <management_namespace> -ptl_ns <portal_namespace> -a7s_ns
<analytics_namespace> -gw_ns <gateway_namespace> -u admin -p <password> -s <platform_api_endpoint> -r admin/default-idp-1
--storage_class <storage_class> -registry_secret <image_pull_secret> -extract_image <extract_image_url>
```

Note: Command help for the script is available with `--help`:

```
python3 save_v2018_source_configuration.py --help
```

3. The save script creates a `data` directory and two yaml files that are called `gateway_portal_mapping.yaml` and `provider_org_credentials.yaml`. Copy the data directory and the two yaml files to your v10 `apicv10install` directory.

What to do next

Install your target v10 deployment:

- [Installing the v10 target on Kubernetes.](#)
- [Installing the v10 target system on OpenShift and Cloud Pak for Integration.](#)
- [Installing the v10 target system on VMware.](#)

Extracting the v2018 source data on VMware

Run the `save_v2018_source_configuration.py` script to gather the source deployment's configuration settings.

Before you begin

Complete the steps described in [Migration preparation](#).

About this task

The operations in the task are run on the Management and Portal VMs where you configured the migration scripts and tools, as described in [Migration preparation](#).

Note: It is recommended that you keep the console output of all python scripts that are run. On most MacOS and Linux environments, appending the following to the end of the command saves the output to the specified file:

```
2>&1 | tee <output filename>
```

Procedure

Management subsystem

1. SSH to your VM as the `apicadm` user, run `'sudo -i'`, change to your project directory that you created in [Migration preparation](#), and add the directory to your `PATH` variable.

```
ssh apicadm@<VM hostname>
sudo -i
cd /root/ffm/<project dir>
export PATH=/root/ffm/<project dir>:$PATH
```

2. Load the extract image file into the VMs local docker registry. Run:

- On v2018.4.1.20 and previous releases:

```
# docker load -i /root/ffm/<project_dir>/build/v2018-dr-upgrade/extract-image.tar.gz
```

- Verify that the image is loaded with `docker images`

```
# docker images
REPOSITORY                                TAG
IMAGE ID      CREATED      SIZE
apiconnect/ibm-apiconnect-management-v2018-to-v10-extract  v10.0.5-21-EXTRACT
24d49cf227cb  5 weeks ago  939MB
...
```

- Take note of the version in the TAG column.
- On v2018.4.1.24 and later releases:

- Uncompress the image file:

```
gzip -d extract-image.tar.gz
```

- Load the image file:

```
ctr --namespace=k8s.io images import extract-image.tar
```

- List the images to confirm successful load:

```
ctr -n k8s.io images ls |grep v2018-to-v10-extract
```

```
docker.io/apiconnect/ibm-apiconnect-management-v2018-to-v10-extract:v10.0.5-38-EXTRACT
```

- Take note of the image version in output.

3. Verify and fix any inconsistencies in the Management database by running the `apicops preupgrade` command:

```
apicops preupgrade -m fix --upgrade_to v10 -l apicopsOutput.txt
```

This command checks for known data issues and cleans up the data. The time the command takes to run depends on the size of the management database. `apicops` reports any problems that it is unable to fix at the end of the `apicopsOutput.txt` output file. If `apicops` reports any problems, open a support case and include the `apicopsOutput.txt` file, do not attempt the migration until the case is resolved.

4. Run the extraction script:

```
python3 save_v2018_source_configuration.py -n default -u admin -p <password> -r admin/default-idp-1 -s <management hostname> -storage_class local-storage -extract_image <image path>:<version>-EXTRACT -skip_ptl -skip_a7s -skip_gw
```

Where

- `<password>` is the Cloud Manager UI admin password.
- `<management VM>` is the fully qualified hostname of your Management VM (the endpoint for your Management admin API).
- `<image path>` is the path to the image file:
 - On v2018.4.1.20 and earlier releases, `<image path>` is:

```
apiconnect/ibm-apiconnect-management-v2018-to-v10-extract
```

- On v2018.4.1.24 and later releases, `<image path>` is:

```
docker.io/apiconnect/ibm-apiconnect-management-v2018-to-v10-extract
```

- `<version>` is the version of the extract image, as noted in [step 2](#).
- Note: The extract script must be run within 2 hours of running the `apicops` health check.

5. The save script creates a `data` directory and two yaml files `gateway_portal_mapping.yaml` and `provider_org_credentials.yaml`. Copy the `data` directory and the two yaml files to your v10 `apicv10install` directory.

```
tar -cvf data_mgmt.tar data
scp data_mgmt.tar <username>@<servername>:<path>
scp gateway_portal_mapping.yaml <username>@<servername>:<path>
scp provider_org_credentials.yaml <username>@<servername>:<path>
```

Portal subsystem

6. SSH to your Portal VM as the `apicadm` user, run `sudo -i`, change to your project directory, and add the directory to your PATH variable.

```
ssh apicadm@<VM hostname>
sudo -i
cd /root/ffm/<project_dir>
export PATH=/root/ffm/<project_dir>:$PATH
```

7. From the project directory, run:

```
python3 save_v2018_source_configuration.py -ptl_ns default -skip_mgmt -skip_gw -skip_a7s
```

The script creates a `data` directory where all the extracted data is stored.

8. Upon completion of the script, copy the new `data` directory off the Portal VM to your v10 `apicv10install` directory.

```
tar -cvf data_portal.tar data
scp data_portal.tar <username>@<servername>:<path>
```

9. In your `apicv10install` directory, merge the two data directories that you copied from the Portal and Management VMs. The contents of this data directory should appear as shown:

```
$ tar -xf data_portal.tar
$ tar -xf data_mgmt.tar
```

```
$ ls -l data
total 20
-rw-r----- 1 <user> <user> 541 Oct 24 15:32 config_portal.yaml
-rw-r----- 1 <user> <user> 2552 Oct 24 17:19 config.yaml
drwxr-x--- 3 <user> <user> 4096 Oct 24 17:19 <management deployment name>
drwxr-x--- 2 <user> <user> 4096 Oct 24 15:29 <portal deployment name>
drwxr-x--- 2 <user> <user> 4096 Oct 24 17:19 temp
```

you should also have the two yaml files from Management subsystem extraction in the same location as the data directory:

```
$ ls -l
total 116452
drwxr-x--- 5 <user> <user> 4096 Oct 24 17:19 data
-rw-r----- 1 <user> <user> 2505 Oct 25 09:49 gateway_portal_mapping.yaml
-rw-r----- 1 <user> <user> 1146 Oct 25 09:49 provider_org_credentials.yaml
```

What to do next

Install your target v10 deployment:

- [Installing the v10 target on Kubernetes.](#)
- [Installing the v10 target system on OpenShift and Cloud Pak for Integration.](#)
- [Installing the v10 target system on VMware.](#)

Installing the v10 target on Kubernetes

Prepare your Kubernetes environment, create your API Connect secrets, install v10.

About this task

Follow this task along with the Kubernetes installation instructions: [Deploying on Kubernetes](#). The installation of v10 for v2018 form factor migration differs from a standard v10 installation as follows:

- You must use the v2018 Management encryption secret from your v2018 source deployment (a new key will be generated for the Portal subsystem).
- You must not use the same Management subsystem backup location and path as you use for your v2018 source deployment.
- You can use the same Portal subsystem backup location and path as you use for your v2018 source deployment. Reuse the v2018 portal backup path if you want to restore your v2018 portal site backups - to migrate your site customizations.
- Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.

This task describes the steps of the standard v10 installation that must be followed, and at which points in the process to apply the v2018 extracted data.

Note: It is recommended that you keep the console output of all python scripts that are run. On most MacOS and Linux environments, appending the following to the end of the command saves the output to the specified file:

```
2>&1 | tee <output filename>
```

Procedure

1. Obtain the API Connect v10 product files: [Obtaining product files](#).
2. Create your v10 namespaces, deploy the API Connect v10 operators, and cert-manager. The steps differ depending on whether you use one namespace for all API Connect subsystems, or whether you want different namespaces for each subsystem. In both cases, complete all steps on these pages except for the last step of installing your API Connect subsystems:

- [Deploying operators in a single-namespace API Connect cluster.](#)
- [Deploying operators in a multi-namespace API Connect cluster.](#)

Important: Return to this page and complete [#ffm_installing_2018-to-10_k8s_create_sec](#) and [4](#) before installing the API Connect subsystems.

3. Create the secrets based on your v2018 extracted data.

- a. Create the secrets by running the `create_secrets_in_target.py` script:

- If both Management and Portal are in the same namespace, or if Portal is not installed:

```
python3 create_secrets_in_target.py -n <namespace>
```

- If Management and Portal are in different namespaces:

```
python3 create_secrets_in_target.py -mgmt_ns <mgmt_namespace> -ptl_ns <portal_namespace>
```

When the script detects more than one portal subsystem, it prompts you to select the portal subsystem name that you want to create the secrets for. For the remaining portal subsystems, specify the different portal namespace and name with the `-ptl_ns` and `-ptl_subsys_name` arguments:

```
python3 create_secrets_in_target.py -skip_mgmt -ptl_ns <portal_x_namespace> -ptl_subsys_name <portal_subsystem_name>
```

- b. Verify that the secrets were created.

Run the `kubect1 get secrets` command as in the following example:

```
# kubect1 get secrets -n <namespace>
NAME                                TYPE      DATA   AGE
...
<mgmt deployment name>-enc-key      Opaque    1       2m47s
<portal deployment name>-enc-key    Opaque    1       2m47s
management-backup-secret            Opaque    2       2m47s
portal-backup-secret                 Opaque    2       2m47s
```

- c. Delete the v2018 Portal database encryption secret `<ptl_deployment_name>-enc-key`.

Run the following command to delete the secret:

```
# kubectl -n <namespace> delete secret <portal deployment name>-enc-key
```

Note: The v2018 Portal database encryption secret is not compatible with v10. After you delete the `<ptl_deployment_name>-enc-key`, a new secret will be generated when you apply the subsystem CR in a later step.

4. Edit the subsystem YAML files as described in [Installing the API Connect subsystems](#). You must update the following properties with the data that is extracted from your source v2018 deployment, which can be found in `data/config.yaml` for the Management subsystem, and `data/config_portal.yaml` for the Portal. Important: If you do not use the configuration from the source system, the migration fails.

- Management subsystem properties:

```
encryptionSecret:
  secretName: mgmt-enc-key
```

- Portal database backup details,:

```
portalBackup:
  credentials: portal-backup-secret
  host: <remote backup server IP>
  path: <example path>
  port: <remote backup server path>
  protocol: sftp
```

5. Continue with the installation of the subsystems, as described in [Installing the API Connect subsystems](#).

Note: To migrate all your v2018 data, install at least as many Portal and Gateway subsystems as you have on your v2018 source deployment. If you want to do a staged migration, you can install any remaining subsystems later.

Postinstallation verification and v10 toolkit CLI download.

6. Log in to the Cloud Manager UI: [Login to Cloud Manager UI](#).
7. Download the v10 toolkit CLI (CLI only) and `credentials.json` file, see [Installing the v10 toolkit](#).
8. Unpack the v10 toolkit CLI, and copy the `apic-slim` and `credentials.json` files to your `apicv10install` directory. Rename `apic-slim` to `apic`.
9. Ensure that your v10 toolkit CLI `apic` command is in your `PATH` variable:

```
EXPORT PATH=<apicv10install directory>:$PATH
```

10. Set your toolkit CLI credentials with:

```
apic client-creds:set <apicv10install directory>/credentials.json
```

11. Verify you can log in to your Management subsystem with the toolkit CLI. Use the same password as you used to log in to the Cloud Manager UI.

```
apic login --server <platform_api_endpoint> --username admin --realm admin/default-idp-1
```

where `<platform_api_endpoint>` is the FQDN of the platform api endpoint that is defined for your v10 Management subsystem, as returned by this command:

```
kubectl get ingress -n <namespace> | grep platform-api
```

For more information, see [v10 toolkit CLI login](#)

What to do next

Restore your v2018 source data to your v10 target deployment: [Restoring the v2018 data to the v10 target deployment](#).

Installing the v10 target system on OpenShift and Cloud Pak for Integration

On the target system, configure a cluster, create the necessary secrets, and install API Connect.

Before you begin

Check that your `apicv10install` directory contains:

- The migration scripts, as described in [v10 target deployment preparation](#).
- The `data` directory that contains the v2018 extracted data.

About this task

The installation of v10 for v2018 form factor migration differs from a standard installation in that you must use the v2018 encryption secret for your Management subsystem, instead of the default encryption secret that is created in a standard v10 installation. You can also use the same portal backup configuration if you want to restore your v2018 portal backup to v10 to keep your v2018 portal site customizations. This task describes the steps of the standard v10 installation that should be followed, and at which points in the process to apply the v2018 extracted data.

All operations in this task are completed from your `apicv10install` directory.

Note: It is recommended that you keep the console output of all python scripts that are run. On most MacOS and Linux environments, appending the following to the end of the command saves the output to the specified file:

```
2>&1 | tee <output filename>
```

Procedure

1. Install the API Connect operators and create your namespace. Follow the steps described on [Installing operators](#).

2. Create the secrets based on your v2018 extracted data.

a. Create the secrets by running the `create_secrets_in_target.py` script:

- If both Management and Portal are in the same namespace, or if Portal is not installed:

```
python3 create_secrets_in_target.py -n <namespace>
```

- If Management and Portal are in different namespaces:

```
python3 create_secrets_in_target.py -mgmt_ns <mgmt_namespace> -ptl_ns <portal_namespace>
```

When the script detects more than one portal subsystem, it prompts you to select the portal subsystem name that you want to create the secrets for. For the remaining portal subsystems, specify the different portal namespace and name with the `-ptl_ns` and `-ptl_subsys_name` arguments:

```
python3 create_secrets_in_target.py -skip_mgmt -ptl_ns <portal_x_namespace> -ptl_subsys_name <portal subsystem name>
```

b. Verify that the secrets were created.

Run the `oc get secrets` command as in the following example:

```
# oc get secrets -n <namespace>
NAME                                TYPE      DATA  AGE
...
<mgmt deployment name>-enc-key      Opaque    1       2m47s
<portal deployment name>-enc-key    Opaque    1       2m47s
management-backup-secret            Opaque    2       2m47s
portal-backup-secret                 Opaque    2       2m47s
```

c. Delete the v2018 Portal database encryption secret `<ptl_deployment_name>-enc-key`.

Run the following command to delete the secret:

```
# oc -n <namespace> delete secret <portal deployment name>-enc-key
```

Note: The v2018 Portal database encryption secret is not compatible with v10. After you delete the `<ptl_deployment_name>-enc-key`, a new secret will be generated when you apply the subsystem CR in a later step.

3. Cloud Pak for Integration: Install the Platform UI, as described in <https://www.ibm.com/docs/en/cloud-paks/cp-integration>.

4. Create a top-level CR YAM: file, but do not apply it: run `install_apic_on_ocp.py` with `-no_install`:

On OpenShift, run:

```
# python3 install_apic_on_ocp.py -name <name> -n <apic-namespace> -no_install -license "<license>" -storageclass_apic <storage class>
...
Create top level CR::
no_install flag is set to true. Not installing API Connect.
Location of API Connect top level CR file : /root/installapic/data/top_level_cr.yaml
...
This script performed the following actions in the target cluster:
*****
- Generated the yamls for catalog sources, subscriptions and top level CR. Check the data directory and data/temp
directory.
...

```

Where

- `<name>` is the name that you want for your v10 top-level CR deployment. If not specified the default is `minimum`.
- `<namespace>` is the namespace that you created for your v10 API Connect.
- `<license>` is the license ID, see [API Connect licenses](#).
- `<storage class>` is the name of the storage class your v10 API Connect deployment is using.

On Cloud Pak for Integration you must specify your Platform UI storage class and license: `-cp4i -storage_class_pn`

```
<platform ui storage class> -license_pn <platform ui license>
```

```
# python3 install_apic_on_ocp.py -name <name> -n <namespace> -no_install -license "<license>" -storageclass_apic <storage class> -cp4i -storage_class_pn <platform ui storage class> -license_pn <platform ui license>
```

The `top_level_cr.yaml` is created in your `data` directory.

Important: Save the generated Portal encryption key

5. Edit the generated `data/top_level_cr.yaml` file. You must set the `management.databaseBackup` section to your new location for v10 backups. You can change other settings in this file, but do not change the `management.encryptionSecret`. Example `top_level_cr.yaml` file:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APICConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-<name>
  name: <name>
  namespace: <namespace>
spec:
  analytics:
    storage:
      enabled: true
      type: unique
  license:
    accept: true
    license: <license>
    use: nonproduction
  management:
    customApplicationCredentials: []
    databaseBackup:
      credentials: management-backup-secret
      host: backup.ibm.com
      path: /backups/management
      port: 22
```

```

    protocol: sftp
    schedule: 0 0 1 1 *
    encryptionSecret:
      secretName: v2018source-management-enc-key
portal:
  portalBackup:
    credentials: portal-backup-secret
    host: backup.ibm.com
    path: /backups/portal
    port: 22
    protocol: sftp
    schedule: 0 0 1 1 *
  profile: nlxc7.m48
  storageClassName: <storage class>
  version: 10.0.x.x

```

6. Apply the `top_level_cr.yaml` file:

```
oc apply -f top_level_cr.yaml
```

Your v10 API Connect cluster is deployed. You can monitor the progress with:

```
oc get all -n <apic-namespace>
```

7. Install additional Portal, Gateway, and Analytics subsystems as needed, as individual subsystem CRs.

Note: To migrate all your v2018 data, install at least as many Portal and Gateway subsystems as you have on your v2018 source deployment. If you want to do a staged migration, you can install any remaining subsystems later.

Postinstallation verification and v10 toolkit CLI download.

8. Log in to the Cloud Manager UI: [Login to Cloud Manager UI](#).

9. Download the v10 toolkit CLI (CLI only) and `credentials.json` file, see [Installing the v10 toolkit](#).

10. Unpack the v10 toolkit CLI, and copy the `apic-slim` and `credentials.json` files to your `apicv10install` directory. Rename `apic-slim` to `apic`.

11. Ensure that your v10 toolkit CLI `apic` command is in your PATH variable:

```
EXPORT PATH=<apicv10install directory>:$PATH
```

12. Set your toolkit CLI credentials with:

```
apic client-creds:set <apicv10install directory>/credentials.json
```

13. Verify you can log in to your Management subsystem with the toolkit CLI. Use the same password as you used to log in to the Cloud Manager UI.

```
apic login --server <platform_api_endpoint> --username admin --realm admin/default-idp-1
```

where `<platform_api_endpoint>` is the FQDN of the platform api endpoint that is defined for your v10 Management subsystem, as returned by this command:

```
oc get routes -n <apic namespace> | grep platform-api
```

For more information, see [v10 toolkit CLI login](#).

What to do next

Restore your v2018 source data to your v10 target deployment: [Restoring the v2018 data to the v10 target deployment](#).

Installing the v10 target system on VMware

Install your v10 OVA deployments and prepare them for restoring your v2018 data.

About this task

Follow the standard VMware installation procedure, but set the encryption-secret for your v10 deployment to be the same as the encryption-secret extracted from your v2018 source deployment. Copy your `apicv10install` directory to your v10 VMs, and prepare the v2018 data load image.

Procedure

1. Install your v10 API Connect target deployment. Follow the standard v10 installation steps: [Install API Connect on VMware](#), but with the following differences:

- Ensure you specify different Management backup settings from your v2018 source deployment.
- If you want to restore portal backups, set the portal backup settings the same as on your v2018 source.
- **IMPORTANT:** Before you create the ISO files for your Management VM, set the encryption secret to the one you extracted from your v2018 source deployment:

```
apicup certs set <subsystem name> encryption-secret --encoded-string <v2018 enc secret>
```

Where:

- `<subsystem name>` is the name of your Management subsystem.
- `<v2018 enc secret>` is the v2018 encryption secret from your source Management deployment, located in `data/<mgmt_subsystem_name>/<mgmt_subsystem_name>-enc-key.yaml` file; for example:

```

apiVersion: v1
data:
  encryption_secret.bin: Xv2ES/0aIZnxwMdnGYsrfNM6c3S5iQ2qDbsfjL5bJlT7En0Ddm7qlbKMWJIeSbAUVK2AXaMIlNCGV+tNX6ASn2
  kind: Secret
...

```

Important: If you do not set the encryption secret before you created the ISO files, you must create the ISO files again. You cannot update the encryption secret after you deploy the management VM.

Postinstallation verification and v10 toolkit CLI download.

2. Log in to the Cloud Manager UI: [Login to Cloud Manager UI](#).
3. Download the v10 toolkit CLI (CLI only) and `credentials.json` file, see [Installing the v10 toolkit](#).
4. Unpack the v10 toolkit CLI, and copy the `apic-slim` and `credentials.json` files to your `apicv10install` directory. Rename `apic-slim` to `apic`.
5. SSH to your Management VM and Portal VMs, copy over your `apicv10install` directory, and set it as the first entry in your PATH variable:

```
ssh apicadm@<VM hostname>
sudo -i
scp -r <apicv10install directory> /root
export PATH=/root/<apicv10install directory>:$PATH
```

Note: If you are deploying a three node cluster, you need to copy the `apicv10install` and run the load commands on just one node in each cluster.

6. Set your toolkit CLI credentials with:

```
apic client-creds:set <apicv10install directory>/credentials.json
```

7. Verify you can log in to your Management subsystem with the toolkit CLI. Use the same password as you used to log in to the Cloud Manager UI.

```
apic login --server <platform_api_endpoint> --username admin --realm admin/default-idp-1
```

where `<platform_api_endpoint>` is the FQDN of the platform api endpoint that is defined for your v10 Management subsystem, this can be found in your `apiconnect-up-v10.yml` file in your project directory. For more information, see [v10 toolkit CLI login](#).

8. On your Management VM, prepare the full path string of the migration load image `ibm-apiconnect-management-v2018-to-v10-load`.

```
cd /var/lib/apiconnect-subsystem/registry/<apic version>/ibm-apiconnect-management-v2018-to-v10-load/<version>-LOAD
```

Get the `sha256sum` of the `manifest.json` file. Example:

```
# ls -l
...
-rw-r--r-- 1 apicadm apicadm 3254 Sep 16 21:36 manifest.json
-rw-r--r-- 1 apicadm apicadm 33 Sep 16 21:36 version

# sha256sum manifest.json
e9360e36f2544c84e83d2b0be7e2b47f9dc223dee2f604ee8e98778a01302d32 manifest.json
```

Use the `sha256sum` to assemble the full image name:

```
127.0.0.1:8675/<apic version>/ibm-apiconnect-management-v2018-to-v10-load@sha256:<sha256sum of manifest.json>
```

```
127.0.0.1:8675/10.0.5.1/ibm-apiconnect-management-v2018-to-v10-load@sha256:e9360e36f2544c84e83d2b0be7e2b47f9dc223dee2f604ee8e98778a01302d32
```

What to do next

Restore your v2018 source deployment data to your v10 target deployment: [Restoring the v2018 data to the v10 target deployment](#).

Restoring the v2018 data to the v10 target deployment

Restore the saved configuration and backups from the source deployment onto the target deployment.

Before you begin

- Complete the installation of v10 for your target platform:
 - [Installing the v10 target system on OpenShift and Cloud Pak for Integration](#).
 - [Installing the v10 target on Kubernetes](#).
 - [Installing the v10 target system on VMware](#)
- If you want to migrate any changes on your v2018 deployment that happened since you did the extract process, repeat the extract steps:
 - [Extracting the v2018 source data on VMware](#).
 - [Extracting the v2018 source data on Kubernetes and OpenShift](#).
- Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.
- **OVA Users:** All operations are run from the `apicv10install` directory, which you copied to your VMs after installation: [Installing the v10 target system on VMware](#). SSH to your target VMs as the `apicadm` user, run `'sudo -i'`, and `cd` to this directory:

```
ssh apicadm@<VM hostname>
sudo -i
cd /root/<apicv10install directory>
```

- Ensure you have the v10 toolkit CLI setup in your `apicv10install` directory, see [Installing the v10 toolkit](#). Set your PATH variable as follows:

```
EXPORT PATH=<full path of apicv10install directory>:$PATH
```

Verify that you can log in to the Management server as the Cloud Manager admin user with the toolkit CLI:

```
apic login --server <platform_api_endpoint> --username admin --realm admin/default-idp-1
```

where `<platform_api_endpoint>` is the FQDN of the platform api endpoint that is defined for your v10 Management subsystem. To find this:

- OpenShift: Run

```
oc get routes -n <apic namespace> | grep platform-api
```

- o Kubernetes: Run

```
kubectl get ingress -n <apic namespace> | grep platform-api
```

- o OVA: The platform api endpoint is defined in your `apiconnect-up-v10.yml` file.

The password is the same as the admin user password for the Cloud Manager UI, and is set to the default for a new v10 installation on your platform. For more information, see [v10 toolkit CLI login](#).

- Update your `gateway_portal_mapping.yaml` mapping file in your `apicv10install` directory, adding your v10 endpoints. For any subsystems that you do not want to migrate, leave them set to the placeholder value. The example below shows a mapping file where the gateway service called `v5gway_service_1` is not migrated.

```
analytics_mapping:
  analytics_servicel:
    https://analytics_ingestion.v2018.example.com: https://analytics_ingestion.v10.example.com
gateway_mapping:
  apigway_servicel:
    https://gateway.v2018.example.com: https://gateway.v10.example.com
    https://gateway-manager.v2018.example.com: https://gateway-manager.v10.example.com
  v5gway_service_1:
    https://gw.source-apic.fyre.example.com: https://NEW_GATEWAY_ENDPOINT_HOST_IN_TARGET_SYSTEM
    https://gwd.source-apic.fyre.example.com: https://NEW_GATEWAY_API_ENDPOINT_BASE_HOST_IN_TARGET_SYSTEM
portal_mapping:
  portal_service_1:
    https://portal-director.v2018.example.com: https://portal-director.v2018.example.com
    https://portal-web.v2018.example.com: https://portal-web.v2018.example.com
```

You can find your new v10 endpoints with:

- o OpenShift:

```
oc get routes -n <apic namespace>
```

- o Kubernetes:

```
kubectl get ingress -n <apic namespace>
```

- o OVA: Endpoints are defined in your `apiconnect-up-v10.yml` file.

Note: On the gateway appliance, the Gateway Manager URL uses port 3000. The port number is appended to the v10 endpoint in the mappings file. For example, `https://gateway-manager.v10.example.com:3000`.

Unmigrated subsystems can be migrated later, see [Migrating additional v2018 subsystems: Staged migration](#).

Note: If you want your v10 target deployment to use the same endpoint URLs as your v2018 source deployment, you can skip updating this file.

About this task

In this task, migration scripts are used to:

- Restore the Management subsystem.
- Register Gateways and Portals on the target system.
- Update Portals in the catalog to point to new Portal systems.
- Restore Portal backups for each site.
- Update Gateways in the catalog to point to new Gateway systems.

All operations in this task are run from your `apicv10install` directory.

Note: It is recommended that you keep the console output of all python scripts that are run. On most MacOS and Linux environments, appending the following to the end of the command saves the output to the specified file:

```
2>&1 | tee <output filename>
```

Procedure

1. Verify that all pods in your v10 target deployment are running and no errors are reported:

- Kubernetes:

```
kubectl get pods -n <namespace>
```

- OpenShift:

```
oc get pods -n <namespace>
```

- OVA:

```
kubectl get pods
```

2. **OpenShift and Cloud Pak for Integration only:** Run the following command:

```
# oc adm policy add-scc-to-user anyuid system:serviceaccount:<apic namespace>:default
```

Where `<apic namespace>` is your v10 API Connect namespace.

3. Run the load script:

```
python3 load_v2018_data_to_v10.py -storage_class <storage_class> -registry_secret <image_pull_secret> -load_storage_size 50 -load_image <load_image_url> -n <apic_namespace> -operator_namespace <apic_operator_namespace> -s <platform_api_endpoint> -silent
```

Where

- `<storage_class>` is the name of the storage class your v10 API Connect deployment is using. **OVA users:** This must be set to `local-storage`.

- **Non-OVA users:** `<image_pull_secret>` is the secret that is used to pull the API Connect images. Not needed for OVA. For OpenShift, the cluster default is used if not specified.
- `<load_image_url>` is the full name and path of the `ibm-apiconnect-management-v2018-to-v10-load` image. On OVA this URL is obtained as described in the installation steps: [Get OVA load image URL](#)
- `<apic_namespace>` is the namespace where your v10 API Connect subsystem instances are installed. **OVA users:** This must be set to `default`.
- `<apic_operator_namespace>` is the namespace where you v10 API Connect operators are installed. **OVA users:** This must be set to `default`.
- `<platform_api_endpoint>` is the FQDN of the platform api endpoint that is defined for your v10 Management subsystem. To find this:
 - OpenShift: Run

```
oc get routes -n <apic_namespace> | grep platform-api
```

- Kubernetes: Run

```
kubectl get ingress -n <apic_namespace> | grep platform-api
```

- OVA: The platform api endpoint is defined in your `apiconnect-up-v10.yml` file.

The script takes some time to complete. Check the status of the pods in your API Connect subsystem namespace and check for any pods in Error state. The script attempts to pull the API Connect migration load image from your image repository, failure to pull the image can be observed by checking the pods:

- Kubernetes:

```
kubectl get pods -n <namespace>
```

- OpenShift:

```
kubectl get pods -n <namespace>
```

- OVA:

```
kubectl get pods
```

If see output such as:

```
v2018-mgmt-load-bczzdf 0/1 ImagePullBackOff 0 2m4s
```

terminate the load script and investigate why the image cannot be loaded. When the load script is rerun it cleans up failed pods from previous attempts. OVA users: if the problem is not clear, for example an incorrect load image path, gather logs and open a support case.

Note: The v2018 load script overwrites any data that you configured on your v10 target deployment, with the v2018 source data. For example, the admin password for your v10 Cloud Manager UI is replaced with the one from your v2018 source deployment.

4. If you want your v10 target deployment to use the same endpoint URLs as your v2018 source deployment, skip to step [8](#).

5. Register Gateways and Portals on the target system.

Run the `register_gateway_portals_in_target.py` script:

OVA users: On your Management VM, run:

```
python3 register_gateway_portals_in_target.py -s <platform_api_endpoint> -u admin -p <password> -r admin/default-idp-1 -n default -silent
```

Where

- `<platform_api_endpoint>` is the FQDN of the platform api endpoint that is defined for your v10 Management subsystem.
- `<password>` is the Cloud Manager UI admin user password, from your v2018 deployment.

Kubernetes, OpenShift, and Cloud Pak for Integration users:

- If Management, Portal and Gateway subsystems are in the same namespace:

```
python3 register_gateway_portals_in_target.py -s <platform_api_endpoint> -u admin -p <password> -r admin/default-idp-1 -n <apic_namespace> -silent
```

Where

- `<platform_api_endpoint>` is the FQDN of the platform api endpoint that is defined for your v10 Management subsystem.
- `<password>` is the Cloud Manager UI admin user password, from your v2018 deployment.
- `<apic_namespace>` is the namespace where your v10 API Connect subsystem instances are installed.
- If Management, Portal and Gateway subsystems are in different namespaces, use `-mgmt_ns`, `-ptl_ns`, and `-gw_ns` to specify each, for example:

```
python3 register_gateway_portals_in_target.py -s <platform_api_endpoint> -u admin -p <password> -r admin/default-idp-1 -mgmt_ns <mgmt_namespace> -ptl_ns <portal_namespace> -gw_ns <gateway_namespace> -silent
```

- If you are using SSO authentication, replace:

```
-u <username> -p <password>
```

with:

```
--sso
```

- Multiple namespaces can alternatively be specified with "ns1|ns2|ns3" notation. For example:

```
python3 register_gateway_portals_in_target.py -n "ns1|ns2|ns3" -u admin -p <password> -s <platform_api_endpoint> -r admin/default-idp-1 -silent
```

```
python3 register_gateway_portals_in_target.py -s PLATFORM_API_HOSTNAME -u admin -p <password> -r admin/default-idp-1 -mgmt_ns ns1 -ptl_ns "ns1|ns2" -gw_ns "ns1|ns2|ns3" -silent
```

Note: If you run `register_gateway_portals_in_target.py` for a Cloud Pak for Integration target system, and you see the error

The API Connect Gateway Service is already registered to another API Manager instance

restart all the gateway pods, wait for them to reach `Ready` state, and run `register_gateway_portals_in_target.py` again.

6. Run `update_to_new_portals.py` to update portals defined in your catalogs to point to your new Portal subsystems.

Note: If your source system has no portal services, skip this step. Also, skip this step if no portal sites are created for any of you catalogs.

OVA users: On your Management VM (not your Portal VM), run:

```
python3 update_to_new_portals.py -s <platform_api_endpoint> -u admin -p <password> -r admin/default-idp-1 -n default -
api_manager_hostname <platform_api_endpoint> -silent
```

Kubernetes, OpenShift, and Cloud Pak for Integration users:

- If the Management and Portal subsystems are in the same namespace:

```
python3 update_to_new_portals.py -s <platform_api_endpoint> -u admin -p <password> -r admin/default-idp-1 -n
<apic_namespace> -api_manager_hostname <platform_api_endpoint> -silent
```

- If the Management and Portal subsystems are in different namespaces:

```
python3 update_to_new_portals.py -s <platform_api_endpoint> -u admin -p <password> -r admin/default-idp-1 -mgmt_ns
<mgmt_namespace> -ptl_ns <portal_namespace> -gw_ns <gateway_namespace> -silent
```

- If you are using SSO authentication, replace:

```
-u USERNAME -p PASSWORD
```

with:

```
--sso
```

7. Run `update_to_new_gateways.py` to update Gateways in the catalog to point to new Gateway systems.

Note: The response might indicate that you should run a health check but that is not needed because you will run a health check later as part of the verification task.

OVA users: On your Management VM, run:

```
python3 update_to_new_gateways.py -s <platform_api_endpoint> -u admin -p <password> -r admin/default-idp-1 -n default -
api_manager_hostname <platform_api_endpoint> -silent
```

Kubernetes, OpenShift, and Cloud Pak for Integration users:

- If the Management and Gateway subsystems are in the same namespace:

```
python3 update_to_new_gateways.py -s <platform_api_endpoint> -u admin -p <password> -r admin/default-idp-1 -n
<apic_namespace> -api_manager_hostname <platform_api_endpoint> -silent
```

- If the Management and Gateway subsystems are in different namespaces:

```
python3 update_to_new_gateway.py -s <platform_api_endpoint> -u admin -p <password> -r admin/default-idp-1 -mgmt_ns
<mgmt_namespace> -gw_ns <gateway_namespace> -silent
```

- If you are using SSO authentication, replace:

```
-u USERNAME -p PASSWORD
```

with:

```
--sso
```

8. Restore Portal backups for each site.

Note: If your source system has no portal services, skip this step. Also, skip this step if no portal sites are created for any of your catalogs.

To restore the Portal sites on the target system, you can either use the script `restore_portal_db.py` to restore all sites, or restore sites individually with the `restore_site` command.

Restoring all sites with the restore script:

- OVA users: On your Portal VM, run:

```
python3 restore_portal_db.py -n default
```

- Non-OVA users: Run the following:

```
python3 restore_portal_db.py -n <portal_subsystem_namespace>
```

Note: If there are more than one Portal subsystems on the target system, run the script for each of the matching source and target Portal subsystems with the `-ptl_ns` and `-ptl_subsys_name` arguments:

```
python3 restore_portal_db.py -ptl_ns <portal_namespace> -ptl_subsys_name <portal_subsystem_name>
```

Restoring sites individually, using `restore_site`. For OVA users, these steps should be run from the Portal VM:

- a. Identify the portal `www` pod:

- OpenShift:

```
oc get pods -n <portal_subsystem_namespace> | grep www
```

- Kubernetes:

```
kubectl get pods -n <portal_subsystem_namespace> | grep www
```

- OVA:

```
oc get pods | grep www
```

- b. Exec into the portal `www` pod's `admin` container:

- OpenShift:

```
oc exec -it -n <portal_subsystem_namespace> <www_pod> -c admin -- bash
```

- Kubernetes:

```
kubectl exec -it -n <portal_subsystem_namespace> <www_pod> -c admin -- bash
```

- OVA:

```
kubectl exec -it <www_pod> -c admin -- bash
```

c. List the site backups:

```
remote_transfer_backup -l
```

d. Download each site backup, and run it for all sites:

```
remote_transfer_backup -d <site_backup_filename>
```

e. Restore each of the site backups:

```
restore_site -f -u <site_url> <site_backup_filename>
```

Post-restore verification

9. Check that your v10 migration was successful and remove any v2018 subsystems or data that you do not want: [Verifying the v10 target deployment](#).

Note: If you are doing a staged migration, it is recommended you do the verification before and after you add further subsystems: [Migrating additional v2018 subsystems: Staged migration](#).

Verifying the v10 target deployment

Verify that the target deployment is working correctly. Remove any unwanted v2018 data and subsystems.

Before you begin

Complete [Restoring the v2018 data to the v10 target deployment](#).

Procedure

1. From your `apicv10install` directory, use the `health_check_post_migration.py` script to health check the target system. See the following examples:

- If all the subsystems are in the same namespace, and the deployment uses username and password authentication (this applies to OVA):

```
python3 health_check_post_migration.py -s <platform_api_endpoint> -r admin/default-idp-1 -u admin -p <password> -n <apic_namespace>
```

Where:

- `<platform_api_endpoint>` is the FQDN of the platform api endpoint that is defined for your v10 Management subsystem.
- `<password>` is the Cloud Manager UI admin user password that you used on your v2018 deployment.
- `<apic_namespace>` is the namespace where your v10 API Connect subsystem instances are installed. **OVA users:** This must be set to `default`.

To check the health of your portal sites, add `-check_portal_site_health` to the above command. Portal sites take time to restore, so if you recently completed the restore steps, the script `health_check_post_migration.py` run with the `-check_portal_site_health` argument might report that sites are not healthy.

- **Non-OVA users:** When all subsystems are in different namespaces, and the deployment uses username/password authentication:

```
python3 health_check_post_migration.py -s <platform_api_endpoint> -r admin/default-idp-1 -u admin -p <password> -n <apic_namespace> -mgmt_ns <mgmt_namespace> -gw_ns <gateway_namespace> -ptl_s <portal_namespace> -a7s_ns <analytics_namespace>
```

- **Non-OVA users:** When all subsystems are in the same namespace, and the deployment uses SSO authentication:

```
python3 health_check_post_migration.py -n <apic_namespace> --sso -s <platform_api_endpoint>
```

- **Non-OVA users:** When all subsystems are in the same namespace, and the deployment uses SSO authentication silent mode:

```
python3 health_check_post_migration.py -n <apic_namespace> --sso -s <platform_api_endpoint> -api_key <api_key_value> -silent
```

Where:

- `<api_key_value>` is the API-key that is used in Cloud Manager SSO authentication.

- **Non-OVA users:** When you have multiple subsystems across namespaces:

```
python3 health_check_post_migration.py -s <platform_api_endpoint> -r admin/default-idp-1 -u admin -p <password> -n "<namespace1>|<namespace2>|<namespace3>"
```

2. Complete any further configuration steps needed for your deployment:

a. If necessary, update redirect URLs in the authorization server.

If OIDC or SSO authentication is being used, the redirect URLs must be updated in the authorization server after migration. For example, for Google OIDC, you must add the new redirect URLs in Google Developer Console. The new redirect URLs can be found in the user registry in Cloud Manager.

b. Complete configuration for Analytics.

- If Analytics services are present on the target system, configure analytics backup settings.
- Use the Cloud Manager UI to associate the Analytics services with the Gateways.

c. If the target system is Cloud Pak for Integration, your Platform UI password is unchanged when you installed Platform UI, it is not updated with any v2018 migrated data.

d. Review any v2018 scripts or utilities that you have that use the toolkit CLI. If you want to use these scripts in v10, check if the scripts referred to your v2018 portal and gateway services by name. If it did use the service names and not the IDs, then update these scripts to use the new v10 names for these services.

3. Validate configuration data:

a. Validate the data in the target API Connect system by logging in to Cloud Manager and API Manager UIs.

b. Validate the APIs published in the Gateways.

c. Validate the Portal site URLs

d. If necessary, update the DNS-mapping information.

When all of the APIs are verified, you might need to update the DNS-mapping information, to redirect the calls to the new Gateways and Portals.

- e. Delete any v2018 provider organization data (APIs, Products, Consumer organizations) that you do not want from the API Manager UI.
 - f. Delete any v2018 portal or gateway subsystems that you do not want from the Cloud Manager UI.
- The v10 migration is now complete.
4. If you migrated all your subsystems, you can uninstall v2018 API Connect on the source system. If you are doing a staged migration, do not uninstall your v2018 source system until all your subsystems are migrated, see [Migrating additional v2018 subsystems: Staged migration](#).

Migrating additional v2018 subsystems: Staged migration

If you did not migrate all your v2018 portal and gateway subsystems initially, and now want to migrate the remaining ones.

For adding gateways after initial migration, migrate your v2018 source data to them by following these steps:

1. Add the new Gateway and Analytics related endpoints to the `gateway_portal_mapping.yaml` file.
2. Register Gateways and Analytics on the target system. Complete Step 5 in [Restoring the v2018 data to the v10 target deployment](#)
3. Update gateways in the catalog to point to new Gateway systems. Complete Step 7 in [Restoring the v2018 data to the v10 target deployment](#)
4. Associate your new Analytics subsystems with your gateways in the Cloud Manager UI.

For adding portals after initial migration, migrate your v2018 source data to them by following these steps:

1. Add the new Portal related endpoints to the `gateway_portal_mapping.yaml` file.
2. Register portals on the target system. Complete Step 5 in [Restoring the v2018 data to the v10 target deployment](#)
3. Update portals in the catalog to point to new portal systems. Complete Step 6 in [Restoring the v2018 data to the v10 target deployment](#)
4. Restore portal backups for each site. Complete Step 8 in [Restoring the v2018 data to the v10 target deployment](#)

Repeat the health check and verification steps after migrating each subsystem, see [Verifying the v10 target deployment](#).

Troubleshooting the form-factor migration from v2018

Troubleshoot problems with migrating from v2018 to v10 on a different form factor.

Script help

You can access help for all the migration scripts by using the `--help` argument:

```
python3 <script_file_name> --help
```

Restarting migration

On the target system, if the `register_gateway_portals_in_target.py`, `update_to_new_portals.py`, or `update_to_new_gateways.py` scripts fail, run the load script 3 again, with the `-reset_gateway_portal` flag as shown:

```
python3 load_v2018_data_to_v10.py ... -reset_gateway_portal
```

This resets the portals and deletes the gateway pods.

Note: If you deleted the data directory after you registered the Gateways or Portals, but want to use the same target API Connect system that you already installed, then extract the data again:

- [Extracting the v2018 source data on VMware](#).
- [Extracting the v2018 source data on Kubernetes and OpenShift](#).

Factory reset of portal subsystem

The migration load script with `-reset_gateway_portal` does a factory reset of your portal subsystems. Portals can also be factory reset by following these steps:

1. Log in to the portal `www` pod `admin` container:

```
kubectl exec -it <portal www pod> -c admin -n <apic namespace> -- bash
```

2. Run the command:

```
curl -X DELETE -k --cert /etc/nginx/ssl/portal-director-client-both.pem https://localhost:3009/v2/portal/factory-reset
```

3. Use the `list_sites` command to check that all sites are deleted.
4. Check health of the Portal subsystem.

Avoid error when a gateway is already registered to another API manager

Error messages

```
Error: An error occurred communicating with the gateways subsystem at 'some_url' (status: 400, response: '"Unable to perform initial registration for API Management. Error: The API Connect Gateway Service is already registered to another API Manager instance"')
```

To fix this first try restarting the gateways, or if you are using Gateway appliances, restart them. If the problem persists, reload the v2018 data with the `load_v2018_data_to_v10.py` script and repeat the remaining steps of the migration process, starting with Step 5 in [Restoring the v2018 data to the v10 target deployment](#).

x-ibm-gateway-cors-allow-credentials-when-no-cors-policy API property is deprecated in v10.

In v2018, when cross-origin resource sharing (CORS) is enabled for an API, every response to a CORS request contains the header:

```
Access-Control-Allow-Credentials: true
```

Inclusion of Access-Control-Allow-Credentials (ACAC) does not provide optimal security, so starting with v2018.4.1.17, an API property can be set to prevent this header from being returned:

```
Name: x-ibm-gateway-cors-allow-credentials-when-no-cors-policy
Collection: *
Value (string): off
```

The `Collection` property refers to a specific Catalog to which a property value applies. The "*" value means the value applies to all catalogs. You can either specify * or a Catalog (collection) name.

The property can also be set by using the DataPower CLI:

```
api-definition myAPI
  property x-ibm-gateway-cors-allow-credentials-when-no-cors-policy * off
exit
```

Important: The value of this property must be exactly the string `off` (case-sensitive) in order to remove the header.

It is only possible to turn off this header, or leave it on, for an entire API. In order to have more control, such as returning the header for some origins and not others, you must upgrade to v10 and use the CORS policy feature. For more info, see:

- [Enabling CORS support for an API](#)
- OpenAPI 3.0 editor: [Setting API properties](#)
- OpenAPI 2.0 editor: [Setting API properties](#)

In API Connect 10.0.3.0 or later, the `x-ibm-gateway-cors-allow-credentials-when-no-cors-policy` property works, but only for API definitions which do NOT contain a cors-policy. You cannot define both this property and a CORS Policy on the same API definition.

This property is deprecated in v10: a warning will be written to the log for every CORS request received by an API whose definition contains this property.

For v10, the recommended way to ensure the ACAC header does not appear in CORS responses is to add a CORS policy to the API definition. In v10, any API definition which has a cors-policy defined will NOT return the ACAC header by default. Note that it is possible in the CORS policy rules to explicitly return the ACAC header for some or all origins.

If you move your configuration from Version 2018 to 10.0.3.0 or later, and have this custom property defined in your API definitions, you will not see any change in behavior, other than new warnings in the log. This property will remove the ACAC header for any API definition where it appears.

If, when you move your configuration from Version 2018 to Version 10, you want to have the ACAC header present in the CORS responses, you can leave the API definitions as-is (without the new property defined) and the ACAC header will be returned, as long as a cors-policy is not added to the API definition. Note also that even with a CORS policy defined for an API, the ACAC header can be returned if desired by explicitly allowing it in the rules of the CORS policy.

Note that the `x-ibm-gateway-cors-allow-credentials-when-no-cors-policy` property in an API definition:

- Will cause a commit-time error in v10 if a cors-policy is also present in the same API definition
- Will NOT work in v10 or v2018 to turn ON the ACAC header; it can ONLY be used to turn OFF the header. Explanation:
 - In v2018, ACAC is on by default
 - In v10, without cors-policy, ACAC is on by default
 - In v10, with cors-policy, ACAC can be turned on for specific origins via rules in cors-policy

Replacing passwords, keys, and certificates

Ensure the security of your API Connect deployment by replacing compromised passwords, keys, and certificates.

About this task

Each subsystem uses one or more passwords, database keys, and registration secrets. In some cases, an update takes effect immediately or on the next log-in, but some components require a restart to apply the update. Follow the procedure for updating each subsystem to ensure that you complete all required steps.

All subsystems use TLS certificates to encrypt communications both within each subsystem, between subsystems, and with clients. The procedure for renewing a certificate depends on whether you use cert-manager. After you replace a certificate in a subsystem, you must restart all pods that are affected by the certificate, so there will be a service interruption.

The instructions in this section are written for deployments on Kubernetes and details for other platforms appear at the end of the section. Before you begin updating passwords, keys, and certificates, review the entire section to ensure you understand the procedures and are aware of any platform-specific differences that affect your deployment.

Attention: Before you change any passwords, keys, or certificates, you should disable scheduled backups for the Management subsystem as explained in this section. After the updates are complete, enable backups.

- [Disabling backups before updating secrets and certificates](#)
Disable scheduled backups to ensure that you don't update secrets and certificates while a backup is running in your API Connect deployment.
- [Management subsystem: updating the password, keys, and secrets](#)
Update the cloud administrator password, the key for encrypted database fields, and the `client_ID` and `client_secret` values for the Management subsystem in an API Connect deployment.

- [Gateway subsystem: updating the password and secret](#)
Update the administrator password and the `client_secret` values for the Gateway subsystem in an API Connect deployment.
- [Portal subsystem: updating keys and secrets](#)
Update the database passwords, keys, and the `client_secret` values for the Portal subsystem in an API Connect deployment.
- [Analytics subsystem: replacing the TLS profile and keys](#)
Update the Analytics subsystem's TLS profile and keys for backup and restore operations in your API Connect deployment.
- [Renewing TLS certificates](#)
Renew TLS certificates in your API Connect deployment.
- [Management subsystem: restarting pods](#)
Restart Management subsystem pods in your API Connect deployment.
- [Gateway subsystem: restarting pods](#)
Restart Gateway subsystem pods and components in your API Connect deployment.
- [Analytics subsystem: restarting endpoints and pods](#)
Restart the pods that support the Analytics service and endpoints in your API Connect deployment.
- [Re-enabling scheduled backups](#)
If you disabled scheduled backups before updating keys, secrets, or passwords, enable the backups again for your API Connect deployment.

Disabling backups before updating secrets and certificates

Disable scheduled backups to ensure that you don't update secrets and certificates while a backup is running in your API Connect deployment.

