- Literal configuration takes precedence over any existing object reference.

You can configure the policy to support one or more of the following processing components:

Validate request
: Validates the authorization request from the client.

Generate authorization code
: Generates the authorization code for the client, which represents the resource owner's authorization that grants access to the requested resource.

Verify authorization code
: Verifies the authorization code from the client.

Verify refresh token
: Verifies the refresh token that is presented by the client.

Generate access token
: Generates the access token to the client when the authorization code or refresh token is verified.

Introspect token
: Introspects the token to determine its state and, when active, its metadata.

When the policy does not support a processing component but that processing is requested, the unsupported component is not run.

You can include multiple OAuth policies in your OAuth provider assembly. For example, your assembly might include the following flow:

1. OAuth policy that validates the request.
2. GatewayScript policy.
3. OAuth policy that generates authorization code.

For more information, see Example - using multiple OAuth policies in an OAuth provider assembly and OAuth context variables.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. OAuth policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is `oauth`.	string
Description	No	A description of the policy	string
Default OAuth Provider Settings Object	Yes	The name of an existing OAuth provider that defines the required settings.	string
Dynamic OAuth configuration from a URL	No	A URL to a document that contains serialized XML or JSON properties that defines OAuth token generate settings.	string
Dynamic OAuth configuration from a literal string	No	A literal string that contains serialized XML or JSON properties that defines OAuth token generate settings.	string
Supported OAuth components	No	Select the OAuth components that are supported by this policy.	string

Overriding the default OAuth provider settings

You can use either the Dynamic OAuth configuration from a literal string property or the Dynamic OAuth configuration from a URL property to dynamically override any OAuth provider configuration settings defined by the Default OAuth Provider Settings Object property.

For example, to override the access token expiration time with a value of 200 seconds, include the following configuration in either the literal string or the document at the specified URL:

```
<OAuthProviderSettings><APICAccessTokenTTL>200</APICAccessTokenTTL></OAuthProviderSettings>
```

For a list of all OAuth provider settings, refer to the **OAuthProviderSettings** management schema, defined in the xml-mgmt.xsd file located in the store: directory on the DataPower API Gateway.

If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Connect Designer.

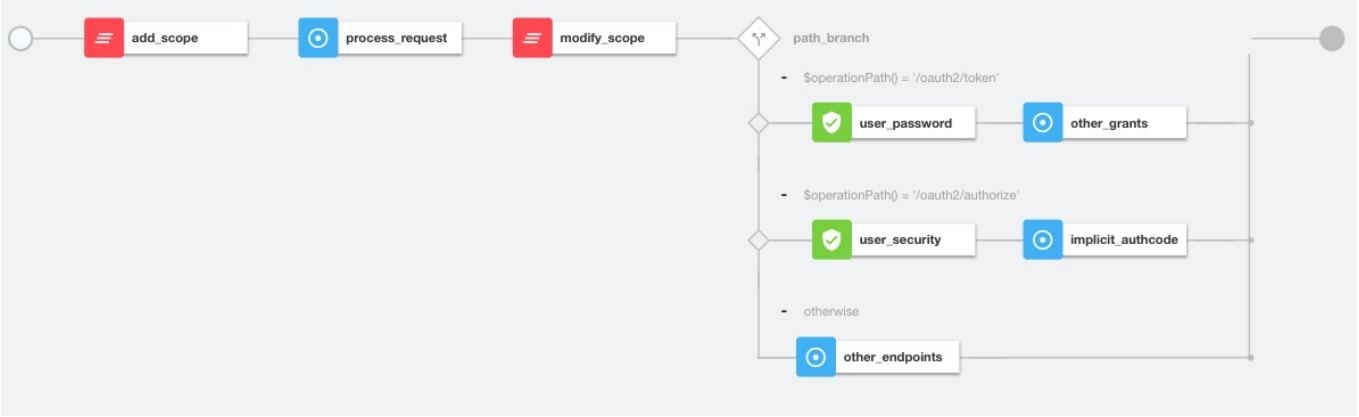
Example - using multiple OAuth policies in an OAuth provider assembly

This example demonstrates the use of multiple OAuth policies in the assembly flow for a native OAuth provider.

The example is based on the default assembly that is generated when you create a native OAuth provider, and is customized with the addition of **gatewayscript** policies that use OAuth context variables to manipulate the OAuth flow. For details on creating a native OAuth provider, see Configuring a native OAuth provider.

It has the following assembly flow:



The following sections describe the OpenAPI source code that underlies each of the policies in the assembly; for the complete assembly code, download multiple_oauth_policies.txt.

Sample policy to add a custom scope

The **add_scope** policy is a **gatewayscript** policy that adds a custom scope to the request.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
    version: 2.0.0
    title: add_scope
    source: |-
      // Add another custom scope to the request
      let scope = context.get("request.parameters.scope.values[0]);
      if (scope)
        context.set("oauth.processing.scope", scope + " custom");
```

Validate the initial OAuth request

The first **process_request** policy is an **oauth** policy that processes the initial request and verifies that the request is valid. The result of the processing is stored automatically in the oauth.processing context variables for use, as required, by the next OAuth policy in the assembly flow.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
    title: process_request
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect protocol steps
```

```
      that are needed for OAuth Validation by default. The inputs and
      outputs of each of the steps are driven by documented context
      variables. Add or remove the Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthValidateRequest
```

Sample policy to modify the scope

The **modify_scope** policy is a **gatewayscript** policy that modifies the scope depending on the calling application.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
    version: 2.0.0
    title: modify_scope
    source: |-
      let admin_id = '1f1a2aa4-db9f-4423-b2f1-e2572b12123a';

      // Check application and modify the scope
      let app = context.get("oauth.processing.client_id");
      let scope = context.get("oauth.processing.scope");
      if (app === admin_id) {
        context.set("oauth.processing.scope", scope + " admin");
      } else {
        context.set("oauth.processing.scope", scope + " customer");
      }
```

Branch conditionally according to the OAuth path

The **path_branch** policy is a **switch** policy that branches according to the different OAuth paths to process the resource owner.

The underlying OpenAPI source YAML is as follows:

```
- switch:
    version: 2.0.0
    title: path_branch
    case:
      - condition: ($operationPath() = '/oauth2/token')
        execute:
            .
            .
            .
          definition of the user_security and other_grants policies
            .
            .
            .
      - condition: ($operationPath() = '/oauth2/authorize')
        execute:
            .
            .
            .
          definition of the user_password and implicit_authcode policies
            .
            .
            .
      - otherwise:
            .
            .
            .
          definition of the other_endpoints policy
            .
            .
            .
```

Process the user name and password, and enable grant type component

The following two policies operate on the token endpoint.

- The **user_password** policy for password grant type processes the user name and password from the **x-www-form-urlencoded** body. The authentication method is derived from the User Security settings in the OAuth provider; see Configuring user security for a native OAuth provider.
- The **other_grants** policy is an **oauth** policy that enables the **OAuthGenerateAccessToken**, **OAuthVerifyAZCode**, **OAuthVerifyRefreshToken**, and **OAuthCollectMetadata** components to perform the operations for client credentials, authorization code, refresh token, and password grant types.

The underlying OpenAPI source YAML is as follows:

```
- user-security:
    title: user_password
    version: 2.0.0
    description: ''
    factor-id: default
    extract-identity-method: context-var
    user-context-var: request.parameters.username.values
    pass-context-var: request.parameters.password.values
    ei-stop-on-error: false
    user-auth-method: auth-url
    au-stop-on-error: false
    auth-url: 'http://httpbin.org/basic-auth/user/pass'
    user-az-method: authenticated
```

```
    az-stop-on-error: true
    auth-response-headers-pattern: (?)x-api*
    auth-response-header-credential: X-API-Authenticated-Credential
- oauth:
    title: other_grants
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for token path by default.
      The inputs and outputs of each of the steps are driven by
      documented context variables. Add or remove the Supported
      OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthGenerateAccessToken
      - OAuthVerifyAZCode
      - OAuthVerifyRefreshToken
      - OAuthCollectMetadata
```

Perform authorization checks, and enable grant type components

These following two policies operate on the authorize endpoint.

- The **user_security** policy configuration is derived from the User Security settings in the OAuth provider; see Configuring user security for a native OAuth provider.
- The **implicit_authcode** policy is an **oauth** policy that enables the **OAuthGenerateAZCode**, **OAuthGenerateAccessToken**, and **OAuthCollectMetadata** components to perform the operations for the implicit and authorization code grant types.

The underlying OpenAPI source YAML is as follows:

```
- user-security:
    title: user_security
    version: 2.0.0
    description: >-
      This user security policy performs EI(basic) and AU(auth
      url) check for oauth assembly. Change the security check
      method as required
    factor-id: default
    extract-identity-method: basic
    ei-stop-on-error: true
    user-auth-method: auth-url
    au-stop-on-error: true
    user-az-method: authenticated
    az-stop-on-error: true
    auth-response-headers-pattern: (?)x-api*
    auth-response-header-credential: X-API-Authenticated-Credential
    auth-url: 'http://httpbin.org/basic-auth/user/pass'
- oauth:
    title: implicit_authcode
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for az code path by
      default. The inputs and outputs of each of the steps are
      driven by documented context variables. Add or remove the
      Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthGenerateAZCode
      - OAuthGenerateAccessToken
      - OAuthCollectMetadata
```

Process all other endpoints

The **otherwise** condition catches all other endpoints such as the introspect and revoke endpoints. The **other_endpoints** policy in the **otherwise** condition is an **oauth** policy that enables the **OAuthIntrospectToken**, and **OAuthRevokeTokencomponents** components to perform the operations for introspect and revoke.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
    title: other_endpoints
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for all other paths by
      default. The inputs and outputs of each of the steps are
      driven by documented context variables. Add or remove the
      Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthIntrospectToken
      - OAuthRevokeToken
```

Parse

Use the Parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later) 2.2.0 (DataPower API Gateway Version 10.5.0.5 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see parse.

About Parse

With the parse policy, you can retrieve parse settings by using the following methods in increasing order of precedence.

1. Specify a valid parse settings configuration from which to retrieve its properties as the default parse settings.
   Note: If you change the default name, you must separately configure a corresponding ParseSettings object on the DataPower API Gateway.
2. Specify a literal string as serialized XML or JSON properties as parse settings. These properties take precedence over any existing default properties. The literal string must be XML or JSON formatted.
   - The XML format is `"<ParseSettings><propertyName>propertyValue</propertyName></ParseSettings>"`.
   - The JSON format is `"{ \"ParseSettings\" : { \"propertyName\" : propertyValue } }"`.
3. A URL that represents a named context from which to retrieve the serialized XML or JSON properties as parse settings. These properties take precedence over any existing literal or default properties.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Parse policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **parse**.	string
Description	No	A description of the policy.	string
Use Content Type	No	If this setting is enabled and the parse setting is configured to detect the document type, the parse operation uses the **Content-Type** specified in the request headers. If this setting is enabled and the document type in the parse setting is configured for either JSON or XML, the parse operation uses the **Content-Type** specified in the request headers and fails if the **Content-Type** in the request headers does not match the parse setting. Enabling this setting is applicable only when the expected **Content-Type** is either JSON or XML. If this setting is not enabled, the parse operation uses either the document type that is specified in the parse setting, or the detected document type if the parse setting is configured to detect the document type. The check box is cleared by default.	boolean
Parse settings object reference	No	An existing valid object from which to retrieve default property values for the dynamic object.	string

Property label	Required	Description	Data type
Document type	No	The type of document to parse. Select one of the following options: • Detect: the document type is detected and the payload is parsed accordingly. This type is the default option. • JSON: the payload is parsed as JSON. • XML: the payload is parsed as XML. • Graphql: parsing is performed in one of the following ways: ◦ As GraphQL in the body of a POST request. The GraphQL is in the following format: `{ me { name } }` ◦ As a JSON string in the body of a POST request that contains a GraphQL query. The JSON object is in the following format: `{ "query": "query MyData ($idVar: Int!) { user (id: $idVar) { name }}", "operationName": "MyData", "variables": {"idVar": 123} }` ◦ Through the URL query of a GET request. The URL is in the following format: `https://myapi/graphql?query={me{name}}` The following example includes the **variables** and **operationName** properties, with URL encoding (line-breaks are for table formatting only, your value will not include line-breaks): `https://hostname/basepath/graphql?query=query%20fetchAccounts %20($limit:%20Int)%20{accounts(limit:%20$limit)%20{name{first,last}}} &variables={"limit":100}&operationName=fetchAccounts` Query variables in a GET request can be sent as a JSON string in a query parameter called **variables**. If the query contains several named operations, an **operationName** query parameter is required to determine which operation is to be executed.	string
Maximum document size	No	Optionally, the maximum document size in bytes of a JSON, XML, or GraphQL input document that the parse operation accepts. This setting provides threat protection by enforcing the maximum document size. Enter a value in the range 0 - 5368709121. A document is rejected when its size exceeds the maximum size. A value of 0 indicates an unlimited document size. When set to 0, the operation result does not return the document size. The default value is 4194304.	integer
Maximum nesting depth	No	Optionally, the maximum nesting depth of an XML, JSON, or GraphQL message that the parse operation accepts. This setting provides threat protection by enforcing limits in the message. • When XML, it is the maximum level of element depth. • When JSON, it is the maximum level of nested label-value pairs, the maximum number of nested arrays, or the maximum number of combination of label-value pairs and arrays. • When GraphQL, it is the maximum level of nested selection sets. Enter a value in the range 0 - 4096. A document is rejected when its nesting depth exceeds the maximum depth. A value of 0 indicates unlimited nesting depth. When set to 0, the operation result does not return the nesting depth. The default value is 512.	integer
Maximum width	No	Optionally, the maximum width of the payload that the parse operation accepts. • When the input document is XML, this property specifies the maximum number of attributes for an element or the maximum number of child elements for an element. • When the input document is JSON, this property specifies the maximum number of properties on a JSON object or the maximum number of JSON items in a JSON array. • When the input document is GraphQL, this property specifies the maximum number of selections in a selection set. Enter a value in the range 0 - 65535. The document is rejected when its width exceeds the maximum width. A value of 0 indicates unlimited width. When set to 0, the operation result does not return the width of the document. The default value is 4096.	integer
Maximum name length	No	Optionally, the maximum name length in bytes in a document that the parse operation accepts. • For XML, it is the length of the name portion of a tag. • For JSON, it is the length of the label portion of the JSON label-value pair. • For GraphQL, it is the maximum length of the identifiers, including field names and directive names. The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 8192. A document is rejected when its name length exceeds the maximum length. A value of 0 indicates unlimited name length. When set to 0, the operation result does not return the name length of a document. The default value is 256.	integer

Property label	Required	Description	Data type
Maximum value length	No	Optionally, the maximum value length in bytes in a document that the parse operation accepts. • For XML, it is the length of an attribute or the length of a text value. • For JSON and GraphQL, it is the length of a string value. The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 5368709121. A document is rejected when its value length exceeds the maximum length. A value of 0 indicates unlimited value length. When set to 0, the operation result does not return the value length of a document. The default value is 8192.	integer
Maximum number of unique names	No	Optionally, the maximum number of unique names in a JSON or XML document that the parse operation accepts. • For XML, it is the number of unique XML local names. • For JSON, it is the number of unique JSON labels. Enter a value in the range 0 - 1048575. A document is rejected when the number of unique names in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique names. When set to 0, the operation result does not return the number of unique names in a document. The default value is 1024.	integer
Maximum number of unique prefixes	No	Optionally, the maximum number of unique XML namespace prefixes in a document that the parse operation accepts. This limit counts multiple prefixes defined for the same namespace, but does not count multiple namespaces defined in different parts of the input document under a single prefix. Enter a value in the range 0 - 262143. A document is rejected when the number of unique prefixes in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique prefixes. When set to 0, the operation result does not return the number of unique prefixes in a document. The default value is 1024.	integer
Maximum number of unique namespaces	No	Optionally, the maximum number of unique XML namespace URIs that the parse operation accepts. This limit counts all XML namespaces, regardless of how many prefixes are used to declare them. Enter a value in the range 0 - 65535. A document is rejected when the number of unique namespaces in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique namespaces. When set to 0, the operation result does not return the number of unique namespaces in a document. The default value is 1024.	integer
Maximum number length	No	Optionally, the maximum number of bytes in the value portion of a JSON label-value pair when the value is a number. The number must be a contiguous string of bytes that contain no white space. The number can include a minus sign and a positive or negative exponent. Enter a value in the range 0 - 256. A document is rejected when the number length in the document exceeds the maximum length. A value of 0 indicates unlimited number length. When set to 0, the operation result does not return the number length in a document. The default value is 128.	integer
Parse settings literal configuration	No	A literal string as serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing default properties.	string
Parse settings URL reference	No	A URL that represents a named context from which to retrieve the serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing literal or default properties.	string
Message for parsing	No	The name of a variable in the API context. The content of the **`body`** field of the variable is the input to the policy. The default variable name is **`message`**.	string
Message for resulting parsed data	No	The name of a variable in the API context. The content of the body field of the variable is the output of the parse operation. The parse metrics of the parsed document can be stored in a different part of the message. The default variable name is the same as the input name, so by default the input message is overwritten by the output message.	string

Use the YAML source to set the following option.

Property	Required	Description	Data type
strict-utf8-encoding	No	For JSON documents, whether to enforce strict UTF-8 encoding throughout the entire document. • When **`on`**, the entire document is checked for valid UTF-8 encoding. • When **`off`**, only the first few bytes are checked for proper encoding. The rest of the document is assumed to be in the same encoding. The default value is **`off`**.	boolean

For examples, see parse.

Proxy

Apply the Proxy policy to invoke another API within your assembly, particularly if the separate API contains a large payload. The response from the backend is stored in the **`message.body`** and in the response object variable if it is defined. Only one policy is permitted to be run per unique assembly flow.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by Invoke	

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see proxy.

About

Only one Proxy policy is permitted to be run per unique flow of your assembly. More than one Proxy policy can be applied, if they are contained in mutually exclusive branches of the assembly.

You can use the Proxy policy to return multipart form data, that is, when the response is set to `Content-Type: multipart/related`. However, Proxy must be the last policy in the assembly, otherwise the response that is received can be manipulated during subsequent steps, thereby causing the multipart form data to be lost.

The proxy policy, if inside a conditional policy, must be the **final** policy to be executed in the API. If you need further processing afterward, use the invoke policy rather than the proxy policy.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Proxy policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`proxy`**.	string
Description	No	A description of the policy.	string
Invoke URL	Yes	Specifies a URL for the target service. For a SOAP API, a URL is added by default. Where possible, the Proxy URL value is pre-supplied from information that is defined in the imported WSDL.	string
TLS profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	Yes	The time to wait before a reply back from the endpoint (in seconds). The default value is **`60`**.	integer
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
HTTP Method	Yes	The HTTP method to use for the proxy. Valid values are: • Keep • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is **`Keep`**. By using **`Keep`**, or removing the property from the source, the HTTP method from the incoming request is used.	string
Compression	No	Select this check box to enable Content-Encoding compression on upload. The check box is cleared by default.	boolean

Property label	Required	Description	Data type
Cache Type	No	The cache type determines whether to cache documents, honoring or overriding the HTTP Cache Control directives received in the response from the target URL. This property takes effect only when a response is received, otherwise the policy always returns the non-expired response that was previously saved in cache. Valid values are: Protocol The cache behavior is determined by the Cache-Control headers on the response, in accordance with RFC 7234. To optimize performance, if the gateway receives more than one request for a resource that is not in the cache but could be cached when the response from the target URL is received, the gateway sends only one request to the target URL; the remaining requests are not processed until the response from the first request has been received and the cache behavior has been determined from this response. If the response indicates that caching is possible, the gateway responds to all waiting requests with the cached resource. If the response indicates that caching is not possible, the gateway sends all waiting requests to the target URL. Use this option only if you expect that responses from the target URL can be cached, in which case it should improve performance and limit the demand on the target URL. If, however, the target URL never indicates that the gateway should cache its response, performance might be impaired when compared to the No Cache option. No Cache Responses from the target URL are not cached on the gateway regardless of any caching headers returned. In this case, every request from the client is sent to the target URL. Use this option if you do not want to cache any of the backend responses on the gateway, or if it is unlikely that a response from the target URL will allow caching through the Cache-Control header settings. Time to Live This option is similar to the Protocol option except it allows you to specify the amount of time that you want the successful response from the invoke or proxy to remain in the cache. Use this option only if you expect that responses from the target URL can be cached. The default value is Protocol.	string
Time to Live	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property Cache type is set to **`Time to Live`**. Enter a value in the range 5 - 31708800. The default value is **`900`**.	integer
Cache key	No	Specifies the unique identifier of the document cache entry. If omitted, the entire URL string is used as the key.	string
Stop on error	No	Select the errors that, if thrown during the policy execution, cause the assembly flow to stop. If there is a **`catch`** flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors selected for the Stop on error setting, or if the error thrown is not one of the selected errors, the policy execution is allowed to complete, and the assembly flow continues.	string
Response object variable	No	The name of a variable that will be used to store the response data from the request. This variable can then be referenced in other actions, such as 'Map'.	string
X-Forwarded header	No	This header can be provided by 1. If **`X-Forwarded-Host`** exists, processing continues. If it does not exist prior to calling the proxy policy, it is set with the value of the **`Host`** header. 2. The **`X-Forwarded-For`** header is always set, in all cases. This header maintains breadcrumbs, showing a comma-separated list of IPs, from the client through any preceding proxy. 3. If all three of **`X-Forwarded-Host`** , **`X-Forwarded-Port`** , and **`X-Forwarded-Proto`** headers are missing at the time of calling the proxy policy, they are set automatically. To prevent this, set **`X-Forwarded-Host`** header to some value before calling the proxy policy.	string

API Gateway only

Rate Limit

Use the Rate Limit policy to apply one or more rate, burst, or count limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.0 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.5.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see ratelimit.

About

The defined rate, burst, and count limits are applied to whatever follows in the assembly flow. For example, if a Rate Limit policy is placed before an Invoke policy, and the call made by the Invoke policy exceeds the limits defined by the Rate Limit policy, the API call itself fails.

Note: For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Rate Limit policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`ratelimit`**.	string
Description	No	A description of the policy.	string
Source	Yes	The location of all the rate limit, burst limit, and count limit definitions that are included in this policy. Select one of the following options: • Catalog by Name: the limits to be applied are defined in the appropriate **`api-collection`** object on the DataPower API Gateway, which is the object that represents your API Connect Catalog in the gateway configuration. For details of how to configure a rate, burst, or count limit in the **`api-collection`** object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. • Plan by Name: the limits to be applied are assembly burst limits or assembly count limits defined on the Plan to which the calling application is subscribed. For details on how to configure assembly burst limits and assembly count limits in a Plan, see Editing a draft Product. Note: The following conditions apply to a Plan by Name rate limit policy: ◦ Every Plan that contains the API that is being limited must have the named rate limit applied. ◦ A Plan by Name rate limit policy cannot be used with automatically generated Products. • Gateway by Name: the limits to be applied are defined in the **`apigw`** object, named **`apiconnect`**, on the DataPower API Gateway gateway. For details of how to configure a rate, burst, or count limit in the **`apigw`** object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. • Plan Default: the rate and burst limits that are applied are the default ones configured in the Plan to which the calling application is subscribed. For details on how to configure default Plan rate and burst limits, see Editing a draft Product. Note: The use of this option does not disable any automatic preflow rate limit policy that might be in place, and could result in the application of the rate limiting being repeated. For more information on preflow policies, see Customizing the preflow policies.	string
Rate Limit Name	Yes[1]	If Source property is set to Catalog by Name, the name of a rate limit as defined in the DataPower API Gateway configuration, To display the Rate Limit Name field, click Add Rate Limit; you can add as many rate limits as you want. [1]You must provide at least one rate, burst, or count limit.	string

Property label	Required	Description	Data type
Burst Limit Name	Yes[2]	If Source property is set to Catalog by Name, the name of a burst limit as defined in the DataPower API Gateway configuration. If Source is set to Plan by Name, the name of an assembly burst limit in a Plan. To display the Burst Limit Name field, click Add Burst Limit; you can add as many burst limits as you want. [2]You must provide at least one rate, burst, or count limit.	string
Count Limit Name	Yes[3]	If Source property is set to Catalog by Name, the name of a count limit as defined in the DataPower API Gateway configuration. If Source is set to Plan by Name, the name of an assembly count limit in a Plan. To display the Count Limit Name field, click Add Count Limit; you can add as many count limits as you want. [3]You must provide at least one rate, burst, or count limit.	string
Operation	No	For a rate limit, select one of the following options: • Consume: the policy reduces the balance of available requests that remain in the interval defined by the rate limit specified in the Rate Limit Name field. The amount by which the remaining balance is reduced is the value that results from the weight expression defined in the specified rate limit. • Replenish: the policy increases the balance of available requests that remain in the interval defined by the rate limit specified in the Rate Limit Name field. The amount by which the remaining balance is increased is the value that results from the weight expression defined in the specified rate limit. The purpose of the replenish operation is to restore an appropriate amount of remaining balance in cases where the amount calculated by an earlier consume operation turns out to be too high. For example, for an assembly rate limit with a limit of 100, a consume operation with a weight of 60 uses 60 requests, leaving 40 requests remaining for the interval. If the weight expression in the subsequent replenish operation computes to 15, meaning that the weight expression calculated that the actual request usage was only 45, the replenish operation increases the remaining requests by 15, to a remaining balance of 55. Note that the replenish operation cannot increase the remaining requests allowed beyond the original limit defined in the assembly rate limit scheme. In this example, a replenish operation cannot replenish requests beyond 100. A replenish operation is skipped if the weight expression evaluates to a value of less than 1. The default value is Consume. For a count limit, select one of the following options: • Increment: the current count is incremented by the value that results from the weight expression defined in the count limit specified in the Count Limit Name field. • Decrement: the current count is decremented by the value that results from the weight expression defined in the count limit specified in the Count Limit Name field. By default, the count limit is automatically decremented at the end of the API assembly by the total amount incremented during the assembly, minus any decrement operations that are defined in the assembly. You do not need to explicitly define decrement operations unless you want the decrements to occur at specific points in the assembly. However, if the auto decrement feature has been explicitly disabled in the count limit configuration, you must include a corresponding decrement operation, otherwise when the count limit is reached all future calls are blocked. For more information on configuring a count limit, see Configuring a rate, burst, or count limit on the DataPower API Gateway. The default value is Increment. For a burst limit, the only option is Consume, meaning that the limit applied is that defined in the burst limit specified in the Burst Limit Name field.	string

- **Configuring a rate, burst, or count limit on the DataPower API Gateway**
  If you want to include a rate limiting policy in your API assembly flow, you must first configure the required rate, burst, and count limits on the Gateway. Rate and burst limits restrict the number of calls that an application can make to API in specified time period, while count limits impose a strict limit on the total number of calls.

Configuring a rate, burst, or count limit on the DataPower API Gateway

If you want to include a rate limiting policy in your API assembly flow, you must first configure the required rate, burst, and count limits on the Gateway. Rate and burst limits restrict the number of calls that an application can make to API in specified time period, while count limits impose a strict limit on the total number of calls.

About this task

You configure rate, burst, and count limits on the DataPower® API Gateway by defining them in one or more configuration files that you package and then add to the Gateway as a Gateway extension.

You define *Catalog scoped* rate, burst, and count limits in the appropriate **api-collection** object on the DataPower API Gateway, which is the object that represents your API Connect Catalog in the gateway configuration. The defined rate, burst, and count limits will be available to be included in Rate Limit policies in the assembly flows of all the APIs that are published to that Catalog.

You define *Gateway scoped* rate, burst, and count limits in the appropriate **apigw** object on the DataPower API Gateway. The defined rate, burst, and count limits will be available to be included in Rate Limit policies in the assembly flows of all the APIs that are published to that Gateway.

Note:

- Only one Gateway extension can be in use at any one time, so you should package all required rate, burst, and count limits in a single Gateway extension.
- To apply a Catalog scoped or Gateway scoped rate, burst, or count limit, it must be referenced in a Rate Limit policy in an API assembly.
- You should ensure that all rate, burst, and count limit names are unique across all your Plans and Catalogs. When an API is called, information about any rate, burst, or count limits (such as name, limiting criteria, and remaining number of calls) is returned in the HTTP headers of the response. If two or more limit definitions with exactly the same name are applied during the invocation of an API, information about only **one** of them is returned. However, **all** limiting criteria are applied.

Procedure

1. Create a .cfg file that includes the DataPower API Gateway CLI commands that define the rate, burst, or count limit.
   To define a rate limit, use the **assembly-rate-limit** command. To define a burst limit, use the **assembly-burst-limit** command. To define a count limit, use the **assembly-count-limit** command. For details of the command parameters, see assembly-rate-limit, assembly-burst-limit, and assembly-count-limit in the DataPower product documentation.

   Example 1: Configuring a Catalog scoped rate limit

   ```
   top; config;
   switch apiconnect;

   api-collection myorg_mycatalog_collection
     assembly-rate-limit  30per1min 30 1 minute on off on on off off "" "my.vars.expected-amount - my.vars.actual-
   amount"
   exit
   ```

   In this example, the **assembly-rate-limit** command specifies a rate limit name, and the API call limits that you want to impose, 30 calls per minute in this case. The final, optional argument, **"my.vars.expected-amount - my.vars.actual-amount"**, is a weight expression. You use weight expressions in cases where you want to restore an appropriate amount of remaining rate limit balance when an earlier usage calculation in your assembly flow turns out to be too high. You define two rate limiting policies in your assembly flow, one with a **consume** operation, and a subsequent one with a **replenish** operation that restores some of the remaining rate limit balance if appropriate. The weight expression calculates the amounts to be consumed or replenished; for more information, see Rate Limit.

   The **api-collection** command specifies the **api-collection** object in which you want to configure the rate, burst, or count limits. The name of the **api-collection** object has the following format:

   ***org_catalog*_collection**

   where:
   - *org* is the name of the provider organization that contains your Catalog.
   - *catalog* is the name of the Catalog.

   This **api-collection** object name is assigned automatically by the Gateway the first time that a Product is published to the Catalog.

   Example 2: Configuring a Catalog scoped count limit

   ```
   top; config;
   switch apiconnect;

   api-collection myorg_mycatalog_collection
     assembly-count-limit  maxsixty 60 1 on on off off off off "" "1" off
   exit
   ```

   The final argument is the **autodecrement** property that controls whether the count limit is automatically decremented at the end of an API assembly. The default value is **on**, meaning that at the end of the assembly the count limit is automatically decremented by the total amount incremented during the assembly, minus any decrement operations that are defined in the assembly. You do not need to explicitly define decrement operations unless you want the decrements to occur at specific points in the assembly.

   Example 3: Configuring a Gateway scoped rate limit

   ```
   top; config;
   switch apiconnect;

   apigw apigw_object_name
     assembly-rate-limit  30per1min 30 1 minute on off on on off off "" "my.vars.expected-amount - my.vars.actual-
   amount"
   exit
   ```

   The **apigw** command specifies the name of the **apigw** object in which you want to configure the rate, burst, or count limits; the **apigw** object name is the same as the name of the API Connect domain in your DataPower API Gateway configuration.

2. Package the .cfg file in a **.zip** file.
   You can package multiple .cfg files in a single **.zip** file if you want; the .cfg files must all be at the root of the **.zip** file.
3. Add the **.zip** file to the DataPower API Gateway as a Gateway extension. For details, see Configuring your Gateway server extensions.

What to do next

Apply the rate, burst, or count limits to an API by adding a Rate Limit policy to the API assembly flow.

Related information

- Gateway extension guidelines - DataPower API Gateway.

Redaction - DataPower API Gateway

Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This page describes the Redaction policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see Redaction - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see redact - DataPower API Gateway.

Note: With the DataPower API Gateway, the input to the Redaction policy must be parsed data. One way to produce parsed data is to use a Parse policy before a Redaction policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Redaction policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`redact`**.	string
Description	No	A description of the policy.	string
Root	No	Specifies the data source that contains the content to redact or remove. If no value is entered in the Root field, the action is applied to the entire API context. You can use any supported JSONata path expression. If you want to apply the action to either request or response data, specify a value of `message.body`. The actual content to which the action is applied then depends on the positioning of the Redaction policy in the overall assembly flow; for example: • If positioned at the beginning, the action is applied to the client request. • If positioned after an Invoke policy, the action is applied to the response from the back end. • If positioned at the end, the action is applied to the response that is returned to the client. If, in your assembly flow, the Redaction policy is used after a Log policy that specifies Gather-only mode, specify a Root value of `log.request_body` for the logged request payload, or `log.response_body` for the logged response payload.	string
Path	Yes	Specifies a JSONata path expression that identifies the content to redact or remove from the source. For more information, see Constructing JSONata expressions to redact fields	string
Action	No	Specifies whether you want to remove or redact the content. Choose one of the following options: • Remove: Completely removes the specified fields. • Redact: Redacts (obfuscates with "*"s) the fields to block out the data. The default value is Redact. Note: If a numerical value is being redacted, the redacted value is depicted as `******` and the type is changed to **`string`**.	string

Tip: You can optionally click Add action to specify JSONata expressions for additional fields that you want to remove or redact from the specified content source.

- **Constructing JSONata expressions to redact fields**
  To define a field for redaction or removal when using the Redaction policy with the DataPower API Gateway, you supply a JSONata expression that defines the path to the field that you want to redact or remove.

Constructing JSONata expressions to redact fields

To define a field for redaction or removal when using the Redaction policy with the DataPower® API Gateway, you supply a JSONata expression that defines the path to the field that you want to redact or remove.

Note: For a list of known limitations to DataPower API Gateway support for JSONata, see Limitations to support for JSONata.
The following JSONata functions are supported:

- Aggregation functions:
  - `$average(array)`
  - `$max(array)`
  - `$min(array)`
  - `$sum(array)`
- Array functions:
  - `$append(array1, array2)`
  - `$count(array)`
  - `$reverse(array)`
  - `$sort(array [, function])`
  - `$zip(array1, ...)`
- Boolean functions:
  - `$boolean(arg)`
  - `$exists(arg)`
  - `$not(arg)`
- Numeric functions:
  - `$abs(number)`
  - `$ceil(number)`
  - `$floor(number)`
  - `$formatBase(number [, radix])`
  - `$number(arg)`
  - `$power(base, exponent)`
  - `$round(number [, precision])`
  - `$sqrt(number)`
- Object functions:
  - `$keys(object)`
  - `$lookup(object, key)`
  - `$merge(array<object>)`
  - `$spread(object)`
  - `$type(value)`
    In addition to the standard values returned by `$type()`, the API gateway implementation of `$type()` can return the following values: `binary`, `empty`, `graphql`, `stream`, or `xml`.
- String functions:
  - `$contains(str, pattern)`
  - `$join(array[, separator])`
  - `$length(str)`
  - `$lowercase(str)`
  - `$match(str, pattern [, limit])`
  - `$pad(str, width [, char])`
  - `$replace(str, pattern, replacement [, limit])`
  - `$split(str, separator [, limit])`
  - `$string(arg)`
  - `$substring(str, start[, length])`
  - `$substringAfter(str, chars)`
  - `$substringBefore(str, chars)`
  - `$trim(str)`
  - `$uppercase(str)`
- You can use the following functional extensions to standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description
`$header(name)`	`message.headers.name`	Message header
`$httpVerb()`	`request.verb`	HTTP method of the request
`$operationID()`	`api.operation.id`	ID of the operation
`$operationPath()`	`api.operation.path`	Path of the operation
`$queryParameter('name')`	• `request.parameters.`*`name`*`.locations` The supported keyword is `query`. • `request.parameters.`*`name`*`.values`	Searches for the index of `query` in `request.parameters.`*`name`*`.locations` and returns `request.parameters.`*`name`*`.values[index]`, where `[index]` is the value for `query` in locations. Parameter values are not URL decoded.
`$statusCode()`	`message.status.code`	Status code
`$storageType([arg])`	*`variable`*`.body` You can specify any variable in the API context. When no variable is specified, the default variable `message.body` is used.	Storage type of the message. The supported values are `binary`, `empty`, `graphql`, `json`, `stream`, or `xml`.

Extension	Variable	Description
`$urlParameter('name')`	• `request.parameters.name.locations` The supported keywords are `path` and `query` • `request.parameters.name.values`	Searches for the index of `path` and `query` in `request.parameters.name.locations` and returns a single array that contains both `path` and `query` values from `request.parameters.name.values`. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values. `http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese` The `$urlParameter('breed')` URL returns the following array of values. `[cats, adopt, Sphynx, Siamese]` In this example, the URL includes an API path that is configured as `/petstore/{breed}/{breed}`, where `breed` is configured to be a path parameter of the API path. As a result, `cats` and `adopt` are included in the output.
`$xpath(path, xpathExpression)`	You can specify any writable variable in the API context. The `xpathExpression` must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. `$xpath($, '//price')`

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
`$gqlActiveOperation([graphql_message])`	`message.body`	Gets the active operation found in the specified GraphQL message. The `operationName` must be the same as the name of the active operation.
`$gqlAlias(graphql_field_node)`	`message.body`	Gets the alias of a GraphQL field node.
`$gqlFragments([graphql_message])`	`message.body`	Gets the fragments found in the specified GraphQL message.
`$gqlName([graphql_node])`	`message.body`	Gets the node name. For operations, the node name is the `operationName`. For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the `operationName` of `message.body` is retrieved.
`$gqlOperations([graphql_message])`	`message.body`	Gets the operations found in the specified GraphQL message.
`$gqlType([graphql_node])`	`message.body`	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

- You can use the `&` (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- / (division)
- % (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- `query`
  The entire GraphQL query including operations and fragments.

- *`operationName`*
  For an anonymous operation, *`operationName`* can be empty.

- *`~fragmentSpreadName`*
- *`on~typeCondition`*
- *`~~fragmentDefinitionName`*

You can define the path in either of the following ways:

- Use a JSONata expression
- Use the `$xpath()` JSONata extension

Using a JSONata expression

The path specified by the JSONata expression is relative to any value specified for the **root** property of the Redaction policy. If the **root** property has no value or is absent, begin the expression with the absolute content path. If the **root** property has a value then you can either begin the expression with **$** to use the **root** path directly, or you can provide a sub-path relative to the **root** path.

JSONata expressions can be used with content that is in either JSON or XML format.

Example 1
: If the **root** property of the Redaction policy has no value or is absent, use the following expression to redact or remove all occurrences of the **price** field in the request and response data:

```
message.body.**.price
```

Example 2
: If the **root** property of the Redaction policy has the value **log.request_body**, use the following expression to redact or remove all occurrences of the **price** field, specifically within an **item** element, in the logged request payload:

```
$.item.price
```

Example 3
: If the **root** property of the Redaction policy has the value **log**, use the following expression to redact or remove all occurrences of the **price** field in the logged response payload:

```
response_body.**.price
```

The ****** descendant wildcard traverses all descendants at all hierarchical levels.

Using the `$xpath()` JSONata extension

The **$xpath()** function has the following format:

```
$xpath(content_path, xpath_expression)
```

where:

- *content_path* is the path to the content that contains the field that you want to redact or remove.
- *xpath_expression* is the XPath expression that defines the field that you want to redact or remove.

The *content_path* is relative to any value specified for the **root** property of the Redaction policy. If the **root** property has no value or is absent, provide the absolute content path. If the **root** property has a value then you can either provide the value **$** for the *content_path* parameter to use the **root** path directly, or you can provide a sub-path relative to the **root** path.

The **$xpath()** function can be used only with content that is in XML format.

Example 1
: If the **root** property of the Redaction policy has no value or is absent, use the following expression to redact or remove all occurrences of the **price** field in the request and response data:

```
$xpath(message.body, '//price')
```

Example 2
: If the **root** property of the Redaction policy has the value **log.request_body**, use the following expression to redact or remove all occurrences of the **price** field, specifically within an **item** element, in the logged request payload:

```
$xpath($, 'item/price')
```

Example 3
: If the **root** property of the Redaction policy has the value **log**, use the following expression to redact or remove all occurrences of the **price** field in the logged response payload:

```
$xpath(response_body, '//price')
```

The **//** expression in the second parameter selects all occurrences anywhere in the content.

DataPower Gateway (v5 compatible)

Redaction - DataPower Gateway (v5 compatible)

Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This topic describes the Redaction policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see Redaction - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see redact - DataPower Gateway (v5 compatible).

About

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Redaction policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **redact**.	string
Description	No	A description of the policy.	string
Path	Yes	Specifies an XPath expression that defines the field to remove or redact. You can construct an XPath expression that is based on JSON or XML depending on whether your API requests and responses use a JSON or an XML format. If the payload is JSON, use the DataPower XML representation of the JSON content (JSONx) to construct the expression. Note: Use a JSONx representation only to identify the XPath expressions for the fields to remove or redact. Do not change the format of any response bodies in API Manager. To learn more about constructing XPath expressions that are based on JSON or XML, see Constructing XPath expressions to redact fields.	string
Action	Yes	Specifies whether you want to remove or redact the field. Valid values: • **remove**: Completely removes the specified field. • **redact**: Redacts (obfuscates with "*"s) the field to block out the data. The default value is **redact**. Note: If a numerical value is being redacted, the redacted value is depicted as ****** and the type is changed to **string**.	string
From	Yes	Specifies where to remove or redact the specified field from. Valid values: • **all**: Removes or redacts the specified field from the Request body, the Response body, and the activity logs. • **request**: Removes or redacts the specified field from the Request body. • **response**: Removes or redacts the specified field from the Response body. • **logs**: Removes or redacts the specified field from the activity logs. The default value is **all**. Optionally click Add item to specify additional values.	string

Tip: You can optionally click Add item to specify XPath expressions for additional fields that you want to remove or redact from the Request body, Response body, and logs.

- **Constructing XPath expressions to redact fields**
  To define a field for redaction when using the DataPower Gateway (v5 compatible), you supply an XPath expression that specifies the field that you want to redact. If your API requests and responses use XML format, you can base your XPath statements directly on the XML content. If your API requests and responses use JSON format, you must use the DataPower XML representation of the JSON content, JSONx, to construct your XPath expression.

- API Connect context variables

DataPower Gateway (v5 compatible) only

Constructing XPath expressions to redact fields

To define a field for redaction when using the DataPower® Gateway (v5 compatible), you supply an XPath expression that specifies the field that you want to redact. If your API requests and responses use XML format, you can base your XPath statements directly on the XML content. If your API requests and responses use JSON format, you must use the DataPower XML representation of the JSON content, JSONx, to construct your XPath expression.

About this task

The following sections provide examples for constructing XPath expressions to redact a field; examples are provided for API responses in both XML and JSON format:

XPaths for XML

Consider the following example of an XML response:

```
<xml>
  <primaryAddress>
    <streetAddress>21 2nd Street</streetAddress>
    <city>New York</city>
    <state>NY</state>
    <postalCode>10021</postalCode>
  </primaryAddress>
  <secondaryAddress>
    <streetAddress>412 Brooklyn Avenue</streetAddress>
    <city>New Jersey</city>
    <state>NJ</state>
    <postalCode>12302</postalCode>
  </secondaryAddress>
</xml>
```

To redact "streetAddress" in the preceding example the XPath expression would be: `//streetAddress`
where the components of the expression have the following meaning:

Expression	Meaning
`//`	search anywhere in the XML structure
`//streetAddress`	search anywhere in the XML structure for an element of type "streetAddress"

The XML response that results from applying this XPath expression is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<xml>
  <primaryAddress>
    <streetAddress>*******</streetAddress>
    <city>New York</city>
    <state>NY</state>
    <postalCode>10021</postalCode>
  </primaryAddress>
  <secondaryAddress>
    <streetAddress>*******</streetAddress>
    <city>New Jersey</city>
    <state>NJ</state>
    <postalCode>12302</postalCode>
  </secondaryAddress>
</xml>
```

Note: Both incidences of "streetAddress" have been redacted.
To redact one specific incidence of "streetAddress" in the initial example, the XPath expression would be: `//secondaryAddress/streetAddress`
where the components of the expression have the following meaning:

Expression	Meaning
`//secondaryAddress`	search anywhere in the XML structure for an element of type "secondaryAddress"
`//secondaryAddress/streetAddress`	search under the preceding element for a child element of type "streetAddress"

The XML response that results from applying this XPath expression is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<xml>
  <primaryAddress>
    <streetAddress>21 2nd Street</streetAddress>
    <city>New York</city>
    <state>NY</state>
    <postalCode>10021</postalCode>
  </primaryAddress>
  <secondaryAddress>
    <streetAddress>*******</streetAddress>
    <city>New Jersey</city>
    <state>NJ</state>
    <postalCode>12302</postalCode>
  </secondaryAddress>
</xml>
```

Note: Only the secondary address has been redacted.
XPaths for JSON
Consider the following example of a JSON response:

```
{
  "primaryAddress": {
    "streetAddress": "21 2nd Street",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  },
  "secondaryAddress": {
    "streetAddress": "412 Brooklyn Avenue",
    "city": "New Jersey",
    "state": "NJ",
    "postalCode": 12302
  }
}
```

Unlike the preceding XML example, to construct an XPath for this example you must use the corresponding DataPower XML representation, JSONx. The JSONx equivalent of this JSON response is as follows:

```
<json:object xsi:schemaLocation="http://www.datapower.com/schemas/json jsonx.xsd"
xmlns:json="http://www.ibm.com/xmlns/prod/2009/jsonx" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <json:object name="primaryAddress">
    <json:string name="streetAddress">21 2nd Street</json:string>
    <json:string name="city">New York</json:string>
    <json:string name="state">NY</json:string>
    <json:number name="postalCode">10021</json:number>
  </json:object>
  <json:object name="secondaryAddress">
    <json:string name="streetAddress">412 Brooklyn Avenue</json:string>
    <json:string name="city">New York</json:string>
    <json:string name="state">NY</json:string>
    <json:number name="postalCode">10021</json:number>
  </json:object>
</json:object>]
```

To redact the element "streetAddress" from the preceding JSONx structure, the XPath expression would be: `//*[@name='streetAddress']`
where the components of the expression have the following meaning:

Expression	Meaning
`//*`	find any element anywhere in the structure
`[@name='streetAddress']`	this element has a 'name' property with value "streetAddress"

The JSON response that results from applying this XPath expression is as follows:

```
{
  "primaryAddress": {
    "streetAddress": "*******",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  },
  "secondaryAddress": {
    "streetAddress": "*******",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  }
}
```

Note: All incidences of "streetAddress" have been redacted in the preceding JSON structure.
To redact a specific occurrence of the "streetAddress" element, the XPath expression would be: `//*[@name='secondaryAddress']/*[@name='streetAddress']`
where the components of the expression have the following meaning:

Expression	Meaning
`//*`	find any element anywhere in the structure
`//*[@name='secondaryAddress']`	find an element anywhere in the structure that is named "secondaryAddress"
`//*[@name='secondaryAddress']/*[@name='streetAddress']`	find a child element of any type (`/*`) where the child element has a name of "streetAddress"

The JSON response that results from applying this XPath expression is as follows:

```
{
  "primaryAddress": {
    "streetAddress": "21 2nd Street",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  },
  "secondaryAddress": {
    "streetAddress": "*******",
    "city": "New York",
    "state": "NY",
    "postalCode": 10021
  }
}
```

Note: Only the street address for the secondary address has been redacted.

What to do next

See Including elements in your OpenAPI 2.0 API assembly, Including elements in your OpenAPI 2.0 API assembly to learn how to apply a redact policy using XPath.

Set Variable

Use the Set Variable policy to set the value of a runtime variable, or to clear a runtime variable, or to add a header variable.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see set-variable.

- **Configuring the Set Variable policy for DataPower API Gateway**
  Follow these steps to configure the Set Variable policy for DataPower API Gateway in the assembly user interface.
- **Configuring the Set Variable policy for DataPower Gateway (v5 compatible)**
  Follow these steps to configure the Set Variable policy for DataPower Gateway (v5 compatible) in the assembly user interface.

API Gateway only

Configuring the Set Variable policy for DataPower API Gateway

Follow these steps to configure the Set Variable policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the Set Variable policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the Set Variable policy for DataPower Gateway (v5 compatible). For more information about the different types of gateway, see API Connect gateway types. For information about how to configure the policy in your OpenAPI source, see set-variable.

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Set Variable policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Set Variable policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`set-variable`**.	string
Description	No	A description of the policy.	string
Action	Yes	Defines what action to apply on a runtime variable. Choose one of the following values: • Set: Indicates that you want to set a runtime variable to a string value. Can be used to set new headers or to override existing values. • Add: Indicates that you want to add a header variable. Can be used only to set new headers or to append a new entry of the same header name. • Clear: Indicates that you want to delete a runtime variable. Can be used to remove a header when the data is processed in the assembly flow. The default value is Set.	string
Set, Add, or Clear	Yes	Specifies the name of the variable that you want to set , add or clear, depending on the selected Action.	string
Type	Yes	Select the data type of the variable. Choose one of the following values: • any • string • number • boolean For all values other than any, the value is validated against the specified data type.	string
Value	Yes*	Allocates this value to the specified variable. Can be a literal value, or another variable. * Value is required only when **`Set`** or **`Add`** is specified as the action. For example, to *set* a named variable of **`billing-hostname`** to a literal value, you can specify the Value as **`acme.com`**. As another example, to *set* a named variable to the value of the Content-Type header in a request, you can specify the Value entry as **`$(request.headers.content-type)`**. If the selected value of the Type field is boolean, select the Value check box to indicated a value of **`true`**. Note: You can only set single string elements. Values are retrieved as strings and therefore you cannot clone a complete nodeset.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - set-variable:
```

```
    version: 2.0.0
    title: set-variable
  ...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

Example

For examples, see set-variable.

DataPower Gateway (v5 compatible) only

Configuring the Set Variable policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the Set Variable policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the Set Variable policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the Set Variable policy for DataPower API Gateway. For more information about the different types of gateway, see API Connect gateway types.
For details on how to configure the policy in your OpenAPI source, see set-variable.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Set Variable policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Set Variable policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **set-variable**.	string
Description	No	A description of the policy.	string
Action	Yes	Defines what action to apply on a runtime variable. Choose one of the following values: • Set: Indicates that you want to set a runtime variable to a string value. Can be used to set new headers or to override existing values. • Add: Indicates that you want to add a header variable. Can be used only to set new headers or to append a new entry of the same header name. • Clear: Indicates that you want to delete a runtime variable. Can be used to remove a header when the data is processed in the assembly flow. The default value is Set.	string
Set, Add, or Clear	Yes	Specifies the name of the variable that you want to set , add or clear, depending on the selected Action.	string
Type	Yes	Select the data type of the variable. Choose one of the following values: • string • number • boolean The value is validated against the specified data type.	string
Value	Yes*	Allocates this value to the specified variable. Can be a literal value, or another variable. * Value is required only when **Set** or **Add** is specified as the action. For example, to *set* a named variable of **billing-hostname** to a literal value, you can specify the Value as **acme.com**. As another example, to *set* a named variable to the value of the Content-Type header in a request, you can specify the Value entry as **$(request.headers.content-type)**. If the selected value of the Type field is boolean, select the Value check box to indicated a value of **true**. Note: You can only set single string elements. Values are retrieved as strings and therefore you cannot clone a complete nodeset.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **version** section of the policy YAML. For example:

```
execute:
  - set-variable:
    version: 1.0.0
    title: set-variable
  ...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

Example

For examples, see set-variable.

User Security

Use the User Security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see user-security.

About

When you define an assembly user security action, you can define the processing for identity-extraction, authentication, and authorization or you can selectively disable any of these this aspects of processing. When disabled, this processing aspect is skipped.

When identity-extraction is enabled, the following methods are supported.

- Use basic authentication, which requires no additional configuration.
- Use context variables. For this method, specify which variable contains the user name and password.
- Use a redirect. For this method, specify the URL fragment to redirect to, and the time allowed to process.
- Use an HTML login form. For this method, specify whether to use the default or custom form and the time allowed to submit the form. For a custom form, specify the location of the form and the TLS client profile to secure the connection to the remote server.

When authentication is enabled, the following methods are supported.

- Contact an LDAP server. For this method, specify which server to contact.
- Send a request to an authentication endpoint. For this method, specify the URL of the endpoint, the TLS client profile to secure the connection, the pattern to select which response header to add, and the response header that contains the authenticated credentials.

When authorization is enabled, the following methods are supported.

- Implicitly accept any previously authenticated users, which requires no additional configuration.
- Use an HTML authorization form. For this method, specify whether to use the default or custom form and the time allowed to submit the form. For a custom form, specify the location of the form and the TLS client profile to secure the connection to the remote server.

You can attach this policy to the REST API flow.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. User Security policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`user-security`**.	string
Description	No	A description of the policy.	string
Factor ID	No	The identity that identifies the results of factor-authentication in the API context.	string

Property label	Required	Description	Data type
Extract Identity Settings	Yes	Select the method that is used to extract the user credentials. The following options are available: Basic Use basic authentication; no additional configuration is required. Context Variable The credentials are provided by API Connect context variables; specify the following properties: • Username content variable: the context variable that is used to obtain the user name. • password context variable: the context variable that is used to obtain the password. HTML Form Use forms based identity-extraction. Select whether to use the default form or a custom form. For a custom form, specify the following properties: • Custom form endpoint: the location of the form. • Custom form TLS profile: the TLS client profile that is used to secure the connection to the remote server. In the HTML form time limit field, specify the time allowed to submit the form. Redirect Use a redirect for identity-extraction; specify the following properties: • Redirect URL: the URL fragment to which to redirect the request to obtain user credentials. • Redirect time limit: the time allowed for the transaction to complete. Disabled Identity-extraction is disabled; this aspect of processing is skipped. Select Stop on error to halt assembly processing in the event of identity-extraction failure.	string
Authenticate User Settings	Yes	Select the authentication method. The following options are available: Authentication URL The credentials are authenticated by an external endpoint; specify the following properties: • Authentication URL: the URL of the authentication endpoint. • Authentication TLS profile: the TLS client profile that is used to secure the connection to the authentication endpoint. • Authentication response header pattern: the pattern that is used to select which response headers to add to the API context. • Authentication response header credential: the response header that contains the authenticated user credentials. LDAP The credentials are authenticated by an LDAP user registry; from the LDAP registry list, select the required registry. Disabled Authentication is disabled; this aspect of processing is skipped. Select Stop on error to halt assembly processing in the event of authentication failure.	string
Authorize User Settings	Yes	Select the authorization method. The following options are available: authenticated Implicitly accept any previously authenticated users; no additional configuration is required. HTML Form The user provides authorization through an HTML form. Select whether to use the default form or a custom form. For a custom form, specify the following properties: • Custom form endpoint: the location of the form. • Custom form TLS profile: the TLS client profile that is used to secure the connection to the remote server. In the Dynamic table entries field, enter the name of a context variable that specifies the scopes that are to be added automatically to the authorization consent form. In the HTML form time limit field, specify the time allowed to submit the form. Disabled Authorization is disabled; this aspect of processing is skipped. Select Stop on error to halt assembly processing in the event of authorization failure.	string

API Gateway

Validate - DataPower API Gateway

Use the Validate policy to validate the payload in an assembly flow against a schema.

Gateway support

Note: This page describes the Validate policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see Validate - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.0 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.4.0 (DataPower API Gateway Version 10.0.4.0 or later) 2.5.0 (DataPower API Gateway Version 10.5.0.0 or later) 2.6.0 (DataPower API Gateway Version 10.5.0.2 or later 2.7.0 (DataPower API Gateway Version 10.5.0.3 or later

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see validate - DataPower API Gateway.

About

Position this policy where required in the assembly flow as follows:

- To validate the original input, position a Validate policy at the start of your flow.
- To validate an intermediate response that is returned from other invoke actions or tasks, position a Validate policy after those actions or tasks.
- To validate the response that is returned to the client application, position a Validate policy after the task that collates the response.

Note: With the DataPower API Gateway, the input to the Validate policy must be parsed data. One way to produce parsed data is to use a Parse policy before a Validate policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Validate policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **validate**.	string
Description	No	A description of the policy.	string
Input	No	Specifies the name of a variable in the API context. The content of the **body** field of the variable, which is represented by ***variable_name*.body**, is the input data to validate. By default, the variable name is **message**.	string
Output	No	Specifies the name of a variable in the API context. • If the validation passes, the body field of the output variable, which is represented by ***variable_name*.body**, stores the output of the assembly validate action. • If the schema to validate is a JSON schema, the validation also adds any default values that are missing from the payload. • If the validation fails, no output is stored. • If an output variable is not specified, the results of the assembly validate action are not saved.	string

Property label	Required	Description	Data type
Validate against	Yes	Specifies the schema to be used for validating the payload. Select one of the following values: • **`definition`**: Select this value if you want to use a previously defined schema to validate the payload that is returned from other invoke actions or tasks in the assembly flow. From the Definition Object list, select the required schema. For information on defining a schema for an OpenAPI 2.0 API definition, see Defining schema definitions for an API. For information on defining a schema for an OpenAPI 3.0 API definition, see Defining schema components. • **`URL`**: the schema is identified by a URL location. ◦ In the JSON Schema URL field, enter the URL of the JSON schema to be used for validating a JSON payload. ◦ From the XML Validation Mode list, select how XML validation is to be performed: ▪ **`None`**: no XML payload validation is required. ▪ **`xsd`**: an XML schema will be used to validate an XML payload. In the XML Schema URL field, enter the URL of the XML schema. ▪ **`wsdl`**: a WSDL schema will be used to validate a SOAP payload. In the WSDL URL field, enter the URL of the WSDL schema. ▪ **`soap-body`**: validate the body of a SOAP message against the XML schema only. Note: The following limitations apply to schemas used for JSON validation, which include JSON schemas and OpenAPI documents that are used as schemas for validation. Exceeding these limits can impact compilation performance and is not supported. ▪ Maximum of 6,500 lines. Each key and each item in an array count as a line. ▪ Maximum recursion depth of 250. ▪ Maximum of 3,000 items in **`enum`** lists. • **`WSDL`**: (available with a SOAP service based API only) use the XML schema in the WSDL file associated with the API operation or the API path. • **`body-param`**: validate the request input against the schema definition that is specified in the TYPE field for the request parameter for this operation. For information about how to create a request parameter, see Defining parameters for an operation. • **`response-param`**: validate the response to be returned to the client application, against the schema definition that is specified in the SCHEMA field for the response parameter for this operation. For information about how to create a response parameter, see Defining responses for an operation. • **`GraphQL`**: (available for a GraphQL proxy API only) validate the payload against the GraphQL schema that has been imported into the GraphQL proxy API. In addition, either the GraphQL query or response, depending on the input, is analyzed against the GraphQL schema to calculate the cost, and the result is placed in the API context. For more information on GraphQL proxy APIs, see Creating a GraphQL proxy API and GraphQL context variables.	string
XSLT version	No	The XSLT processor version. The default value is XSLT10.	string
Strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
Profile rule	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
Debug rule	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
Streaming rule	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
Attempt streaming rule	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
Minimum output escaping rule	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
Maximum stack size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer
WS-I Basic Profile validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string

Property label	Required	Description	Data type
Validate message body	No	The validation behavior for the **soap:Body**. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message headers	No	The validation behavior for the **soap:Header**. The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message fault details	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Require wrappers on fault details specified by type	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
Specifically allow xsi:type='SOAP-ENC:Array' rule	No	Whether to allow the schema to accept most uses of elements with **xsi:type='SOAP-ENC:Array'** consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the **xsi:type** attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, **xsi:type** is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from **SOAP-ENC:Array**. The opposite is the normal allowable case. By default, elements with **xsi:type='SOAP-ENC:Array'** are not accepted.	boolean
Validate SOAP 1.1 encoding rule	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
Wildcards ignore xsi:type rule	No	Whether **xs:any** elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an **xsi:type** attribute on it. This option ignores those **xsi:type** attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, **xsi:type** attributes are not ignored.	boolean
Strict SOAP envelope version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
Debug XACML policy	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean
Accept MTOM/XOP optimized messages	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an **xop:Include** reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. • When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as **xs:base64Binary** or **xs:string**, but the message contains an **xop:Include** element instead. • When enabled, an **xop:Include** element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The **xop:Include** element itself will be validated according to the built-in schema in **store:///schemas/xop.xsd**.	boolean

For examples, see validate - DataPower API Gateway.

Related tasks

- Defining Paths for a REST API

DataPower Gateway (v5 compatible)

Validate - DataPower Gateway (v5 compatible)

Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.

Gateway support

Note: This topic describes the Validate policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see Validate - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see validate - DataPower Gateway (v5 compatible).

Restriction:

- The schema that represents the XML can reference only one XML namespace.
- The schema cannot reference polymorphic XML elements.
- The validation works on the `message.body` variable and not any other output/context variable. If the invoke policy contains a configured response object variable, then `message.body` is not set, and validate is not able to act.
- If you use the `multipleOf` keyword in a schema definition for the API then, due to rounding behavior, the specified value must satisfy the following conditions, otherwise the validation fails when the API is called:
  - The value must not be less than `0.00000099999999999999848869`.
  - If the value is greater than 1, the amount before the decimal point must not be greater than `99999999999999934463`.

About

You can attach this policy to the following API flow:

- REST

Position this policy where required in the assembly flow as follows:

- To validate the original input, position a Validate policy at the start of your flow.
- To validate an intermediate response that is returned from other invoke actions or tasks, position a Validate policy after those actions or tasks.
- To validate the response that is returned to the client application, position a Validate policy after the task that collates the response.

You can apply a different OpenAPI schema definition to each Validate policy either by choosing from the set of schema definitions that is specified at the API level, or the schema definition at the operation level.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Validate policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is `validate`.	string
Description	No	A description of the policy.	string
Definition	Yes	Specifies the schema definition to be used for validating the payload. Valid values: • `request`: Select this value to validate the request input against the schema definition that is specified in the TYPE field for the request parameter for this operation. For information about how to create a request parameter, see Configuring an operation. • `response`: Select this value to validate the response to be returned to the client application, against the schema definition that is specified in the SCHEMA field for the response parameter for this operation. For information about how to create a response parameter, see Configuring an operation. • `#/definitions/definition_name`: Select this value for a previously defined schema definition to be used to validate the payload that is returned from other invoke actions or tasks in the assembly flow. For information on defining a schema for an API definition, see Editing an API definition.	string

Validate Username Token

Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0 1.1.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see validate-usernametoken.

About

A WS-Security UsernameToken enables a user identity to be passed securely over a multi-point message path. The Validate Username Token policy extracts the UsernameToken element from the request payload, authenticates the extracted username and password, and provides access to the protected resource based on the authentication result. The policy has two authentication methods: Lightweight Directory Access Protocol (LDAP) user registry, or Authentication URL.

The Validate Username Token policy supports both passwordText and passwordDigest types of password. When the authentication method is Authentication URL with a passwordDigest, a basic authentication header that contains a Base64 encoded username and passwordDigest is sent to the URL. In addition, a custom header named X-IBM-PasswordType is set with a value of digest. The following table shows the authentication process based on password type:

Table 2. Authentication URL process by password type

passwordText	passwordDigest
Authentication: Basic base64(username:password)	Authentication: Basic base64(username:passwordDigest) X-IBM-PasswordType: 'digest'

Position this policy where required in the assembly flow as follows:

- To validate the original input, position a Validate Username Token policy at the start of your flow.
- To validate an intermediate response that is returned from other invoke actions or tasks, position a Validate Username Token policy after those actions or tasks.
- To validate the response that is returned to the client application, position a Validate Username Token policy after the task that collates the response.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 3. Validate Username Token policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`validate-usernametoken`**.	string
Description	No	A description of the policy.	string
Authentication type (policy version 1.0.0 only)	Yes	The authentication type to use to validate the UsernameToken. Valid values: • **`Authentication URL`**: Select this value to validate the user credentials against an authentication URL. • **`LDAP registry`**: Select this value to validate the user credentials against an LDAP user registry. The default value is: **`Authentication URL`**.	string
Authentication URL (policy version 1.0.0 only)	Yes	The authentication URL to use to validate the UsernameToken user credentials against. Note: This property is required only if Authentication type is set to **`Authentication URL`**.	string
TLS profile (policy version 1.0.0 only)	No	The TLS profile to use for the secure transmission of data to the authentication URL. Note: This property is available only if Authentication type is set to **`Authentication URL`**.	string
LDAP registry name (policy version 1.0.0 only)	Yes	The name of the LDAP user registry to validate the UsernameToken user credentials against. You can select a name from the drop-down list, or type a name manually. Note: This property is required only if Authentication type is set to **`LDAP registry`**.	string
User Registry Name (policy version 1.1.0 and later)	Yes	Select the LDAP or Authentication URL registry to use to validate the UsernameToken.	string
LDAP search attribute[1]	Yes	The name of the LDAP user password attribute. Note: This property is required only for an LDAP user registry.	string

Examples

The following example shows an LDAP user registry authentication:

```
- validate-usernametoken:
    version: 1.0.0
    title: "validate-usernametoken"
    auth-type: "LDAP Registry"
    ldap-registry: "wstest"
    ldap-search-attribute: "userPassword"
```

The following example shows an Authentication URL definition:

```
- validate-usernametoken:
    version: 1.0.0
    title: "validate-usernametoken"
    auth-type: "Authentication URL"
    auth-url: "https://www.google.com"
    tls-profile: "default-ssl-profile"
```

Errors

The policy returns an HTTP `200` status code when successful, and the input payload is copied to the output flow. For all failure types the policy returns an HTTP `500` status code, and the output contains the SOAP fault.

Tip: If there are authentication failures, try verifying the LDAP user registry configuration as follows:

- Ensure Search (DN) is set as the communication method.
- Ensure Authenticated Bind is set so that specific permissions are required to search the registry.
- Ensure the Admin DN and Password fields are correctly completed for the Distinguished Name (DN) of a user authorized to carry out searches in the LDAP directory.
- Ensure that a combination of Base DN, Prefix, and Suffix are set, such that they fully describe the user DN. For example:
  - For a user named: **`cn=alice`**, **`dc=ibm`**, **`dc=com`**

    ```
    BaseDN: dc=ibm
    Prefix: cn=alice
    Suffix: dc=com
    ```

    where the user DN is calculated as: Prefix + BaseDN + Suffix.

Related information

- Creating an LDAP registry
- Authenticating by using your enterprise user registry

[1] When authenticating with LDAP and passwordText, the policy uses the username and password as LDAP bind credentials. However, when authenticating with LDAP and passwordDigest, the digest itself cannot be used for authentication. Instead, an LDAP search for the username is performed by using the administrator's distinguished name (DN) and password, and an attribute corresponding to the contents of the ldap-search-attribute is retrieved. A hash of the contents of this attribute (along with the Nonce and Created attributes, as in the WS-Security UsernameToken profile specification) is then compared to the passwordDigest.

Websocket Upgrade

Use the Websocket Upgrade policy to process API requests and responses through a WebSocket connection.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

- **Configuring the Websocket Upgrade policy for DataPower API Gateway**
  Follow these steps to configure the Websocket Upgrade policy for DataPower API Gateway in the assembly user interface.
- **Configuring the Websocket Upgrade policy for DataPower Gateway (v5 compatible)**
  Follow these steps to configure the Websocket Upgrade policy for DataPower Gateway (v5 compatible) in the assembly user interface.

API Gateway only

Configuring the Websocket Upgrade policy for DataPower API Gateway

Follow these steps to configure the Websocket Upgrade policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the Websocket Upgrade policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the Websocket Upgrade policy for DataPower Gateway (v5 compatible). For more information about the different types of gateway, see API Connect gateway types.
For information about how to configure the policy in your OpenAPI source, see websocket-upgrade.

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Websocket Upgrade policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Websocket Upgrade policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`websocket-upgrade`**.	string
Description	No	A description of the policy.	string
URL	Yes	Specify the URL to be invoked.	string
TLS Profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is **`60`**.	integer
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code **`301 Moved Permanently`**. If you select this check box, the **`invoke`** policy follows the URL redirection by making a further call to the URL specified in the **`Location`** header in the response. If you clear this check box, the **`invoke`** saves the **`301`** status code and the API call is considered to be complete. Note: The **`follow-redirect`** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **`invoke`** always follows the URL redirection; the **`proxy`** policy (not supported by the DataPower API Gateway) saves the **`301`** status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
Inject proxy headers	No	If you select this check box, the **`invoke`** policy injects the **`X-Forwarded-For`**, **`X-Forwarded-To`**, **`X-Forwarded-Host`**, and **`X-Forwarded-Proto`** headers to the request that is sent to the target URL. The check box is cleared by default.	boolean
Decode Request Params	No	If you select this check box, any request parameters that are referenced by a variable definition on the target URL of the invoke policy are URL-decoded. The check box is cleared by default.	boolean
Queryparam encode	No	If you select this check box, all "+" characters in the query parameter values of the target URL are encoded to %2F. The check box is cleared by default.	boolean
Header control	No	Specifies the headers in **`message.headers`** that you want to copy to the target URL. To prevent headers from being copied, complete the following steps: a. Select Blocklist. b. Click Add blocklist. c. In the empty field that is displayed, enter the header name. d. To add further headers, repeat the previous steps. To specify headers that you want to be copied, complete the following steps: a. Select Allowlist. b. Click Add allowlist. c. In the empty field that is displayed, enter the header name. d. To add further headers, repeat the previous steps. The values that you specify are in regular expression format. For example, to specify the Content-Type header, enter **`^Content-Type$`** By default, Blocklist is selected, with no blocklist entries, meaning that **all** headers are copied.	string

Property label	Required	Description	Data type
Parameter control	No	Specifies the parameters in the incoming request that you want to be copied to the target URL. To prevent parameters from being copied, complete the following steps: a. Select Blocklist. b. Click Add blocklist. c. In the empty field that is displayed, enter the parameter name. d. To add further parameters, repeat the previous steps. To specify parameters that you want to be copied, complete the following steps: a. Select Allowlist. b. Click Add allowlist. c. In the empty field that is displayed, enter the parameter name. d. To add further parameters, repeat the previous steps. The values that you specify are in regular expression format. For example, if the incoming request is `http://apigw/org/sandbox/petstore/base?petid=100&display=detailed` and you specify a white list entry of `^petid$`, the target URL at run time will be `http://myhost/mypath?storeid=3&petid=100` By default, Allowlist is selected, with no allowlist entries, meaning that **no** parameters are copied.	string
Request assembly	No	The request processing assembly. For details on configuring an assembly in the `execute` section, see execute. For example: `request-assembly:` `  execute` `  .` `  .` `  .` `  policy assembly` `  .` `  .` `  .`	object
Response assembly	No	The response processing assembly. For details on configuring an assembly in the `execute` section, see execute. For example: `response-assembly:` `  execute` `  .` `  .` `  .` `  policy assembly` `  .` `  .` `  .`	object

6. Specify a version for the policy by clicking the Source icon </>, and completing the `version` section of the policy YAML. For example:

```
execute:
  - websocket-upgrade:
      version: 2.0.0
      title: websocket-upgrade
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

DataPower Gateway (v5 compatible) only

Configuring the Websocket Upgrade policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the Websocket Upgrade policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the Websocket Upgrade policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the Websocket Upgrade policy for DataPower API Gateway. For more information about the different types of gateway, see API Connect gateway types. For details on how to configure the policy in your OpenAPI source, see websocket-upgrade.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Websocket Upgrade policy in the palette, and drag the policy onto your canvas.

5. Specify the following properties.

Table 1. Websocket Upgrade policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`websocket-upgrade`**.	string
Description	No	A description of the policy.	string
URL	Yes	Specify the URL to be invoked.	string
TLS Profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is **`60`**.	integer
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code **`301 Moved Permanently`**. If you select this check box, the **`invoke`** policy follows the URL redirection by making a further call to the URL specified in the **`Location`** header in the response. If you clear this check box, the **`invoke`** saves the **`301`** status code and the API call is considered to be complete. Note: The **`follow-redirect`** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **`invoke`** always follows the URL redirection; the **`proxy`** policy (not supported by the DataPower API Gateway) saves the **`301`** status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
Inject proxy headers	No	If you select this check box, the **`invoke`** policy injects the **`X-Forwarded-For`**, **`X-Forwarded-To`**, **`X-Forwarded-Host`**, and **`X-Forwarded-Proto`** headers to the request that is sent to the target URL. The check box is cleared by default.	boolean
Decode Request Params	No	If you select this check box, any request parameters that are referenced by a variable definition on the target URL of the invoke policy are URL-decoded. The check box is cleared by default.	boolean
Queryparam encode	No	If you select this check box, all "+" characters in the query parameter values of the target URL are encoded to %2F. The check box is cleared by default.	boolean
Request assembly	No	The request processing assembly. For details on configuring an assembly in the **`execute`** section, see execute. For example: `request-assembly:` `  execute` `  .` `  .` `  .` `  policy assembly` `  .` `  .` `  .`	object
Response assembly	No	The response processing assembly. For details on configuring an assembly in the **`execute`** section, see execute. For example: `response-assembly:` `  execute` `  .` `  .` `  .` `  policy assembly` `  .` `  .` `  .`	object

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - websocket-upgrade:
      version: 1.0.0
      title: websocket-upgrade
  ...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

XML to JSON

Use the XML to JSON policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

The XML to JSON policy uses a simple convention, based on BadgerFish, to convert your API context payload from XML to JSON. The XML content is preserved, including the attributes and namespaces. No additional configuration is required. For more information about the BadgerFish convention, including some examples, see BadgerFish.

Use the API Designer assembly view when you are creating your API definition to add a built-in policy to the flow.

The policy must be attached to the flow at the point at which you require the conversion to be performed. For example, if you need to convert an XML-formatted request into a JSON-formatted request, the policy must be attached to the request flow.

The policy reads input from the **`message.body`**, if that context exists, otherwise from the **`request.body`**, and then writes the output to the **`message.body`**.

Note: If you are using the DataPower API Gateway, the input to the XML to JSON policy must be parsed data. One way to produce parsed data is to use a Parse policy before an XML to JSON policy in your assembly flow, which provides explicit control of the parse action.

Examples

For example, the following simple XML object

```
<a>hello</a>
```

becomes

```
{ "a": { "$" : "hello" } }
```

The following XML object with an attribute

```
<a type="world">hello</a>
```

becomes

```
{ "a": { "$" : "hello", "@type" : "world" } }
```

For examples, see xml-to-json.

- **Configuring the XML to JSON policy for DataPower API Gateway**
  Follow these steps to configure the XML to JSON policy for DataPower API Gateway in the assembly user interface.
- **Configuring the XML to JSON policy for DataPower Gateway (v5 compatible)**
  Follow these steps to configure the XML to JSON policy for DataPower Gateway (v5 compatible) in the assembly user interface.

API Gateway only

Configuring the XML to JSON policy for DataPower API Gateway

Follow these steps to configure the XML to JSON policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the XML to JSON policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the Set Variable policy for DataPower Gateway (v5 compatible). For more information about the different types of gateway, see API Connect gateway types. This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see xml-to-json.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the XML to JSON policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. XML to JSON policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`xml-to-json`**.	string
Description	No	A description of the policy.	string
Input	No	The input message to convert. Specify the name of a variable in the API context. ***`variableName`*`.body`**, the message payload, represents the XML input to convert. The default value of the variable is **`message`** and **`message.body`** is the default input.	string
Output	No	The output message to store the conversion result. Specify the name of a variable in the API context. ***`variableName`*`.body`** represents the result of conversion from XML format to JSON format. When the specified input message is the default message, the default output is **`message.body`**. Otherwise, when the input message is the variable **`my-message-variable`**, for example, the default output is **`my-message-variable.body`**. The variable cannot be any read-only in the API context.	string
Conversion type	No	The conversion type that determines the target format of the output. The following options are available: • badgerFish: BadgerFish convention is used to determine the target conversion format of the output. • apicv5: apicv5 convention is used to determine the target conversion format of the output.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **`version`** section of the policy YAML. For example:

```
execute:
  - xml-to-json:
      version: 2.0.0
      title: xml-to-json
  ...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

Example

For example, the following simple XML object

```
<a>hello</a>
```

becomes

```
{ "a": { "$" : "hello" } }
```

The following XML object with an attribute

```
<a type="world">hello</a>
```

becomes

```
{ "a": { "$" : "hello", "@type" : "world" } }
```

For more examples, see xml-to-json.

DataPower Gateway (v5 compatible) only

Configuring the XML to JSON policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the XML to JSON policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the XML to JSON policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the XML to JSON policy for DataPower API Gateway. For more information about the different types of gateway, see API Connect gateway types.
This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see xml-to-json.

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the XML to JSON policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. XML to JSON policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **xml-to-json**.	string
Description	No	A description of the policy.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **version** section of the policy YAML. For example:

```
execute:
  - xml-to-json:
      version: 1.0.0
      title: xml-to-json
  ...
```

You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.

7. Click Save.

Example

For examples, see xml-to-json.

XSLT

Use the XSLT policy to apply an XSLT transform to the payload of the API definition.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.4.0 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see xslt.

Note: If you are using the DataPower API Gateway, the input to the XSLT policy must be parsed data. One way to produce parsed data is to use a Parse policy before an XSLT policy in your assembly flow, which provides explicit control of the parse action.
For examples of the OpenAPI definitions of XSLT policies, see XSLT policy examples.

For more examples of how to use XSLT to access and modify properties and context, see Implementation code examples and, if you are using the DataPower API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Errors

The following error can be thrown while the policy is being executed:

- **`TransformError`** - a generic error that captures all errors that occur during the execution of the policy.

- **Configuring the XSLT policy for DataPower API Gateway**
  Follow these steps to configure the XSLT policy for DataPower API Gateway in the assembly user interface.
- **Configuring the XSLT policy for DataPower Gateway (v5 compatible)**
  Follow these steps to configure the XSLT policy for DataPower Gateway (v5 compatible) in the assembly user interface.
- **XSLT policy examples**
  Examples of the OpenAPI definitions of XSLT policies.
- **Implementation code examples**
  Example XSLT and GatewayScript code snippets.

API Gateway only

Configuring the XSLT policy for DataPower API Gateway

Follow these steps to configure the XSLT policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the XSLT policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the XSLT policy for DataPower Gateway (v5 compatible). For more information about the different types of gateway, see API Connect gateway types.
For information about how to configure the policy in your OpenAPI source, see xslt.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the XSLT policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. XSLT policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`xslt`**.	string
Description	No	A description of the policy.	string

Property label	Required	Description	Data type
Input	No	Indicates whether this XSLT input document uses the context current payload, or if there is no input. The check box is cleared by default, which indicates that there is no input.	boolean
Serialize output	No	If you select this option, the output tree that is generated by the XSLT policy is serialized. The content of **`message.body`** is updated with the serialized binary data rather than the XML tree. The check box is cleared by default, which indicates that the output tree is not serialized.	boolean
Source	Yes	The XSLT transform source to execute.	string
XSLT version	No	The XSLT processor version. The default value is XSLT10.	string
Strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
Profile rule	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
Debug rule	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
Streaming rule	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
Attempt streaming rule	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
Minimum output escaping rule	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
Maximum stack size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer
WS-I Basic Profile validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string
Validate message body	No	The validation behavior for the **`soap:Body`**. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message headers	No	The validation behavior for the **`soap:Header`**. The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
Validate message fault details	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string

Property label	Required	Description	Data type
Require wrappers on fault details specified by type	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
Specifically allow xsi:type='SOAP-ENC:Array' rule	No	Whether to allow the schema to accept most uses of elements with `xsi:type='SOAP-ENC:Array'` consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the `xsi:type` attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, `xsi:type` is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from `SOAP-ENC:Array`. The opposite is the normal allowable case. By default, elements with `xsi:type='SOAP-ENC:Array'` are not accepted.	boolean
Validate SOAP 1.1 encoding rule	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
Wildcards ignore xsi:type rule	No	Whether `xs:any` elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an `xsi:type` attribute on it. This option ignores those `xsi:type` attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, `xsi:type` attributes are not ignored.	boolean
Strict SOAP envelope version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
Debug XACML policy	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean
Accept MTOM/XOP optimized messages	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an `xop:Include` reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. • When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as `xs:base64Binary` or `xs:string`, but the message contains an `xop:Include` element instead. • When enabled, an `xop:Include` element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The `xop:Include` element itself will be validated according to the built-in schema in `store:///schemas/xop.xsd`.	boolean

6. Specify a version for the policy by clicking the Source icon </>, and completing the `version` section of the policy YAML. For example:

```
execute:
  - xslt:
      version: 2.1.0
      title: xslt
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

DataPower Gateway (v5 compatible) only

Configuring the XSLT policy for DataPower Gateway (v5 compatible)

Follow these steps to configure the XSLT policy for DataPower® Gateway (v5 compatible) in the assembly user interface.