About this task

Manually disable any configured backup schedule prior to updating passwords, keys, profiles, secrets, or certificates. If a backup is taken while an update is running, then that backup should be considered potentially corrupted.

Procedure

1. Disable backups by completing the following steps:
 - a. Open the management cluster CR for editing by running the following command:

```
kubectl -n namespace edit CR-name
```

where:

- `namespace` is the namespace where the Management subsystem is installed.
- `CR-name` is the name of the CR that was used to install the Management subsystem.

- b. In the `databaseBackup` section of the CR, remove the `schedule` entry.
 - c. Save and close.
2. Verify that no backups are running by completing the following steps:
 - a. List all your Management backups by running the following command:

```
kubectl -n namespace get managementbackup
```

where `namespace` is the namespace where the Management subsystem is installed.

- b. In the results, check the STATUS column to ensure that all backups are listed as **Ready**.
If any backups are still running, wait for them to complete before proceeding to the next topic. The **Ready** status indicates that the backup was finished successfully. If the status is **Failed** then the backup did not complete successfully.

Management subsystem: updating the password, keys, and secrets

Update the cloud administrator password, the key for encrypted database fields, and the `client_ID` and `client_secret` values for the Management subsystem in an API Connect deployment.

About this task

- [Changing the cloud administrator password](#)
Update the cloud administrator password for the Management subsystem using the Cloud Manager UI, the toolkit CLI, or an API call.
- [Changing the database encryption key](#)
Replace the value of the secret that is used for encrypting database fields in the Management subsystem.
- [Changing the registration client id and client secret for applications](#)
Change the registration credentials (the `client_id` and `client_secret`) for applications provided by the Management subsystem.

Changing the cloud administrator password

Update the cloud administrator password for the Management subsystem using the Cloud Manager UI, the toolkit CLI, or an API call.

About this task

In the Management subsystem for an API Connect on-premises deployment, the administrator is called the *cloud administrator* and works with the management server to configure the deployment of the local server cloud. Updating the cloud administrator password for the Management subsystem requires no service interruption because

the change takes place immediately.

You can change the cloud administrator's password using any of the following methods.

Note: Passwords must contain eight or more characters, with at least one character from three of the following categories: lowercase letters, uppercase letters, numerals, and punctuation (for example: ! \$ # %). The same character cannot be used more than twice consecutively.

Cloud Manager UI

1. [Log in to the Cloud Manager UI.](#)
2. [Change your Cloud Manager password.](#)

Toolkit CLI

1. Run the `apic login` command to [log in to a management server](#).
2. Run the `apic me:change-password` command to [change your password](#).

API call

1. Run the `apic login` command to [log in to a management server](#).
You must log in to a management server with the toolkit CLI before you can call the API Connect APIs.
2. Execute the [/api/me/change-password](#) API call, as explained in the "Resource: Me" section of the IBM API Connect Platform - Cloud Management API.

The next time that you log in as the cloud administrator, you must use the new password.

Changing the database encryption key

Replace the value of the secret that is used for encrypting database fields in the Management subsystem.

About this task

This update does not require an outage; however some operations might take longer than usual due to database locking.

Procedure

1. Create a secret rotation CR that specifies the name of your management cluster.
You can optionally specify the name of a secret containing the new `encryption_secret.bin` as shown in the following example, or you can omit it so that a new key is generated automatically.

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementSecretRotation
metadata:
  name: rotate-secret
spec:
  managementCluster: management
  rotateEncryptionSecret:
    rotate: true
    # encryptionSecret: name_of_secret
```

- Note: If you upgraded from V2018, the database encryption key was carried forward and is called `managementUpgradeName-encryption-secret`.
2. Run the following command to apply the CR and change the secret:

```
kubectl -n namespace create -f rotate_secret.yaml
```

where:

- `namespace` is the namespace where you installed the Management subsystem.
 - `rotate_secret.yaml` is the name of the file containing the CR. Notice that the file name does not have to match the value of the `name` specified in the CR.
3. Verify that the secret was generated using one of the following methods:
 - Run the `kubectl get job` command and verify that the results include a job for the new CR.
The job is named based on the management cluster name and the CR name, using the following format: `managementCluster-crName`. For the example CR `rotate-secret` created for the `management` cluster, the job is named `management-rotate-secret`.
 - Look in the pod logs of the `apiconnect` operator and locate the record with the name that you specified in the `kind` field in the CR, and check its progress.
For the example CR, the `kind` value is "ManagementSecretRotation".
You can also use the log to verify that database tables were updated.

Changing the registration `client_id` and `client_secret` for applications

Change the registration credentials (the `client_id` and `client_secret`) for applications provided by the Management subsystem.

About this task

Update the application registration `client_id` and `client_secret` by changing the Kubernetes secret containing them. The `apim` file-watcher detects the change and automatically updates the following secrets in the database:

- toolkit: `management-cli-cred` (Customer facing)
When you update the secret for the toolkit, users must download and install new toolkit credentials as explained in [Installing the toolkit](#).

- consumer-toolkit: `management-ccli-cred` (Customer facing)
When you update the secret for the toolkit, users must download and install new toolkit credentials as explained in [Installing the toolkit](#).
- designer: `management-dsgr-cred` (Customer facing)
When you update the secret for API Designer, users must download and install new credentials as explained in [Installing the toolkit](#).
- atm: `management-atm-cred` (Internal)
- governance: `management-governance-cred` (Internal)
- consumer-ui: `management-cui-cred` (Internal)
- juhu: `management-juhu-cred` (Internal)
- ui: `management-ui-cred` (Internal)
The API Manager and Cloud Manager read the credentials from the back-end on start-up.

When you update registration credentials, the registration name that is associated with the updated secret changes. Table 1 lists the registration secrets with the default registration name and the pattern used for generating updated registration names for each secret. The new registration names follow the patterns shown in the table. The second and subsequent updates append a number to the name; for example, `toolkit-application-registration`, `toolkit-application-registration0` and then `toolkit-application-registration1`.

Table 1. Secret names and the corresponding default, and new, registration names for each secret

Secret	Default registration name	New registration name pattern
<code>management-cli-cred</code>	<code>toolkit-default</code>	<code>toolkit-application-registration*</code>
<code>management-ccli-cred</code>	<code>consumer-toolkit-default</code>	<code>consumer-toolkit-application-registration*</code>
<code>management-dsgr-cred</code>	<code>designer-default</code>	<code>designer-registration*</code>
<code>management-atm-cred</code>	<code>atm-default</code>	<code>atm-default*</code>
<code>management-governance-cred</code>	<code>compliance-default</code>	<code>compliance-default*</code>
<code>management-cui-cred</code>	<code>consumer-ui-default</code>	<code>consumer-ui-default*</code>
<code>management-juhu-cred</code>	<code>juhu-default</code>	<code>juhu-default*</code>
<code>management-ui-cred</code>	<code>ui-default</code>	<code>ui-default*</code>

Procedure

1. To renew an internal certificate, complete the following steps:
 - a. Create a `ManagementSecretRotation` CR (for example, `operationcr.yaml`) with contents similar to the following example, and list the secrets that you want to update:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementSecretRotation
metadata:
  name: rotate-credentials
spec:
  managementCluster: management
  rotateClientIDandSecret:
    secrets:
      - management-ui-cred
      - management-cui-cred
      - management-juhu-cred
      - management-atm-cred
```

- b. Apply the CR by running the following command:

```
kubectl create -f operationcr.yaml -n namespace
```

where:

- `namespace` is the namespace where you installed the Management subsystem
- `operationcr.yaml` is the file that contains the CR

Applying the resource updates the credential for the specified secrets with new values.

2. To update customer-facing credentials, complete the following steps:
 - a. For each of the credential secrets, run the following command to update the `client_id` and `client_secret`:

```
kubectl edit secret credential_secret_name -n namespace
```

where:

- `namespace` is the namespace where the Management subsystem is installed.
- `credential_secret_name` is the name of the secret that you want to update.

The response opens the secret in a text editor as shown in the following example:

```
apiVersion: v1
data:
  credential.json:
    eyAiaWQiOiAiNTY3MTYyNjYtZDE0Zi00ODZmLWI0MwYtZTE3MzZkZTg3NjE0IiwgInNlY3JldCI6ICJmYjU5MDdhNy0zMjZjLTQ4ZWYtYjQ0ZC1hMTI5ZmZkMzNiMTEiIH0=
```

In the secret, the value of `credential.json` is a base64 encoded string of the following JSON format. Decode it first, modify the values of `id` and `secret`, and encode back as base64 and paste it in the secret. (Note that either `id` or `secret` or both can be updated, but if the credentials have been compromised then it's recommended to update both `id` and `secret`). For example:

- b. Decode the value of `credential.json`.

To decode the value, copy it from the secret in step 2a, and paste it between the quotation marks as the `encoded_value` in the following command:

```
echo "encoded_value" | base64 --decode
```

Using the value returned in step 1, the command looks like the following example:

```
echo
"eyJhIAWQiOiAiNTY3MTYyNjYtZDE0Zi00ODZmLWI0MwYtZTE3MzZkZTg3NjE0IiwgInNlY3JldCI6ICJmYjU5MDdhNy0zMjZjLTQ4ZWYtYjQ0ZC1hMTI5ZmZkMzNiMTEiIH0="
```

```
ZmZkMzNiMTEiIH0=" | base64 --decode
```

The response displays decoded values of the `id` and `secret`, as in the following example:

```
{ "id": "56716266-d14f-486f-b41f-e1736de87614", "secret": "fb5907a7-326c-48ef-b44d-a129ffd33b11" }
```

c. Update the values of `id` and `secret`.

You can use any string that meets the following requirements:

- The `id` (it becomes `client_id`) must be unique across all credentials in your entire deployment.
- The values must be enclosed in straight quotation marks. To make sure you use the correct character, create the values in a plain text editor.

d. Encode the updated `id` and `secret` as base64 by running the following command:

```
echo -n '{ "id": "new_id", "secret": "new_secret" }' | base64
```

Replace `new_id` and `new_secret` with your updated values. For example:

```
echo -n '{ "id": "21034840-b439-a393-4482-a948bcb39603", "secret": "43450ab9-4038-acf0-0498-793b29ade396" }' | base64
```

Returns the following base64-encoded value:

```
aWQ6IDIxMDM0ODQwLWI0MzktYTM5My00NDgyLWE5NDhiY2IzOTYwMywgc2VjcmV0OiA0MzQ1MGFiOS00MDM4LWFjZjAtMDQ5OC03OTNiMjhlhZGUzOTY=
```

e. Paste the newly coded value for `credential.json` into the secret.

f. Save the secret.

When you save the secret, the logs in the `apim` pods indicate that a new registration was created. For example, if the `client_id` changed, the display looks similar to the following messages

```
2020-09-14T09:55:58.331Z bhendi:audit [ce64fd50-e4de-4cfb-baa7-7379a892b2c9] Created internal resource "Registration"

2020-09-14T11:00:52.377Z audit [866bb70b-3bb5-4ac3-9a59-0b60ade7feb2] Creating a new registration for type, ui, with
client_id: ui-client-id.
```

g. If the response shows any errors, you must correct the errors.

When the logs show no errors, the saved values are updated in the Management subsystem's database.

h. Confirm that the new registration exists in the registrations list by running the following toolkit CLI command:

```
apic --server server registrations:list
```

where `server` is the Management server endpoint URL.

i. Verify that the updated registration is now in effect by running the following toolkit CLI command:

```
apic --server server registrations:get new_registration_name --output -
```

where:

- `server` is the Management server endpoint URL
- `new_registration_name` is the new registration name (including any numeric suffix) following the patterns in Table 1.

j. Save the old registration (refer to Table 1 to determine the previous registration's file name) in case you need it when restoring an older backup.

Restoring a backup restores the registration credentials (`client_ID`, `client_secret`) that were in use at the time that the selected backup was created.

k. If you updated the registration credentials for API Designer or the toolkit, inform users so they can download new credentials.

Users can download and set up new credentials as explained in [Installing the toolkit](#). Other credentials are updated automatically and require no actions from the user.

Gateway subsystem: updating the password and secret

Update the administrator password and the `client_secret` values for the Gateway subsystem in an API Connect deployment.

About this task

- [Changing the Gateway administrator password](#)
Change the Gateway administrator password by updating the CR and reinstalling the subsystem.
- [Changing the Gateway client secret](#)
The Gateway subsystem receives its `client_secret` from the Management subsystem.
- [Changing the secret for Gateway peering](#)
Update the secret that protects gateway-peering communications within a Gateway cluster in your API Connect deployment.
- [Updating the TLS profile for Gateway](#)
Update the TLS profile that secures communications with the Gateway subsystem in your API Connect deployment.

Changing the Gateway administrator password

Change the Gateway administrator password by updating the CR and reinstalling the subsystem.

Before you begin

Updating the administrator password for the Gateway subsystem causes an API outage while servers are restarted. Changing the admin user password should be avoided outside of scheduled maintenance windows whenever possible.

Procedure

1. Get the name of the secret that is used in the Gateway CR.

- a. Run the following command to get the Gateway's `secretName`:

```
kubectl -n <namespace> get gatewaycluster <gw-cluster-name> -o yaml
```

where `<namespace>` is the namespace where you installed the Gateway subsystem, and `<gw-cluster-name>` is the name of the Gateway cluster.

In the CR, the Gateway's `secretName` is in the `adminUser` section.

- b. Note down the secret name for use in a later step.

2. Scale the `<gw-cluster-name>` to 0 pods.

- a. Using the following example as a guide, set `replicaCount=0` for the `<gw-cluster-name>`.

```
kubectl -n <namespace> patch gatewaycluster <gw-cluster-name> --type json -p='[{"op": "add", "path": "/spec/replicaCount", "value": 0}]'
```

- b. Validate that `statefulset READY = 0/0`.

Run the following command:

```
kubectl -n <namespace> get statefulset <gw-cluster-name>
```

A successful response looks like the following example:

NAME	READY	AGE
gwv6	0/0	18h

3. Update the Gateway's secret.

- a. Run the following command to edit the Gateway's `secretName`:

```
kubectl -n <namespace> edit secret secretName
```

- b. Change the value of `.data.password` to be the base64-encoded value of a new password. The new password can be any string you want but you must encode it to base64.

4. Scale the Gateway back up to the correct number of pods.

- a. Using the following example as a guide, set `replicaCount=3` for `<gw-cluster-name>`.

```
kubectl -n <namespace> patch gatewaycluster <gw-cluster-name> --type json -p='[{"op": "add", "path": "/spec/replicaCount", "value": 3}]'
```

- b. Validate that `statefulset READY = 3/3` (this step might take few minutes to complete).

Run the following command:

```
kubectl -n <namespace> get statefulset <gw-cluster-name>
```

A successful response looks like the following example:

NAME	READY	AGE
gwv6	3/3	18h

5. Verify that the Gateway subsystem is fully updated.

Run the following command, replacing `<namespace>` with the appropriate namespace.

```
kubectl -n namespace get GatewayCluster
```

The update is complete when the **READY** status is **True**, and the **SUMMARY** reports that all services are online (2/2) for all the Gateway subsystems that were updated. Example:

NAME	READY	SUMMARY	VERSION	RECONCILED VERSION	AGE
gww5	True	2/2	10.0.0.0	10.0.5.6-1219	7m31s
gww6	True	2/2	10.0.0.0	10.0.5.6-1219	7m32s

Changing the Gateway `client_secret`

The Gateway subsystem receives its `client_secret` from the Management subsystem.

About this task

If you changed the `client_secret` on the Management subsystem, force a dynamic reconfiguration and reregistration (DRR) as explained in [How can I force re-population of the configuration data?](#) On completion, the Gateway subsystem uses the new `client_secret` in its communications with the Management subsystem.

Changing the secret for Gateway peering

Update the secret that protects gateway-peering communications within a Gateway cluster in your API Connect deployment.

About this task

You can update the secret for an appliance-based gateway or a Kubernetes-based gateway. This task causes a disruption in API transactions because the secret must be changed on all gateways at the same time, and all gateways must be restarted.

Procedure

1. Appliance only: Manually update the Gateway Peering Identification Credential and Validation Credential objects.
Attention: If your Gateway is not deployed on an appliance, skip to step 2.
As soon as you begin this process, nodes will be out of sync. The nodes will remain out of sync until the entire process is complete. If the nodes do not recover from the out-of-sync condition, you might need to perform a DRR. For information about dynamic reregistration and reconfiguration and (DRR), see [Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment](#).

2. Kubernetes only: If your Gateway is deployed on Kubernetes, update the secret by completing the following steps.
 - a. Determine the name of your Gateway cluster by running the following command:

```
kubectl -n namespace get gatewayCluster
```

where `namespace` is the namespace where the Gateway subsystem is deployed.

- b. Determine the name of the secret currently being used for gateway peering by running the following command:

```
kubectl -n namespace describe gatewayCluster gateway-cluster
```

where:

- `namespace` is the namespace where the Gateway subsystem is deployed.
- `gateway-cluster` is the name that you obtained in step 2a.

In the response, the name of the secret currently being used displays after the heading **Apic Gateway Peering TLS** as shown in the following example:

```
Spec:
  Admin User:
    Secret Name:      datapower-admin-credentials
  API Debug Probe:   true
  API Debug Probe Expiration Minutes: 60
  API Debug Probe Max Records: 1000
  Apic Gateway Peering TLS:
    Secret Name: gateway-peering
```

- c. Show the age of the secret currently being used by running the following command:

```
kubectl -n namespace get secret gateway-peering-secret
```

where:

- `namespace` is the namespace where the Gateway subsystem is deployed.
- `gateway-peering-secret` is the secret name that you obtained in step 2b.

- d. Delete the secret and then immediately delete all of the Gateway pods in the Gateway cluster by running the following two commands:

```
kubectl -n namespace delete secret gateway-peering-secret
kubectl -n namespace delete pod gw-pod1 gw-pod2 gw-pod3
```

where:

- `namespace` is the namespace where the Gateway subsystem is deployed.
- `gateway-peering-secret` is the secret name that you obtained in step 2b.

When you delete the secret and the pods, the following events occur automatically:

- i. The cert-manager recreates the secret.
- ii. The DataPower operator recreates the gateway pods.
- iii. Dynamic reconfiguration re-installs the API metadata onto the gateways.

For information about dynamic reregistration and reconfiguration and (DRR), see [Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment](#).

e. To verify the update, show the age of the new gateway peering secret by running the following command:

```
kubect1 -n namespace get secret gateway-peering-secret
```

where:

- `namespace` is the namespace where the Gateway subsystem is deployed.
- `gateway-peering-secret` is the secret name that you obtained in step 2b.

Make sure that the secret is new and does not show the same age as previously.

Updating the TLS profile for Gateway

Update the TLS profile that secures communications with the Gateway subsystem in your API Connect deployment.

Procedure

1. Appliance only: update the TLS profile by modifying the configuration of the REST management interface.

Attention: If your Gateway is not deployed on an appliance, skip to step 2.

For information on the REST management interface commands, see *REST management interface commands* in the appropriate version of the [DataPower documentation](#).

2. Kubernetes only: update the TLS profile using the Domain API, which is exposed in the GatewayCluster CRD.

The update requires a change the `rest-mgmt` service in the `default` domain. For information, see [Domain API](#) in the DataPower Operator documentation. For information on updating the domain definition, see [Domain configuration](#) in the same documentation.

Note: The Gateway's API call SNI endpoint already supports replacing customer-provided keys and certifications as explained in [Binding a TLS server profile to a gateway service](#).

Portal subsystem: updating keys and secrets

Update the database passwords, keys, and the `client_secret` values for the Portal subsystem in an API Connect deployment.

About this task

- [Changing the secret for Portal data and system tools](#)
Replace the encryption key that generates the secret used for securing the database and system tools that are used by the Portal subsystem.
- [Changing the Portal client secret](#)
Change the `client_secret` for the Portal subsystem to keep it in sync with the Management subsystem.
- [Rotating the portal intra-subsystem certificates on VMware](#)
Use the `apicup` command to rotate the portal intra-subsystem certificates.

Changing the secret for Portal data and system tools

Replace the encryption key that generates the secret used for securing the database and system tools that are used by the Portal subsystem.

Before you begin

If you are using a stand-alone, single data center deployment, you can update the encryption key with the PortalSecretRotation CR, as explained in [Renewing the portal CA with the PortalSecretRotation CR](#). The PortalSecretRotation CR is not supported for a two data center configuration or a Cloud Pak for Integration deployment, so you must update the key manually as explained in the following steps.

About this task

The Portal subsystem uses a database plus several system tools to manage storage, hot backups, and cluster synchronization. The following services are all secured with the secret that is generated by the Portal CR during installation:

- MySQL root account for each Portal site
- Csync2 cluster synchronization service

Updating the portal-encryption-secret will make the following changes to your deployment:

- Change the root MySQL password
- Generate a new, site-specific MySQL password for each site
- Generate a new csync2 cluster key
- Re-encrypt all `client_ids` and `client_secrets` in the portal database

If you need to change the secret, the update is applied to all of the listed services. You can change the secret by generating a new value and restarting pods to pick up the new value. In a two data center deployment, you must manually copy the new secret to the other site.

Procedure

Generate a new secret and apply it to the deployment using the appropriate steps for your environment:

- Single data center
Run the following command to generate a new secret and apply it to the deployment:

```
kubectl -n namespace patch secret portal-enc-key -p "{\"data\": {\"encryption_secret\": \"$(head -c72 /dev/urandom | base64 -w0 | base64 -w0)\"}\"}
```

where *namespace* is the namespace where you installed the Portal subsystem.

The `portal-enc-key` was generated during installation and added to the CR as the `encryptionSecret` setting. When you generate a new secret, the value is updated automatically. If you saved the secret in a file after the [Portal installation](#) as recommended, be sure to update that file now.

- Two data centers
a. Generate the new secret on DC1 by running the following command:

```
head -c72 /dev/urandom | base64 -w0 | base64 -w0 > secret.txt
```

The `portal-enc-key` was generated during installation and added to the CR as the `encryptionSecret` setting. When you generate a new secret, the value is updated automatically. If you saved the secret in a file after the [Portal installation](#) as recommended, be sure to update that file now.

- b. Open a terminal to each DC in the same working directory where you saved `secret.txt` (or, copy the file to somewhere you can open a terminal to each DC).

- c. In each terminal, verify that you can access `secret.txt` by typing the following command:

```
echo $(cat secret.txt)
```

- d. In each terminal, type the following command -- but do not press Enter yet:

```
kubectl -n namespace patch secret portal-enc-key -p "{\"data\": {\"encryption_secret\": \"$(cat secret.txt)\"}\"}
```

where *namespace* is the namespace where you installed the Portal subsystem.

- e. Press Enter in both terminals at the same time (or as close in time as possible).
There is a 5-minute time-out that starts as soon as any of the pods has the new secret mounted by Kubernetes. All pods will get the secret at slightly different times, but within about a minute of each other. If the 5-minute time-out expires before all pods across both DCs have the new secret, then the pods will rotate the new secret in at different times, resulting in errors in the logs and some down time for various pods, until they manage to rotate the new secret into use and recover.

Results

When pods restart, the new secret is used to secure the services. The `portal-www` admin logs display messages as the new secret is used to re-encrypt the database. The following example shows sample log messages when the updated secret is applied to the database:

```
[ upgrade stdout] 2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: NEW k8s encryption key detected on this system!  
Reencrypting portal data  
[ upgrade stderr] 2954 888ec0:73add2:7fceb1b 2020-08-06 13:16:21: refresh_encryption_key: Command Started:  
/opt/ibm/bin/refresh_encryption_key  
FEgX8F5MxtwvoJ8Wpxw5DB/6MKK/qPKfRt5FaId3jy5IjbpXL8wi3/33q3KOySh8/zh11rVNFZTlzRnVfkGheLr9Le/Pb9jq  
[ upgrade stdout] 2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: No portal service exists! Simply overriding the key  
[ upgrade stdout] 2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: New key installed  
(FEgX8F5MxtwvoJ8Wpxw5DB/6MKK/qPKfRt5FaId3jy5IjbpXL8wi3/33q3KOySh8/zh11rVNFZTlzRnVfkGheLr9Le/Pb9jq)  
[ upgrade stderr] 2954 888ec0:73add2:7fceb1b 2020-08-06 13:16:21: refresh_encryption_key: Command Finished:  
/opt/ibm/bin/refresh_encryption_key  
FEgX8F5MxtwvoJ8Wpxw5DB/6MKK/qPKfRt5FaId3jy5IjbpXL8wi3/33q3KOySh8/zh11rVNFZTlzRnVfkGheLr9Le/Pb9jq with RC 0  
[ upgrade stderr] 2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: Command Finished: /opt/ibm/bin/sysupgrade with RC 0
```

If there is a Portal service registered and Developer Portal sites installed, then this task re-encrypts that data as well. When the site encryption is complete, the log displays a "Command Finished" message for the `refresh_encryption_key` command, as shown in the following example:

```
Command Finished: /opt/ibm/bin/refresh_encryption_key <KEY> with RC 0
```

Changing the Portal `client_secret`

Change the `client_secret` for the Portal subsystem to keep it in sync with the Management subsystem.

About this task

The Portal subsystem uses the same `client_secret` as the Management subsystem. If you change the `client_secret` on the Management subsystem, update the Portal subsystem by pulling the credential from the Management subsystem.

Note: If you did not deploy the Portal subsystem, skip this task.

Procedure

1. On a Portal pod, run the following command to pull the Portal service's `client_secret` from the Management subsystem:

```
kubectl -n namespace exec -t portal-mydc-www-0 -- bash -ic refresh_cloud_credentials
```

where *namespace* is the namespace where you installed the Portal subsystem.

2. Then, run the following command to update the credential for the Portal sites:

Note: If you did not deploy any Portal sites, skip this step.

```
kubect1 -n namespace exec -t portal-mydc-www-0 -- bash -ic "refresh_site_credentials -a"
```

where `namespace` is the namespace where you installed the Portal subsystem.

Rotating the portal intra-subsystem certificates on VMware

Use the `apicup` command to rotate the portal intra-subsystem certificates.

The portal's intra-subsystem certificates: `portal-ca`, `portal-client`, and `portal-server`, are not shown in the `apicup certs list` output, and cannot be updated with `apicup certs set`. If you want to renew these certificates, you can use the `apicup subsys rotate-secrets` command.

Warning: The portal intra-subsystem certificates are internal certificates that are created and renewed automatically. Renewing these certificates with `apicup subsys rotate-secrets` is only necessary in specific failure scenarios and should be done only if advised by IBM support.

To rotate the Developer Portal subsystem secrets, certificates, or both, run the following command:

```
apicup subsys rotate-secrets portal
```

Rotate portal subsystem secrets

Usage:

```
apicup subsys rotate-secrets SUBSYS [flags]
```

Flags:

```
--certs strings          List of certificates you want to rotate (Listing an issuer will rotate any certs issued by the issuer e.g listing just portal-ca will rotate portal-ca, portal-client and portal-server)
--encryption-secret string Optional value to set the encryption secret to, if supplied secret exists in the env. If not supplied the rotated secret will be random.
-h, --help              help for rotate-secrets
--rotate-encryption-secret Set to true if you want to rotate the encryption secret.
--wait                 Wait for the operation to complete or fail.
--wait-timeout duration Command timeout in seconds. (default 40s)
```

Global Flags:

```
--accept-license  Deprecated. Use apicup licenses commands to work with licenses
--debug           Enable debug logging
```

For example, to rotate the encryption secret to a random value run the following command:

```
apicup subsys rotate-secrets portal --rotate-encryption-secret true
```

The following example rotates the encryption secret to a named secret (note that first you must exec into the Developer Portal OVA to create the secret):

```
apicup subsys rotate-secrets portal --rotate-encryption-secret --encryption-secret my-new-secret
```

The following example rotates all of the Developer Portal certificates:

```
apicup subsys rotate-secrets portal --certs portal-ca
```

The following example rotates just the server and client certificates:

```
apicup subsys rotate-secrets portal --certs portal-server,portal-client
```

To list any Developer Portal secret rotations that were created by using the `rotate-secrets` command:

```
apicup subsys list-rotate-secrets portal --timeout 30
```

Where:

- `portal` is the name of your Developer Portal subsystem.
- `--timeout` (optional) is the duration in seconds of the command timeout. Default is 40 seconds.

To delete any Developer Portal secret rotations that were created by using the `rotate-secrets` command:

```
apicup subsys delete-rotate-secret portal --rotate-secret-name secret_name --wait true --wait-timeout 80
```

Delete a secret rotation of the subsystem

Usage:

```
apicup subsys delete-rotate-secret SUBSYS [flags]
```

Flags:

```
-h, --help              help for delete-rotate-secret
--rotate-secret-name string Value of a Portal Secret Rotation CR name to delete.
--wait                 Wait for the operation to complete or fail.
--wait-timeout duration Command timeout in seconds. (default 1m0s)
```

Global Flags:

```
--accept-license  Deprecated. Use apicup licenses commands to work with licenses
--debug           Enable debug logging
```

Analytics subsystem: replacing the TLS profile and keys

Update the Analytics subsystem's TLS profile and keys for backup and restore operations in your API Connect deployment.

- [Updating the TLS profile for Analytics](#)
Update the TLS Profile for the Analytics service in your API Connect deployment.
- [Updating the Analytics backup/restore secret](#)
Update the secret that secures backed-up data for the Analytics subsystem in an API Connect deployment.

Updating the TLS profile for Analytics

Update the TLS Profile for the Analytics service in your API Connect deployment.

Procedure

1. Unassociate Analytics service from the Gateway service.
Unassociate the Analytics service from all gateway services as explained in step 7 in the topic, [Associating an analytics service with a gateway service](#).
2. Update the TLS Profile for the Analytics service.
See step 3 in the topic, [Registering an analytics service](#).
3. Associate the Analytics service with the Gateway service.
See [Associating an analytics service with a gateway service](#).

Updating the Analytics backup/restore secret

Update the secret that secures backed-up data for the Analytics subsystem in an API Connect deployment.

About this task

When you configure S3 storage for backing up Analytics data, you encrypt the S3 provider's access key and save it as a Kubernetes secret for your Analytics deployment. If the S3 access key or your Kubernetes secret is compromised, obtain a new key from the S3 provider and use it to generate a new Kubernetes secret.

Important: When you invalidate a key, be sure to save a copy of it with a notation listing the dates when it was used. If you need to restore a backup that was created with the invalidated key, you will need to use that key to access the data. One method of saving the key is to create a new version of the CR every time you change the key, so that you can easily refer to the settings and key that were used for each backup.

This task assumes that you have already [configured the backup settings for your Analytics subsystem](#) and now want to replace the Kubernetes secret that is specified as the `analytics-backup-secret` in the Analytics CR.

Procedure

1. Update the secret for your S3 storage:
 - a. Obtain a new access key and corresponding access key secret from your S3 provider.
 - b. Invalidate the previous credentials that were specified in the Analytics CR.
2. Delete the invalidated Kubernetes secret by running the following command:

```
kubectl -n namespace delete secret name
```

where:

- `namespace` is the namespace where Analytics is deployed.
- `name` is the name of the current (invalidated) Kubernetes secret, which is specified in the `credentials` setting in the `databaseBackup` section of the Analytics CR. Every time you update the secret, you must assign it a new name.

3. Create a new Kubernetes secret by running the following command and filling in your access key, access key secret, and namespace:

```
kubectl -n namespace create secret generic new_secret_name --from-literal=access_key='S3_access_key' --from-literal=secret_key='S3_access_key_secret'
```

where:

- `namespace` is the namespace where Analytics is deployed.
- `new_secret_name` is a new name for storing the new Kubernetes secret. Every time you update the secret, you must assign it a new name.
- `S3_access_key` and `S3_access_key_secret` are the values that you received from the S3 provider.

4. Edit the Analytics CR file and replace the invalidated secret with the new secret.
 - a. In the CR, locate the `credentials` setting in the `databaseBackup` section.
 - b. Replace the invalidated secret name with the name of the new secret that you just generated.
 - c. Save and close the CR file.
5. Run the following command to apply the updated CR so that the new secret takes effect:

```
kubectl -n namespace apply -f path/to/analytics-cr
```

where:

- `namespace` is the namespace where Analytics is deployed.
- `path/to/analytics-cr` is the path and file name of the Analytics CR.

Renewing TLS certificates

Renew TLS certificates in your API Connect deployment.

A default API Connect deployment uses cert-manager to create *issuers*, *CA certificates*, *server certificates*, and *client certificates*. Cert-manager monitors all the certificates that it creates, and renews them before they expire.

Note: If you are not using cert-manager, or if you customized some or all of your API Connect certificates, then you are responsible for monitoring and renewing those certificates.

Certain API Connect configuration and maintenance operations can require that some or all TLS certificates that are used by API Connect are renewed before their expiry. The process of updating API Connect TLS certificates is called "certificate renewal". The process to renew certificates involves the following steps:

1. Manually deleting Kubernetes secrets that contain the TLS certificates that need renewal.
2. Cert-manager detecting the deletion of these secrets, and automatically creating new secrets that contain newly generated x509 certificates.

Steps steps for identifying and renewing API Connect certificates are described in the following topics:

- [Renewing certificates with cert-manager](#)
Use cert-manager to renew the issuers, CA certificates, and derived certificates that it manages for your API Connect deployment.
- [Renewing custom certificates](#)
If you did not use cert-manager to generate certificates for your API Connect deployment, you must renew them manually.
- [List of Issuers, CA certificates, and secrets](#)
A summary of certificate issuers, with the CA issued by each, and the corresponding secret used to sign certificates in an API Connect deployment.
- [List of ingress certificates](#)
A summary of certificates that are used for communications between subsystems and clients in an API Connect deployment.
- [List of intra-subsystem certificates](#)
A summary of certificates used for communications within subsystems in an API Connect deployment.
- [V2018 upgrade: List of certificates to update manually](#)
If you upgraded to API Connect V10 from V2018, some external certificates are carried over from the V2018 deployment and are not managed by cert-manager. When you update any of the retained certificates, you must restart the affected pods manually.
- [Renewing certificates in a two data center deployment on Kubernetes and OpenShift](#)
Renewing TLS certificates in an API Connect two data center disaster recovery deployment requires you to copy some updated information between data centers while ensuring that the shared information is not overwritten during the remaining updates.

Related information

- [API Connect TLS certificates reference page.](#)

Renewing certificates with cert-manager

Use cert-manager to renew the issuers, CA certificates, and derived certificates that it manages for your API Connect deployment.

Cert-manager monitors and automatically renews all API Connect certificates before they expire. However, some API Connect maintenance operations require the manual renewal of certificates. The topics in this section describe how to manually trigger cert-manager to renew the certificates that it manages.

Key points to understand:

- If you replaced any cert-manager certificates with custom certificates, you must update these certificates manually before they expire. Cert-manager does not monitor custom certificates.
- Some API Connect pods must be restarted when certain API Connect certificates are renewed. See [Pods that require restart after certificate renewal](#).
- When you renew a CA certificate, you must renew all the end-entity certificates that the CA signs. See [API Connect TLS certificates reference](#).

Note: If your API Connect deployment was originally installed at v10.0.1.2 or earlier, then the certificate might be missing the `duration` and `renewBefore` properties. Before you renew any API Connect connect certificates, verify that your certificates have these properties, and if not then add them:

1. Run the following command to list of all the certificate names, with their `duration` and `renewBefore` properties:

```
kubectl -n <namespace> get certificate -o custom-  
columns=NAME:metadata.name,DURATION:spec.duration,RENEWBEFORE:spec.renewBefore
```

Example output where `management-ca` is missing the `duration` and `renewBefore` properties:

NAME	DURATION	RENEWBEFORE
analytics-ai-endpoint	17520h0m0s	720h0m0s
...		
management-ca	<none>	<none>

2. For each certificate output from step 1 that shows `<none>` for `duration` and `renewBefore`, edit the certificate and add these properties:

```
kubectl -n <namespace> edit certificate <certificate name>
```

Add the `duration` and `renewBefore` properties under the `spec` property as shown in the following example:

```
...  
spec:  
...  
  duration: <duration>  
  renewBefore: 720h # 30 days  
...
```

where `<duration>` is:

- `87600h` for CA certificates.
 - `17520h` for all other certificates.
- [Renewing the management CA with the ManagementSecretRotation CR](#)
Use the ManagementSecretRotation CR to renew the management CA and all end-entity certificates that the management CA signs.

- [Renewing the portal CA with the PortalSecretRotation CR](#)
Use the PortalSecretRotation CR to renew the portal CA and all end-entity certificates that the portal CA signs.
- [Renewing the ingress-ca](#)
Renew the ingress CA certificate, and all the end-entity certificates that the ingress CA signs.
- [Renewing the analytics CA](#)
Renew the analytics CA certificate, and all end-entity certificates that the analytics CA signs.
- [Renewing end-entity certificates](#)
Renew an API Connect end-entity certificate.
- [Monitoring cert-manager certificate renewal](#)
How to monitor when your certificates are nearing their expiry, confirm that cert-manager is renewing them, and verify that dependent certificates are also renewed and related pods are restarted.

Renewing the management CA with the ManagementSecretRotation CR

Use the ManagementSecretRotation CR to renew the management CA and all end-entity certificates that the management CA signs.

About this task

Applying the `ManagementSecretRotation` CR (Custom Resource) is the recommended method for renewing the `management-ca` and all its end-entity certificates. The alternative method is to manually renew the management CA certificate and then each of its end-entity certificates, which you can identify from the certificates table [Management certificates](#).

Restriction: The `ManagementSecretRotation` CR is for use with a single data center deployment. Do not attempt to use it with a two data center disaster recovery deployment. See [Renewing certificates in a two data center deployment on Kubernetes and OpenShift](#).

Procedure

1. Create a file called `management_cert_rotate.yaml` and paste in the following contents:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementSecretRotation
metadata:
  name: mgmt-rotate-issuer
spec:
  managementCluster: <management CR name>
  rotateCertificates:
    certificates:
      - <management CR name>-ca
```

where `<management CR name>` is the name of your `ManagementCluster` CR. You can identify this name with:

```
kubectl get ManagementCluster -n <management namespace>
```

2. Apply the CR by running the following command:

```
kubectl create -f management_cert_rotate.yaml -n <management namespace>
```

Applying the CR updates the `management-ca`, and all end-entity certificates that `management-ca` signs. To view a list of the renewed certificates, run the following command:

```
kubectl describe ManagementSecretRotation mgmt-rotate-issuer -n <management namespace>
```

The `status` block in the command output shows the renewed certificates:

```
Status:
...
Phase: Completed
Rotated Certs:
  def-management-ca
  def-management-db-client-replicator
  def-management-db-client-primaryuser
  def-management-client
  def-management-db-client-postgres
  def-management-natscluster-mgmt
  def-management-sitel-postgres
  postgres-operator
  def-management-sitel-postgres-pgbouncer
  def-management-db-client-pgbouncer
  def-management-db-client-apicuser
  def-management-server
State: 1/1
...
```

3. When certificate rotation is successfully completed, delete the `ManagementSecretRotation` CR. Confirm that certificate rotation is finished with the command:

```
kubectl get ManagementSecretRotation mgmt-rotate-issuer -n <management namespace>
```

The output should show `Completed`:

NAME	READY	STATUS	AGE
mgmt-rotate-issuer	1/1	Completed	6m52s

Then delete the CR:

```
kubectl delete ManagementSecretRotation mgmt-rotate-issuer -n <management namespace>
```

Renewing the portal CA with the PortalSecretRotation CR

Use the PortalSecretRotation CR to renew the portal CA and all end-entity certificates that the portal CA signs.

About this task

Applying the `PortalSecretRotation` CR (Custom Resource) is the recommended method for renewing the portal CA certificates and all its end-entity certificates. The alternative method is to manually renew the portal CA certificate and then each of its end-entity certificates, which you can identify from the certificates table [Portal certificates](#).

Renewing the `portal-ca` certificate causes downtime because all the `portal-db` pods need to restart the MySQL process to allow for the certificate to update. The pods do not restart, but they go non-ready and then ready again, which takes a few minutes.

Restriction: The `PortalSecretRotation` CR is for use with a single data center deployment. Do not attempt to use it with a two data center disaster recovery deployment. See [Renewing certificates in a two data center deployment on Kubernetes and OpenShift](#).

Procedure

1. Create a file called `portal-secret-cr.yaml` and paste in the following contents:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalSecretRotation
metadata:
  name: portal-rotate-secret
spec:
  portalCluster: <portal CR name>
  # List of certificates you want to rotate (Listing an issuer will rotate any certs issued by the issuer e.g listing just
  # portal-ca will rotate portal-ca, portal-client and portal-server)
  rotateCertificates:
    certificates:
      - <portal CR name>-ca
  rotateEncryptionSecret:
    # Set to true if you want to rotate the encryption secret.
    rotate: true
    # Optional value to set the encryption secret to, if supplied secret exists in the env. If not supplied the rotated
    # secret will be random.
    encryptionSecret: new-encryption-secret
```

where `<portal CR name>` is the name of your `PortalCluster` CR. You can identify this name with:

```
kubectl get PortalCluster -n <portal namespace>
```

If you set `rotate: true` in the `rotateEncryptionSecret` section, the `portal-encryption-secret` is updated and the following changes are made:

- Change the root MySQL password.
- Generate a new, site-specific MySQL password for each site.
- Reencrypt all `client_ids` and `client_secrets` in the portal database.

2. Apply the CR by running the following command:

```
kubectl create -f portal-secret-cr.yaml -n <portal namespace>
```

Applying the CR updates the `<portal CR name>-ca`, along with all end-entity certificates that it signs. To view a list of the updated certificates, run the following command:

```
kubectl describe PortalSecretRotation portal-rotate-secret -n <portal namespace>
```

The `status` block in the command output shows the renewed certificates:

```
Status:
...
Phase: Completed
Rotated Certs:
  def-portal-ca
  def-portal-server
  def-portal-client
State: Completed Portal Secret Rotation.
...
```

3. When the certificate rotation is finished, delete the `PortalSecretRotation` CR.

Confirm that certificate rotation is finished with the command:

```
kubectl get PortalSecretRotation portal-rotate-issuer -n <portal namespace>
```

The output should show `Completed`:

NAME	STATUS	MESSAGE	AGE
portal-rotate-secret	Completed	Completed Portal Secret Rotation.	7m50s

Then delete the CR:

```
kubectl delete PortalSecretRotation portal-rotate-issuer -n <portal namespace>
```

Renewing the ingress-ca

Renew the ingress CA certificate, and all the end-entity certificates that the ingress CA signs.

About this task

The ingress CA certificate signs all user-facing and inter-subsystem certificates. When you renew the ingress CA, you must renew all the end-entity certificates that the ingress CA signs.

For more information about API Connect certificates, see [API Connect TLS certificates](#).

Procedure

1. Run the following command to renew the ingress CA certificate:

```
kubectl -n <management namespace> get certificate <ingress CA name> -o=jsonpath='{.spec.secretName}' | xargs kubectl -n <management namespace> delete secret
```

where *<ingress CA name>* is the name of the ingress CA certificate. On Kubernetes and OpenShift individual subsystem installations this name is `ingress-ca`. On Cloud Pak for Integration and OpenShift top-level CR installations, this name is `<apic instance name>-ingress-ca`.

2. Run the following command to renew all the end-entity certificates that the ingress CA signs:

```
kubectl get secrets -n <management namespace> -o custom-columns='NAME:.metadata.name,ISSUER:.metadata.annotations.cert-manager.io/issuer-name' --no-headers=true | grep ingress-issuer | awk '{ print $1 }' | xargs kubectl delete secret -n <management namespace>
```

3. If you have other subsystems that are in different namespaces from the management subsystem, then follow the steps in [Copying renewed ingress-ca to subsystems in different namespaces](#).

4. Verify analytics in the developer portal.

Due to a known issue, when the `ingress-ca` is renewed, it is possible that [Analytics in the Developer Portal](#) might stop working. If this happens, complete the following steps to ensure that certificate changes take effect:

- a. Log in to the Cloud Manager user interface.
- b. In the navigation list, click  Topology.
- c. Edit the Analytics service.
- d. On the Analytics page, edit the Summary field to force a change; for example, by adding a space to the end of a sentence.
- e. Click Save.

Copying renewed ingress-ca to subsystems in different namespaces

When the ingress CA certificate on the management subsystem is renewed, you must copy the renewed certificate to any subsystems that are in a different namespace.

Before you begin

Complete the steps in [Renewing the ingress-ca](#) to renew the ingress CA in your management subsystem namespace.

Note: If all your API Connect subsystems are in the same namespace, you do not need to follow this procedure.

About this task

The ingress CA signs all the inter-subsystem communication certificates that are used between API Connect subsystems. If your subsystems are installed in different namespaces, then the ingress CA must be manually synchronized across all those namespaces.

These steps must be repeated for all namespaces where you have subsystems that are registered with your management subsystem.

For more information about API Connect certificates, see [API Connect TLS certificates](#).

Procedure

1. Export the management namespace ingress CA secret to a YAML file called `ingress-ca.yaml`:

```
kubectl -n <management namespace> get secret ingress-ca -o yaml > ingress-ca.yaml
```

2. Edit `ingress-ca.yaml` and remove all `metadata` fields except for the secret name. The resulting file contents look like this:

```
apiVersion: v1
data:
  ca.crt: ...
  tls.crt: ...
  tls.key: ...
kind: Secret
metadata:
  name: ingress-ca
type: kubernetes.io/tls
```

3. Apply the updated `ingress-ca.yaml` in the namespace of the other subsystem:

```
kubectl -n <other subsystem namespace> apply -f ingress-ca.yaml
```

4. Verify that the ingress CA is now identical in both namespaces.

- a. Extract your `ingress-ca` secret to a file in your management namespace:

```
kubectl -n <management namespace> get secrets ingress-ca -o yaml | grep tls.crt | grep -v 'f:tls' | awk '{print $2}' | base64 -d > ingress.pem.mgmt
```

b. Extract your `ingress-ca` secret to a file in your other subsystems' namespace:

```
kubectl -n <other subsystem namespace> get secrets ingress-ca -o yaml | grep tls.crt | grep -v 'f:tls' | awk '{print $2}' | base64 -d > ingress.pem.other
```

c. Verify that the files that are created for each namespace are identical:

```
diff ingress.pem.mgmt ingress.pem.other
```

5. Run the following command to renew all the `ingress-ca` end-entity certificates in the other subsystems' namespace:

```
kubectl get secrets -n <other subsystem namespace> -o custom-columns='NAME:.metadata.name,ISSUER:.metadata.annotations.cert-manager.io/issuer-name' --no-headers=true | grep ingress-issuer | awk '{ print $1 }' | xargs kubectl delete secret -n <other subsystem namespace>
```

Renewing the analytics CA

Renew the analytics CA certificate, and all end-entity certificates that the analytics CA signs.

About this task

The pods that comprise the analytics subsystem communicate with each other using certificates that are signed by the analytics CA certificate. If you renew the analytics CA certificate, you must also renew the analytics end-entity certificates that the analytics CA signs.

For more information about API Connect certificates, see [API Connect TLS certificates](#).

Procedure

1. Run the following command to renew the analytics CA certificate:

```
kubectl -n <analytics namespace> get certificate <analytics CA name> -o=jsonpath='{.spec.secretName}' | xargs kubectl -n <analytics namespace> delete secret
```

where `<analytics CA name>` is the name of the analytics CA certificate. On Kubernetes and OpenShift individual subsystem installations this name is `analytics-ca`. On Cloud Pak for Integration and OpenShift top-level CR installations, this name is `<apic instance name>-a7s-ca`.

Verify that a new `<analytics CA name>` secret is created:

```
kubectl -n <analytics namespace> get secret
```

Output should show a new `<analytics CA name>` secret:

NAME	TYPE	DATA	AGE
...			
<code><analytics CA name></code>	kubernetes.io/tls	4	28s

Check that the `AGE` column shows the secret was recently created.

2. Renew the end-entity certificates signed by the analytics CA. Run the following command for each certificate:

```
kubectl get certificate <analytics certificate> -o=jsonpath='{.spec.secretName}' | xargs kubectl delete secret
```

where `<analytics certificate>` is the name of the end entity certificate. The analytics end-entity certificates are:

- `analytics-client` or `a7s-client`.
- `analytics-server` or `a7s-server`.

On Cloud Pak for Integration and OpenShift top-level CR installations, the certificate name is prefixed with `<apic instance name>`.

3. Restart the analytics pods so that they use the renewed certificates: [Restarting Analytics pods and data collection](#).

Renewing end-entity certificates

Renew an API Connect end-entity certificate.

About this task

To renew an end-entity certificate, delete the secret that corresponds to the certificate. Cert-manager detects the deletion of the secret and re-creates it with a new x509 certificate.

For more information about API Connect certificates, see [API Connect TLS certificates](#).

Procedure

1. Get a list of all certificates in your API Connect namespace:

```
kubectl -n <namespace> get certificates
```

The output lists all certificates with their status, age, and the name of the corresponding secret. In this example, the certificate that is used by the API Manager UI is shown:

NAME	READY	SECRET	AGE
...			
apim-endpoint	True	apim-endpoint	13d
...			

By default the secret names are identical to the certificate names.

2. Delete the secret for the certificate that you want to renew:

```
kubectl -n <namespace> delete secret <secret name>
```

Cert-manager detects the deletion of the secret and creates a new secret with a newly generated x509 certificate.

Monitoring cert-manager certificate renewal

How to monitor when your certificates are nearing their expiry, confirm that cert-manager is renewing them, and verify that dependent certificates are also renewed and related pods are restarted.