About this task

Note: This topic describes the XSLT policy implementation in the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway, see Configuring the XSLT policy for DataPower API Gateway. For more information about the different types of gateway, see API Connect gateway types.
For details on how to configure the policy in your OpenAPI source, see xslt.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API that you want to work with, or create a new API.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the XSLT policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. XSLT policy properties

Property label	Required	Description	Data type

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **xslt**.	string
Description	No	A description of the policy.	string
Input	No	Indicates whether this XSLT input document uses the context current payload, or if there is no input. The check box is cleared by default, which indicates that there is no input.	boolean
Source	Yes	The XSLT transform source to execute.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **version** section of the policy YAML. For example:

```
execute:
  - xslt:
      version: 1.0.0
      title: xslt
  ...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

XSLT policy examples

Examples of the OpenAPI definitions of XSLT policies.

- Simple example with no context current payload
- Concatenation and transformation
- Obtain query parameter values and refer to context variables
- Return DataPower object name associated with a client TLS profile

Attention:

- The mechanisms described here for interacting with the API Connect context are intended for v5-compatible gateways and also to provide v5 compatibility for APIs created for the API Gateway. However, if you are writing an XSLT policy or user-defined policy for a new API Gateway API, use the mechanisms described in Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway for better performance and long-term support. For API Gateway APIs, the v5-compatibility functions listed here are to be used for v5 migration only.
- The XML specification https://www.w3.org/TR/xml/ does not specify a preferred order for XML namespace (XMLNS) attributes. Best practice is to not rely upon the sequence of XMLNS attributes if you write custom parsing code.

Simple example with no context current payload

The following is an example of where the XSLT input document does not use the context current payload (there is no input):

```
- xslt:
  title: example xslt
  source: |
    <xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
      <xsl:template match="/">
        <Hello>World!</Hello>
      </xsl:template>
    </xsl:stylesheet>
```

Concatenation and transformation

The following example shows a more complex XSLT transform source, where the stylesheet concatenates two input strings and transforms the third input string to the IP address of the client:

```
- xslt:
  title: xslt
  input: true
  source: |
    <?xml version="1.0" encoding="UTF-8"?>
    <xsl:stylesheet
        xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
        xmlns:xalan="http://xml.apache.org/xslt"
        xmlns:fn="http://www.w3.org/2005/xpath-functions"
        xmlns:dp="http://www.datapower.com/extensions"
        xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xmlns:xs4xs="http://www.w3.org/2001/XMLSchema"
        xmlns:io="http://xformMessage"
        xmlns:map="http://xformMessage/xform"
        xmlns:msl="http://www.ibm.com/xmlmap"
        exclude-result-prefixes="fn dp dp map xalan msl"
        version="1.0">
      <xsl:output method="xml" encoding="UTF-8" indent="no"/>

      <!-- root wrapper template  -->
      <xsl:template match="/">
        <msl:datamap>
          <xsl:choose>
            <xsl:when test="not(msl:datamap/dataObject[1]/@xsi:nil)">
              <xsl:element name="dataObject">
                <xsl:attribute name="xsi:type">
                  <xsl:value-of select="'io:data'"/>
                </xsl:attribute>
```

```
              <xsl:call-template name="map:xform">
                <xsl:with-param name="data" select="msl:datamap/dataObject[1]"/>
              </xsl:call-template>
            </xsl:element>
          </xsl:when>
          <xsl:otherwise>
            <xsl:element name="dataObject">
              <xsl:attribute name="xsi:type">
                <xsl:value-of select="'io:data'"/>
              </xsl:attribute>
              <xsl:attribute name="xsi:nil">
                <xsl:text>true</xsl:text>
              </xsl:attribute>
            </xsl:element>
          </xsl:otherwise>
        </xsl:choose>
      </msl:datamap>
    </xsl:template>

    <!-- This rule represents a type mapping: "data" to "io:data".  -->
    <xsl:template name="map:xform">
      <xsl:param name="data"/>
      <!-- a simple data mapping: "$data/StringOne"(string) to "StringOne"(string) -->
      <xsl:if test="$data/StringOne">
        <StringOne>
          <xsl:value-of select="concat($data/StringOne, $data/StringTwo)"/>
        </StringOne>
      </xsl:if>
      <!-- a simple mapping with no associated source:  to "StringTwo"(string) -->
      <StringTwo>
        <xsl:value-of select="dp:client-ip-addr()"/>
      </StringTwo>
      <!-- a simple data mapping: "$data/NumberOne"(int) to "NumberOne"(int) -->
      <xsl:if test="$data/NumberOne">
        <NumberOne>
          <xsl:value-of select="$data/NumberOne"/>
        </NumberOne>
      </xsl:if>
      <!-- a simple data mapping: "$data/NumberTwo"(int) to "NumberTwo"(int) -->
      <xsl:if test="$data/NumberTwo">
        <NumberTwo>
          <xsl:value-of select="$data/NumberTwo"/>
        </NumberTwo>
      </xsl:if>
      <!-- a simple data mapping: "$data/NumberThree"(int) to "NumberThree"(int) -->
      <xsl:if test="$data/NumberThree">
        <NumberThree>
          <xsl:value-of select="$data/NumberThree"/>
        </NumberThree>
      </xsl:if>
    </xsl:template>

    <!-- *****************    Utility Templates    ******************  -->
    <!-- copy the namespace declarations from the source to the target -->
    <xsl:template name="copyNamespaceDeclarations">
      <xsl:param name="root"/>
      <xsl:for-each select="$root/namespace::*[not(name() = '')]">
        <xsl:copy/>
      </xsl:for-each>
    </xsl:template>
  </xsl:stylesheet>
```

Obtain query parameter values and refer to context variables

The following example shows a complete OpenAPI source file. The API includes an XSLT policy that obtains a query parameter value in XSLT, and also uses the **getvariable** method to retrieve the value of the context variable **request.headers.user-agent**.

```
swagger: '2.0'

Return DataPower object name associated with a client TLS profile

The following example uses the **apim:getTLSProfileObjName** function to return the DataPower object name associated with a specified client TLS profile.

```
- xslt:
  title: xslt
  input: false
  version: 2.0.0
  source: >-
    <?xml version="1.0" encoding="UTF-8"?>
    <xsl:stylesheet
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
      xmlns:dp="http://www.datapower.com/extensions"
      xmlns:apim="http://www.ibm.com/apimanagement"
      exclude-result-prefixes="dp apim"
```

```
      extension-element-prefixes="dp"
      version="1.0">

      <!-- For apigw ... store:///dp/apim.custom.xsl -->
      <!-- For v5/v5c ... local:///isp/policy/apim.custom.xsl -->
      <!-- <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"/
> -->
      <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl"/>

      <xsl:template match="/">
        <xsl:variable name="httpHeaders">
          <header name="Accept">application/xml</header>
        </xsl:variable>
        <!--
          For v5, the name returned is client:<orgname>-my-test
          For v5c, the name returned is client:<orgname>-my-testV1.0.0
          For API Gateway, the name returned is client:<orgname>_<catalogname>_tlsp-my-testV1.0.0
        -->
        <xsl:variable name="tlsClientProfile" select="apim:getTLSProfileObjName('my-test')" />
        <xsl:variable name="targetUrl" select="'https://127.0.0.1:6201/PingRequest'"/>
        <dp:url-open target="{$targetUrl}" response="responsecode" timeout="20" http-headers="$httpHeaders" ssl-proxy="
{$tlsClientProfile}"/>
      </xsl:template>

    </xsl:stylesheet>
```

For more examples of how to use XSLT to access and modify properties and context, see Implementation code examples and, if you are using the DataPower® API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Implementation code examples

Example XSLT and GatewayScript code snippets.

Note: If you are using GatewayScript, you must include one or other of the following commands depending on your gateway type:

DataPower Gateway (v5 compatible) `var apic = require(./apim.custom.js);`

API Gateway `var apic = require('apim');`

where *apic* is the common name used for the GatewayScript examples in this topic. However, *apic* could be any given name of your choice, for example you could use:

```
var apim = require(./apim.custom.js);
```

and then you would start your calls with `apim`.

- Access to input properties code snippet
- Access to runtime context code snippet
- Access to input payload code snippet
- Access to HTTP headers code snippet
- Modify the payload code snippet
- Configure error information code snippet
- Accessing the caught exception in a catch block
- Set variables code snippet

Access to input properties code snippet

The following code block shows an example of how to access the input properties by using the XSLT `policyProperties()` function. The example defines a property that is named `a_property`, which is declared as an integer value, but is retrieved in XSLT as text.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
```

DataPower Gateway (v5 compatible)

```
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/>
```

API Gateway

```
  <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">
    <xsl:variable name="p" select="apim:policyProperties()" />
    <xsl:message>
      The value of my input property is
      <xsl:value-of select="$p/a_property" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, call the following function:

```
apic.getPolicyProperty(propertyName)
```

where ***propertyName*** is the name of the input property that you want to access. If the input property name is blank, the action will return all input properties.

Access to runtime context code snippet

The following code block shows an example of how to access the runtime context by using the XSLT **getContext()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/>
  API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">
    <xsl:variable name="client-id" select="apim:getContext('client.app.id')" />
    <xsl:message>
      The calling application is
      <xsl:value-of select="$client-id" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, call the following function:

```
apic.getContext(varName)
```

where ***varName*** is the name of the context variable that you want to access.
For a complete list of context variables, see API Gateway context variables. If you are using the DataPower® API Gateway, see also Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Access to input payload code snippet

The following code block shows an example of how to access the input payload by using the XSLT **payloadRead()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/>
  API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">
    <xsl:variable name="input" select="apim:payloadRead()" />
    <xsl:message>
      The input payload is
      <xsl:copy-of select="$input" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, call the following function:

```
apic.readInput(callback)
```

A callback is required because the actual payload read is asynchronous. The callback method is called when the payload is ready.
This function returns an XML node-set that contains the payload of the request. If the payload is in JSON format, a JSONx node-set is returned that can then be manipulated within an XSLT or GatewayScript stylesheet. If the payload is not in JSON or XML format, the node-set that is returned is empty.
The following example shows how to use the **payloadType()** function to determine what type of payload (XML or JSONx) will be returned by the XSLT **payloadRead()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
```

```
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/>
  API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">
    <xsl:variable name="payloadType" select="apim:payloadType()" />
    <xsl:message>
      <xsl:text>Payload type is [</xsl:text>
      <xsl:value-of select="$payloadType" />
      <xsl:text>]</xsl:text>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

Access to HTTP headers code snippet

The following code block shows an example of how to access the HTTP headers in XSLT by using the `getContext()` function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/>
  API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">
    <xsl:variable name="content-type" select="apim:getContext('request.headers.content-type')" />
    <xsl:message>
      The request content type is
      <xsl:value-of select="$content-type" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, call the following function:

```
apic.getContext(request.headers.headerName)
```

where ***headerName*** maps to the name of the header you want to access.
Note: Access or modification of HTTP headers by using DataPower extensions, such as `dp:set-request-header`, is not advisable, as such actions might yield unexpected results when the policy is combined with other policies and assembly steps.

Modify the payload code snippet

The output from a user-defined policy must be an XML node-set, which represents an XML or SOAP message, or a JSON message by using JSONx. The following code block shows an example of how to modify the payload in XSLT. To assist the API Gateway policy framework to accept the new or transformed message, call the `apim-output` template, as shown in the following example.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:apim="http://www.ibm.com/apimanagement"
  xmlns:jsonx="http://www.ibm.com/xmlns/prod/2009/jsonx">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/>
  API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">
    <!-- Creates a JSON document (empty object is for simplicity) -->
    <jsonx:object>
    </jsonx:object>

    <!-- Indicates the media type of the output being produced -->

    <xsl:call-template name="apim:output">
      <xsl:with-param name="mediaType" select="'application/json'" />
    </xsl:call-template>
  </xsl:template>

</xsl:stylesheet>
```

where **mediaType**:

- **'application/json'** is when the output is written in JSONx format.
- **'application/xml'** is when the output is written in XML format.

If you are using GatewayScript, call the following function:

```
apic.output(mediaType)
```

where ***mediaType*** is:

- **application/json** is when the output is written in JSONx format.
- **application/xml** is when the output is written in XML format.

Specifying the media type allows the next steps in the assembly flow to understand how to process the new payload.

Tip: The output from a user-defined policy must be XML or JSONx. JSONx is an IBM standard format to represent JSON as XML. One way to convert output GatewayScript JSON data into JSONx, is to add a **Convert Query Params to XML** action to follow the GatewayScript action within the same policy rule. The **Convert Query Params to XML** action must have an **Input Conversion** with the **Default Encoding** set to **JSON**. The output from the GatewayScript action must be the input for the **Convert Query Params to XML** action for JSONx to be produced.

Configure error information code snippet

The following XSLT code block shows an example of how to configure the policy implementation to produce error information by calling the **apim-error** template.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:apim="http://www.ibm.com/apimanagement">

  <!-- Contains the APIM functions -->
  DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/>
  API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <!-- Indicates this policy has a failure and provides
       additional information for the client application -->
  <xsl:template match="/">
    <xsl:call-template name="apim:error">
      <xsl:with-param name="httpCode" select="'401'" />
      <xsl:with-param name="httpReasonPhrase" select="'Unauthorized'" />
      <xsl:with-param name="errorMessage" select="'Please select a Plan'" />
    </xsl:call-template>
  </xsl:template>

</xsl:stylesheet>
```

where:

- **httpCode** is the code of the required error message.
- **httpReasonPhrase** is the reason for the error.
- **errorMessage** is the suggested action for the user.

If you are using GatewayScript, call the following function:

```
apic.error(name, httpCode, httpReasonPhrase, message)
```

where:

- **name** is the name of the error.
- **httpCode** is the code of the required error message.
- **httpReasonPhrase** is the reason for the error.
- **message** is the suggested action for the user.

Accessing the caught exception in a catch block

The following XSLT code block shows an example of how, in the **catch** block of an API assembly, you can obtain the details of the current caught exception. A possible use would be to create a custom error response using the details of the caught exception.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  DataPower Gateway (v5 compatible)xmlns:apim="http://www.ibm.com/apimanagement"
  API Gatewayxmlns:apigw="http://www.ibm.com/xmlns/datapower/2017/11/apigateway"
  extension-element-prefixes="dp"
  DataPower Gateway (v5 compatible)exclude-result-prefixes="dp apim">
  API Gatewayexclude-result-prefixes="dp apim apigw">

  <xsl:output method="xml" />
```

```
  <!-- Contains the APIM functions -->
    DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/>
    API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">

    DataPower Gateway (v5 compatible)<xsl:variable name="exception" select="apim:getError()"/>
    API Gateway<xsl:variable name="exception" select="apigw:get-error()"/>
    <!-- output desired error message based on the exception -->
    <myError>
       <errorReason><xsl:value-of select="$exception/error/message"/></errorReason>
    </myError>

    <!-- Propagate the HTTP status code and reason phrase from the exception -->
    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'message.status.code'"/>
      <xsl:with-param name="value" select="$exception/error/status/code"/>
      <xsl:with-param name="action" select="'Set'" />
    </xsl:call-template>

    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'message.status.reason'"/>
      <xsl:with-param name="value" select="$exception/error/status/reason"/>
      <xsl:with-param name="action" select="'Set'" />
    </xsl:call-template>

    </xsl:template>

</xsl:stylesheet>
```

The `apim:getError()` and `apigw:get-error()` functions return an XML node set; for example:

```
<?xml version="1.0" encoding="UTF-8"?>
<error>
    <name>RuntimeError</name>
    <message>This is a thrown Runtime Error</message>
    <policyTitle>Throw Runtime Error</policyTitle>
    <status>
        <code>500</code>
        <reason>Internal Server Error</reason>
    </status>
</error>
```

If you are using GatewayScript, call the following function:

```
apim.getError()
```

which returns a JSON object; for example:

```
{
  "name": "OperationError",
  "message": "This is a thrown Operation Error",
  "policyTitle": "Throw Operation Error",
  "status": {
    "code": "500",
    "reason": "Internal Server Error"
  }
}
```

Set variables code snippet

The following XSLT code block shows an example of how to set a runtime variable to a specified string value by calling the `setVariable` template.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
    DataPower Gateway (v5 compatible)<xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/>
    API Gateway<xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">
    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'serviceEndpoint'" />
      <xsl:with-param name="value" select="'https://endpoint.host.com/data'" />
    </xsl:call-template>
    <xsl:message>
      <xsl:text>Variable [</xsl:text>
      <xsl:value-of select="'serviceEndpoint'" />
      <xsl:text>] set to [</xsl:text>
```

```
      <xsl:value-of select="'https://endpoint.host.com/data'" />
      <xsl:text>]</xsl:text>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

where:

- **varName** is the name of the runtime variable that you want to set a value to.
- **value** is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the **value** as **$(request.headers.content-type)**.

If you are using GatewayScript, call the following function:

```
apic.setvariable(varName, varValue, action)
```

where:

- **varName** is the name of the runtime variable that you want to set a value to, or that you want to add or clear.
- **varValue** is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the **varValue** as **request.headers.content-type**. This property is only required when **set** or **add** is specified as the action.
- **action** is the action that you want to apply to the variable. Valid options are:
  - **set**
  - **add**
  - **clear**

  If no option is set, the default option of **set** is applied.

The following XSLT example shows how to retrieve the value of a runtime variable by using the **getVariable()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
```
DataPower Gateway (v5 compatible)
```
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_local:_isp_policy_apim.custom.xsl"
/>
```
API Gateway
```
  <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.toolkit.doc_store:_dp_apim.custom.xsl" />

  <xsl:template match="/">
    <xsl:variable name="varValue" select="apim:getVariable('serviceEndpoint')" />
    <xsl:message>
      <xsl:text>Variable [</xsl:text>
      <xsl:value-of select="'serviceEndpoint'" />
      <xsl:text>] = [</xsl:text>
      <xsl:value-of select="$varValue" />
      <xsl:text>]</xsl:text>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

where

- **varValue** is the name of the runtime variable that you want to retrieve a value for.

If you are using GatewayScript, call the following function:

```
apic.getvariable(varName)
```

where ***varName*** is the name of the runtime variable that you want to retrieve a value for.

Logic Constructs

IBM® API Connect includes a number of logic constructs that you can use to apply preconfigured logic to an assembly to control the flow of data through your assembly when the API is called.

Logic constructs are configured in the context of an API. You can use the API Designer assembly editor to add a logic construct to an API and to configure the properties for that construct.

The logic constructs are described in the following subtopics:

- **if**
  Use the if construct to apply a section of the assembly when a condition is fulfilled.
- **operation-switch**
  Use the operation-switch component to apply a section of the assembly to a specific operation.
- **switch**
  Use the switch component to execute one of a number of sections of the assembly based on which specified condition is fulfilled.

- **throw**
  Use the throw policy to throw an error when it is reached during the execution of an assembly flow.

Related concepts

- The assembly editor

if

Use the if construct to apply a section of the assembly when a condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by switch	

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see if.

An if construct provides a way to branch an API's assembly when a specified condition is fulfilled. Each if construct contains a section of the assembly that is only executed when the script within the construct returns a **`true`** value.

When using the assemble view's property sheet, use the Condition field to write your condition that returns **`true`** or **`false`**.

If you want one or more policies or constructs to be executed when the condition of the if construct is fulfilled, drag the new policy or construct onto one of the dashed boxes that are displayed within the if construct. Constructs and policies included in the if construct are part of the case that is executed when the condition of the if construct is returned as true.

For information about the OpenAPI implementation of an if construct, see if.

In the Condition field, use the form **`apim.getvariable('`*`context.location.variable`*`')`** to reference your variables, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable.

Construct property details

You can configure a construct's properties in the property sheet in the assemble view.

Table 2. The properties of an if construct

Property	Required	Description
Title	No	A custom title for your construct when it is displayed in the canvas. If a title is not specified, **`if`** is used by default.
Description	No	A description of your construct, it is not displayed on the canvas.
Condition	Yes	Use GatewayScript to provide conditions. A list of context variables that you can use to generate conditions can be found in API Connect context variables.

operation-switch

Use the operation-switch component to apply a section of the assembly to a specific operation.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see operation-switch.

An operation-switch component provides a way to branch an API's assembly depending on the operation that is called. For each case, a separate piece of the assembly is applied to the operations that belong to the case.

When using the assemble view's property sheet, click the Case field to view suggested operations. Type in the Case field to refine the list of suggested operations.

Each case behaves as an assembly. To add components to a case, drag the component from the palette to the area included in the operation-switch component. Dashed boxes are displayed where the component can be included in the case.

For information about the OpenAPI implementation of an operation-switch component, see operation-switch.

Restriction: Nesting an operation-switch component inside an if or switch construct, or another operation-switch component, is **not** supported.

Component property details

You can configure a component's properties in the property sheet in the assemble view.

Table 2. The properties of an operation-switch component

Property	Required	Description
Title	No	A custom title for your component when it is displayed in the canvas. If a title is not specified, `operation-switch` is used by default.
Description	No	A description of your component, it is not displayed on the canvas.
Case	Yes	Each case includes one or more operations to which the branch provided by the operation switch applies.

switch

Use the switch component to execute one of a number of sections of the assembly based on which specified condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see switch.

A switch construct provides a way to branch an assembly based on multiple conditions. Each switch component contains multiple cases, each corresponding to a section of the assembly that is only executed when the condition or operation specified by the case is met or used. Additionally, an otherwise case executes when no other case is fulfilled.

Add new cases by clicking + Case and add an "otherwise" case by clicking + Otherwise.

If multiple cases are fulfilled, the highest priority case will be executed. Change the priority of cases by clicking the Move up ↑and Move down ↓ icons.

To configure a case to be executed if a specific operation is called, use the search operations field and select your operation from the list. You can refine the results of the search by typing in the search operations field.

To configure a case to be executed based on a GatewayScript condition, click edit condition and enter your script in the "Condition editor" window. When you have supplied a script, you can edit your script either in the Condition field or by clicking edit condition.

If you are using the DataPower Gateway (v5 compatible), you enter your condition as GatewayScript directly in a code area in the Condition editor. If you are using DataPower API Gateway, the Condition editor provides a script builder to help you construct your condition script; for more information, see Using the switch policy condition editor.

To delete a case, click the Remove case icon .

If you want one or more policies or constructs to be executed when the condition of a case is fulfilled, drag the new policy or construct onto one of the dashed boxes that are displayed within the case's section of the switch construct.

Note: A switch case **must** contain at least one policy, otherwise the Gateway server returns an error.

Construct property details

You can configure a construct's properties in the property sheet in the assemble view.

Table 2. The properties of a switch construct

Property	Required	Description
Title	No	A custom title for your construct when it is displayed in the canvas. If a title is not specified, `switch` is used by default.
Description	No	A description of your construct, it is not displayed on the canvas.
case	Yes (one or more)	Specify one or more operations or write a script for a condition. API Gateway Use the Condition editor to construct your condition script. See Using the switch policy condition editor. DataPower Gateway (v5 compatible) Use GatewayScript to provide conditions. You can reference variables by using the form `apim.getvariable('context.location.variable')`, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable. A list of context variables that you can use to generate conditions can be found in API Connect context variables.
otherwise	No	Add an otherwise case if you want to execute a section of the assembly when no other cases are fulfilled.

- **Using the switch policy condition editor**
  The switch policy condition editor provides a user interface to help you build the conditions for the `case` clauses in a switch policy.

API Gateway only

Using the switch policy condition editor

The switch policy condition editor provides a user interface to help you build the conditions for the **case** clauses in a switch policy.

You build a condition script by using the Add Group and Add Condition options, together with operator selections, and pre-supplied function selections. The Output field shows the resultant condition script, and updates dynamically as you build your condition.

Adding conditions

When you open the policy condition editor, an initial condition is pre-supplied ready for you to configure.

Use the drop-down list to select the function that you want to begin your condition.

The following JSONata functions are supported:

- Aggregation functions:
  - `$average(array)`
  - `$max(array)`
  - `$min(array)`
  - `$sum(array)`
- Array functions:
  - `$append(array1, array2)`
  - `$count(array)`
  - `$reverse(array)`
  - `$sort(array [, function])`
  - `$zip(array1, ...)`
- Boolean functions:
  - `$boolean(arg)`
  - `$exists(arg)`
  - `$not(arg)`
- Numeric functions:
  - `$abs(number)`
  - `$ceil(number)`
  - `$floor(number)`
  - `$formatBase(number [, radix])`
  - `$number(arg)`
  - `$power(base, exponent)`
  - `$round(number [, precision])`
  - `$sqrt(number)`
- Object functions:
  - `$keys(object)`
  - `$lookup(object, key)`
  - `$merge(array<object>)`
  - `$spread(object)`
  - `$type(value)`
    In addition to the standard values returned by **`$type()`**, the API gateway implementation of **`$type()`** can return the following values: **`binary`**, **`empty`**, **`graphql`**, **`stream`**, or **`xml`**.
- String functions:
  - `$contains(str, pattern)`
  - `$join(array[, separator])`
  - `$length(str)`
  - `$lowercase(str)`
  - `$match(str, pattern [, limit])`
  - `$pad(str, width [, char])`
  - `$replace(str, pattern, replacement [, limit])`
  - `$split(str, separator [, limit])`
  - `$string(arg)`
  - `$substring(str, start[, length])`
  - `$substringAfter(str, chars)`
  - `$substringBefore(str, chars)`
  - `$trim(str)`
  - `$uppercase(str)`
- You can use the following functional extensions to standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description
`$header(name)`	`message.headers.name`	Message header
`$httpVerb()`	`request.verb`	HTTP method of the request
`$operationID()`	`api.operation.id`	ID of the operation
`$operationPath()`	`api.operation.path`	Path of the operation

Extension	Variable	Description
`$queryParameter('name')`	• `request.parameters.name.locations` The supported keyword is `query`. • `request.parameters.name.values`	Searches for the index of `query` in `request.parameters.name.locations` and returns `request.parameters.name.values[index]`, where `[index]` is the value for `query` in locations. Parameter values are not URL decoded.
`$statusCode()`	`message.status.code`	Status code
`$storageType([arg])`	`variable.body` You can specify any variable in the API context. When no variable is specified, the default variable `message.body` is used.	Storage type of the message. The supported values are `binary`, `empty`, `graphql`, `json`, `stream`, or `xml`.
`$urlParameter('name')`	• `request.parameters.name.locations` The supported keywords are `path` and `query` • `request.parameters.name.values`	Searches for the index of `path` and `query` in `request.parameters.name.locations` and returns a single array that contains both `path` and `query` values from `request.parameters.name.values`. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values. `http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese` The `$urlParameter('breed')` URL returns the following array of values. `[cats, adopt, Sphynx, Siamese]` In this example, the URL includes an API path that is configured as `/petstore/{breed}/{breed}`, where `breed` is configured to be a path parameter of the API path. As a result, `cats` and `adopt` are included in the output.
`$xpath(path, xpathExpression)`	You can specify any writable variable in the API context. The `xpathExpression` must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. `$xpath($, '//price')`

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
`$gqlActiveOperation([graphql_message])`	`message.body`	Gets the active operation found in the specified GraphQL message. The `operationName` must be the same as the name of the active operation.
`$gqlAlias(graphql_field_node)`	`message.body`	Gets the alias of a GraphQL field node.
`$gqlFragments([graphql_message])`	`message.body`	Gets the fragments found in the specified GraphQL message.
`$gqlName([graphql_node])`	`message.body`	Gets the node name. For operations, the node name is the `operationName`. For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the `operationName` of `message.body` is retrieved.
`$gqlOperations([graphql_message])`	`message.body`	Gets the operations found in the specified GraphQL message.
`$gqlType([graphql_node])`	`message.body`	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

- You can use the `&` (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- / (division)
- % (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- `query`
  The entire GraphQL query including operations and fragments.

- ***operationName***
  For an anonymous operation, ***operationName*** can be empty.

- ***~fragmentSpreadName***
- **on~*typeCondition***
- ***~~fragmentDefinitionName***

You can also use the following functional extensions to standard JSONata notation. Each extension corresponds to a part of the API context.

Extension	Variable	Description
$header(name)	**message.headers.name**	Message header
$httpVerb()	**request.verb**	HTTP method of the request
$operationID()	**api.operation.id**	ID of the operation
$operationPath()	**api.operation.path**	Path of the operation
$queryParameter('*name*')	• **request.parameters.*name*.locations** • **request.parameters.*name*.values**	Returns the value of a request query parameter given the parameter name. The function searches the **request.parameters.*name*.locations** array for the index position of the value **query**, and returns **request.parameters.*name*.values[index]**, where **index** is the index position. Parameter values are not URL decoded.
$statusCode()	**message.status.code**	Status code
$storageType([arg])	***variable*.body** You can specify any variable in the API context. When no variable is specified, the default variable **message.body** is used.	Storage type of the message. The supported values are: • **binary** • **json** • **stream** • **xml**
$urlParameter('*name*')	• **request.parameters.*name*.locations** • **request.parameters.*name*.values**	Given a request parameter name, returns the parameter values for all occurrences of that parameter as a path parameter or query parameter. The function searches the **request.parameters.*name*.locations** array for the index positions of the values **path** and **query**, and returns, in a single array, the **request.parameters.*name*.values[index]** values for all identified index positions. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values: **http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese** The function call **$urlParameter('breed')** returns the following array of values: **[cats, adopt, Sphynx, Siamese]** In this example, the URL includes an API path that is configured as **/petstore/{breed}/{breed}**, where **breed** is configured to be a path parameter of the API path. As a result, **cats** and **adopt** are included in the output.
$xpath(path, xpathExpression)	You can specify any writable variable in the API context. The **xpathExpression** must be a literal string.	Allows use of XPath expressions

After you select the function, additional fields are displayed, depending on the selected function, so that you can complete the condition. For example, if you select the function **$httpVerb()**, a comparison operator selection list is displayed (**=** or **!=**), together with a list of HTTP verbs to select on the right hand side of the expression (**GET**, **PUT**, **POST**, **DELETE**, **HEAD**, **OPTIONS**, or **PATCH**).

If you select NOT, your condition is negated with a **$not** function.

To add further conditions, click Add Condition; you then select whether to insert an **and** or an **or** operator between this condition and the preceding one.

To group two or more conditions inside parentheses, click Add Group, then add your conditions to the group; you then select whether to insert an **and** or an **or** operator between this group and the preceding condition or group.

To write your own condition from scratch, select Custom, then enter your script in the field provided.

Example

To build the following condition:

```
($statusCode() != 200 and ($httpVerb() = 'GET' or $httpVerb() = 'PUT'))
```

complete these steps in the condition editor:

1. Select **$statusCode()**, select **!=** for the comparison operator, and enter **200** in the field on the right hand side of the condition.
2. Click Add Group.
3. In the new group sub pane that is displayed, click Add Condition.
4. Select **httpVerb()**, leave the comparison operator as **=**, and select **GET** on the right hand side of the condition.
5. Click Add Condition in the group sub pane again.
6. Select **httpVerb()**, leave the comparison operator as **=**, and select **PUT** on the right hand side of the condition.
7. For the comparison operator between the two conditions, select **or**.

Simple condition statements

The following examples show conditions that use a single function.

This example uses the **$httpVerb()** extension to specify the HTTP method of the request.

```
$httpVerb()="GET"
```

This example uses the **$operationPath()** extension to specify the path of the operation.

```
$operationPath()="/base/path-2"
```

This example uses the **$operationID()** extension to specify the operation ID.

```
$operationID()="test-gatewayscript-GET"
```

This example uses the **$statusCode()** extension to specify the message status code.

```
$statusCode()=200
```

This example uses the **$header(name)** extension to specify the content type of the message header.

```
$header("Content-Type")="application/json"
```

Combining conditions with logical operators

You can use **and** and **or** operators to combine multiple functions in a single condition.

This example specifies an HTTP GET request and an API operation path equal to **test-gatewayscript-GET**.

```
$httpVerb()="GET" and $operationPath()="test-gatewayscript-GET"
```

This example specifies either a **POST** or **PUT** request.

```
$httpVerb()="POST" or $httpVerb()="PUT"
```

This example specifies an API operation ID equal to **test-gatewayscript_POST** and a message status code equal to **200**, or an API operation ID equal to **test-gatewayscript-GET** and a message status code equal to **500**.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) or ($operationID()="test-gatewayscript-GET" and $statusCode()=500)
```

This example specifies an API operation ID equal to **test-gatewayscript-POST** and a message status code equal to **200** with an API operation path equal to **/base/path-2**.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) and $operationPath()="/base/path-2"
```

This example specifies a message header content type equal to **text/plain** and a message header length equal to **300**, or a message status code equal to **200**.

```
($header("Content-Type")="text/plain" and $header("Content-Length")=300) or $statusCode()= 200
```

throw

Use the throw policy to throw an error when it is reached during the execution of an assembly flow.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see throw.

When the throw policy is encountered, the specified error and error message is produced.

If a catch has been configured that the error produced by the throw policy fulfills, the catch will be triggered.

If no catch is triggered by the thrown error, then a `500 Internal Server Error` is returned to the API caller.

Component property details

You can configure a component's properties in the property sheet in the assemble view.

Table 2. The properties of a throw component

Property	Required	Description
Title	No	A custom title for your component when it is displayed in the canvas. If a title is not specified, **throw** is used by default.
Error name	Yes	The error name that is thrown by the policy.

Property	Required	Description
API Gateway only Error status code (policy version 2.1.0 and later)	No	Specify the HTTP status code for the error. You can use the `$(variable)` format to reference the `message.status.code` API context variable.
API Gateway only Error status reason (policy version 2.1.0 and later)	No	Specify the HTTP reason phrase for the error. You can use the `$(variable)` format to reference the `message.status.reason` API context variable.
Error message	No	The error message that is returned with the error name.

API Gateway only

Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway

In the code for GatewayScript and XSLT policies in your API assemblies, you can use API context variables to work with the messages that are generated when an API is called.

All API context variables are stored in a JSON-like tree; each context variable is a node in this tree. A non-leaf node can be either an object or an array, while a leaf node can be a number, string, boolean, or document; a document can contain an XML document, BLOB, Stream, or another JSON document.

Each context variable has a name and a value. You can access a context variable by name when using the GatewayScript and XSLT APIs. Dot notation is used to access a context variable, reflecting the position of the corresponding node in the JSON-like tree; for example, `request.headers.Host`. Where a node name contains special characters, bracket notation is supported; for example, `request.headers['Content-Type']`.

For the GatewayScript policy, all the APIs for the DataPower® API Gateway are in the `context` module, which is a global module. You can therefore access the `context` module directly, you do not need to use the `require()` function first.

For the XSLT policy, the APIs are in the `http://www.ibm.com/xmlns/datapower/2017/11/apigateway` namespace; to use these APIs you must declare this namespace.

Attention: The mechanisms described here for interacting with the API Connect context are preferred and provide the best performance if you are writing new GatewayScript or XSLT policies, or if you are authoring user-defined policies. However, for v5-compatible gateways and v5 compatibility for APIs created for the API Gateway, the preferred mechanisms are as described in GatewayScript code examples and XSLT policy examples.

Accessing context variables

GatewayScript examples

To read the `client.app.id` context variable:

```
var clientID = context.get('client.app.id');
```

To set the value of a context variable:

```
context.set('my.vars.amount', 100);
```

The resulting tree has the following structure:

```
{ "my": { "vars": { "amount": 100 } } }
```

To delete the node `my.vars`, and all its child nodes:

```
context.clear('my.vars');
```

The resulting tree has the following structure:

```
{ "my": { } }
```

XSLT examples

To read the `client.app.id` context variable:

```
<xsl:variable name="clientID" select="apigw:get-variable('client.app.id')"/>
```

To set the value of a context variable:

```
<apigw:set-variable name="'my.vars.amount'" value="100"/>
```

The resulting tree has the following structure:

```
{ "my": { "vars": { "amount": 100 } } }
```

To delete the node `my.vars`, and all its child nodes:

```
<apigw:clear-variable name="'my.vars'"/>
```

The resulting tree has the following structure:

```
{ "my": { } }
```

About payloads

When the assembly flow for an API call begins, the following two message objects are predefined in the API context tree:

- **request**: holds the information for the original payload; the **request** message is a read-only object.
- **message**: holds the information for the current payload.

Typically, a message object has **headers** and **body** properties. For the current payload, the **message** message object might have **variables** and **status** properties, and other properties created during the execution of the assembly.
The following example shows the general structure of a typical message:

```
{
  "headers": {
    "Content-Type": "application/xml",
    "X-Client-ID": "1234567890"
  },
  "variables": {
    "amount": 123,
    "name": "xyz"
  },
  "status": {
    "code": 200,
    "reason": "OK"
  },
  "body": <XML/Blob/Stream/JSON Document>
}
```

Manipulating the message headers

GatewayScript examples

To delete a header:

```
context.message.header.remove('X-My-Header');
```

To read a header:

```
var reqType = context.request.header.get('Content-Type');
var currType = context.message.header.get('Content-Type');
```

To set a header:

```
context.message.header.set('Content-Type', 'application/json');
```

To iterate through the headers:

```
var reqHdrs = context.request.headers;
for (var h in reqHdrs) {
   console.log('>>> Reading the request header: ', h, '=', reqHdrs[h]);
}

var currHdrs = context.message.headers;
for (var h in currHdrs) {
   console.log('>>> Reading the current header: ', h, '=', currHdrs[h]);
}
```

To create a message context called **headersContext**, if one doesn't already exist, and add to it a boolean context variable called **HelloWorld**, with the value **true**:

```
var ctx = context.getMessage("headersContext") || context.createMessage("headersContext");
ctx.setVariable('HelloWorld', true);
```

The **setVariable** call writes the variable into **headersContext.variables.HelloWorld**; therefore a condition statement in any subsequent **switch** policy should check for **headersContext.variables.HelloWorld** rather than **headersContext.HelloWorld**.
To read the context variable in any subsequent **gatewayscript** policy, use the following call:

```
ctx.getVariable("HelloWorld")
```

Note: If you are either migrating an API from IBM® API Connect Version 5.0, or from the DataPower Gateway (v5 compatible), to the DataPower API Gateway, or you are configuring a new API for the DataPower API Gateway, creating a message context, rather than using the context variable mechanism described in Accessing context variables, is the preferred option. In the case of migration, it most closely matches the behavior of IBM API Connect Version 5.0, and **setVariable** and **getVariable** calls will continue to work without modification.
Creating a message context is also the preferred option if you are creating a new API for the DataPower API Gateway because it most closely aligns the API context with the way that various native DataPower API Gateway policies process it.

XSLT examples

To delete a header:

```
<apigw:clear-header message="'message'" name="'X-My-Header'"/>
```

To read a header:

```
<xsl:variable name="reqType" select="apigw:get-header('request', 'Content-Type')"/>
<xsl:variable name="currType" select="apigw:get-header('message', 'Content-Type')"/>
```

To set a header:

```
<apigw:set-header name="'Content-Type'" value="'text/xml'"/>
```

To get all headers:

```
<xsl:variable name="allReqHdrs" select="apigw:all-headers('request')"/>
<xsl:variable name="allCurrHdrs" select="apigw:all-headers('message')"/>
```

Manipulating the message status - examples

Note: Only the `message` object has the status property, not the `request` object.

GatewayScript examples

To read the status code and reason phrase:

```
var code = context.message.statusCode;
var reason = context.message.reasonPhrase;
```

To update the status code:

```
context.message.statusCode = 400; //integer, update the code, with default reason
```

To update the status code and reason phrase in a single operation:

```
context.message.statusCode = '200 Wonderful'; //string, update code along with customized reason
```

Note: The `context.message.reasonPhrase` context variable is read-only.

XSLT examples

To read the status code and reason phrase:

```
<xsl:variable name="code" select="apigw:get-variable('message.status.code')"/>
<xsl:variable name="reason" select="apigw:get-variable('message.status.reason')"/>

<apigw:set-variable name="'message.status.code'" value="200"/>
<apigw:set-variable name="'message.status.reason'" value="'OK'"/>
```

Accessing the message body

Note: The request body is read-only.

GatewayScript examples

To read the request body:

```
context.request.body.readAsJSON(function(error, json) {});
context.request.body.readAsXML(function(error, xml) {});
context.request.body.readAsBuffer(function(error, buffer) {});
```

To read the message body:

```
context.message.body.readAsJSON(function(error, json) {});
context.message.body.readAsXML(function(error, xml) {});
context.message.body.readAsBuffer(function(error, buffer) {});
```

To write the message body and update the content type accordingly:

```
// text response
context.message.body.write("Hello world.");
context.message.header.set('Content-Type', "text/plain");

// JSON response
var pet = { "kind": "dog", "age": 3, "color": "black" };
context.message.body.write(pet);
context.message.header.set('Content-Type', "application/json");

// XML response
var resp = "<order><id>100</id><timestamp>20181231</timestamp><status>fulfilled</status></order>";
context.message.body.write(resp);
context.message.header.set('Content-Type', "text/xml");
```

XSLT examples

Note:

- There is no XSLT API to write the message body; the output of the stylesheet transformation is used to update `message.body`.
- To read the request body or the message body, you must parse `message.body` with a Parse policy before the XSLT policy is executed. At the beginning of the assembly flow, `message.body` contains `request.body` so, after parsing `message.body`, you can then read the request from `message.body`.
- If the XSLT input document uses the context current payload, `message.body` is used for the input document `'/'` that can be accessed from the XSLT policy if `message.body` has been parsed as XML in advance; this is determined by the `input` property of the XSLT policy, see xslt.

Read the message body:

```
<xsl:variable name="currentPayload" select="apigw:read-payload('message')" />
```

Read the message body when the `input` property of the XSLT policy is set to `true`:

```
<xsl:variable name="currentPayload" select="/" />
```

Rejecting the session

Note: After the session is rejected, the API assembly flow is stopped and a fault response is returned, unless a catch handler is defined.

GatewayScript example

To reject the session with an error name and message, and update the status reason and code:

```
context.reject('CustomError', 'You are not authorized to make this API call');
context.message.statusCode = '401 Unauthorized';
```

XSLT example

To reject the session with an error name and message, and update the status reason and code:

```
<apigw:reject identifier="'CustomError'" status-code="401" reason="'Unauthorized'">You are not authorized to make this API call</apigw:reject>
```

- **Manipulating attachments in a message object**
  The message object provides APIs and properties to manipulate message attachments.

API Gateway only

Manipulating attachments in a message object

The message object provides APIs and properties to manipulate message attachments.

If the assembly includes a parse policy, attachments in the request or response of a multipart message can be manipulated and sent back to the client. By default, the response is sent to the client in multipart format. Alternatively, you can clear `context.message.attachments` to discard the attachments and send only `message.body` to the client.
Note: If the assembly does not include a parse policy, the following processing rules apply.

- For a multipart request where the `message.body` variable is not changed, the invoke policy keeps and passes the attachments to the server.
- For a multipart request or response where the `message.body` variable is not changed, the result API action passes the attachments as the final response.
- If the `message.body` variable is changed, attachments are discarded.

Retrieving an attachment

GatewayScript examples

Retrieve the attachment by index location.

```
context.message.attachments[1]
```

Retrieve the attachment by looking up the value of `pic1` in the `Content-Id` header.

```
context.message.attachments['cid:pic1']
```

Retrieve the attachment by looking up the value of `uri1` in the `Content-Location` header.

```
context.message.attachments['uri1']
```

Appending an attachment to the message

GatewayScript example

```
var headers = JSON.parse ( '{ "Content-Type": "text/xml; charset=utf-8", "Content-Id": "<data>" }' );
message.attachments.append(headers, 'Hello world.');
```

Retrieving the number of attachments in an array

Example

```
for (var i = 0; i < context.message.attachments.count; i++) {
  context.message.attachments[i].header.set('X-Foo', 'bar');
}
```

Removing an attachment from the message

GatewayScript examples

Remove the attachment by index location.

```
context.message.attachments.remove(1)
```

Remove the attachment by looking up the value of `pic1` in the `Content-Id` header.

```
context.message.attachments.remove('cid:pic1')
```

Remove the attachment by looking up the value of `uri1` in the `Content-Location` header.

```
context.message.attachments.remove('uri1')
```

Reading, accessing, and manipulating the body of an attachment

GatewayScript examples

To read the payload of an attachment in binary and return the contents as either a `Buffer`, `Buffers`, `JSON`, or `XML NodeList` object:

```
context.message.attachments[0].body.readAsBuffer(function(errorObject,bufferObject){})
context.message.attachments[0].body.readAsBuffers(function(errorObject,buffersObject){})
context.message.attachments[0].body.readAsJSON(function(errorObject,jsonObject){})
context.message.attachments[0].body.readAsXML(function(errorObject,nodeList){})
```

To write content `Hello world` to the current payload of the attachment:

```
message.attachments[0].body.write("Hello world")
```

Manipulating the headers of an attachment

GatewayScript examples

To retrieve the values of the whole attachment headers:

```
context.message.attachments[0].headers
```

To retrieve the value of the named header of the attachment:

```
context.message.attachments[0].header.get();
```

To delete the current `Content-Type` header of the attachment.

```
context.message.attachments[0].header.remove('Content-Type');
```

You can set the value of the named header of an attachment. The header can be coalesced and noncoalesced. Take the following code as an example.

```
context.message.attachments[0].header.set('MyCookie', ['cookie1', 'cookie2']);
```

If the value type is array, the `MyCookie` header is noncoalesced and it is present with different entries in HTTP header.

```
MyCookie: cookie1
MyCookie: cookie2
```

User-defined policies

Make a user-defined policy available to a Catalog, and apply that policy to a REST or SOAP API.

A policy is a piece of configuration that controls a specific aspect of processing in the Gateway server during the handling of an API invocation at run time. IBM® API Connect provides built-in policies for many capabilities, including logging, redaction, proxy, and transformations, but you can also create user-defined policies to provide more processing control.

The following information outlines how to create and manage user-defined policies:

Creating a user-defined policy

A user-defined policy is created outside of API Connect by using a standard development tool, but the policy must conform to a particular schema. For information about how to create a policy, see Authoring policies.

Note: If you are running your policies on a DataPower® Gateway, you must ensure that the DataPower processing to be controlled by the user-defined policy, is supported by the level of IBM DataPower Gateway that the policy will be run on. When using the GatewayScript actions, the minimum DataPower firmware that should be used is version 7.2.0.

Importing a user-defined policy into API Connect

To make a user-defined policy available to an API, the policy must be imported into one or more Catalogs in the API Manager. If you also want to be able to apply the policy to your policy assembly in API Designer, you will have to import that policy into the developer toolkit environment.

Make your policy accessible to API Designer by using the developer toolkit. For detailed instructions, see Packaging and importing your policies into IBM API Connect.

Make your policy available by using the API Manager UI. For detailed instructions, see:

- Importing a user-defined policy into a Catalog. If you want to create a new Catalog and import a user-defined policy as part of the configuration, follow the instructions in Creating and configuring Catalogs.
- Packaging and importing your policies into IBM API Connect.

Note: You must import a user-defined policy into every Catalog in API Manager that you require the policy to run in.

Applying a user-defined policy to an API

Apply a user-defined policy to an API definition by using the assemble view in API Designer or API Manager, to add the component to your assembly and configure its properties. For detailed instructions, see Including elements in your OpenAPI 2.0 API assembly, Including elements in your OpenAPI 2.0 API assembly.

Deleting a user-defined policy

Delete a user-defined policy from a Catalog, by clicking the Delete icon next to the policy in the associated Catalog in API Manager.

Tags in API Connect

There are a number of forms of tagging in IBM® API Connect.

- You can create tags in an API that are visible in its OpenAPI definition and can be used to filter operations in the Developer Portal.
- You can tag items in the Developer Portal so that they can be searched for.

Tags within an API

The OpenAPI specification allows the inclusion of tags in an API definition, and you can create these tags through the API Manager user interface. You can assign tags to an operation within an API.

Tags that are assigned to an operation can be used to group the operations of an API in the Developer Portal, by using the filter options for the API. These tags are visible to anyone who can view any of the Products to which the API belongs.

For more information, see Editing an OpenAPI 2.0 API definition and Configuring an operation.

Note: Though you can tag the API itself in the API Setup section, by using this method the tag is not visible in the Developer Portal.

Tags in the Developer Portal

An administrator can assign tags to items in the Developer Portal, which are then available through the API Products search function in the Developer Portal.

For more information, see Editing tags for a specific item and Managing tags in the Developer Portal.

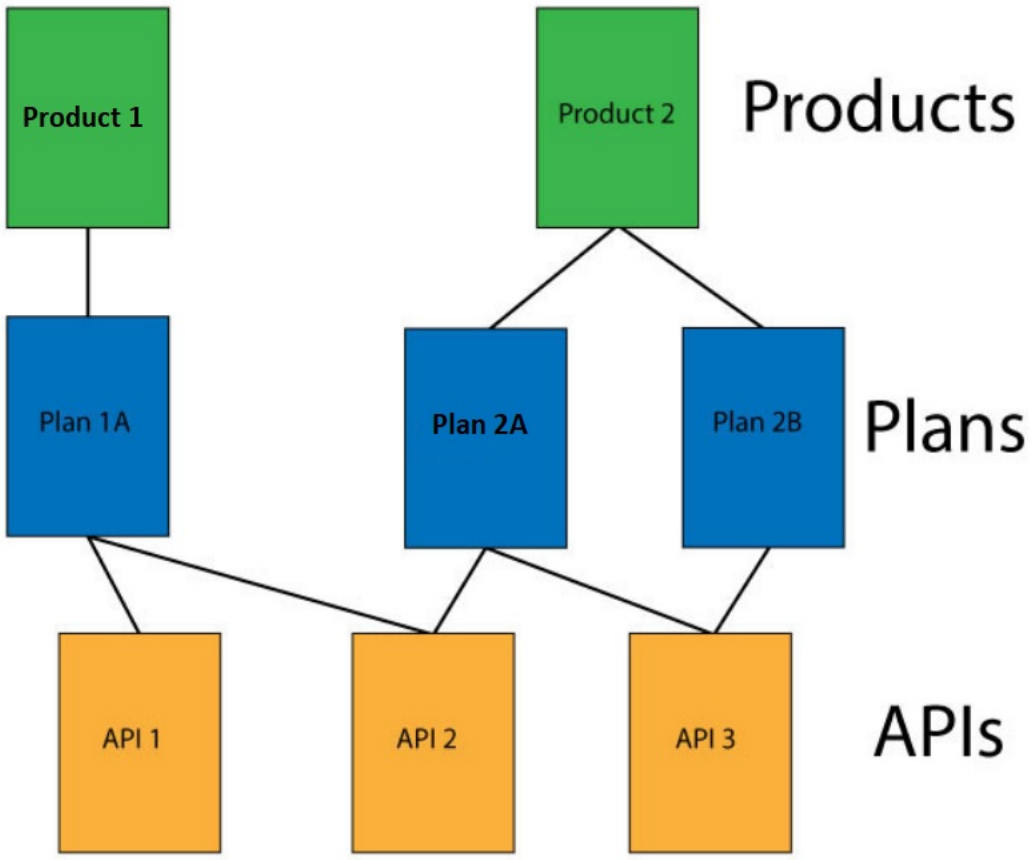
Working with Products

In IBM® API Connect, Plans and APIs are grouped together in Products, with which you can manage the availability and visibility of APIs and Plans.

The following diagram demonstrates how Products, Plans, and APIs relate to one another.
Note: Plans belong to only one Product, but they can possess different APIs to other Plans within the same Product, and they can share APIs with Plans from any Product.

Figure 1. The hierarchy of Products, Plans, and APIs.



Products provide a method by which you can group APIs into a package that is intended for a particular use. Additionally, they contain Plans, which can be used to differentiate between different offerings. Plans can share APIs, but whether subscription approval is required depends upon the Plan itself. Additionally, you can enforce

rate limits through these Plans, or through operations within the APIs of a Plan that override the rate limit of the Plan. You can also assign different subscription costs to your Plans to differentiate the rates of API calls. For more information, see Monetizing your Products.

To make an API available to an application developer, it must be included in a Plan. You can create Plans only within Products, and these Products are then published in a Catalog. A lifecycle manager can then control the availability and visibility of APIs and Plans through the API Manager. By using the API Manager, you can specify the Plans that an application developer is able to subscribe to through the Developer Portal. The application developer can only subscribe to one Plan from a specific Product. Multiple Plans within a single Product are useful in that they can fulfill similar purposes but with differing levels of performance and cost. For example, you can have a "Demo Plan", which makes a single API available free of charge, and a "Full Plan" which makes several APIs available with a monthly subscription cost.

As well as controlling which APIs an application developer can use, different Plans can be used to implement different rate limits. A rate limit can be implemented as a default rate that is shared across an entire Plan, or can be set for specific operations of an API within that Plan, exempting them from the shared Plan rate limit. Different Plans can have differing rate limits, both between operations and for the overall limit. This is useful for providing differing levels of service to customers. For example, a "Demo Plan" might enforce a rate limit of ten calls per minute, while a "Full Plan" might permit up to 1000 calls per second.

In addition, you can apply burst limits to your Plans, to prevent usage spikes that might damage infrastructure. Multiple burst limits can be set per Plan, at second and minute time intervals. You can also set multiple rate limits per Plan and per operation, at second, minute, hour, day, and week time intervals.

Note:

- Applying a rate limit at the Plan level creates a default rate limit that is shared across all the operations within the Plan. If you need to set specific rate limits for specific operations, you must set these within the operations themselves and these settings will override the setting at the Plan level.
- The test application that is used by the API Manager test tool is not subject to rate limits if you have enabled automatic subscriptions for the Catalog in which you are testing. For more information, see Working with Catalogs

API Connect also supports the implementation of multiple versions of Products. You can choose version numbers and use them to aid the development of your Products and Plans.
Note: The version for a Product is distinct from the version of any APIs that are contained in the associated Plans. Plans cannot themselves have their own version, they use the version of their parent Product.

- **Creating a draft Product**
  Create a draft Product to collect a set of APIs and Plans into one offering that you make available to your developers. A Plan includes rate limit settings that can be applied to the Plan as a whole, or specified for each operation in an API. Through Products and Plans, you have greater control over what APIs your developers have access to, and the subscription terms.
- **Downloading a draft Product**
  You can download the details of your draft Product so that you can store them for later recovery.
- **Importing a draft Product**
  You can create a Product by importing a Product definition in a .yaml file.
- **Searching for a draft Product**
  Quickly locate a draft API or Product by searching on the title and version.
- **Editing a draft Product**
  After initially creating a draft Product, you can continue to further configure the Product, or you can make configuration changes later.
- **Staging a draft Product**
  Stage a draft Product to a Catalog to create a specific version of that Product, before publishing. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers.. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.
- **Publishing a draft Product**
  Publish a draft Product to make the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.
- **Creating a new version of your Product**
  You can have multiple versions of a Product in IBM API Connect. These versions can occupy any of the lifecycle stages, which facilitates development.
- **Specifying the gateway type for a Product**
  You can edit the Product configuration to specify a gateway type.
- **Deleting a draft Product**
  You can delete draft Products that are no longer required.
- **Organizing your Products into categories**
  You can organize your Products into categories. The Products that you categorize are displayed within the Developer Portal, in their defined categories.

- Working with Products in the API Manager

Creating a draft Product

Create a draft Product to collect a set of APIs and Plans into one offering that you make available to your developers. A Plan includes rate limit settings that can be applied to the Plan as a whole, or specified for each operation in an API. Through Products and Plans, you have greater control over what APIs your developers have access to, and the subscription terms.

Before you begin

Define your APIs. For more information, see Creating an API definition.
Tip: As well as using the method described in this task, you can also create a Product when you create an API. If you create an API by using the developer toolkit command line editor, a Product is automatically created for you. You can then change any of the Product settings by opening your new Product in the Products page of the API Designer.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you first create your Product, it has *draft* status. When you have finished configuring your draft Product, you stage it to a Catalog so that the APIs in the Product can be made available to your application developers.

Procedure

To create a Product, complete the following steps:

1. In the navigation pane, click  Develop, select the Products tab, then click Add > Product.
   The Add Product page opens.
2. Select New Product, then click Next.
3. On the Info page, complete the following steps:
   a. Enter the Title and Version of the Product and, optionally, a description. A Name is entered automatically.
      Note: The value in the Name field is a single string that is used to identify the Product in developer toolkit CLI commands. The Title is used for display.
      To view the CLI commands to manage draft Products, see apic draft-products.

   b. Click Next.
4. On the APIs page, select the APIs that you want to include in the Product. You can include only APIs whose gateway type matches the gateway type of the Product, or APIs for which the Enforced option is disabled, meaning that the API is not managed on an API Connect gateway. If you select an incompatible API whose gateway type does not match the gateway type of the Product, a warning message is displayed and you cannot save your changes until you clear the incompatible selection. For more information on gateway types, see API Connect gateway types, Specifying the gateway type for a Product, and Specifying the gateway type for an API definition.
5. Click Next.
6. On the Plans page, complete the following steps:
   a. Optional: Change the Title, Description, or Rate limit settings for the default Plan.
   b. Optional: To add further Plans, click Add, then scroll down and modify the Plan settings as required.
   c. Click Next.
7. To have the Product published to the Sandbox Catalog automatically after creation, select Publish product.
   Note: The publish option is not available in the API Designer UI.
8. If Publish product is selected, you can select which gateway service the Product is published to. By default, the Product is published to all relevant gateway services.
9. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to.
   If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.

   Visibility can also be set at the Catalog or Space level. For more information, see Configuring Product visibility in a Catalog.

10. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product.
    If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product. If you selected custom visibility, only the consumer organizations and consumer organization groups selected there are available for adding to the custom subscribability list. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.
    Note: If you select custom visibility or subscribability, the consumer organizations and consumer organization groups that you can choose from are those in the Sandbox Catalog for the management server and provider organization that you are connected to. If you want to specify consumer organizations or groups that are in another Catalog, or in a Space, publish the Product to that Catalog or Space, then configure the visibility or subscribability there; for details, see Changing the availability of a Product.
    If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Connect Designer.

    If you are working offline in API Designer, you must type in the exact name of the organization or group.

    For more information about consumer organizations in a Catalog, see Administering Consumer organizations.

11. Click Next to create your Product.
    a. To further configure your Product, click Edit Product.
       For details, see Editing a draft Product
    b. If you do not want to configure your Product further at this time, click the initial Develop link in the breadcrumb trail to return to the Develop page; you can then move on immediately to another task.
       For details on how to configure your Product later, see Editing a draft Product.

Results

You have created a draft Product, and specified a set of APIs and Plans into one offering that you can now make available to your developers.

What to do next

Stage your Product to a Catalog. For more information, see Staging a draft Product.

Downloading a draft Product

You can download the details of your draft Product so that you can store them for later recovery.

Before you begin

To complete this task, you must have created a draft Product. For more information, see Creating a draft Product.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Product-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

You can download the details of your Product as a .yaml file. This file can be used to re-create your Product, although it includes only references to APIs, not the API definitions themselves. This function does not provide a way to export an entire implementation. For information about creating a Product from a .yaml file, see Importing a draft Product.

Procedure

To download a .yaml file containing details of your Product, complete the following instructions:

1. In the navigation pane, click  Develop.
2. Select the Products tab.
3. Alongside the Product version that you want to work with, click the options icon ⋮ and then click Download.
4. Save the file to the required location.

Results

You have downloaded a .yaml representation of your Product.

Related tasks

Importing a draft Product

You can create a Product by importing a Product definition in a .yaml file.

Before you begin

To complete this task, you must have a .yaml representation of a Product. This can be created as described in the Downloading a draft Product task.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can import details of your Product as a .yaml file. This file can be used to re-create your Product, although it includes only references to APIs, not the API definitions themselves. This function does not provide a way to import an entire implementation.

You can import the file from your local file system.

Procedure

To create a Product from a .yaml file, complete the following instructions:

1. In the navigation pane, click Develop.
2. Select the Products tab.
3. Click Add > Product.
4. Select Existing Product, then click Next.
5. To import a file from your local file system, you can either drag and drop your files, or click Browse and select the file that you want to use.
   The wizard checks the validity of the YAML, and displays a message indicating successful validation.
6. Click Next.
7. To have the Product published to the Sandbox Catalog automatically after creation, select Publish product.
8. Click Next to create your Product.
   a. To further configure your Product, click Edit Product.
      For details, see Editing a draft Product
   b. If you do not want to configure your Product further at this time, click the initial Develop link in the breadcrumb trail to return to the Develop page; you can then move on immediately to another task.
      For details on how to configure your Product later, see Editing a draft Product.

Results

You have imported a Product from a .yaml file. If the same APIs and versions of APIs as referenced in the file are present, then they will be included in the Product.

Importing a Product in this way does not include the API definitions, only references to them.

- Downloading a draft Product

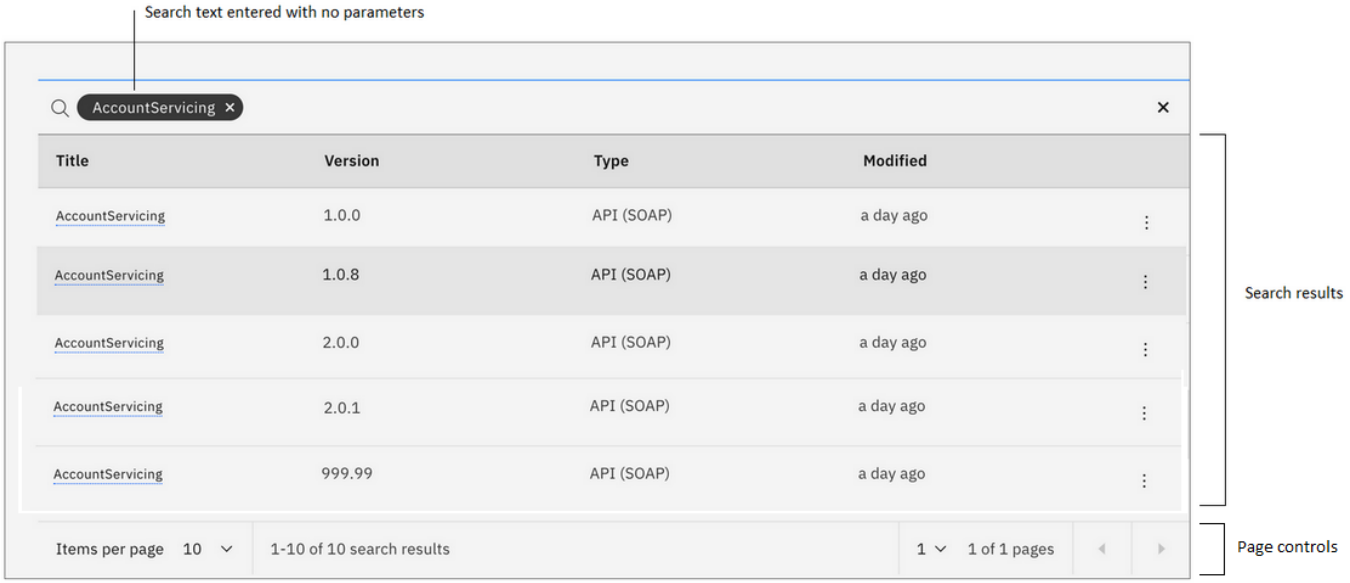
Searching for a draft Product

Quickly locate a draft API or Product by searching on the title and version.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

On the Develop page, type your search string into the search field and click (or press Enter) to run the search.

The search returns a list of APIs (or Products) that most closely resemble your keywords, rather than limiting the results to identical matches. The following image shows a search string that includes "AccountServicing". The results include all draft APIs and Products with a title that is similar to the search text, with duplicates sorted by creation date.



Resources with a name, title, or version that are not similar to the search text are not included in the results. If you select a resource type to search for but do not specify any keywords, the results are sorted by title and then by creation date. For example, if you search for Products but do not include any keywords, then all Products appear in the results table.

Search text
: The search is case insensitive. Trailing spaces and accents (for example: é, è, â) are ignored. For best results, provide as much of the title and version as possible in your search text. Detailed search strings return more accurate results. Results include all titles that are similar to your search string, and not just identical matches.

What's included in the search?
: The scope of the search includes the API or Product Title, Name and Version fields. The search applies only to the current provider organization (displayed in the product banner's Organization field).
You can optionally restrict your search to Products only, or to a specific type of API. Click in the search field and then in the "Types" list that displays, select Product or an API type (REST or SOAP).

How are results displayed?

Search results display as a table, sorted by API or Product title and version. If the results overflow onto additional pages, navigate between pages using the standard page controls that follow the table. When you clear the search, APIs and Products are listed alphabetically by title and, within each title, by newest version first.

Editing a draft Product

After initially creating a draft Product, you can continue to further configure the Product, or you can make configuration changes later.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

During the initial creation of a Product, the Product creation wizard guides you to enter the minimum configuration settings, and then provides an Edit Product button. You have the option to specify additional configuration immediately, or to return to Product to edit it later. This topic describes how to specify additional configuration in either case.

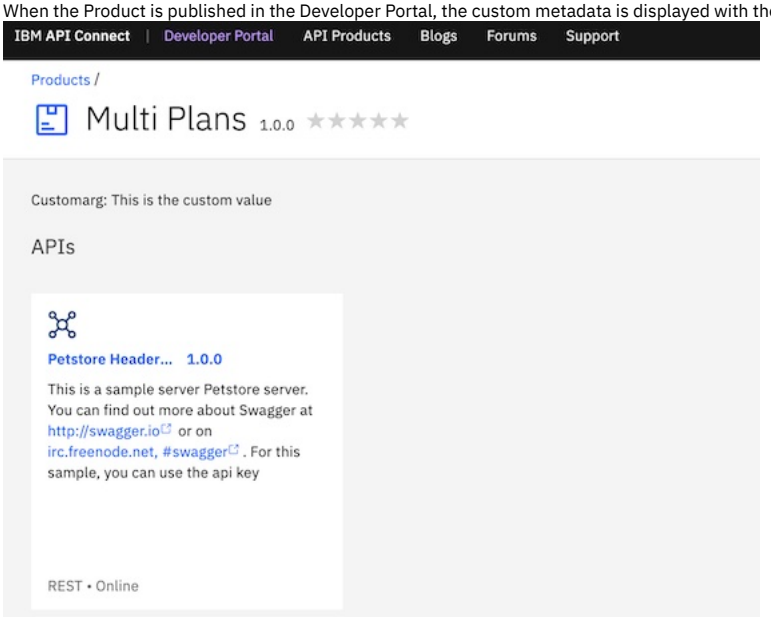
Procedure

To edit a draft Product, complete the following steps:

1. Access the Product Setup page in one of the following ways:
   - After completing the initial creation of the Product, click Edit Product.
   - In the navigation pane, click Develop, then select the Products tab.
   - Click the title of the Product that you want to edit.
2. On the Product Setup page, you can make the following configuration changes:
   a. In the Info section, change the Title, Version, or Summary.
   b. Use the Contact, Terms of Service, and License sections to enter the corresponding details as required.
   c. Change the gateway type. For more information, see API Connect gateway types and Specifying the gateway type for a Product.
   d. Click Save to save your changes.
3. Optional: Specify Product metadata to be displayed with the Product in the Developer Portal:
   a. Click the Source tab to see the OpenAPI source for the Product.
   b. Add the custom attribute **`x-name`**:
   `value` into the **`info`** section. For example:

```
info:
  version: 1.0.0
  title: Multi Plans
  name: multi-plans
  x-customarg: This is the custom value
...
```

   Where ***`customarg`*** is the name of the custom metadata, and ***`This is the custom value`*** is the information content.
   c. Click Save.
   When the Product is published in the Developer Portal, the custom metadata is displayed with the Product. For example:



4. Click Visibility, then make the following changes as required:
   a. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to.
   If you select Custom, complete the following steps:
   - Select the Catalog for which you want to control visibility.
   - Use the Search organizations and groups field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be visible to. For information about how to create and manage consumer organizations and consumer organization

groups, see Administering Consumer organizations.

b. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product.
If you select Custom, complete the following steps:
- Select the Catalog for which you want to control subscribability.
- Use the Search organizations and groups field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be subscribable to. If you selected custom visibility, only the consumer organizations and consumer organization groups selected there are available for adding to the custom subscribability list. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.

Note:
- If you select custom visibility or subscribability, only 10 search results are displayed in the selection list for the consumer organizations and consumer organization groups. If necessary, enter a more specific search string to refine the search.
- Although the title of each organization or group is displayed, followed by the name in parentheses, in the table of selected organizations and groups only the name is displayed

a. Click Save to save your changes.

Note: You can change the visibility and subscribability settings when you publish the Product; see Publishing a draft Product. You can also change the settings in the Catalog to which the Product is published; see Changing the availability of a Product.

5. To specify the APIs that you want to include in the Product, click APIs, then complete the following steps:.
   a. Click Edit.
   All draft APIs are listed.
   b. Select the APIs that you want to include. You can include only APIs whose gateway type matches the gateway type of the Product, or APIs for which the Enforced option is disabled, meaning that the API is not managed on an API Connect gateway. If you select an incompatible API whose gateway type does not match the gateway type of the Product, a warning message is displayed and you cannot save your changes until you clear the incompatible selection. For more information on gateway types, see API Connect gateway types, Specifying the gateway type for a Product, and Specifying the gateway type for an API definition.
   c. Click Save when done.
   The selected APIs are listed.

   Note: To make an API available to application developers, you must include it in a Plan.
6. Optional: Add billing integration to the Product. Click Plans, and in the Billing integration section, select the billing integration resource that you want to apply to the Product.
   In the Plans section, you can then either edit the Default Plan to add pricing information, or create a new Plan with pricing information. For more information about billing integration, see Monetizing your Products.
7. Optional: Add one or more Plans to the Product, or modify an existing Plan. Note that a default plan is automatically created for you, with a rate limit of 100 API calls per hour.
   a. Click Plans.
   b. To add a new Plan, click Add. To modify an existing Plan, click the options icon alongside the required Plan, then click Edit.
   c. Specify the Title of the Plan and, optionally, a description. A Name is entered automatically.
   Note: The value in the Name field is a single string that is used to identify the Plan in developer toolkit CLI commands. The Title is used for display.
   d. Specify whether your Plan requires subscription approval. If you want subscriptions by developers to require approval, select the Approval check box; otherwise, ensure the check box is cleared.
   e. In the Plan pricing section, you can add pricing information by completing the following steps:
      i. Change the toggle to On for Plan pricing. The Plan pricing definition section is displayed.
      ii. If you want to include any free trial days in your Plan, select Include free trial days, and then enter the number of trial days that a subscriber can use the Plan without charge, after which their billing cycle begins.
      iii. Select the Currency for the billing process use.
      iv. Enter the Price per month to bill the subscriber for. If the selected currency supports fractional units, enter the price including any fractional units, such as cents.

   For more information about Product billing integration, see Defining a Product with billing integration.
   f. In the Plan Rate Limits section, you can modify a rate limit, and click Add to add further rate limits. You can set multiple rate limits, at second, minute, hour, day, and week time intervals. To remove a rate limit, click the corresponding delete icon .
   Note: For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.
   g. In the Plan Burst Limits section, you can modify a burst limit, and click Add to add further burst limits. You use burst limits to prevent usage spikes that might damage infrastructure. You can set multiple burst limits, at second and minute intervals. To remove a burst limit, click the corresponding delete icon .
   Rate and burst limits work together to manage network traffic for the APIs covered under a Plan. A Plan can have multiple rate and burst limits, but it is recommended that each time interval be assigned only one set of limits. Adjust the rate and burst limits to allow for maximum traffic without overloading your network. The **rate limit** sets the maximum amount of sustainable, ongoing traffic for accessing the APIs on your network within a time interval (for example, one day). The **burst limit** sets the maximum short-term traffic volume for your network within a time interval (per second or minute).

   The **burst limit** allows for short bursts of increased traffic. When the **burst limit** is exceeded, all subsequent API calls are rejected until the start of the next **burst limit interval**. The **burst limit counter** is reset to zero at the start of the next interval, which allows API calls to be accepted again. These API calls count toward the **rate limit counter**, but the resetting of the **burst limit counter** does not affect the **rate limit counter**.

   The **rate limit** is the number of API calls allowed in a time interval, for example, 1000 calls per day. When the **rate limit** is exceeded, and Hard limit is enabled, all subsequent API calls will be rejected. The **rate limit counter** is reset to zero at the start of the next **rate limit interval**, which allows API calls to be accepted again. If Hard limit is disabled, all subsequent API calls are still accepted, and a message is logged stating that the **rate limit** has been exceeded. This is referred to as a "soft limit."

   Hard limit affects only the **rate limit**, as illustrated by the following scenarios:

   Scenario A

Table 1. Hard limit enabled

Hard limit	Burst limit	Rate limit
ON	100 calls/minute	1000 calls/day

- If a user calls an API 100 times in one minute, the **burst limit** is reached. The 101st call (and any subsequent calls) within the same minute will be rejected. Once the minute is up, the **burst limit counter** is reset. All API calls are tallied toward the **rate limit** of 1000 calls per day. The resetting of the **burst limit counter** does not affect the **rate limit counter**.

- If a user calls the API 99 times per minute, they will not hit the **burst limit**. They will eventually hit the 1000 calls per day rate limit, and the 1001st call will be rejected until the end of the same one day **rate limit interval**. During the period of time when API calls are rejected due to the daily **rate limit** being exceeded, the **burst limit** will not be activated since the calls are already rejected.
- Both **burst limits** and **rate limits** are applied per consumer.

Scenario B

Table 2. Hard limit disabled

Hard limit	Burst limit	Rate limit
OFF	100 calls/minute	1000 calls/day

- As in Scenario A, if a user calls the API 100 times in one minute, the 101st call within the same minute will be rejected, until that minute is up and the counter resets. These calls count toward the 1000 calls per day **rate limit** as well.
- If a user calls the API 99 times per minute, they will not hit the **burst limit**. They will eventually hit the 1000 calls per day **rate limit**, and the 1001st call will be accepted (since there is no hard limit). A message will be logged for each subsequent call until the time interval (one day) is up and the counter resets. During the remainder of the day, the **burst limit** will still be enforced, and calls will be rejected once the number of calls exceeds the 100 calls per minute within any given minute.
- Both burst limits and rate limits are applied per consumer.
  Note: When Hard limit is unchecked, the **rate limit** is considered a "soft limit." With a soft limit, calls are not rejected after the **rate limit** is reached. Instead, a message is recorded in the log file. With a soft limit, the **burst limit** still rejects API calls after it is exceeded.

h. To include in the Plan all the APIs that were included in the Product in step 5, select Same as product in the Plan APIs section.
i. In the GraphQL Rate Limits section you can configure rate limits that will be applied to any GraphQL proxy APIs that are added to the Product.
The following rate limits are available:

graphql-field-cost
: Applies a limit to the total calculated field cost of GraphQL query calls made to the GraphQL proxy APIs in this Plan.

graphql-design-request
: Applies a limit to the total number of calls of any of the following types made to the GraphQL proxy APIs in this Plan:
  - Requests sent to the `graphql/cost` endpoint for retrieving the cost of a GraphQL query. For more information, see Enabling the cost endpoint for a GraphQL API.
  - Standard introspection requests sent to the `/graphql` endpoint. For more information, see Supporting introspection for a GraphQL API.
  - HTML web browser requests for a GraphiQL editor sent to the `/graphql` endpoint. For more information, see Enabling the GraphiQL editor for a GraphQL API.

graphql-input-type-cost
: Applies a limit to the total calculated input type cost of GraphQL query calls made to the GraphQL proxy APIs in this Plan.

graphql-type-cost
: Applies a limit to the total calculated type cost of GraphQL query calls made to the GraphQL proxy APIs in this Plan.

The calculated costs depend on weighting factors applied to the types and fields in the GraphQL schema. For details on the GraphQL proxy API, and configuring type and field weights, see Creating a GraphQL proxy API and Using the GraphQL schema editor.

j. To define one or more assembly burst limits or assembly count limits, click Add in the Assembly Burst Limits or Assembly Count Limits section as appropriate. For a burst limit you specify the maximum number of calls allowed in a specified time period, for a count limit you specify a maximum call limit. The name that you supply is for use in a Rate Limit policy in an API assembly, enabling the policy to define the burst or count limit that is to be applied; for more information, see Rate Limit.
k. To select the APIs that you want to include in the Plan, select Customize the plan API list in the Plan APIs section, then click Edit. The Edit plan APIs window opens. The APIs that are available for selection are those that were included in the Product in step 5. Use the check boxes to specify the required APIs, then click Save when done.
l. To select specific API operations to include in the Plan, click the options icon ⋮ alongside the required API , then click Edit operation list. The Select operations you want to include window opens. Use the check boxes to specify the required operations, then click Save when done.
m. To remove an API from the Plan, click the options icon ⋮ alongside the required API in the Plan APIs section, then click Remove.
n. For any GraphQL APIs in the Plan, if you want to prevent subscribers to this Plan from using certain types or fields, complete the following steps:
   i. Click the options icon ⋮ alongside the required GraphQL API in the Plan APIs section, then click Edit show/hide settings.
   ii. To prevent use of a GraphQL type, clear the check box selection alongside that type.
   iii. To prevent use a of a field in a type, expand the type then clear the check box selection alongside that field.
   iv. When done, click Next. A summary window opens. If the operation is permitted, any related elements that will also be hidden are listed; for example, if you hide a type, and that type is referenced as the data type of a field on another type, that field is also hidden. If the operation is not permitted, an explanation is displayed.
   v. If the operation is permitted, click Done to apply your changes. If the operation is not permitted, either click Cancel to close the window or click Back and amend your settings.

   You can use the Edit show/hide settings option to change existing settings; you can hide additional types or fields, and you can show types or fields that were previously hidden.

o. To define rate limits for specific API operations, select Override plan rate limits for individual operation in the Plan APIs section; for further details, see Defining rate limits for an API operation
p. Click Save to save your changes.

8. Optional: Specify Plan metadata to be displayed with the Plan in the Developer Portal:
   a. Click the Source tab to see the OpenAPI source for the Plan.
   b. Add the custom attribute `x-name: value` into the appropriate `plan` section. For example:

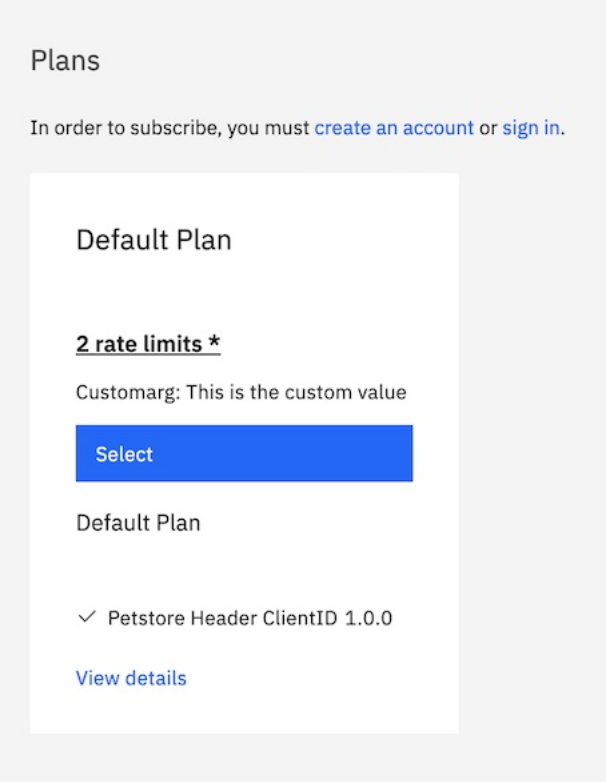
```
...
plans:
  default-plan:
    title: Default Plan
    description: Default Plan
    x-customarg: This is the custom value
    rate-limits:
      default:
        value: 100/1hour
        hard-limit: false
      minute:
```