CA certificate renewal

If cert-manager renews a CA certificate, you must renew all the certificates that the CA signs. See [API Connect TLS certificates reference](#).

Monitoring when your certificates are due to expire

Check when your certificates are due to expire with the following command:

```
kubectl -n <namespace> get certificate -o custom-columns=NAME:metadata.name,DURATION:spec.duration,RenewBEFORE:spec.renewBefore,NotAFTER:status.notAfter
```

Example output:

NAME	DURATION	RenewBEFORE	NotAFTER
analytics-ingestion-client	17520h0m0s	720h0m0s	2025-08-28T08:25:58Z
api-endpoint	17520h0m0s	720h0m0s	2025-08-28T08:28:40Z
apim-endpoint	17520h0m0s	720h0m0s	2025-08-28T08:28:21Z

The example output shows that your `analytics-ingestion-client` is due to expire at `2025-08-28T08:25:58Z`. The `RenewBEFORE` property shows that cert-manager should renew this certificate 720 hours before it expires.

Monitoring the cert-manager manager logs

Monitor the cert-manager logs to confirm when certificates are renewed. Run the following command to display the cert-manager log:

```
kubectl logs <cert-manager pod name> -n <cert-manager namespace>
```

Example output:

```
I0108 14:23:18.001074      1 controller.go:129] cert-manager/controller/certificates "level"=0 "msg"="syncing item"
"key"="default/test-cert"
I0108 14:23:18.009940      1 issue.go:109] cert-manager/controller/certificates/certificates/issue "level"=0
"msg"="certificate issued" "related_resource_kind"="Secret" "related_resource_name"="test-cert"
"related_resource_namespace"="default"
I0108 14:23:18.018664      1 sync.go:331] cert-manager/controller/certificates/certificates "level"=0 "msg"="certificate
scheduled for renewal" "duration_until_renewal"="-5.018566857s" "related_resource_kind"="Secret" "related_resource_name"="test-
cert" "related_resource_namespace"="default"
I0108 14:23:18.019070      1 controller.go:135] cert-manager/controller/certificates "level"=0 "msg"="finished processing work
item" "key"="default/test-cert"
```

The 4 statements (shown in the example) indicate when a certificate is about to be renewed, and when the renewal is complete a few seconds later.

Tip: Set up a logs-based alerting mechanism that informs you when cert-manager renews any certificate.

Pods that require restart after certificate renewal

Some API Connect pods must be restarted when certificates that are used by the pod are renewed. The certificates that require pods to be restarted after renewal are:

- `analytics-ingestion-client` or `a7s-ing-client`. Restart `apim`, `taskmanager`, and `analytics-proxy` pods on the management subsystem.
- `gateway-client-client` or `gw-dr-client`. Restart the `apim` and `taskmanager` pods on the management subsystem.
- `analytics-ai-endpoint` or `a7s-ai-endpoint`. Restart the `mtls-gw` pod on the analytics subsystem.

Renewing custom certificates

If you did not use cert-manager to generate certificates for your API Connect deployment, you must renew them manually.

About this task

You can recreate custom certificates that you generated, or that were generated by the operator during installation. After you renew certificates, restart the affected pods to ensure that the updated certificates are used.

Procedure

1. Renew the certificates that you generated:
Use one of the following methods to renew the certificates that you created:
 - Update the secret
 - Delete and then recreate the secret
 - Update the CR to reference a different secret name
2. Renew the certificates that were generated by the operator:
To renew the certificates generated by the operator, delete each certificate so that it can be recreated by the operator.
3. Restart the affected pods so they can pick up the renewed certificates.
For information on which pods are associated by each certificate, see the following topics:
 - [List of ingress certificates](#)
 - [List of intra-subsystem certificates](#)For instructions on restarting pods, see the following topics:
 - [Restarting Analytics pods and data collection](#)
 - [Management subsystem: restarting pods](#)
 - [Gateway subsystem: restarting pods](#)Note: Portal pods do not require manual restart after updating certificates.

List of Issuers, CA certificates, and secrets

A summary of certificate issuers, with the CA issued by each, and the corresponding secret used to sign certificates in an API Connect deployment.

Table 1 presents a list of the certificate issuers used in an API Connect deployment, with the CA issued by each, and the corresponding secret used to sign certificates. The `selfsigning-issuer` is used only for creating CAs, and does not have a corresponding certificate or secret of its own. If you have customized certificates, the certificates generated by the issuers in Table 1 use the `custom-certs-external.yaml` template.

Table 1. Issuers, CAs, and secrets

Issuer	CA certificate	Secret
<code>selfsigning-issuer</code>	N/A	N/A
<code>ingress-issuer</code>	<code>ingress-ca</code> issued by <code>selfsigning-issuer</code>	<code>ingress-ca</code> Attention: If you change the <code>ingress-ca</code> secret in a 2 data center deployment, you must change it to the same value in both data centers.
<code>analytics-ca</code>	<code>analytics-ca</code> issued by <code>selfsigning-issuer</code>	<code>analytics-ca</code>
<code>management-ca</code>	<code>management-ca</code> issued by <code>selfsigning-issuer</code>	<code>management-ca</code>
<code>portal-ca</code>	<code>portal-ca</code> issued by <code>selfsigning-issuer</code>	<code>portal-ca</code>

Note: On Cloud Pak for Integration, and OpenShift top-level CR deployments, some certificate names are contracted and prefixed with the `APIConnectCluster` instance name. For example, the certificate `management-ca` is called `<apic instance name>-mgmt-ca`.

List of ingress certificates

A summary of certificates that are used for communications between subsystems and clients in an API Connect deployment.

Note: On Cloud Pak for Integration, and OpenShift top-level CR deployments, some certificate names are contracted and prefixed with the `APIConnectCluster` instance name. For example, the certificate `management-ca` is called `<apic instance name>-mgmt-ca`.

User-facing certificates

Table 1 presents a list of user-facing certificates. The corresponding secrets use the same names. If you customized your certificates, the certificates in Table 1 use the `custom-certs-external.yaml` template.

Table 1. User-facing certificates

Certificate name	Issuer	Description
<code>api-endpoint</code> or <code>mgmt-platform-api</code>	<code>ingress-issuer</code>	Platform API endpoint server certificate. The certificate that is presented to callers of the platform REST API, and to the toolkit CLI.
<code>consumer-endpoint</code> or <code>mgmt-consumer-api</code>	<code>ingress-issuer</code>	Consumer API endpoint server certificate. The certificate presented that is presented to callers of the consumer REST API, and to the toolkit CLI.
<code>apim-endpoint</code> or <code>mgmt-api-manager</code>	<code>ingress-issuer</code>	API Manager UI server certificate.
<code>cm-endpoint</code> or <code>mgmt-admin</code>	<code>ingress-issuer</code>	Cloud Manager UI server certificate.

Certificate name	Issuer	Description
portal-web	ingress-issuer	The server certificate used on the <code>portalUIEndpoint</code> . It is the server certificate that is presented to portal site users, and which their browser authenticates. If there is a problem with this certificate, then users see an error message about an invalid or insecure certificate in their browser when they access a portal site. The default <code>portal-web</code> certificate is issued by the <code>ingress-issuer</code> , which has a self-signed root certificate. Portal users might see a browser warning about use of a self-signed certificate.
hub-endpoint	ingress-issuer	Used by the Automated API behavior testing application. User-facing server certificate for the <code>hub-endpoint</code> . If there is a problem with this certificate, then the user's browser shows a warning or error message.
turnstile-endpoint	ingress-issuer	Used by the Automated API behavior testing application. User-facing server certificate for the <code>turnstile-endpoint</code> . If there is a problem with this certificate, then the user's browser shows a warning or error message.

Inter-subsystem certificates

Table 2 lists all of the common subsystem communication certificates. The corresponding secrets use the same names. If you have customized your certificates, the certificates in Table 2 use the `custom-certs-external.yaml` template.

Table 2. Inter-subsystem certificates

Certificate name	Issuer	Description
-ingress-ca	selfsigning-issuer	The CA and issuer of all API Connect inter-subsystem and user-facing certificates. If there is a problem with this certificate, then all API Connect subsystems are inaccessible and unable to sync with each other. Update this certificate with <code>kubectl</code> . When updated, all child certificates must also be updated by deleting their corresponding secrets. See ingress-ca renewal . The <code>ingress-ca</code> certificate is also stored in the management subsystem database. It is visible from the Cloud Manager UI, in the truststores of the analytics, gateway, event gateway, and portal default TLS client profiles. When the management subsystem <code>apim</code> pod is restarted the certificate is reloaded into the database from the Kubernetes <code>ingress-ca</code> certificate. Do not attempt to update this certificate from the Cloud Manager UI. In 2DCDR deployments, and when you have subsystems in different namespaces, it is necessary to manually copy the <code>ingress-ca</code> certificate from the management subsystem to the other subsystems. Steps are provided in the 2DCDR and multi-namespace install sections of this documentation. If this certificate is updated, and you have a portal deployed, then restart the <code>portal-www</code> pods for the update to take effect.
analytics-ingestion-client or a7s-ing-client	ingress-issuer	Client certificate used for communication with the analytics subsystem on the ingestion endpoint. This certificate must have: <ul style="list-style-type: none"> The same CA as the server certificate <code>analytics-ai-endpoint</code> on the analytics subsystem. The common name must match the <code>spec.clientSubjectDN</code> in the analytics CR: <pre>kubectl describe cert analytics-admin-client</pre> <pre>Spec: Common Name: a7s-ing-client</pre> <pre>kubectl get a7s -o yaml</pre> <pre>spec: clientSubjectDN: CN=a7s-ing-client</pre> <p>For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be <code>CN=a7s-ingestion-client</code>, or they could both be <code>CN=a7s-ingestion-client, O=cert-manager</code>, but they must be identical.</p> <p>To update this certificate, use <code>kubectl</code>. Restart the <code>apim</code>, <code>taskmanager</code>, and <code>analytics-proxy</code> pods after the update. This certificate is also used by the gateways for sending API events to the analytics subsystem. The updated certificate is sent by the management subsystem to the gateways, it is not necessary to restart any gateway pods.</p>
portal-admin-client or ptl-adm-client	ingress-issuer	Client certificate used for communication with the portal subsystem on the <code>portalAdminEndpoint</code> . This certificate must have: <ul style="list-style-type: none"> The same CA as the server certificate <code>portal-admin</code> or <code>ptl-director</code> on the portal subsystem. The common name must match the <code>spec.adminClientSubjectDN</code> in the portal CR: <pre>kubectl describe cert portal-admin-client</pre> <pre>Spec: Common Name: ptl-adm-client</pre> <pre>kubectl get ptl -o yaml</pre> <pre>spec: adminClientSubjectDN: CN=ptl-adm-client</pre> <p>For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be <code>CN=portal-admin-client</code>, or they could both be <code>CN=ptl-adm-client, O=cert-manager</code>, but they must be identical.</p>
gateway-client-client or gw-dr-client	ingress-issuer	Client certificate for communications with the gateway service. Restart the <code>apim</code> , and <code>taskmanager</code> pods after update. This certificate must have the same CA as the <code>gwv6-manager-endpoint</code> or <code>gw-gateway-manager</code> certificate on the gateway.
api-endpoint or mgmt-platform-api	ingress-issuer	Platform API endpoint server certificate. The certificate that is presented to callers of the platform REST API, and to the toolkit CLI.
consumer-endpoint or mgmt-consumer-api	ingress-issuer	Consumer API endpoint server certificate. The certificate presented that is presented to callers of the consumer REST API, and to the toolkit CLI.

Certificate name	Issuer	Description
apim-endpoint or mgmt-api-manager	ingress-issuer	API Manager UI server certificate.
cm-endpoint or mgmt-admin	ingress-issuer	Cloud Manager UI server certificate.
mgmt-replication-client	ingress-issuer	2DCDR deployments only. Client certificate used in the warm-standby data center's <code><remote-sitename>-postgres</code> pod to connect to the active data center.
mgmt-replication-server	ingress-issuer	2DCDR deployments only. Server certificate used in the active data center's <code><management_CR>-tunnel</code> pod. This certificate must contain the DNS Subject Alternative Name of this data center's hostname and must be valid for the <code>spec.multiSiteHA.replicationEndpoint</code> defined in the management CR.
hub-endpoint	ingress-issuer	Used by the Automated API behavior testing application. User-facing server certificate for the <code>hub-endpoint</code> . If there is a problem with this certificate, then the user's browser shows a warning or error message.
turnstile-endpoint	ingress-issuer	Used by the Automated API behavior testing application. User-facing server certificate for the <code>turnstile-endpoint</code> . If there is a problem with this certificate, then the user's browser shows a warning or error message.
analytics-ai-endpoint or a7s-ai-endpoint	ingress-issuer	Server certificate used on the analytics ingestion endpoint, in the <code>mtls-gw</code> pod. Management and gateway subsystems communicate with the analytics subsystem on this endpoint. The client certificates that are used by the management and gateway subsystems must use the same CA certificate as the analytics-ai-endpoint certificate.
portal-admin or ptl-director	ingress-issuer	Server certificate used on the <code>portalAdminEndpoint</code> . The management subsystem communicates with the portal subsystem on this endpoint. The corresponding client certificate used in the management to portal communication is the <code>portal-admin-client</code> certificate. This certificate must have the same CA as the <code>portal-admin-client</code> certificate on the management subsystem.
portal-web	ingress-issuer	The server certificate used on the <code>portalUIEndpoint</code> . It is the server certificate that is presented to portal site users, and which their browser authenticates. If there is a problem with this certificate, then users see an error message about an invalid or insecure certificate in their browser when they access a portal site. The default <code>portal-web</code> certificate is issued by the <code>ingress-issuer</code> , which has a self-signed root certificate. Portal users might see a browser warning about use of a self-signed certificate.
ptl-replication-client	ingress-issuer	2DCDR deployments only. Client certificate that is used in the warm-standby data center's <code><remote-sitename>-www</code> and <code><remote-sitename>-db</code> pods to connect to the active data center.
ptl-replication-server	ingress-issuer	2DCDR deployments only. Server certificate used in the active data center's <code><portal_CR>-tunnel</code> pod, the counterpart to the <code>ptl-replication-client</code> certificate. This certificate must contain the DNS Subject Alternative Name of this data center's hostname and must be valid for the <code>spec.multiSiteHA.replicationEndpoint</code> defined in the portal CR.
gateway-peering or gw-peer	ingress-issuer	This certificate secures the communication between gateways in your gateway cluster.
gwv6-endpoint or gw-gateway	ingress-issuer	
gwv6-manager-endpoint or gw-gateway-manager	ingress-issuer	The <code>gatewayManager</code> endpoint certificate. This is the server certificate on the gateway director endpoint, which the management subsystem communicates with. This certificate must be signed by the same CA as the <code>gateway-client-client</code> certificate on management subsystem.
event-gateway-management-client	ingress-issuer	The <code>event-gateway-management-client</code> certificate exists only on Cloud Pak for Integration deployments.

List of intra-subsystem certificates

A summary of certificates used for communications within subsystems in an API Connect deployment.

Note: On Cloud Pak for Integration, and OpenShift top-level CR deployments, some certificate names are contracted and prefixed with the `APICConnectCluster` instance name. For example, the certificate `management-ca` is called `<apic instance name>-mgmt-ca`.

Table 1 presents a list of certificates used for communications between pods in the same subsystem. The certificates are managed by cert-manager. For details of all the API Connect certificates, see [API Connect certificates](#).

Table 1. Intra-subsystem certificates

Certificate name	Issuer	Description
management-ca or mgmt-ca	selfsigning-issuer	The issuer for the management subsystems intra-subsystem certificates: management-client, management-server, postgres, and nats certificates. Communication between management subsystem pods fails if there is a problem with this certificate. This certificate is also used as the CA for REST API calls to the management subsystem from the other subsystems, when using <code>in-cluster</code> communication. See In-cluster service communication between subsystems .
management-client or mgmt-client	management-ca	Client certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate.
management-server or mgmt-server	management-ca	Server certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate. Required DNS names in the certificate: <ul style="list-style-type: none"> * <code><namespace></code> * <code><namespace>.svc</code> * <code><instance name>-server.<namespace>.svc</code> <code><instance name>-server</code>

Certificate name	Issuer	Description
db-client-apicuser	management-ca	Intra-subsystem certificate for the management database subsystem.
db-client-pgbouncer	management-ca	Intra-subsystem certificate for the management database subsystem.
db-client-postgres	management-ca	Intra-subsystem certificate for the management database subsystem.
db-client-primaryuser	management-ca	Intra-subsystem certificate for the management database subsystem.
postgres	management-ca	Intra-subsystem certificate for the management database subsystem.
postgres-pgbouncer	management-ca	Intra-subsystem certificate for the management database subsystem.
postgres-operator	management-ca	Intra-subsystem certificate for the management database subsystem.
natscluster-mgmt	management-ca	Intra-subsystem certificate for the <code>nats</code> pods.
db-client-replicator	management-ca	2DCDR deployments only. Client certificate used by the <code><management_CR>-tunnel</code> pod to connect to the other data center's <code><management_CR>-tunnel</code> pod.
analytics-ca or a7s-ca	selfsigning-issuer	The issuer for the analytics-client and analytics-server certificates. Communication between analytics subsystem pods fails if there is a problem with this certificate. If this certificate is updated, restart the <code>storage</code> and <code>ingestion</code> pods for the update to take effect.
analytics-client or a7s-client	analytics-ca	Client certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. If this certificate is updated, restart the <code>storage</code> and <code>ingestion</code> pods for the update to take effect.
analytics-server or a7s-server	analytics-ca	Server certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. Required DNS names in the certificate: <pre>*.<namespace> *.<namespace>.svc *.<instance name>-server.<namespace>.svc <instance name>-server <instance name>-storage</pre> If this certificate is updated, restart the <code>storage</code> and <code>ingestion</code> pods for the update to take effect.
portal-ca or ptl-ca	selfsigning-issuer	The issuer for the portal-client and portal-server certificates. Communication between portal subsystem pods fails if there is a problem with this certificate. V10.0.5.3 and previous releases: If this certificate is updated, then all portal pods must be manually restarted. In later releases, the restart is automatic.
portal-client or ptl-client	portal-ca	Client certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate. V10.0.5.3 and previous releases: If this certificate is updated, then all portal pods must be manually restarted. In later releases, the restart is automatic.
portal-server or ptl-server	portal-ca	Server certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate. Required DNS names in the certificate: <pre>*.<namespace> *.<namespace>.svc *.<instance name>-server.<namespace>.svc <instance name>-server *.<instance name>-<site name>-db-all.<namespace>.svc *.<instance name>-<site name>-www-all.<namespace>.svc *.<instance name>-<site name>-db-all.<namespace>.svc.cluster.local *.<instance name>-<site name>-www-all.<namespace>.svc.cluster.local *.<namespace>.svc.cluster.local <instance name>-db #<remote portal CR name>-db # For 2DCDR only.</pre> <code><instance name></code> and <code><remote portal CR name></code> are truncated if more than 15 characters. V10.0.5.3 and previous releases: If this certificate is updated, then all portal pods must be manually restarted. In later releases, the restart is automatic.

V2018 upgrade: List of certificates to update manually

If you upgraded to API Connect V10 from V2018, some external certificates are carried over from the V2018 deployment and are not managed by cert-manager. When you update any of the retained certificates, you must restart the affected pods manually.

Ingress (front-end) certificates

Table 1 presents a list of the ingress certificates that were carried forward when you upgraded from V2018, and the pods that you must restart when you update each certificate.

If multiple Portal web ingress endpoints have been configured, then the certificates for those additional endpoints must be updated manually as well.

Table 1. V2018 ingress certificates and affected pods

Certificate and Secret	Pods
------------------------	------

Certificate and Secret	Pods
client-tls-xxxxxxxxxxx	<ul style="list-style-type: none"> analytics-mtls-gw-hashed-suffix
ingestion-tls-xxxxxxx	<ul style="list-style-type: none"> analytics-mtls-gw-hashed-suffix
platform-api-tls-xxxxxxx	N/A
api-manager-tls-xxxxxxx	N/A
cloud-manager-tls-xxxxxxx	N/A
consumer-api-tls-xxxxxxx	N/A
v5GwName-datapower-admin-credentials	N/A
v5GwName-apic-gateway-peering-tls	N/A
v5GwName-apic-gateway-service-tls	N/A
v6GwName-datapower-admin-credentials	N/A
v6GwName-apic-gateway-peering-tls	N/A
v6GwName-apic-gateway-service-tls	N/A
portal-uuid-admin	<ul style="list-style-type: none"> portal-nginx
www-tls-xxxxxxxxxxxxxxxx	N/A

Subsystem communication certificates

Table 2 presents a list of the subsystem communication certificates that were carried forward when you upgraded from V2018, and the pods that you must restart when you update each certificate.

Table 2. V2018 subsystem communication certificates and affected pods

Usage	Certificate and Secret	Pods
client	<i>managementUpgradeName</i> -analytics-ingestion-client	<ul style="list-style-type: none"> management-apim management-taskmanager gateway (via webhook, no restart needed)
client	<i>managementUpgradeName</i> -portal-admin	<ul style="list-style-type: none"> management-apim management-taskmanager management-portal-proxy
client	gw-apic-gateway-service-tls	<ul style="list-style-type: none"> gwv6 gwv5
clientserver	gw-apic-gateway-peering-tls	<ul style="list-style-type: none"> gwv6 (redis) gwv5 (redis)

Database encryption key

The database encryption key is carried forward from V2018, and uses the name: *managementUpgradeName*-encryption-secret. You can update the value of this secret as explained in [Changing the database encryption key](#).

Renewing certificates in a two data center deployment on Kubernetes and OpenShift

Renewing TLS certificates in an API Connect two data center disaster recovery deployment requires you to copy some updated information between data centers while ensuring that the shared information is not overwritten during the remaining updates.

About this task

Begin the process by updating certificates as needed on data center 1 (DC1). Then, copy the *ingress-ca* from DC1 to data center 2 (DC2) before updating certificates on DC2. Finally, you will copy encryption keys for the Management and Portal subsystem from DC1 to DC2.

Procedure

Complete the following steps in the sequence shown to ensure that you do not overwrite information that was copied from DC1 while updating DC2.

1. DC1: Renew TLS certificates as explained in [Renewing TLS certificates](#).
2. DC2: Complete the following steps to copy the *ingress-ca* from DC1:
 - a. On DC1, export the *ingress-ca* secret to a YAML file by running the following command:

```
kubectl -n namespace get secret ingress-ca -o yaml > ingress-ca.yaml
```
 - b. Still on DC1, edit the *ingress-ca.yaml* file to remove all labels, annotations, `creationTimestamp`, `resourceVersion`, `uid`, and `selfLink`.
 - c. Copy the *ingress-ca.yaml* to DC2.
 - d. On DC2, apply the *ingress-ca.yaml* file by running the following command:

```
kubectl -n namespace apply -f ingress-ca.yaml
```
 - e. Validate that the *ingress-ca* on DC2 matches the *ingress-ca* on DC1:
 - i. On DC1, run the following command to save the original *ingress-ca* as a PEM file:

```
kubect1 -n namespace get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d > /tmp/ingress.pem.dc1
```

ii. On DC2, run the following command to save the copied `ingress-ca` as a PEM file::

```
kubect1 -n namespace get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d > /tmp/ingress.pem.dc2
```

iii. Copy `/tmp/ingress.pem.dc1` from DC1 and store it in the `/tmp` folder on DC2.

iv. On DC2, run the following command to compare the two files and verify that there are no differences:

```
diff /tmp/ingress.pem.dc1 /tmp/ingress.pem.dc2
```

3. DC2: Update all external certificates that are based on the `ingress-ca` (see [List of ingress certificates](#)).

4. DC2: Update all of the internal certificates (see [List of intra-subsystem certificates](#)).

At this point, DC1 and DC2 have the same `ingress-ca` secrets. Next, copy the encryption keys for the Management and Portal subsystems from DC1 to DC2.

5. Copy the encryption key for the Management subsystem to DC2 by completing the following steps:

a. On DC1, copy the management encryption key:

i. Get the name of the management encryption key by running the following command:

```
$ kubect1 -n namespace get mgmt -o yaml | grep enc
```

The response looks like the following example:

```
encryptionSecret: dallas-enc-key
```

Make a note of the secret name for the next step. In the example, the key's name is `dallas-enc-key`.

ii. Retrieve the secret from the encryption key by running the following command (substitute in the name of the key from the previous step):

```
kubect1 get secret dallas-enc-key -o yaml
```

The output looks like the following example:

```
apiVersion: v1
data:
  encryption_secret.bin:
VKBNFj7sAOizxvE1H6i+9P31oJHvWwsO+x*****EGe/K+x6b3D7FEWGgoyG1WBUJKB4+T21My2iR5rBTov
pyLiY5g*****tSiRcQKegMPNBPgL829SVBCxuv3I=
kind: Secret
metadata:
  creationTimestamp: "2020-08-28T12:53:41Z"
  labels:
    app.kubernetes.io/instance: m1
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: dallas-enc-key
  name: dallas-enc-key
  namespace: default
  resourceVersion: "43039"
  selfLink: /api/v1/namespaces/default/secrets/m1-enc-key
  uid: 46c92395-9cc2-4421-b2c4-48e472c0cbb1
type: Opaque
```

iii. Copy the output and save it in a YAML file; for example `dc1-enc-key.yaml`.

iv. Edit the file and make the following changes:

- Delete the contents of the `metadata`: section (retain the section).
- In the `metadata`: section, add in a `name`: attribute, with `dc1-enc-key` as the value.

The following example shows the updated file:

```
apiVersion: v1
data:
  encryption_secret.bin:
VKBNFj7sAOizxvE1H6i+9P31oJHvWwsO+x*****EGe/K+x6b3D7FEWGgoyG1WBUJKB4+T21My2iR5rBTov
pyLiY5g*****tSiRcQKegMPNBPgL829SVBCxuv3I=
kind: Secret
metadata:
  name: dc1-enc-key
type: Opaque
```

v. Copy the updated file (`dc1-enc-key.yaml`) to the `/tmp` folder on DC2.

b. On DC2, run the following command to create a secret from the encryption key file (`dc1-enc-key.yaml`) that you copied from DC1:

```
$ kubect1 -n namespace create -f /tmp/dc1-enc-key.yaml
```

The response looks like the following example:

```
secret/dc1-enc-key created
```

6. Update the encryption key for the Portal subsystem on DC1 and then copy it to DC2 as explained in [Changing the secret for Portal data and system tools](#).

Management subsystem: restarting pods

Restart Management subsystem pods in your API Connect deployment.

About this task

This section describes how to restart Management subsystem pods.

Procedure

1. Determine the deployment name by running the following command:

```
kubectl -n namespace get deployment | grep CR_name
```

where:

- *namespace* is the namespace where the Management subsystem is installed.
- *CR_name* is the name of the CR used for installing the Management subsystem.

2. Restart pods by running the appropriate `kubectl` commands, shown in Table 1.
Use the deployment name that you obtained in step 1.

Table 1. Management pods and the commands to restart them

Pod	Restart command
management-analytics-proxy	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code>
management-apim	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code> A manual restart is not needed when the certificate is updated.
management-client-downloads-server	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code> A manual restart is not needed when the certificate is updated.
management-hub	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code>
management-juhu	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code>
management-ldap	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code> A manual restart is not needed when the certificate is updated.
management-lur	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code> A manual restart is not needed when the certificate is updated.
management-natscluster	Execute for each <code>natscluster</code> pod, one at a time: <code>kubectl exec <i>management-natscluster-n</i> -- bash -c "kill -HUP 1"</code> A manual restart is not needed when the certificate is updated.
postgres-operator	<code>kubectl rollout restart deployment postgres-operator -n <<i>namespace</i>></code>
management-random-postgres*	Rollout restart all the postgres deployments: <code>kubectl -n <<i>namespace</i>> get deploy -o name grep postgres egrep -v "backrest pgbouncer operator" xargs kubectl -n <<i>namespace</i>> rollout restart</code>
management-random-postgres-pgbouncer	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code> A manual restart is not needed when the certificate is updated.
management-portal-proxy	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code> A manual restart is not needed when the certificate is updated.
management-taskmanager	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code> A manual restart is not needed when the certificate is updated.
management-tunnel	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code>
management-turnstile	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code>
management-ui	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code>
management-analytics-ui	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code>
management-remote-sitename-postgres	<code>kubectl rollout restart deployment/<i>deployment_name</i> -n <<i>namespace</i>></code>

3. Verify that all Management pods are ready by running the following command:

```
kubectl -n namespace get po
```

where *namespace* is the namespace where the Management subsystem is installed.

The restart is complete when all pods are **Running** and **Ready**.

Gateway subsystem: restarting pods

Restart Gateway subsystem pods and components in your API Connect deployment.

About this task

When you update Gateway subsystem secrets and certificates, the pods restart automatically.

Analytics subsystem: restarting endpoints and pods

Restart the pods that support the Analytics service and endpoints in your API Connect deployment.

- [Restarting the Analytics ingestion endpoint](#)
Restart the pods that support the Analytics ingestion endpoint in your API Connect deployment.
- [Restarting Analytics pods and data collection](#)
Restart the pods that support the internal communications within the Analytics subsystem in your API Connect deployment.

Restarting the Analytics ingestion endpoint

Restart the pods that support the Analytics ingestion endpoint in your API Connect deployment.

About this task

The ingestion endpoint contains the external certificates that secure communications with the Analytics subsystem. The default names of these of the secrets for these certificates are `ingress-ca`, `analytics-ai-endpoint` (server), and `analytics-ingestion-client` (client).

When you refresh the certificates for the ingestion endpoint, restart the Analytics pods by completing the following steps.

Procedure

1. **OVA users:** log in to your analytics VM and ssh to the root user:

```
ssh apicadm@<vm hostname>
sudo -i
```

2. Reload the NGINX configuration in the `analytics-mtls-gw` pod by running the following command:

```
kubectl -n namespace exec analytics-mtls-gw -- openresty -s reload
```

where:

- `namespace` is the namespace where Analytics is installed.
- `analytics-mtls-gw` is the name of the `analytics-mtls-gw` pod.

The Management and Gateway subsystems pick up the change automatically and do not require a restart.

3. Verify that the Analytics service is working by completing the following steps:
 - a. Invoke an API on your gateway that uses the associated Analytics subsystem.
 - b. Use the Analytics user interface to confirm that new data was posted to the Analytics service.

Restarting Analytics pods and data collection

Restart the pods that support the internal communications within the Analytics subsystem in your API Connect deployment.

Before you begin

This operation requires the use of the Analytics CLI. [Using the Analytics CLI](#).

About this task

The internal certificates are used for all Analytics microservices to communicate with each other within the subsystem. The default names of the secrets for these are `analytics-ingestion-client`, `analytics-ai-endpoint`, `analytics-server`, and `analytics-ca`.

When you refresh the internal certificates for the Analytics subsystem, restart the Analytics pods by completing the following steps.

Procedure

1. **OVA users:** log in to your analytics VM and ssh to the root user:

```
ssh apicadm@<vm hostname>
sudo -i
```

2. Restart all of the Analytics pods by running the following command:

```
kubectl -n namespace delete po -l app.kubernetes.io/instance=CR_name
```

where:

- `namespace` is the namespace where the Analytics subsystem is installed.
- `CR_name` is the name of the CR for installing the Analytics subsystem (default name: `analytics`).

3. Verify that all Analytics pods are ready by running the following command:

```
kubectl -n namespace get po
```

where `namespace` is the namespace where the Analytics subsystem is installed.

Make sure that every pod is **Running** and **Ready**.

4. Associate the Analytics service with the Gateway service.
Note: If you did not unassociate the Analytics service from the Gateway, skip this step.
See [Associating an analytics service with a gateway service](#).
5. Check the storage cluster's health again and wait until the status is **green**.
6. Verify that the Analytics service is working by completing the following steps:
 - a. Invoke an API on your gateway that uses the associated Analytics subsystem.
 - b. Use the Analytics user interface to confirm that new data was posted to the Analytics service.

Re-enabling scheduled backups

If you disabled scheduled backups before updating keys, secrets, or passwords, enable the backups again for your API Connect deployment.

About this task

Procedure

1. Open the management cluster CR for editing by running the following command:

```
kubectl -n namespace edit CR-name
```

where:

- **namespace** is the namespace where the Management subsystem is installed.
- **CR-name** is the name of the CR that was used to install the Management subsystem.

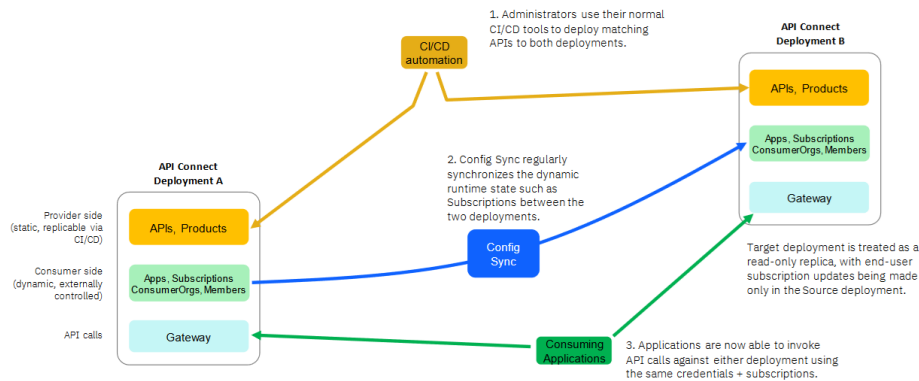

2. In the **databaseBackup** section of the CR, replace the **schedule** entry that you removed earlier when you disabled scheduled backups.
3. Save and close the file.

[Technical Preview] Using Config Sync to replicate consumer-side catalog data

Use the API Connect Config Sync utility to replicate consumer-side data from a source catalog in an API Connect cluster to a target catalog in a different API Connect cluster, so that API calls can be served by either API Connect cluster interchangeably to enable hybrid deployments and high-availability style scenarios.

API Connect Config Sync (apic-configsync) can be run either as a standalone binary, or a schedule with a Kubernetes cronjob, to facilitate the unidirectional replication of consumer-side data (consumer organizations, members, apps, subscriptions, credentials) from a catalog in a source API Connect cluster to a corresponding catalog in a separate, target API Connect cluster.

The following image shows how you can use Config Sync to replicate consumer-side data from a source deployment to a target deployment:

Config Sync can be run as frequently as required, and detects the differences between the replicated resource types in the source and target catalogs so that it efficiently replicates only the new changes that have been made in the source instance.

As shown in the following image, Config Sync helps to enable a range of hybrid cloud API topologies such as:

- Independent disaster recovery instances
- Software and SaaS hybrid scenarios
- Geo-replication
- Side-by-side version upgrade

This feature is provided as a Technical Preview

As such, the feature might not be fully functional in your environment and support is limited. In addition, the feature's appearance and functionality are subject to change both in this release and in later releases of API Connect. For more information, see <https://ibm.biz/api-connect-config-sync>.

Requirements

For API Connect Config Sync to run successfully, the following requirements that must be satisfied:

- You are responsible for configuring the API Connect the target deployment to appropriately match the source deployment, so that replication of consumer-side data can take place:
 - The target API Connect deployment must be configured correctly including topology setup, provider organization creation, and catalog creation.
 - The APIs and Products in the source catalog must be replicated in the target catalog using either CI/CD or manual procedures.
 - The target catalog settings (including any spaces if they are enabled in the source catalog) must be configured to match the configuration of the source catalog. This includes compatible gateways and any extensions, user registries, and any other relevant catalog settings (such as lifecycle approvals, application lifecycle, and so on).
 - Compatible onboarding User Registries must be configured in the target catalog (the user registry name and type must match that of the corresponding source user registry, that is, the source and target catalog names must match if you are using the default user registry).
 - All OAuth providers must be configured on the target catalog and spaces.
 - All API User Registries must be configured on the target catalog and spaces.
 - All TLS client profiles must be configured on the target catalog and spaces.
- The Config Sync utility makes use of the API Connect Provider REST API, so you must have connectivity (into both the source and target clusters) with sufficient provider organization user permissions.
- The `metadata.source_id` key is reserved for use by Config Sync.
 - Because the underlying creation of resources in the target catalog uses the API Connect Provider REST API, the IDs and URLs associated with resources in the target catalog will be different from their corresponding resources in the source catalog (only the cluster-agnostic data of a resource is synchronized).
 - To track which resources in the source catalog map to which resources in the target catalog, Config Sync uses the `metadata` field of a particular resource. When a new resource is created in the target catalog, the `metadata` field of that resource is set to contain a key named `source_id` with a value equal to the ID of the corresponding resource in the source catalog that is being synchronized.
- API Connect Config Sync also uses the `name` field of some resources to determine a match. This is typically done for resources that are not synchronized by the utility but are needed in the target catalog for the synchronization to be successful; for example, User Registries, Consumer Org Groups, Roles, and published Products (the `name` and `version` fields are used for product matching).

Note: The first time API Connect Config Sync runs, it might take longer to complete than subsequent runs require (depending on the number of resources to synchronize). The first run of the utility creates all new resources in the target cluster; subsequent runs only perform synchronization of any data that was added, updated, or deleted since the last run of the utility.

Limitations

API Connect Config Sync has the following limitations:

- Config Sync does not back up data; it merely replicates the contents of a source catalog to a target catalog. You must still perform periodic backups to ensure the safety of your data.
- The target catalog is a read-only replica: only unidirectional synchronization of data from the source catalog to the target catalog is supported. Subsequent changes made in the target catalog cannot be synchronized back to the source.
- Source and target deployments operate independently of each other:
 - API rate limiting on Plans is counted independently in the source catalog and the target catalog.
 - OIDC tokens are not replicated. OIDC tokens generated in the source cluster are not valid within the target cluster.
 - Local User Registry (LUR) passwords are not replicated. Consumer organization members belonging to a Local User Registry (LUR) must reset their password in the target cluster.
 - Analytics data is tracked independently in the source cluster and the target cluster. Analytics data is not replicated or aggregated across clusters.
 - Developer portal configuration is not replicated. If you want to enable consumer organization access in the target catalog, you must replicate your Developer Portal site for consistency (restore the site with UUID/URL update where needed).
- Config Sync operates on a single source-target catalog pair at a time. If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.

Supported versions of API Connect

Config Sync can synchronize consumer-side resources across different versions of API Connect clusters. The target API Connect cluster version must always be greater or equal to the source API Connect cluster version. Table 1 shows the supported version combinations:

Table 1. Supported source and target version combinations of API Connect

Source version	Target Version	Release Stream
10.0.1.15	10.0.5+	Earlier LTS -> Current LTS

Source version	Target Version	Release Stream
10.0.5+	10.0.5+	Current LTS -> Current LTS
10.0.5+	10.0.7	Current LTS -> Current CD
10.0.7	10.0.7	Current CD -> Current CD

- [Downloading the API Connect Config Sync utility](#)
Download and extract the API Connect Config Sync utility from the Early Access Program site.
- [Setting environment variables for Config Sync](#)
Configure environment variables that can be used by the API Connect Config Sync utility.
- [Running Config Sync as a standalone binary](#)
The pre-built binaries allow you to run the API Connect Config Sync utility from a Mac, Windows, or Linux x86 platform.
- [Running Config Sync as a cronjob on OpenShift](#)
Running the apic-configsync utility as a cronjob on Red Hat OpenShift or IBM Cloud Pak for Integration enables the utility to be run on a timed basis, such as every 10 minutes.
- [Running Config Sync as a cronjob on Kubernetes](#)
Running the apic-configsync utility as a cronjob on Kubernetes enables the utility to be run on a timed basis, such as every 10 minutes.
- [Running Config Sync as a cronjob on VMware](#)
Running the apic-configsync utility as a cronjob on VMware enables the utility to be run on a timed basis, such as every 10 minutes.

Downloading the API Connect Config Sync utility

Download and extract the API Connect Config Sync utility from the Early Access Program site.

About this task

The apic-configsync.tar.gz file contains the following artifacts:

- A binaries directory with sub-directories containing the apic-configsync utility for each of the supported client platforms (Mac, Windows, and Linux x86).
- A helper_files directory containing YAML files for configuring cronjobs if you want to run the utility on a schedule.
- An ibm-apic-configsync-image.tar.gz file containing the Docker image for running the utility on a schedule in a Kubernetes cluster with a cronjob.

Procedure

1. Sign up to the API Connect Config Sync Early Access Program at the following location: <https://ibm.biz/api-connect-config-sync>.
2. Agree to the terms.
3. Download the apic-configsync.tar.gz file.
4. Extract the apic-configsync.tar.gz package by running the following command:

```
tar xf apic-configsync.tar.gz
```

Setting environment variables for Config Sync

Configure environment variables that can be used by the API Connect Config Sync utility.

API Connect Config Sync consumes a set of configuration properties required to connect to and perform REST calls against the source and target API Connect clusters. The configuration properties are passed to the utility with environment variables.

The following environment variables must be set to the appropriate values for the source and target API Connect cluster:

```
# Properties for source catalog
export SOURCE_MGMT_SERVER=https://yoursourcehostname.com/path
export SOURCE_ORG=sourceporg
export SOURCE_REALM=provider/default-idp-2
export SOURCE_ADMIN_USER=sourceadmin
export SOURCE_ADMIN_PASSWORD=sourceadminpassword
#export SOURCE_ADMIN_APIKEY=1010101010101010
export SOURCE_CATALOG=sourcecatalog
export SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=00000000-0000-0000-0000-000000000000
export SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=11111111-1111-1111-1111-111111111111

# Properties for target catalog
export TARGET_MGMT_SERVER=https://yourtargethostname.com/path
export TARGET_ORG=targetporg
export TARGET_REALM=provider/default-idp-2
export TARGET_ADMIN_USER=targetadmin
export TARGET_ADMIN_PASSWORD=targetadminpassword
#export TARGET_ADMIN_APIKEY=2020202020202020
export TARGET_CATALOG=targetcatalog
export TARGET_TOOLKIT_CREDENTIALS_CLIENTID=22222222-2222-2222-2222-222222222222
export TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=33333333-3333-3333-3333-333333333333
```

Download the Toolkit credentials file

A number of the required configuration properties can be obtained from the Toolkit credentials file that can be downloaded from the API manager UI for the API Connect cluster.

1. Log in to the API Manager UI.

2. From the Home page, select the Download Toolkit tile.
3. In "Step 2" of the Download dialog box, select Toolkit credentials - Download.
4. Open the resulting credentials.json file in a text editor so that you can locate and copy settings as explained in the next section.

Locating information for the environment variables

The following list explains how to obtain the setting for each of the environment variables.

* **_MGMT_SERVER**

This property specifies the hostname and path that provides access to the REST API endpoint for your catalog. Locate `toolkit.endpoint` property in the `toolkit.credentials.json` file, and set the `*_MGMT_SERVER` variable to the value of the `toolkit.endpoint` property. The value might look like the following example:

```
https://platform-api.hostname.com/api
```

* **_TOOLKIT_CREDENTIALS_CLIENTID**, * **_TOOLKIT_CREDENTIALS_CLIENTSECRET**

The toolkit credentials `clientId` and `clientSecret` are used to authenticate the utility to be able to make REST API calls against the API Connect cluster. Locate following properties in the toolkit `credentials.json` file, and set the environment variables as shown:

- Set the `*_TOOLKIT_CREDENTIALS_CLIENTID` variable to the value of the `toolkit.client_id` property
- Set the `*_TOOLKIT_CREDENTIALS_CLIENTSECRET` variable to the value of the `toolkit.client_secret` property

* **_ORG**

This is the short name of the provider organization in which your catalog is hosted. Set the `*_ORG` variable to the value of the provider organization's `Name` property. To locate the provider organization name, complete the following steps:

1. Log in to the API Manager.
2. From the Home tab, select Manage settings.
3. On the Settings page, click the Overview tab and locate the value of the `Name` property (not the `Title`).

* **_REALM**

This property specifies the identity provider realm of the API Manager registry for your instance of API Connect. Set the `*_REALM` variable to the value of the realm name. This parameter is not required in API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example, API Connect Enterprise as a Service on AWS). Instead, you authenticate using an API key (see `*_API_KEY` for details).

To obtain the realm name, run the following toolkit CLI command:

```
apic identity-providers:list --scope provider --server <mgmt_endpoint_url> --fields title,realm
```

where `<mgmt_endpoint_url>` is the API Manager URL with any segments (for example, `/manage`) removed from the end of the URL. If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in [Viewing platform and UI endpoints](#).

The following example shows a response listing the available realms for a deployment:

```
apic identity-providers:list --scope provider --server <mgmt_endpoint_url> --fields title,realm
```

```
total_results: 2
results:
- title: 'API Manager User Registry'
  realm: 'provider/default-idp-2'
- title: 'Common Services User Registry'
  realm: 'provider/common-services'
```

In the example, the realm for the API Manager registry is `provider/default-idp-2`.

For more information on obtaining the realm name, see [How to determine the identity provider](#).

* **_CATALOG**

This property indicates the name of the Catalog that you want to synchronize. Set the `*_CATALOG` variable to the value of the catalog's `Name` property. To locate the catalog name, complete the following steps:

1. Log in to the API Manager UI.
2. From the Home tab, select Manage catalogs.
3. Select the tile for the catalog you want to synchronize.
4. Click the Catalog settings tab.
5. On the Settings page, locate the value of the catalog's `Name` property (not the `Title`).

* **_ADMIN_USER**

This property is the name of the user account under which you will authenticate to the catalog. Set the `*_ADMIN_USER` variable to the value of the username that the utility will log in with to perform the synchronization task. This parameter is not required in API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example, API Connect Enterprise as a Service on AWS). Instead, you authenticate using an API key (see `*_API_KEY` for details).

In the source catalog, the user must be a Catalog Administrator or Organization Administrator with the ability to create consumer objects on behalf of the end users. In the target catalog, the user must have authorization to [Update the catalog settings](#) and enable or disable the `hash_client_secret` property.

To confirm the username, complete the following steps:

1. Log in to the API Manager UI with the user account you will use to synchronize the catalog.
2. Click the username in the page header.
3. Select My account.
4. Locate the value of the Username property.

* **_ADMIN_PASSWORD**

In most cases you will authenticate to the API Manager with the password associated to your username. Set the `*_ADMIN_PASSWORD` property to your password, being careful with any non-alphanumeric characters that may be in your password. This parameter is not required in API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example, API Connect Enterprise as a Service on AWS). Instead, you authenticate using an API key (see `*_API_KEY` for details).

Attention: If you set the `*_ADMIN_PASSWORD` variable, then skip the `*_ADMIN_APIKEY` variable. Do not set both variables when synchronizing a particular catalog.

* **_ADMIN_APIKEY**

In API Connect instances with single-sign-on (SSO) enabled on the API Manager user registry (for example API Connect Enterprise as a Service), you must authenticate using an API key instead of your password.

To locate your API key, complete the following steps:

1. Log in to the API Manager UI using your IBM ID.
2. In the page header, click  and select My API Keys.
3. On the My API Keys page, click Add.
4. Set a title and description for your new API key and click Create.
5. Copy the new API key from the dialog box.

Attention: If you set the `*_ADMIN_APIKEY` variable, then skip the `*_ADMIN_PASSWORD` variable. Do not set both variables when synchronizing a particular catalog.

Setting the environment variables

- Mac and Linux x86:

On Mac or Linux x86, you can either export the environment variables individually on the command line directly or create a script to export the environment variables and source that file from the command line, as in the following example:

```
# Properties for source catalog
export SOURCE_MGMT_SERVER=https://yoursourcehostname.com/path
export SOURCE_ORG=sourceorg
export SOURCE_REALM=provider/default-idp-2
export SOURCE_ADMIN_USER=sourceadmin
export SOURCE_ADMIN_PASSWORD=sourceadminpassword
#export SOURCE_ADMIN_APIKEY=1010101010101010
export SOURCE_CATALOG=sourcecatalog
export SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=00000000-0000-0000-0000-000000000000
export SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=11111111-1111-1111-1111-111111111111

# Properties for target catalog
export TARGET_MGMT_SERVER=https://yourtargethostname.com/path
export TARGET_ORG=targetorg
export TARGET_REALM=provider/default-idp-2
export TARGET_ADMIN_USER=targetadmin
export TARGET_ADMIN_PASSWORD=targetadminpassword
#export TARGET_ADMIN_APIKEY=2020202020202020
export TARGET_CATALOG=targetcatalog
export TARGET_TOOLKIT_CREDENTIALS_CLIENTID=22222222-2222-2222-2222-222222222222
export TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=33333333-3333-3333-3333-333333333333
```

In the example, notice that the command to set the `*_ADMIN_APIKEY` variable is commented out because the `*_ADMIN_PASSWORD` is used instead.