```
        value: 20/1minute
        hard-limit: false
    apis:
      petstore-header-clientid1.0.0: {}
...
```

Where ***customarg*** is the name of the custom metadata, and ***This is the custom value*** is the information content.

c. Click Save.

When the Plan is published in the Developer Portal, the custom metadata is displayed with the Plan. For example:



Note: After adding custom metadata to a Plan, if you need to edit the Plan details further, you must do this in the Source view, or the custom metadata will be deleted.

9. Optional: Click Categories, then define any categories that you want to organize your Product into. Click Save to save any updates.
   By organizing your Products into categories, you can provide a hierarchical display for your Products in the Developer Portal. For more information, see Organizing your Products into categories.

What to do next

Stage your Product to a Catalog. For more information, see Staging a draft Product.

- **Defining rate limits for an API operation**
  For any Plan in a draft Product, you can apply one or more rate limits to a specific operation on any of the APIs in that Plan.

Defining rate limits for an API operation

For any Plan in a draft Product, you can apply one or more rate limits to a specific operation on any of the APIs in that Plan.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

During the initial creation of a Product, the Product creation wizard guides you to enter the minimum configuration settings, and then provides an Edit Product button. You have the option to specify additional configuration immediately, or to return to Product to edit it later. This topic describes how to specify additional configuration in either case.

Note: For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.

Procedure

1. Access the Product Setup page in one of the following ways:
   - After completing the initial creation of the Product, click Edit Product.
   - In the navigation pane, click Develop, then select the Products tab.
   - Click the title of the Product that you want to edit.
2. Click Plans.
3. Click the options icon ⋮ alongside the required Plan, then click Edit.
4. Scroll down to the Plan APIs section, then select Override plan rate limits for individual operation.
   The Override Rate Limits section is displayed.
5. Click Add. The Override plan rate limits window opens.
6. Select the API, and the specific operation in that API, to which you want to apply rate limits.
   By default, calls to the operation are unlimited.
7. To apply one or more rate limits to the operation, select Rate Limits.
8. To define a rate limit, click Add.
9. Supply a name for the rate limit, and define the maximum number of calls allowed in a specified time period; for example, 100 calls per 1 minute. If you select HARD LIMIT and the limit is exceeded, subsequent calls are rejected, otherwise calls are still accepted and a message is logged.
10. Click Save when done.
    An entry for the operation is listed in the Override Rate Limits section.
11. To modify the rate limiting definition for an operation, click the options icon ⋮ alongside the required operation, then click Edit Operation; to delete it, click Remove.
12. Click Save to save your changes.

Staging a draft Product

Stage a draft Product to a Catalog to create a specific version of that Product, before publishing. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers.. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see Creating and configuring Catalogs.
Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in IBM API Connect®.
To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product > Stage permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see Creating and configuring Catalogs or Managing user access in a Space.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.
Staging is not available when working offline in API Designer.

A Catalog is a staging target, and behaves as a logical partition of the DataPower® Gateway, and the Developer Portal.

You stage a Product so that the appropriate approvals, internally within the organization, can be given for it to then be published. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests. For information on publishing a Product, see Publishing a Product.

You cannot re-stage an existing Product version to a production Catalog. If you update an API, you must create a new version of that API. Then, create a new version of the Product so that it includes the newer version of the API. For more information on creating new versions of APIs and Products, see Creating a new version of an API definition and Creating a new version of your Product. If Spaces are enabled in a production Catalog, you cannot re-stage the same API or Product version to any Space in the Catalog.

You can, however, re-stage a Product version to the Sandbox Catalog, or other non-production Catalog, for ease of iterative testing. Note that when you re-stage a Product version to a non-production Catalog, any application subscriptions are deleted; this is done to facilitate scripted deployment in a continuous integration environment, where the re-creation of application subscriptions will be controlled by the scripts. If Spaces are enabled in a non-production Catalog and you re-stage a Product version to a different Space to the one in which it was previously staged, it is removed from the previous Space and staged to the newly specified Space. If billing integration is enabled in a Product, you cannot re-stage the same Product version into a non-production, or production, Catalog. For more information about billing integration, see Monetizing your Products.

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (https://www.npmjs.com/package/@apidevtools/swagger-parser).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
  - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either `X-IBM-Client-Id` or `X-IBM-Client-Secret`.
  - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.

- De-referencing of local references in the definition file (that is, values of **$ref** properties), and ensuring these are valid JSON Pointers within the file.

Note: If the OpenAPI file that defines your API uses a **$ref** field to reference a fragment of OpenAPI code that is defined in a separate file, the **$ref** field is replaced with the contents of the target file before the product that contains the API is staged or published (the **$ref** field is supported only if you are using the API Connect for IBM Cloud developer toolkit). For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Procedure

To stage a Product, complete the following steps:

1. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
2. In the navigation pane, click Develop.
3. Select the Products tab.
4. You can stage a Product either from the Develop listing page, or from within the Product itself.
   a. To stage a Product from the Develop listing page, click the options menu icon alongside the required Product version, and then select Stage.
   b. To stage a Product from within the Product itself, complete the following steps:
      i. Click the Product version that you want to work with.
      ii. Click the options menu icon:

      
      iii. Select Stage.
5. Select the Catalog to which you want to stage the Product.
6. If Spaces have been enabled in the selected Catalog, select the Space that you require.
   Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to.
   If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Connect Designer.

   For details of how to create a Catalog in a provider organization, see Creating and configuring Catalogs.
7. If, when the staged Product is subsequently published, you want it to be published only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see API Connect gateway types.
8. Click Stage.

Results

Your Product is staged to a Catalog. You can view the state of the Product in the Catalog in API Manager. If you staged the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Staged.

For information about the lifecycle of a product, see The Product lifecycle.

If approval is required to stage Products in the Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is staged when the request is approved. If approval is not required, the Product is staged immediately.

For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

What to do next

- Publish your Product for application developers to access it in the Developer Portal. For more information, see Publishing a Product.

Related information

- Managing your Products
- Removing a Product from a Catalog
- Working with Products in the API Manager

Publishing a draft Product

Publish a draft Product to make the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see Creating and configuring Catalogs.
Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in IBM API Connect®.
To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product > Manage permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see Creating and configuring

Catalogs or Managing user access in a Space.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI. Publishing is not available when working offline in API Designer.

You cannot re-publish a Product version to a production Catalog, you must create a new version of the Product for publication; see Creating a new version of your Product. If Spaces are enabled in a production Catalog, you cannot re-publish the same Product version to any Space in the Catalog, neither the same Space nor a different Space.

You can, however, re-publish a Product version to the Sandbox Catalog, or other non-production Catalog, for ease of iterative testing. When you re-publish a Product version to a non-production Catalog, you can choose whether or not to preserve any application subscriptions; deleting subscriptions can facilitate scripted deployment in a continuous integration environment, where the re-creation of application subscriptions will be controlled by the scripts.

If Spaces are enabled in a non-production Catalog and you re-publish a Product version to a different Space to the one in which it was previously published, it is removed from the previous Space and published to the newly specified Space.

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (https://www.npmjs.com/package/@apidevtools/swagger-parser).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
  - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either **`X-IBM-Client-Id`** or **`X-IBM-Client-Secret`**.
  - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.
  - De-referencing of local references in the definition file (that is, values of **`$ref`** properties), and ensuring these are valid JSON Pointers within the file.

Note: If the OpenAPI file that defines your API uses a **`$ref`** field to reference a fragment of OpenAPI code that is defined in a separate file, the **`$ref`** field is replaced with the contents of the target file before the product that contains the API is staged or published (the **`$ref`** field is supported only if you are using the API Connect for IBM Cloud developer toolkit). For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Procedure

To publish a Product, complete the following steps:

1. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
2. In the navigation pane, click  Develop.
3. Select the Products tab.
4. You can publish a Product either from the Develop listing page, or from within the Product itself.
   a. To publish a Product from the Develop listing page, click the options menu icon ⋮ alongside the required Product version, and then select Publish.
   If you are re-publishing a Product to non-production Catalog, and the Product has application subscriptions, the Publish option deletes them. To preserve application subscriptions, click Publish (Preserve Subscriptions) instead.
   Note: If there are any existing subscriptions to the Product, the Publish (Preserve Subscriptions) operation will fail if you remove any consumer organizations or consumer organization groups from the Product visibility or subscribability settings; you can, however, add further organizations or groups.
   For information on managing visibility and subscribability settings, see Editing a draft Product.

   For information on consumer organization groups, see Working with consumer organization groups.

   b. To publish a Product from within the Product itself, complete the following steps:
      i. Click the Product version that you want to work with.
      ii. Click the options menu icon:
      
      iii. Select Publish.
5. Select the Catalog to which you want to publish the Product. You must have a compatible gateway type associated with the catalog to proceed, as described in Creating and configuring Catalogs.
6. If Spaces have been enabled in the selected Catalog, select the Space that you require.
   Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to.
   If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Connect Designer.

   For details of how to create a Catalog in a provider organization, see Creating and configuring Catalogs.

7. If you want to publish the Product only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see API Connect gateway types.
8. The Visibility and Subscribability sections display the visibility and subscribability settings that have been configured for the draft Product, but you can modify these before publishing if required; proceed as follows:
   a. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to.
   If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be visible to. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.
   b. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product.
   If you select Custom, use the Search organizations and groups field to search for the consumer organizations and consumer organization groups, in the selected Catalog, that you want the Product to be subscribable to. If you selected custom visibility, only the consumer organizations and consumer

organization groups selected there are available for adding to the custom subscribability list. For information about how to create and manage consumer organizations and consumer organization groups, see Administering Consumer organizations.
Note:
- If you select custom visibility or subscribability, only 10 search results are displayed in the selection list for the consumer organizations and consumer organization groups. If necessary, enter a more specific search string to refine the search.
- If custom visibility or subscribability has already been configured in the draft Product, the titles that are displayed in the table of selected organizations and groups are derived by taking the names that are defined in the draft Product and finding the corresponding titles in the Catalog that has been selected as the publish target.

9. Click Publish.

Results

Your Product is published to a Catalog. The state of the Product is shown as Published in the header of the Product itself, and you can click Published to see which Catalogs or Spaces the Product is published to.

You can also view the state of the Product in the Catalog in API Manager. If you published the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Published.

For information about the lifecycle of a product, see The Product lifecycle.

If approval is required to publish Products in the Catalog, a publish approval request is sent, and the Product moves to the Pending state; the Product is published in the Catalog when the request is approved. If approval is not required, the Product is published immediately.

Note: If approval is required to stage Products to the Catalog, a stage approval request is sent. When the request is approved, the Product moves to the staged state and must be separately published in the Catalog. For information on publishing a staged Product in a Catalog, see Publishing a Product.
For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

Creating a new version of your Product

You can have multiple versions of a Product in IBM® API Connect. These versions can occupy any of the lifecycle stages, which facilitates development.

Before you begin

Create your Product and assign it a version. For more information, see Creating a draft Product.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can create multiple versions of a Product, and these versions can be named according to your own preferences, and function as distinct Products when staged.

Procedure

To create a new version of a Product, complete the following steps:

1. In the navigation pane, click Develop.
2. Select the Products tab.
3. Alongside the Product version that you want to work with, click the options icon, then click Save as a new version.
   The Save Product as a new version window opens.
4. Enter your new version number, then click Save.

Results

Your Product is saved as a new version.

Related information

- Managing your Products
- Working with Products in the API Manager

Specifying the gateway type for a Product

You can edit the Product configuration to specify a gateway type.

Before you begin

IBM® API Connect supports two gateway types: DataPower® Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can specify the gateway type for a Product.

Products can use only one type of gateway, and the APIs in the Product must use the same type of gateway. See Specifying the gateway type for an API definition.

When you create a new Product, or import a Product definition that has no gateway type configured, the gateway type defaults according to the gateway types of the gateway services that are enabled in your Sandbox Catalog, as indicated in the following table.

Table 1. Default gateway type for a new Product

Gateway Service enablement in Sandbox Catalog	Default gateway type for new Product
No gateway services enabled	DataPower API Gateway
At least one gateway service of each type enabled	DataPower API Gateway
One or more gateway services only of type DataPower API Gateway enabled	DataPower API Gateway
One or more gateway services only of type DataPower Gateway (v5 compatible) enabled	DataPower Gateway (v5 compatible)

If you import a Product definition that already has a gateway type configured, that gateway type is retained.
For details of how to enable gateway services in a Catalog, see Creating and configuring Catalogs.

Procedure

To specify the gateway type for a Product, complete the following steps:

1. Ensure that you know the type of gateway that your APIs are configured to use.
2. In the navigation pane, click  Develop, then select the Products tab.
3. Click the title of the Product you want to update.
4. On the Product Setup page, go to the Gateway Type section. Select the gateway type for your Product:
   - DataPower Gateway (v5 compatible)
   - DataPower API Gateway

   Note:
   You can only select the gateway type that satisfies the selected enforced APIs in your Product. To change the APIs included in your product, see Editing a draft Product.
5. Click Save to retain your changes.

Deleting a draft Product

You can delete draft Products that are no longer required.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Product-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Note:

- Deleting a draft Product does not remove it from any Catalogs to which it has been published. For details on how to remove a Product from a Catalog, see Removing a Product from a Catalog.
- You cannot directly delete a Product that was generated automatically from an API with the Activate API option; these Products have the title *api_title* auto product. To delete such Products, delete the API from which it was generated; the Product is deleted together with the API. For more information, see Deleting an API definition.

Procedure

1. In the navigation pane, click  Develop.
2. Select the Products tab.
3. Alongside the Product version that you want to delete, click the options icon ⋮ and then click Delete.

Organizing your Products into categories

You can organize your Products into categories. The Products that you categorize are displayed within the Developer Portal, in their defined categories.

Before you begin

Your role must have the necessary permissions to stage and publish Products.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

By organizing your Products into categories, you can provide a hierarchical display for your Products in the Developer Portal.
Note: Organizing Products into a hierarchical view in the API Designer or API Manager UI is different to tagging in the Developer Portal.

Procedure

1. In the navigation pane, click  Develop, then select the Products tab..
2. Click the title of the Product that you want to work with.
3. Click Categories.
4. In the Categories text box, enter the hierarchical taxonomy path that you want your Product to follow, in the following format:

   `top_level_element / next_level_element / x_level_element`

   For example:

   `Animals / Fluffy / Cat`

5. After you have completed entering the category specifications for the Product, click Save.

What to do next

- Publish the Product; see Publishing a draft Product.
- After publishing the Product, you can, in the Developer Portal, display Products in the categories that you have defined. For more information, see Displaying APIs and Products in categories.

Creating and validating API and Product definitions by using the CLI

The developer toolkit of IBM® API Connect provides a command line interface that you can use to create and publish API and Product definitions, and also to validate YAML or JSON definitions.

The following topics explain how to use the command line interface to create an OpenAPI definition file, create a Product definition file, and validate a YAML or JSON definition.

- **Creating an OpenAPI definition file**
  APIs are defined in OpenAPI definition files, in YAML format. You can create a default OpenAPI definition file by using the **create** command and then modify it by using an editor of your choice.
- **Specifying a gateway type for an API definition**
  An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). API definitions must specify which type of gateway the API uses.
- **Referring to an extension in an API definition**
  To refer to an OpenAPI extension in your API definition YAML (or JSON) file, add an **`extensions`** key under **`x-ibm-configuration`**.
- **Using $ref to reuse code fragments in your OpenAPI files**
  If you deploy an API to an IBM API Connect Management server by using the developer toolkit command line, you can use the **`$ref`** field in your OpenAPI YAML and JSON API definition files to reference a fragment of OpenAPI code that is defined in a separate file. When API Connect processes the source API definition file, the **`$ref`** field is replaced with the contents of the target file.
- **Creating a Product definition file**
  You define a Product by creating a Product definition file.
- **Using x-ibm-languages to create multilingual API and Product documentation**
  Create multilingual API and Product documentation by using the **`x-ibm-languages`** extension in your API and Product OpenAPI definitions.
- **Using x-example to control the examples displayed in the Developer Portal**
  OpenAPI does not support the use of **`example`** attributes on parameters, only on request and response objects and their properties. To allow API Developers to be able to control the examples displayed in the portal you can use **`x-example`** in OpenAPI parameters.
- **Using x-embedded-doc to add additional documentation to products and APIs**
  You can use **`x-embedded-doc`** to add additional documentation to a product or an API as part of their definition.
- **Using x-pathalias to give consistent URLs for products and APIs**
  You can use **`x-pathalias`** to assign a URL to a product or an API.
- **Validating the YAML or JSON definition of an API or Product**
  You can validate a YAML or JSON definition by using the IBM API Connect developer toolkit.
- **Creating and using API and Product definitions templates**
  You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form **`{{variable-name}}`** that are substituted with values when you create the API or Product definition.

Related reference

- API development and management commands

Creating an OpenAPI definition file

APIs are defined in OpenAPI definition files, in YAML format. You can create a default OpenAPI definition file by using the **create** command and then modify it by using an editor of your choice.

You can stage or publish the API directly to a Catalog in API Manager by referencing the API in a Product definition file, and then using the **`apic products:publish`** command to publish the Product. You can also create a draft API in API Manager by using the **apic draft-apis:create** command.

You can create an API in the CLI by running **`apic create:api`**, and supplying additional arguments on the command line.

Another option is to create an API interactively in the command line by running **`apic create:api`** and following the prompts.

You can see further details and available options for the **`apic create:api`** command by running:

```
apic create:api --help
```

IBM provides an extension to the OpenAPI specification; this extension is described in IBM extensions to the OpenAPI specification.

Note: Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "**`(?`**" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:
0)
400
```

Creating an API definition from a template

You can use a custom Handlebars template to create an API by using the following command:

```
apic create:api --template template_filename --title api_title
```

where *template_filename* is the name of the Handlebars template to use, and *api_title* is the title of your API.
An API template file must have a .hbs file name extension. You can create a template from scratch, or start with the example (default) API template provided in API and Product definition template examples.

You can create multilingual API and Product documentation by using an **`x-ibm-languages`** extension directly in the OpenAPI definition. For more information, see Using x-ibm-languages to create multilingual API and Product documentation.

- **IBM extensions to the OpenAPI specification**
  You use the **`x-ibm-configuration`** object in your OpenAPI definition file to add extensions that are specific to IBM API Connect.

Related reference

- API development and management commands

IBM extensions to the OpenAPI specification

You use the **`x-ibm-configuration`** object in your OpenAPI definition file to add extensions that are specific to IBM® API Connect.

The x-ibm-configuration extension has the following structure:

```
x-ibm-configuration:
  enforced: enforced_boolean
  phase: Phase
  testable: test_boolean
  cors:
    enabled: cors_boolean
  activity-log:
      activity_logging_extension
  assembly:
    execute:
      - assembly_component
  gateway: gateway_type
  type: api_type
  properties:
      properties_extension
  catalogs:
      catalogs_extension
```

The following table lists the various extensions used by API Connect, whether they are required, a description of their use and behavior, and their type.

Table 1. IBM extensions

Extension	Required	Description	Type

Extension	Required	Description	Type
phase	No	Use the phase extension to describe the maturity of the API. It can take the following values: • **identified**: the API is in the early conceptual phase and is neither fully designed nor implemented. • **specified**: the API has been fully designed and passed an internal milestone but has not yet been implemented. • **realized**: the API is in the implementation phase.	String
testable	No	Use the **testable** extension to specify whether the API can be tested using the test tool in the Developer Portal.	Boolean
enforced	No	Use the **enforced** extension to specify if the API Connect gateway is used to enforce the API. • **true** indicates that the API Connect gateway is used to enforce the API. • **false** indicates that the API Connect gateway is not used to enforce the API.	Boolean
cors	No	Use the **cors** extension to specify whether CORS access control is used for the API. The extension has an **enabled** field which is a Boolean.	Object (with a single Boolean field)
API Gateway only activity-log	No	Use the **activity-log** extension to configure your logging preferences for the API activity that is stored in analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.	Object
assembly	No	Use the **assembly** extension to describe the application of policies and logic to an API. It contains an **execute** field that contains an array of policies that are applied in order. It can contain a **catch** field that contains an array of error cases to be caught. For information about use of the **execute** field, see execute. For information about use of the **catch** field, see catch.	Object
gateway	No	Use the **gateway** extension to specify which type of gateway you want to use. If you are using the DataPower® Gateway (v5 compatible) or DataPower API Gateway, it must be included and take one of the following values: • `datapower-gateway` (DataPower Gateway (v5 compatible)) • `datapower-api-gateway` (DataPower API Gateway) For information about types of gateways, see API Connect gateway types.	String
type	No	The **type** extension takes one of the following values: • **rest** • **wsdl**	
properties	No	Use the **properties** extension to define properties for use in an API.	Object (properties)
catalogs	No	Use the **catalogs** extension to define Catalog-specific values for properties defined in the **properties** extension.	Object (catalogs)

The following example shows the **x-ibm-extension** section of an API that is enforced by API Connect, is in the realized state, is testable through the test tool in the Developer Portal, has CORS access control enabled, and has a simple assembly that invokes a URL and then redacts a field from the request or response.

```
x-ibm-configuration:
  enforced: true
  phase: realized
  testable: true
  cors:
    enabled: true
  assembly:
    execute:
      - invoke:
          title: Example Invoke
          target-url: 'https://example.com/api'
          description: Example description
      - redact:
          actions:
            - action: redact
              from:
                - request
                - response
              path: //*[@name='secondaryAddress']/*[@name='streetAddress']
  properties:
    ID:
      value: 1234
      description: An ID to be used for validating.
      encoded: false
  catalogs:
    Sandbox:
      properties:
        ID: 5678
```

- **catch**
  Use the catch extension to catch errors that occur during an API call.
- **properties**
  Use the **properties** extension to define properties for referencing in an API.
- **catalogs**
  Use the **catalogs** extension to assign catalog-specific values to properties defined in the **properties** section.
- **activity-log**
  If you're using the DataPower API Gateway, you can use the **activity-log** extension to configure your logging preferences for the API activity that is stored in analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.

execute

The execute field of an assembly has the following structure:

```
execute:
 - Policy_1
 - Policy_2
```

Note: Although some built-in policies can be used with both the DataPower® Gateway (v5 compatible) and the DataPower API Gateway, some policies are restricted to a particular Gateway. The following icons indicate which Gateway each policy can be used with:

- DataPower Gateway Indicates that the policy can be run on the DataPower Gateway (v5 compatible).
- API Gateway Indicates that the policy can be run on the DataPower API Gateway.

For details of the two types of gateway, see API Connect gateway types.

The following table describes the possible policies and logic constructs that can be included in an execute field.

Table 1. execute properties

Property	Required	Description	Data Type	DataPower Gateway	API Gateway
activity-log	No	Use the activity-log policy to log information that relates to the calling of API operations.	object (activity-log)	✓	✓ Functionality provided by the activity-log extension
client-security	No	Provides a range of options for authenticating client access to your APIs, extending the capabilities of the OpenAPI specification.	object (client-security)	✗	✓
gatewayscript	No	Include a GatewayScript program.	object (gatewayscript)	✓	✓
graphql-introspect	No	Use the graphql-introspect policy to introspect a GraphQL schema.	object (graphql-introspect)	✗	✓
if	No	Use the if policy to execute a section of the assembly only when a condition is fulfilled.	object (if)	✓	✓ Functionality provided by switch
invoke	No	Use the invoke policy to call an API. The last invoke in your policy might be replaced by a proxy automatically to improve performance. To disable this, see: API properties.	object (invoke)	✓	✓
json-to-xml	No	Convert payload from JSON to XML.	object (json-to-xml)	✓	✓
jwt-generate	No	Generate a JSON Web Token (JWT).	object (jwt-generate)	✓	✓
jwt-validate	No	Validate a JSON Web Token (JWT).	object (jwt-validate)	✓	✓
log	No	Use the log policy to customize or override the default activity logging configuration for an API.	object (log)	✗	✓
map	No	Use the map policy to transform variables.	object (map)	✓	✓
operation-switch	No	Use the operation-switch policy when you want to execute alternative policy assemblies, conditional on the operation that is being called.	object (operation-switch)	✓	✓
oauth	No	Use the oauth policy to policy to perform OAuth processing based on defined OAuth provider settings.	object (oauth)	✗	✓
parse	No	Use the parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.	object (parse)	✗	✓
proxy	No	Proxy a service.	object (proxy)	✓	✓ Functionality provided by invoke
ratelimit	No	Use the ratelimit policy to apply one or more rate or burst limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls that an application can make to an API in a specified time period.	object (ratelimit)	✗	✓
redact	No	Use the redact policy to completely remove or to redact specified fields from the request body, the response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.	object (redact - DataPower API Gatewayredact - DataPower Gateway (v5 compatible))	✓	✓
set-variable	No	Use the set-variable policy to set a runtime variable to a string value, or to add or clear a runtime variable.	object (set-variable)	✓	✓
switch	No	Use the switch policy to execute one of a number of sections of the assembly based on which specified condition is fulfilled.	object (switch)	✓	✓
throw	No	Use the throw policy to specify points at which an error should be thrown.	object (throw)	✓	✓
user-defined-policy	No	You can apply your own user-defined policies to your APIs.	object (User-defined policies)	✓	✓
user-security	No	Extract a user's credentials, authenticate those credentials, and obtain authorization from the user.	object (user-security)	✗	✓

Property	Required	Description	Data Type	DataPower Gateway	API Gateway
validate	No	Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.	object (validate - DataPower API Gateway, validate - DataPower Gateway (v5 compatible))	✓	✓
validate-usernametoken	No	Validate a WS-Security UsernameToken.	object (validate-usernametoken)	✓	✗
xml-to-json	No	Convert payload from XML to JSON.	object (xml-to-json)	✓	✓
xslt	No	Apply an XSLT transform to the payload.	object (xslt)	✓	✓

The following example shows an execute field for an assembly that invokes a URL and then redacts a field from the request or response.

```
execute:
 - invoke:
  title: Example Invoke
  target-url: 'https://example.com/api'
  description: Example description
 - redact:
  actions:
   - action: redact
     from:
      - request
      - response
    path: //*[@name='secondaryAddress']/*[@name='streetAddress']
```

activity-log

Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM® API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Activity Log.

Note: If you are using the DataPower API Gateway, you configure your logging preferences by using the activity-log extension.

About

The activity-log policy has the following format:

```
- activity-log:
  version: version
  title: title
  description: description
  content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
```

Apply this policy by adding an assembly extension with an execute field to your OpenAPI definition file.

You can also apply an activity-log policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see Activity Log in the built-in policies section.

Note: If payload logging is enabled, for the gateway to capture payloads buffering must also be enabled.

```
activity-log:
  success-content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
  enabled: is_activity_logging_enabled
buffering: true
```

Properties

The following table describes the policy properties:

Table 2. Activity Log policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	A title for the policy.	string
description	No	A description of the policy.	string

Property	Required	Description	Data type
content	Yes	Defines the type of content to be logged when the operation is successful. Valid values: • **none**: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • **activity**: Logs invocation only (only the resource URI is recorded). • **header**: Logs activity and header. • **payload**: Logs activity, header, and payload (the original request, if any, and the final response). The default value is **activity**.	string
error-content	No	Indicates what content to log if an error occurs. Valid values: • **none**: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • **activity**: Logs invocation only (only the resource URI is recorded). • **header**: Logs activity and header. • **payload**: Logs activity, header, and payload (the original request, if any, and the final response). The default value is **payload**.	string

Example 1

```
# use defaults

- activity-log:
  version: 1.0.0
  title: default activity logging
```

Example 2

```
- activity-log:
  version: 1.0.0
  title: no logging for successful calls
  content: none
  error-content: activity
```

client-security

The client-security policy can be used to extend client authentication access for your APIs.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Client Security.

About

You use the client-security policy to create an assembly action that's separate from the OpenAPI specification, to allow for more options to authenticate an application. Note that you cannot use the client-security policy to perform rate-limiting enforcement.

In a client security action, you define the following settings.

- Control whether to stop processing if client security fails. When client security fails, stops assembly processing and returns an error.
- Control whether to require the client secret. When required, the secret is compared to the registered secret on the application that is identified by the client ID.
- Define the method to extract client credentials from the request.
  - For all methods except **http**, use the id-name and the secret-name properties to specify the location that contains the ID and the location that contains the secret.
    - When **cookie**, specify which cookie.
    - When **context-var**, specify which runtime context variable.
    - When **form**, specify the form data.
    - When **header**, specify which header.
    - When **query**, specify which query parameter.
  - For the **http** method, use the http-type property to specify the format of the authorization header, which expects the **basic** form in the **basic base64_id:secret** format.
- Define the method to authenticate the extracted client credentials. The supported methods are **native** (this means by using IBM® API Connect), or by using a specified **third-party** user registry.
  - If **third-party**, use the user-registry property to specify the user-registry to authenticate the extracted client credentials. The supported registry types are LDAP and authentication URL.

Properties

The client-security policy has the following format:

```
- client-security:
    version: version
    title: title
    description: description
    stop-on-error: is_processing_stopped_on_client_security_failure
    secret-required: is_client_secret_required_in_request
    extract-credential-method: method_for_supplying_credentials
    id-name: parameter_that_specifies_client_id
    secret-name: parameter_that_specifies_client_secret
    http-type: authentication_type
    client-auth-method: method_for_client_authentication
    user-registry: user_registry_for_client_authentication
```

Table 2. client-security policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
stop-on-error	Yes	If set to **true**, assembly processing stops if client security fails, and an error is returned.	boolean
secret-required	Yes	If set to **true**, the client secret must be sent in the request. The secret is compared to the registered secret on the application that is identified by the client ID.	boolean
extract-credential-method	Yes	Specify one of the following values to define how the calling application authenticates: • **header**: client ID and client secret credentials must be supplied in the request header. • **query**: client ID and client secret credentials must be supplied as query parameters in the request URL. • **form**: client ID and client secret credentials must be supplied as form data sent in a POST request. • **cookie**: client ID and client secret credentials must be supplied in a header called **Cookie**. • **http**: the calling application must authenticate by using basic authentication. • **context-var**: the credentials that are used for authenticating the client are obtained from context variables that you set in the assembly flow prior to the Client Security policy, by using a gatewayscript policy for example. The names of these context variables are determined by the values that you supply in the id-name and secret-name properties of the client-security policy.	string
id-name	Yes, unless extract-credential-method is set to **http**	The name of the parameter whose value specifies the client ID. For all values of extract-credential-method other than **context-var** and **http**, the calling application must supply a parameter with this name, in the location defined by the extract-credential-method setting. For **context-var**, this property specifies the name of a context variable. This option does not apply if the extract-credential-method property is set to **http**.	string
secret-name	Yes, if secret-required is set to **true** and extract-credential-method is other than **http**	The name of the parameter whose value specifies the client secret. For all values of extract-credential-method other than **context-var** and **http**, the calling application must supply a parameter with this name, in the location defined by the extract-credential-method setting. For **context-var**, this property specifies the name of a context variable. This option does not apply if the extract-credential-method property is set to **http**.	string
http-type	Yes, if extract-credential-method is set to **http**	The authentication type. Currently, this must be set to **basic**.	string
client-auth-method	Yes	Specify one of the following values: • **native**: only client ID and client secret are used to authenticate the request. If extract-credential-method is set to **http** then the calling application must supply the client ID for the user name, and the client secret for the password. • **third-party**: a user registry is used to authenticate the client. If extract-credential-method is set to a value other than **http** then the calling application must supply the user name for the client ID, and the password for the client secret.	string
user-registry	Yes, if the client-auth-method is set to **third-party**	Specify the value of the **name** property of the user registry that will be used to authenticate the client. The supported registry types are LDAP and authentication URL.	string

client-security policy example

```
- client-security:
    version: 2.0.0
    title: client-security
    stop-on-error: true
    secret-required: true
    extract-credential-method: cookie
    id-name: my-client-id
    secret-name: my-client-secret
    client-auth-method: third-party
    user-registry: myauthurl
```

extract

Use the extract policy to extract and transform data from fields in the API context.

Gateway support

Table 1. Gateways that support this policy and the corresponding policy versions

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Extract.

About

The extract policy specifies the data source that contains the content to transform, the fields that contain the content, and expressions that define how to transform the content. You use a subset of JSONata notation to specify the fields to extract and transform. For more information, see Constructing JSONata expressions to extract and transform data.

The input to the extract policy must be parsed data. One way to produce parsed data is to add a parse policy before the extract policy in your assembly.

The extract policy has the following format:

```
- extract:
    version: 2.0.0
    title: title
    root: data source
    extracts:
      - capture: path expression that identifies the field
        transform: expression that defines how to transform the content
                   .
                   .
                   .
    description: description
```

Apply this policy by adding an `assembly` extension with an `execute` field to your OpenAPI definition file.

Properties

Table 2. extract policy properties

Property label	Required	Description	Data type
version	Yes	The policy version number. You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.	string
title	Yes	The title of the policy. The default value is `extract`.	string
description	No	A description of the policy.	string
root	Yes	The data source that contains the content to transform. The default value is `message.body`.	string
capture	Yes	The path expression that identifies the field. The default setting is `$`, which indicates the entire input.	string
transform	Yes	The expression that defines how to transform the content.	string

Example

Transform the contents of the `account` field to include only the last 4 characters.

```
- extract:
    version: 2.0.0
    title: extract
    root: message.body
    extracts:
      - capture: $.members.policy.**.account
        transform: $substring($,-4)
    description: Include only the last 4 characters of the account field.
```

gatewayscript

Use the gatewayscript policy to execute a specified DataPower GatewayScript program.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see GatewayScript.

About

The gatewayscript policy has the following structure:

```
- gatewayscript:
    version: version
    title: Title
    desription: Description
    source: Script
```

Properties

The following table describes the policy properties:

Table 2. gatewayscript policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
source	Yes	The GatewayScript source code to execute.	string

Example

The following is an example of a simple gatewayscript policy:

```
- gatewayscript:
    version: 1.0.0
    title: Example_GatewayScript
    source: console.debug('Hello World!');
    description: A simple GatewayScript policy.
```

For more information about how to use a gatewayscript policy, see GatewayScript in the built-in policies section.

For more code examples, see GatewayScript code examples and, if you are using the DataPower API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

For general information on using GatewayScript, see the following topics in the DataPower product documentation:

- GatewayScript APIs for API management
- Accessing and manipulating a variable in the API context
- OAuth context variables

Related concepts

- Variable references in API Connect

Related reference

graphql-introspect

Use the graphql-introspect policy to introspect a GraphQL schema.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see GraphQL introspect.

Properties

Table 2. graphql-introspect policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
input	No	A variable in the API context that contains the input to introspect. The content of the **body** field of the variable is the input to introspect. By default, the variable name is **message**.	string
output	No	A variable in the API context where the results of the introspection are stored. The content of the **body** field of the variable is the result of GraphQL introspection. The default variable name is the same as that of the variable specified for the **input** field. Therefore, by default, the input of the introspection is overwritten by the output.	string

Example

```
- graphql-introspect:
    version: 2.0.0
    title: introspect the accounts graphql schema
    input: message
```

if

Use the if construct when you want to execute a portion of your assembly only when a specific condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by switch	

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see if.

About

The if policy has the following format:

```
- if:
  version: version
  title: title
  description: description
  condition: 'condition_1
      execute:
        policy_assembly_1 ...
```

In the condition field, use the form **apim.getvariable('*context.location.variable*')** to reference your variables, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable.

The **execute:** section can define any policy assembly, including further if policies. For more information, see execute.

Properties

Table 2. if policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
condition	Yes	A script that returns **true** or **false**. Use GatewayScript for a DataPower Gateway implementation. For information about the context variables you can use and how to reference them in your script, see API Connect context variables.	string
execute	Yes	The policy assembly that you want to execute if the condition returns **true**. For more information, see execute.	string

Example

```
# carry out different redaction actions depending on the operation

- if:
  version: 1.0.0
  title: clear_region_and_set_body
  condition: 'apim.getvariable('request.body.secret') == true'
    execute:
      - redact:
          title: remove secret field
          actions:
            - action: remove
              from: all
              path: /document/user/secret
```

invoke

Use the invoke policy to call an API.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.1 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Invoke.

About

The invoke policy does not support responses with multipart form data, that is, when the response is set to `Content-Type: multipart/related`.

The invoke policy has the following format:

```
- invoke:
  version: version
  title: title
  description: description
  target-url: URL_of_target_API
  backend-type: how_payload_is_sent_to_backend
  tls-profile: TLS_profile_to_be_used
  verb: method_type
  timeout: timeout_value_in_seconds
  compression: is_data_to_be_compressed
  username: username_if_authentication_required
  password: password_if_authentication_required
  output: location_of_the_invoke_result
  cache-key: unique_identifier_of_the_document_cache_entry
  cache-response: cache_behavior
  cache-putpost-response: response_caching_behavior
  cache-ttl: cache_time_to_live
  inject-proxy-headers: are_proxy_headers_sent_to_target_url
  decode-request-params: are_request_parameters_decoded
  encode-plus-char: are_plus_characters_encoded
  keep-payload: is_payload_sent_on_delete
  use-http-10: are_transactions_restricted_to_http_1.0
  chunked-uploads: are_chunked_encoded_documents_sent_to_the_server
  persistent-connection: are_persistent_connections_enabled
  header-control:
        .
        .
        .
    headers_to_copy_to_target_url
        .
        .
        .
  parameter-control:
        .
        .
        .
    parameters_to_copy_to_target_url
        .
        .
        .
  follow-redirects: url_redirection_behavior
  stop-on-error: errors_that_stop_the_flow
```

Properties

The following table describes the properties of the invoke policy.

Table 2. Invoke policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
target-url	Yes	The URL of the target API.	string

Property	Required	Description	Data type
API Gateway only backend-type	No	Specify one of the following values to determine how the payload is sent to the backend: • **detect**: detect the message type and send the payload to the backend accordingly. • **xml**: package the payload as XML and send. If the message type is not XML, the operation fails. • **json**: package the payload as JSON and send. If the message type is not JSON, the operation fails. • **binary**: package the payload as binary and send, regardless of the message type. • **graphql**: package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. The default value is **detect**.	string
API Gateway only graphql-send-type(policy version 2.2.0 and later)	Yes, if backend-type is set to **graphql** or **detect**, and verb is set to **POST** or **keep**.	Specify one of the following values to determine how the GraphQL payload is sent to the back end: • **detect**: detect the message type and send the payload to the back end accordingly. • **graphql**: package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. • **json**: package the payload as JSON and send. If the message type is not GraphQL, the operation fails. Note: graphql-send-type is supported only if backend-type is set to **graphql** or **detect**, and verb is set to **POST** or **keep**.	string
tls-profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
verb	No	The operation method type. Valid values: • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is **GET**. However, if the property is omitted from the source, the HTTP method from the incoming request is used.	string
timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is **60**.	integer
API Gateway only http-version (policy version 2.1.0 and later)	Yes	The HTTP version that will be used when connecting to the backend server. Valid values: • **HTTP/1.0** • **HTTP/1.1** • **HTTP/2**	string
API Gateway only http2-required (policy version 2.1.0 and later)	No	Set this property to **true** to require that the server selects HTTP/2 during a TLS connection, otherwise the DataPower API Gateway rejects the connection and fails the request. For a non TLS connection, a warning is logged stating that the requirement can't be enforced. This setting applies only if http-version is set to **HTTP/2**.	boolean
compression	No	Specifies whether data is to be compressed by using compress before it is uploaded. The default value is **false**.	boolean
username	No	The username to use for HTTP Basic authentication.	string
password	No	The password to use for HTTP Basic authentication.	string
output	No	The name of a variable that will be used to store the response data from the request. By default, the invoke response, that is the body, headers, statusCode and statusMessage, is saved in the variable *message*. Use this property to specify an alternate location to store the invoke response. This variable can then be referenced in other actions, such as map. Note: If you want the response to be saved in *message*, leave the output property blank, do **not** supply the value `message`.	string
cache-key	No	Specifies the unique identifier of the document cache entry.	string
API Gateway only websocket-upgrade (policy version 2.1.0 and later)	No	Set this property to **true** to allow an HTTP or HTTPS connection to be upgraded to the WebSocket protocol if the request received by the corresponding HTTP or HTTPS handler on the DataPower API Gateway uses WebSocket (ws) or WebSocket Secure (wss). Note: • This property is available only for GraphQL APIs. • The **websocket-upgrade** property is deprecated. To allow WebSocket upgrade requests that can manage API processing data, define an assembly WebSocket upgrade policy. For more information, see websocket-upgrade.	boolean
cache-response	No	The cache response type. Valid values: • **protocol**: The cache behavior is defined by the Cache-Control headers on the request and response. • **no-cache**: Specifies that there is no caching. However, if the document is already in the cache, the document is retrieved from the cache. • **time-to-live**: Specifies that the response stays in the cache for the specified time. The default value is **protocol**.	string

Property	Required	Description	Data type
cache-putpost-response	No	Specifies whether to cache the response from POST and PUT requests. Caching the response from POST and PUT requests can reduce server load and reduce latency in the response to the client request. The default value is **false**.	boolean
cache-ttl	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property cache-response is set to **time-to-live**. Enter a value in the range 5 - 31708800. The default value is **900**.	integer
API Gateway only inject-proxy-headers	No	When set to true, the **invoke** policy injects the **X-Forwarded-For**, **X-Forwarded-To**, **X-Forwarded-Host**, and **X-Forwarded-Proto** headers to the request that is sent to the t**arget-url**. The default value is **false**.	boolean
API Gateway only decode-request-params	No	When set to true, any request parameters that are referenced by a variable definition on the **target-url** of the invoke policy are URL-decoded. The default value is **false**.	boolean
API Gateway only encode-plus-char	No	When set to true, all "+" characters in the query parameter values of the **target-url** are encoded to %2F. The default value is **false**.	boolean
API Gateway only keep-payload	No	When set to true, the invoke policy sends a payload on an **HTTP DELETE** method. The default value is **false**.	boolean
API Gateway only use-http-10 (policy version 2.0.0 only)	No	When set to true, HTTP transactions are restricted to version 1.0. The default value is **false**.	boolean
API Gateway only chunked-uploads	No	If you set this property to **true**, chunked-encoded documents are sent to the server. When the HTTP 1.1 protocol is used, the body of the document can be delimited by either **Content-Length** or chunked encoding. While all servers can interpret **Content-Length**, many applications fail to understand chunked-encoded documents. For this reason, **Content-Length** is the standard method. The use of **Content-Length** interferes with the ability of the DataPower Gateway to fully stream. If you must stream full documents to the target server, enable this property. When enabled, the server must be RFC 2616 compatible. Unlike all other HTTP 1.1 features that can be negotiated down at run time, you must know beforehand that the target server is RFC 2616 compatible. The default value is **true**. Note: Chunked encoding is not supported by the HTTP 1.0 protocol.	boolean
API Gateway only persistent-connection (policy version 2.3.0 and later)	No	Set this property to **true** to enable HTTP persistent connections, allowing connection re-use. The default value is **true**.	boolean
API Gateway only **header-control:** **type** **values**	No	Specifies the headers in **message.headers** that you want to copy to the target URL. If the **type** property is set to **blocklist**, the **values** property lists the headers that you don't want to be copied. If the **values** property is empty then all headers are copied. If the **type** property is set to **allowlist**, the **values** property lists the headers that you want to be copied. The items that are listed in the **values** property are in regular expression format. The values are not case-sensitive. The default value of the **header-control** property is **header-control:** **type: blocklist** **values: []** See header-control examples	object
API Gateway only **parameter-control:** **type** **values**	No	Specifies the parameters in the incoming request that you want to be copied to the target URL. If the **type** property is set to **blocklist**, the **values** property lists the parameters that you don't want to be copied. If the **type** property is set to **allowlist**, the **values** property lists the parameters that you want to be copied. If the **values** property is empty then no parameters are copied. The items that are listed in the **values** property are in regular expression format. The values are not case-sensitive. The default value of the **parameter-control** property is **parameter-control:** **type: allowlist** **values: []** See parameter-control examples	object
API Gateway only follow-redirect	No	Specifies the behavior if the back-end server returns the HTTP status code **301 Moved Permanently**. If this property is set to **true**, the **invoke** policy follows the URL redirection by making a further call to the URL specified in the **Location** header in the response. If this property is set to **false**, the **invoke** saves the **301** status code and the API call is considered to be complete. Note: The **follow-redirect** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **invoke** always follows the URL redirection; the **proxy** policy (not supported by the DataPower API Gateway) saves the **301** status code and completes the API call without following the URL redirection.	boolean

Property	Required	Description	Data type
stop-on-error	No	List the errors that, if thrown during the policy execution, cause the flow to stop. If there is a `catch` flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors specified for the Stop on error property, or if the error thrown is not one of the specified errors, the policy execution is allowed to complete, and the assembly flow continues.	string

Example

```
- invoke:
    version: 2.0.0
    title: get the account status
    target-url: https://example.com/accounts/{id}?status={status}
    cache-response: time-to-live
    cache-putpost-response: true
    tls-profile: MyTLSProfile
    verb: POST
    timeout: 60
    compression: false
    username: MyUser
    password: MyPassword
    stop-on-error:
      - ConnectionError
      - OperationError
```

API Gateway only `header-control` examples

```
# copy all headers to the target URL

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: blocklist
      values: []

# copy all headers except X-Client-ID and Content-Type

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: blocklist
      values:
        - ^X-Client-ID$
        - ^Content-Type$

# copy no headers

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values: []

# copy only the Content-Type header

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values:
        - ^Content-Type$
```

API Gateway only `parameter-control` examples

```
# copy no request parameters to the target URL

- invoke:
    target-url: http://myhost/path?storeid=3
    parameter-control:
      type: allowlist
      values: []

# append the petid parameter to the target URL
# if the incoming request is http://apigw/org/sandbox/petstore/base?petid=100&display=detailed,
# the target URL at runtime will be http://myhost/mypath?storeid=3&petid=100

- invoke:
    target-url: http://myhost/path?storeid=3
    parameter-control:
      type: allowlist
      values:
        - ^petid$
```

json-to-xml

Use the json-to-xml policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see JSON to XML.

About

The json-to-xml policy has the following structure:

```
- json-to-xml:
    version: version
    title: Title
    description: Description
```

Note: If you are using the DataPower API Gateway, the input to the json-to-xml policy must be parsed data. One way to produce parsed data is to use a **parse** policy before a json-to-xml policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. Policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
API Gateway only input	No	The input message to convert. Specify the name of a variable in the API context. ***variableName*.body**, the message payload, represents the JSON input to convert. The default value of the variable is **message** and **message.body** is the default input.	string
API Gateway only output	No	The output message to store the conversion result. Specify the name of a variable in the API context. ***variableName*.body** represents the result of conversion from JSON format to XML format. When the specified input message is the default message, the default output is **message.body**. Otherwise, when the input message is the variable **my-message-variable**, for example, the default output is **my-message-variable.body**. The variable cannot be any read-only in the API context.	string
API Gateway only conversionType	No	The conversion type that determines the target format of the output. The following options are available: • None: No conversion of the output takes place. • badgerFish: BadgerFish convention is used to determine the target conversion format of the output.	string
root-element-name	Yes	The root element name of the resultant XML document. This property is used only if the input JSON document is not hierarchical and has more than one uppermost level property, or if the always-output-root-element property is set to **true**.	
always-output-root-element	Yes	Select this property to **true** you always want the policy to output the root element, even if it is not required to make the XML document well formed.	boolean
unnamed-element-name	No	The XML element name to be used for JSON array elements.	string

Example

The following is an example of a json-to-xml policy:

```
- json-to-xml:
    version: 1.0.0
    title: JSON to XML transform
    description: Transforms JSON message body to XML format
```

jwt-generate

Use the Generate JWT security policy in IBM® API Connect to generate a JSON Web Token (JWT).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Generate JWT.

About

The jwt-generate policy has the following structure:

```
- jwt-generate:
  version: version
  title: title
  description: description
  jwt: json_web_token
  jti-claim: jwt_id_claim
  iss-claim: issuer_claim
  exp-claim: validity_period
  sub-claim: subject_claim
  aud-claim: audience_claim
  jws-jwk: sign_jwk_variable_name
  jws-alg: cryptographic_algorithm
  jws-crypto: sign_crypto_object
  jwe-enc: encryption_algorithm
  jwe-jwk: encrypt_jwk_variable_name
  jwe-alg: key_encryption_algorithm
  jwe-crypto: encrypt_crypto_object
```

Properties

The following table describes the policy properties:

Table 2. Generate JWT policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
jwt	No	Runtime variable in which to place the JWT that is generated. The default value is: **`generated.jwt`**. However, if not set, the JWT that is generated is written to the Authorization Header as a Bearer token.	string
jti-claim	No	Indicates whether a JWT ID (jti) claim should be added to the JWT. If selected, the property is set to **`true`**, and a UUID is generated and set as the JTI claim value.	boolean
iss-claim	Yes	Runtime variable from which the Issuer (iss) claim string can be retrieved. This claim represents the Principal that issued the JWT. The default value is: **`iss.claim`**	string
sub-claim	No	Runtime variable from which the Subject (sub) claim string can be retrieved.	string
aud-claim	No	Runtime variable from which the Audience (aud) claim string can be retrieved. Multiple variables are set by using a comma-separated string.	string
exp-claim	Yes	The length of time (in seconds), that is added to the current date and time, in which the JWT is considered valid. The default value is **`3600`**.	integer
private-claims	No	Runtime variable from which a valid set of JSON claims can be retrieved. These claims are added to any set of claims specified previously.	string
jws-jwk	No	Runtime variable that contains the JWK that is used to sign the JWT. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to sign the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jws-alg	No	The cryptographic algorithm to use. Valid values are: • HS256 • HS384 • HS512 • RS256 • RS384 • RS512 • ES256 • ES384 • ES512 • PS256 • PS384 • PS512	string
jws-crypto	No	The cryptographic object to use to sign the JWT. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to sign the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jwe-enc	No	The encryption algorithm to use. Valid values are: • A128CBC-HS256 • A192CBC-HS384 • A256CBC-HS512	string
jwe-jwk	No	Runtime variable that contains the JWK to use to encrypt the JWT.	string

Property	Required	Description	Data type
jwe-alg	No	The key encryption algorithm to use. Valid values are: • RSA1_5 • RSA-OAEP • RSA-OAEP-256 • dir • A128KW • A192KW • A256KW	string
jwe-crypto	No	The cryptographic object to use to encrypt the claim.	string

Example

The following is an example of a jwt-generate policy:

```
- jwt-generate:
    version: 1.0.0
    title: jwt-generate
    iss-claim: iss.claim
    exp-claim: 3600
    jwt: generated.jwt
    jti-claim: true
    sub-claim: sub.claim
    aud-claim: aud.claim
    private-claims: private.claims
    jws-jwk: jws.jwk
    jws-alg: HS256
    jws-crypto: jwsCryptoObjectName
    jwe-enc: A128CBC-HS256
    jwe-jwk: jwe.jwk
    jwe-alg: A128KW
    jwe-crypto: jweCryptoObjectName
```

For more information about how to use a jwt-generate security policy, see Generate JWT in the built-in policies section.

jwt-validate

Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Validate JWT.

Note:

- If the original message was signed with a Shared Secret Key, the cryptographic object that is specified must also be a Shared Secret Key.
- If the original message was signed with a Private Key, the cryptographic object that is specified must be a Crypto Certificate (public certificate).
- The cryptographic material can be provided through a JSON Web Key (JWK).
- If a JWK header parameter is included in the header of the JWT, the parameter must match the JWK or cryptographic object that is specified in the policy, or the JWT validation will fail.
- If both a cryptographic object and a JWK are specified, the cryptographic object is used to decrypt or verify the JWT.
- The JWT validate action on the DataPower API Gateway can verify a JWT by using either a single JWK, or a JWK set.

About

The jwt-validate policy has the following structure:

```
- jwt-validate:
  version: version
  title: title
  description: description
  jwt: json_web_token
  output-claims: output_full_set_of_jwt_claims
  iss-claim: issuer_claim
  aud-claim: audience_claim
  jwe-crypto: decrypt_crypto_object
  jwe-jwk: decrypt_crypto_jwk_variable_name
  jws-crypto: verify_crypto_object
  jws-jwk: verify_crypto_jwk_variable_name
```

Properties

The following table describes the policy properties:

Table 2. Validate JWT policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
jwt	Yes	Context or runtime variable that contains the JWT to be validated. The default value is: **`request.headers.authorization`**. However, if this property is not set, the policy looks for the JWT in the **`request.headers.authorization`** location by default. Note: The format of the authorization header must be: **`"Authorization: Bearer jwt-token"`** where *jwt-token* is the encoded JWT.	string
output-claims	Yes	Runtime variable to which the full set of claims that are contained in the JWT is assigned. The default value is: **`decoded.claims`**.	string
iss-claim	No	The Perl Compatible Regular Expressions (PCRE) to use to validate the Issuer (iss) claim.	string
aud-claim	No	The PCRE to use to validate the Audience (aud) claim.	string
jwe-crypto	No	The cryptographic object (a shared key or certificate) to use to decode the claim. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to decrypt the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jwe-jwk	No	Runtime variable that contains the JWK to use to decrypt the JWT. A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to decrypt the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jws-crypto	No	The cryptographic object (a shared key or certificate) to use to verify the signature. A JWK, or a JWK set, and a Crypto Object are both valid ways of providing the cryptographic data necessary to verify the JWT. However, if both data types are specified, only the Crypto Object is used.	string
jws-jwk	No	Runtime variable that contains the JWK, or a JWK set, to use to verify the signature. A JWK, or a JWK set, and a Crypto Object are both valid ways of providing the cryptographic data necessary to verify the JWT. However, if both data types are specified, only the Crypto Object is used.	string

Example

The following is an example of a jwt-validate policy:

```
- jwt-validate:
    version: 1.0.0
    title: jwt-validate
    jwt: request.headers.authorization
    output-claims: decoded.claims
    iss-claim: "'^data.*'"
    aud-claim: "'^id.*'"
    jwe-crypto: jweCryptoObjectName
    jwe-jwk: jwe.jwk
    jws-crypto: jwsCryptoObjectName
    jws-jwk: jws.jwk
```

For more information about how to use a jwt-validate security policy, see Validate JWT in the built-in policies section.

log

Use the log policy to customize or override the default activity logging configuration for an API.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Log.

About

The log policy has the following format:

```
- log:
  version: version
  title: title
  description: description
  mode: activity_logging_actions
  log-level: type_of_content_to_log
```

Properties

The following table describes the properties of the log policy.

Table 2. log policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
mode	Yes	Specify one of the following values: • **`gather-only`**: gather all analytics data and write it to the **`log`** context variable, which populates the API event record on completion of the API execution. For more information on the fields in the **`log`** context variable, and the consequent API event record, see API event record field reference. • **`send-only`**: perform the following actions: ◦ Read the data from the **`log`** context variable. ◦ Truncate all message payloads and convert to a textual representation. ◦ Send the data to the analytics server. • **`gather-and-send`**; perform a **`gather-only`** operation, immediately followed by a **`send-only`** operation. If you use the Send-only or Gather-and-send option, data is buffered and sent to the analytics server in batches according to the time interval configured for the Analytics Endpoint on the DataPower API Gateway. For more information, see Configuring an analytics endpoint in the DataPower knowledge center. Note: If you are offloading to a third party analytics server, you can redact any aspect of the event data. If you are using API Connect analytics, you can redact only request and response payloads.	string
log-level	No	The type of content to log. Specify one of the following values: • **`none`**: Indicates no logging. • **`activity`**; Logs the invocation only, which is only the resource URI. • **`header`**: Logs activity and header. • **`payload`**:Logs activity, header, and payload. • **`default`**; Use the log level setting defined in the API definition; for more information, see activity-log. This is the default value. • **`$(value)`**: An inline parameter in the format **`$(value)`** to retrieve a value from the API context.	string

Example

```
- log:
  version: 2.0.0
  title: Gather activity log data for processing
  mode: gather-only
```

map

Use the map policy to transform your assembly flow and specify relationships between variables.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.5.0.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Map.

About

For information about the use and structure of the map policy, see The Map policy structure. For more information about API properties that affect the map policy, see API properties.

The map policy has the following format:

```
- map
   version: version
   title: title
   description: description

   inputs:
      - input_1:
         variable: context_1
         $ref: '#/definitions/definition_1'
      - input_2
         variable: context_2
```

```
        type: type_2
        content: content_type

  outputs:
     - output_3
        variable: context_3
        type: type_3

  actions:
     - set: output_3.output_property_3
       from: input_1.input_property_1

     - set: output3.output_property_3
       from:
        - input1.input_property_1
        - input2.input_property_2
       value: 'script_A'
       default: 'default_A'

     - create: output3.output_property_3
       from: input1.input_property_1
       foreach: input1.input_property_1
       actions:
         - further_actions
  options:
        .
        .
        .
   advanced_XML_and_general_configuration_options
        .
        .
        .
```

Properties

Table 2.

Property	Required	Description	Data type	Belongs to
version	Yes	The policy version number	string	N/A
title	No	A title for the policy.	String	N/A
description	No	A policy description.	String	N/A
inputs	No	An array listing the inputs of the map policy.	Object	N/A
outputs	Yes	An array listing the outputs of the map policy.	Object	N/A
variable	Yes	A reference to the context variable that is the location of the input or output variable..	String	inputs or outputs
$ref	Yes[1]	A reference to the definition of the type of the variable.	String	inputs or outputs
type	Yes[1]	The type of the variable.	String	inputs or outputs
content	No	The content type of the variable: `application/xml` or `application/json`. If None is selected, or the field is not included, then the type is treated as JSON.	String	inputs or outputs
actions	Yes	Lists actions to be performed by the map policy.	Object	N/A
set	Yes[2]	Specifies by name the output variable that is to be set to a value by the action.	String	actions
create	Yes[2]	Specifies by name the output variable that is to have a value appended to it by the action.	String	actions
from	No	Specifies by name any input variables used by the action.	String	actions
value	No	Contains a script that maps and transforms input variables into output variables.	String	actions
default	No	Contains a static value, or an inline variable reference, to be applied to the output when no input value is provided. For information on inline variable references, see Inline references.	String	actions
foreach	No	Specifies by name an array for which further actions should be performed for each element.	String	actions
includeEmptyXMLElements	No	If set to **true**, empty XML elements are included in the output of the map policy. Set to **false** if you do not want empty XML elements to be included in the output of the map policy. The default value is **true**.	Boolean	options
namespaceInheritance	No	If set to **true**, XML namespaces are inherited from the parent element. Set to **false** if you want the map policy to use explicit namespaces. The default value is **true**.	Boolean	options
inlineNamespaces	No	If set to **true**, XML namespaces will be inserted into the document where they are first used. Set to **false** if you want namespaces to all be defined on the root element. The default value is **true**.	Boolean	options
API Gateway only mapResolveXMLInputDataType	No	If set to **true**, XML elements whose schema is configured as type boolean or numeric will be converted to that data type. Set to **false** if you want all XML element values to be returned as a string.	Boolean	options
API Gateway only mapParseXMLOutput	No	If set to **true**, the map policy will write XML output to **message.body** as a parsed XML document. By default, the XML will be output as an XML string. XML output to any other variable will always be written as an XML string. The default value is **false**.	Boolean	options

Property	Required	Description	Data type	Belongs to
API Gateway only mapXMLEmptyElement	No	This property controls how the map policy handles the output of an empty XML element. Specify one of the following values: • **`string`** (the default option): An empty XML element is handled as an empty string. • **`null`**: An empty XML element is handled as a null value. • **`none`**: The data is ignored. • API Gateway only **`string-badgerfish`**: The value for an empty XML element is considered to be an empty string. The empty string value will be placed into a JSON badgerfish value property. • API Gateway only **`null-badgerfish`**: The value for an empty XML element is considered to be null. The null value will be placed into a JSON badgerfish value property. A mapping of this element to a JSON output property does not occur unless the **`mapNullValue`** property is set to **`true`**.	String	options
API Gateway only mapArrayFirstElementValue	No	If set to **`true`**, then if an array is encountered in the traversal of the input, only the first element is used. Set to **`false`** if you want the map policy to use all array elements. The default value is **`false`**.	Boolean	options
API Gateway only mapResolveApicVariables	No	If set to **`true`**, API Connect variable references found in the map properties are resolved. Set to **`false`** if you want the map policy to ignore API Connect variable references in the map policies. The default value is **`false`**.	Boolean	options
API Gateway only mapNullValue	No	If set to **`true`**, an input property value with a null value is mapped to the output document. Set to **`false`** if you want the map policy to ignore null input values. The default value is **`false`**.	Boolean	options
API Gateway only mapOptimizeSchemaDefinition	No	If set to **`true`**, complex schema types evaluation handles circular type references in an optimized manner. Set to **`false`** to evaluate these schema types in a standard manner. The default value is **`false`**.	Boolean	options
API Gateway only mapEmulateV4DefaultRequiredProps	No	If set to **`true`**, default values are generated in the output for required properties that are either not mapped, or for which there is no input data present, in the following specific cases: • An array consists of objects that contain one or more required properties. • An object which is optional has one or more child properties that are required. By default, these required properties are not present in the output. If you set this property to **`true`**, these required properties will be present in the output. If the output schema defines a **`default`** property for the output property then the specified default value is used, otherwise a default value is assigned dependent on the data type, as follows: • String: empty string ("") • Number: 0 • Boolean: false • Object: empty object • Array: empty array Example 1 The input data has the following array of objects: `[{"a": "value1"}, {"a": "value2", "b": "value3"}]` The output schema defines the output object as having two properties, **`a`** and **`b`**, of which **`b`** is required. The map policy defines the following mappings: • **`input.array.a`** to **`output.array.a`** • **`input.array.b`** to **`output.array.b`** If this property is set to **`true`**, and **`b`** is either not mapped or has no input data present, then **`b`** is assigned a default value of an empty string, and the output is as follows: `[{"a": "value1", "b": ""}, {"a": "value2", "b": "value3"}]` Example 2 The output schema defines the following structure: `{"a" : {"b" : {"c" : "value1", "d" : "value2"} } }` Property **`b`** is optional but property **`d`** within **`b`** is required. The map policy defines a mapping to **`output.a.b.c`**. If this property is set to **`true`**, and **`d`** is not mapped, then **`d`** is assigned a default value of an empty string, and the output is as follows: `{"a" : {"b" : {"c" : "value1", "d" : ""} } }` If this property is set to **`false`**, these required properties are **not** created in the output with their default values. The default value is **`false`**.	Boolean	options

Property	Required	Description	Data type	Belongs to
API Gateway only mapEnablePostProcessingJSON	No	If set to **true**, mapped JSON output is post processed. The post processing of JSON output will use the output schema to ensure that property values are of the same data type as that defined in the schema. It will also normalize output property values that have a Badgerfish JSON syntax due to object mapping of an XML input. Set to **false** if you want no post processing of mapped JSON output. The default value is **false**.	Boolean	options
API Gateway only mapCreateEmptyArray	No	This property controls how the map policy handles the output of an empty array. Specify one of the following values: • **all**: Output all empty arrays, including empty children arrays. • **parent**: Output only the current property's empty array value. Children map actions of this property are not attempted. • **none**: Prevent any empty output array values from being produced. The default value is **all**.	String	options
API Gateway only mapReferenceLimit	No	Set the value of this property to an integer value that specifies the maximum allowed number of iterations of a circular schema definition. The default value is 1, which means that circular schema definitions are not followed. The maximum possible value is 5. If you specify a value greater than 5, a value of 5 is assumed. If you specify a non-numeric value, a value of 1 is assumed.	String	options
messagesInputData	No	This property defines the severity level for log messages that relate to input data. Specify one of the following values: • **error** • **warn** • **info**	String	options
API Gateway only mapEmulateV4EmptyJSONObject	No	If a mapping fails because its input is not present and there is no default mapping configured, the default behavior is to not to make any change to the output mapping. Set this property to **true** to create an empty object for the parent of the target mapping, emulating the behavior of IBM® API Management Version 4.0. Example The map policy defines a mapping to **output.a.b.c**. If input data is present, the output is as follows: `{ "a": { "b": { "c": "inputvalue" } } }` If there is no input data, and the mapEmulateV4EmptyJSONObject option is set to **true**, the output is as follows: `{ "a": { "b": { } } }` Properties **a** and **b** are created but the value of **b** is an empty object. The default value is **false**.	Boolean	options

[1] There must be one of $ref or type in the description of a variable.

[2] There must be one of set or create in an actions field.

Example

```
    - map:
        version: 1.0.0
        title: Output mapping
        inputs:
          Monthly_cost:
            schema:
              type: double
            variable: loan_invoke.body.monthly_payment
            content: application/json
          Duration:
            schema:
              type: integer
            variable: request.parameters.duration
        outputs:
          Quote_Output:
            schema:
              $ref: '#/definitions/Quote_Output'
            variable: message.body
            content: application/json
        actions:
          - set: Quote_Output.monthly_repayment
            from: Monthly_cost
```

```
            value: ''
          - set: Quote_Output.total_cost
            from:
              - Duration
              - Monthly_cost
            value: '$(Duration)*$(Monthly_cost)'
        description: Maps and transforms contexts to the operation output.
        options:
            includeEmptyXMLElements: false
            namespaceInheritance: false
            inlineNamespaces: false
            API Gateway only mapResolveXMLInputDataType: true
            API Gateway only mapXMLEmptyElement: null
            API Gateway only mapArrayFirstElementValue: false
            API Gateway only mapResolveApicVariables: false
            API Gateway only mapNullValue: true
            API Gateway only mapOptimizeSchemaDefinition: true
            API Gateway only mapCreateEmptyArray: parent
            API Gateway only mapReferenceLimit: 5
            messagesInputData: warn
            mapEmulateV4EmptyJSONObject: true
```

operation-switch

Use the operation-switch construct when you want to execute alternative policy assemblies, conditional on the operation that is being called.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see operation-switch.

About

An operation can be described with a **verb/path** pair, or with an **operationId**. The **operationIds** are strings, or names, that are defined in the OpenAPI document.

The operation-switch policy has the following format:

```
- operation-switch:
  version: version
  title: title
  description: description
  case:
    - operations:
      - verb: operation_verb_1_1
        path: operation_path_1_1
      - verb: operation_verb_1_2
        path: operation_path_1_2
                    .
                    .
                    .
          further verb/path combinations
                    .
                    .
                    .
      execute:
        policy_assembly_1 ...
    - operations:
      - verb: operation_verb_2_1
        path: operation_path_2_1
      - verb: operation_verb_2_2
        path: operation_path_2_2
                    .
                    .
                    .
          further verb/path combinations
                    .
                    .
                    .
      execute:
        policy_assembly_2 ...
                  .
                  .
                  .
    - operations:
      - operationID_3_1
```

```
    - operationID_3_2
    - operationID_3_3

                    .
                    .
                    .
        further operationIDs
                    .
                    .
                    .
    execute:
      policy_assembly_3 ...
                  .
                  .
                  .
       further operations sections
                  .
                  .
                  .
```

For each **operations:** section, if the operation that is being called matches any of the **verb/path** combinations or **operationId** strings listed in that **operations:** section, then the policy assembly that is defined in the **execute:** section is executed. Therefore, each **operations:** section defines execution of a policy assembly conditional on the operation that is being called.

You can have as many **operations:** sections as you want, and each **operations:** section can have one or more **verb/path** combinations or **operationId** strings.

The **execute:** section can define any policy assembly, including further operation-switch policies.

Properties

Table 2. operation-switch policy properties

Property	Required	Description	Data type	Contained in
version	Yes	The policy version number	string	N/A
title	No	A title for the policy.	string	N/A
description	No	A policy description.	string	N/A
case	Yes	An array containing different cases, each entry contains an operations and execute field.	array (object)	N/A
operations	Yes	The operations to which a case applies.	object	case
verb	No	An operation verb. Valid values: • **GET** • **POST** • **PUT** • **DELETE** • **HEAD** • **PATCH** • **OPTIONS**	string	operations
path	No	A relative path to an individual endpoint. For example, **/account_status**.	string	operations
operationID	No	The operation is defined in OpenAPI. The policy operation refers to the OpenAPI operation.	string	operations
execute	Yes	The policy assembly that you want to execute if the operation that is being called matches any one of the verb/path combinations. For more information, see execute.	string	case

Example

Example that defines match operations with **verb/path** combinations:

```
# carry out different redaction actions depending on the operation

- operation-switch:
  version: 1.0.0
  title: clear_region_and_set_body
  case:
    - operations:
      - verb: GET
        path: /account_details
      execute:
        - redact:
            title: remove secret field
            actions:
              - action: remove
                from: all
                path: /document/user/secret
    - operations:
      - verb: GET
        path: /account_status
      execute:
        - redact:
            title: redact address
            actions:
              - action: redact
                from: response
                path: //*[@name='secondaryAddress']/*[@name='streetAddress']
```

Example that defines match operation with **operationIDs**:

```
# match on operationIDs

- operation-switch:
  title: customer_actions
  case:
    - operations:
      - getCustomerByName
      - deleteCustomer
      - addACustomer
      execute:
            .
            .
            .
```

oauth

Use the oauth policy to policy to perform OAuth processing based on defined OAuth provider settings.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see OAuth.

About

The oauth policy has the following format:

```
- oauth:
  version: version
  title: title
  description: description
  oauth-provider-settings-ref:
            .
            .
            .
    references_to_oauth_settings
            .
            .
            .
  supported-oauth-components:
    - oauth_component_1
    - oauth_component_2
            .
            .
            .
```

Note: You add an oauth policy to the OpenAPI source in a native OAuth provider. For more information, see the following topics:

- Editing the native OAuth provider configuration using the API Editor (Cloud Manager UI)
- Editing the native OAuth provider configuration using the API Editor (API Manager UI)

Properties

Table 2. oauth policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A description of the policy.	string
`oauth-provider-settings-ref: default`	Yes	The name of an existing OAuth provider that defines the required settings.	string
`oauth-provider-settings-ref: url`	No	A URL to a document that contains serialized XML or JSON properties that defines OAuth token generate settings. URL reference takes precedence over any existing literal configuration or object reference.	string
`oauth-provider-settings-ref: literal`	No	A literal string that contains serialized XML or JSON properties that defines OAuth token generate settings. Literal configuration takes precedence over any existing object reference.	string

Property	Required	Description	Data type
`supported-oauth-components:` `  -` `oauth_component_1` `  -` `oauth_component_2` `.` `.` `.`	Yes	Specify the OAuth components that are supported by this policy, as follows: - OAuthValidateRequest Validates the authorization request from the client. - OAuthGenerateAZCode Generates the authorization code for the client, which represents the resource owner's authorization that grants access to the requested resource. - OAuthVerifyAZCode Verifies the authorization code from the client. - OAuthVerifyRefreshToken Verifies the refresh token that is presented by the client. - OAuthCollectMetadata Collects metadata about a client for later user interaction - OAuthGenerateAccessToken Generates the access token to the client when the authorization code or refresh token is verified. - OAuthIntrospectToken Introspects the token to determine its state and, when active, its metadata.	string

Overriding default OAuth provider settings

You can use either the **`literal`** property or the **`url`** property to dynamically override any OAuth provider configuration settings to dynamically override any OAuth provider configuration settings defined by the **`default`** property.

For example, to override the access token expiration time with a value of 200 seconds, include the following configuration in either the literal string or the document at the specified URL:

```
<OAuthProviderSettings><APICAccessTokenTTL>200</APICAccessTokenTTL></OAuthProviderSettings>
```

For a list of all OAuth provider settings, refer to the **`OAuthProviderSettings`** management schema, defined in the xml-mgmt.xsd file located in the store: directory on the DataPower API Gateway.

If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Connect Designer.

oauth policy example

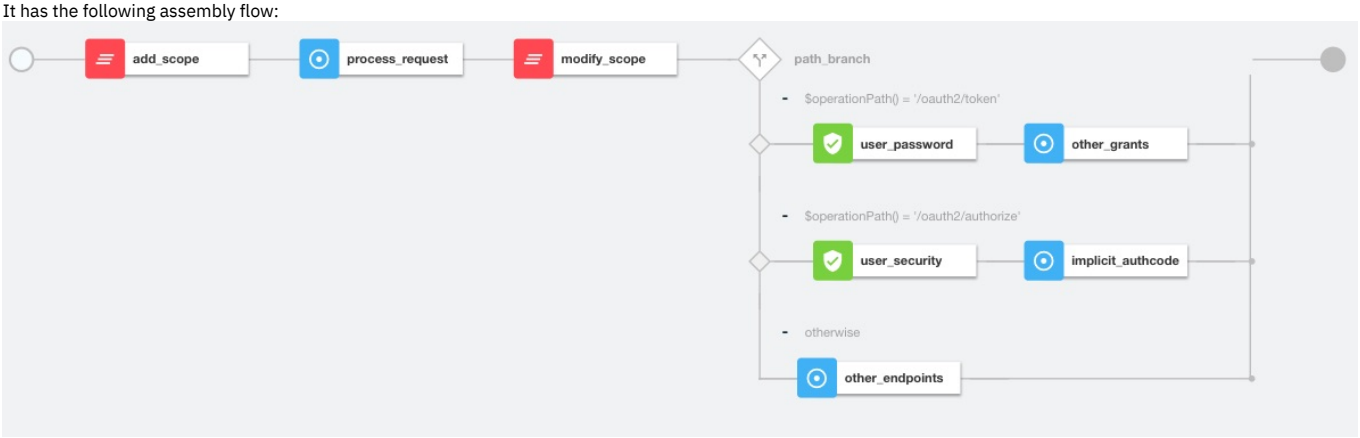
```
- oauth:
    version: 2.0.0
    title: my-oauth-policy
    oauth-provider-settings-ref:
      default: my-oauth
    supported-oauth-components:
      - OAuthGenerateAZCode
      - OAuthGenerateAccessToken
      - OAuthIntrospectToken
      - OAuthVerifyAZCode
      - OAuthVerifyRefreshToken
```

Example - using multiple OAuth policies in an OAuth provider assembly

This example demonstrates the use of multiple OAuth policies in the assembly flow for a native OAuth provider.

The example is based on the default assembly that is generated when you create a native OAuth provider, and is customized with the addition of **`gatewayscript`** policies that use OAuth context variables to manipulate the OAuth flow. For details on creating a native OAuth provider, see Configuring a native OAuth provider.

It has the following assembly flow:



The following sections describe the OpenAPI source code that underlies each of the policies in the assembly; for the complete assembly code, download multiple_oauth_policies.txt.

Sample policy to add a custom scope

The **add_scope** policy is a **gatewayscript** policy that adds a custom scope to the request.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
    version: 2.0.0
    title: add_scope
    source: |-
      // Add another custom scope to the request
      let scope = context.get("request.parameters.scope.values[0]);
      if (scope)
        context.set("oauth.processing.scope", scope + " custom");
```

Validate the initial OAuth request

The first **process_request** policy is an **oauth** policy that processes the initial request and verifies that the request is valid. The result of the processing is stored automatically in the oauth.processing context variables for use, as required, by the next OAuth policy in the assembly flow.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
    title: process_request
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect protocol steps
      that are needed for OAuth Validation by default. The inputs and
      outputs of each of the steps are driven by documented context
      variables. Add or remove the Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthValidateRequest
```

Sample policy to modify the scope

The **modify_scope** policy is a **gatewayscript** policy that modifies the scope depending on the calling application.

The underlying OpenAPI source YAML is as follows:

```
- gatewayscript:
    version: 2.0.0
    title: modify_scope
    source: |-
      let admin_id = '1f1a2aa4-db9f-4423-b2f1-e2572b12123a';

      // Check application and modify the scope
      let app = context.get("oauth.processing.client_id");
      let scope = context.get("oauth.processing.scope");
      if (app === admin_id) {
        context.set("oauth.processing.scope", scope + " admin");
      } else {
        context.set("oauth.processing.scope", scope + " customer");
      }
```

Branch conditionally according to the OAuth path

The **path_branch** policy is a **switch** policy that branches according to the different OAuth paths to process the resource owner.

The underlying OpenAPI source YAML is as follows:

```
- switch:
    version: 2.0.0
    title: path_branch
    case:
      - condition: ($operationPath() = '/oauth2/token')
        execute:
            .
            .
            .
          definition of the user_security and other_grants policies
            .
            .
            .
      - condition: ($operationPath() = '/oauth2/authorize')
        execute:
            .
            .
            .
          definition of the user_password and implicit_authcode policies
            .
            .
            .
      - otherwise:
            .
```

```
          .
          .
        definition of the other_endpoints policy
          .
          .
          .
```

Process the user name and password, and enable grant type component

The following two policies operate on the token endpoint.

- The `user_password` policy for password grant type processes the user name and password from the `x-www-form-urlencoded` body. The authentication method is derived from the User Security settings in the OAuth provider; see Configuring user security for a native OAuth provider.
- The `other_grants` policy is an `oauth` policy that enables the `OAuthGenerateAccessToken`, `OAuthVerifyAZCode`, `OAuthVerifyRefreshToken`, and `OAuthCollectMetadata` components to perform the operations for client credentials, authorization code, refresh token, and password grant types.

The underlying OpenAPI source YAML is as follows:

```
- user-security:
    title: user_password
    version: 2.0.0
    description: ''
    factor-id: default
    extract-identity-method: context-var
    user-context-var: request.parameters.username.values
    pass-context-var: request.parameters.password.values
    ei-stop-on-error: false
    user-auth-method: auth-url
    au-stop-on-error: false
    auth-url: 'http://httpbin.org/basic-auth/user/pass'
    user-az-method: authenticated
    az-stop-on-error: true
    auth-response-headers-pattern: (?)x-api*
    auth-response-header-credential: X-API-Authenticated-Credential
- oauth:
    title: other_grants
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for token path by default.
      The inputs and outputs of each of the steps are driven by
      documented context variables. Add or remove the Supported
      OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthGenerateAccessToken
      - OAuthVerifyAZCode
      - OAuthVerifyRefreshToken
      - OAuthCollectMetadata
```

Perform authorization checks, and enable grant type components

These following two policies operate on the authorize endpoint.

- The `user_security` policy configuration is derived from the User Security settings in the OAuth provider; see Configuring user security for a native OAuth provider.
- The `implicit_authcode` policy is an `oauth` policy that enables the `OAuthGenerateAZCode`, `OAuthGenerateAccessToken`, and `OAuthCollectMetadata` components to perform the operations for the implicit and authorization code grant types.

The underlying OpenAPI source YAML is as follows:

```
- user-security:
    title: user_security
    version: 2.0.0
    description: >-
      This user security policy performs EI(basic) and AU(auth
      url) check for oauth assembly. Change the security check
      method as required
    factor-id: default
    extract-identity-method: basic
    ei-stop-on-error: true
    user-auth-method: auth-url
    au-stop-on-error: true
    user-az-method: authenticated
    az-stop-on-error: true
    auth-response-headers-pattern: (?)x-api*
    auth-response-header-credential: X-API-Authenticated-Credential
    auth-url: 'http://httpbin.org/basic-auth/user/pass'
- oauth:
    title: implicit_authcode
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for az code path by
      default. The inputs and outputs of each of the steps are
      driven by documented context variables. Add or remove the
      Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
```

```
      - OAuthGenerateAZCode
      - OAuthGenerateAccessToken
      - OAuthCollectMetadata
```

Process all other endpoints

The **otherwise** condition catches all other endpoints such as the introspect and revoke endpoints. The **other_endpoints** policy in the **otherwise** condition is an **oauth** policy that enables the **OAuthIntrospectToken**, and **OAuthRevokeTokencomponents** components to perform the operations for introspect and revoke.

The underlying OpenAPI source YAML is as follows:

```
- oauth:
    title: other_endpoints
    version: 2.0.0
    description: >-
      This oauth policy performs all OAuth/OpenID Connect
      protocol steps that are needed for all other paths by
      default. The inputs and outputs of each of the steps are
      driven by documented context variables. Add or remove the
      Supported OAuth Components as required.
    oauth-provider-settings-ref:
      default: custom-form
    supported-oauth-components:
      - OAuthIntrospectToken
      - OAuthRevokeToken
```

parse

Use the parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later) 2.2.0 (DataPower API Gateway Version 10.5.0.5 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Parse.