- Windows:

On Windows, you can set each environment variable individually by opening a command window and running the following command for each variable:

```
setx <variable_name> "<variable_value>"
```

where:

- `<variable_name>` is the name of the environment variable to set
- `<variable_value>` is the value to set for the specified variable name

Alternatively, you can create a batch file that uses the `setx` command to set the environment variables, as in the following example:

```
REM Properties for source catalog
setx SOURCE_MGMT_SERVER "https://yoursourcehostname.com/path"
setx SOURCE_ORG "sourceorg"
setx SOURCE_REALM "provider/default-idp-2"
setx SOURCE_ADMIN_USER "sourceadmin"
setx SOURCE_ADMIN_PASSWORD "sourceadminpassword"
REM setx SOURCE_ADMIN_APIKEY "1010101010101010"
setx SOURCE_CATALOG "sourcecatalog"
setx SOURCE_TOOLKIT_CREDENTIALS_CLIENTID "00000000-0000-0000-0000-000000000000"
setx SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET "11111111-1111-1111-1111-111111111111"

REM Properties for target catalog
setx TARGET_MGMT_SERVER "https://yourtargethostname.com/path"
setx TARGET_ORG "targetorg"
setx TARGET_REALM "provider/default-idp-2"
setx TARGET_ADMIN_USER "targetadmin"
setx TARGET_ADMIN_PASSWORD "targetadminpassword"
REM setx TARGET_ADMIN_APIKEY "2020202020202020"
setx TARGET_CATALOG "targetcatalog"
setx TARGET_TOOLKIT_CREDENTIALS_CLIENTID "22222222-2222-2222-2222-222222222222"
setx TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET "33333333-3333-3333-3333-333333333333"
```

In the example batch file, notice that the command to set the `*_ADMIN_APIKEY` variable is commented out because the `*_ADMIN_PASSWORD` is used instead.

Running Config Sync as a standalone binary

The pre-built binaries allow you to run the API Connect Config Sync utility from a Mac, Windows, or Linux x86 platform.

About this task

Running a standalone invocation of `apic-configsync` using one of the pre-built binaries is the most flexible option. For optimal performance, `apic-configsync` should run as close to the target cluster as possible.

Complete the following steps to configure environment variables and run the standalone binary.

Procedure

1. [Download and extract the API Connect Config Sync package.](#)
2. In the extracted package, navigate to the `/binaries/<platform>` directory that contains the appropriate version of the `apic-configsync` utility for your platform.
3. [Define the environment variables for the source and target catalogs.](#)
4. Run the utility with the following command:
 - Mac and Linux x86: `./apic-configsync`
 - Windows: `apic-configsync.exe`

Running Config Sync as a cronjob on OpenShift

Running the `apic-configsync` utility as a cronjob on Red Hat OpenShift or IBM Cloud Pak for Integration enables the utility to be run on a timed basis, such as every 10 minutes.

Before you begin

Ensure that the following prerequisites are satisfied before attempting to configure the cronjob:

- Ensure that you have a tool available for copying the image into your image registry. The examples in this topic use `skopeo` to copy the image to the target registry, but you could use equivalent `docker` or `podman` commands instead.
- Expose the OpenShift registry with `defaultRoute` by running the following command:

```
oc patch configs.imageregistry.operator.openshift.io/cluster --patch '{"spec":{"defaultRoute":true}}' --type=merge
```

For more information, see [Exposing the registry](#) in the OpenShift documentation. It is not necessary to perform step 5 (the "podman login" step) in the instructions.

- Set the `REGISTRY_HOST` environment variable to the OpenShift registry by running the following command:

```
REGISTRY_HOST=$(oc get route default-route -n openshift-image-registry --template='{{`{{ .spec.host }}`}}')
```

- Set the `APIC_PROJECT` environment variable to the namespace (project) where you intend to run the cronjob. For optimal performance, the cronjob should run within the same OpenShift environment as the target API Connect cluster.

About this task

You can configure the `apic-configsync` utility to run as a cronjob in an API Connect deployment running on OpenShift or Cloud Pak for Integration. The `apic-configsync` utility should run as close to the target cluster as possible, so the cronjob should be configured to run within the same OpenShift environment as the target API Connect cluster.

Procedure

1. [Download and extract the API Connect Config Sync package.](#)
2. Extract the Config Sync image from the extracted API Connect Config Sync package by running the following command:

```
tar xf ibm-apic-configsync-image.tar.gz
```

3. Copy the extracted Config Sync image to the target registry. For example, if you use `skopeo`, run the following command:

```
skopeo copy --dest-tls-verify=false --dest-registry-token=$(oc whoami -t) dir:./ibm-apic-configsync/ibm-apic-configsync-  
<version>/<tag> docker://$REGISTRY_HOST/$APIC_PROJECT/ibm-apic-configsync-<version>:<tag>
```

Replace `<version>` and `<tag>` with their actual values. To ensure that you use the most recent values, copy them from the README file located in the root of the extracted API Connect Config Sync package.

4. [Define the environment variables for the source and target catalogs.](#)
5. Create secrets to host configuration details for the source cluster and the target cluster.
 - a. Create a secret to host the configuration details for the source cluster in the namespace where you intend to run the cronjob:

```
oc create secret --namespace $APIC_PROJECT generic source-catalog-details \  
  --from-literal=SOURCE_MGMT_SERVER=$SOURCE_MGMT_SERVER \  
  --from-literal=SOURCE_ORG=$SOURCE_ORG \  
  --from-literal=SOURCE_REALM=$SOURCE_REALM \  
  --from-literal=SOURCE_ADMIN_USER=$SOURCE_ADMIN_USER \  
  --from-literal=SOURCE_ADMIN_PASSWORD=$SOURCE_ADMIN_PASSWORD \  
  --from-literal=SOURCE_CATALOG=$SOURCE_CATALOG \  
  --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTID \  
  --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET
```

- b. Create a secret to host the configuration details for the target cluster in the namespace where you intend to run the cronjob:

```
oc create secret --namespace $APIC_PROJECT generic target-catalog-details \  
  --from-literal=TARGET_MGMT_SERVER=$TARGET_MGMT_SERVER \  
  --from-literal=TARGET_ORG=$TARGET_ORG \  
  --from-literal=TARGET_REALM=$TARGET_REALM \  
  --from-literal=TARGET_ADMIN_USER=$TARGET_ADMIN_USER \  
  --from-literal=TARGET_ADMIN_PASSWORD=$TARGET_ADMIN_PASSWORD \  
  --from-literal=TARGET_CATALOG=$TARGET_CATALOG \  
  --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTID=$TARGET_TOOLKIT_CREDENTIALS_CLIENTID \  
  --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=$TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET
```

6. Create the cronjob:
 - a. Open the `helper_files/configsync-cronjob-ocp.yaml` file located in the extracted API Connect Config Sync package.
 - b. Modify the `schedule` property to specify how frequently the job will run.
The minimum recommended schedule period is 1 minute; however, a deployment with a large number of objects might require more time for the job to complete. Because concurrent jobs are not allowed, the total time between the start of two consecutive jobs might be longer.
 - c. Set the `concurrencyPolicy` to `Forbid`.
Config Sync operates on a single source-target catalog pair at a time. If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.
 - d. In the `image` property, replace the `<APIC_PROJECT>` variable with the namespace (project) where you will run the cronjob.
 - e. Create the cronjob resource in the cluster by running the following command:

```
oc --namespace $APIC_PROJECT apply -f helper_files/configsync-cronjob-ocp.yaml
```

Running Config Sync as a cronjob on Kubernetes

Running the `apic-configsync` utility as a cronjob on Kubernetes enables the utility to be run on a timed basis, such as every 10 minutes.

Before you begin

Ensure that the following prerequisites are satisfied before attempting to configure the cronjob:

- Ensure that you have a tool available for copying the image into your image registry.
The examples in this topic use `skopeo` to copy the image to the target registry, but you could use equivalent `docker` or `podman` commands instead.

About this task

You can configure the `apic-configsync` utility to run as a cronjob in an API Connect deployment running on Kubernetes. The `apic-configsync` utility should run as close to the target cluster as possible, so the cronjob should be configured to run within the same Kubernetes environment as the target API Connect cluster.

Procedure

1. [Download and extract the API Connect Config Sync package.](#)
2. Extract the Config Sync image from the extracted API Connect Config Sync package by running the following command:

```
tar xf ibm-apic-configsync-image.tar.gz
```

3. Copy the extracted Config Sync image to the target registry.
For example, if you use `skopeo`, run the following command:

```
skopeo copy dir:./ibm-apic-configsync/ibm-apic-configsync-<version>/<tag> docker://<registry>/ibm-apic-configsync/ibm-apic-configsync-<version>:<tag>
```

Replace `<version>` and `<tag>` with their actual values. To ensure that you use the most recent values, copy them from the README file located in the root of the extracted API Connect Config Sync package.

Replace `<registry>` with the actual registry value for your image registry. Refer to the `skopeo` documentation on configuring credentials for your destination registry.

4. [Define the environment variables for the source and target catalogs.](#)
5. Create secrets to host configuration details for the source cluster and the target cluster.
 - a. Create a secret to host the configuration details for the source cluster in the namespace where you intend to run the cronjob:

```
kubectl create secret --namespace <namespace> generic source-catalog-details \
  --from-literal=SOURCE_MGMT_SERVER=$SOURCE_MGMT_SERVER \
  --from-literal=SOURCE_ORG=$SOURCE_ORG \
  --from-literal=SOURCE_REALM=$SOURCE_REALM \
  --from-literal=SOURCE_ADMIN_USER=$SOURCE_ADMIN_USER \
  --from-literal=SOURCE_ADMIN_PASSWORD=$SOURCE_ADMIN_PASSWORD \
  --from-literal=SOURCE_CATALOG=$SOURCE_CATALOG \
  --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTID \
  --from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET
```

- b. Create a secret to host the configuration details for the target cluster in the namespace where you intend to run the cronjob:

```
kubectl create secret --namespace <namespace> generic target-catalog-details \
  --from-literal=TARGET_MGMT_SERVER=$TARGET_MGMT_SERVER \
  --from-literal=TARGET_ORG=$TARGET_ORG \
  --from-literal=TARGET_REALM=$TARGET_REALM \
  --from-literal=TARGET_ADMIN_USER=$TARGET_ADMIN_USER \
  --from-literal=TARGET_ADMIN_PASSWORD=$TARGET_ADMIN_PASSWORD \
  --from-literal=TARGET_CATALOG=$TARGET_CATALOG \
  --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTID=$TARGET_TOOLKIT_CREDENTIALS_CLIENTID \
  --from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=$TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET
```

6. Create the cronjob:
 - a. Open the `helper_files/configsync-cronjob-k8s.yaml` file located in the extracted API Connect Config Sync package.
 - b. Modify the `schedule` property to specify how frequently the job will run.
The minimum recommended schedule period is 1 minute; however, a deployment with a large number of objects might require more time for the job to complete. Because concurrent jobs are not allowed, the total time between the start of two consecutive jobs might be longer.

- c. Set the `concurrencyPolicy` to `Forbid`.

Config Sync operates on a single source-target catalog pair at a time. If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.

- d. In the `image` property, replace the `<registry>` variable with the actual registry value for your image registry.
- e. Create the cronjob resource in the cluster by running the following command:

```
kubectl --namespace <namespace> apply -f helper_files/configsync-cronjob-k8s.yaml
```

Running Config Sync as a cronjob on VMware

Running the `apic-configsync` utility as a cronjob on VMware enables the utility to be run on a timed basis, such as every 10 minutes.

About this task

You can configure the `apic-configsync` utility to run as a cronjob in an API Connect deployment running on VMware. The `apic-configsync` utility should run as close to the target cluster as possible, so the cronjob should be configured to run from the management subsystem virtual machines in the target API Connect cluster.

Ensure that your virtual machines have enough resources available (CPU/Memory) for the cronjob to run the `apic-configsync` utility.

Procedure

1. [Download and extract the API Connect Config Sync package.](#)
2. [Define the environment variables for the source and target catalogs.](#)

3. For each node in the management subsystem:

- a. In the extracted `apic-configsync.tar.gz` package, locate the `ibm-apic-configsync-image.tar.gz` file.
- b. Upload the `ibm-apic-configsync-image.tar.gz` file using the following command:

```
scp ibm-apic-configsync-image.tar.gz apicadm@<hostname>:~
```

where `<hostname>` is the hostname or IP address of the node.

- c. SSH into the node and become root with `sudo -i`.
- d. Switch into the registry directory with the following command:

```
cd /var/lib/apiconnect-subsystem/registry/
```

- e. Extract the image from the `tar.gz` file with the following command:

```
tar xf /home/apicadm/ibm-apic-configsync-image.tar.gz
```

Extracting the file creates the following directory:

```
/var/lib/apiconnect-subsystem/registry/ibm-apic-configsync/ibm-apic-configsync-<version>/<tag>
```

where `<version>` is the current version of the `apic-configsync` utility and `<tag>` is the tag of the built image.

- f. Restart the appliance-manager by running the following command:

```
systemctl restart appliance-manager
```

4. Create secrets to host configuration details for the source cluster and the target cluster.

- a. SSH into one of the nodes in the management subsystem and become root with `sudo -i`.
- b. Create a secret to host the configuration details for the source cluster in the namespace where you intend to run the cronjob:

```
kubectl create secret generic source-catalog-details \
--from-literal=SOURCE_MGMT_SERVER=$SOURCE_MGMT_SERVER \
--from-literal=SOURCE_ORG=$SOURCE_ORG \
--from-literal=SOURCE_REALM=$SOURCE_REALM \
--from-literal=SOURCE_ADMIN_USER=$SOURCE_ADMIN_USER \
--from-literal=SOURCE_ADMIN_PASSWORD=$SOURCE_ADMIN_PASSWORD \
--from-literal=SOURCE_CATALOG=$SOURCE_CATALOG \
--from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTID=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTID \
--from-literal=SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET=$SOURCE_TOOLKIT_CREDENTIALS_CLIENTSECRET
```

- c. Create a secret to host the configuration details for the target cluster in the namespace where you intend to run the cronjob:

```
kubectl create secret generic target-catalog-details \
--from-literal=TARGET_MGMT_SERVER=$TARGET_MGMT_SERVER \
--from-literal=TARGET_ORG=$TARGET_ORG \
--from-literal=TARGET_REALM=$TARGET_REALM \
--from-literal=TARGET_ADMIN_USER=$TARGET_ADMIN_USER \
--from-literal=TARGET_ADMIN_PASSWORD=$TARGET_ADMIN_PASSWORD \
--from-literal=TARGET_CATALOG=$TARGET_CATALOG \
--from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTID=$TARGET_TOOLKIT_CREDENTIALS_CLIENTID \
--from-literal=TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET=$TARGET_TOOLKIT_CREDENTIALS_CLIENTSECRET
```

5. Create the cronjob:

- a. Open the `helper_files/configsync-cronjob-ova.yaml` file located in the extracted API Connect Config Sync package.
- b. Modify the `schedule` property to specify how frequently the job will run.
The minimum recommended schedule period is 1 minute; however, a deployment with a large number of objects might require more time for the job to complete. Because concurrent jobs are not allowed, the total time between the start of two consecutive jobs might be longer.

- c. Set the `concurrencyPolicy` to `Forbid`.

Config Sync operates on a single source-target catalog pair at a time. If you want to sync multiple different source-target catalog pairs, create a separate cronjob for each pair.

- d. Upload the `helper_files/configsync-cronjob-ova.yaml` file to one of the management nodes.
To upload the file, run the following command:

```
scp helper_files/configsync-cronjob-ova.yaml apicadm@<hostname>:~
```

Replace `<hostname>` with the host name or IP of one of the nodes in the management subsystem.

- e. SSH into one of the nodes in the management subsystem and become root with `sudo -i`.
f. Create the cronjob resource in the cluster by running the following command:

```
kubectl apply -f /home/apicadm/configsync-cronjob-ova.yaml
```

The API Connect operations tool: apicops

Use the apicops operations tool to check the health, troubleshoot, and run maintenance operations on your API Connect installation.

The API Connect apicops tool is in active development and is available to download from github.com. It is available for Linux® and macOS. All suggestions, feedback, and bug reports can be raised in this repository.

Installing

Download the binary for your operating system from [latest release](#). Rename the file to `apicops`, and give it execute permission: `chmod +x apicops`.

Running apicops

Apicops requires access to your Kubernetes or OpenShift environment. For more information about using apicops, see: [Requirements for running apicops](#).

Configuring and managing your server environment

You configure and manage the servers that comprise your IBM® API Connect on-premises cloud by using the Cloud Manager user interface.

The Cloud Manager user interface is the part of IBM API Connect that enables a Cloud Administrator to define and manage the API Connect on-premises cloud.

You can use the Cloud Manager to define the API Connect cloud by performing the following tasks:

- Create Provider organizations and invite users to serve as the owner
- Create and manage user roles and role defaults
- Create availability zones for services
- Register the relevant servers that will provide the gateway, analytics, and portal services
- Associate an analytics service with a gateway to enable reports for API Events
- Configure resources for user authentication, TLS security, and OAuth providers and make the resources visible to all or selected provider organizations
- Connect to an existing SMTP mail server and edit templates for system-generated emails
- Set the default gateway service for catalogs
- [Cloud Manager configuration checklist](#)
A summary, with links, of the key initial configuration tasks that you must complete in the Cloud Manager user interface after installing and deploying IBM API Connect, and further supplementary tasks.
- [Activating your Cloud Manager user account](#)
If you have been invited to be an administrator of your API Connect cloud, you must activate your account by using the activation link that was sent by another administrator. You can then access the Cloud Manager user interface.
- [Accessing the Cloud Manager user interface](#)
How to navigate to and login to the Cloud Manager user interface.
- [Defining your Cloud Manager topology](#)
To define your API Connect on-premises cloud, you define availability zones and register services within those zones to securely create, promote, and track APIs. A Default Availability Zone is provided on installation.
- [Managing authentication and security](#)
Secure Cloud Manager and API Manager as well as your Catalogs with a user registry. Secure your APIs with OAuth. Create TLS profiles to ensure that information you share among web servers will not be stolen or tampered with.
- [Configuring the cloud settings](#)
Before you can add a provider organization to your cloud, you must specify your cloud settings to configure an email server for notifications as well as user registry options and catalog defaults.
- [Administering provider organizations](#)
Manage the provider organizations who have accounts to publish APIs in your API Connect cloud.
- [Administering members and roles](#)
Cloud Administrators can add members and assign them roles to enable them to work in Cloud Manager. The Cloud and Topology Administrators can also create roles and role defaults. You can also delete users to prevent them from accessing Cloud Manager.
- [Monitoring the cloud](#)
API Connect generates events to monitor the status of your cloud.
- [Changing your Cloud Manager password and profile information](#)
You can change your Cloud Manager password and update your profile information.
- [Resolving login problems by increasing HTTP header size](#)
You can resolve login problems for the Cloud Manager UI by increasing the maximum HTTP client header size.

- [Onboarding a new admin for Cloud Pak for Integration](#)
Use the API Connect toolkit CLI to create a new admin account for use with Cloud Pak for Integration.
- [Extending the Gateway server behavior](#)
To support your enterprise requirements, you can extend the Gateway servers within IBM API Connect to provide extra enforcement behavior.
- [Cloud Manager Tutorials](#)
Tutorials for using the Cloud Manager user interface in IBM API Connect.

Cloud Manager configuration checklist

A summary, with links, of the key initial configuration tasks that you must complete in the Cloud Manager user interface after installing and deploying IBM® API Connect, and further supplementary tasks.

Key initial tasks

Task	Description
Log in to the Cloud Manager user interface	A default admin user account is provided for you to begin your configuration tasks.
Configure an email server for notifications	The email server sends registration invitations and other event-driven emails. You must configure the email server before you add any provider organizations or register a Portal service.
Specify your email server as the notification server	Select the email server to be used as the notification server, and configure the sender name and email address to be included in the emails.
Register a Gateway service	A Gateway service represents a cluster of gateway servers that host published APIs and provide the API endpoints used by client applications. Gateways execute API proxy invocations to backend systems and enforce API policies including client identification, security and rate limiting.
Register an Analytics service	The Analytics service collects API event data from the Gateway service.
Associate the Analytics service with a Gateway service	You must associate an Analytics service with each of the Gateway services from which you want to collect API event data.
Register a Portal service	The Portal service provides a developer portal used by application developers to discover APIs and onboard consumers.
Create a provider organization	For developers to be able to publish APIs, and for API managers to be able to manage the API lifecycle, they must be a member of a provider organization. You must create a least one provider organization specifying the owner, who can add further members.

Further supplementary tasks

Task	Description
Configure authentication and security	API Connect provides default local user registries, but you can configure your own user registries, of various types, for user interface and API access control. You can also configure TLS profiles for securing data transmission over HTTPS, and OAuth providers for securing third-party website or application access to APIs.
Create an Availability Zone	An Availability Zone is a logical grouping of one or more API Connect services. A default Availability Zone is provided on installation, but you can add further Availability Zones to reflect your data center topology.
Administer members and roles	You can add further users as members of the administration organization, and control their permissions by assigning predefined roles. You can also create your own custom roles.
Monitor your API Connect cloud	API Connect generates events to allow you to monitor the status of your cloud.

Activating your Cloud Manager user account

If you have been invited to be an administrator of your API Connect cloud, you must activate your account by using the activation link that was sent by another administrator. You can then access the Cloud Manager user interface.

Before you begin

A cloud administrator invited you to join API Connect .

Procedure

1. Complete the following steps to activate your Cloud Manager account:

If the Identity Provider uses LDAP

An invitation email with an activation link is sent. Click the activation link, or paste it in a browser, to log in directly with your LDAP user credentials. Upon authentication, the API Connect user record is updated from the backend identity provider.

If the Identity Provider uses a local registry

An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your first name, last name and password. Passwords must have a minimum of 8 characters and contain characters from at least three of the four following categories:

- Uppercase letters
- Lowercase letters
- Numbers
- Special characters (for example: ! # \$ %)

Note:

- The email address that you enter on the sign up page must match the email address to which the invitation email was sent, otherwise the account activation fails.
- If you previously had an account that was removed, and you are being invited again, you must re-activate your account by using the Sign In option on the page, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail.

If the Identity Provider uses an authentication URL

An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your credentials, which then become your user name and password. Upon authentication, the API Connect user record is updated from the backend identity provider.

If multiple user registries are available for selection on the sign up page, then make sure that the correct registry for your Cloud Manager account is selected. You might need to ask your administrator which user registry is appropriate for your account.

For information on configuring user registries and making them available for Cloud Manager login, see [User registries overview](#) and [Selecting user registries for Cloud Manager and API Manager](#).

2. Click Sign up to complete your registration, then click Sign in to open the Cloud Manager login page.

Results

You have created your API Connect administrator account.

What to do next

Log in to the Cloud Manager user interface and, depending on your role, start to manage the cloud topology, and work with provider organizations and cloud resources. To access the Cloud Manager login page in the future, use the following URL:

```
https://host/admin
```

where *host* is the fully qualified host name or IP address of the Management server.

Related concepts

- [Administering members and roles](#)

Accessing the Cloud Manager user interface

How to navigate to and login to the Cloud Manager user interface.

Procedure

1. Open a browser and enter the URL for the cloud-admin-ui endpoint followed by /admin. Note that this is a secure connection that uses HTTPS, for example:

```
https://<cloud-admin-ui>/admin.
```

- VMware installations: The cloud-admin-ui endpoint was set during installation of the Management subsystem by the following command: `apicup subsys set mgmt cloud-admin-ui <endpoint>`. Append /admin to this value.
- Kubernetes, OpenShift, Cloud Pak for Integration installations: The cloud-admin-ui endpoint is specified in the Management subsystem CR, in the `Endpoints` section, for example:

```
Endpoints:  
...  
Name: admin  
Type: UI  
Uri: https://example.com/admin  
...
```

2. Enter the Cloud Administrator user name and password.

- Kubernetes, VMware, and OpenShift individual Management subsystem install:

If you are logging in for the first time, enter `admin` for the user name and `7iron-hide` for the password. Otherwise, enter `admin` for the user name and your own password.

- OpenShift top-level CR install:
The default user name is `admin`. If you are logging in for the first time, run the following commands to retrieve the initial password, which is generated automatically during deployment:

```
oc get secret -n <namespace> | grep mgmt-admin-pass
```

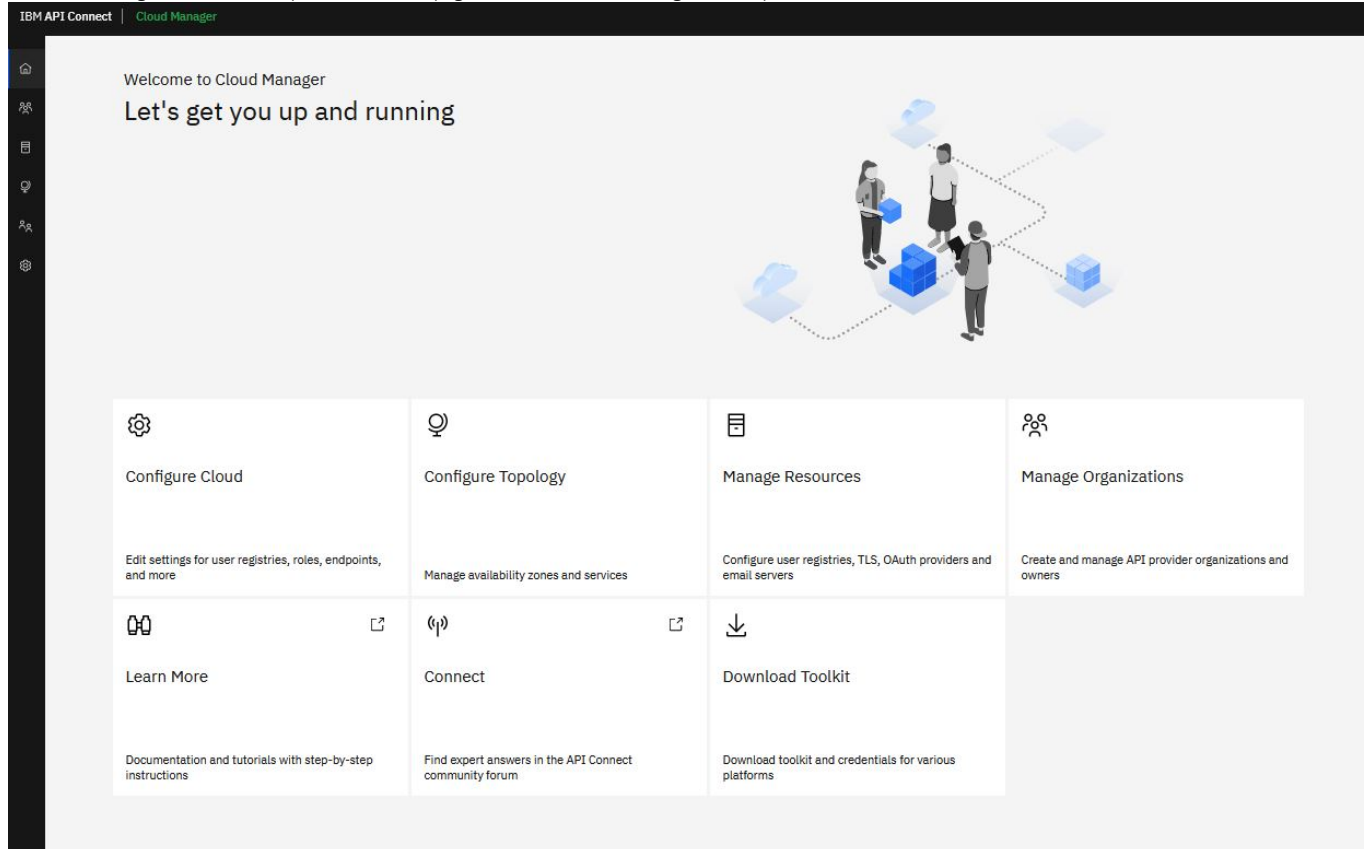

```
oc get secret -n <namespace> <secret_name_from_previous_command> -o jsonpath="{.data.password}" | base64 -d && echo ""
```

3. If your cloud contains multiple user registries, as configured on the Settings_>User Registries screen, then choose the user registry that contains your login credentials. You might need to ask your administrator which user registry is appropriate for your account.
4. Click Sign In.

Important: The first time that you access the cloud console, you must, for security reasons, enter a new password and your email address. If you forget your password and request a password reset, the notification email is sent to this email address. The email is sent by the email server that is configured in the **Notifications** section of the cloud **Settings**.

Results

The Cloud Manager user interface opens to the home page, as shown in the following screen capture:

What to do next

Configure the email server so you can reset your password if needed and send other notifications. See [Tutorial: Configuring the Cloud](#).

Configure your topology by registering services. See [Tutorial: Configuring the Cloud](#).

Create a Provider Organization. See [Tutorial: Creating a Provider Organization](#).

- [Changing your Cloud Manager password and profile information](#)

Defining your Cloud Manager topology

To define your API Connect on-premises cloud, you define availability zones and register services within those zones to securely create, promote, and track APIs. A Default Availability Zone is provided on installation.

About this task

The Cloud Manager topology consists of Availability Zones that contain the API Connect services. Availability Zones can contain one or more gateway services, analytics services, and portal services.

The following diagram illustrates the topology for services and Availability Zones in an API Connect network:

One of the following roles is required to register and manage services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

Following are the tasks involved in defining the API Connect topology:

- Create one or more Availability Zones.
- Register one or more Gateway, Analytics, and Portal services in each Availability Zone
- Associate an Analytics service with each Gateway service
- Set the visibility for the services

Once the cloud is defined and an email server has been configured, you invite other users to access API Manager to create APIs. You expose these APIs to the development community through the Developer Portal user interface.

To define the API Connect cloud, complete the following tasks:

- **Creating an availability zone**
An Availability Zone is a logical group of one or more API Connect services. The Default Availability Zone is created during installation.
- **Registering a gateway service**
A gateway service is required to handle incoming traffic for APIs.
- **Registering an analytics service**
Configure at least one analytics service in your API Connect on-premises cloud. The analytics service is always associated with a gateway service, from which it collects API event data.
- **Registering a portal service**
Define one or more Portal services in your API Connect on-premises cloud.
- **Associating an analytics service with a gateway service**
To collect data about your API usage and other statistics, you must associate an analytics service with each gateway service. You can associate multiple gateway services with one analytics service, but each gateway can be associated with only one analytics service.
- **Setting visibility for a service**
The visibility setting determines which provider organizations can access a service.

Related concepts

- [Configuring and managing your server environment](#)

Creating an availability zone

An Availability Zone is a logical group of one or more API Connect services. The Default Availability Zone is created during installation.

About this task

Availability zones allow you to logically group API Connect services to suit your environment. For example, you can group gateway services according to the region or data center they are located in.

The Default Availability Zone is created during the installation process.

When you create an availability zone, you should provide a descriptive title; a name is generated automatically for internal identification. For example:

Table 1. Example availability zones

Title	Name
US Availability Zone	us-availability-zone
Hampshire Availability Zone	hampshire-availability-zone
Newport Availability Zone	newport-availability-zone
London South Availability Zone	london-south-availability-zone

One of the following roles is required to add and manage Availability Zones:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

Procedure

Follow these steps to add one or more additional Availability Zones to your on-premises cloud:

1. In the Cloud Manager, click  Topology.
2. You will see the current Availability Zones configured in your cloud. The Default Availability Zone is created at installation. To add another Availability Zone, choose Create Availability Zone.
3. Enter the following values:

Field	Description
Title (required)	Enter a descriptive title for the availability zone. This title will display on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Summary (optional)	Enter a brief description.

4. Click Create to complete the operation.

Results

The availability zone will be added on the Topology page. You can now add gateway, analytics, and portal services to the availability zone.

Related tasks

- [Registering a gateway service](#)
- [Registering an analytics service](#)
- [Registering a portal service](#)

Registering a gateway service

A gateway service is required to handle incoming traffic for APIs.

Before you begin

Before registering a Gateway service in Cloud Manager, the DataPower® API Connect Gateway Service has to either be installed as a subsystem in your Kubernetes cluster or enabled on the DataPower appliance. For a Kubernetes environment, see [DataPower Gateway subsystem on Kubernetes](#). For appliances, see [Configuring the API Connect Gateway Service](#) in the appropriate version of the [DataPower documentation](#).

Note:

If you enabled Event Endpoint Management in Cloud Pak for Integration, an Event Gateway Service is provided for event endpoints. For more information about registering an Event Gateway Service, see the [Cloud Pak for Integration documentation](#).

About this task

A Gateway service represents a cluster of gateway servers that host published APIs and provide the API endpoints used by client applications. Gateways execute API proxy invocations to backend systems and enforce API policies including client identification, security and rate limiting.

One of the following roles is required to register and manage a gateway services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

Note: You can also register, and manage, gateway services by using the developer toolkit CLI; for details, see [apic gateway-services](#).

Procedure

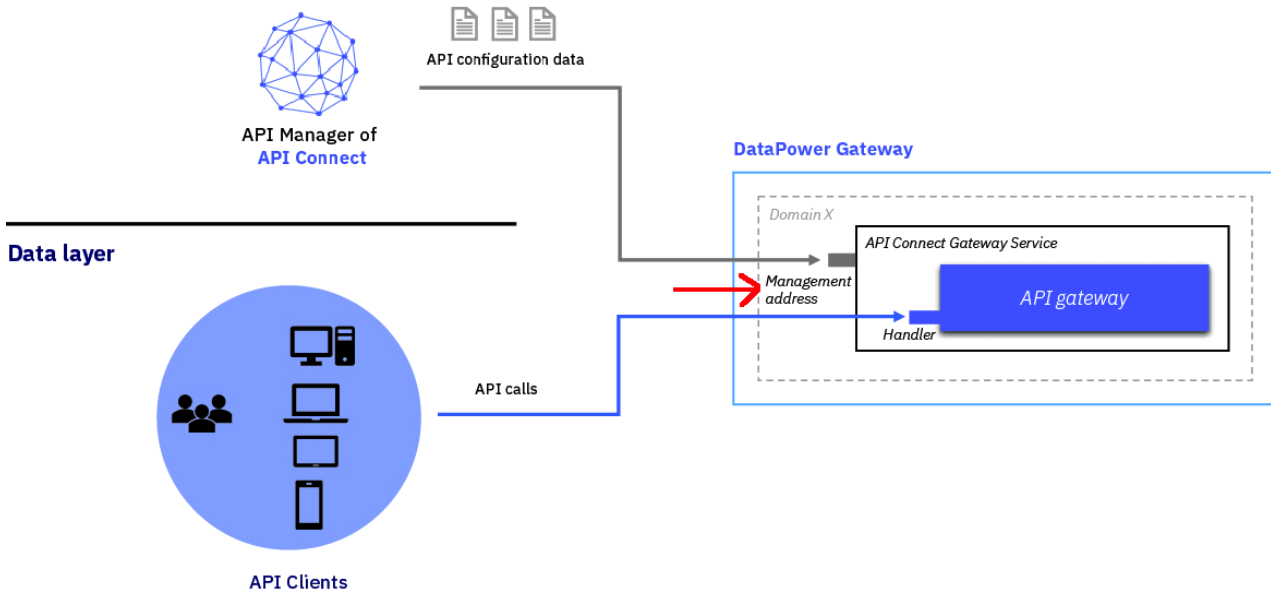

Complete the following steps to configure a Gateway service for your cloud:

1. In the Cloud Manager, click  Topology.
2. From the Availability Zone that will contain the Gateway service, select Register Service.
3. On the Configure Service page, select DataPower Gateway as the service type. Select the Gateway type that you want to create, either DataPower Gateway (v5 compatible) or DataPower API Gateway. For a description of the gateway types, see [API Connect gateway types](#)
4. Enter the values to configure the Gateway service. You will need to obtain the endpoints from your deployment configuration. For a Kubernetes environment, the endpoints are configured by the following values in the CR (custom resource) file. For an appliance, the endpoint is configured in DataPower.

Field	Description
Title (required)	Enter a descriptive title for the gateway service. This title will be displayed on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Summary (optional)	Enter a brief description.
Management endpoint on the gateway service: Endpoint (required)	<p>Enter the API Connect Gateway Service endpoint.</p> <ul style="list-style-type: none"> • For a Kubernetes environment, the Management Endpoint is the endpoint created in the CR (custom resource). See DataPower Gateway subsystem on Kubernetes for more information. • For an appliance, the Management Endpoint is the <i>Management address</i> to the API Connect Gateway Service shown in the gateway service connection diagram. For one gateway, this takes the form <code>http://<ip-address-for-gateway>:3000</code>. For multiple gateways, it would be the address:port of the load balancer • If you are using <code>in-cluster</code> communication, set this to the service endpoint URL for the gateway, which has the format: <pre>https://<name>.<namespace>.svc</pre> <p>where:</p> <ul style="list-style-type: none"> ◦ <code><name></code> is the <code>name</code> property from the gateway subsystem CR. If you are using the top-level CR this is <code><apic instance name>-gw</code> ◦ <code><namespace></code> is the namespace that the gateway CR exists in.
Management endpoint on the gateway service: TLS client profile (required)	<p>Specify the TLS Client profile to use when contacting the gateway through the management endpoint.</p> <p>Note:</p> <ul style="list-style-type: none"> • The default value is Gateway management client TLS client profile:1.0.0. If you are using a DataPower Gateway in a Kubernetes deployment, with mutual TLS enabled, use this setting. For any other gateway, if the gateway is not configured with the correct TLS credentials the gateway registration will fail with this setting. To prevent registration failure, select either Default TLS client profile:1.0.0 or your own custom TLS client profile. For information on configuring a custom TLS client profile, see Creating a TLS Client Profile. • TLS protocol version 1.3 is not supported.
Management endpoint on the gateway service: Use <code>in-cluster</code> communication switch	If you want to use <code>in-cluster</code> communication between the management and gateway subsystems, then enable this switch. For more information about this option, see In-cluster or external communication between subsystems . If you are not sure, then leave this switch disabled (the default).
Management endpoint on the gateway service: Use JWT for gateway authentication to analytics service. Available in v10.0.5.4 and later.	If you plan to associate an analytics service with this gateway, and you want to use JWT authentication between the gateway and analytics service, then enable this switch. If this switch is not enabled, then mutual TLS authentication is used between the gateway and analytics service. For more information about JWT security, see Enable JWT security instead of mTLS
API invocation endpoint: API endpoint base (required)	<p>Enter the base portion of the URL that maps to the base portion of the URL for incoming API traffic. It is a public FQDN with additional paths that are specific to your API calls. For example: https://api.mycompany.com</p> <p>Note: If you are using the DataPower API Gateway, HTTP/2 is enabled automatically on the API invocation endpoint. If you are using the DataPower Gateway (v5 compatible), HTTP/2 is not supported on the API invocation endpoint.</p>
API invocation endpoint: Server Name Indication (SNI) - Host name	<p>For supporting Server Name Indication (SNI) at the API Endpoint Base. The default hostname of <code>***</code> is required to allow all hosts. Enter other host names as needed. Wild card format is supported. The SNI capability enables you to serve multiple TLS secure host names through the same Gateway service, using the same IP address and port, without requiring them to use the same TLS profile.</p> <p>Note: To allow requests from clients that don't support SNI, you must include a host name value of <code>***</code>.</p>
API invocation endpoint: Server Name Indication (SNI) - TLS server profile	<p>The TLS server profile that supports the given hostname for SNI.</p> <p> Restriction: If you are using the DataPower API Gateway, HTTP/2 is enabled automatically on the API invocation endpoint. Therefore, using a TLS server profile that supports only TLS protocol version 1.3 is not supported and will result in the gateway being unable to receive API traffic. You must use a TLS server profile that includes TLS protocol version 1.2 as one of its supported protocols.</p> <p>This restriction does not apply if you are using the DataPower Gateway (v5 compatible), which does not support HTTP/2.</p>
OAuth shared secret (optional)	For sites using native OAuth providers, enter the shared secret that will be used by all API calls going through the gateway. Note: The specified shared secret must be 64 characters (64 bytes) in length, prefixed with <code>0x</code> , and must consist only of hexadecimal characters. For example: <code>0xa354282f227c10250511ae9c9e8c7ed9f4f1bd0d7c04cb6d5bd178f8c62296e3</code>

The following diagram illustrates the gateway service connection:

Management layer

5. When you are finished, click Save.

Results

The Gateway service is added to the appropriate Availability Zone for your cloud.

What to do next

Add additional gateway services. Add one or more analytics services. Add one or more portal services. Associate the gateway service with an analytics service. Set the visibility for the gateway.

Related tasks

- [Registering a portal service](#)
- [Registering an analytics service](#)
- [Associating an analytics service with a gateway service](#)
- [Setting visibility for a service](#)

Registering an analytics service

Configure at least one analytics service in your API Connect on-premises cloud. The analytics service is always associated with a gateway service, from which it collects API event data.

Before you begin

You must complete the following tasks:

- [Creating an availability zone](#)
- [Registering a gateway service](#)

About this task

The analytics service collects API event data from the gateway service. In Cloud Manager, you configure the analytics service and then associate it with one or more gateways. Multiple gateways can be associated with a single analytics service, but each gateway can be associated with only one analytics service.

One of the following roles is required to register and manage analytics services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

When you register the analytics service, you must select from one of three inter-subsystem communication methods. Before you decide which method to use, familiarize yourself with the difference between **external** and **in-cluster** communication: [In-cluster or external communication between subsystems](#). If you are an OVA user, or are in doubt as to what communication method to use, then use the default **external** setting.

The analytics subsystem has two separate communication flows:

- Management to analytics. The management service communicates with the analytics subsystem to query for analytics data to present in the UI dashboards. This flow is known as "analytics queries".
- Gateway to analytics. The gateway sends API event data to the analytics service. This flow is known as "analytics ingestion".

What you select depends on what is most suitable for your network configuration. The options are:

Use **external** communication for both ingestion and queries

This option is the default, and is what is used for analytics services that are upgraded from a pre-10.0.5.3 release. For OVA deployments, or if your analytics subsystem is in a different environment then **external** is the only option that you can use. Both the gateway and the management service communicate with the analytics service by using the external endpoint, which is a Kubernetes **ingress** or OpenShift **route** depending on your platform.

Use **in-cluster** communication for both ingestion and queries

You can select **in-cluster** if you have a Kubernetes or OpenShift deployment where all subsystems are within the same cluster. When this option is selected, the management, gateway, and analytics subsystems communicate with each other through internal service endpoints rather than externally accessible **ingresses** (Kubernetes) or **routes** (OpenShift).

Use **in-cluster** for ingestion and **external** for queries, or vice versa

You can select this option if you have a Kubernetes or OpenShift deployment and you have some of your subsystems installed in the same cluster. When this option is selected, you can use different communication methods for the different analytics communication flows. For example, the management to analytics communication can use **in-cluster**, and the gateway to analytics can use **external**. You might choose this configuration if your gateway is in a different cluster to the rest of your subsystems.

Procedure

Complete the following steps to configure the analytics services for your cloud:

1. In the Cloud Manager, click  Topology.
2. Select Register Services > Analytics in the Availability Zone where you have the gateways you want to associate with the analytics service.
3. Enter the values to configure the analytics service:

Field	Description																								
Title	Enter a descriptive title for the analytics service.																								
Name	This field is auto-populated by the system and used as the internal field name.																								
Summary	Enter a brief description.																								
Service endpoint configuration: Communication method.	Select your communication method, for more information on the options see, Communication types . If your API Connect deployment is OVA then you must select the first option: Use external communication for both ingestion and queries.																								
Service endpoint configuration: External analytics endpoint.	<p>Enter the fully qualified domain name for the analytics ingestion endpoint that you defined during installation. To determine the endpoint, run the following command:</p> <ul style="list-style-type: none"> • Kubernetes <pre>kubectl get ingress -n <namespace></pre> <p>The endpoint has -ai- in its name:</p> <table border="1"> <thead> <tr> <th>NAME</th> <th>CLASS</th> <th>HOSTS</th> <th>ADDRESS</th> <th>PORTS</th> <th>AGE</th> </tr> </thead> <tbody> <tr> <td>def-analytics-ai-endpoint</td> <td>nginx</td> <td>a7s-in.example.com</td> <td></td> <td>80, 443</td> <td>87d</td> </tr> </tbody> </table> • OpenShift <pre>oc get routes -n <namespace></pre> <p>The endpoint has -ai- in its name:</p> <table border="1"> <thead> <tr> <th>NAME</th> <th>CLASS</th> <th>HOSTS</th> <th>ADDRESS</th> <th>PORTS</th> <th>AGE</th> </tr> </thead> <tbody> <tr> <td>def-analytics-ai-endpoint</td> <td>nginx</td> <td>a7s-in.example.com</td> <td></td> <td>80, 443</td> <td>87d</td> </tr> </tbody> </table> • VMware <pre>apicup subsys get <analytics subsystem></pre> <p>The endpoint is the value of property analytics-ingestion.</p> <p>This field is disabled if "Use in-cluster communication for both ingestion and queries" is set as the communication type.</p>	NAME	CLASS	HOSTS	ADDRESS	PORTS	AGE	def-analytics-ai-endpoint	nginx	a7s-in.example.com		80, 443	87d	NAME	CLASS	HOSTS	ADDRESS	PORTS	AGE	def-analytics-ai-endpoint	nginx	a7s-in.example.com		80, 443	87d
NAME	CLASS	HOSTS	ADDRESS	PORTS	AGE																				
def-analytics-ai-endpoint	nginx	a7s-in.example.com		80, 443	87d																				
NAME	CLASS	HOSTS	ADDRESS	PORTS	AGE																				
def-analytics-ai-endpoint	nginx	a7s-in.example.com		80, 443	87d																				
Service endpoint configuration: TLS client profile for external analytics endpoint.	Select the TLS Client Profile to use for management to analytics subsystem communication. The Client Profile applies to the endpoint that you specified in the previous row. The default is "Analytics Ingestion TLS client profile". This field is disabled if "Use in-cluster communication for both ingestion and queries" is set as the communication type.																								
Service endpoint configuration: In-cluster analytics endpoint.	<p>Enter the fully qualified domain name for the analytics ingestion service endpoint. The format of the service endpoint is</p> <pre>https://<name>.<namespace>.svc</pre> <p>where:</p> <ul style="list-style-type: none"> • <name> is the name property from the analytics subsystem CR. If you are using the top-level CR this is <apic instance name>-a7s. • <namespace> is the namespace that the analytics CR exists in. <p>This field is disabled if Use external communication for both ingestion and queries is set as the communication type.</p>																								

Field	Description
Service endpoint configuration: TLS client profile for in-cluster endpoint.	Select the TLS Client Profile to use for management to analytics subsystem communication. The Client Profile applies to the Endpoint that you specified in the previous row. The default is "Analytics Ingestion TLS client profile". This field is disabled if Use external communication for both ingestion and queries is set as the communication type.
Service endpoint configuration: Use in-cluster endpoint for analytics queries.	If you want the management subsystem to use the in-cluster service endpoint to communicate with the analytics subsystem, then select this option. If this option is not selected, then the management subsystem uses the external endpoint. Selection of external or in-cluster communication between the gateway and analytics subsystem is done when the gateway is associated with the analytics service, see Associating an analytics service with a gateway service . This setting is enabled when "Use in-cluster for ingestion and external for queries, or vice versa" is selected.

4. Click Save to complete the operation.

Results

The analytics service is added to your cloud settings.

What to do next

- Set preferred retention and rollovers settings for the new analytics service: [Configuring data retention and index rollover time periods](#).
- Associate the analytics service with one or more gateway services. For more information, see [Associating an analytics service with a gateway service](#).

Related tasks

- [Registering a gateway service](#)
- [Registering a portal service](#)

Registering a portal service

Define one or more Portal services in your API Connect on-premises cloud.

Before you begin

You must complete the following tasks:

- [Creating an availability zone](#)
- [Registering a gateway service](#)
- [Configuring an email server for notifications](#)
- [Setting up notifications](#)

Note:

When you create or register a Developer Portal service, the Portal subsystem checks that the Portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the `portal-www` pod, admin container logs, if the endpoint cannot be reached:

```
An error occurred contacting the provided portal web endpoint: example.com
The provided Portal web endpoint example.com returned HTTP status code 504
```

In this instance, you can disable the Portal web endpoint check so that the Developer Portal service can be created successfully. To disable the endpoint check, complete one of the following updates depending on your platform:

On Kubernetes, OpenShift, and IBM® Cloud Pak for Integration
Add the following section to the Portal custom resource (CR) template:

```
spec:
  template:
    - containers:
      - env:
        - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
          value: "true"
        name: admin
      name: www
```

On VMware

In your `apicup` project, create a file called `ptl-extra-values.yaml` (or edit the file if one already exists), and add the following section:

```
spec:
  template:
    - containers:
      - env:
        - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
          value: "true"
        name: admin
      name: www
```

Run the following commands:

```
apicup subsys set <ptl_subsys> extra-values-file <path-to-ptl-extra-values-yaml-file>
apicup subsys install <ptl_subsys>
```

About this task

Each Availability Zone contains one or more Portal services. The Portal service provides a Developer Portal used by application developers to discover APIs and onboard consumers. An email server must be configured and set as the email server for the cloud before registering a Portal service. One of the following roles is required to register and manage Portal services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

Important: It's not recommended to have more than 100 sites per Developer Portal service. Note that it's not necessary to have a Portal site for every Catalog, for example Catalogs that are only for API Developers don't need a Portal site, as the APIs can be tested by using credentials from the API Manager. If more than 100 sites are required, you should configure additional Developer Portal services.

Procedure

Complete the following steps to configure the Portal services for your cloud:

1. In the Cloud Manager, click  Topology.
2. In the Availability Zone that will contain the Portal service, select Register Services > Portal.
3. Enter the values to configure the Portal service.