About parse

The parse policy has the following format:

```
- parse:
  version: version
  title: title
  description: description
  use-content-type: request_header_usage_setting
  parse-settings-reference:
            .
            .
            .
    references_to_parse_settings
            .
            .
            .
  input: input_message
  output: output_message
```

Properties

Table 2. parse policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string

Property	Required	Description	Data type
description	No	A description of the policy.	string
use-content-type	No	If this setting is enabled and the parse setting is configured to detect the document type, the parse operation uses the **Content-Type** specified in the request headers. If this setting is enabled and the document type in the parse setting is configured for either JSON or XML, the parse operation uses the **Content-Type** specified in the request headers and fails if the **Content-Type** in the request headers does not match the parse setting. Enabling this setting is applicable only when the expected **Content-Type** is either JSON or XML. If this setting is not enabled, the parse operation uses either the document type specified in the parse setting, or the detected document type if the parse setting is configured to detect the document type. The default value is **false**.	boolean
parse-settings-reference: default	No	An existing valid object from which to retrieve default property values for the dynamic object.	string
document_type	No	The type of document to parse. Specify one of the following values: • **detect**: the document type is detected and the payload is parsed accordingly. This type is the default option. • **JSON**: the payload is parsed as JSON. • **XML**: the payload is parsed as XML. • **graphql**: parsing is performed in one of the following ways: ◦ As GraphQL in the body of a POST request. The GraphQL is in the following format: `{ me { name } }` ◦ As a JSON string in the body of a POST request that contains a GraphQL query. The JSON object is in the following format: `{ "query": "query MyData ($idVar: Int!) { user (id: $idVar) { name }}", "operationName": "MyData", "variables": {"idVar": 123} }` ◦ Through the URL query of a GET request. The URL is in the following format: `https://myapi/graphql?query={me{name}}` The following example includes the **variables** and **operationName** properties, with URL encoding: `https://hostname/basepath/graphql?query=query%20fetchAccounts%20($limit:%20Int)%20{accounts(limit:%20$limit)%20{name{first,last}}}&variables={"limit":100}&operationName=fetchAccounts` Query variables in a GET request can be sent as a JSON string in a query parameter called **variables**. If the query contains several named operations, an **operationName** query parameter is required to determine which operation is to be executed.	string
max_doc_size	No	Optionally, the maximum document size in bytes that the parse operation accepts. This setting provides threat protection by enforcing the maximum document size. Enter a value in the range 0 - 5368709121. A document is rejected when its size exceeds the maximum size. A value of 0 indicates an unlimited document size. When set to 0, the operation result does not return the document size. This setting is applicable to JSON, XML, or GraphQL input documents. The default value is 4194304.	integer
max_nesting_depth	No	Optionally, the maximum nesting depth of an XML, JSON, or GraphQL message that the parse operation accepts. This setting provides threat protection by enforcing limits in the message. • When XML, it is the maximum level of element depth. • When JSON, it is the maximum level of nested label-value pairs, the maximum number of nested arrays, or the maximum number of combination of label-value pairs and arrays. • When GraphQL, it is the maximum level of nested selection sets. Enter a value in the range 0 - 4096. A document is rejected when its nesting depth exceeds the maximum depth. A value of 0 indicates unlimited nesting depth. When set to 0, the operation result does not return the nesting depth. The default value is 512.	integer

Property	Required	Description	Data type
max_width	No	Optionally, the maximum width of the payload that the parse operation accepts. • When the input document is XML, this property specifies the maximum number of attributes for an element or the maximum number of child elements for an element. • When the input document is JSON, this property specifies the maximum number of properties on a JSON object or the maximum number of JSON items in a JSON array. • When the input document is GraphQL, this property specifies the maximum number of selections in a selection set. Enter a value in the range 0 - 65535. The document is rejected when its width exceeds the maximum width. A value of 0 indicates unlimited width. When set to 0, the operation result does not return the width of the document. The default value is 4096.	integer
max_name_length	No	Optionally, the maximum name length in bytes in a document that the parse operation accepts. • For XML, it is the length of the name portion of a tag. • For JSON, it is the length of the label portion of the JSON label-value pair. • For GraphQL, it is the maximum length of the identifiers, including field names and directive names. The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 8192. A document is rejected when its name length exceeds the maximum length. A value of 0 indicates unlimited name length. When set to 0, the operation result does not return the name length of a document. The default value is 256.	integer
max_value_length	No	Optionally, the maximum value length in bytes in a document that the parse operation accepts. • For XML, it is the length of an attribute or the length of a text value. • For JSON and GraphQL, it is the length of a string value. The length includes any white space that is contained between tags in XML or quotation marks in JSON. Enter a value in the range 0 - 5368709121. A document is rejected when its value length exceeds the maximum length. A value of 0 indicates unlimited value length. When set to 0, the operation result does not return the value length of a document. The default value is 8192.	integer
max_unique_names	No	Optionally, the maximum number of unique names in a JSON or XML document that the parse operation accepts. • For XML, it is the number of unique XML local names. • For JSON, it is the number of unique JSON labels. Enter a value in the range 0 - 1048575. A document is rejected when the number of unique names in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique names. When set to 0, the operation result does not return the number of unique names in a document. The default value is 1024.	integer
max_unique_prefixes	No	Optionally, the maximum number of unique XML namespace prefixes in a document that the parse operation accepts. This limit counts multiple prefixes defined for the same namespace, but does not count multiple namespaces defined in different parts of the input document under a single prefix. Enter a value in the range 0 - 262143. A document is rejected when the number of unique prefixes in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique prefixes. When set to 0, the operation result does not return the number of unique prefixes in a document. The default value is 1024.	integer
max_unique_namespaces	No	Optionally, the maximum number of unique XML namespace URIs that the parse operation accepts. This limit counts all XML namespaces, regardless of how many prefixes are used to declare them. Enter a value in the range 0 - 65535. A document is rejected when the number of unique namespaces in the document exceeds the maximum number. A value of 0 indicates an unlimited number of unique namespaces. When set to 0, the operation result does not return the number of unique namespaces in a document. The default value is 1024.	integer
max_number_length	No	Optionally, the maximum number of bytes in the value portion of a JSON label-value pair when the value is a number. The number must be a contiguous string of bytes that contain no white space. The number can include a minus sign and a positive or negative exponent. Enter a value in the range 0 - 256. A document is rejected when the number length in the document exceeds the maximum length. A value of 0 indicates unlimited number length. When set to 0, the operation result does not return the number length in a document. The default value is 128.	integer
strict-utf8-encoding	No	For JSON documents, whether to enforce strict UTF-8 encoding throughout the entire document. • When **`on`**, the entire document is checked for valid UTF-8 encoding. • When **`off`**, only the first few bytes are checked for proper encoding. The rest of the document is assumed to be in the same encoding. The default value is **`off`**.	boolean
`parse-settings-reference: literal`	No	A literal string as serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing default properties.	string
`parse-settings-reference: url`	No	A URL that represents a named context from which to retrieve the serialized XML or JSON properties that are merged into the dynamic object. These properties take preference over any existing literal or default properties.	string

Property	Required	Description	Data type
input	No	The name of a variable in the API context. The content of the **body** field of the variable is the input to the policy. The default variable name is **message**.	string
output	No	The name of a variable in the API context. The content of the body field of the variable is the output of the parse operation. The parse metrics of the parsed document can be stored in a different part of the message. The default variable name is the same as the input name, so by default the input message is overwritten by the output message.	string

parse policy example

```
- parse:
    version: 2.0.0
    title: my-parse-policy
    use-content-type: true
    parse-settings-reference:
      default: my-parse
    input: input-message
    output: output-message
```

parse-settings-reference: literal example

In XML:

```
- parse:
    version: 2.0.0
    title: parse
    parse-settings-reference:
    default: apic-default-parsesettings
    literal: <ParseSettings><DocumentType>xml</DocumentType></ParseSettings>
```

In JSON:

```
- parse:
    version: 2.0.0
    title: parse
    parse-settings-reference:
    default: apic-default-parsesettings
    literal: { \"ParseSettings\" : { \"propertyName\" : propertyValue } }
```

proxy

Apply the proxy policy to proxy another API within your operation, particularly if you need to call a large payload.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway, functionality provided by Invoke	

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Proxy.

About

Keep the following considerations in mind regarding the proxy policy.

- Only one proxy policy is permitted to be called per assembly.
- More than one proxy policy can be applied, if they are contained in mutually exclusive branches of the assembly.
- You can use the proxy policy to return multipart form data, that is, when the response is set to `Content-Type: multipart/related`. However, proxy must be the final policy in the assembly, otherwise the response that is received is manipulated causing the multipart form data to be lost.
- The proxy policy, if inside a conditional policy, must be the **final** policy to be executed in the API. If you need further processing afterward, use the invoke policy rather than the proxy policy.
- The Proxy policy does not currently attempt to rewrite a Location header that is returned from the back end.

The proxy policy has the following structure:

```
- proxy:
  version: version
  title: title
  description: description
  target-url: URL_of_target_API
  tls-profile: TLS_profile_to_be_used
  verb: method_type
  http-version: HTTP_version
  timeout: timeout_value_in_seconds
  compression: is_data_to_be_compressed
  username: username_if_authentication_required
```

```
password: password_if_authentication_required
output: location_of_the_proxy_result
cache-key: unique_identifier_of_the_document_cache_entry
cache-response: cache_behavior
cache-putpost-response: response_caching_behavior
cache-ttl: cache_time_to_live
stop-on-error: errors_that_stop_the_flow
```

Properties

The table describes the properties of the proxy policy.

Table 2. Proxy policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
target-url	Yes	The URL of the target API.	string
tls-profile	No	The TLS profile to be used.	string
verb	No	The operation method type. Valid values: • Keep • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is **Keep**.	string
http-version	No	The HTTP version. The default value is **1.1**.	string
timeout	No	The timeout value in seconds. The default value is **60**.	integer
compression	No	Specifies whether data is to be compressed by using gzip before it is uploaded. The default value is **false**.	boolean
username	No	The user name, if authentication is required.	string
password	No	The password, if authentication is required.	string
output	No	Specifies the location of the proxy result. By default, the proxy result, that is the body, headers, statusCode and statusMessage, is saved in the variable **context.message**. The assembly developers can specify an additional location to store the proxy result with the output property.	string
cache-key	No	Specifies the unique identifier of the document cache entry.	string
cache-response	No	The cache response type. Valid values: • protocol: The cache behavior is defined by the Cache-Control headers on the request and response. • no-cache: Specifies that there is no caching. However, if the document is already in the cache, the document is retrieved from the cache. • time-to-live: Specifies that the response stays in the cache for the specified time. The default value is **protocol**.	string
cache-putpost-response	No	Specifies whether to cache the response from POST and PUT requests. Caching the response from POST and PUT requests can reduce server load and reduce latency in the response to the client request. The default value is **false**.	boolean
cache-ttl	No	Specifies the amount of time in seconds that the response stays in the cache. Applies only if the property cache-response is set to **time-to-live**. Enter a value in the range 5 - 31708800. The default value is **900**.	integer
stop-on-error	No	List the errors that, if thrown during the policy execution, cause the flow to stop. If there is a **catch** flow configured for the error, it is triggered to handle the error thrown. If an error is thrown and there are no errors specified for the Stop on error property, or if the error thrown is not one of the specified errors, the policy execution is allowed to complete, and the assembly flow continues.	string

API Gateway only

ratelimit

Use the ratelimit policy to apply one or more rate, burst, or count limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.0 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.5.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Rate Limit.

About

The defined rate, burst, and count limits are applied to whatever follows in the assembly flow. For example, if a ratelimit policy is placed before an invoke policy, and the call made by the invoke policy exceeds the limits defined by the ratelimit policy, the API call itself fails.

The ratelimit policy has the following format:

```
- ratelimit:
    version: version
    title: title
    description: description
    source: rate_and_burst_limit_location
    rate-limit: rate_limits_to_apply
    burst-limit: burst_limits_to_apply
```

Properties

The following table describes the properties of the ratelimit policy.

Table 2. ratelimit policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
source	Yes	The location of all the rate limit, burst limit, and count limit definitions that are included in this policy. Specify one of the following values: • **catalog-named**: the rate or burst limits to be applied are defined in the appropriate **api-collection** object on the DataPower API Gateway, which is the object that represents your API Connect Catalog in the gateway configuration. For details of how to configure a rate, burst, or count limit in the **api-collection** object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. • **plan-named**: the limits to be applied are assembly burst limits or assembly count limits defined on the Plan to which the calling application is subscribed. For details on how to configure assembly burst limits and assembly count limits in a Plan, see Editing a draft Product. Note: The following conditions apply to a **plan-named** rate limit policy: ◦ Every Plan that contains the API that is being limited must have the named rate limit applied. ◦ A **plan-named** rate limit policy cannot be used with automatically generated Products. • **gateway-named**: the limits to be applied are defined in the **apigw** object, named **apiconnect**, on the DataPower API Gateway gateway. For details of how to configure a rate, burst, or count limit in the **apigw** object, see Configuring a rate, burst, or count limit on the DataPower API Gateway. • **plan-default**: the rate and burst limits that are applied are the default ones configured in the Plan to which the calling application is subscribed. For details on how to configure default Plan rate and burst limits, see Editing a draft Product. Note: The use of this option does not disable any automatic preflow rate limit policy that might be in place, and could result in the application of the rate limiting being repeated. For more information on preflow policies, see Customizing the preflow policies.	string
rate-limit	Yes[1]	If the **source** property is set to **catalog-named**, a list of rate limit names as defined in the DataPower API Gateway configuration, [1]You must provide at least one rate, burst, or count limit.	string
burst-limit	Yes[2]	If the **source** property is set to **catalog-named**, a list of a burst limit names as defined in the DataPower API Gateway configuration. If **source** is set to **plan-named**, a list of names of assembly burst limits defined in a Plan. [2]You must provide at least one rate, burst, or count limit.	string
count-limit	Yes[3]	If **source** property is set to **catalog-named**, a list of count limit names as defined in the DataPower API Gateway configuration. If **source** is set to **plan-named**, a list of names of assembly count limits defined in a Plan. [3]You must provide at least one rate, burst, or count limit..	string

Property	Required	Description	Data type
operation	No	For a rate limit, specify one of the following values: • **consume**: the policy reduces the balance of available requests that remain in the interval defined by the rate limit specified by the **rate-limit** property. The amount by which the remaining balance is reduced is the value that results from the weight expression defined in the specified rate limit. • **replenish**: the policy increases the balance of available requests that remain in the interval defined by the rate limit specified by the **rate-limit** property. The amount by which the remaining balance is increased is the value that results from the weight expression defined in the specified rate limit. The purpose of the replenish operation is to restore an appropriate amount of remaining balance in cases where the amount calculated by an earlier consume operation turns out to be too high. For example, for an assembly rate limit with a limit of 100, a consume operation with a weight of 60 uses 60 requests, leaving 40 requests remaining for the interval. If the weight expression in the subsequent replenish operation computes to 15, meaning that the weight expression calculated that the actual request usage was only 45, the replenish operation increases the remaining requests by 15, to a remaining balance of 55. Note that the replenish operation cannot increase the remaining requests allowed beyond the original limit defined in the assembly rate limit scheme. In this example, a replenish operation cannot replenish requests beyond 100. A replenish operation is skipped if the weight expression evaluates to a value of less than 1. The default value is **consume**. For a count limit, specify one of the following values: • **inc**: the current count is incremented by the value that results from the weight expression defined in the count limit specified by the **count-limit** property. • **dec**: the current count is decremented by the value that results from the weight expression defined in the count limit specified in the **count-limit** field. By default, the count limit is automatically decremented at the end of the API assembly by the total amount incremented during the assembly, minus any decrement operations that are defined in the assembly. You do not need to explicitly define decrement operations unless you want the decrements to occur at specific points in the assembly. However, if the auto decrement feature has been explicitly disabled in the count limit configuration, you must include a corresponding decrement operation, otherwise when the count limit is reached all future calls are blocked. For more information on configuring a count limit, see Configuring a rate, burst, or count limit on the DataPower API Gateway. The default value is **inc**. For a burst limit, the only possible value is **consume**, meaning that the limit applied is that defined in the burst limit specified by the **burst-limit** field.	string

Example

```
- ratelimit:
    version: 2.0.0
    title: Apply rate and burst limits
    source: catalog-named
    rate-limit:
      - 30perMinute
      - 2000per3Hours
    burst-limit:
      - 5per10Seconds
```

redact - DataPower API Gateway

Use the redact policy to completely remove or to redact specified fields from the request body, the response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This page describes the redact policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see redact - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Redaction - DataPower API Gateway.

About

The redact policy has the following format:

```
- redact:
    version: version
    title: title
    description: description
    redactions:
      - action: remove_or_redact
        path: JSONata_expression_for_field_to_remove_or_redact
                .
                .
                .
    root: content_source
```

Note: With the DataPower API Gateway, the input to the redact policy must be parsed data. One way to produce parsed data is to use a **parse** policy before a redact policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the properties of the redact policy.

Table 2. redact policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
root	No	Specifies the data source that contains the content to which the redact or remove action applies. If the root property is omitted, the action is applied to the entire API context. You can use any supported JSONata path expression. If you want to apply the action to either request or response data, specify a value of `message.body`. The actual content to which the action is applied then depends on the positioning of the redact policy in the overall assembly flow; for example: • If positioned at the beginning, the action is applied to the client request. • If positioned after an invoke policy, the action is applied to the response from the back end. • If positioned at the end, the action is applied to the response that is returned to the client. If, in your assembly flow, the redact policy is used after a log policy that specifies **gather-only** for the mode property, specify a root value of **log.request_body** for the logged request payload, or **log.response_body** for the logged response payload.	string
path	Yes	Specifies a JSONata path expression that identifies the fields to redact or remove from the source. For more information, see Constructing JSONata expressions to redact fields	string
action	Yes	Specifies whether you want to remove or redact the content. Supply one of the following values: • **remove**: Completely removes the specified fields. • **redact**: Redacts (obfuscates with "*"s) the fields to block out the data. The default value is **redact**. Note: If a numerical value is being redacted, the redacted value is depicted as ****** and the type is changed to **string**.	string

Example

```
# Specify separate remove and redact actions

- redact:
    version: 2.0.0
    title: remove price, redact author
    redactions:
      - action: remove
        path: xpath($, ''//price'')"
      - action: redact
        path: $.**.author"
    root: message.body
```

DataPower Gateway (v5 compatible)

redact - DataPower Gateway (v5 compatible)

Use the redact policy to completely remove or to redact specified fields from the request body, the response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.

Gateway support

Note: This page describes the redact policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see redact - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Redaction - DataPower Gateway (v5 compatible).

About

The redaction policy has the following format:

```
- redact:
  version: version
  title: title
  description: description
  actions:
    - action: remove_or_redact
      from:
        - where_the_redaction_is_to_be_applied
      path: XPath_expression_for_field_to_remove_or_redact
                        .
                        .
                        .
            further action/from/path combinations
                        .
                        .
                        .
```

You can specify as many **action**/**from**/**path** combinations as you want.

Properties

The following table describes the policy properties:

Table 2. redact policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
action	No	Specifies whether you want to remove or redact the fields. Valid values: • **remove**: Completely removes the specified fields. • **redact**: Redacts (obfuscates with "*"s) the fields to block out the data. The default value is **redact**. Note: If a numerical value is being redacted, the redacted value is depicted as ****** and the type is changed to **string**.	string
from	No	Determines where the redaction is to be applied. Valid values: • **all**: Apply the redaction to the request body, the response body, and the activity logs. • **request**: Apply the redaction to the request body only. • **response**: Apply the redaction to the response body only. • **logs**: Apply the redaction to the activity logs only. You can supply one or more values. The default value is **all**.	string
path	Yes	Specifies an XPath expression that defines the fields to remove or redact. You can construct an XPath expression that is based on JSON or XML depending on whether your API requests and responses use a JSON or an XML format. If the payload is JSON, use the DataPower XML representation of the JSON content (JSONx) to construct the expression. Note: Use a JSONx representation only to identify the XPath expressions for the fields to remove or redact. Do not change the format of any response bodies in API Manager. To learn more about constructing XPath expressions that are based on JSON or XML, see Constructing XPath expressions to redact fields.	string

Example

```
# Specify separate remove and redact actions

- redact:
  version: 1.0.0
```

```
  title: remove secret field, redact address
  actions:
    - action: remove
      from:
        - all
      path: /document/user/secret
    - action: redact
      from:
        - request
        - response
      path: //*[@name='secondaryAddress']/*[@name='streetAddress']
```

set-variable

Use the set-variable policy to set the value of a runtime variable, or to add or clear a runtime variable.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Set Variable.

About

The set-variable policy has the following format:

```
- set-variable:
  version: version
  title: title
  description: description
  actions:
    - action_type: variable_name
      value: value
      type: data_type
```

Properties

Table 2. set-variable policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
actions	Yes	Lists the actions to be performed by the set-variable policy.	array
set	Yes[1]	For setting a variable. specifies the name of the variable that you want to set. [1]One of the properties set, add, or clear is required.	string
add	Yes[2]	For adding a variable. specifies the name of the variable that you want to add. [2]One of the properties set, add, or clear is required.	string
clear	Yes[3]	For clearing a variable. specifies the name of the variable that you want to clear. [3]One of the properties set, add, or clear is required.	string
value	Yes[4]	Allocates this value to the specified variable. Can be a literal value, or another variable. [4]value is required only when **set** or **add** is specified as the action.	string
API Gateway only type	Yes	Specifies the data type of the variable. Valid values: • **any** • **string** • **number** • **boolean** For all values other than **any**, the value is validated against the specified data type. If the data type is specified as **boolean**, the value property must be set to **true** or **false**.	string

Example 1

```
# clear a variable

set-variable:
  version: 1.0.0
  title: clear_region
  actions:
    - clear: message.headers.region
```

Example 2

```
# set a variable to the value of an API Gateway context variable

set-variable:
  version: 2.0.0
  title: set content type
  actions:
    - set: message.headers.contenttype
      value: $(message.headers.content-type)
      type: string
```

Example 3

```
# add a variable

assembly:
    execute:
      - set-variable:
          version: 2.0.0
          title: set-variable
          actions:
            - value: testing add
              add: message.headers.jja
              type: string
```

switch

Use the switch component to execute one of a number of sections of the assembly based on which specified condition is fulfilled.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see switch.

About

The switch policy has the following format:

```
- switch:
  version: version
  title: switch
  description: 'Description'
  case:
    - condition: Script_1
      execute:
      Assembly_Section_1
    - condition: Script_2
      execute:
      Assembly_Section_2
    - otherwise:
      Assembly_Section_3
```

The `execute:` section can define any policy assembly, including further switch policies. For more information, see execute.

Properties

Table 2. switch policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
case	Yes	Contains the condition and execute pairs of the switch policy.	string
condition	Yes (one or more)	A script that returns `true` or `false`. API Gateway Use the JSONata expression language to define your condition. See Writing switch condition scripts - DataPower API Gateway DataPower Gateway (v5 compatible) Use GatewayScript to define your condition. See Writing switch condition scripts - DataPower Gateway (v5 compatible).	string
execute	Yes (one per condition)	The policy assembly that you want to execute if the condition returns `true`. For more information, see execute.	string

Property	Required	Description	Data type
otherwise	No	The case you want to execute if no other cases are fulfilled. It functions in the same manner as an execute property. For more information, see execute.	string

For examples, see one or other of the following topics, depending on which gateway type you are using:

- Writing switch condition scripts - DataPower API Gateway
- Writing switch condition scripts - DataPower Gateway (v5 compatible)

API Gateway only

Writing switch condition scripts - DataPower API Gateway

You write condition scripts for the switch policy in the DataPower® API Gateway by using the JSONata expression language.

The payload of the message must be parsed before you can use JSONata in a switch policy condition. Therefore, a parse policy must precede the switch policy. You can then use a JSONata condition on the parsed content that is stored in the **body** field of the output variable. The default variable is **message**. For example, if the output variable is **message**, you can use the JSONata condition **$exists(message.body.username)** on the parsed content.

The following JSONata functions are supported:

- Aggregation functions:
  - **$average(array)**
  - **$max(array)**
  - **$min(array)**
  - **$sum(array)**
- Array functions:
  - **$append(array1, array2)**
  - **$count(array)**
  - **$reverse(array)**
  - **$sort(array [, function])**
  - **$zip(array1, ...)**
- Boolean functions:
  - **$boolean(arg)**
  - **$exists(arg)**
  - **$not(arg)**
- Numeric functions:
  - **$abs(number)**
  - **$ceil(number)**
  - **$floor(number)**
  - **$formatBase(number [, radix])**
  - **$number(arg)**
  - **$power(base, exponent)**
  - **$round(number [, precision])**
  - **$sqrt(number)**
- Object functions:
  - **$keys(object)**
  - **$lookup(object, key)**
  - **$merge(array<object>)**
  - **$spread(object)**
  - **$type(value)**
    In addition to the standard values returned by **$type()**, the API gateway implementation of **$type()** can return the following values: **binary**, **empty**, **graphql**, **stream**, or **xml**.
- String functions:
  - **$contains(str, pattern)**
  - **$join(array[, separator])**
  - **$length(str)**
  - **$lowercase(str)**
  - **$match(str, pattern [, limit])**
  - **$pad(str, width [, char])**
  - **$replace(str, pattern, replacement [, limit])**
  - **$split(str, separator [, limit])**
  - **$string(arg)**
  - **$substring(str, start[, length])**
  - **$substringAfter(str, chars)**
  - **$substringBefore(str, chars)**
  - **$trim(str)**
  - **$uppercase(str)**
- You can use the following functional extensions to standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description
$header(name)	**message.headers.name**	Message header
$httpVerb()	**request.verb**	HTTP method of the request
$operationID()	**api.operation.id**	ID of the operation

Extension	Variable	Description
`$operationPath()`	`api.operation.path`	Path of the operation
`$queryParameter('name')`	• `request.parameters.name.locations` The supported keyword is `query`. • `request.parameters.name.values`	Searches for the index of `query` in `request.parameters.name.locations` and returns `request.parameters.name.values[index]`, where `[index]` is the value for `query` in locations. Parameter values are not URL decoded.
`$statusCode()`	`message.status.code`	Status code
`$storageType([arg])`	*variable*`.body` You can specify any variable in the API context. When no variable is specified, the default variable `message.body` is used.	Storage type of the message. The supported values are `binary`, `empty`, `graphql`, `json`, `stream`, or `xml`.
`$urlParameter('name')`	• `request.parameters.name.locations` The supported keywords are `path` and `query` • `request.parameters.name.values`	Searches for the index of `path` and `query` in `request.parameters.name.locations` and returns a single array that contains both `path` and `query` values from `request.parameters.name.values`. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values. `http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese` The `$urlParameter('breed')` URL returns the following array of values. `[cats, adopt, Sphynx, Siamese]` In this example, the URL includes an API path that is configured as `/petstore/{breed}/{breed}`, where `breed` is configured to be a path parameter of the API path. As a result, `cats` and `adopt` are included in the output.
`$xpath(path, xpathExpression)`	You can specify any writable variable in the API context. The `xpathExpression` must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. `$xpath($, '//price')`

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
`$gqlActiveOperation([graphql_message])`	`message.body`	Gets the active operation found in the specified GraphQL message. The `operationName` must be the same as the name of the active operation.
`$gqlAlias(graphql_field_node)`	`message.body`	Gets the alias of a GraphQL field node.
`$gqlFragments([graphql_message])`	`message.body`	Gets the fragments found in the specified GraphQL message.
`$gqlName([graphql_node])`	`message.body`	Gets the node name. For operations, the node name is the `operationName`. For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the `operationName` of `message.body` is retrieved.
`$gqlOperations([graphql_message])`	`message.body`	Gets the operations found in the specified GraphQL message.
`$gqlType([graphql_node])`	`message.body`	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

- You can use the `&` (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- / (division)
- % (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- `query`
  The entire GraphQL query including operations and fragments.

- ***operationName***
  For an anonymous operation, ***operationName*** can be empty.

- ***~fragmentSpreadName***
- **on~*typeCondition***
- ***~~fragmentDefinitionName***

You can also use the following functional extensions to standard JSONata notation. Each extension corresponds to a part of the API context.

Extension	Variable	Description
$header(name)	**message.headers.name**	Message header
$httpVerb()	**request.verb**	HTTP method of the request
$operationID()	**api.operation.id**	ID of the operation
$operationPath()	**api.operation.path**	Path of the operation
$queryParameter('*name*')	• **request.parameters.*name*.locations** • **request.parameters.*name*.values**	Returns the value of a request query parameter given the parameter name. The function searches the **request.parameters.*name*.locations** array for the index position of the value **query**, and returns **request.parameters.*name*.values[index]**, where **index** is the index position. Parameter values are not URL decoded.
$statusCode()	**message.status.code**	Status code
$storageType([arg])	***variable*.body** You can specify any variable in the API context. When no variable is specified, the default variable **message.body** is used.	Storage type of the message. The supported values are: • **binary** • **json** • **stream** • **xml**
$urlParameter('*name*')	• **request.parameters.*name*.locations** • **request.parameters.*name*.values**	Given a request parameter name, returns the parameter values for all occurrences of that parameter as a path parameter or query parameter. The function searches the **request.parameters.*name*.locations** array for the index positions of the values **path** and **query**, and returns, in a single array, the **request.parameters.*name*.values[index]** values for all identified index positions. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values: **http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese** The function call **$urlParameter('breed')** returns the following array of values: **[cats, adopt, Sphynx, Siamese]** In this example, the URL includes an API path that is configured as **/petstore/{breed}/{breed}**, where **breed** is configured to be a path parameter of the API path. As a result, **cats** and **adopt** are included in the output.
$xpath(path, xpathExpression)	You can specify any writable variable in the API context. The **xpathExpression** must be a literal string.	Allows use of XPath expressions

Simple condition statements

The following examples show conditions that use a single function.

This example uses the **$httpVerb()** extension to specify the HTTP method of the request.

```
$httpVerb()="GET"
```

This example uses the **$operationPath()** extension to specify the path of the operation.

```
$operationPath()="/base/path-2"
```

This example uses the **$operationID()** extension to specify the operation ID.

```
$operationID()="test-gatewayscript-GET"
```

This example uses the **$statusCode()** extension to specify the message status code.

```
$statusCode()=200
```

This example uses the **$header(name)** extension to specify the content type of the message header.

```
$header("Content-Type")="application/json"
```

Combining conditions with logical operators

You can use **and** and **or** operators to combine multiple functions in a single condition.

This example specifies an HTTP GET request and an API operation path equal to **test-gatewayscript-GET**.

```
$httpVerb()="GET" and $operationPath()="test-gatewayscript-GET"
```

This example specifies either a `POST` or `PUT` request.

```
$httpVerb()="POST" or $httpVerb()="PUT"
```

This example specifies an API operation ID equal to `test-gatewayscript_POST` and a message status code equal to `200`, or an API operation ID equal to `test-gatewayscript-GET` and a message status code equal to `500`.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) or ($operationID()="test-gatewayscript-GET" and $statusCode()=500)
```

This example specifies an API operation ID equal to `test-gatewayscript-POST` and a message status code equal to `200` with an API operation path equal to `/base/path-2`.

```
($operationID()="test-gatewayscript-POST" and $statusCode()=200) and $operationPath()="/base/path-2"
```

This example specifies a message header content type equal to `text/plain` and a message header length equal to `300`, or a message status code equal to `200`.

```
($header("Content-Type")="text/plain" and $header("Content-Length")=300) or $statusCode()= 200
```

Example switch policy

```
- switch:
  version: 2.0.0
  title: switch
  case:
    - condition: ($statusCode() = 200)
      execute:
        - invoke:
          title: invoke
          timeout: 60
          verb: GET
          cache-response: protocol
          cache-ttl: 900
          target-url: 'https://example.com/1'
    - condition: ($statusCode() != 200 and ($httpVerb() = 'GET' or $httpVerb() = 'PUT'))
      execute:
        - invoke:
          title: invoke
          timeout: 60
          verb: GET
          cache-response: protocol
          cache-ttl: 900
          target-url: 'https://example.com/2'
    - otherwise:
      - set-variable:
        title: set-variable
        actions:
          - set: message.body
            value: Default result
            description: 'Set the default result for the otherwise case'
```

DataPower Gateway (v5 compatible) only

Writing switch condition scripts - DataPower Gateway (v5 compatible)

You write condition scripts for the `switch` policy in the DataPower® Gateway (v5 compatible) by using GatewayScript.

To reference variables in your `switch` conditions, use the form `apim.getvariable('context.location.variable')`, where *context* is the context that you want to reference, *location* is the location of the variable within that context, and *variable* is the name of the variable.

to define a `switch` condition based on the operation called, use one of the following forms:

```
- condition: "((request.verb==='GET')&&(api.operation.path==='/path-1'))"
```

```
- condition: "((api.operation.id=='Operation_ID'))"
```

where the context variables `request.verb` and `api.operation.path` retrieve the HTTP verb and the path segment of the API and operation that you want your case to apply to, while `api.operation.id` retrieves the operation ID of your operation, if one has been specified.
For information about the context variables you can use and how to reference them in your script, see API Connect context variables.

Example switch policy

```
- switch:
  version: 1.0.0
  title: switch
  case:
    - condition: message.status.code===200
      execute:
        - invoke:
          title: invoke
          timeout: 60
          verb: GET
          cache-response: protocol
          cache-ttl: 900
          target-url: 'https://example.com/1'
```

```
    - condition: ((request.verb==='GET')&&(api.operation.path==='/path-2'))||((request.verb==='GET')&&
(api.operation.path==='/path-1'))
      execute:
        - invoke:
          title: invoke
          timeout: 60
          verb: GET
          cache-response: protocol
          cache-ttl: 900
          target-url: 'https://example.com/2'
    - otherwise:
      - set-variable:
        title: set-variable
        actions:
          - set: message.body
            value: Default result
            description: Set the default result for the otherwise case
```

throw

Use the throw construct to throw an error when it is reached during an assembly flow, usually as a result of a condition being reached.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.3.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see throw.

About

The throw policy has the following format:

```
- throw:
   title: title
   name: 'error_name'
   error-status-code: http_status_code_for_error
   error-status-reason: http_reason_phrase_for_error
   message: error_message
```

When the throw policy is encountered, the specified error and error message is returned. If a catch has been configured that the error produced by the throw policy fulfills, the catch will be triggered.

Properties

Table 2. throw policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
name	Yes	The name of the error to be thrown.	string
API Gateway only error-status-code (policy version 2.1.0 and later)	No	Specify the HTTP status code for the error. You can use the `$(variable)` format to reference the `message.status.code` API context variable.	integer
API Gateway only error-status-reason (policy version 2.1.0 and later)	No	Specify the HTTP reason phrase for the error. You can use the `$(variable)` format to reference the `message.status.reason` API context variable.	string
message	No	The message to accompany the error.	string

Example

```
      - throw:
          version: 1.0.0
          title: throw
          name: '404'
          message: Not found
```

User-defined policies

You can apply your own user-defined policies to your APIs.

The policy configuration that you add to the OpenAPI definition file must conform to the schema that you defined in the YAML file that describes the policy, and will have the following general format:

```
policy_name:
  property1: value1
  property2: value2
       .
       .
       .
```

For details on user-defined policies, and how to describe and implement them, see Authoring policies.

user-security

Use the user-security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see User Security.

About

The user-security policy has the following format:

```
- user-security:
  version: version
  title: title
  description: description
  factor-id: factor ID
  extract-identity-method: method_used_to_extract_credentials
        .
        .
        .
     properties_specific_to_the specified_identity_extraction_method
        .
        .
        .
  user-auth-method: authentication_method
        .
        .
        .
     properties_specific_to_the specified_authentication_method
        .
        .
        .
  user-az-method: authorization_method
        .
        .
        .
     properties_specific_to_the specified_authorization_method
        .
        .
        .
```

Properties

Table 2. user-security policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
factor-id	No	The identity that identifies the results of factor-authentication in the API context.	string

Property	Required	Description	Data type
extract-identity-method	Yes	Select the method that is used to extract the user credentials. The following options are available: basic Use basic authentication; no additional configuration is required. context-var The credentials are provided by API Connect context variables; specify the following properties: • user-context-var: the context variable that is used to obtain the user name. • pass-context-var: the context variable that is used to obtain the password. html-form Use forms based identity-extraction. You can use the default form or a custom form. To use the default form, specify **`ei-default-form: true`**. To use a custom form, specify **`ei-default-form: false`** and supply the following properties: • ei-custom-form: the location of the form. • ei-custom-form-tls-client-profile: the TLS client profile that is used to secure the connection to the remote server. Use the ei-form-time-limit property to specify the time allowed to submit the form. redirect Use a redirect for identity-extraction; specify the following properties: • redirect-url: the URL fragment to which to redirect the request to obtain user credentials. • redirect-time-limit: the time allowed for the transaction to complete. disabled Identity-extraction is disabled; this aspect of processing is skipped. Specify **`ei-stop-on-error: true`** to halt assembly processing in the event of identity-extraction failure. This field is required if identity extraction is not disabled.	string
user-auth-method	Yes	Select the authentication method. The following options are available: auth-url The credentials are authenticated by an external endpoint; specify the following properties: • auth-url: the URL of the authentication endpoint. • auth-tls-client-profile: the TLS client profile that is used to secure the connection to the authentication endpoint. • auth-response-headers-pattern: the pattern that is used to select which response headers to add to the API context. • auth-response-header-credential: the response header that contains the authenticated user credentials. ldap The credentials are authenticated by an LDAP user registry; use the ldap-registry property to specify the required registry. disabled Authentication is disabled; this aspect of processing is skipped. Specify **`au-stop-on-error: true`** to halt assembly processing in the event of user authentication failure. This field is required if authentication is not disabled.	string
user-az-method	Yes	Select the authorization method. The following options are available: authenticated Implicitly accept any previously authenticated users; no additional configuration is required. html-form The user provides authorization through an HTML form. You can use the default form or a custom form. To use the default form, specify **`az-default-form: true`**. To use a custom form, specify **`az-default-form: false`**. Supply the following properties: • az-table-dynamic-entries: the name of a context variable that specifies the scopes that are to be added automatically to the authorization consent form. • az-form-time-limit: the time allowed to submit the form. For a custom form, supply the following properties: • az-custom-form: the location of the form. • az-custom-form-tls-client-profile: the TLS client profile that is used to secure the connection to the remote server. disabled Authorization is disabled; this aspect of processing is skipped. Specify **`az-stop-on-error: true`** to halt assembly processing in the event of user authorization failure. This field is required if authorization is not disabled.	string

Example

```
# basic authentication with LDAP registry

- user-security:
    version: 2.0.0
    title: user-security
    factor-id: default
    extract-identity-method: basic
    ei-stop-on-error: true
    user-auth-method: ldap
    ldap-registry: corporate-ldap
    au-stop-on-error: true
    user-az-method: authenticated
    az-stop-on-error: true
```

API Gateway

validate - DataPower API Gateway

Use the validate policy to validate the payload in an assembly flow against a schema.

Gateway support

Note: This page describes the validate policy implementation in the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see validate - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.0 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.4.0 (DataPower API Gateway Version 10.0.4.0 or later) 2.5.0 (DataPower API Gateway Version 10.5.0.0 or later) 2.6.0 (DataPower API Gateway Version 10.5.0.2 or later 2.7.0 (DataPower API Gateway Version 10.5.0.3 or later

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Validate - DataPower API Gateway.

About

The validate policy has the following format:

```
- validate:
    version: version
    title: title
    description: description
    validate-against: validation_mechanism
          .
          .
          .
       properties_specific_to_the specified_validation_mechanism
          .
          .
          .
```

Apply this policy by adding an assembly extension with an execute field to your OpenAPI definition file.

Note: With the DataPower API Gateway, the input to the validate policy must be parsed data. One way to produce parsed data is to use a **parse** policy before a validate policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. validate policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string

Property	Required	Description	Data type
input	No	Identifies a variable in the API context. The content of the **body** field of the variable, which is represented by ***variable_name*.body**, is the input data to validate. By default, the variable name is **message**.	string
output	No	Specifies the name of a variable in the API context. • If the validation passes, the body field of the output variable, which is represented by ***variable_name*.body**, stores the output of the assembly validate action. • If the schema to validate is a JSON schema, the validation also adds any default values that are missing from the payload. • If the validation fails, no output is stored. • If an output variable is not specified, the results of the assembly validate action are not saved.	string
validate-against	Yes	Specifies the schema to be used for validating the payload. Valid values: • **definition**: A previously defined schema will be used to validate the payload that is returned from other invoke actions or tasks in the assembly flow. In addition, supply a **definition** property to specify the required schema. • **url**: the schema is identified by a URL location. In addition, supply the following properties: ◦ **json-schema** field: the URL of the JSON schema to be used for validating a JSON payload. ◦ **xml-validation-mode**, specify one of the following values to define how an XML payload is validated: ▪ **xsd**: use an XML schema; in addition, supply an **xml-schema** property that specifies the URL of the XML schema. ▪ **wsdl**: use a WSDL schema; in addition, supply an **xml-schema** property that specifies the URL of the WSDL schema to be used for validating a SOAP payload.. ▪ **soap-body**: validate the body of a SOAP message against the XML schema only. Note: The following limitations apply to schemas used for JSON validation, which include JSON schemas and OpenAPI documents that are used as schemas for validation. Exceeding these limits can impact compilation performance and is not supported. ▪ Maximum of 6,500 lines. Each key and each item in an array count as a line. ▪ Maximum recursion depth of 250. ▪ Maximum of 3,000 items in **enum** lists. • **wsdl**: (use with a SOAP service based API only) use the XML schema in the WSDL file associated with the API operation or the API path. • **body-param**: validate the request input against the schema definition that is specified in the **schema** property for the request parameter for this operation. • **response-param**: validate the response to be returned to the client application, against the schema definition that is specified in the **schema** property for the response parameter for this operation. • **graphql**: (use with a GraphQL proxy API only) validate the payload against the GraphQL schema that has been imported into the GraphQL proxy API. In addition, either the GraphQL query or response, depending on the input, is analyzed against the GraphQL schema to calculate the cost, and the result is placed in the API context. For more information on GraphQL proxy APIs, see Creating a GraphQL proxy API and GraphQL context variables. .	string
xslt-version	No	The XSLT processor version. The default value is XSLT10.	string
strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
profile	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
debug	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
stream	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
try-stream	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
minimum-escaping	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
stack-size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer

Property	Required	Description	Data type
wsi-validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string
wsdl-validate-body	No	The validation behavior for the **`soap:Body`**. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
wsdl-validate-headers	No	The validation behavior for the **`soap:Header`**. The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
wsdl-validate-faults	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
wsdl-wrapped-faults	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
allow-soap-enc-array	No	Whether to allow the schema to accept most uses of elements with **`xsi:type='SOAP-ENC:Array'`** consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the **`xsi:type`** attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, **`xsi:type`** is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from **`SOAP-ENC:Array`**. The opposite is the normal allowable case. By default, elements with **`xsi:type='SOAP-ENC:Array'`** are not accepted.	boolean
validate-soap-enc-array	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
wildcards-ignore-xsi-type	No	Whether **`xs:any`** elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an **`xsi:type`** attribute on it. This option ignores those **`xsi:type`** attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, **`xsi:type`** attributes are not ignored.	boolean
wsdl-strict-soap-version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
xacml-debug	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean

Property	Required	Description	Data type
allow-xop-include	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an `xop:Include` reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. • When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as `xs:base64Binary` or `xs:string`, but the message contains an `xop:Include` element instead. • When enabled, an `xop:Include` element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The `xop:Include` element itself will be validated according to the built-in schema in `store:///schemas/xop.xsd`.	boolean

You can also apply a validate policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see Validate - DataPower API Gateway in the built-in policies section.

Example 1