Field	Description
Title (required)	Enter a descriptive title for the portal service. This title will display on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Summary (optional)	Enter a brief description.
Management endpoint on the portal service: Endpoint (required)	Enter the IP address, fully-qualified host name, service, or ingress name. Used for communication with API Manager. <ul style="list-style-type: none">• In a Kubernetes deployment, the endpoint is defined in the CR by <code>api.portal.\$STACK_HOST</code>. See Developer Portal subsystem on Kubernetes.• If configured during installation in a VMware environment, it is the <code>apicup subsys set portal portal-admin</code> value.• If you are using <code>in-cluster</code> communication, set this to the service endpoint URL for the portal, which has the format: <pre>https://<name>.<namespace>.svc</pre>where:<ul style="list-style-type: none">◦ <code><name></code> is the <code>name</code> property from the portal subsystem CR. If you are using the top-level CR this is <code><apic instance name>-ptl</code>◦ <code><namespace></code> is the namespace that the portal CR exists in.
Management endpoint on the portal service: TLS client profile (optional)	Select the TLS Client Profile that will be used to communicate with the portal service. The profile applies to the Management Endpoint. Note: TLS protocol version 1.3 is not supported.
Management endpoint on the portal service: Use <code>in-cluster</code> communication switch	If you want to use <code>in-cluster</code> communication between the management and portal subsystems, then enable this switch. For more information about this option, see In-cluster or external communication between subsystems . If you are not sure, then leave this switch disabled (the default).
Portal website URL (required)	The URL that will be used for public access to the portal. <ul style="list-style-type: none">• In a Kubernetes deployment, the endpoint is defined in the CR by <code>portal.\$STACK_HOST</code>. See Developer Portal subsystem on Kubernetes.• If configured during installation in a VMware environment, it is the <code>apicup subsys set portal portal-www <portal>.<hostname>.<domainname></code> value. Multiple <code>portal-www</code> endpoints may be configured, as described here in these topics: Defining multiple portal endpoints for a Kubernetes environment and Defining multiple portal endpoints for a VMware environment .

4. When you are finished, click Save.

Results

The Portal service is configured in your cloud and can be used to publish APIs.

Associating an analytics service with a gateway service

To collect data about your API usage and other statistics, you must associate an analytics service with each gateway service. You can associate multiple gateway services with one analytics service, but each gateway can be associated with only one analytics service.

About this task

The associated analytics service receives API event data from the gateway service.

To associate an analytics service with a gateway, you must first configure at least one analytics service and one gateway service.

One of the following roles is required to associate an analytics service with a gateway service:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

Follow these steps to associate an analytics service with a gateway service:

Procedure

1. In the Cloud Manager, click  Topology.
2. In the section for the Availability Zone you want to work on, locate the gateway service that requires an analytics service in the SERVICE column.
3. Locate the ASSOCIATED ANALYTICS SERVICE column.
4. If an analytics service is configured, the Associate Analytics service link is enabled for each gateway service. Click Associate Analytics Service in the same row as the gateway service that requires an analytics service.
5. In Associate Analytics Service, you see the name of the gateway service and a list of analytics services that have been configured in your cloud.
6. Select the analytics service to associate with the gateway service by adding a checkmark next to the analytics services.
7. If you specified **in-cluster** communication when you registered the analytics service, you can enable the gateway to send API event data to the internal analytics endpoint. Enable the "Use internal endpoint for ingestion of analytics data from the gateway service" switch. For more information about **in-cluster** communication, see [Communication types](#).
8. Click Associate.
9. To remove the associated analytics service, select Unassociate analytics service from the actions menu. The gateway stops sending API event data to the analytics service.

Results

The analytics service is associated with a gateway service and starts to receive API event data from that gateway.

Setting visibility for a service

The visibility setting determines which provider organizations can access a service.

Before you begin

You must complete the following tasks:

- Create additional availability zones if needed, see [Creating an availability zone](#)
- Register at least one gateway service, see [Registering a gateway service](#)
- Register other services.

About this task

The visibility setting controls which provider organizations can use a service. The default visibility setting is Public.

One of the following roles is required to set the visibility for services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **Topology:Manage** permission

Procedure

Follow these steps to set the visibility for the services in your on-premises cloud:

1. In the Cloud Manager, click  Topology.
2. From the list of Services, choose Set visibility from the actions menu next to the name of the service that requires the visibility setting.
3. Select the visibility setting for the service. The options are:
 - Private - the service is not visible and cannot be used by any provider organization

- Public - the service is visible and can be used by all provider organizations
 - Custom - the service is visible only to the provider organizations designated by you
4. For Custom visibility, select the provider organizations that will be able to use the service.
 5. Click Make visible to complete the operation.

Results

For Private, the service cannot be used by any provider organizations. For Public, the service can be used by all provider organizations. For Custom, the service can be used by the provider organizations that you designate.

Managing authentication and security

Secure Cloud Manager and API Manager as well as your Catalogs with a user registry. Secure your APIs with OAuth. Create TLS profiles to ensure that information you share among web servers will not be stolen or tampered with.

As Cloud Administrator or Topology Administrator (or with a custom role that contains the `Settings:Manage` permission), you can configure the following authentication and security mechanisms:

- User registries to authenticate users of Cloud Manager and API Manager and of your Catalogs and APIs.
- OAuth providers to provide protection for APIs.
- TLS profiles to secure transmission of data through the Gateway to external web sites and among web servers.

The following topics describe how to configure user registries, OAuth providers, and TLS profiles:

- [User registries overview](#)
API Connect supports several types of user registries for authenticating users. The credentials for all users of Cloud Manager, API Manager, and the Developer Portal must be stored in a user registry.
- [TLS profiles overview](#)
API Connect supports TLS Profiles for securing data transmission over HTTPS.
- [OAuth Provider overview](#)
API Connect supports OAuth Specification 2.0, for both Native and Third party implementations.

User registries overview

API Connect supports several types of user registries for authenticating users. The credentials for all users of Cloud Manager, API Manager, and the Developer Portal must be stored in a user registry.

Introduction to user registries

A user registry holds unique user account credentials, primarily usernames and passwords, which are accessed during authentication for logging into Cloud Manager, API Manager, the Developer Portal, and also for calling APIs (if the API is configured to use Basic Authentication in the Security Definition). The Cloud Administrator configures user registries to ensure that all users are successful at logging in.

User registries also provide security when calling APIs. For information on configuring Security Definitions for APIs, see [Creating a basic authentication security definition](#).

User registries are configured as Resources. Once the user registry has been configured as a resource in Resources, the next step is indicate the active user registries for your cloud in Settings, User registries. The user registry must be made active in your cloud in order to make it available for authentication. When a user logs into Cloud Manager or API Manager, the specified user registry is queried for credentials to confirm the user's identity. To make a user registry available to the Developer Portal, you must define the registry for consumer onboarding in the associated Catalog. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Settings, Onboarding; for more information see [Creating and configuring Catalogs](#).

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access. In Cloud Manager and API Manager, a registry cannot be changed after a user is invited to be the owner of a provider organization, even if the invitation is not yet accepted.

User registries in API Connect serve the following primary functions:

- To authenticate a user at login time based upon username and password.
- To store basic profile information such as first name, last name, and email address.
- To provide secure access to Catalogs.
- To provide Basic Authentication for APIs when called by an application.

In order to log in to Cloud Manager, API Manager, the Developer Portal, or access a catalog, a user must have valid credentials (username and password) stored in a user registry that is configured in API Connect.

The Security Definition for an API can be configured to require a username and password, called the Basic Authentication method. With Basic Authentication, the username and password are included in the HTTP authorization header, and the credentials are verified through user registry.

User registries that are configured in Cloud Manager have the following characteristics:

- They are available to Cloud Manager, API Manager, the Developer Portal, and for Basic Authentication for APIs.
- They are available to provider organizations, as determined by the visibility setting.
- They can be edited and deleted only in Cloud Manager.

User registries that are configured in API Manager have the following characteristics:

- They are available to the Developer Portal (for Catalogs) and for Basic Authentication for APIs.
- They are available only to the Provider Organization that created them.

User registries supported by API Connect

API Connect integrates with several types of user registries to accommodate all security solutions. You can use your corporate LDAP registry, an Authentication URL, or an LUR to provide secure access to Cloud Manager, API Manager, the Developer Portal, and APIs. API Connect includes two internal databases that serve as local user registries, or LURs. The Providers LUR supports credentials for Provider organizations and the Admin LUR supports credentials for the Administrator organization. Multiple registries may be configured.

The following user registry types can serve as a resource in API Connect:

- Local user registry (LUR) - An internal database of usernames and passwords stored on the local server. Contains the Admin user account which may not be modified or deleted.
- LDAP - A user registry definition that points to an existing corporate LDAP directory. May be set up as case-sensitive.
- Authentication URL - Accesses a URL that points to a service for validating user credentials.
- OpenID Connect (OIDC).
- [Configuring an Authentication URL user registry](#)
An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.
- [Configuring a shared custom user registry](#)
You can configure a custom user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal.
- [Configuring an LDAP user registry in the Cloud Manager](#)
You can use the Cloud Manager UI to configure an LDAP user registry as a shared resource to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.
- [Configuring a Local User Registry](#)
A Local User Registry (LUR) can be configured to provide user authentication for both Cloud Manager and API Manager.
- [Configuring an OIDC user registry in Cloud Manager](#)
Configure a shared OIDC user registry for user onboarding and authentication when multi-factor authentication (MFA) is required.
- [Setting visibility for a user registry](#)
The visibility setting determines which provider organizations can access a resource, for example, user registries.
- [Deleting a user registry](#)
As the Cloud Manager administrator, you can delete user registries.
- [Removing a user from a user registry](#)
As an API Connect user, you can remove yourself from an API Connect user registry. As an administrative user, you can remove other users from an API Connect user registry.

Related tasks

- [Configuring an Authentication URL user registry](#)
- [Configuring a Local User Registry](#)
- [Configuring an LDAP user registry in the Cloud Manager](#)
- [Setting visibility for a user registry](#)

Configuring an Authentication URL user registry

An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.

About this task

This topic describes how to configure a new Authentication URL user registry as a Resource in your cloud. After the user registry is configured, you must select it for use in your cloud in Settings > User Registries. See [Selecting user registries for Cloud Manager and API Manager](#).

One of the following roles is required to configure user registries.:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note:

API Connect issues an HTTP `GET` call to the Authentication URL endpoint, sending the user's credential. The following example shows a call made to an Authentication URL identity provider with an endpoint defined as `https://myauthurl.example.com/user/authenticate`:

```
GET /user/authenticate HTTP/1.1
Host: myauthurl.example.com
Authorization: Basic c3Bvb246Zm9yaw=
```

If the Authentication URL endpoint returns an HTTP status code of `200`, the user authenticates successfully. An HTTP status code other than `200` indicates a failed login attempt. API Connect forwards any HTTP Header starting with `x-` (with the exception of `x-Client-Certificate`), and Cookie to the Authentication URL identity

provider, to aid the authentication decision; for example:

```
GET /user/authenticate HTTP/1.1
Host: myauthurl.example.com
Authorization: Basic c3Bvb246Zm9yaw=
X-Forwarded-For: 8.8.9.9
X-Custom-Header-From-Customer: special
Cookie: MyCookie=VGhpc0lzV21ja2VkQW1hemluZw==
```

When a user is presented with the form for completing their API Connect user registration, which fields are prepopulated depends on which fields are returned in the response from the Authentication URL identity provider. If any of the following fields are returned, they will be prepopulated in the registration form:

- `username`
- `email`
- `first_name`
- `last_name`

If the `username` field is not returned, the registration form displays the user name that was provided by the user. The pre-population capability requires that the response from the Authentication URL identity provider satisfies the following conditions:

- The `Content-Type` must be `application/json`.
- The response body format must be JSON.

A sample response is as follows:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache
```

```
{
  "username": "myuser",
  "email": "myuser@example.com",
  "first_name": "My",
  "last_name": "User"
}
```

Procedure

1. In the Cloud Manager, click .
2. Select User Registries to see the list of current user registries in your cloud.
3. Click Create in the User Registries section.

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

4. Select Authentication URL User Registry and enter the following parameters:

Field	Description
Title (required)	Enter a descriptive name to use on the screen.
Name (required)	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see apic user-registries .
Summary (optional)	Enter a brief description.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface , Accessing the API Manager user interface , and Activating your API Manager user account . Note: The Developer Portal uses the Title of the User Registries when rendering them at the login page, rather than the Display Name .
URL (required)	Enter the URL for the authentication service. When establishing authentication, API Connect makes a GET call to the URL. The call includes the user name and password it has collected from the user in its authorization header. Either 200 OK or 401 Unauthorized will be returned.
TLS Client Profile (optional)	Select a TLS Client Profile to allow secure authentication with a specific web server.
Case sensitive	To ensure proper handling of user name capitalization, you must ensure that your case-sensitivity setting here matches the setting on your backend Authentication URL server: <ul style="list-style-type: none">• Only select Case sensitive if your backend server supports case-sensitivity.• Do not select Case sensitive if your backend server does not support case-sensitivity. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

5. Click Save.

Results

The Authentication URL user registry is saved and is available to be selected as a user registry for Cloud Manager or API Manager by selecting it in Settings > User Registries. It can also be used for Basic Authentication in the Security Definition for an API.

Related concepts

Configuring a shared custom user registry

You can configure a custom user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal.

Before you begin

To configure a custom user registry as a resource in the Cloud Manager, the external user directory must be created and available to use with your API Connect ecosystem.

Custom user registries can be used for authenticating users to the Cloud Manager, the API Manager, and the Developer Portal, but cannot be used to secure APIs.

One of the following roles is required to configure a custom user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

About this task

You can create a custom user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific custom user registry can be used for authenticating Developer Portal users, while a shared custom user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure a shared custom user registry. If you want to create an organization-specific registry, see [Creating an organization-specific custom user registry](#) for more information. Note also that the visibility of a user registry is set to **shared** by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see [Setting visibility for a user registry](#).

Note:

- You can also create custom user registries by using the API Connect REST APIs (see the [API Connect REST API documentation](#)).

You can use the following instructions to create a writable or a read-only custom user registry.

API Connect provides two methods for creating a shared custom user registry in the Cloud Manager, as described in the following sections:

- [Creating a shared custom user registry by using the Cloud Manager UI](#)
- [Creating a shared custom user registry by using the developer toolkit CLI](#)

Creating a shared custom user registry by using the Cloud Manager UI

You configure a custom user registry by first creating a custom user registry type that defines your external user registry, and then creating a new custom user registry resource that references the custom user registry type that you just created. To make the registry available for user authentication, you need to add the registry to the Cloud Manager, or to the API Manager, or both, depending on your requirements. When the custom user registry is used for authentication, API Connect makes a REST call to the endpoint of your external registry, as defined in the custom user registry type.

Creating a custom user registry type

Use the following instructions to create a custom user registry type that defines your external user registry.

1. In the Cloud Manager, click  Resources.
2. Click Create in the User registry type section.
3. Enter the following information:

Property	Description
Title	A descriptive name of the custom user registry type to display in the UI. For example, <i>My custom user registry type</i> .
Name	The name of the user registry type. This name is auto-generated, and is used in CLI commands.
Version	The version number of the custom user registry type.
Summary	A brief description of the custom user registry type.
Properties	Enter the properties of your external user registry. Must include the property: <code>remote: true</code> This property must be set to <code>true</code> to indicate that this is an external user registry.

Property	Description
Secured Endpoint	Denotes the external registry secured endpoint section of the custom user registry type.
URL	The secure endpoint of your external user registry interface, where your platform REST API is located. It is made up of the URL and port, for example: <code>https://custom.ms.com:8888</code> API Connect will make REST calls to this endpoint for the user registry actions.
TLS Client Profile	Optionally set the TLS Client Profile URL that the custom server requires.
Headers	Optionally complete the user-defined header section to your external registry specification.
Configuration schema	Optionally complete the user-defined configuration schema section to your external registry specification.

- Click Create. A new user registry with a Type of Custom is displayed in the User registry type list.

Creating a custom user registry resource

Use the following instructions to create a new custom user registry resource that references the custom user registry type that you just created.

- Click Create in the User Registries section of Resources.
- Click the Custom user registry tile.
- Enter the following information:

Property	Description
Custom type	The name of the custom user registry type that you just created. For example, <i>my-custom-user-registry-type</i> . Use the drop-down arrow to select different custom user registry types.
Title	A descriptive name to display in the UI.
Name	The name of the custom user registry. This name is auto-generated, and is used in CLI commands.
Summary	A brief description of the custom user registry.
Endpoint	Optional endpoint information.
Case sensitive	To ensure proper handling of user name capitalization, you must ensure that your case-sensitivity setting here matches the setting on your backend server: <ul style="list-style-type: none"> Only select Case sensitive if your backend server supports case-sensitivity. Do not select Case sensitive if your backend server does not support case-sensitivity. Note: <ul style="list-style-type: none"> The Developer Portal does not support case sensitive usernames. After at least one user has been onboarded into the registry, you cannot change this setting.
User registry managed	Determines whether API Connect manages your user registry. Valid values are: <ul style="list-style-type: none"> true - select the checkbox false - clear the checkbox
User managed	Determines whether your user registry is writable or not. Select the checkbox to set to true for writable. Clear the checkbox for the non-writable option.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

- Click Create. The new user registry is displayed in the User registries list.

Adding your custom user registry to the Cloud Manager or API Manager login

To make the custom user registry available for user authentication in the Cloud Manager or the API Manager, you must set it as active in the Settings > User Registries section of the Cloud Manager UI. See [Selecting user registries for Cloud Manager and API Manager](#) for more information.

If you want to make the custom user registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Catalog settings > Onboarding. In the Catalog User Registries section, click Edit, select the user registry, and click Save. For more information, see [Creating and configuring Catalogs](#).

Creating a shared custom user registry by using the developer toolkit CLI

You configure a custom user registry by first configuring an integration document that defines your external user registry, and then creating a new custom user registry resource that references the integration document that you just created. You use developer toolkit CLI commands to create the integration document, and then the custom user registry. Finally, to make the registry available for user authentication, you need to configure the registry in the management server, or in the appropriate Catalog, or both, depending on your requirements. When the custom user registry is used for authentication, API Connect makes a REST call to the endpoint of your external registry, as defined in the integration document.

Logging in to the management server CLI

Before you can define the custom user registry, you must log in to your management server from the developer toolkit CLI as a member of the cloud administration organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
- title: Cloud Manager User Registry
  realm: admin/default-idp-1
- title: Corporate LDAP user registry
  realm: admin/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**. For full details of the login command, see [Logging in to a management server](#).

For more information about how to use the CLI, see [Installing the toolkit](#), and [Overview of the command-line tool](#).

Defining your integration document

You define the configuration of your external user registry in an **integration_file.yaml** document, as shown in the following example.

```
integration: '1.0.0'
integration_type: 'user_registry'
info:
  name: 'custom_user_registry'
  version: '1.0.0'
  title: 'Custom External User Registry'
  summary: 'Configure External User Registry'
properties:
  remote: true
secured_endpoint:
  endpoint: 'https://custom.ms.com:8888'
  tls_client_profile_url: {$tlsClientProfileUrl}
headers:
  key1: value1
  key2: value2
configuration_schema:
  option_config1:
    type: string
  option_config2:
    type: boolean
```

The integration document properties are described in the following table:

Property	Description
integration_type	The type of integration, which in this case is user_registry .
info	Denotes the information section for the integration document.
name	The name of the user registry type, for example custom_user_registry . This name is used in the user registry file to denote the registry type.
version	The version number of the integration document.
title	A descriptive name to display in a graphical user interface.
summary	A brief description of the integration document.
properties	Denotes the property section of the integration document.
remote	Indicates that this is an external user registry. Must be set to true .
secured_endpoint	Denotes the external registry endpoint section of the integration document.
endpoint	The secure endpoint of your external user registry interface, where your platform REST API is located. It is made up of the url and port, for example: https://custom.ms.com:8888 API Connect will make REST calls to this endpoint for the user registry actions.
tls_client_profile_url	Optionally set the TLS Client Profile URL that the custom server requires.
headers	Complete the user-defined header section to your external registry specification.
configuration_schema	Complete the user-defined configuration schema section to your external registry specification.

Save your **integration_file.yaml** so it can be accessed by the **integrations:create** command in the following section.

Creating your custom integration

To create your custom user registry integration, run the following CLI command:

```
apic integrations:create --server mgmt_endpoint_url --subcollection user-registry integration_file.yaml
```

where:

- **mgmt_endpoint_url** is the management platform API endpoint URL.
- **integration_file** is the name of the YAML file that defines the configuration of your external user registry.

At this point API Connect makes a REST request call to the **endpoint** that is configured in the integration document, and the external platform REST API will need to return the requested information.

On completion of the integration creation, the command displays the following summary details:

```
integration_name custom_integration_url
```

The **integration_name** is derived from the **name** property in the configuration YAML file. The **custom_integration_url** is the URL with which the integration can be accessed. Both properties are needed when defining your custom user registry in the next section.

After your custom integration has completed successfully, you can continue to create the custom user registry.

Defining your custom user registry

You define the configuration of your custom user registry in a `custom_config_file.yaml` file, as shown in the following example.

```
name: 'custom_registry_name'
title: 'display_title'
registry_type: 'custom_user_registry'
integration_url: custom_integration_url
case_sensitive: true_or_false
user_managed: true_or_false
user_registry_managed: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
- name: provider_name
  title: 'provider_title'
configuration:
  custom_config1: 'value1'
  customize: true
```

The registry properties are described in the following table:

Property	Description
<code>name</code>	The name of the custom user registry. This name is used in the CLI commands.
<code>title</code>	A descriptive name to display in a graphical user interface.
<code>registry_type</code>	The registry type that you configured in the <code>name</code> property in the integration document, for example <code>custom_user_registry</code> .
<code>integration_url</code>	The custom integration URL in your API Connect configuration. You can determine the custom integration URL by using the following CLI command: <code>apic integrations:list --server mgmt_endpoint_url --subcollection user-registry</code> Or you can copy and paste from the summary of the integration creation.
<code>case_sensitive</code>	Determines whether your user registry is case-sensitive. Valid values are: <ul style="list-style-type: none"><code>true</code><code>false</code> To ensure proper handling of user name capitalization, you must ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: <ul style="list-style-type: none">Only set <code>case_sensitive</code> to <code>true</code> if your backend LDAP server supports case-sensitivity.Set <code>case_sensitive</code> to <code>false</code> if your backend LDAP server does not support case-sensitivity. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
<code>user_managed</code>	Determines whether your user registry is writable or not. Must be set to <code>true</code> for writable. Set to <code>false</code> if you don't want the registry to be writable.
<code>user_registry_managed</code>	Determines whether API Connect manages your user registry. Valid values are: <ul style="list-style-type: none"><code>true</code><code>false</code>
<code>email_required</code>	Determines whether an email address is required as part of the user onboarding process. Valid values are: <ul style="list-style-type: none"><code>true</code><code>false</code> If set to <code>true</code> , the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
<code>email_unique_if_exist</code>	Determines whether email addresses must be unique within the user registry. Valid values are: <ul style="list-style-type: none"><code>true</code><code>false</code> Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
<code>identity_providers</code>	An array containing the details of your custom server, where: <ul style="list-style-type: none"><code>name</code> - is the name of the custom server and is the name that is used in CLI commands<code>title</code> - is the display name of the custom server
<code>configuration</code>	The user-defined configuration based on the <code>configuration_schema</code> that is defined in the integration document.

Save your `custom_config_file.yaml` so it can be accessed by the `user-registries:create` command in the following section.

Creating your custom user registry

To create your shared custom user registry, run the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org admin custom_config_file.yaml
```

where:

- `mgmt_endpoint_url` is the platform API endpoint URL.

- `--org admin` means that the registry will be created in the admin organization, which is required for a user registry to be shared.
- `custom_config_file` is the name of the YAML file that defines the configuration of your custom user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

The `registry_name` is derived from the `name` property in the custom user registry YAML file. The `registry_url` is the URL with which the custom registry resource can be accessed.

Your shared custom user registry is now created; see the following sections for instructions on how to make the registry available to users.

Configuring your custom registry for Cloud Manager or API Manager login

If you want to make your custom registry available for authenticating Cloud Manager and API Manager users, you must configure it on the management server.

1. Determine the URL of your custom user registry by using the following command (or you can copy and paste from the summary of the registry creation):

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

2. Determine what the current user registries are, because you will need to confirm these as well as add your new custom registry:

```
apic user-registry-settings:get --server mgmt_endpoint_url --output -
```

This command outputs a list of all the current user registries in your environment, similar to the following example:

```
type: user_registry_setting
api_version: 2.0.0
name: user-registry-setting
admin_user_registry_default_url: >-
  https://server.com/api/user-registries/xxxxx/xxxxx-1234
admin_user_registry_urls:
  - >-
    https://server.com/api/user-registries/xxxxx/xxxxx-1234
provider_user_registry_default_url: >-
  https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
provider_user_registry_urls:
  - >-
    https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
created_at: '2019-09-30T12:22:19.467Z'
updated_at: '2019-10-17T10:05:37.867Z'
url: 'https://server.com/api/cloud/settings/user-registries'
```

3. Enter the following command to update your user registries (the terminating hyphen character means that the command takes input from the command line):

```
apic user-registry-settings:update --server mgmt_endpoint_url -
```

The following message is output:

```
Reading USER_REGISTRY_SETTING_FILE arg from stdin
```

4. If you want to make your custom registry available for authenticating Cloud Manager users, enter the following data, followed by a new line:

```
admin_user_registry_urls:
  - >-
    current_admin_user_registry_urls
  - new_custom_user_registry_url
```

where:

- `current_admin_user_registry_urls` are the current admin user registry URLs, as listed in Step 2 in the `admin_user_registry_urls` section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
- `new_custom_user_registry_url` is the URL of your new custom user registry, as determined in Step 1.

5. If you want to make your custom registry available for authenticating API Manager users, enter the following data, followed by a new line:

```
provider_user_registry_urls:
  - >-
    current_provider_user_registry_urls
  - new_custom_user_registry_url
```

where:

- `current_provider_user_registry_urls` are the current provider organization user registry URLs, as listed in Step 2 in the `provider_user_registry_urls` section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
- `new_custom_user_registry_url` is the URL of your new custom user registry, as determined in Step 1.

6. Press `CTRL D` to terminate the input. A confirmation message is output, for example:

```
user-registry-setting https://server.com/api/cloud/settings/user-registries
```

where `server.com` is your management server endpoint.

Configuring your custom registry in a Catalog

If you want to make your custom registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your custom user registry by using the following command (or you can copy and paste from the summary of the registry creation):

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

2. Log in to the management server as a member of a provider organization by entering the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

For full details of the `apic login` command, see [Logging in to a management server](#).

3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
```

where `catalog_name` is the value of the `name` property of the required Catalog. The command returns:

```
Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
```

4. Enter the following data, followed by a new line:

```
user_registry_url: custom_registry_url
```

where `custom_registry_url` is the URL of your custom registry, obtained in step 1.

5. Press **CTRL D** to terminate the input.

Configuring an LDAP user registry in the Cloud Manager

You can use the Cloud Manager UI to configure an LDAP user registry as a shared resource to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

Before you begin

To configure an LDAP user registry as a shared resource in the Cloud Manager, the LDAP directory must be created for use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, to authenticate users to the Cloud Manager and the API Manager, or for securing a Catalog to authenticate Developer Portal users.

Important: If you are using an LDAP registry to secure APIs, the STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.

One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for authenticating Developer Portal users in a specific provider organization. While a shared LDAP user registry can be used across the Cloud Manager, the API Manager, and the Developer Portal components in your environment.

This topic describes how to configure a shared LDAP user registry that is available to all of the provider organizations in your API Connect environment. If you want to create an organization-specific registry, see [Creating an LDAP user registry in API Manager](#) for more information. Note also that the visibility of a user registry is set to **shared** by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see [Setting visibility for a user registry](#).

Note:

- If you configure your LDAP user registry to be writable (by selecting the User Managed check box on the registry), you can use the Developer Portal UI for onboarding and authenticating new Developer Portal users, as well as those users that already exist in the LDAP database. A writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
- You can also create and manage LDAP user registries by using the developer toolkit CLI (see [Using the CLI to configure a shared LDAP user registry](#)), and by using the API Connect REST APIs (see the [API Connect REST API documentation](#)).
- You can map external LDAP groups to API Connect user roles to enable greater control of user access, but this configuration can be done only by using the developer toolkit CLI; see [Using the CLI to configure a shared LDAP user registry](#) for details.

You create an LDAP user registry by configuring a set of properties in the Cloud Manager UI. If you want to enable writable LDAP, you must complete the Attribute Mapping section by selecting the User Managed checkbox, and providing the mapping of your source LDAP attribute names to the target API Connect values. You can also change a registry to be read-only again by clearing the User Managed checkbox. After configuring the user registry, you must set it as active in `Settings > User Registries`. To make the registry available to the Developer Portal, you must define the registry for consumer onboarding in the associated Catalog. To secure APIs with an LDAP registry, you must configure security definitions.

For general information about authenticating with LDAP, see [LDAP authentication](#).

Procedure

Follow these steps to configure a new LDAP user registry as a shared resource in the Cloud Manager UI.

1. In the Cloud Manager, click  Resources.
2. Click Create in the User Registries section.

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the

Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

3. Select LDAP User Registry for the user registry type, and enter the following information:

Field	Description
Title	Enter a descriptive name to display on the screen.
Name	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see apic user registries .
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface , Accessing the API Manager user interface , and Activating your API Manager user account . Note: The Developer Portal uses the Title of the User Registries when rendering them at the login page, rather than the Display Name .
Summary (optional)	Enter a brief description.
Address	Enter the IP address or host name of the LDAP server.
Port	Enter the Port number that API Connect can use to communicate with the LDAP registry. For example, 389.
Select a TLS Client Profile (optional)	Select the TLS Client Profile that the LDAP server requires.
Select an LDAP protocol version	Select the version number for the LDAP protocol that you are using.
Remote directory is Microsoft Active Directory	Select this option if you use Active Directory.
Case sensitive	To ensure proper handling of user name capitalization, you must ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: <ul style="list-style-type: none"> • Only select Case sensitive if your backend LDAP server supports case-sensitivity. • Do not select Case sensitive if your backend LDAP server does not support case-sensitivity. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Enable External Group Mapping	Enable this property if you want user to use this user registry to map external LDAP groups to API Connect user roles to enable more control of user authorization.
Email required	Select this check box if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this check box if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Next and enter the authentication information, which will vary depending on the selected Authentication Method. The choices are:

- Compose DN - Select this format if you can compose the user LDAP Distinguished Name (DN) from the user name. For example, `uid=<username>,ou=People,dc=company,dc=com` is a DN format that can be composed from the user name. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, Compose DN is not supported with the DataPower API Gateway.
- Compose UPN - Select this format if your LDAP directory supports binding with User Principal Names such as `john@acme.com`. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator.
Note: The Admin Bind DN and Admin Bind Password are not used with this authentication method.
- Search DN - Select this format if you cannot compose the user LDAP Distinguished Name from the user name; for example, if the base DNs of the users are different. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.
Optionally select a scope to specify which part of the directory information tree is examined:
 - Whole subtree (default)
 - Base object
 - Single level

For all of the authentication methods:

If you are creating an LDAP registry to authenticate users of an API, you can specify an LDAP authorization group to restrict API access. To be able to call an API that is secured by the LDAP registry, a user must successfully authenticate with their LDAP user ID and password **and** they must be a member of the specified authorization group. The authorization group can be a Static Group or Dynamic Group. A static group is one in which the individual members of the group are explicitly listed. A dynamic group is one which is defined according to the set of attributes that the group members share in common.

5. For authentication method Compose DN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example <code>cn=admin,dc=company,dc=com</code> .
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Prefix	Specify the prefix to the DN. For example <code>(uid=</code> .
Suffix	Specify the suffix to the DN. For example <code>)</code> .
Base DN (optional)	Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN.
Use group authentication (optional)	Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.

6. For authentication method Compose UPN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.

Field	Description
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example <code>cn=admin,dc=company,dc=com</code> .
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Suffix	Enter the domain part of the user principal name. For example, <code>@acme.com</code> .
Use group authentication (optional)	Enter the Filter condition for the group.

7. For authentication method Search DN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example <code>cn=admin,dc=company,dc=com</code> .
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Prefix	Specify the prefix to the DN. For example <code>(uid=</code> .
Suffix	Specify the suffix to the DN. For example <code>)</code> .
Base DN (optional)	Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN.
Use group authentication (optional)	Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.

8. Optional: Click Test configuration to test the settings for your LDAP user registry. Enter valid credentials to ensure that you can access the LDAP database.

9. Optional: If you want to make your LDAP user registry writable, select the User Managed checkbox in the Attribute Mapping section, and provide the mapping of your source LDAP attribute names to the target API Connect values. Click Add to add each name/value pair, specified as follows:

- LDAP ATTRIBUTE NAME - is the name of the source LDAP attribute.
- API CONNECT VALUE - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in [] with the value that the user supplies when signing up.

The default user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`, as shown in the following example:

LDAP ATTRIBUTE NAME	API CONNECT VALUE
<code>dn</code>	<code>uid=[username],ou=users,dc=company,dc=com</code>
<code>cn</code>	<code>{first_name} {last_name}</code>
<code>sn</code>	<code>{last_name}</code>
<code>mail</code>	<code>{email}</code>
<code>userPassword</code>	<code>{password}</code>

You must ensure that you enter the correct attribute mapping values for your LDAP configuration, to enable API Connect to access the LDAP database. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.

10. Click Create.

Your new LDAP registry is shown in the list of User Registries on the Resources page.

What to do next

To make the LDAP registry available for user authentication in the Cloud Manager and the API Manager, you must set it as active in the Settings > User Registries section. See [Selecting user registries for Cloud Manager and API Manager](#) for more information.

If you want to make the LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Settings, Onboarding. In the Catalog User Registries section, click Edit, select the user registry, and click Save. For more information, see [Creating and configuring Catalogs](#).

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see [Creating a basic authentication security definition](#).
- To use for authentication in the User Security configuration for a native OAuth provider, see [Configuring user security for a native OAuth provider](#).
- [Using the CLI to configure a shared LDAP user registry](#)
You can use the developer toolkit CLI to configure an LDAP user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

- [Securing your API Connect Cloud with LDAP \(series of developer articles\)](#)

Using the CLI to configure a shared LDAP user registry

You can use the developer toolkit CLI to configure an LDAP user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

Before you begin

To configure an LDAP user registry as a resource in the Cloud Manager, the LDAP directory must be created and available to use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, or for authenticating users to the Cloud Manager, the API Manager, and the Developer Portal.

Important: If you are using an LDAP registry to secure APIs, the STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.

One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for onboarding and authenticating Developer Portal users, while a shared LDAP user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure a shared LDAP user registry. If you want to create an organization-specific registry, see [Using the CLI to create an organization-specific LDAP user registry](#) for more information. Note also that the visibility of a user registry is set to `shared` by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see [Setting visibility for a user registry](#).

Note:

- If the LDAP user registry is configured as writable (by enabling the `user-managed` property on the registry), you can use the Developer Portal UI for onboarding and authenticating new Developer Portal users, as well as those users that already exist in the LDAP database. A writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
- You can also create LDAP user registries by using the Cloud Manager UI (see [Configuring an LDAP user registry in the Cloud Manager](#)), and by using the API Connect REST APIs (see the [API Connect REST API documentation](#)).
- If you are using the DataPower® API Gateway, LDAP group authentication is not supported.
- You can map external LDAP groups to API Connect user roles to enable more control of user authorization by using the developer toolkit CLI. The following instructions explain how to set the `external_group_mapping_enabled` configuration on your LDAP user registry resource. For information about how to set external role mapping on your API Connect user roles, see [Configuring LDAP group mappings on Cloud Manager user roles](#).

You configure an LDAP user registry by first defining the registry details in a configuration file. You then use a developer toolkit CLI command to create the registry, passing the configuration file as a parameter. Finally, to make the registry available for user authentication, you need to configure the registry in the management server, or in the appropriate Catalog, or both, depending on your requirements. To secure APIs with an LDAP registry, you must configure security definitions. You can use the following instructions to create a writable or a read-only LDAP user registry.

For general information about authenticating with LDAP, see [LDAP authentication](#).

Logging in to the management server CLI

Before you can define the LDAP user registry configuration, you must log in to your management server from the developer toolkit CLI as a member of the cloud administration organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
- title: Cloud Manager User Registry
  realm: admin/default-idp-1
- title: Corporate LDAP user registry
  realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.

For full details of the login command, see [Logging in to a management server](#).

For more information about how to use the CLI, see [Installing the toolkit](#), and [Overview of the command-line tool](#).

Defining your LDAP configuration

You define the configuration of your LDAP user registry in an `ldap_config_file.yaml` file, as shown in the following example. Note that the actual contents of your YAML file will vary depending on the authentication method of your LDAP server, and this is explained in the following tables.

```
name: registry_name
title: "display_title"
integration_url: LDAP_integration_url
```

```

user_managed: true_or_false
user_registry_managed: false
directory_type: ad
external_group_mapping_enabled: true_or_false
case_sensitive: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
- name: provider_name
  title: provider_title
endpoint:
  endpoint: "ldap_server_url_and_port"
configuration:
  authentication_method: authentication_method
  authenticated_bind: "true_or_false"
  admin_dn: "admin_dn"
  admin_password: admin_password
  search_dn_base: "search_dn_base"
  search_dn_scope: search_dn_scope
  search_dn_filter_prefix: prefix
  search_dn_filter_suffix: suffix
  attribute_mapping:
    dn: "distinguished_name"
    cn: "common_name"
    sn: "last_name"
    mail: "email_address"
    userPassword: "password"

```

The registry properties that are common to each authentication method are described in the following table:

Property	Description
name	The name of the registry. This name is used in CLI commands.
title	A descriptive name to display in a graphical user interface.
integration_url	The LDAP integration URL in your API Connect configuration. You can determine the LDAP integration URL by using the following CLI command: <code>apic integrations:list --server mgmt_endpoint_url --subcollection user-registry</code>
user_managed	Determines whether your user registry is writable or not. Must be set to true for writable LDAP. You can change this setting to false if you don't want the registry to be writable; see the Switching your LDAP registry between writable and read-only section at the end of this topic for details. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
user_registry_managed	Must be set to false for LDAP. Determines whether API Connect manages your user registry. Only LUR registries are managed by API Connect.
directory	Specify one of the of following values for the directory type: <ul style="list-style-type: none"> ad - Indicates that the LDAP is Microsoft Active Directory standard - (Default value) Indicates any other LDAP
external_group_mapping_enabled	Determines whether your user registry supports LDAP group mapping. Valid values are: <ul style="list-style-type: none"> true false <p>The default value is false.</p>
case_sensitive	Determines whether your user registry is case-sensitive. Valid values are: <ul style="list-style-type: none"> true false <p>To ensure proper handling of user name capitalization, you must ensure that your case-sensitivity setting here matches the setting on your backend LDAP server:</p> <ul style="list-style-type: none"> Only set case_sensitive to true if your backend LDAP server supports case-sensitivity. Set case_sensitive to false if your backend LDAP server does not support case-sensitivity. <p>Note: After at least one user has been onboarded into the registry, you cannot change this setting.</p>
email_required	Determines whether an email address is required as part of the user onboarding process. Valid values are: <ul style="list-style-type: none"> true false <p>If set to true, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.</p>
email_unique_if_exist	Determines whether email addresses must be unique within the user registry. Valid values are: <ul style="list-style-type: none"> true false <p>Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.</p>
identity_providers	An array containing the details of your LDAP server, where: <ul style="list-style-type: none"> name - is the name of the LDAP server and is the name that is used in CLI commands title - is the display name of the LDAP server
endpoint	The endpoint of your LDAP server, made up of the url and port, for example: <code>"ldap://server.com:389"</code>
tls_profile	Optionally set the TLS Client Profile that the LDAP server requires.

Property	Description
protocol_version	Optionally set the version number for the LDAP protocol that you are using. Valid values are: <ul style="list-style-type: none"> • 2 • 3 Defaults to 3 if not explicitly set.

The properties in the configuration section will vary depending on the selected authentication method. The three authentication methods are:

- **compose_dn** - Set this format if you can compose the user LDAP Distinguished Name (DN) from the user name. For example, `uid=<username>,ou=People,dc=company,dc=com` is a DN format that can be composed from the user name. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, **compose_dn** is not supported with the DataPower API Gateway.
- **compose_upn** - Set this format if your LDAP directory supports binding with User Principal Names such as `john@acme.com`. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator.
Note: The Admin Bind DN and Admin Bind Password are not used with this authentication method.
- **search_dn** - Select this format if you cannot compose the user LDAP Distinguished Name from the user name; for example, if the base DNs of the users are different. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.

For authentication method **compose_dn**, set the following configuration properties:

Properties	Description
authentication_method	compose_dn
authenticated_bind	The bind method. Valid values are: <ul style="list-style-type: none"> • "true" - authenticated bind • "false" - anonymous bind If specific permissions are not needed to search the registry, select "false". If specific permissions are necessary, select "true".
admin_dn	If authenticated_bind is set to "true", enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: <code>"cn=admin,dc=company,dc=com"</code>
admin_password	If authenticated_bind is set to "true", enter the user password for the admin_dn .
search_dn_base	Optionally set a base DN, for example: <code>"dc=company,dc=com"</code>
bind_prefix	Set the prefix to the DN, for example: <code>(uid=</code>
bind_suffix	Set the suffix to the DN, for example: <code>)</code>
attribute_mapping	If user_managed is set to true , provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows: <code>ldap_registry_attribute_name: "apic_ldap_attribute_value"</code> Where: <ul style="list-style-type: none"> • <code>ldap_registry_attribute_name</code> - is the name of the source LDAP attribute • <code>apic_ldap_attribute_value</code> - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in [] with the value that the user supplies when signing up. The user profile properties that API Connect requires during user registration are username , first_name , last_name , email , and password . The following extract shows an example of an attribute mapping: <code>attribute_mapping: dn: "uid=[username],ou=users,dc=company,dc=com" cn: "[first_name] [last_name]" sn: "[last_name]" mail: "[email]" userPassword: "[password]"</code>

For authentication method **compose_upn**, set the following configuration properties:

Properties	Description
authentication_method	compose_upn
authenticated_bind	The bind method. Valid values are: <ul style="list-style-type: none"> • "true" - authenticated bind • "false" - anonymous bind If specific permissions are not needed to search the registry, select "false". If specific permissions are necessary, select "true".
admin_dn	If authenticated_bind is set to "true", enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: <code>"cn=admin,dc=company,dc=com"</code>
admin_password	If authenticated_bind is set to "true", enter the user password for the admin_dn .
bind_suffix	Enter the domain part of the user principal name. For example: <code>@acme.com</code>

Properties	Description
<code>attribute_mapping</code>	<p>If <code>user_managed</code> is set to <code>true</code>, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows:</p> <pre>ldap_registry_attribute_name: "apic_ldap_attribute_value"</pre> <p>Where:</p> <ul style="list-style-type: none"> <code>ldap_registry_attribute_name</code> - is the name of the source LDAP attribute <code>apic_ldap_attribute_value</code> - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in [] with the value that the user supplies when signing up. <p>The user profile properties that API Connect requires during user registration are <code>username</code>, <code>first_name</code>, <code>last_name</code>, <code>email</code>, and <code>password</code>. The following extract shows an example of an attribute mapping:</p> <pre>attribute_mapping: dn: "uid=[username],ou=users,dc=company,dc=com" cn: "[first_name] [last_name]" sn: "[last_name]" mail: "[email]" userPassword: "[password]"</pre>

For authentication method `search_dn`, set the following configuration properties:

Property	Description
<code>authentication_method</code>	<code>search_dn</code>
<code>authenticated_bind</code>	<p>The bind method. Valid values are:</p> <ul style="list-style-type: none"> <code>"true"</code> - authenticated bind <code>"false"</code> - anonymous bind <p>If specific permissions are not needed to search the registry, select <code>"false"</code>. If specific permissions are necessary, select <code>"true"</code>.</p>
<code>admin_dn</code>	<p>If <code>authenticated_bind</code> is set to <code>"true"</code>, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example:</p> <pre>"cn=admin,dc=company,dc=com"</pre>
<code>admin_password</code>	If <code>authenticated_bind</code> is set to <code>"true"</code> , enter the user password for the <code>admin_dn</code> .
<code>search_dn_base</code>	<p>Optionally set a base DN, for example:</p> <pre>"dc=company,dc=com"</pre>
<code>search_dn_scope</code>	<p>Optionally set the search DN scope. The scope determines which part of the directory information tree is examined. Possible values are:</p> <ul style="list-style-type: none"> <code>base</code> <code>one</code> <code>sub</code> (default value)
<code>search_dn_filter_prefix</code>	<p>Set the prefix to the DN, for example:</p> <pre>(uid=</pre>
<code>search_dn_filter_suffix</code>	<p>Set the suffix to the DN, for example:</p> <pre>)</pre>
<code>attribute_mapping</code>	<p>If <code>user_managed</code> is set to <code>true</code>, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows:</p> <pre>ldap_registry_attribute_name: "apic_ldap_attribute_value"</pre> <p>Where:</p> <ul style="list-style-type: none"> <code>ldap_registry_attribute_name</code> - is the name of the source LDAP attribute <code>apic_ldap_attribute_value</code> - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in [] with the value that the user supplies when signing up. <p>The user profile properties that API Connect requires during user registration are <code>username</code>, <code>first_name</code>, <code>last_name</code>, <code>email</code>, and <code>password</code>. The following extract shows an example of an attribute mapping:</p> <pre>attribute_mapping: dn: "uid=[username],ou=users,dc=company,dc=com" cn: "[first_name] [last_name]" sn: "[last_name]" mail: "[email]" userPassword: "[password]"</pre>

Save your `ldap_config_file.yaml` so it can be accessed by the `user-registries:create` command in the following section. See the [Example](#) section for an example configuration file.

Creating your LDAP user registry

To create your shared LDAP user registry, run the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org admin ldap_config_file.yaml
```

where:

- `mgmt_endpoint_url` is the platform API endpoint URL.
- `--org admin` means that the registry will be created in the admin organization, which is required for a user registry to be shared.
- `ldap_config_file` is the name of the YAML file that defines the configuration of your LDAP user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

The `registry_name` is derived from the `name` property in the configuration YAML file. The `registry_url` is the URL with which the registry resource can be accessed. Your shared LDAP user registry is now created; see the following sections for instructions on how to make the registry available to users.

Configuring your LDAP registry for Cloud Manager or API Manager login

If you want to make your LDAP registry available for authenticating Cloud Manager and API Manager users, you must configure it on the management server.

1. Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

2. Determine what the current user registries are, because you will need to confirm these as well as add your new LDAP registry:

```
apic user-registry-settings:get --server mgmt_endpoint_url --output -
```

This command outputs a list of all the current user registries in your environment, similar to the following example:

```
type: user_registry_setting
api_version: 2.0.0
name: user-registry-setting
admin_user_registry_default_url: >-
  https://server.com/api/user-registries/xxxxx/xxxxx-1234
admin_user_registry_urls:
- >-
  https://server.com/api/user-registries/xxxxx/xxxxx-1234
provider_user_registry_default_url: >-
  https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
provider_user_registry_urls:
- >-
  https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
created_at: '2019-09-30T12:22:19.467Z'
updated_at: '2019-10-17T10:05:37.867Z'
url: 'https://server.com/api/cloud/settings/user-registries'
```

3. Enter the following command to update your user registries (the terminating hyphen character means that the command takes input from the command line):

```
apic user-registry-settings:update --server mgmt_endpoint_url -
```

The following message is output:

```
Reading USER_REGISTRY_SETTING_FILE arg from stdin
```

4. If you want to make your LDAP registry available for authenticating Cloud Manager users, enter the following data, followed by a new line:

```
admin_user_registry_urls:
- >-
  current_admin_user_registry_urls
- new_ldap_user_registry_url
```

where:

- `current_admin_user_registry_urls` are the current admin user registry URLs, as listed in Step 2 in the `admin_user_registry_urls` section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
- `new_ldap_user_registry_url` is the URL of your new LDAP user registry, as determined in Step 1.

5. If you want to make your LDAP registry available for authenticating API Manager users, enter the following data, followed by a new line:

```
provider_user_registry_urls:
- >-
  current_provider_user_registry_urls
- new_ldap_user_registry_url
```

where:

- `current_provider_user_registry_urls` are the current provider organization user registry URLs, as listed in Step 2 in the `provider_user_registry_urls` section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
- `new_ldap_user_registry_url` is the URL of your new LDAP user registry, as determined in Step 1.

6. Press **CTRL D** to terminate the input. A confirmation message is output, for example:

```
user-registry-setting https://server.com/api/cloud/settings/user-registries
```

where `server.com` is your management server endpoint.

Configuring your LDAP registry in a Catalog

If you want to make your LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

2. Log in to the management server as a member of a provider organization by entering the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

For full details of the `apic login` command, see [Logging in to a management server](#).

3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
```

where `catalog_name` is the value of the `name` property of the required Catalog. The command returns:

```
Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
```

4. Enter the following data, followed by a new line:

```
user_registry_url: ldap_registry_url
```

where `ldap_registry_url` is the URL of your LDAP registry, obtained in step 1.

5. Press **CTRL D** to terminate the input.

Switching your LDAP registry between writable and read-only

After an LDAP user registry has been created, it can be switched between writable and read-only by updating the `user_managed` property in the registry configuration. Complete the following steps.

1. Determine the name or ID of the LDAP user registry that you want to update, by running the following command (or you can use the summary from the registry creation):

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

The command returns a list of all the user registries on that server, shown by name followed by their registry URL. The registry ID is located at the end of the URL, for example `https://company.com/api/user-registries/x-x-x-x-x/registry_id`.

2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic user-registries:update --server mgmt_endpoint_url --org admin registry_name_or_id -
```

where `registry_name_or_id` is the name or ID of the LDAP user registry that you want to update (as determined in the previous step). The command returns:

```
Reading USER_REGISTRY_FILE arg from stdin
```

3. Enter the following data, followed by a new line:

```
user_managed: true_or_false
```

where `true` makes the registry writable, and `false` makes the registry read-only.

4. Press **CTRL D** to terminate the input.

Note that if you are changing your registry from read-only to writable, you must also set the `attribute_mapping` configuration, as described in the previous registry property tables.

Using an LDAP user registry to secure APIs

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see [Creating a basic authentication security definition](#).
- To use for authentication in the User Security configuration for a native OAuth provider, see [Configuring user security for a native OAuth provider](#).

For details of all the `apic user-registries` and `apic configured-catalog-user-registries` commands, see [apic user-registries](#) and [apic configured-catalog-user-registries](#).

Example

The following example shows a configuration file that uses the Search DN authentication method for setting up writable LDAP:

```
name: sdn-ldap
title: "SDN LDAP User Registry"
integration_url: https://mycompany.com/api/cloud/integrations/user-registry/xxx-xxx-xxx
user_managed: true
user_registry_managed: false
directory_type: standard
case_sensitive: false
identity_providers:
- name: ldap
  title: "SDN LDAP Identity Provider"
endpoint:
  endpoint: "ldap://mycompany.com:389"
configuration:
  authentication_method: search_dn
  authenticated_bind: "true"
  admin_dn: "cn=admin,dc=company,dc=com"
  admin_password: xxxx
  search_dn_base: "dc=company,dc=com"
  search_dn_scope: sub
  search_dn_filter_prefix: (uid=
  search_dn_filter_suffix: )
  attribute_mapping:
    dn: "uid=[username],ou=users,dc=company,dc=com"
    cn: "[first_name] [last_name]"
    sn: "[last_name]"
    mail: "[email]"
    userPassword: "[password]"
```

Configuring a Local User Registry

A Local User Registry (LUR) can be configured to provide user authentication for both Cloud Manager and API Manager.

About this task

Local User Registries (LURs) are the default user registries included in API Connect. LURs are local databases included with API Connect. Two default LURs are installed and configured during installation of API Connect. They cannot be deleted. The default Admin user account is stored in the Provider LUR.

You can create and configure a new LUR. After you create it, you must set it as active in Settings > User Registries. See [Selecting user registries for Cloud Manager and API Manager](#).

One of the following roles is required to configure user registries:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

Procedure

Follow these steps to configure a new LUR:

1. In the Cloud Manager, click .
2. Click Create in the User Registries section.
Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
3. Select Local User Registry as the type for the user registry and enter the following information:

Field	Description
Title (required)	Enter a descriptive name for use on the screen.
Name (required)	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see apic user-registries .
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface , Accessing the API Manager user interface , and Activating your API Manager user account . Note: The Developer Portal uses the Title of the User Registries when rendering them at the login page, rather than the Display Name .
Summary (optional)	Enter a brief description.
Case sensitive	Select this setting if user names are case-sensitive. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. For new Local User Registries, this setting is always selected; so if email addresses are contained in the user record, they must be unique. However, for existing Local User Registries this setting can be edited. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Save.

Results

The user registry is saved and is available to be configured for user authentication in Cloud Manager or API Manager by selecting it in Settings > User Registries. See [Selecting user registries for Cloud Manager and API Manager](#).

Configuring an OIDC user registry in Cloud Manager

Configure a shared OIDC user registry for user onboarding and authentication when multi-factor authentication (MFA) is required.

You can create an OIDC user registry that is specific to a provider organization, or that is shared and available to all the provider organizations in your API Connect environment. An organization-specific OIDC user registry is used for onboarding and authenticating Developer Portal users, while a shared OIDC user registry can be used for onboarding and authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to create a shared registry. For information on how to create an organization-specific registry, see [Creating an OIDC user registry in API Manager](#).

Important: If you are using X (formerly known as Twitter) as your OIDC provider, API Connect supports only the OAuth 1.0a method, so your X application must be configured to use OAuth 1.0a. Other OIDC providers support OAuth 2.0.

API Connect provides two methods for creating an OIDC user registry in Cloud Manager, as described in the following sections:

- [Using the UI to configure an OIDC user registry](#)
- [Using the CLI to configure an OIDC user registry](#)

Using the UI to configure an OIDC user registry

Use the Cloud Manager application's user interface to configure a shared OIDC user registry when multi-factor authentication (MFA) is required.

1. In the Cloud Manager navigation pane, click  Resources.
2. Click User Registries.
3. Click Create and select OIDC User Registry.

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

4. On the Create OIDC User Registry page, use the fields in each of the following sections to configure the registry settings, and then click Create. Many of the registry settings are preconfigured to simplify the configuration steps.

Provider Type

Use the settings in Table 1 to define the provider type.

Table 1. Provider Type settings

Field	Description
Provider Type	OIDC provider. Select one of the following supported OIDC providers: <ul style="list-style-type: none"> • Facebook • GitHub • Google • LinkedIn • Slack • X (formerly Twitter) • Windows Live • Standard OIDC (default value allows you to specify another provider)
Title	Provide a descriptive name for display purposes.
Name	Automatically generated. This name is used in CLI commands to reference the registry. For details of the CLI commands for managing user registries, see the apic user-registries topic in the Command Line tool reference section of this documentation.
Summary	Provide a brief description of the new registry.
Email required	Select this check box if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this check box if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

Provider Endpoint

Automatically generated for most supported providers. In the Authorization Endpoint field, type the URL of the provider's authorization endpoint.

Token Endpoint

Fill in the settings as described in Table 2.

Table 2. Token Endpoint settings

Field	Description
URL	Preconfigured for most of the supported OIDC providers. Type the URL of the provider's token endpoint.
TLS	Select the TLS Client Profile for the token endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

UserInfo Endpoint

Fill in the settings as described in Table 3.

Table 3. UserInfo Endpoint settings

Field	Description
-------	-------------

Field	Description
URL	Preconfigured for most of the supported OIDC providers. Type the URL of the provider's userinfo endpoint. For LinkedIn, the endpoint changed and now uses the following value: <code>https://api.linkedin.com/v2/me</code> If you previously configure the OIDC registry using the legacy LinkedIn OIDC protocol, you do not need to specify this endpoint.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

Email Endpoint

Required for the legacy LinkedIn OIDC protocol.

Due to changes in LinkedIn, the configuration settings for the OIDC registry in API Connect also changed. If you are configuring a new OIDC registry for LinkedIn, you can leave the Email Endpoint field blank.

If you previously configured an OIDC registry for use with the legacy LinkedIn OIDC protocol, update your configuration by providing the Email endpoint settings as described in Table 4. The new setting is required for the legacy LinkedIn OIDC protocol.

Table 4. Email Endpoint settings

Field	Description
URL	For the legacy LinkedIn OIDC protocol, this field defaults to the following value: <code>https://api.linkedin.com/v2/emailAddress?q=members&projection=(elements*(handle~))</code> You can override the setting by typing in a new value.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

JWKS Endpoint

Fill in the settings as described in Table 5.

Table 5. JWKS Endpoint settings

Field	Description
URL	Type the URL of the read-only endpoint that contains the public keys' information in JWKS format.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

Logout

Fill in the settings as described in Table 6.

Table 6. Logout

Field	Description
Logout redirect	Optionally, give a logout redirect URL, allowing APIC to initiate an https 302 redirect to the configured endpoint. Note: When the Developer Portal uses this feature, it does not retain control afterward. Instead, the content is presented from the redirected endpoint.

Client Information

Fill in the settings as described in Table 7.

Table 7. Client Information settings

Field	Description
Client ID	Provide the client ID of the application that is registered with the selected OIDC provider.
Client Secret	Provide the client secret of the application that is registered with the selected OIDC provider. This field is optional when you create an OIDC directory of type Standard and set the Client Authentication Method to Data encoded form body. If you do not use the Client Secret, make sure that mutual TLS is possible with the OIDC provider.
Response Type	Preconfigured for most of the supported OIDC providers. Specify the data type of the response that will be received from the OIDC provider.
Scopes	Preconfigured for most of the supported OIDC providers. Specify the access scope for the OIDC provider.
Client Authentication Method	Preconfigured for most of the supported OIDC providers. Select the authentication method to be used with the OIDC provider. Options are: <ul style="list-style-type: none"> HTTP Basic authentication schema Data encoded form body

Additional Support

Optional. Select the additional security parameters described in Table 8.

Table 8. Additional security options

Security parameter	Setting name for CLI	Description
NONCE	<code>nonce</code>	Enable the NONCE extension to prevent compromised requests from being used again (replayed).
Proof Key for Code Exchange (PKCE)	<code>pkce</code>	Enable the PKCE extension to allow public clients to mitigate the threat of having the authorization code intercepted.

Advanced Features

Optional. Select the advanced features described in Table 9.

Table 9. Advanced features

Feature / UI Label	Setting name for CLI	Description
Auto onboard	<code>auto_onboard</code>	Allow users to executes calls to APIs without logging in first, provided they present a valid token issued by the OIDC provider. Note: Does not apply to consumer organizations.
Always use the userinfo endpoint	<code>userinfo</code>	Configures the OIDC user registry to always fetch user data from the userinfo endpoint, if populated.
Use Portal as Endpoint for external OIDC provider traffic	<code>proxy_redirect</code>	When authenticating users, redirect the external OIDC provider to communicate with the Developer Portal instead of API Manager.

Feature / UI Label	Setting name for CLI	Description
Return third-party access token	<code>proxy_access_token</code>	Include the third-party OIDC access token in the response. Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an <code>ERR_HTTP2_PROTOCOL_ERROR</code> or <code>ERR_CONNECTION_CLOSED</code> error.
Return third-party id_token	<code>proxy_id_token</code>	Include the third-party OIDC id_token in the response. Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an <code>ERR_HTTP2_PROTOCOL_ERROR</code> or <code>ERR_CONNECTION_CLOSED</code> error.
Token Relay	<code>token_relay</code>	Allow <code>access_token/refresh_token</code> to send in 302 redirect for logout
Userinfo POST	<code>post_userinfo</code>	If supported by your OIDC provider, by using HTTP POST method when contacting userinfo endpoint. Note: Not all OIDC providers support POST. Ensure that your OIDC provider supports this before you enable the feature.
Use IBM APIC token expiration setting from cloud	<code>override_provider_ttl</code>	Override the OIDC provider's token expiration setting with the access token and refresh token expiration settings that are configured in API Connect. For information on configuring the access token and refresh token expiration settings in API Connect, see Configuring timeouts for access tokens and refresh tokens .
Disable hash verification (CLI only)	<code>disable_hash_verification</code>	Disable <code>at_hash, c_hash</code>

User Mapping

Fill in the settings as described in Table 10.

Note: The User Mapping fields are preconfigured for most of the supported OIDC providers to minimize potential errors; use care when changing the settings. For the Standard OIDC option, contact your OIDC provider to obtain the details of the fields.

Table 10. User mapping settings

Field	Description
Username	The name of the field in the response token that contains the user's user name. Note: The Username field must be unique for this OIDC registry, because it identifies the user in the system and cannot be changed.
Email	The name of the field in the response token that contains the user's email address.
First name	The name of the field in the response token that contains the user's given name.
Last name	The name of the field in the response token that contains the user's surname.

Redirect URI

The Redirect URI section lists the endpoints to which the OIDC authorization server will redirect the authorization code. There is one endpoint for each API Connect organization type: Cloud administration, Provider organization, and Consumer organization. The redirect endpoint is required when a user registers their application with the OIDC provider. For example, if this OIDC user registry is used by a provider organization, the user must register the provider organization's redirect endpoint with the OIDC provider. These read-only fields are provided for you to copy the endpoint values as required.

Enabling the OIDC user registry

Complete the following steps to enable the new user registry for Cloud Manager, API Designer, or both.

1. On the navigation pane, click  Settings.
2. Click User Registries, > Edit.
3. Click Edit in the section that corresponds to the application for which you are enabling the new user registry.
4. Select the new OIDC user registry.
5. When you have finished enabling the registry, click Save.

Using the CLI to configure an OIDC user registry

Use the developer toolkit CLI to configure a shared OIDC user registry when multi-factor authentication (MFA) is required.

Configure an OIDC user registry by first defining the registry details in a configuration file. Then, use a CLI command to create the registry by passing the configuration file as a parameter. To make the registry available to the Developer Portal, you must enable the registry in the associated Catalog.

Note:

- An OIDC registry cannot be used to secure APIs on the gateway.
- Because the interaction with the third-party OIDC provider is handled by the Management server, the Management server is the application from the point of view of the third-party OIDC provider. Your OIDC redirection endpoint is used by the authorization server to send the token to the Management server, so it must be accessible to the OIDC provider through your firewall. When you register your application with the third-party OIDC provider, you are required to supply the associated OIDC redirect URI, `https://consumer.mycompany.com/consumer-api/oauth2/redirect` for example. However, this information is not available until you have created your OIDC user registry in API Connect. You must first register your application without this information and then update it later, as detailed in the instructions on this page.

Logging in to the Management server

Before you can create an OIDC user registry, you must log in to your management server from the CLI. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```

apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
- title: Cloud Manager User Registry
  realm: admin/default-idp-1
- title: Corporate LDAP user registry
  realm: admin/corporate-ldap

```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`. For full details of the `apic login` command, see [Logging in to a management server](#).

Defining your OIDC registry configuration

Define the configuration of your OIDC user registry in a YAML file. At a minimum, the YAML file must include the settings from the following list. For additional settings, see the tables provided with the UI version of the procedure in this topic.

```

title: registry_title
integration_url: oidc_integration_url
case_sensitive: case_sensitivity_setting
email_required: true_or_false
email_unique_if_exist: true_or_false
configuration:
  client_id: 'app_client_id'
  client_secret: 'my-client-secret'
  provider_type: oidc_provider_type

```

where:

- `registry_title` is your chosen descriptive title for the user registry.
- `oidc_integration_url` is the OIDC integration URL in your API Connect configuration. You can determine the OIDC integration URL by using the following CLI command:

```
apic integrations:list --server mgmt_endpoint_url --subcollection user-registry
```

- `case_sensitivity_setting` determines whether your user registry is case-sensitive. Valid values are:
 - `true`
 - `false`

To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on the backend OIDC provider:

- **Only** set `case_sensitive` to `true` if the backend OIDC provider supports case-sensitivity.
- Set `case_sensitive` to `false` if the backend OIDC provider does not support case-sensitivity.

Note: After at least one user has been on-boarded into the registry, you cannot change this setting.

- `email_required` determines whether an email address is required as part of the user onboarding process. Valid values are:
 - `true`
 - `false`

If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding.

Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.

- `email_unique_if_exist` determines whether email addresses must be unique within the user registry. Valid values are:
 - `true`
 - `false`

Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

- `app_client_id` is the client ID of the application that is registered with the OIDC server, and must be in string format.
- `my-client-secret` is the client secret of the application that is registered with the OIDC server, and must be in string format.
- `oidc_provider_type` is the type of OIDC provider; specify one of the following values:

- `facebook`
- `github`
- `google`
- `linkedin`
- `slack`
- `twitter`
- `windows_live`
- `standard`

Note:

- Use the `twitter` provider type if your OIDC provider is X (formerly known as Twitter).
- Use the `standard` provider type for any OIDC provider that is compliant with the OIDC standard.

If the provider type is `standard`, you must include the following additional properties in the `configuration` section of your YAML file:

```

authorization_endpoint: 'oidc_auth_endpoint'
token_endpoint:
  endpoint: 'oidc_token_endpoint'

```

where:

- `oidc_auth_endpoint` is the authorization endpoint on the OIDC server, and must be in string format.
- `oidc_token_endpoint` is the token endpoint on the OIDC server, and must be in string format.

Default OIDC configurations

For each OIDC provider type, API Connect assumes a default configuration, but you can override the default configuration properties in your YAML file.

Note: Endpoints are subject to change; when you create a registry you must verify the default endpoint provided by API Connect.

API Connect makes the best effort to update endpoints for the known OIDC user registry types. However the OIDC provider can change the endpoint at any time. It is the customer's responsibility to confirm that the endpoints provided by API Connect are supported by the OIDC provider and to update the OIDC configuration as needed.

The default configurations are as follows:

- Facebook

```
authorization_endpoint: 'https://www.facebook.com/v3.1/dialog/oauth'  
token_endpoint:  
  endpoint: 'https://graph.facebook.com/v3.1/oauth/access_token'  
userinfo_endpoint:  
  endpoint: 'https://graph.facebook.com/me'  
scope: email public_profile  
field_mapping:  
  username: email  
  email: email  
  last_name: last_name  
  first_name: first_name
```

- GitHub

```
authorization_endpoint: 'https://github.com/login/oauth/authorize'  
token_endpoint:  
  endpoint: 'https://github.com/login/oauth/access_token'  
userinfo_endpoint:  
  endpoint: 'https://api.github.com/user'  
scope: 'read:user user:email'  
field_mapping:  
  username: login  
  email: email  
  last_name: name  
  first_name: name
```

- Google

```
authorization_endpoint: 'https://accounts.google.com/o/oauth2/v2/auth'  
token_endpoint:  
  endpoint: 'https://www.googleapis.com/oauth2/v4/token'  
scope: openid profile email  
field_mapping:  
  username: email  
  email: email  
  last_name: family_name  
  first_name: given_name
```

- LinkedIn

Some settings differ between the legacy configuration and the newer configuration. Be sure to use the correct settings for the LinkedIn protocol that you are using.

- New OIDC protocol:

```
authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'  
credential_location: form_body  
field_mapping:  
  email: email  
  username: name  
  first_name: given_name  
  last_name: family_name  
scope: openid profile email  
token_endpoint:  
  endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'  
userinfo_endpoint:  
  endpoint: 'https://api.linkedin.com/v2/me'
```

- Legacy OIDC protocol:

```
authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'  
token_endpoint:  
  endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'  
userinfo_endpoint:  
  endpoint: 'https://api.linkedin.com/v1/people/~:(id,first-name,last-name,picture-url,public-profile-url,email-address)?format=json'  
scope: r_basicprofile r_emailaddress  
field_mapping:  
  username: emailAddress  
  email: emailAddress  
  last_name: lastName  
  first_name: firstName  
credential_location: form_body
```

- Slack

```
authorization_endpoint: 'https://slack.com/oauth/authorize'  
token_endpoint:  
  endpoint: 'https://slack.com/api/oauth.access'  
userinfo_endpoint:  
  endpoint: 'https://slack.com/api/users.identity'  
scope: identity.basic identity.email  
field_mapping:  
  username: user.email  
  email: user.email  
  last_name: user.name  
  first_name: user.name
```

- X (formerly known as Twitter)

Although Twitter re-branded to X, the URL for the OIDC endpoint remains twitter.com.

```
request_endpoint: https://api.twitter.com/oauth/request_token'  
authorization_endpoint: https://api.twitter.com/oauth/authenticate'  
token_endpoint:  
  endpoint: 'https://api.twitter.com/oauth/access_token'
```

```

userinfo_endpoint:
  endpoint: 'https://api.twitter.com/1.1/account/verify_credentials.json'
  oauth_signature_method: 'HMAC-SHA1'
  field_mapping:
    email: email
    first_name: name
    last_name: name
    username: screen_name

```

- Windows Live

```

authorization_endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/authorize'
token_endpoint:
  endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/token'
  scope: openid offline_access profile email
  field_mapping:
    email: email
    username: preferred_username
    first_name: name
    last_name: name

```

- Standard

```

response_type: code
scope: openid
field_mapping:
  username: sub
  email: email
  last_name: family_name
  first_name: given_name
credential_location: auth_header

```

Although this is the default configuration for the **standard** provider type, you should contact your OIDC provider to obtain the details of the fields that you need to define.

Creating your OIDC user registry

To create your OIDC user registry, use the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org admin oidc_config_file
```

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.
- *organization_name* is the value of the **name** property of your provider organization.
- *oidc_config_file* is the name of the YAML file that defines the configuration of your OIDC user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

By default, the *registry_name* is derived from the **title** property in the configuration YAML file but you can override this by including a **name** property in the file. The *registry_url* is an internal URL that API Connect assigns to the registry.

After you have created your OIDC user registry, you must update your application registration with the third party OIDC provider to include the OIDC redirect URI; you can obtain this information by using the following command, which displays the details of the registry in the command window:

```
apic user-registries:get --server mgmt_endpoint_url --org organization_name registry_name --output -
```

The required **oidc_redirect_uri** value is in the **consumer:** section; for example:

```

consumer:
  oidc_redirect_uri: https://consumer.mycompany.com/consumer-api/oauth2/redirect

```

Enabling your OIDC registry in a Catalog

If you want to make your OIDC registry available for onboarding and authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your OIDC user registry by using the following command:

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

2. Log in to the Management server as a member of a provider organization; enter the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

For full details of the **apic login** command, see [Logging in to a management server](#).

3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

```
apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
```

where *catalog_name* is the value of the **name** property of the required Catalog. The command returns

```
Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
```

4. Enter the following data, followed by a new line:

```
user_registry_url: oidc_registry_url
```

where *oidc_registry_url* is the URL of your OIDC registry, obtained in step [1](#).

5. Press **CTRL D** to terminate the input.

For details of all the `apic user-registries` and `apic configured-catalog-user-registries` commands, see [apic user-registries](#) and [apic configured-catalog-user-registries](#).

You can also complete the operations described in this topic by using the API Connect REST APIs; see the [API Connect REST API documentation](#).

Setting visibility for a user registry

The visibility setting determines which provider organizations can access a resource, for example, user registries.

Before you begin

You must complete the following tasks:

- [Creating an availability zone](#)
- [Registering a gateway service](#)

About this task

The user registry visibility setting controls which provider organizations are able to use that registry for authenticating Developer Portal users, or for securing APIs. For details on how to specify the user registries that can be used for authenticating users of the Cloud Manager and API Manager user interfaces, see [Selecting user registries for Cloud Manager and API Manager](#).

Procedure

Follow these steps to set the visibility for the resources (user registries) in your on-premises cloud:

1. In the Cloud Manager, click  Resources.
2. Select User Registries as the resource to view.
3. From the list of user registries, choose Edit visibility from the actions menu next to the name of the user registry you are working with.
4. Select the visibility setting for the user registry. The options are:
 - Private - the user registry is not visible and cannot be used by any provider organization
 - Public - the user registry is visible and can be used by all provider organizations
 - Custom - the user registry is visible only to the provider organizations designated by you
5. For Custom visibility, select the provider organizations that you want to have access to the user registry.
6. Click Make visible to complete the operation.

Results

For Private, the user registry cannot be used by any provider organizations. For Public, the user registry can be used by all provider organizations. For Custom, the user registry can be used by the provider organizations that you designate.

Deleting a user registry

As the Cloud Manager administrator, you can delete user registries.

About this task

Complete the following steps to delete a user registry. All users within the user registry will be deleted. The pre-configured user registries (API Manager Local User Registry and Cloud Manager Local User Registry) may not be deleted. Any user registry marked as the Default in Settings > User Registries also may not be deleted.

One of the following roles is required to delete a user registry:

- Administrator
- Owner

Procedure

1. In the Cloud Manager, click .
2. Select User Registries to see the list of current user registries in your cloud.
3. Choose Delete from the overflow menu that is adjacent to the user registry you want to delete.
4. Optionally, you can delete multiple user registries by marking the checkboxes and selecting Delete Selected User Registries from the overflow menu for the list.
5. Confirm the deletion.

Results

The user registry is deleted and removed from the User Registries list in Cloud Manager. All user accounts contained in the user registry are deleted.

Removing a user from a user registry

As an API Connect user, you can remove yourself from an API Connect user registry. As an administrative user, you can remove other users from an API Connect user registry.

For details on how to remove a user from a user registry, see the following subtopics:

- [Removing yourself from a user registry](#)
As an API Connect user, you can remove yourself from the API Connect user registry in which you were registered, by using the developer toolkit CLI.
- [Removing another user from a user registry](#)
You can remove a user from an API Connect user registry by using the developer toolkit CLI.

Removing yourself from a user registry

As an API Connect user, you can remove yourself from the API Connect user registry in which you were registered, by using the developer toolkit CLI.

Before you begin

You cannot remove yourself from a user registry if you are a member of a provider organization. Before removing yourself from a user registry, ensure that you have been deleted from any provider organizations. For more information, see [Removing a user from an organization](#).

Procedure

1. Log in to the management server as the user that you want to remove.

The format of the login command depends on whether you are a user in the Cloud Manager admin organization, or you are a user in a provider organization.

If you are a Cloud Manager admin user, enter the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

If you are a provider organization user, enter the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

If you want to log in as a member of the cloud administration organization, or as a member of a provider organization, you can help determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope scope --server mgmt_endpoint_url --fields title,realm
```

where `scope` has the value `admin` or `provider` depending on whether you want to log in as a member of the cloud administration organization, or as a member of a provider organization. The output lists the names and titles of all identity providers, for example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
- title: Cloud Manager User Registry
  realm: admin/default-idp-1
- title: Corporate LDAP user registry
  realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`, and the default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.

For full details of the `apic login` command, see [Logging in to a management server](#).

Note: If the same user registry is used for both the Cloud Manager and API Manager user interfaces, and you have access to both, when you remove yourself from the user registry you will lose access to both user interfaces regardless of which organization you log in to.

2. Remove yourself from the user registry. Enter the following command:

```
apic me:delete --server mgmt_endpoint_url
```

For example:

```
apic me:delete --server platform-api.myserver.com.com
```

The command confirms successful removal by returning the details of the deleted user; for example:

```
user1 [state: enabled] https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
```

Removing another user from a user registry

You can remove a user from an API Connect user registry by using the developer toolkit CLI.

Before you begin

To complete this task, you must have Administrator access to your API Connect cloud, or be the owner of a provider organization, depending on the scope of the user registry.

You cannot remove a user from a user registry if that user is a member of the Cloud Manager admin organization, a provider organization, or a consumer organization, and that user registry is used for the associated login. Before removing a user from a user registry, ensure that they have been deleted from any organizations for which that user registry is used for login. For more information, see [Deleting a member](#) or [Removing a user from an organization](#).

Procedure

1. Log in to the management server.
 - If the user registry is defined at the cloud administration level, and therefore available to all provider organizations, you must log in as a member of the Cloud Manager admin organization.
 - If the user registry is defined at a provider organization level, and therefore specific to that provider organization, you must log in as the organization owner.For full details of the `apic login` command, see [Logging in to a management server](#).

Note: If the same user registry is used for both the Cloud Manager and API Manager user interfaces, and the user has access to both, when you remove them from the user registry they will lose access to both even though you are logging in to the admin organization.

2. Identify the name of the user registry from which you want to remove the user. Enter the following command:

```
apic user-registries:list --server mgmt_endpoint_url --org organization_name
```

where `organization_name` has the value `admin` if you are logged in as a member of the Cloud Manager admin organization, or is the name of the provider organization if you are logged in as an organization owner.

For example:

```
apic user-registries:list --server platform-api.myserver.com.com --org admin
```

The command returns a list of all user registries, with the registry name displayed first; for example:

```
api-manager-lur https://platform-api.myserver.com.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245
cloud-manager-lur https://platform-api.myserver.com.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/3adb5f524-cd74-4051-99c0-89ce5ffcc9c0
my-ldap https://platform-api.myserver.com.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/29eae4113-cd74-4051-99c0-89ce5ffcc9c0
```

3. Identify the name of the user, from the required user registry, that you want to remove. Enter the following command:

```
apic users:list --server mgmt_endpoint_url --org organization_name --user-registry user_registry_name
```

For example:

```
apic users:list --server platform-api.myserver.com.com --org admin --user-registry my-ldap
```

The command returns a list of all users in the user registry, with the user name displayed first; for example:

```
user1 [state: enabled] https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
user2 [state: enabled] https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/12f1aa82-d9f0-4670-99f1-7500d1fb6583
```

4. Remove the required user from the user registry. Enter the following command:

```
apic users:delete user_name --server mgmt_endpoint_url --org organization_name --user-registry user_registry_name
```

For example:

```
apic users:delete user1 --server platform-api.myserver.com.com --org admin --user-registry my-ldap
```

The command confirms successful removal by returning the details of the deleted user; for example:

```
user1 [state: enabled] https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
```

TLS profiles overview

API Connect supports TLS Profiles for securing data transmission over HTTPS.

Introduction to TLS profiles

Important: API Connect includes several default TLS profiles to help you get started working with the application. The default profiles should not be used in a production environment. It is important to create your own profiles to ensure a secure network.

API Connect may need to transmit data across an untrusted network, for example, when accessing the Gateway, email server, or LDAP server. TLS provides secure network layer transportation of data between two parties.

There are two types of TLS Profiles: a TLS Server Profile and a TLS Client Profile. A TLS Server Profile is used by the Gateway to configure its endpoint for use during API execution. A TLS Client profile is used whenever the system needs to communicate with another endpoint over TLS.

The components of a TLS Profile are:

- TLS Protocol version indicates the versions of the Transport Layer Security Protocol required for the profile. TLS Protocol versions 1.0, 1.1, 1.2, and 1.3 are supported.
- Optional support for mutual authentication and renegotiation for Server Profiles.
- Optional support for weak server connections and Server Name Indication for Client Profiles.
- Cipher suites to secure HTTPs communication within the API Connect ecosystem.
- Keystores containing public and private key pairs.
- Truststores containing public keys for trusted third party services, such as Google, Facebook, or Verisign.

- [Viewing TLS Profiles, Keystores, and Truststores](#)
The current list of TLS profiles, Keystores, and Truststores can be viewed on the main TLS screen.
- [Creating a TLS Server Profile](#)
In Cloud Manager, you can configure the profile that is used on the gateway when it acts as a TLS server.
- [Creating a TLS Client Profile](#)
In Cloud Manager, TLS profiles are configured as a Resource to provide secure transmission of data over HTTPs.
- [Creating a Keystore](#)
Each keystore contain a matched pair of a public certificates and its private keys. These artifacts provide identity information during a TLS handshake.
- [Creating a Truststore](#)
A truststore contains a list of certificates. The certificates are used to verify the peer during a TLS handshake.
- [Viewing certificate details and adding certificates to a keystore or truststore](#)
You can view details for the certificates in an existing keystore or truststore and add additional certificates.
- [Generating a self-signed certificate using OpenSSL](#)
OpenSSL is an open source implementation of the SSL and TLS protocols. It provides the transport layer security over the normal communications layer, allowing it to be intertwined with many network applications and services.
- [Generating a PKCS#12 file for Certificate Authority](#)
PKCS#12 (P12) files define an archive file format for storing cryptographic objects as a single file. API Connect supports the P12 file format for uploading a keystore and truststore. The keystore should contain both a private and public key along with intermediate CA certificates.
- [Binding a TLS server profile to a gateway service](#)
You can bind the SSL certificate of a TLS profile to a gateway service to establish an HTTPS binding. This enables you to access the service by using the HTTPS communication protocol.
- [Updating the PKCS#12 certificate for a TLS server profile](#)
A server certificate bound to a gateway service can be invalidated if the host name in the digital certificate of the server does not match the URL specified by the client, or because it has expired. When this happens, you must update the TLS profile with a new CA certificate or PKCS#12 (P12) file.

Viewing TLS Profiles, Keystores, and Truststores

The current list of TLS profiles, Keystores, and Truststores can be viewed on the main TLS screen.

Before you begin

Important: API Connect includes several default TLS profiles to help you get started working with the application. The default profiles should not be used in a production environment. It is important to create your own profiles to ensure a secure network.

One of the following roles is required to view TLS Server Profiles:

- Administrator
- Owner
- Topology Administrator
- Viewer
- Custom role with the `Settings: Manage` or `Settings: view` permissions

About this task

The TLS list screen provides a list of TLS Profiles, Keystores and Truststores configured for your cloud. Users with view permissions can use this screen as a reference for the TLS Profiles.

Users with manage permissions can create new Profiles, Keystores, and Truststores; edit existing ones; and delete items that are no longer needed. Users can view the Keystores and Truststores assigned to the profiles.

Users can view and set the visibility for Client Profiles. For more information on visibility, see [Setting visibility for a TLS Client Profile](#)

Procedure

Following are the tasks you can perform using the list screen as a base:

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Complete your management task:
 - To create a new item, click Create next to the table for the type of item you want to create.
 - To edit an existing item, either click the Title of the item, or click the options menu  and then click Edit.
 - To set the visibility of a TLS Client Profile, click the options menu  for the profile, and then click Edit Visibility.
 - To delete an existing item, click the options menu  for the profile, and then click Delete.

Creating a TLS Server Profile

In Cloud Manager, you can configure the profile that is used on the gateway when it acts as a TLS server.

Before you begin

Important: API Connect includes several default TLS profiles to help you get started. The default profiles should not be used in a production environment. It is important to create your own profiles to secure your network.

One of the following roles is required to configure TLS Server Profiles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage permissions`

About this task

The Server profile is for the gateway when it is acting as the TLS server.

Procedure

Perform the following steps to create a TLS Server profile:

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Click Create in the TLS Server Profile table.
4. Enter the fields to configure the TLS Server Profile:

Field	Description
Title (required)	Enter a Title for the profile. The title is displayed on the screen.
Name (required)	The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage TLS Server Profiles, see apic tls-server-profiles .
Version (required)	Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, <i>MyProfile 1.0</i> and <i>MyProfile 1.1</i> .
Summary (optional)	Enter a description of the profile.
Protocols (required)	Select one or more supported TLS protocol versions. The default is 1.2.
Mutual Authentication (required)	Determines the level of two-way authentication for the server profile. In two-way authentication, the server responds to a client by sending a request for the client certificate. <ul style="list-style-type: none">• None (default) No support for mutual authentication.• Request Enable this option to request client authentication during the TLS handshake. When the application sends the request, the gateway requests that the application sends the certificate. If the client does not send the certificate, the certificate is not checked on the gateway.• Require Enable this option to require client authentication during the TLS handshake. When the application sends the request, the gateway requests that the application sends the certificate. If the client does not send the certificate, the TLS handshake fails and the request is blocked.
Limit Renegotiation (optional)	Client-initiated renegotiation allows the connection to be retried. The default is to prevent renegotiation. Remove the checkmark to allow renegotiation.
Keystore (required)	A keystore is a repository containing a public and private key pair. The Server Profile requires a keystore in order to securely identify the system. When an application sends an API request, the keystore is used to verify a matching certificate.
Truststore (optional)	A truststore is a repository containing certificates. The certificates are used to verify the peer during a TLS handshake. If, in addition to a keystore, a truststore is specified, the certificate is further checked for validity by ensuring that is signed by the root certificate, which must be in the truststore.
Ciphers (required)	Cipher suites are encryption/decryption algorithms used to secure HTTPs communication within the API Connect ecosystem. Select the ciphers that the profile supports. Note: The TLS 1.3 ciphers are clearly indicated. If you select TLS version 1.3 as one of the protocols for the profile but do not select any TLS 1.3 ciphers, all the TLS 1.3 ciphers are added to the list of ciphers supported by the profile. If you do not select TLS version 1.3 but select one or more TLS 1.3 ciphers, those ciphers are not added to the list of ciphers supported by the profile.

5. Click Save.

Creating a TLS Client Profile

In Cloud Manager, TLS profiles are configured as a Resource to provide secure transmission of data over HTTPs.

Before you begin

One of the following roles is required to configure TLS Profiles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

About this task

API Connect uses both TLS Server and TLS Client profiles. A TLS Server profile is presented when a communication request is received. The Server profile validates the request against the Keystore and protocol version to determine whether the connection is secure. The Client profile is presented to initiate communication with another system. Client Profiles may be made visible for use by provider organizations in policies in API Manager. See [Setting visibility for a TLS Client Profile](#).

Procedure

Perform the following steps to create a TLS Client profile:

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Click Create in the TLS Client Profile table.
4. Enter the fields to configure the TLS Client Profile:

Field	Description
Title (required)	Enter a Title for the profile. The title is displayed on the screen.
Name (required)	The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage a TLS Client Profile, see apic tls-client-profiles .
Version (required)	Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, <i>MyProfile 1.0</i> and <i>MyProfile 1.1</i> .
Summary (optional)	Enter a description of the profile.
Protocols (required)	Select one or more supported TLS protocol versions. The default is 1.2.
Server Connection (optional)	Specify whether to support weak or insecure credentials. <ul style="list-style-type: none">• Allow insecure server connections - Insecure server connections may result from self-signed certificates, expired or corrupted certificates, or certificates from an unknown or untrusted source. Check this box to allow the connection to proceed with an insecure connection. The default is to not allow insecure server connections.• Support Server Name Indication (SNI) - Check this box to enable SNI. SNI allows support for multiple certificates presented on the same IP address using different host names. The client profile sends the name of a virtual domain as part of the TLS negotiation. The default is to enable SNI.
Keystore (optional)	A Keystore is a repository containing public and private key pairs. Select the keystore where you will store the certificates for the profile. Default keystores are provided, and you can also create your own.
Truststore (optional)	A Truststore is a repository containing verified public keys, which are usually obtained from a third-party certificate authority. Truststores provide list of certificates to verify a peer's certificate. If used in a TLS Server Profile, a truststore is used when mutual authentication is enabled. Select a truststore for the profile. Default truststores are provided, and you can also create your own.
Ciphers (required)	Cipher suites are encryption/decryption algorithms used to secure HTTPs communication within the API Connect ecosystem. Select the ciphers that the profile supports. Note: The TLS 1.3 ciphers are clearly indicated. If you select TLS version 1.3 as one of the protocols for the profile but do not select any TLS 1.3 ciphers, all the TLS 1.3 ciphers are added to the list of ciphers supported by the profile. If you do not select TLS version 1.3 but select one or more TLS 1.3 ciphers, those ciphers are not added to the list of ciphers supported by the profile.

5. Click Save.

Setting visibility for a TLS Client Profile

The visibility setting determines which provider organizations can access a resource.

Before you begin

You must complete the following task:

- [Creating a TLS Client Profile](#)

About this task

The visibility setting gives you control over the resources that are available to provider organizations.

Procedure

Follow these steps to set the visibility for the resources in your on-premises cloud:

1. In the Cloud Manager, click  Resources.
2. Select TLS as the resource to view.
3. From the table of TLS Client Profiles, choose Edit visibility from the  options menu next to the name of the profile you are managing.
4. Select the visibility setting for the profile. The options are:
 - Private - the profile is visible only in Cloud Manager and cannot be used by any provider organization
 - Public - the profile is visible and can be used by all provider organizations
 - Custom - the profile is visible only to the provider organizations designated by you
5. For Custom visibility, select the provider organizations that you want to have access to the profile.
6. Click Save to complete the operation.

Results

For Private, the profile cannot be used by any provider organizations. For Public, the profile can be used by all provider organizations. For Custom, the profile can be used by the provider organizations that you designate. If visible, the profiles will be available in API Manager.

Defining elliptic curve cryptographic schemes for a TLS client profile

You define the elliptic curve cryptographic schemes for a TLS client profile by using the developer toolkit CLI.

About this task

To define elliptic curve cryptographic schemes for a TLS client profile, you include `elliptic_curve_auto_negotiation` and `elliptic_curve` properties in a YAML file definition for the TLS client profile. The `elliptic_curve` property lists the required elliptic curve cryptographic schemes. For example:

```
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - secp521r1
  - secp384r1
  - prime256v1
```

You then use the developer toolkit CLI to create the TLS client profile in API Connect.

When `elliptic_curve_auto_negotiation` is set to `true`, the system negotiates the Elliptic-curve Diffie-Hellman (ECDH) key agreement automatically with its peer, and any `elliptic_curve` property settings are ignored.

The following example shows a complete YAML file for a TLS client profile:

```
type: tls_client_profile
name: my-tls-client-profile
version: 1.0.0
title: My TLS client profile
protocols:
  - tls_v1.2
ciphers:
  - ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - sect163k1
insecure_server_connections: false
server_name_indication: true
```

Note:

- The `elliptic_curve_auto_negotiation` option is not supported by any of the API Connect gateway types. If the TLS client profile is targeted for an API Connect gateway; this setting is ignored by the gateway.
- The elliptic curve cryptographic schemes shown in each row of the following table are equivalent. However, API Connect recognizes only one or the other depending on how the TLS profile is used, as indicated in the table.

Table 1.

API enforcement on the gateway	API Connect server access security
secp192r1	prime192v1
secp256r1	prime256v1

Therefore, if you want to use either of these schemes and are unsure whether you are targeting the TLS client profile to the API Connect gateway for API enforcement, whether you are using it to secure user access to the API Connect servers, or whether it will be used for both purposes, specify both equivalent schemes; API Connect will simply ignore the non-relevant scheme. For example:

```
elliptic_curve:  
  .  
  .  
  .  
  - secp256r1  
  - prime256v1  
  .  
  .  
  .
```

Procedure

To create a TLS client profile with elliptic curve cryptographic schemes defined, complete the following steps:

1. Create a YAML file definition for your TLS client profile, with the required `elliptic_curve` property.
2. Log in to the management server from the developer toolkit CLI. Log in either as a member of the cloud administration organization or as a member of a provider organization, depending on where you want to create the TLS client profile. For details, see [Logging in to a management server](#).
3. Create the TLS client profile by using the following command:

```
apic tls-client-profiles:create --server mgmt_endpoint_url --org organization_name tls_client_profile_yaml_file
```

where:

- `mgmt_endpoint_url` is the platform API endpoint URL, and is the same as that which was used when you logged in at step 2.
- `organization_name` is either `admin`, for the cloud administration organization, or the name of your provider organization, and is the same as that which was used when you logged in at step 2.
- `tls_client_profile_yaml_file` is the name of the YAML file that contains the definition for your TLS client profile.

Note: When you install IBM® API Connect, the API Connect gateway has a pre-supplied default TLS client profile that is used for API enforcement if you do not configure a TLS client profile; you cannot configure this default TLS client profile on the gateway.

For reference details of all the `apic tls-client-profiles` commands, see [apic tls-client-profiles](#).

You can also complete the operations described in this topic by using the API Connect REST APIs; see the [API Connect REST API documentation](#).

Creating a Keystore

Each keystore contain a matched pair of a public certificates and its private keys. These artifacts provide identity information during a TLS handshake.

Before you begin

Cloud Manager and API Manager both support and use TLS certificates, but they do not themselves produce strong encryption keys or manage your encryption keys. Encryption keys are generated and managed according to your own procedures. For more information, see [Generating a PKCS#12 file for Certificate Authority](#) and [Generating a self-signed certificate using OpenSSL](#).

One of the following roles is required to configure Keystores:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings`: `Manage permissions`

About this task

API Connect includes pre-configured Keystores which may be used for testing purposes. For production environments, we suggest creating a new, secure Keystore.

Procedure

Perform the following steps to create a TLS Client profile:

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Click Create in the Keystore table.

Field	Description
Title (required)	Enter a Title for the Keystore. The title is displayed on the screen.

Field	Description
Name (required)	The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage keystores, see apic keystores .
Summary (optional)	Enter a brief description.
Private Key & Public Key: Step 1: Upload private key	Upload the file containing the private key certificate. If necessary, you can click Browse to locate the file. If the file contains both the private and public keys, upload it in Step 1. Private and public keys are always uploaded in pairs, either in a single file or separate files.
Private key password (optional)	Enter the password for the private key if it has a password.
Private Key & Public Key: Step 2: Upload public key	If the public key is contained in a separate file, upload it in Step 2. Private and Public keys are always uploaded in pairs, either in a single file or separate files.

4. Click Save.

Note: After they have been uploaded, private keys cannot be downloaded from API Connect.

Viewing certificate details and adding certificates to a keystore or truststore

You can view details for the certificates in an existing keystore or truststore and add additional certificates.

Before you begin

One of the following roles is required to edit Keystores and Truststores:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

About this task

API Connect includes pre-configured Keystores and Truststores which you can use for testing purposes. For production environments, we suggest creating a new, secure Keystore or Truststore. From an existing Keystore or Truststore, you can edit the title, view the details of the certificates, and add new certificates.

Procedure

To work with existing keystores and truststores:

1. In the Cloud Manager, click  Resources.
2. Select TLS.
3. Click the name of the keystore or truststore.
4. Edit the name and summary if needed.
5. The Subject, Finger Print, and Expiration date is shown for each certificate in the keystore or truststore. Click > to view the certificate details.
6. Add additional private and/or public keys if needed.
7. Click Save.

Note: After they have been uploaded, private keys cannot be downloaded from API Connect.

Generating a self-signed certificate using OpenSSL

OpenSSL is an open source implementation of the SSL and TLS protocols. It provides the transport layer security over the normal communications layer, allowing it to be intertwined with many network applications and services.

Before you begin

One of the following roles is required to complete this task:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

About this task

This topic tells you how to generate a self-signed SSL certificate request using the OpenSSL toolkit to enable HTTPS connections.

Procedure

To generate a self-signed SSL certificate using the OpenSSL, complete the following steps:

1. Write down the Common Name (CN) for your SSL Certificate. The CN is the fully qualified name for the system that uses the certificate. For static DNS, use the hostname or IP address set in your Gateway Cluster (for example, `192.16.183.131` or `dp1.acme.com`).
2. Run the following OpenSSL command to generate your private key and public certificate. Answer the questions and enter the Common Name when prompted.

```
openssl req -newkey rsa:2048 -nodes -keyout key.pem -x509 -days 365 -out certificate.pem
```

3. Review the created certificate:

```
openssl x509 -text -noout -in certificate.pem
```

4. Combine your key and certificate in a PKCS#12 (P12) bundle:

```
openssl pkcs12 -inkey key.pem -in certificate.pem -export -out certificate.p12
```

5. Validate your P2 file.

```
openssl pkcs12 -in certificate.p12 -noout -info
```

Once the certificate file is created, it can be uploaded to a keystore.

6. In the Cloud Manager, click  Resources.

7. Select TLS.

8. Click Create in the Keystore table.

9. Create a Keystore and upload the certificate file following the instructions at [Creating a Keystore](#).

Note:

- API Connect supports only the P12 (PKCS12) format file for the present certificate.
- Your P12 file must contain the private key, the public certificate from the Certificate Authority, and all intermediate certificates used for signing.
- Your P12 file can contain a maximum of 10 intermediate certificates.

10. Click Save.

Generating a PKCS#12 file for Certificate Authority

PKCS#12 (P12) files define an archive file format for storing cryptographic objects as a single file. API Connect supports the P12 file format for uploading a keystore and truststore. The keystore should contain both a private and public key along with intermediate CA certificates.

Before you begin

One of the following roles is required to add a key to a keystore or truststore:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings`: `Manage permissions`

Before you can generate a P12 file, you must have a private key (for example: `key.pem`), a signed certificate by a Certificate Authority (for example `certificate.pem`) and one or more certificates from the CA authority.

Note: If your certificate file contains more than one certificate, you must manually split the file and create a single file for each entry. Each entry must be bound by the following markers:

```
-----BEGIN CERTIFICATE-----
```

```
-----END CERTIFICATE-----
```

Procedure

1. If you have intermediate certificates from your CA, concatenate them into a single `.pem` file to build your `caChain`. Be sure to enter a new line following each certificate's data.

```
cat ca1.pem ca2.pem ca3.pem > caChain.pem
cat caChain.pem
-----BEGIN CERTIFICATE-----
MIIEPjCCA46gAwIBAgIQEod26KZabjd+BQMG1Dw16jANBgkqhkiG9w0BAQUFADCB
...
lQX7CkTJn61AJUusyEa8H/gjVQnHp4VOLFR/dKgeVcCRvZF7Tt5AuiyHY
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
MIIEPDCCAySgAwIBAgIQSEus8arH1xND0aJ0NUmXJTANBgkqhkiG9w0BAQUFADBv
...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
MIIEjCCAx6gAwIBAgIBATANBgkqhkiG9w0BAQUFADBvMQswCQYDVOQGEWJTRTEU
...
-----END CERTIFICATE-----
```

2. Create the P12 file including the private key, the signed certificate and the CA file you created in step 1, if applicable. Omit the `-cafile` option if you don't have CA certificates to include.

The following command uses OpenSSL, an open source implementation of the SSL and TLS protocols.

```
openssl pkcs12 -inkey key.pem -in certificate.pem -export -out certificate.p12 -CAfile caChain.pem -chain
```

Once the certificate file is created, it can be uploaded to a keystore.

3. In the Cloud Manager, click  Resources.
4. Select TLS.
5. Click Create in the Keystore table.
6. Create a Keystore and upload the certificate file following the instructions at [Creating a Keystore](#).

Note:

- API Connect supports only the P12 (PKCS12) format file for the present certificate.
- Your P12 file must contain the private key, the public certificate from the Certificate Authority, and all intermediate certificates used for signing.
- Your P12 file can contain a maximum of 10 intermediate certificates.

7. Click Save.

Binding a TLS server profile to a gateway service

You can bind the SSL certificate of a TLS profile to a gateway service to establish an HTTPS binding. This enables you to access the service by using the HTTPS communication protocol.

Before you begin

One of the following roles is required:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Topology: Manage permissions`

For more information on which user roles have access, see [Adding members to the admin organization](#).

About this task

Perform the following steps to bind a TLS profile to a gateway service.

Procedure

1. In the Cloud Manager user interface, click  Topology, then select the gateway service that you want to work with.
2. Scroll down to the API Invocation Endpoint section, and under Server Name Indication (SNI) select the required TLS server profile.
You can also bind a TLS server profile during the initial registration of a gateway service; see [Registering a gateway service](#).
3. Click Save when done.

Results

The TLS profile binds to the gateway service.

Related tasks

- [Creating a TLS Server Profile](#)

Updating the PKCS#12 certificate for a TLS server profile

A server certificate bound to a gateway service can be invalidated if the host name in the digital certificate of the server does not match the URL specified by the client, or because it has expired. When this happens, you must update the TLS profile with a new CA certificate or PKCS#12 (P12) file.

Before you begin

One of the following roles is required:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage permissions`

About this task

If the expiration date of a certificate or a P12 file is approaching, or if a certificate is invalidated, use the steps in this topic to update a TLS profile bound to a gateway service. CA certificate and P12 file expiration dates are displayed in the details of the containing keystore; see [step 3](#).

You update the certificate for a TLS server profile by replacing the certificate in the keystore that is associated with the TLS server profile.

Complete the following steps to update a TLS profile that has an invalidated or expired certificate or P12 file.

Procedure

1. In the Cloud Manager user interface, click  Resources, then click TLS.
2. To identify the keystore that is associated with the TLS server profile, complete the following steps:
 - a. In the TLS Server Profile section, select the required profile.
 - b. In the Keystore/Truststore section, note the selected keystore, then click Cancel to close the TLS server profile details page.
3. In the Keystore section, select the required keystore.
The Certificates section displays the expiration date of a certificate. You can expand a certificate to see further details.
4. Click Browse and select the required P12 file.
Note:
 - API Connect supports only the P12 (PKCS12) format file for the present certificate.
 - Your P12 file must contain the private key, the public certificate from the Certificate Authority, and all intermediate certificates used for signing.
 - Your P12 file can contain a maximum of 10 intermediate certificates.
5. Click Save when done.

OAuth Provider overview

API Connect supports OAuth Specification 2.0, for both Native and Third party implementations.

Introduction to OAuth

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information. In API Connect, you can secure an API with OAuth.

In Cloud Manager, you configure both Native and Third party OAuth providers that can be made visible to selected Provider organizations. The OAuth Provider configuration is based on the OAuth 2.0 Specification, which is available at <https://tools.ietf.org/html/rfc6749>. Knowledge of the OAuth 2.0 specification is required to implement an OAuth Provider in API Connect.

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage permissions`

Note: In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- [Configuring a native OAuth provider](#)
Native OAuth providers are configured and managed by you within your cloud.
- [Configuring a third-party OAuth provider](#)
Enter the secure endpoints to provide OAuth authentication from a third party.

The visibility setting determines which provider organizations can use an OAuth provider to secure APIs.
- [OAuth concepts for API Connect](#)

Configuring a native OAuth provider

Native OAuth providers are configured and managed by you within your cloud.

About this task

A native OAuth provider object provides settings for OAuth processing operations such as generating and validating OAuth tokens. An OAuth provider object is referenced by an OAuth security definition to protect an API. When a native OAuth provider is used, the OAuth operations are performed natively by API Connect.

Every OAuth provider object has a backing API. Your configuration here automatically updates the OpenAPI document of the API. You can edit the OpenAPI document directly by navigating to the  Resources > OAuth Providers page, selecting your OAuth provider, then clicking API Editor.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example:

- If you change the name of auto generated assembly actions in the source code, the assembly will be prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the `oauth-provider-settings-ref` field in each OAuth assembly action.

When a published API references an OAuth provider object, the backing API is automatically made available in the gateway.

Token requests and client_id checks:

If you are calling an OAuth endpoint, the sequence of `client_id` checks in the token request is as follows:

1. Check both body and query.
 - If found in only the body, validate and return a **200** or appropriate return code.
 - If found in only the query, return a **wrong location** error.
 - If found in both the body and the query, return a **more than one location** error.
2. When not found in the body or the query, check the **Authorization** header.
 - If found in this header, validate and return a **200** or appropriate return code.
3. Not found, return the appropriate error and code.

The best location for the `client_id` is in the request body.

One of the following roles is required to configure a native OAuth provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note:

- The OAuth provider logs Analytics data for failure cases, but does not log successful cases. Activity log policies that call for logging of Analytics data upon success do not apply for the OAuth provider.
- You must ensure the OAuth Provider is configured in the Sandbox Catalog before using the OAuth Provider in a non-Sandbox Catalog.

Procedure

OAuth provider configuration uses a series of screens. The first set of screens controls a basic OAuth provider configuration. Perform the following steps to configure a native OAuth Provider for your cloud:

1. In the Cloud Manager, click  Resources.
2. Click OAuth Providers > Add > Native OAuth provider.
 - a. Complete the following parameters for the first screen, then click Next.

Field	Description
Title	Enter a title for the native OAuth provider.
Name	This field is auto-populated by the system.
Description (optional)	Enter a brief description.
Base path (optional)	The base path is the URL segment of the API that is shared by all operations in the API. It does not include the host name or any additional segments for paths or operations. The base path must be unique for a given catalog. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
Gateway Type	Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For information about types of gateways, see API Connect gateway types . OAuth Providers apply to one gateway type.

- b. In the next screen, enter the following additional configuration parameters, then click Next.

Field	Description
Authorize Path	<code>/oauth2/authorize/</code> is the standard OAuth endpoint to login to account
Token Path	<code>/oauth2/token/</code> is the standard OAuth endpoint to exchange code for access token.
Supported grant types	<ul style="list-style-type: none"> • Implicit - An access token is returned immediately without an extra authorization code exchange step. • Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." Does not require User Security. • Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code." • Resource owner - Password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients. • API Gateway only Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token.
Supported client types	<ul style="list-style-type: none"> • Confidential - Client can maintain secure credentials on a secure server • Public - Client credentials are not secure.

- c. Enter the scopes in the next screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

Field	Description
sample_scope_1	Scope for token
additional scopes	Scope for token

- d. Enter the parameters for User Security in the next screen. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User Security is not required for the Application grant type. Click Next when done.

Field	Description
Identity Extraction	<p>Determines how the user credential is extracted:</p> <ul style="list-style-type: none"> Basic Authentication - HTTP basic authentication (requires no additional configuration) Default HTML Form - Use default login form for user name and password API Gateway only Context variable - Specify which variable contains the user name and password. API Connect OAuth context variables as listed here API Connect context variables Note: DataPower API Gateway only. Not available for DataPower Gateway (v5 compatible). Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML login form for user security. Redirect - Enter an endpoint to redirect to a third-party identity provider. For more information, see Authenticating and authorizing through a redirect URL. API Gateway only Disabled - do not collect the user credential <p>Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint must maintain the order of the query parameters before the <code>state_nonce</code> query parameter, otherwise the authorization fails.</p>
Authentication	<p>Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL User Registry. For a DataPower API Gateway, you have the option to disable authentication with a user registry.</p>
Authorization	<p>The following methods for extracting the user credential are available:</p> <ul style="list-style-type: none"> Authenticated - Authorize authenticated users automatically. Default HTML Form - Use default HTML form to authorize. Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML authorization form for user security. API Gateway only Disabled - Disable authorization.

- Review the Summary for the native OAuth provider configuration.
- Click Back to make changes.
- Click Finish to save the basic configurations and to proceed to the Advanced Parameters for a native OAuth Provider.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring basic settings for a native OAuth provider

You can update the identification details and basic configuration settings for a native OAuth provider.

About this task

One of the following roles is required to configure the basic settings for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the basis settings pages for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the basic settings for an existing native OAuth provider. If you want to update the basic settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

- Click  Resources > OAuth Providers.
- Select the required native OAuth provider.

Procedure

1. To modify the identification details, click Info in the sidebar menu, then update the following fields as required:

Field	Description
Title	Enter a title for the native OAuth provider.
Name	This field is auto-populated by the system.
Description (optional)	Enter a brief description.
Base path (optional)	The base path is the URL segment of the API that is shared by all operations in the API. It does not include the host name or any additional segments for paths or operations. The base path must be unique for a given catalog. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.

2. To modify the basic configuration settings, click Configuration in the sidebar menu, then update the following fields as required:

Field	Description
Authorize Path	<code>/oauth2/authorize/</code> is the standard OAuth endpoint to login to account
Token Path	<code>/oauth2/token/</code> is the standard OAuth endpoint to exchange code for access token.
Supported grant types	<ul style="list-style-type: none">• Implicit - An access token is returned immediately without an extra authorization code exchange step.• Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." Does not require User Security.• Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code."• Resource owner - Password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients.• API Gateway only Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token. Tip: Selecting only the Resource owner - JWT grant type when defining a native OAuth provider in the user interface is not supported and results in an invalid configuration. To avoid this problem, additionally select either the Access code or the Resource owner - Password grant type. Note: If you plan to configure OpenID Connect (OIDC) for a native OAuth provider, you must include at least one of the following grant types: Implicit, Access code.
Supported client types	<ul style="list-style-type: none">• Confidential - Client can maintain secure credentials on a secure server• Public - Client credentials are not secure.

DataPower Gateway (v5 compatible) only Note: If the gateway type is DataPower® Gateway (v5 compatible) and, when the native OAuth provider was created, only the Application grant type was selected, you cannot add further grant types until you configure the user security settings. In particular, you must specify the user registry for authenticating application users. To configure the user security settings, complete the following steps:

- a. Click User Security in the sidebar menu, then click Edit.
 - b. Update the user security settings as required; for more details, see [Configuring user security for a native OAuth provider](#).
 - c. Click Save when done.
3. Click Save when done.

Configuring scopes for a native OAuth provider

Access tokens contain authorization for specific scopes.

About this task

Client applications can request only the scopes or a subset of the scopes that you define here. The scopes are included in the access tokens that are generated from the provider. When an OAuth protected API is invoked, the gateway checks the scopes carried in the access tokens against the list of allowed scopes in the security definition for the API to determine whether to grant access.

In addition, you can enforce advanced scope checks. The advanced scope check URLs are invoked after application authentication or after user authentication based on which URLs are configured. The final scope permission that is granted by the access token is the result of all scope checks.

Per IETF RFC 6749, the value of the scope parameter is a list of space-delimited, case-sensitive strings. For more information, see [The OAuth 2.0 Authorization Framework](#).

One of the following roles is required to configure scopes for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the scope settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the scope settings for an existing native OAuth provider. If you want to update the scope settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure the scopes for the access token:

1. Click Scopes in the sidebar menu. The currently configured scopes are listed. Review and update the scopes as required.

Field	Description
-------	-------------

Field	Description
sample_scope_1	Scope for token
additional scopes	Scope for token

In the Default scopes section, select the default scopes to be used if the API request doesn't contain any scopes. If no default scope is defined, and the request doesn't contain a scope, an invalid scope error is returned for the request.

If the user authorization method is set to Default HTML Form in the User Security settings, all scopes specified here are added automatically to the authorization consent form.

- Advanced scope check before token generation. This setting specifies the scope check endpoint where additional scope verification is performed in addition to the basic scopes. The advanced scope check URLs are invoked after application authentication or after owner authentication based on which URLs are configured. The scopes are included in the token and will overwrite any previous scopes.

Field	Description
Application scope check	Allow extra verification by running a scope check from an endpoint. Enter the endpoint and an optional TLS Profile to use for an application scope check.
Owner scope check	Further refine the scope with an additional check. Enter the endpoint and an optional TLS Profile to use for an owner scope check.

For more information about scope, see [Scope](#)

- Advanced scope check after token generation. This setting specifies an additional scope check at the API consumer level to verify compliance with the scope requirements of the API.

Field	Description
Enabled	Select the check box to enable the advanced scope check after token validation. Enter an optional default validator endpoint.
Use endpoint from API	Select the check box to use the endpoint from the API, or clear the check box to override the endpoint from the API.

For more information about scope, see [Scope](#)

- Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider with the specified scopes can be used to secure the APIs in catalog.

Related information

- [Scope](#)

Configuring user security for a native OAuth provider

Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.

About this task

User security authenticates the user. It is required for the Implicit, Access code, and Resource owner - Password grant types. It is not used for the Application or Resource owner - JWT grant types.

One of the following roles is required to configure user security for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the user security settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the user security settings for an existing native OAuth provider. If you want to update the user security settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

- Click  Resources, > OAuth Providers.
- Select the required native OAuth provider.

Procedure

Perform the following steps to configure the user security settings for the OAuth Provider:

- Click User Security in the sidebar menu.
- Specify the following parameters for User Security. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User Security is not required for the Application or Resource owner - JWT grant types. Click Next when done.

Field	Description
-------	-------------

Field	Description
Identity Extraction	<p>Determines how the user credential is extracted:</p> <ul style="list-style-type: none"> Basic Authentication - HTTP basic authentication (requires no additional configuration) Default HTML Form - Use default login form for user name and password API Gateway only Context variable - Specify which variable contains the user name and password. API Connect OAuth context variables as listed here API Connect context variables Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML login form for user security. Redirect - Enter an endpoint to redirect to a third-party identity provider. For more information, see Authenticating and authorizing through a redirect URL. API Gateway only Disabled - do not collect the user credential <p>Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint must maintain the order of the query parameters before the state_nonce query parameter, otherwise the authorization fails.</p>
Authentication	Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL User Registry.
Authorization	<p>Various methods may be used to authorize application users. For a DataPower® API Gateway, the following methods for extracting the user credential are available:</p> <ul style="list-style-type: none"> Authenticated - Authorize authenticated users automatically. Default HTML Form - Use default HTML form to authorize. If you select the Default HTML Form method, all scopes that are specified in the Scopes settings are added automatically to the authorization consent form. Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. API Gateway only Disabled - Disable authorization.

3. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Related information

Configuring tokens for a native OAuth provider

Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.

About this task

Access tokens are granted to the client application to allow the application to access resources on behalf of the application user. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or more narrow scope. You can also specify how long the consent given by the combination of any number of access and refresh token remains valid.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the token settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the token settings for an existing native OAuth provider. If you want to update the token settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

- Click  Resources, OAuth Providers.
- Select the required native OAuth provider.

Procedure

Perform the following steps to configure tokens for the native OAuth provider:

- Click Tokens in the sidebar menu.
- Define the settings to configure tokens.

Field	Description
Access tokens time to live	Enter the expiration time period in seconds for access tokens.

Field	Description
<input checked="" type="checkbox"/> API Gateway only One time use access token	Click the check box to enable one time use for the access token. Access tokens are multiple use by default which allows them to be used for multiple requests. When one time use is enabled, the access token will be consumed after one use. The OAuth flow will need to be repeated to obtain another access token. Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: <ul style="list-style-type: none"> Configuring token management and revocation for a native OAuth provider (Cloud Manager) Configuring token management and revocation for a native OAuth provider (API Manager)
Refresh tokens	Click the check box to enable Refresh tokens. Set the Count to limit the number of times a refresh token can be issued. Set the Refresh Token Time to Live value to determine the time to live, or expiration time period, for each refresh token in seconds.
One time use refresh token	Clear the check box to disable one time use for the refresh tokens. Refresh tokens are one time use by default which allows them to be used one time only to generate an access token and a new refresh token. When refresh token one time use is disabled then the refresh token count is limited to one and the refresh token can be used multiple times to generate new access tokens, however, another refresh token will not be generated unless the initial OAuth flow (Authorization Code or Password) is repeated. Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: <ul style="list-style-type: none"> Configuring token management and revocation for a native OAuth provider (Cloud Manager) Configuring token management and revocation for a native OAuth provider (API Manager)
Maximum consent	Click the check box to enable Maximum consent and enter the Maximum Consent Time to Live value in seconds. This is the time to live, or expiration time period, for all tokens, both access and refresh.
<input checked="" type="checkbox"/> API Gateway only Token secret	Click the check box to select the Shared Secret which was configured for the gateway. If no Shared Secret was entered in the Gateway Configuration, then enter an key name and key value to use as the token secret.
<input checked="" type="checkbox"/> API Gateway only Proof Key for Code Exchange	Proof Key for Code Exchange (PKCE) is a method to protect OAuth 2.0 public clients from an authorization code interception attack when they use Authorization Code grant requests. You can enable this extension when deploying with the DataPower® API Gateway. For more information, see RFC 7636 . Select the options for your OAuth Providers: <ul style="list-style-type: none"> Enable proof key for code exchange If selected, enforces PKCE when submitted in Authorization Code grant requests. Always required If selected, requires PKCE in all Authorization Code grant requests. Allow plain Select this check box to allow the plain challenge method in Authorization Code grant requests.

3. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Related information

- [Refresh tokens](#)

Configuring token management and revocation for a native OAuth provider

Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.

About this task

Token management enables you to prevent replay attacks by configuring token revocation. API Connect supports token revocation using a native gateway (DataPower) or a third party endpoint. For a native gateway, quota enforcement is used to manage tokens. For a third-party endpoint, a URL to an external service is used to manage tokens.

For more information, see the IETF RFC 7009 [OAuth 2.0 Token Revocation](#).

Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

One of the following roles is required to configure token management and revocation for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the token management settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the token management settings for an existing native OAuth provider. If you want to update the token management settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

- Click  Resources, > OAuth Providers.
- Select the required native OAuth provider.

Procedure

Perform the following steps to configure revocation settings for tokens:

1. Select Token Management in the sidebar menu.
2. Enable token management by selecting the check box.
3. From the Type list, select either Native or External. Native points to DataPower as the token storage location; External points to a revocation URL for token storage.
Note: If you are using the API Manager user interface then, for the External option to be available, you must be using DataPower® API Gateway Version 10.0.1.0 or later, and the gateway service must be enabled in the Sandbox Catalog; for details on how to enable a gateway service in a Catalog, see [Creating and configuring Catalogs](#).
4. For Native, select one or both of the Resource owner revocation path and Client revocation path.
 - Resource owner revocation path - Uses the standard OAuth revocation path to allow the resource owner (end user) to revoke the application permission.
 - Client revocation path - Uses the standard OAuth revocation path to allow the client (application) to revoke a single token when the application closes.For more information about managing tokens with the Native DataPower Gateway, see [Token management with the native DataPower Gateway](#).
5. For External, the settings depend on the gateway type, as follows:
 - DataPower API Gateway:
 - Endpoint - the URL of the external management endpoint.
 - TLS Client Profile (optional) - the TLS client profile to secure connections.
 - Security - how to secure connections. The only supported method is basic authentication.
 - Basic authentication username (optional) - the user name for authentication.
 - Basic authentication password (optional) - the password for authentication.
 - Basic authentication request header name (optional) - the request header that contains the authentication string; if you supply both a request header name and user name/password, the request header authentication method is used.
 - Custom header pattern (optional) - the name pattern of the headers to use for sending additional information to the external management service.
 - Cache type - the cache type to control whether and how to cache positive responses. If you select Time to live, specify how long to keep responses in the cache; the default value is 900 seconds.
 - Fail on error - if selected, processing is stopped if the connection to the external management service fails.
 - Note: For details of the JSON format that is required when exchanging messages with the external management service, see [JSON format to exchange messages with the external management service](#).
 - DataPower Gateway (v5 compatible):
 - Endpoint - Enter the URL to an external web server that contains information about access or refresh tokens. API Connect calls the URL to determine if the associated token can be trusted. The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing. For more information see [Token revocation](#).
 - TLS Client Profile - Select a TLS profile to verify the external endpoint.
6. Click Save when done.

Results

Depending on the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring introspection for a native OAuth provider

Define an introspection path to allow the metadata for an access token to be examined.

About this task

Token introspection allows an authorized holder of an access token to examine the contents of tokens using an introspection path. The access token to introspect must be obtained through the native OAuth provider. Introspection provides context for the token by allowing an authorized protected resource to query the authorization server to determine the set of metadata for a given token. The metadata includes whether or not the token is currently active, the scopes assigned to the token, and the authorization context in which the token was granted (including who authorized the token and which client it was issued to). API Connect token introspection conforms to IETF RFC 7662. See [OAuth 2.0 Token Introspection](#).

One of the following roles is required to enable introspection for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the introspection settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the introspection settings for an existing native OAuth provider. If you want to update the introspection settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to enable introspection:

1. Click Introspection in the sidebar menu.
2. Select the check box to enable Introspection. The OAuth standard path for introspection, `/oauth2/introspect` is automatically entered. This path will be used when another entity inspects the token contents.
3. Click Save when done.

Results

Tokens will be queried using the /oauth2/introspect path. Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring metadata for a native OAuth provider

Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

About this task

Configure an Authentication URL or an External URL from which custom metadata is collected for inclusion in the token. The metadata is either stored inside the access token or it is sent along with the access token to the client application. For more information about how the metadata is collected, see [OAuth external URL and authentication URL](#).

Following are examples of metadata that can be included with the access token:

- Metadata about the authenticated resource owner
- Grant type that was used to obtain the token
- A confirmation code to be provided to the client application

One of the following roles is required to configure metadata collection for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the metadata settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the metadata settings for an existing native OAuth provider. If you want to update the metadata settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure metadata collection:

1. Click Metadata in the sidebar menu.
2. Select Collect metadata to enable metadata collection.
3. The Authentication URL user registry is selected by default and is required. For more information about the Authentication URL, see [Authentication URL user registry](#).
4. Select the External URL to collect metadata from an external URL. Enter the endpoint and an option TLS Client Profile.
5.  If required, override the default Header name token value. The value of this header, if returned in the response from the OAuth endpoint, is placed in the response payload and indicated as **metadata**.
6.  If required, override the default Header name payload value. The value of this header, if returned in the response from the OAuth endpoint, is placed within the access token and indicated as **miscinfo**.
7. Save the OAuth Provider.
8. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring the OIDC parameters for a native OAuth provider

Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.

About this task

When you enable OpenID connect, a template is provided for generating ID tokens along with access tokens and the required assembly policies are automatically created. You can customize the policies to suit your needs in the API Editor. The sample key provided is for test purposes only and is used to sign the JWT token.

One of the following roles is required to configure an OIDC template for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note: You can configure OIDC parameters only if the selected grant types for the native OAuth provider include at least one of the Implicit or Access code grant types; see [Configuring basic settings for a native OAuth provider](#).

You can select the OIDC settings page for a native OAuth provider immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the OIDC settings for an existing native OAuth provider. If you want to update the OIDC settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure an OIDC template:

1. Click OpenID Connect in the sidebar menu.
2. Select the initial check box to configure an OIDC Template. Enter the following parameters:

Field	Description
 Support hybrid response types (optional)	Select the response types for the OpenID Connect hybrid flow to be supported by this OAuth provider.
 OpenId Connect URL	Optionally specify a URL that is exposed by the provider and allows a client to send a request for information about the provider's publicly visible configuration. If you select the provider in the OIDC security definition for an OpenAPI 3 API, this URL is configured for you based on that information.
 ID token issuer	Descriptive text to indicate the source of the key.
 ID token signing key	Specify the JSON Web Key (JWK) to be used to sign the ID token.
 ID token signing algorithm	Select the algorithm used to sign the token.

3. Click Save when done. You can edit the policies by using the API Editor.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Editing a native OAuth provider by using the API Editor

You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

About this task

If you have configured an OIDC template, you can customize it in API Editor. In the API Editor, the Source tab allows you to edit the code for the configuration using a text editor. The API Assemble tab provides a graphical drag-and-drop editor (identical to the one in API Manager) that allows you to add additional elements to the assembly for the OAuth Provider.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example:

- If you change the name of auto generated assembly actions in the source code, the assembly will be prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the `oauth-provider-settings-ref` field in each OAuth assembly action.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can modify the native OAuth provider configuration by selecting the API Editor page immediately on completion of the creation operation detailed in [Configuring a native OAuth provider](#), or you can update the configuration for an existing native OAuth provider. If you want to update the configuration for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click  Resources, OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to edit the OAuth configuration:

1. Click API Editor in the sidebar menu.
2. In the Source tab, view and edit the policies to customize the behavior for the OAuth provider.
3. In the API Assemble tab, use the drag and drop editor to add additional policies to the OIDC behavior.
Note: If you add a policy that references a TLS profile, an `invoke` policy for example, then when you publish an API that uses this OAuth provider, you must ensure that the TLS profile is enabled for the Catalog to which you publish the API. For details on how to enable a TLS profile in a Catalog, see [Creating and configuring Catalogs](#).

4. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring a third-party OAuth provider

Enter the secure endpoints to provide OAuth authentication from a third party.

About this task

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Procedure

Complete the following steps to configure a third party OAuth provider:

1. In the Cloud Manager, click  Resources.
2. Select OAuth Providers > Add > Third party OAuth Provider.
 - a. Complete the following parameters for the first screen and click Next.

Field	Description
Title	Enter a descriptive title for the gateway service. This title will be displayed on the screen.
Name	This field is auto-populated by the system and used as the internal field name.
Supported grant types	Select from the following options: <ul style="list-style-type: none"> • Implicit: An access token is returned immediately without an extra authorization code exchange step. • Application: Application to application. Corresponds to the OAuth grant type Client Credentials. Does not require User Security. • Access code: An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type Authorization Code. • Resource owner - Password: The user's username and password are exchanged directly for an access token, so can only be used by first-party clients. • API Gateway only Resource owner - JWT: a JSON Web Token (JWT) Bearer Token is used as a means for requesting an OAuth 2.0 access token, and for client authentication, as defined by the JSON Web Token (JWT) Profile for OAuth 2.0 Client Authentication and Authorization Grants.
Gateway type	Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For information about types of gateways, see API Connect gateway types . OAuth Providers apply to one gateway type.

- b. Specify configuration settings for the endpoints.

Field	Description
Authorization URL	An authorization URL where the resource owner grants authorization to the client application to access a protected resource. Example: <code>https://example.com/oauth2/authorize</code>
Token URL	A token request URL where the client application exchanges an authorization grant for an access token. Example: <code>https://example.com/oauth2/token</code>
Introspect URL	The introspection URL is where the API gateway validates the access tokens that are issued by the third party provider. Example: <code>https://example.com/oauth2/introspect</code> For more information on integrating third party OAuth providers for introspection, see OAuth introspection for third-party OAuth providers .
API Gateway only Introspect cache type	The cache type determines how long responses from the third party provider are cached, if at all. Select one of the following options: <ul style="list-style-type: none"> • No cache (default): Responses are not cached. • Protocol: Defined by the <code>cache-control</code> header in the provider response. • Time to live: Defined by the provider.
API Gateway only Cache Time to Live	The length of time, in seconds, for which provider responses are cached, if the Introspect cache type is set to Time to live. The default value is 900.
TLS Profile (optional)	Select an optional TLS profile for communicating with the third party provider.
Security	Default is Basic Authentication.
Basic authentication request header name	The <code>x-introspect-basic-authorization-header</code> is available to provide a user-configured HTTP Basic authorization header.
API Gateway only Basic authentication username (optional)	The default user name for HTTP Basic authentication.

Field	Description
API Gateway only Basic authentication password (optional)	The default password for HTTP Basic authentication.
API Gateway only Token validation	Specifies the method used to determine the success of the introspection request that is sent to the third party service to validate the provided token. Select one of the following options: <ul style="list-style-type: none"> Connected: The query is successful if the status return code is 200. Active (default): The query is successful if the status return code is 200 and the response JSON body includes the property active: true.
API Gateway only Custom header pattern (optional)	A regular expression for request headers that are to be passed to the third-party provider; for example, <code>x-Introspect-*</code> .
API Gateway only Authorization header pass through	Select this check box if you want to retain the Authorization header for a bearer token. The default behavior is to remove this header.

c. Enter the scopes in the third screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

Field	Description
sample_scope_1	Scope for token
sample_scope_2	Scope for token
additional scopes	Scope for token

d. Review the settings on the Summary panel.

3. Click Save and Edit to complete the configuration.

Setting the visibility for OAuth providers

The visibility setting determines which provider organizations can use an OAuth provider to secure APIs.

About this task

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Procedure

Follow these steps to set the visibility for the OAuth providers in your on-premises cloud:

1. In the Cloud Manager, click  Resources.
2. Select OAuth Providers.
3. Choose Edit visibility from the actions menu next to the name of the OAuth provider that requires a visibility setting.
4. Select the visibility setting for the OAuth provider. The options are:
 - Private - the OAuth provider is not visible and cannot be used by any provider organization. It is accessible only to the admin organization in Cloud Manager.
 - Public - the OAuth provider is visible and can be used by all provider organizations
 - Custom - the OAuth provider is visible only to the provider organizations that you designate
5. For Custom visibility, select the provider organizations that you want to have access to the OAuth provider.
6. Click Save to complete the operation.

Results

For Private, the OAuth provider is not visible and cannot be used by any provider organizations. For Public, the OAuth provider is visible and can be used by all provider organizations. For Custom, the OAuth provider is visible only to the provider organizations designated by you.

OAuth concepts for API Connect

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information.

Note: In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- [OAuth user scenario](#)
Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.
- [OAuth introspection for third-party OAuth providers](#)
OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by IBM API Connect. IBM API Connect can use this feature along with the mentioned provider to protect access to the API.

- [OAuth external URL and authentication URL](#)
You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- [Scope](#)
Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.
- [Tokens](#)
Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.
- [Authentication URL user registry](#)
You can use an Authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides additional metadata to be embedded in the token.
- [Custom forms for user security](#)
You can create custom forms for the authorization and identity extraction phase of OAuth.
- [Securing an API with a JSON Web Token](#)
There are two methods to secure your API with a JSON Web Token. You can use the **jwt-generate** command, or you can use a token that has been generated external to IBM API Connect.
- [Troubleshooting OAuth](#)
You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

OAuth user scenario

Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.

Scenario overview

In this scenario, Alice is a user of an application. Alice can grant permission for an application to access specific information about Alice in a third-party system that is using OAuth. Depending on the type of OAuth that is supported by the target service, Alice does not enter her user name and password into the application. Instead, the application receives an access token that represents her credentials (user name and password). The application can now access the information about Alice in the target system.

For example, Alice maintains a list of books that she reads on a service that is provided by mybooks.com. Following the purchase of a smartphone, Alice installs an application on her new phone to display the book details. The phone application wants to call an API provided by mybooks.com, which can access the information. The mybooks.com API is secured by using the OAuth protocol.

To access the book details, the application must complete a two-step process:

1. The application must first obtain permission from Alice.
2. The application then uses that permission to call the target service and obtain the list of books.

In the first step, the application typically directs Alice to the provider of the target service, mybooks.com. Alice provides her user name and password, and gives permission for the application to access her information. It is important that Alice trusts that she is providing her credentials to the provider of the target service and not to an untrusted proxy application. For example, by checking that the security certificate of the website where Alice enters her credentials matches what Alice expects from the provider of the target service.

The result of this step is the access token that the application can use to call the API. The application then generates the appropriately formatted OAuth request. For example, the Authorization header, or HTTP query parameters, which includes the access token, consumer key, and signature method that are required by OAuth. This OAuth request is used to invoke the API proxy operation.

Scenario within API Connect

No changes to the definition of your API operation are required to support this scenario.

1. Alice grants permission for the application to access her information *before* the invocation of the API.
2. When the application provides the Authorization header, or query parameters, containing the OAuth details about the call to the operation endpoint, the header is automatically passed through to the target service without any additional configuration.

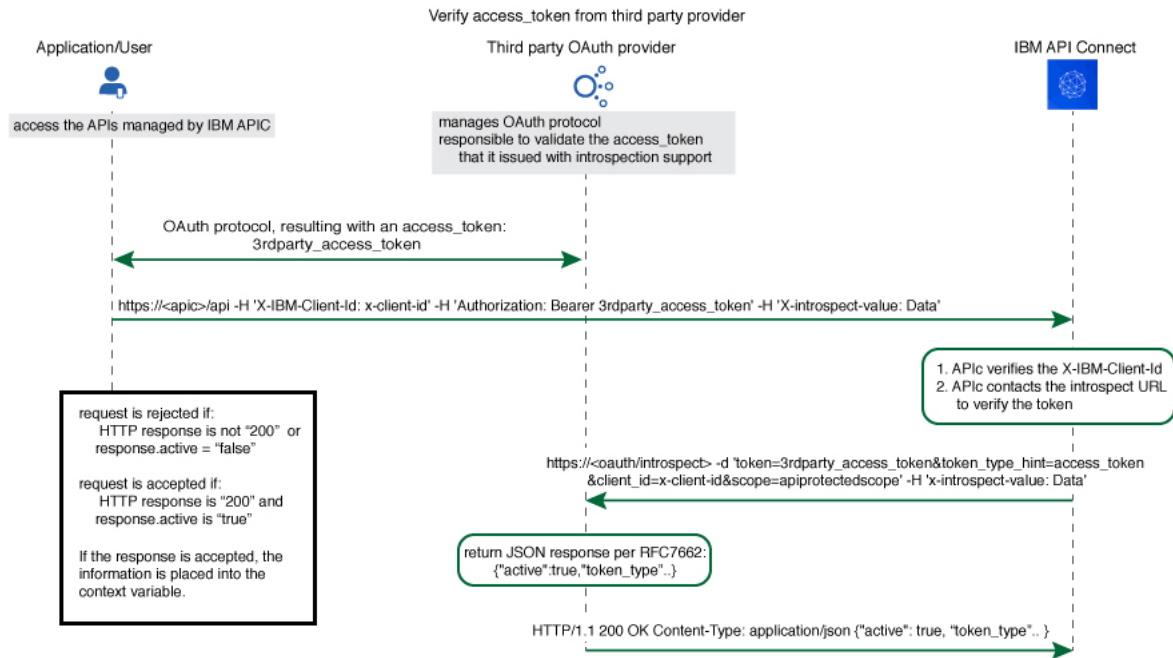

OAuth introspection for third-party OAuth providers

OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by IBM API Connect. IBM® API Connect can use this feature along with the mentioned provider to protect access to the API.

You can use API Connect to protect an API that is secured by using the third-party OAuth access token in accordance with Introspection specification as defined in [RFC 7662](#). In addition to the specification, the **x-Introspect-** header is provided to pass other content to the third party as you require.

Authentication information can be carried in the request by configuring a basic authentication request header.

The following sequence diagram depicts the overall flow of request and response. The purpose of this diagram is only to provide a general visualization of the nature of the flow; for the precise details, refer to the explanatory information after the diagram.

The Introspect URL is configured in the Third Party OAuth provider configuration. See [Configuring a third-party OAuth provider](#).

When an API is protected by a third-party OAuth provider, API Connect will extract the bearer token and issue an HTTP POST request to the endpoint specified in the Introspect URL field.

The GET request is protected by API Connect with this feature.

You can use a header prefix to pass information to the third-party provider. The header prefix can include a regular expression and specifies the name pattern of the headers to use for sending additional information, such as `x-introspect-*`.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
Authorization: Bearer tGzv3JOkF0XG5Qx2TlKWIA
x-IBM-Client-Id: xxx-xxx
```

However, if you want to use a different header prefix, specify the required value in the Custom header pattern field in the third party OAuth provider configuration. For third-party OAuth provider configuration details, see [Configuring a third-party OAuth provider](#). The Custom header pattern feature is available only with the DataPower® API Gateway, if you are using the DataPower Gateway (v5 compatible) the header prefix must be `x-Introspect-`.

API Connect will issue this POST request to the introspection endpoint specified in `x-tokenIntrospect`, as illustrated in the code sample:

```
POST /oauth/introspectURL HTTP/1.1
Host: apiconnect.ibm.com
Content-Type: application/x-www-form-urlencoded
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
token_type_hint=access_token&token=tGzv3JOkF0XG5Qx2TlKWIA
```

The third party OAuth/OIDC provider will respond with HTTP 200 indicating the request was successful and that payload contains the token information. API Connect honors the active claim as defined in the RFC specification.

If the value of the active claim is `true`, the token is treated as valid.

```
HTTP/1.1 200 OK
Content-Type: application/json; charset=UTF-8
Cache-Control: no-store
Pragma: no-cache

{
  "active": true,
  "token_type": "bearer",
  "client_id": "xxx-xxx",
  "username": "John Smith",
  ...
}
```

If the value of the active claim is `false`, the token is treated as invalid.

```
HTTP/1.1 200 OK
Content-Type: application/json; charset=UTF-8
Cache-Control: no-store
Pragma: no-cache

{
  "active": false
}
```

A response code other than **HTTP 200** indicates failure to process the request.

When the OAuth token is valid and active, context variables are populated with information from the introspect JSON response. For more information, see [API Connect context variables](#).

When contacting the introspection endpoint, API Connect uses `client_id/appId` and `client_secret/appSecret` to construct the HTTP Basic authorization header.

By default, if `x-introspect-basic-authorization-header` exists in the request, the value is used for the HTTP Basic authentication header when the introspection endpoint is contacted. API Connect verifies that the HTTP Basic authentication header value is Base64 encoded before it is sent, and encodes it if necessary as shown in the following example. If the header is already encoded, it is sent without modification.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-introspect-basic-authorization-header: user:password
```

API Connect issues the following:

```
POST ..
Authorization: Basic M3JkLXBhcncR5LWNsaWVudF9pZDozcmQtcGFydH1fY2xpZW50X3N1Y3JldA==token_type_hint=access_token&token= ..
```

If you are using the DataPower API Gateway, you can specify your own value for the HTTP Basic authentication header by providing the required value in the Basic authentication request header name field in the third party OAuth provider configuration. The following rules determine what authentication data is passed to the introspection endpoint:

- If there is a basic authentication header in the request, the specified credentials are used. The value must be either a string in the format `user:password`, or the Base64 encoded equivalent; API Connect will Base64 encode the value if necessary before sending the request to the introspection endpoint.
- If there is no basic authentication header in the request but there are values specified in the Basic authentication username and Basic authentication password fields in the third party OAuth provider configuration, those values are used.
- If there is no basic authentication header in the request, and user name and password details are not supplied in the third party OAuth provider configuration, but `client_id` and `client_secret` values are supplied in the body of the request, these are used.
- Otherwise, an error is returned.

For third-party OAuth provider configuration details, see [Configuring a third-party OAuth provider](#).

If either, or both, of `scope` and `scope validate url` are configured, and if the response is an active token with a scope claim from the third-party OAuth Provider introspection endpoint, API Connect will further enforce the scope validation in the following order:

1. If `scope` is configured for the OAuth API protection, verify the third-party scope against the scope that is configured.
2. If `scope validation url` is configured, verify the third-party scope against the scope validation URL.
3. If the third-party OAuth provider introspection endpoint does not return a scope, the Gateway will not check the scope defined in the security definition of the API where the third-party OAuth provider resource is used. For details on configuring an OAuth security definition in an API, see [Creating an OAuth security definition](#).

For more information, see [Scope](#).

DataPower Gateway (v5 compatible) only By default the API Connect client ID and scope are sent to the third party OAuth provider. You can suppress this behavior in either of the following ways:

- Supply a `suppress-parameters` header as follows:

```
suppress-parameters: client_id
suppress-parameters: scope
```

or

```
suppress-parameters: client_id scope
```

depending on which parameters you want to suppress.
- Define an API property called `suppress-parameters` in the API definition itself, with one of the following string values:

```
client_id
scope
or
client_id scope
```

depending on which parameters you want to suppress. For information on how to define API properties, see [Setting API properties](#).

OAuth external URL and authentication URL

You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

Including custom metadata in a token

In many scenarios, custom metadata needs to be included during the access token generation process. The metadata is either stored inside the access token or it is sent along with the access token to the client application. The client application can then send that access token, or the metadata in the payload, in a subsequent request to IBM® API Connect where the metadata is retrieved, validated, or sent to the downstream systems as required.

Examples include, but are not limited to:

- When resource owners are authenticated, metadata about the authenticated resource owner needs to be stored within the access token.
- The grant type that was used to obtain the token is another example of metadata stored within the access token.
- A confirmation code that needs to be sent to the client application along with access token is stored as metadata within the access token.

Configuring External URL or Authentication URL in API Connect to obtain metadata

Metadata can be set by using either or both of the following URLs:

- External URL - When you call the External URL, an HTTP GET request is sent and API Connect expects an HTTP 200 OK along with an optional set of the specified response headers.
- Authentication URL - When you call the Authentication URL, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.
See: [Authentication URL](#).

The External URL endpoint is entered in the Metadata section when you configure an OAuth Provider in the Cloud Manager or API Manager UI.

Use the following HTTP headers in the response, depending on the type of gateway you are using:

- DataPower® API Gateway:

X-API-OAUTH-METADATA-FOR-PAYLOAD

X-API-OAUTH-METADATA-FOR-ACCESSTOKEN

Note: These are the default header names for the DataPower API Gateway but you can override them; see [Configuring metadata for a native OAuth provider](#).

- DataPower Gateway (v5 compatible):

API-OAUTH-METADATA-FOR-PAYLOAD

API-OAUTH-METADATA-FOR-ACCESSTOKEN

The response header value from **X-API-OAUTH-METADATA-FOR-PAYLOAD** or **API-OAUTH-METADATA-FOR-PAYLOAD** is placed in the response payload and indicated as **metadata**.

The response header value from **X-API-OAUTH-METADATA-FOR-ACCESSTOKEN** or **API-OAUTH-METADATA-FOR-ACCESSTOKEN** is placed within the access token and indicated as **miscinfo**.

The two metadata response headers are case insensitive and you must escape any special characters in the string value content.

An example response payload that contains metadata along with the access token:

```
{
  "token_type": "bearer",
  "access_token": "AAEkNzhjDHYyyYy...cL0Mv6ct137w7ZU",
  "metadata": "m:metadata-for-payload_content",
  "expires_in": 3600,
  "scope": "read",
  "refresh_token": "AAEnj5SynCMYbF...oEZ6JjxYax_HdNg",
}
```

This example output from the token introspection endpoint shows the contents of the access token with **miscinfo** containing the metadata information.

```
{
  "active": true,
  "token_type": "bearer",
  "client_id": "78c2f10f-799a-4e1f-8e0a-098634997a35",
  "username": "Fred Smith",
  "sub": "fred",
  "exp": 1479850049,
  "expstr": "2016-11-22T21:27:29Z",
  "iat": 1479846449,
  "nbf": 1479846449,
  "nbfstr": "2016-11-22T20:27:29Z",
  "scope": "read",
  "miscinfo": "m:metadata-for-access-token_content",
  "client_name": "MobileApp"
}
```

Input to the External URL

The following request headers are sent to the External URL.

Note: Any existing metadata values that were previously sent from the Authentication URL are also sent in the two request headers **x-existing-metadata-for-payload** and **x-existing-metadata-for-access-token**. The Metadata URL can make use of this information to create a new set of metadata values.

The two request headers that are sent to the Metadata URL are displayed in bold text.

```
X-existing-metadata-for-payload    payload-from-auth-url
X-existing-metadata-for-access-token token-from-auth-url
X-URI-in      /org/env/miscinfo/oauth2/token (the URL that was sent to APIConnect for this particular token request)
X-METHOD-in  POST
X-POST-Body-in  client_id=client_id&grant_type=password&scope=read&username=name&password=password
X-X-Client-IP   IP_address
X-X-Global-Transaction-ID  ID_number
...
```

Note: If you are using the DataPower API Gateway rather than the DataPower Gateway (v5 compatible), the **X-POST-Body-in** header is not supported.

Retrieving Metadata in API Connect

As described in the previous example scenarios, the metadata can be retrieved from the access token in the Application API and sent to the downstream systems. Retrieval can be done in the API assembly, which is secured to accept tokens in the security definitions.

In the resource API that accepts an access token, the **miscinfo** field can be accessed in the Assembly with the **oauth.miscinfo** context variable, as in the example.

```
apim.setvariable('message.body', apim.getvariable('oauth.miscinfo'));
```

You can also use token introspection to look at the contents of the access token.

Refresh tokens and metadata

The Authentication URL (if configured for authentication) is invoked first, during authentication of the resource owner. The External URL is invoked as the last step, just before the generation of the access token. The only exception is when access tokens are generated from a refresh token. In cases where refresh tokens are used to generate new access tokens, the External URL is not invoked. The metadata from the refresh token is retained and then copied into the newly generated access token.

Identifying the source of the metadata

The metadata is prefixed with keywords to indicate whether it originated from the External URL or the Authentication URL.

- Metadata from the External URL is prefixed with **m**:
- Metadata from the Authentication URL is prefixed with **a**:

Note: When revocation is enabled, some internal details are also stored in the `miscinfo` field, in brackets within the access token as shown in the following example:

```
"miscinfo": "[[tlsprofile@https://api-revoke-url:443/server/revocation-url]m:metadata-for-accesstoken_content"
```

Maximum size of the metadata

Metadata for the access token cannot exceed 512 bytes.

Metadata for the payload does not have a specific size restriction, except for when you use the Authorization code grant type. These restrictions are described in following sections.

Characters are not allowed in metadata in certain scenarios

When you use the Authorization code grant type, or when a consent form is used for implicit grant type, there is a temporary state or code where the metadata from the authentication URL is stored. API Connect internally uses two prefixes - `!ma` and `!mp` to differentiate between payload and token metadata received from the Authentication URL and store them internally in the temporary state/code. Hence these specific character sequences - `!ma` and `!mp` should not be used as the metadata itself.

Grant types and metadata

The OAuth grant types described in the following sections include **authorization code** (access code), **implicit**, and **client credentials** (application).

Authorization code grant type

- When metadata is included from an Authentication URL for an Authorization code grant type, as it is a three legged flow, both the content and the payload are stored within the `dp-state` and carried on to the authorization code and to the access token. Note that around 10 characters are used internally to differentiate between the metadata for payload and metadata for the access token when stored in the `dp-state`. In addition, if revocation is enabled, that will also be part of the token metadata. Hence the combined size of the token metadata, the payload metadata (including the 10 characters of internal data), and internal revocation details, cannot exceed 512 bytes in total.

If the overall size of the metadata exceeds 512 bytes, then the access token generation succeeds, but the metadata fields contain an error message of "metadata too large" as shown in the example.

```
"metadata": "m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-payload]"
"miscinfo": "[r:gateway]m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-token]"
```

This size restriction can be overcome when the metadata is sent from the Metadata URL and not from the Authentication URL, because the metadata is not stored in `dp-state` or in the authorization code.

Example of the **authorization code** (access code) grant type:

```
$ curl -k -d
"grant_type=authorization_code&code=$mycode&client_id=$myid&scope=scope_introspect&redirect_uri="
https://9.70.153.90/fei/sb/introspectpl/oauth2/token
{
  "token_type": "bearer",
  "access_token": "AAEkOTHlZDhhNjYtYTQ1ZS00YTmzLWE0N2QtZmE2OGZkMzQ0NzQ2OZn5T1_TqYFeIfB7BFf6HFGibEoOjWXXEA84oFsWuE4NY-
RRZVdnGSaXAIYJz7s5vczfk5EV-BIb_6P_1YKm3ahrfrR5kI3sPO0uADEoseIP5-09anUpEM5yhysayXvZbJ_6VDYz-hyXSJHTNqVj-
PHBialoRkBD5qca6k00fv2M", "metadata": "a:[Authorization Code-Test-auth-url-payload]", "expires_in": 3600,
  "scope": "scope_introspect", "refresh_token": "AAFAG1EVMbwicr_L0FTZ4q6HZ-
RcQygniXFC9zbSKO4wd3hcniC4KQX21X0fL2c8cnmzCZgws8xxLzNyfjQhUJNG15C1GbIe3dwhXJdiWA0Go-

  Test-auth-url-token]", "client_name":"oauth_app" }
```

Client credentials grant type

Authentication URL will not be invoked when using client credentials grant type, as there is no resource owner. The metadata from Authentication URL is not available for this grant type. However, content returned from Metadata URL will be included as metadata.

Behavior when retrieving metadata with both an External URL and an Authentication URL

If an External URL is configured and a connection to the external server is successful, the response headers overwrite any existing metadata obtained from the Authentication URL to become the final value. Therefore, you must carefully examine the incoming request headers and create appropriate response headers from the External URL.

If an External URL is configured, but the connection to the External URL fails, then a failure message of "error on metadata url" is written for metadata in both the payload and the access token.

If an External URL is configured and the connection is successful, but the remote server does not send any of the specified HTTP response headers, a blank value is written for metadata in both the payload and the access token.

Attention: An External URL overwrites existing values from Authentication URL. This includes blank values.

If no External URL is configured, the metadata that is obtained from the Authorization URL is retained as the final value.

Scope

Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.

In IBM® API Connect, scopes have no inherent meaning. Instead, scopes are defined in the OAuth Provider so that an application can request an access token that is valid for one or more of the scopes. In the secured API, scopes are listed as requirements for an access token to be considered valid. All scopes that are listed by the security definition for the API must be granted by the access token.

Note:

- An OAuth Provider must have at least one scope.
- An OAuth token will not be granted unless a default scope is configured at the provider, or one or more predefined scopes are included in the grant request.
- If no default scope is defined, and the request does not contain a scope, an invalid scope error is returned for the request.

OAuth provider

To provide more refined support for the OAuth scope handling, API Connect allows the [Authentication URL user registry](#) extension to modify the scope value.

When you define an [OAuth provider](#), the Advanced scope check extensions provide the flexibility to check and override allowed scopes. The optional extensions are Application scope check and Owner scope check.

The scope that is eventually received by the application is determined by the interactions that are described in the three following paragraphs. Scope processing follows the sequence of items 1, 2, and 3 in the following list, offering three opportunities to override the scope value. Figure 1 provides an overview of the process.

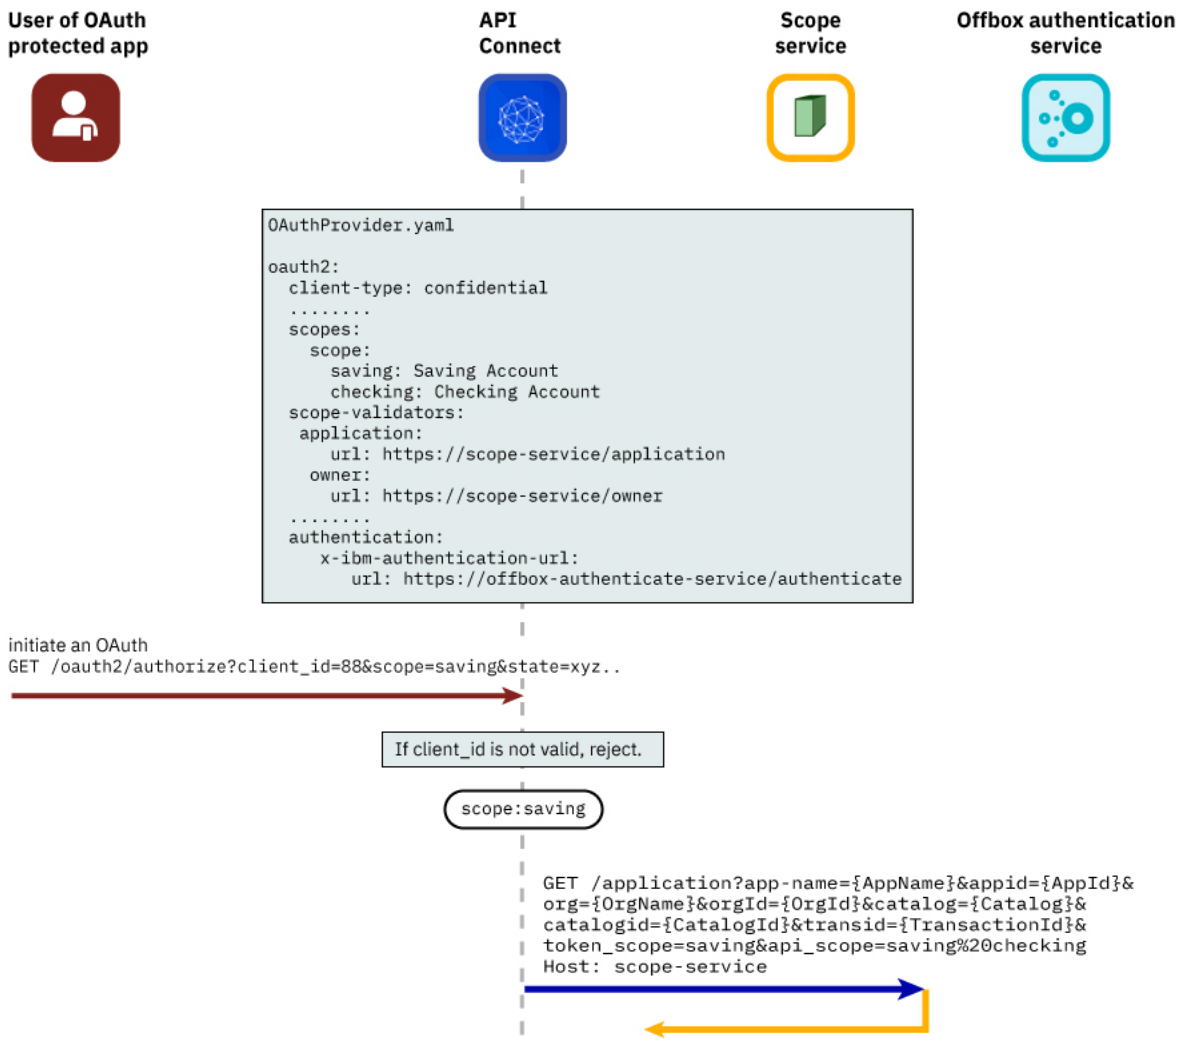

1. After the application successfully authenticates, and if OAuth Native provider [Advanced scope check](#) Application scope check is configured, API Connect makes a call to allow extra verification and uses the contents of **x-selected-scope** to override the scope value that was initially requested by the application. When Application scope check is enabled, the HTTP response header **x-selected-scope** must be present, or the call fails.
2. If OAuth Native provider [User Security](#) Authentication is configured to authenticate application users using an Authentication URL, then API Connect makes a call, as documented in [Authentication URL user registry](#). When the response code is HTTP 200, and the response header **x-selected-scope** is present, the value that is configured in **x-selected-scope** is used as the new scope value, overriding both what the application already requested and what was provided in the Application scope check described in paragraph 1. In the response header, **x-selected-scope** is an optional element.
3. After the user successfully authenticates, and if OAuth Native provider [Advanced scope check](#) Owner scope check is enabled and configured with a valid URL, API Connect makes a call to allow the content of **x-selected-scope** to refine the scope value. When Owner scope check is enabled, the HTTP response header **x-selected-scope** must be present, or the call fails.

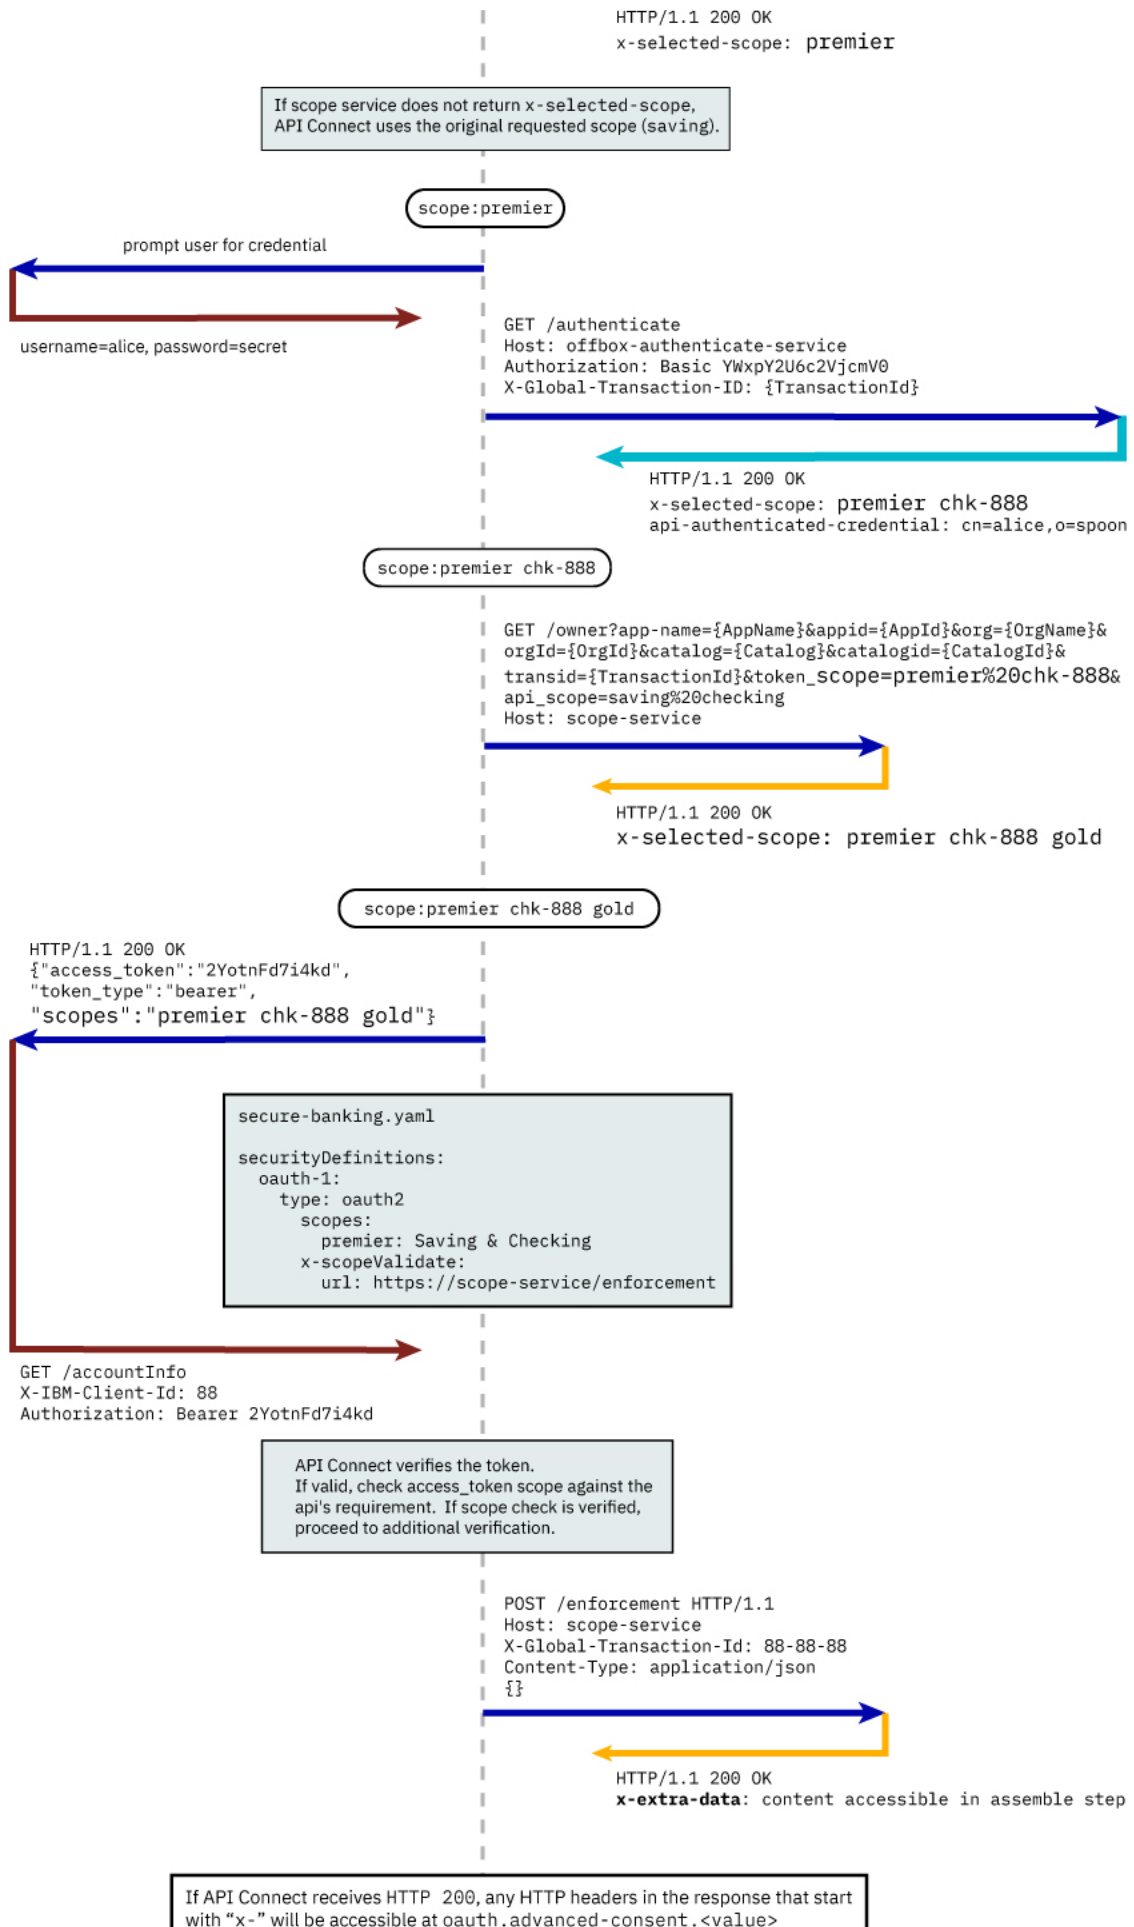

Figure 1. OAuth advanced scope overview

The final scope permission that is granted by the access token is the result of the flow described in items 1, 2, and 3. [Figure 2](#) shows a more detailed view of the transaction flow with examples that show when `x-selected-scope` provides a new scope value.

Figure 2. OAuth advanced scope detail

For the above example, `x-extra-data` is accessible at `oauth.advanced-consent.x-extra-data`.
If other than `HTTP 200` is returned, it has the same effect as if the access token does not contain necessary permissions to access the resource.

Consumer API enforcement

Standard scope validation

To access the API `/getaccount` the application must send a `GET` request with an access token that contains the scope, or scopes, defined in the OAuth provider. If the request doesn't contain a scope, you must specify a default scope to use. If no default scope is defined, and the request doesn't contain a scope, an invalid scope error is returned for the request.

```
GET /getaccount
HTTP/1.1
Host: server.example.com
X-IBM-Client-Id: 8888-8888-8888
Authorization: Bearer AAEkNjVkwOWIyYjgtOWY5ZS00YWQwLWIyYzktZ
```

The following application OpenAPI file `secure-banking.yaml` defines the scope, or scopes, that must exist in the token to be granted access to the API `/getaccount`.

```
secure-banking.yaml

securityDefinitions:
  scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
  security:
    - scope-only:
      - checking
    - scope-only:
      - saving
      - mutual
```

In the examples, the access token `AAEkNjVkwOWIyYjgtOWY5ZS00YWQwLWIyYzktZ` is able to access the API because it contains one, or a combination of `scope-only` that is defined in `secure-banking.yaml` such as:

- `checking`
- `saving mutual`
- `checking saving mutual`

Advanced Scope Check

Administrators can enable an additional scope check by configuring the consumer API property Advanced Scope Check URL that becomes `x-scopeValidate` as shown in the following OpenAPI file example.

```
securityDefinitions:
  advanced-scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
  x-scopeValidate:
    url: 'https://advanced-scope-check.bk.com/validate-scope'
    tls-profile: 'ssl-client'
```

After API Connect successfully verifies the access token against any scope requirement, API Connect will make an `HTTP POST` request to the `x-scopeValidate` endpoint similar to the following example. Response code `HTTP 200` from the endpoint indicates a success. Any other response code, or a connection error, is treated as a permission error for the token.

```
POST /validate-scope?app-name=..&appid=..&org=..&orgid=..&catalog=..&catalogid=..&transid=..
HTTP/1.1
Host: advanced-scope-check.bk.com
Content-Type: application/json
```

```
{
  "context-root" : checking,
  "resource" : accountinfo,
  "method" : GET,
  "api-scope-required" : [jointaccount],
  "access_token" : {
    "client_id" : "2cd71759-1003-4a1e-becb-0474d73455f3",
    "not_after" : 174364070,
    "not_after_text" : "2017-07-11T02:27:50Z",
    "not_before" : 174360470,
    "not_before_text" : "2017-07-11T01:27:50Z",
    "grant_type" : "code",
    "consented_on" : 1499736470,
    "consented_on_text" : "2059-07-11T01:27:50Z",
    "resource_owner" : "cn=spoon,email=spoon@poon.com",
    "scope" : "jointaccount mutual",
    "miscinfo" : "[r:gateway]"
  }
}
```

An example of successful response follows.

```
HTTP/1.1 200 OK
Cache-Control: no-store
Pragma: no-cache
X-Custom-For-Assemble-Process: audit
```

Any HTTP response header that begins with "x-" is kept as the context variable `oauth.advanced-consent`. Based on the example successful response, `X-Custom-For-Assemble-Process: audit` becomes `oauth.advanced-consent.x-custom-for-assemble-process`, and can be accessed in the assemble step.

Additional validation options

You can optionally use additional fields for validation:

Request Header

Defines the regular expression to match against **request** headers. Matching headers are included in the request to the advanced scope validation endpoint.

Response Context Variable

Defines the regular expression to match against **response** headers. Matching headers are saved as context variables in the format `oauth.advanced-consent.*`.

Tokens

Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.

This section contains information regarding token management, including refreshing and revoking tokens, redirecting, and managing tokens with the DataPower Gateway.

- [Refresh tokens](#)
If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.
- [Token revocation](#)
In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.
- [Authenticating and authorizing through a redirect URL](#)
You can use a service that is hosted externally from IBM API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.
- [Token management with the DataPower Gateway \(v5 compatible\)](#)
API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.
- [Token management with the DataPower API Gateway](#)
API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

Refresh tokens

If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.

When you are using OAuth authentication, API requests must include a valid access token, by using the Authorization HTTP header. Access tokens that are issued by the IBM® API Connect Token Endpoint are valid for 3600 seconds (1 hour) by default, as indicated by the `expires_in` property that is returned on the token request. The following code block shows an example API request with an Authorization header:

```
GET /bankingApi/accountSummary?client_id=32427ce5-bb7c-48a7-9de3-4bb629091103
HTTP/1.1
Accept: application/json
Host: api.ibm.com
Authorization: Bearer AAEFYy1hbGxlhdS5nVX4x6iTL2sb3ymBivQb...
```

After an access token expires, if the option is enabled in the OAuth provider configuration Tokens > Refresh tokens screen, the application uses refresh tokens. Each refresh token is valid for approximately 31 days after it is issued (or for the Time to Live time period specified) and can be used only once to request a new access token. Along with the new access token, a new refresh token is also returned. For details on how to enable refresh tokens, see [Configuring a native OAuth provider](#).

If the access token is expired and the application does not have a refresh token, it must restart the OAuth exchange by using the choice of Grant Type(s) allowed by the OAuth provider.

Token revocation

In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.

Token revocation using an external third party service

This topic describes token revocation using a third party, external service. This option is configured in the Native OAuth provider, using the Token Management > Type = Third party screen. The revocation URL is an endpoint that links to an external service which contains information about access or refresh tokens. API Connect is involved in the initial creation and validation of tokens. When an OAuth revocation URL is present, API Connect calls the URL to determine if the associated token can be trusted.

The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing.

Examples

A number of revocation examples follow. The first shows a sample fetch request and the response from a remote revocation URL.

GET request and response

In this example, an API Gateway server issues a GET request to the Revocation URL and receives a result. It shows that different resource owners (Laura and Emily) can revoke all tokens when using the same application (client ID).

Request:

```
<?xml version="1.0" encoding="UTF-8"?>
GET <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Accept: application/xml; text/xml
```

Response:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>

<!--
Access Tokens and/or Refresh Tokens that are revoked can be individually listed.
To keep this list small, please only include access tokens and refresh tokens that are valid.
For access tokens, any token older than 20 minutes is no longer valid.
For refresh tokens, any token older than 44700 minutes is no longer valid.
-->

<token type="access">AAETb2F1dGgtcmV2b2t1LWN1c3RvbfZaRlVbnPSc1...</token>
<token type="refresh">fZaRlVbnPSc1UGTjCRdq4mPbOosD2+aZIKbJ6bTeW...</token>

<!--
If a resource owner has revoked all tokens issued to a given application, please
list them as shown here.
-->

<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">laura</resource-owner>
<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">emily</resource-owner>

</oauth-revocation>
```

POST request and response

The next example shows a post request and response.

Request:

```
POST <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Content-Type: application/xml

<?xml version="1.0" encoding="UTF-8"?>
<token>
  <token_type>bearer</token_type>
  <access_token>AAENYy1hbGwtcmVmcmVzaOfNeQKX8ZeojsBY9v0FI7/OerQvzKHq...</access_token>
  <expires_in>3600</expires_in>
  <scope>3600</scope>
  <resource-owner>alice</resource-owner>
  <client_id>83d9cdcd-ba72-4d00-abae-005da8da5fb1</client_id>
</token>
```

Response:

```
HTTP/1.1 200 OK
```

Provide token information on revocation request

In this example, the application calls an API and passes a bearer token. In response, the Gateway fetches the revocation URL and provides information on the token being verified.

Gateway:

```
GET <revocationURL> HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2t1LWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Alternatively, the same process occurs when using a refresh token to issue a new access token. The application sends a refresh request to the token service. The Gateway then fetches the revocation URL, providing information on the refresh token being verified.

Gateway:

```
GET <revocationURL> GET HTTP/1.1
refresh-token: AAETb2F1dGgtcmV2b2t1LWN1c3RvbfZaRlVbnPSc1
```

```
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Note: If you are using a third party OAuth provider then, for API Calls with bearer tokens, when Introspect URL is enabled on the API, the revocation URL is not applicable. Instead, the third party endpoint must validate the token and also check for revocation before returning a 200 OK response to the Gateway.

Revoking tokens issued to Alice up to and including a specific date

On May 1st, Alice loses her phone and needs to reset her password. As a result, the token provider wants to revoke every token issued before Alice lost her phone. In this example, the Gateway sends a GET request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2t1LWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-05-01T09:30:10Z">alice</resource-owner>
</oauth-revocation>
```

Revoking all tokens issued up to and including a specific date

Under certain catastrophic conditions, you may need to revoke all tokens issued up to and including a specific date, for example, May 1st. In this example, the Gateway sends a GET request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2t1LWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <everytoken before="2015-05-01T09:30:10Z" />
</oauth-revocation>
```

Putting it all together

The following shows the examples contained in this topic executed in a single action:

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2t1LWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
HTTP/1.1 200 OK
Content-Type: application/xml
Cache-Control: public, max-age=120
Date: Fri, 08 May 2015 21:49:03 GMT
```

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-04-08T09:30:10Z">mary</resource-owner>
  <resource-owner before="2015-04-12T09:30:10Z">john</resource-owner>
  <resource-owner before="2015-04-13T09:30:10Z">kevin</resource-owner>
  <resource-owner before="2015-04-01T09:30:10Z">alice</resource-owner>
</oauth-revocation>
```

Notes:

- In the previous example, there are no entries older than one month in the response (the maximum life of a refresh token).
- Each response is cached for up to two minutes according to response's directive.
- The **before** attribute uses the **xs:dateTime** syntax.

Authenticating and authorizing through a redirect URL

You can use a service that is hosted externally from IBM® API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.

Before you begin

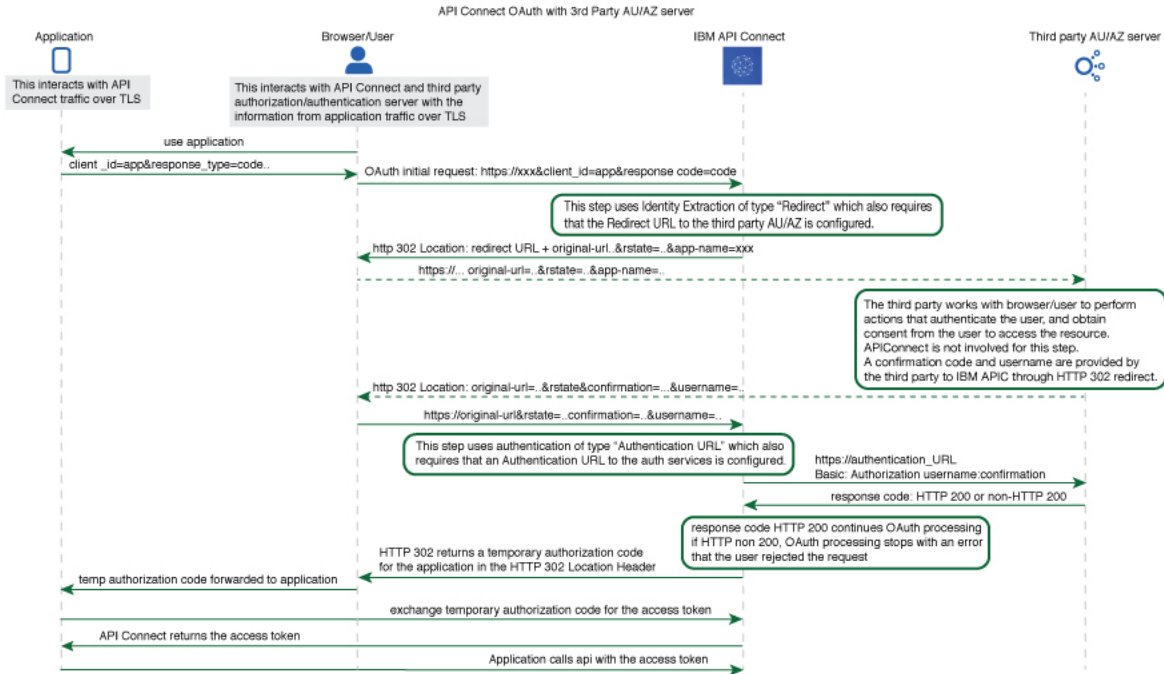

To complete this task, you will need to either create or have created an OAuth security definition that uses Implicit grant type or Access Code (Authorization Code) grant type. For more information, see [Creating an OAuth security definition](#).

About this task

If you use methods for authentication that are not supported by API Connect, you can redirect users to a suitable URL at which they can authenticate. The user is then returned to the OAuth process after authentication and authorization have been confirmed.

The following illustration indicates the transaction flow for third party authentication.

Figure 1. Third party authentication (AU) and authorization (AZ) transaction flow

1. The application initiates a request to access an API protected with a third-party entity. API Connect redirects the application with an **HTTP 302** redirect based on **identity extraction** -> **redirect** -> **redirect-url**, for user authentication (and optional authorization).
2. The application communicates directly with the third-party entity to gather user identity. API Connect is not involved in this communication. After the third-party entity finishes processing authentication (and optional authorization), it returns an **HTTP 302** redirect that uses the **original-url** from the request, with the username and confirmation code appended.
3. API Connect receives the request that includes the username and confirmation code, and communicates with the authentication URL, based on **authentication** -> **x-ibm-authentication-url**, to confirm user identity before the request is completed.
4. An **HTTP 200** response from the third-party entity allows API Connect to continue the OAuth 2.0 request process as if the owner is authenticated. The request is then processed according to the **grants** type.
 - - **accessCode** returns a temporary code to the application.
 - - **implicit** returns the access token to the application.

For any response other than HTTP 200, the request fails with a statement added to the error log.

Procedure

To create an external form, and to indicate the URL to which API Connect will redirect users, complete the following instructions:

1. Create your service for authentication and authorization. You will use the URL of the landing page of this service as your redirect URL.
 - a. To include elements in your form that are provided by API Connect, use the following query parameters from the URL that your user is redirected to. Note: With the exception of **original-url**, none of these parameters are included in the URL automatically; you must add them as required.

app-name
The name of the application requesting access, as provided through the Developer Portal.

appid
The id of the application requesting access.

catalog
The name of the catalog where the product is being used by the application.

catalogid
The id of the catalog where the product is being used by the application.

catalogtitle
User-friendly display name for the catalog.

org
The name of the consumer organization that hosts the application.

orgid
The id of the consumer organization that hosts the application.

orgtitle
User-friendly display name for the organization.

original-url

The original URL that the user was directed to by the application, including query parameters from the original URL that are necessary for standard OAuth 2.0 requests. You can include these parameters in your service to provide information to the user. Additionally the `state_nonce` is appended. The `state_nonce` is a hash code generated by API Connect for verification purposes. The URL is URL-encoded and should be decoded before further use, the `state_nonce` should remain unchanged.

provider

The name of the API provider organization.

providerid

The id of the API provider organization.

providertitle

User-friendly display name for the provider organization.

requested-scope

[optional] If [Application Scope check](#) is enabled and replaces the `scope` from the initial application request, this field holds the `scope` value from the initial application request, and the new replacement scope value is put into `original-url`.

transid

transaction id used in the GW for the transaction which trigger this call

The URL to which the user is sent to when they are redirected to your page has the following form:

`Redirect_URL?original-url=Original_URL&state_nonce=R_State&app-name=Application_Name`

where all variables are as described previously. The Redirect URL does not have a size limit enforced by API Connect.

- b. Create the stages of authentication, authorization, and any intermediate stages that you require to take place before you allow access to the application. Upon completion of these stages, redirect the user to the `Original_URL` and append a user name, their confirmation code, and the application name to be evaluated for access grant or denial by API Connect. The confirmation code does not have a size limit enforced by API Connect.

Original URL requires the following form:

`Original_URL&username=User_Name&confirmation=Confirmation_Code`

where all variables are as described previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtq1B7LDkq4gj1D3SHKq1CbnYdHs/bMz2Y=&username=spoon&confirmation=12345678
```

- c. To send your own error responses after the authentication and authorization service, redirect the user to the `Original_URL` and append an error code. You can also append a user name. Use the following form:

`Original_URL&username=User_Name&error=Error_Response`

where `Error_Response` is the message you wish to send and all other variables are described as previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtq1B7LDkq4gj1D3SHKq1CbnYdHs/bMz2Y=&username=User&error=access_denied
```

2. Create a service to validate the confirmation code and user name. API Connect makes a GET call to your authentication URL after the user is redirected back to the authorization URL. When the call is made, it includes in its authorization header the user name and confirmation code you supplied previously. Confirm that these are correct and respond with an HTTP success code such as 200 OK if you want to allow access, or non-200 HTTP response code, such as 401 Unauthorized to deny access.
3. In your OAuth provider configuration, supply the redirect URL that is used in Step 1 and the authentication URL that is used in Step 2. For more information on configuring an OAuth Provider, see [Configuring a native OAuth provider](#) when using API Manager or [Configuring a native OAuth provider](#) when using Cloud Manager.

Token management with the DataPower Gateway (v5 compatible)

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

In order to manage tokens with the DataPower® Gateway (v5 compatible), you must set the Token Management Type to Native in your Native OAuth provider configuration. See [Configuring token management and revocation for a native OAuth provider](#) when using Cloud Manager or [Configuring token management and revocation for a native OAuth provider](#) when using API Manager.

Also, the DataPower quota enforcement server must be enabled on the DataPower Gateway to use the distributed cache to manage tokens. See [Quota enforcement](#).

Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

When distributed cache support is enabled, replay protection is provided across the gateway cluster through the quota enforcement server. This support ensures that the same token cannot be reused across the members of the quota enforcement peer group.

Important:

If you have a cluster of DataPower Gateway servers, the OAuth data synchronization behavior across the servers depends on whether or not you enable revocation:

- If you enable revocation, API Connect uses the DataPower quota enforcement server, and OAuth data is synchronized across the servers. If an access token is obtained from one server, the OAuth data synchronization ensures that the same authorization code cannot be used to obtain an access code from another server. You must ensure that the DataPower quota enforcement server is configured.
- If you disable revocation, API Connect does **not** use the DataPower quota enforcement server and OAuth data does not synchronize across the cluster of DataPower Gateway servers. Therefore, to prevent the same authorization code being used to obtain an access code from more than one server you must configure

DataPower to synchronize OAuth data across the servers, by using the DataPower Gateway console.

To configure DataPower to synchronize OAuth data, ensure that the DataPower quota enforcement server is configured. For more information, see [Configuring the quota enforcement server](#).

Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user `cn=spoon,o=ibm` with username `spoon` and password `spoon` using a registered administration application of `5287fe53-8747-438a-8262-681ec75b79c5`.

- Request:

```
GET /oauth2/issued
HTTP/1.1
Host: apic.ibm.com
x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uClxT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache
[
  {
    "clientId": "7369ad66-5674-b7d3-4567-de35283421aca",
    "owner": "cn=spoon,o=ibm",
    "clientName": "PetStore Application",
    "scope": "listpet",
    "issuedAt": 1503327054,
    "consentedOn": 1503327054,
    "expiredAt": 1503330654,
    "refreshTokenIssued": false,
    "appId": "d2031f0f27339315333734ab9",
    "org": "PetStoreOrg",
    "orgTitle": "Katie Pet Grooming Inc",
    "orgId": "5887803de4b06e6998c4b2c7",
    "provider": "SuperStore",
    "providerTitle": "Simon SuperStore",
    "providerId": "5887803de4b06e6998c4b2c7",
    "catalog": "publicapi",
    "catalogTitle": "For public",
    "catalogId": "5887803de4b06e6998c4b2d3"
  },
  {
    "clientId": "a8746323-9825-a842-8736-abd8202356ac8",
    "owner": "cn=spoon,o=ibm",
    ...
  }
]
```

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client-id=a8746323-9825-a842-8736-abd8202356ac8
HTTP/1.1
Host: apic.ibm.com
x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uClxT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache
{ "status": "success" }
```

Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to /oauth2/revoke, which supports OAuth 2.0 [IETF RFC 7009](#). An HTTP POST operation that an application can send to this API to revoke either an `access_token`, or `refresh_token` with `token_type_hint` as shown in the following examples:

Revoke access_token

- Request:

```
POST /oauth2/revoke
HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uClxT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
Content-Type: application/x-www-form-urlencoded

token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn941SWX14xuR....
```

- Response:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

{ "status": "success" }
```

Revoke refresh_token

- Request:

```
POST /oauth2/revoke
HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uClxT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
Content-Type: application/x-www-form-urlencoded

token_type_hint=refresh_token&token=.....
```

- Response:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

{ "status": "success" }
```

Token management with the DataPower API Gateway

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

Note: The steps described in this topic are required if you are using the DataPower® OVA or appliance version of the gateway. For the API Connect supplied Kubernetes deployment, the API Security Token Manager is preconfigured provided that, in the gateway service custom resource file, v5 compatibility mode is disabled and the token management service is enabled:

```
.
.
.
spec:
.
.
.
apicGatewayServiceV5CompatibilityMode: false
tokenManagementService:
  enabled: true
.
.
.
```

For more information, see [Installing the DataPower Gateway subsystem](#).

Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

In order to manage tokens with the DataPower API Gateway, you must set the Token Management Type to Native in your Native OAuth provider configuration. See [Configuring token management and revocation for a native OAuth provider](#) when using Cloud Manager or [Configuring token management and revocation for a native OAuth provider](#) when using API Manager.

Note: This setting is also required when you use a third-party OAuth provider and **Introspect cache type** is set to **protocol** or **Time to live**.

For token management with the DataPower API Gateway, you must configure the API Security Token Manager on the gateway. Complete the following steps:

1. Log in to the DataPower administration console, selecting apiconnect for the domain, and WebGUI for the Graphical Interface.
2. In the search box, enter API Security Token Manager, then click on the API Security Token Manager link that displays in the search results.
3. For the Administrative state, select enabled.
4. Click the + icon alongside the Gateway Peering field to create a new gateway peering object.
5. Provide a Name and a Local address.

6. In the Local port and Monitor port fields, provide values that aren't already in use by services for the Local address.
7. Ensure that Peer group mode is selected.
8. Alongside the Peers field, use the add button and accompanying field to add at least two peers, to ensure that quorum is achieved.
9. If the Enable SSL option is selected, select a value for the Identification credentials.
10. For Persistence location, select a setting other than memory.
11. When done, click Apply.
12. Repeat steps 1 to 11 for each DataPower API Gateway in the peer group.
13. When done, click Apply, then click Save Configuration to save your changes.

For more information, see [Defining the API security token manager](#) and [Creating a gateway peering instance](#).

Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user `cn=spoon,o=ibm` with username `spoon` and password `spoon` using a registered administration application of `5287fe53-8747-438a-8262-681ec75b79c5`.

- Request:

```
GET /oauth2/issued
HTTP/1.1
Host: apic.ibm.com
x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uClxT2iN1uU6bt5cV4dN7nW5kM5uP8vL3uF3cT7
Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache
[
  {
    "clientId": "7369ad66-5674-b7d3-4567-de35283421aca",
    "owner": "cn=spoon,o=ibm",
    "clientName": "PetStore Application",
    "scope": "listpet",
    "issuedAt": 1503327054,
    "consentedOn": 1503327054,
    "expiredAt": 1503330654,
    "refreshTokenIssued": false,
    "appId": "d2031f0f27339315333734ab9",
    "org": "PetStoreOrg",
    "orgTitle": "Katie Pet Grooming Inc",
    "orgId": "5887803de4b06e6998c4b2c7",
    "provider": "SuperStore",
    "providerTitle": "Simon SuperStore",
    "providerId": "5887803de4b06e6998c4b2c7",
    "catalog": "publicapi",
    "catalogTitle": "For public",
    "catalogId": "5887803de4b06e6998c4b2d3"
  },
  {
    "clientId": "a8746323-9825-a842-8736-abd8202356ac8",
    "owner": "cn=spoon,o=ibm",
    ...
  }
]
```

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client-id=a8746323-9825-a842-8736-abd8202356ac8
HTTP/1.1
Host: apic.ibm.com
x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uClxT2iN1uU6bt5cV4dN7nW5kM5uP8vL3uF3cT7
Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache
{ "status": "success" }
```

Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to `/oauth2/ revoke`, which supports OAuth 2.0 [IETF RFC 7009](#). An HTTP POST operation that an application can send to this API to revoke either an `access_token`, or `refresh_token` with `token_type_hint` as shown in the following examples:

Revoke `access_token`

- Request:

```
POST /oauth2/revoke
HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uClxT2iN1uU6bt5cV4dN7nW5kM5uP8vL3uF3cT7
Content-Type: application/x-www-form-urlencoded

token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn94lSWX14xuR...
```

- Response:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

{ "status": "success" }
```

Revoke `refresh_token`

- Request:

```
POST /oauth2/revoke
HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
x-ibm-client-secret: E2qM6mG2bX2uClxT2iN1uU6bt5cV4dN7nW5kM5uP8vL3uF3cT7
Content-Type: application/x-www-form-urlencoded

token_type_hint=refresh_token&token=.....
```

- Response:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

{ "status": "success" }
```

Authentication URL user registry

You can use an Authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides additional metadata to be embedded in the token.

This support can optionally enable any of the following:

- Providing the authenticated credential to IBM® API Connect. For example, the user logs-in with user name: `spoon`, and password: `fork`. When the user is authenticated, the credential becomes `cn=spoon,o=eatery`. The credential is kept in the OAuth `access_token` to represent the user.
- Providing metadata support. Allow extra metadata to be stored in the `access_token`.
- Overriding the `scope` that the application receives after a successful OAuth protocol processing. By responding with a specific header, the Authentication URL endpoint can replace the `scope` value that the application receives. For example, you can provide a specific resource owner an account number within the `scope` header response for use in future processing steps.

When you call the Authentication URL user registry, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.

The following response from the REST authentication service indicates that user authentication is successful and that API Connect will use `cn=spoon,o=eatery` as the user identity.

```
HTTP/1.1 200 OK
Server: example.org
X-API-Authenticated-Credential: cn=spoon,o=eatery
```

For information on how to configure a User Security policy in an API assembly for use with an Authentication URL user registry, see [User Security policy](#).

For an example of an OAuth provider configuration that uses an Authentication URL user registry, see [Example - using multiple OAuth policies in an OAuth provider assembly](#).

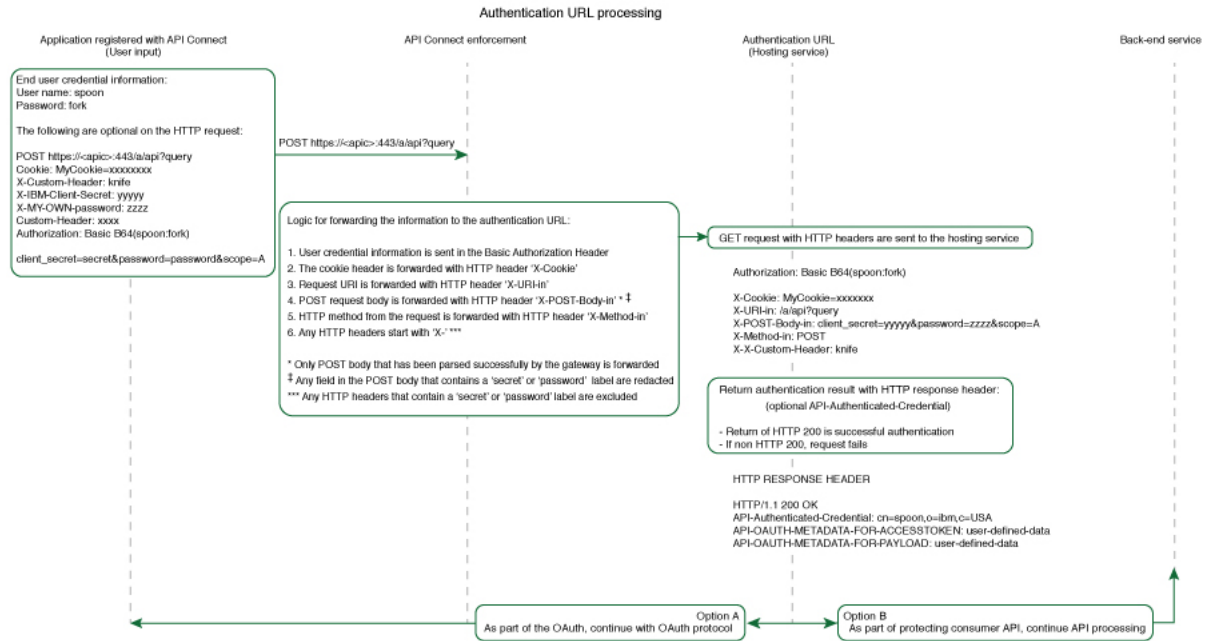

API Connect considers any non-200 HTTP response code a failed user authentication attempt.

When an Authentication URL user registry is invoked, two HTTP response headers are available that include metadata in the access token or the response payload that contains the access token. For more information, see [OAuth external URL and authentication URL](#). The two metadata response headers are:

API-OAUTH-METADATA-FOR-ACCESSTOKEN
API-OAUTH-METADATA-FOR-PAYLOAD

When an Authentication URL is invoked, an HTTP response header is available to override the requested `scope` from the application. For more information, see [Scope](#). The response header is:

`x-selected-scope`

If you are using the DataPower® API Gateway rather than the DataPower Gateway (v5 compatible), this diagram is provided for guidance only and is not fully accurate for this release.

Custom forms for user security

You can create custom forms for the authorization and identity extraction phase of OAuth.

About this task

The Native OAuth provider configuration provides the capability for requiring additional authentication and authorization steps for user security. Custom HTML forms may be created to extract the identity of the user and to authorize the user. This capability applies to Implicit, Resource owner password, and Access code grant types.

- [Creating a custom HTML login form for user security](#)
Custom HTML forms can be created for user security during the identity extraction stage in OAuth.
- [Creating a custom HTML authorization form for user security](#)
Custom HTML forms can be created for user security during the authorization stage in OAuth.

Creating a custom HTML login form for user security

Custom HTML forms can be created for user security during the identity extraction stage in OAuth.

Before you begin

The Native OAuth provider configuration includes Identity Extraction when using the Implicit, Access code, or Resource owner password grant types. You have the option to select how to extract the user credential and one of the choices is Custom HTML Form. For more information, see [Configuring a native OAuth provider](#) when using API Manager or [Configuring a native OAuth provider](#) when using Cloud Manager. For more information, see [Configuring a native OAuth provider](#). This topic describes how to create the Custom HTML form for identity extraction.

About this task

During three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user is presented with a form for signing in to the service provided by the API. You can present a custom form or a default form. Your custom form must fulfill certain requirements.

Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

Procedure

To create a custom sign-in form for your Native OAuth provider, complete the following steps:

1. Create a well formed XHTML document that will be parsed and transformed by API Connect to inject hidden fields.
2. For your XHTML form, set the method as `POST`, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.

For example:

```
<form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
```

3. Create a text input field that is named `username` and create a password input field named `password`.
4. Add the line `<EI-INJECT-HIDDEN-INPUT-FIELDS>`. This third element is a placeholder that API Connect replaces with input fields to complement the user-submitted data.
5. Create a button to initiate the sign-in process.

For example:

```
<button id="home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.apionprem.doc_oauth_custom_login_form_login_button" type="submit" name="login" value="true">Log in</button>
```

6. Optional: Add text that is displayed the first time that the user visits the sign-in page. Use the tag `<EI-LOGINFIRSTTIME>` for the text that you want to display.
7. Optional: Add text that appears when the user is returned to the sign-in page if they fail to authenticate. Use the tag `<EI-LOGINFAILED>` for the text that you want to display.
8. Optional: Have an error message displayed when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<EI-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the end user.
9. Optional: You can add elements that are loaded from external sources, such as images or JavaScript.
10. Insert spacing and other features as you require. Completing Steps 1 through to 8 results in a form similar to the following example:

```
<html lang="en" xml:lang="en">
<head><meta http-equiv="Content-Type" content="text/html; charset=UTF-8"/></head>
<body>
  <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
    <h1>Please sign in</h1>
    <p>Username </p>
    <p><input type="text" name="username" required="required" /> </p>
    <p>Password </p>
    <p><input type="password" name="password" required="required" /> </p>
    <EI-INJECT-HIDDEN-INPUT-FIELDS/>
    <p> <button
id="home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.5_com.ibm.apic.apionprem.doc_oauth_custom_login_form_login_button" type="submit" name="login" value="true">Log in</button> </p>

    <EI-LOGINFIRSTTIME>
      <p>If you have forgotten your user name or password, contact your system administrator.</p>
    </EI-LOGINFIRSTTIME>

    <EI-LOGINFAILED>
      <p>At least one of your entries does not match our records.
        If you have forgotten your user name or password, contact your system administrator.</p>
    </EI-LOGINFAILED>

    <EI-INTERNAL-CUSTOM-FORM-ERROR/>

  </form>
</body>
</html>
```

11. Make your form available at a URL of your choice.
12. If you have not already done so, configure your Native OAuth provider to use a Custom HTML form for identity extraction and provide the URL at which your form is available. For more information, see [Configuring a native OAuth provider](#) when using API Manager or [Configuring a native OAuth provider](#) when using Cloud Manager.

Creating a custom HTML authorization form for user security

Custom HTML forms can be created for user security during the authorization stage in OAuth.

Before you begin

The Native OAuth provider configuration includes user authorization when using the Implicit, Access code, or Resource owner password grant types. You have the option to select how to authorize application users and one of the choices is Custom HTML Form. For more information, see [Configuring a native OAuth provider](#) when using API Manager or [Configuring a native OAuth provider](#) when using Cloud Manager. This topic describes how to create the Custom HTML form for authorization.

About this task

During three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user is presented with a form through which they grant permission to an application to access their data through the API on their behalf. You can present a custom form or a default form. Your custom form must fulfill certain requirements.

Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

Procedure

To create a custom authorization form for your Native OAuth provider, complete the following steps:

1. Create a well-formed XHTML document. This will be parsed and transformed by API Connect to inject hidden fields.
2. For your XHTML form, set the method as `POST`, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.

For example:

```
<form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
```

3. Add the line `<AZ-INJECT-HIDDEN-INPUT-FIELDS/>`. This line is a placeholder that API Connect will replace with input fields necessary for the completion of the OAuth process.
4. Create two buttons with the following code so that the user can grant or deny permission. Edit the text to suit your preferences.

```
<button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
<button class="submit" type="submit" name="approve" value="true">Allow Access</button>
```

5. Optional: Display an error message when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<AZ-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the end user.
6. Optional: You can add to the form HTML elements that will load features from external sources, such as images or JavaScript. For example, `<script src="http://www.example.com/example.js" />`
7. Insert spacing and additional elements as you require. Completing Steps 1 through to 6 results in a form similar to the following example:

```
<html lang="en" xml:lang="en">
  <head><title>Request for permission</title></head>
  <body class="customconsent">
    <div>
      <div>
        <form method="post" enctype="application/x-www-form-urlencoded" action="authorize">
          <AZ-INJECT-HIDDEN-INPUT-FIELDS/>
          <p>Greeting..</p><DISPLAY-RESOURCE-OWNER/>
          <p>This app </p><OAUTH-APPLICATION-NAME/><p> would like to access your data.</p>
          <div>
            <button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
            <button class="submit" type="submit" name="approve" value="true">Allow Access</button>
          </div>
        </form>
      </div>
      <AZ-INTERNAL-CUSTOM-FORM-ERROR/>
    </div>
  </body>
</html>
```

8. Make your form available at a URL of your choice.
9. If you have not already done so, configure your Native OAuth provider to use a Custom HTML Form for authorization for User Security. Provide the URL as the endpoint at which your form is available. For more information, see [Configuring a native OAuth provider](#) when using API Manager or [Configuring a native OAuth provider](#) when using Cloud Manager.

Securing an API with a JSON Web Token

There are two methods to secure your API with a JSON Web Token. You can use the `jwt-generate` command, or you can use a token that has been generated external to IBM® API Connect.

About this task

JSON Web Token (JWT) is an OAuth 2.0 compliant method of authentication that can be useful to secure your API in API Connect.

You can secure your API with a JSON Web Token by using either of the following methods:

- Generate a token through the `jwt-generate` command, and then augment the response payload with your generated token replacing the `id` token.
- Use a token that was generated outside of API Connect and include it into the response payload, by using the metadata URL.

Procedure

Create a `jwt-generate` policy in the assembly.

- a. In API Manager, open the Assembly tab.
- b. Add a jwt-generate policy to the assembly for the API.

Troubleshooting OAuth

You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

You can use the following links to go to the topics:

- [OAuth 2.0 support in the developer portal test tool](#)
- [OAuth requires quorum in a multi-node cluster](#)

OAuth 2.0 support in the developer portal test tool

OAuth 2.0 support is exposed as an API through the provider OpenAPI definition. You can use the test tool that is included with API Connect to test the OAuth 2.0 configuration. For more information, see [Testing an API using the Developer Portal test tool](#).

OAuth requires quorum in a multi-node cluster

In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

Configuring the cloud settings

Before you can add a provider organization to your cloud, you must specify your cloud settings to configure an email server for notifications as well as user registry options and catalog defaults.

The cloud settings let you define basic configuration for your deployment. To view the current settings, log in to Cloud Manager and click  in the navigation pane.

Tip: When you are familiar with the cloud settings, you can modify them using the [Toolkit command-line interface](#) instead of the user interface.

Visit the following pages to configure settings:

Overview

Provide a title and description for your cloud administrator organization. For more information, see [Change the name of your cloud](#).