```
- validate:
    version: 2.0.0
    title: 'validate, response parameter schema'
    validate-against: response-param
```

Example 2

```
- validate:
    version: 2.0.0
    title: 'validate, predefined schema'
    validate-against: definition
    definition: '#/definitions/RouteOutput'
```

Example 3

```
- validate:
    version: 2.0.0
    title: 'validate, JSON and XML schema URLs'
    validate-against: url
    json-schema: 'https://my.json.schema'
    xml-validation-mode: xsd
    xml-schema: 'https://my.xml.schema'
```

DataPower Gateway (v5 compatible)

validate - DataPower Gateway (v5 compatible)

Use the validate policy to validate the payload in an assembly flow against a schema.

Gateway support

Note: This page describes the validate policy implementation in the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see validate - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Validate - DataPower Gateway (v5 compatible).

Restriction:

- The schema that represents the XML can reference only one XML namespace.
- The schema cannot reference polymorphic XML elements.
- The validation works on the `message.body` variable and not any other output/context variable. If the invoke policy contains a configured response object variable, then `message.body` is not set, and validate is not able to act.
- If you use the `multipleOf` keyword in a schema definition for the API then, due to rounding behavior, the specified value must satisfy the following conditions, otherwise the validation fails when the API is called:
  - The value must not be less than `0.00000099999999999999848869`.
  - If the value is greater than 1, the amount before the decimal point must not be greater than `99999999999999934463`.

About

The validate policy has the following format:

```
- validate:
  version: version
  title: title
  description: description
  definition: swagger_schema_definition_to_be_used
```

Apply this policy by adding an assembly extension with an execute field to your OpenAPI definition file.

Properties

The following table describes the policy properties:

Table 2. validate policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	No	A title for the policy.	string
description	No	A policy description.	string
definition	Yes	The schema to be used to validate the payload. Valid values: • `request`: Select this value to validate the request input against the schema definition that is specified in the Type field for the request parameter for this operation. For information about how to create a request parameter, see Configuring an operation. • `response`: Select this value to validate the response to be returned to the client application, against the schema definition that is specified in the Schema field for the response parameter for this operation. For information about how to create a response parameter, see Configuring an operation. • The name of a schema definition, in the following format: `#/definitions/schema_name` The schema must be defined in the `definitions:` section of your OpenAPI file.	string

You can also apply an validate policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see Validate - DataPower Gateway (v5 compatible) in the built-in policies section.

Example 1

```
validate:
  version: 1.0.0
  title: validate the response
  definition: #/definitions/RouteOutput
```

validate-usernametoken

Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0 1.1.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Validate Username Token.

About

The validate-usernametoken policy has the following format:

```
- validate-usernametoken:
    version: version
    title: title
    description: description
    auth-type: Authentication URL_or_LDAP Registry (policy version 1.0.0 only)
    auth-url: authentication_url_to_use (policy version 1.0.0 only)
    tls-profile: tls_profile_to_use (policy version 1.0.0 only)
    ldap-registry: name_of_the_ldap_user_registry (policy version 1.0.0 only)
    registry: name_of_the_ldap_or_authurl_user_registry (policy version 1.1.0 and later)
    ldap-search-attribute: name_of_the_ldap_user_password_attribute
```

Properties

The following table describes the policy properties:

Table 2. Validate Username Token policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
auth-type (policy version 1.0.0 only)	Yes	The authentication type to use to validate the UsernameToken. Valid values: • **`Authentication URL`**: Specify this value to validate the user credentials against an authentication URL. • **`LDAP registry`**: Specify this value to validate the user credentials against an LDAP user registry. The default value is: **`Authentication URL`**.	string
auth-url (policy version 1.0.0 only)	Yes	The authentication URL to use to validate the UsernameToken user credentials against. Note: This property is required only if Authentication type is set to **`Authentication URL`**.	string
tls-profile (policy version 1.0.0 only)	No	The TLS profile to use for the secure transmission of data to the authentication URL. Note: This property is available only if Authentication type is set to **`Authentication URL`**.	string
ldap-registry (policy version 1.0.0 only)	Yes	The name of the LDAP user registry to validate the UsernameToken user credentials against. Note: This property is required only if Authentication type is set to **`LDAP registry`**.	string
registry (policy version 1.1.0 and later)	Yes	The name of the LDAP or Authentication URL registry to use to validate the UsernameToken.	string
ldap-search-attribute	Yes	The name of the LDAP user password attribute. Note: This property is required only for an LDAP user registry.	string

Examples

The following example shows an LDAP user registry authentication:

```
- validate-usernametoken:
    version: 1.0.0
    title: "validate-usernametoken"
    auth-type: "LDAP Registry"
    ldap-registry: "wstest"
    ldap-search-attribute: "userPassword"
```

The following example shows an Authentication URL definition:

```
- validate-usernametoken:
    version: 1.0.0
    title: "validate-usernametoken"
    auth-type: "Authentication URL"
    auth-url: "https://www.google.com"
    tls-profile: "default-ssl-profile"
```

For more information about how to use a validate-usernametoken security policy, see Validate Username Token in the built-in policies section.

websocket-upgrade

Use the websocket-upgrade policy to process API requests and responses through a WebSocket connection.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see Websocket Upgrade.

The websocket-upgrade policy has the following format:

```
- websocket-upgrade:
  version: version
  title: title
  description: description
  target-url: URL_of_target_API
  tls-profile: TLS_profile_to_be_used
  timeout: timeout_value_in_seconds
  follow-redirects: redirect_behavior_on_301_error
  username: username_if_authentication_required
  password: password_if_authentication_required
  inject-proxy-headers: are_proxy_headers_sent_to_target_url
  decode-request-params: are_request_parameters_decoded
  encode-plus-char: are_plus_characters_encoded
  header-control:
        .
        .
        .
    headers_to_copy_to_target_url
        .
```

```
        .
        .
parameter-control:
        .
        .
        .
  parameters_to_copy_to_target_url
        .
        .
        .
```

Properties

Table 2. websocket-upgrade policy properties

Property	Required	Description	Data type
version	Yes	The policy version number.	string
title	No	The title of the policy.	string
description	No	A description of the policy.	string
target-url	Yes	Specify the URL to be invoked.	string
tls-profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
timeout	No	The time to wait before a reply back from the endpoint (in seconds). The default value is **60**.	integer
follow-redirects	No	Specifies the behavior if the back-end server returns the HTTP status code **301 Moved Permanently**. If this property is set to **true**, the **invoke** policy follows the URL redirection by making a further call to the URL specified in the **Location** header in the response. If this property is set to **false**, the **invoke** saves the **301** status code and the API call is considered to be complete. Note: The **follow-redirect** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **invoke** always follows the URL redirection; the **proxy** policy (not supported by the DataPower API Gateway) saves the **301** status code and completes the API call without following the URL redirection.	boolean
username	No	The username to use for HTTP Basic authentication.	string
password	No	The password to use for HTTP Basic authentication.	string
inject-proxy-headers	No	When set to true, the **invoke** policy injects the **X-Forwarded-For**, **X-Forwarded-To**, **X-Forwarded-Host**, and **X-Forwarded-Proto** headers to the request that is sent to the t**target-url**. The default value is **false**.	boolean
decode-request-params	No	When set to true, any request parameters that are referenced by a variable definition on the **target-url** of the invoke policy are URL-decoded. The default value is **false**.	boolean
encode-plus-char	No	When set to true, all "+" characters in the query parameter values of the **target-url** are encoded to %2F. The default value is **false**.	boolean
header-control: **type** **values**	No	Specifies the headers in **message.headers** that you want to copy to the target URL. If the **type** property is set to **blocklist**, the **values** property lists the headers that you don't want to be copied. If the **values** property is empty then all headers are copied. If the **type** property is set to **allowlist**, the **values** property lists the headers that you want to be copied. The items that are listed in the **values** property are in regular expression format. The values are not case-sensitive. The default value of the **header-control** property is **header-control:** **type: blocklist** **values: []** See header-control examples	object
parameter-control: **type** **values**	No	Specifies the parameters in the incoming request that you want to be copied to the target URL. If the **type** property is set to **blocklist**, the **values** property lists the parameters that you don't want to be copied. If the **type** property is set to **allowlist**, the **values** property lists the parameters that you want to be copied. If the **values** property is empty then no parameters are copied. The items that are listed in the **values** property are in regular expression format. The values are not case-sensitive. The default value of the **parameter-control** property is **parameter-control:** **type: allowlist** **values: []** See parameter-control examples	object
request-assembly: **execute** . . . ***policy assembly*** . . .	No	The request processing assembly. For details on configuring an assembly in the **execute** section, see execute.	object

Property	Required	Description	Data type
`response-assembly:` `  execute` `  .` `  .` `  .` `  policy assembly` `  .` `  .` `  .`	No	The response processing assembly. For details on configuring an assembly in the **execute** section, see execute.	object

Example

```
- websocket-upgrade:
  version: 2.0.0
  title: websocket-upgrade
  timeout: 60
  target-url: 'https://my.websocket.upgrade.com'
  secure-gateway: false
  follow-redirects: true
  inject-proxy-headers: true
  decode-request-params: false
  encode-plus-char: true
  response-assembly:
    execute:
      - parse:
          version: 2.0.0
          title: parse
          parse-settings-reference:
            default: apic-default-parsesettings
          description: Parse the response from the backend server
```

header-control examples

```
# copy all headers to the target URL

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: blocklist
      values: []

# copy all headers except X-Client-ID and Content-Type

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values:
        - ^X-Client-ID$
        - ^Content-Type$

# copy no headers

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values: []

# copy only the Content-Type header

- invoke:
    target-url: http://myhost/mypath
    header-control:
      type: allowlist
      values:
        - ^Content-Type$
```

parameter-control examples

```
# copy no request parameters to the target URL

- invoke:
    target-url: http://myhost/path?storeid=3
    parameter-control:
      type: allowlist
      values: []

# append the petid parameter to the target URL
# if the incoming request is http://apigw/org/sandbox/petstore/base?petid=100&display=detailed,
# the target URL at runtime will be http://myhost/mypath?storeid=3&petid=100

- invoke:
    target-url: http://myhost/path?storeid=3
    parameter-control:
      type: allowlist
      values:
        - ^petid$
```

xml-to-json

Use the xml-to-json policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see XML to JSON.

About

The xml-to-json policy has the following structure:

```
- xml-to-json:
    version: version
    title: Title
    description: Description
```

Note: If you are using the DataPower API Gateway, the input to the xml-to-json policy must be parsed data. One way to produce parsed data is to use a **parse** policy before an xml-to-json policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. Policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
API Gateway only input	No	The input message to convert. Specify the name of a variable in the API context. ***variableName*.body**, the message payload, represents the JSON input to convert. The default value of the variable is **message** and **message.body** is the default input.	string
API Gateway only output	No	The output message to store the conversion result. Specify the name of a variable in the API context. ***variableName*.body** represents the result of conversion from JSON format to XML format. When the specified input message is the default message, the default output is **message.body**. Otherwise, when the input message is the variable **my-message-variable**, for example, the default output is **my-message-variable.body**. The variable cannot be any read-only in the API context.	string
API Gateway only conversionType	No	The conversion type that determines the target format of the output. The following options are available: • badgerFish: BadgerFish convention is used to determine the target conversion format of the output. • apicv5: apicv5 convention is used to determine the target conversion format of the output.	string

Example

The following is an example of a xml-to-json policy:

```
- xml-to-json:
    version: 1.0.0
    title: XML to JSON transform
    description: Transforms XML message body to JSON format
```

xslt

Use the xslt policy to apply an XSLT transform to the payload of the API definition.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.4.0 or later)

This topic describes how to configure the policy in your OpenAPI source; for details on how to configure the policy in the assembly user interface, see XSLT.

About

The xslt policy has the following structure:

```
- xslt:
    version: version
    title: Title
    description: Description
    input: Input_True_False
    source: Transform
```

Note: If you are using the DataPower API Gateway, the input to the xslt policy must be parsed data. One way to produce parsed data is to use a **parse** policy before an xslt policy in your assembly flow, which provides explicit control of the parse action.

Properties

The following table describes the policy properties:

Table 2. xslt policy properties

Property	Required	Description	Data type
version	Yes	The policy version number	string
title	Yes	The title of the policy.	string
description	No	A description of the policy.	string
input	No	Indicates whether this XSLT input document uses the context current payload, or if there is no input. The default value is **false**.	boolean
API Gateway only serialize-output	No	If set to **true**, the output tree that is generated by the XSLT policy is serialized. The content of **message.body** is updated with the serialized binary data rather than the XML tree. The default value is **false**.	boolean
source	Yes	The XSLT transform source to execute.	string
API Gateway only xslt-version	No	The XSLT processor version. The default value is XSLT10.	string
API Gateway only strict	No	Whether to enable strict XSLT error checking. Non-strict operations attempt to recover from certain errors, such as use of undeclared variables, calling undeclared templates, and so forth. By default, strict XSLT error checking is enabled.	boolean
API Gateway only profile	No	Whether to enable stylesheet profiling. This option should not be used in production environments. By default, stylesheet profiling is disabled.	boolean
API Gateway only debug	No	Whether to run the stylesheet, XQuery script, and JSONiq script in debug mode. When a stylesheet, XQuery script, or JSONiq script is run in debug mode, it generates a custom web page instead of displaying its normal output. The web page details exactly what occurred during execution, including the values of variables and where particular pieces of the output came from. This option should not be used in production environments. By default, debug mode is disabled.	boolean
API Gateway only stream	No	Whether the stylesheet must be run in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, an error is generated and the input is not processed. By default, streaming mode is disabled.	boolean
API Gateway only try-stream	No	Whether to attempt to run the stylesheet in streaming mode. Transformation of the document begins before the input is fully parsed. Not all stylesheets can be streamed. If the stylesheet cannot be streamed, a warning is generated during compilation and the stylesheet is read in the entire input as normal at execution time. By default, attempting to run the stylesheet in streaming mode is disabled.	boolean
API Gateway only minimum-escaping	No	Whether to escape output produced from the stylesheet during processing. Minimal escaping is particularly useful when handling non-English character sets. By default, minimum escaping is disabled.	boolean
API Gateway only stack-size	No	The maximum number of bytes that the stack is allowed to use while executing a stylesheet or other compiled content. This setting is used to block infinite recursion. The minimum value is 10 kilobytes, or 10,240 bytes. The maximum value is 100 megabytes, or 104,857,600 bytes. The default value is 1 megabyte, or 1,048,576 bytes.	integer
API Gateway only wsi-validation	No	The validation behavior to apply to WSDL files that are checked for conformance to section 5 of WS-I Basic Profile (version 1.0, April 2004). The default setting is Warn. Ignore Disables conformance checking. Warn Logs warnings for violations. Fail Forces conformance. Fails if the file contains any violation.	string
API Gateway only wsdl-validate-body	No	The validation behavior for the **soap:Body**. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string

Property	Required	Description	Data type
API Gateway only wsdl-validate-headers	No	The validation behavior for the **`soap:Header`**. The default setting is Lax. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
API Gateway only wsdl-validate-faults	No	Specifies the validation behavior for the fault detail. The default setting is Strict. Strict Validates this part of the message against the WSDL definition. Allows only messages that contain this part and that match the WSDL definition. Lax Validates this part of the message against the WSDL definition. If the message contains this part and the WSDL definition does not define this part, allow the message. If the message contains this part and the WSDL definition defines this part, allow the message only when there is a match. Skip Disables validation of this part of the message.	string
API Gateway only wsdl-wrapped-faults	No	Whether to require compatibility with RPC-style wrappers. By default, RPC-style wrappers are not required.	boolean
API Gateway only allow-soap-enc-array	No	Whether to allow the schema to accept most uses of elements with **`xsi:type='SOAP-ENC:Array'`** consistent with SOAP 1.1 Section 5, even when these attributes violate the XML Schema specification. Normally, the **`xsi:type`** attribute must name a type equal to or derived from the actual type of the element. For schemas compiled with this option, **`xsi:type`** is accepted specifically for the SOAP 1.1 Encoding 'Array' complex type if the element type is derived from **`SOAP-ENC:Array`**. The opposite is the normal allowable case. By default, elements with **`xsi:type='SOAP-ENC:Array'`** are not accepted.	boolean
API Gateway only validate-soap-enc-array	No	Whether to perform extra schema validation following the encoding rules in SOAP 1.1 Section 5. When enabled, members of SOAP arrays are validated, attributes such as @id and @href are allowed even if they are not allowed by the schema, and @href values are checked to ensure that they have a corresponding @id element. By default, the extra validation is not performed.	boolean
API Gateway only wildcards-ignore-xsi-type	No	Whether **`xs:any`** elements in the schema validate only child elements by name. The XML Schema specification requires that, if a wildcard matches an element but that element does not have an element declaration, the element is instead validated according to an **`xsi:type`** attribute on it. This option ignores those **`xsi:type`** attributes. It should be used for cases such as SOAP envelope validation where a further validation step will validate the contents matching the wildcard, possibly using the SOAP 1.1 encoding rules. By default, **`xsi:type`** attributes are not ignored.	boolean
API Gateway only wsdl-strict-soap-version	No	Whether to strictly follow the SOAP binding in the WSDL. When enabled, only messages bound to SOAP 1.2 appear in SOAP 1.2 envelopes and only messages bound to SOAP 1.1 appear in SOAP 1.1 envelopes. By default, strict SOAP binding is disabled.	boolean
API Gateway only xacml-debug	No	Whether to compile XACML policies with debug information. Note that the XACML debugging messages are also controlled by the log event in the XACML category. Use the debug log level to view the full XACML debugging messages. By default, XACML policies are not compiled with debug information.	boolean
API Gateway only allow-xop-include	No	Specifies whether the schema or WSDL document accepts messages where base64-encoded binary content was optimized according to the MTOM/XOP specifications. XOP binary-optimization replaces base64-encoded binary data with an **`xop:Include`** reference element that references the unencoded binary data located in an attachment. By default, MTOM/XOP optimized messages are disabled. • When disabled, such optimized messages are rejected by validation of the optimized form. Rejection occurs because the schema specifies a simple type that accepts base64-encoded data, such as **`xs:base64Binary`** or **`xs:string`**, but the message contains an **`xop:Include`** element instead. • When enabled, an **`xop:Include`** element can optionally appear in place of content for any XML Schema simple type that validates base64-encoded binary data. The **`xop:Include`** element itself will be validated according to the built-in schema in **`store:///schemas/xop.xsd`**.	boolean

You can also apply an xslt policy by using the API Designer assembly editor to add a built-in policy to the API. For more information, see XSLT in the built-in policies section.

For examples of the OpenAPI definitions of xslt policies, see XSLT policy examples in the built-in policies section.

For more examples of how to use XSLT to access and modify properties and context, see Implementation code examples and, if you are using the DataPower API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

catch

Use the catch extension to catch errors that occur during an API call.

The catch extension takes the following form:

```
catch:
   - errors:
      - Error_1
      - Error_2
   - execute:
      assembly_1
   - errors:
      - Error_3
   - execute:
      assembly_2
   - default:
      assembly_3
```

The following table shows the properties of the **catch** extension:

Table 1. The properties of the catch extension

Property	Required	Description	Type
errors	Yes	The errors for which the catch will activate. For a list of errors, see Error cases supported by assembly catches.	Array (String)
execute	Yes	The section of the assembly that will execute when the catch is activated.	Array (Object)
default	No	The section of the assembly that will execute when an error does not trigger other catches. It behaves in the same manner and has the same structure as **execute**	Array (Object)

The following is an example of a **catch** extension:

```
    catch:
      - errors:
          - ConnectionError
          - JavaScriptError
        execute:
          - activity-log:
              title: activity-log
              content: activity
              error-content: payload
      - default:
          - activity-log:
              title: activity-log
              content: activity
              error-content: payload
```

properties

Use the **properties** extension to define properties for referencing in an API.

The **properties** extension has the following structure:

```
properties:
   property_1:
      value: default_value_1
      description: description_1
      encoded: encoded_boolean_1
   property_2
      value: default_value_2
      description: description_2
      encoded: encoded_boolean_2
```

The following table lists the fields found in the **properties** extension:

Table 1. The properties extension

Property	Required	Description	Data type
property	Yes	The name of the property. It is used when referencing the property. Note that this is the field name, not the contents of the field.	Object
value	No	The default value that the property takes. It can be empty.	String
description	No	The description of the property. It can be empty.	String
encoded	No	Specifies whether to encode the value of this property.	Boolean

The following example shows a sample **properties** field:

```
  properties:
    ID:
      value: 1234
      description: An ID to be used for validating.
      encoded: false
```

catalogs

Use the **catalogs** extension to assign catalog-specific values to properties defined in the **properties** section.

The **catalogs** section has the following structure:

```
catalogs:
   catalog_name_1:
      properties:
         property_name_1: value_1
         property_name_2: value_2
   catalog_name_2:
      properties:
         property_name_1: value_3
```

The following table lists the fields found in the **catalogs** extension:

Table 1. Catalogs properties

Property	Required	Description	Data type
catalog_name	Yes	The name of the catalog. It must match a catalog in API Manager. Note that this is the field name, not the contents of the field.	Object
properties	Yes	This field contains any properties that are to be set.	Object
property_name	Yes	The field name is the property to be set and must match a property defined in the **properties** extension. It contains the value of the property for the catalog to which the field belongs. If, in the **properties** extension, it has been specified as encoded, this will be encoded when saved or staged by IBM® API Connect.	String

The following is an example of a **catalogs** extension:

```
  catalogs:
    Sandbox:
      properties:
        ID: 5678
```

API Gateway only

activity-log

If you're using the DataPower® API Gateway, you can use the **activity-log** extension to configure your logging preferences for the API activity that is stored in analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.

An API event record exists for each API execution event in the Gateway server. By default, the content type that is collected and stored in API event records is **activity** for when API execution completes successfully, and **payload** for when API execution completes with an error code. When you compose your API definition, you can change the type of content to log in these API event records. For more information about API event records, see API event record field reference.

Note that if you're using the DataPower Gateway (v5 compatible), you can configure your logging preferences by using an **activity-log** policy in your API assembly. For more information, see activity-log.

The **activity-log** extension takes the following form:

```
activity-log:
  success-content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
  enabled: is_activity_logging_enabled
```

Note: If payload logging is enabled, for the gateway to capture payloads buffering must also be enabled.

```
activity-log:
  success-content: activity_to_log_if_call_successful
  error-content: activity_to_log_if_call_unsuccessful
  enabled: is_activity_logging_enabled
buffering: true
```

The following table shows the properties of the **activity-log** extension:

Table 1. The properties of the activity-log extension

Property	Required	Description	Type
success-content	No	Defines the type of content to be logged when the operation is successful. Valid values: • **none**: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • **activity**: Logs invocation only (only the resource URI is recorded). • **header**: Logs activity and header. • **payload**: Logs activity, header, and payload (the original request, if any, and the final response). The default value is **activity**.	String
error-content	No	Indicates what content to log when an error occurs. Valid values: • **none**: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • **activity**: Logs invocation only (only the resource URI is recorded). • **header**: Logs activity and header. • **payload**: Logs activity, header, and payload (the original request, if any, and the final response). The default value is **payload**.	String
enabled	No	Indicates whether activity logging is enabled or disabled.	Boolean

Example 1

Override the default activity logging settings:

```
activity-log:
    success-content: none
    error-content: header
    enabled: true
```

Example 2

Turn off activity logging:

```
activity-log:
    enabled: false
```

Specifying a gateway type for an API definition

An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). API definitions must specify which type of gateway the API uses.

Before you begin

IBM® API Connect supports two gateway types: DataPower Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

About this task

You must specify which type of gateway each API uses. APIs can use only one type of gateway.

When you modify your API definitions to use a specific gateway type, you must ensure that each policy and policy version in the API are supported by the gateway type. DataPower Gateway (v5 compatible) and DataPower API Gateway each support policies that the other gateway type does not. In some cases, the same policy is supported by both gateway types, but with a different version number.

For example, DataPower Gateway (v5 compatible) supports version **1.0.0** of the **invoke** policy, but DataPower API Gateway requires version **2.0.0**.

For information on policies, see execute.

For information on policy versions, see the documentation for each individual policy. For example, to review the **invoke** policy, see invoke.

Procedure

1. Edit the API definition YAML file and add the gateway type. For example:
   - DataPower Gateway (v5 compatible):

     ```
     gateway: datapower-gateway
     ```

   - DataPower API Gateway

     ```
     gateway: datapower-api-gateway
     ```

   Note: If your API YAML file includes the `gateway:` property, the `enforced:` property must be set to `true`
2. Ensure that the policies, including policy versions, in your APIs are supported by the gateway type. Review the list of policies on the execute page. If necessary, review the individual policy pages to determine the supported version number.
3. Ensure that any Product that uses this API is configured to use the same gateway type. See Specifying a gateway type for your Product.

Referring to an extension in an API definition

To refer to an OpenAPI extension in your API definition YAML (or JSON) file, add an **`extensions`** key under **`x-ibm-configuration`**.

Before you begin

Add the OpenAPI extension to any Catalogs that the API is to be published to, by importing its definition file; for details, see Working with OpenAPI extensions. If the target Catalog does not contain the OpenAPI extension then attempts to publish the API to it will fail.

About this task

The following example shows an extension definition file that defines a bank branch, in YAML format:

```
extension: '1.0.0'

info:
   title: Banking services
   name: banking
   version: 1.0.0
   description: Banking extensions
   contact:
     name: IBM API Connect
     url: https://apiconnect.ibm.com/
     email: myname@ibm.com

portal-visible: true

properties:
  title: "Branch"
  type: "object"
  properties:
    Branch type:
      type: "string"
      enum:
        - "ATM"
        - "Walk in"
    location:
      type: "object"
      title: "Location"
      properties:
        city:
          type: "string"
          default: "San Francisco"
        state:
          type: "string"
          default: "CA"
        citystate:
          type: "string"
          description: "This is generated automatically from the previous two fields"
          template: "{{city}}, {{state}}"
          watch:
            city: "location.city"
            state: "location.state"
  required:
    - Branch type
```

Procedure

1. Edit the API definition YAML file and add the reference. For example:

   ```
   x-ibm-configuration:
         .
         .
         .
     extensions:
       banking: 1.0.0
   ```

2. In your API definition file, add a property whose name must begin with **x-** and references the name of the extension you created. Specify the values of the properties that were defined in the OpenAPI extension YAML file.
   The following example uses the banking extension:

   ```
         .
         .
         .
   x-banking:
     Branch type: ATM
     location:
       city: San Francisco
       state: CA
       citystate: 'San Francisco, CA'
   ```

Using $ref to reuse code fragments in your OpenAPI files

If you deploy an API to an IBM® API Connect Management server by using the developer toolkit command line, you can use the **$ref** field in your OpenAPI YAML and JSON API definition files to reference a fragment of OpenAPI code that is defined in a separate file. When API Connect processes the source API definition file, the **$ref** field is replaced with the contents of the target file.

Use the following syntax in your source YAML file:

```
$ref: path_to_file_containing_code_fragment
```

Use the following syntax in your source JSON file:

```
{
$ref: path_to_file_containing_code_fragment
```

```
}
```

For example:

```
$ref: code_fragments/my_fragment.yaml
```

```
{
  "$ref": "code_fragments/my_fragment.json"
}
```

The replacement of the `$ref` field with the target code fragment occurs when you perform any of the following actions on the API defined by the source API definition file:

- Stage or publish an API to an API Connect Management server by using the **apic publish** command. For more information, see Publishing APIs and applications.
- Validate the API definition YAML file by using the **apic validate** command. For more information, see Validating the YAML or JSON definition of an API or Product.

Important: You cannot insert a $ref field at the root level of your OpenAPI file.

Example 1

A source YAML file contains the following OpenAPI code:

```
swagger: '2.0'
info:
  version: 1.0.0
  title: Branches
  x-ibm-name: Branches
  description: Provides operations relating to BankA branch information.
basePath: /branches
paths:
  /details:
    get:
      responses:
        - $ref: code_fragments/paths.yaml#/details/get/responses
       .
       .
       .
```

The file paths.yaml contains the following OpenAPI code fragment:

```
details:
  get:
    responses:
      '200':
        description: 200 OK defined in $ref file
        schema:
          $ref: '#/definitions/branch'
    summary: Branch details
    description: Retrieve details of the current branches of BankA.
```

When API Connect processes the source YAML file, the `$ref` field is replaced with the target code fragment, yielding the following OpenAPI code:

```
swagger: '2.0'
info:
  version: 1.0.0
  title: Branches
  x-ibm-name: Branches
  description: Provides operations relating to BankA branch information.
basePath: /branches
paths:
  /details:
    get:
      responses:
        '200':
          description: 200 OK
          schema:
            $ref: '#/definitions/branch'
      summary: Branch details
      description: Retrieve details of the current branches of BankA.
       .
       .
       .
```

Example 2

Example of a reference to an external file that contains just the parameter details:

```
openapi: 3.0.0

info:
  version: 3.0.1
  title: BeamUp API
  x-ibm-name: BeamUpAPI
servers:
  - url: /
paths:
  /customers:
    get:
      parameters:
        - $ref: tests/fixtures/api/referenceFile.yaml
      responses:
        200:
          description: An array of customers
```

```
          content:
            application/json:
              schema:
                type: object
                properties:
                  customerID:
                    type: string
                  customerName:
                    type: string
.
.
.
```

The file referenceFile.yaml contains the following OpenAPI code fragment:

```
name: page
in: query
description: page of results to return
required: true
schema:
  type: integer
```

Example of a reference to an external file that contains the parameters inside a path code fragment:

```
openapi: 3.0.0

info:
  version: 3.0.1
  title: BeamUp API
  x-ibm-name: BeamUpAPI
servers:
  - url: /
paths:
  /customers:
    get:
      parameters:
        - $ref: tests/fixtures/api/referenceFileWithPath.yaml#/customers/get/parameters
      responses:
        200:
          description: An array of customers
          content:
            application/json:
              schema:
                type: object
                properties:
                  customerID:
                    type: string
                  customerName:
                    type: string
```

The file referenceFileWithPath.yaml contains the following OpenAPI code fragment:

```
customers:
  get:
    parameters:
      name: page
      in: query
      description: page of results to return
      required: true
      schema:
        type: integer
```

Creating a Product definition file

You define a Product by creating a Product definition file.

About this task

You can create a Product definition file in either of the following ways:

- Create the file in an editor of your choice.
- Create a Product definition file by using the **apic create:product** command and then modify it. You can base your Product definition file on the default Product template or on your own custom template.

This topic describes the syntax that is needed for both options and also the structure needed when the file is created in the editor. For details on what you can include in the product definition file, see Product definition schema.
You can create a Product in the CLI by running **apic create:product** and supplying additional arguments on the command line. For example, you can enter the following text in a single command:

```
apic create:product --name product_name --title product_title --filename product_file_name.yaml
--apis "filename_of_api1.yaml filename_of_api2.yaml"
```

where:

- *product_name* is the name for your new Product.
- *product_title* is the title of your new Product.
- *product_file_name.yaml* is the name of the yaml file that is created for your new Product.
- *filename_of_api1.yaml* is the file name of one of the APIs that is used within the new Product.

- *filename_of_api2.yaml* is the file name of one of the APIs that is used within the new Product.

Another option is to create a Product interactively in the command line by running **`apic create:product`** and following the prompts.
You can see further details and available options for the **`apic create:product`** command by entering the command:

```
apic create:product --help
```

You can also create a Product from a custom Handlebars template by using the following command:

```
apic create:product --template template_filename --title product_title
```

where *template_filename* is the name of the Handlebars template to use, and *product_title* is the title of your Product. A Product template file must have a .hbs file name extension. You can create a template from scratch, or start with the example (default) Product template provided in API and Product definition template examples.
A Product definition file contains the following sections:

- The specification version
- An information section
- A visibility section
- An APIs section
- A Plans section

In this topic, YAML is used, but the instructions can be adapted to use JSON. Both .yaml and .yml file extensions are supported, but the use of the .yaml file extension is recommended by yaml.org.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.

Procedure

Structure your Product definition file by completing the following steps:

1. Set the specification version by adding the following line to the beginning of the file: `product: 1.0.0`.
   This line specifies the template version, and is always **`product: 1.0.0`**.
   Note: The specification version is distinct from your Product version. The specification version refers to this YAML file, while the Product version is by your discretion.
2. Include an information section with details about the Product, as described in Completing the information section of your Product description.
3. Include a visibility section that specifies who can view and subscribe to the Product, as described in Specifying the visibility of your Product.
4. Include an APIs section that references the APIs to be included in the Product, as described in Referencing the APIs for your Product.
5. Include a Plans section that described the Plans you want include in your Product, as described in Describing Plans in your Product.

Results

You have completed a YAML representation of your Product. A complete example with full indentation can be found in An example YAML representation of a Product.

You can create multilingual API and Product documentation by using an **`x-ibm-languages`** extension directly in the OpenAPI definition. For more information, see Using x-ibm-languages to create multilingual API and Product documentation.

- **Product definition schema**
  The product definition schema defines the properties (and their data types) that you can include in a product definition file.
- **Converting a Product YAML file to use DataPower API Gateway**
  IBM API Connect now supports DataPower® API Gateway. You can optionally specify this gateway type in your Product YAML file.

          },
          "period-unit": {
            "type": "string",
            "enum": [
              "month"
            ]
          },
          "trial-period": {
            "type": "integer"
          },
          "trial-period-unit": {
            "type": "string",
            "enum": [
              "day"
            ]
          }
        }
      }
    }
}
```

Completing the information section of your Product description

Provide users with information about your Product.

About this task

The information section of a YAML representation of a Product contains the Product's name and version. It can also include contact and license details.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.
An example information section for a YAML representation of a Product can be found at the end of this topic. An example of a complete YAML representation of a Product can be found in An example YAML representation of a Product.

Procedure

To complete the information section of your Product description, complete the following steps.

1. Begin the section and provide a name, title, description, and version number; use the following syntax:

   ```
   info:
     version: Product_Version
     title: Product_Title
     name: Short_Name
     summary: Product_Description
   ```

   where:
   - *version* is the version number of the policy.
     Tip: The **version.release.modification** version numbering scheme is recommended, for example `1.0.0`.
   - *Product_Title* is the title of the Product. Any string can be used, but the title should be kept short so that it can be displayed in the API Manager user interface.
   - *Short_Name* is the short name for the policy. It must be a single word and contain only alphanumeric characters, and the - (dash) and _ (underscore) characters. The name is case-sensitive, and should be 20 characters or fewer so that it can be displayed in the API Manager user interface of IBM API Connect.
   - *Product_Description* is a short description of the policy. Any string can be used.
2. Optional: Under info, supply contact information; use the following syntax:

   ```
     contact:
       name: Contact_Name
       url: 'Contact_URL'
       email: Contact_email
   ```

   where:
   - *Contact_Name* is the name of the contact for this Product.
   - *Contact_URL* is the URL for contact your organization.
   - *Contact_email* is an email for contacting your organization.
3. Optional: Under info, add license information for your Product; use the following syntax:

   ```
     license:
       name: License_Name
       url: 'License_URL'
   ```

where:
- *License_Name* is the name of the license that applied to your Product.
- *License_URL* is the URL at which information about the license can be accessed.

4. Optional: Under info, add your terms of service; use the following syntax:

```
termsOfService: Terms
```

where *Terms* is a string that details the terms of service for using your Product.

Results

You have completed the information section of your Product's YAML representation. It should have the following form:

```
info:
  version: Product_Version
  title: Product_Title
  name: Short_Name
  description: Product_Description
  contact:
    name: Contact_Name
    url: 'Contact_URL'
    email: Contact_email
  license:
    name: License_Name
    url: 'License_URL'
  termsOfService: Service_Terms
```

where all variables are as described in previously in this topic. The indentation must be as in the example.

Specifying a gateway type for your Product

Product definitions must specify which type of gateway the Product uses.

Before you begin

IBM® API Connect supports two gateway types: DataPower® Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

About this task

You can specify the gateway type for a Product.

Products can use only one type of gateway, and the APIs in the Product must use the same type of gateway. See Specifying a gateway type for an API definition.

Procedure

1. Determine the gateway type that is configured for the APIs in your Product. The Product gateway type must match the APIs gateway type.
   To review the APIs for your Product, see Referencing the APIs for your Product.
2. Edit the Product definition file (YAML source) to add the gateway type you want to use:
   - DataPower Gateway (v5 compatible):

     ```
     gateways:
               datapower-gateway
     ```

   - DataPower API Gateway

     ```
     gateways:
               datapower-api-gateway
     ```

3. Ensure that the policies, including policy versions, in the APIs in your Product are supported by the gateway type. Review the list of policies on the execute page. If necessary, review the individual policy pages to determine the supported version number.

Related information

- DataPower API Gateway porting notes

Converting a Product YAML file to use DataPower API Gateway

IBM® API Connect now supports DataPower® API Gateway. You can optionally specify this gateway type in your Product YAML file.

Before you begin

IBM API Connect provides two gateway types, DataPower Gateway (v5 compatible) and DataPower API Gateway.

DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

About this task

Product definitions can specify only one type of gateway. The type of gateway must match the gateway type that is used by the APIs that are included in the product. If you want to take advantage of the capabilities of DataPower API Gateway, you can easily modify your existing Product definitions to specify it as the gateway type.

Procedure

1. Verify that the APIs in the product specify DataPower API Gateway as the gateway type, and that the APIs have been converted for use with the DataPower API Gateway.
2. Open the Product YAML file for editing.
   For example:

```
product: '1.0.0'        .

info:
  name: testprod
  title: testprod
  version: 1.0.0
          .
          .
          .
```

3. Add a **gateways:** setting, and specify **datapower-api-gateway**.
   For example:

```
product: '1.0.0'        .

info:
  name: testprod
  title: testprod
  version: 1.0.0
gateways:
  - datapower-api-gateway
            .
            .
            .
```

4. Save the modified YAML file.

Specifying the visibility of your Product

Detail who can view and subscribe to your Product.

About this task

The visibility section of your Product's YAML representation determines who can view and subscribe to your Product in IBM® API Connect.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.
An example visibility section of a YAML representation of a Product can be found at the end of this topic. An example of a complete YAML representation of a Product can be found in An example YAML representation of a Product.

Procedure

To complete the visibility section of your Product description, complete the following steps:

1. Title the section by adding `visibility:`
2. Under visibility, specify who can view the Product; use the following syntax:

```
  view:
     enabled: View_Toggle
     type: View_Audience
     tags:
        - View_Tag_1
        - View_Tag_2
     orgs: View_Organizations
```

   where
   - *View_Toggle* determines whether the Product is visible to anybody or not. It must be `true` or `false`. If `false`, the Product will not be visible in the Developer Portal.
   - *View_Audience* must be `public`, in which case the Product is visible to anybody who uses the Developer Portal, `authenticated`, in which case the Product is visible to anybody registered through the Developer Portal, or `custom`, in which case the Product is visible to a specified group of users.
   - The *View_Tag* variables are strings that contains any tags that you want to attach to your Product's view status. Each tag must be on a new line and preceded with a dash. If you do not want to use any tags, do not include `tags:`.

- *View_Organizations* specifies the organizations that can view the Product if *View_Audience* is set to `custom`. If *View_Audience* is not set to `custom`, do not include `orgs:`. If *View_Audience* is `custom`, specify organizations in the following manner:

  ```
      orgs:
         - Organization 1
         - Organization 2
  ```

  where the *Organization* variables are the names of the organizations that are to be allowed to view the Product.

3. Under visibility, specify who can subscribe to your Product's Plans; use the following syntax:

```
   subscribe:
      enabled: Subscribe_Toggle
      type: Subscribe_Audience
      tags:
         - Subscribe_Tag_1
         - Subscribe_Tag_2
      orgs: Subscribe_Organizations
```

where:

- *Subscribe_Toggle* must be `true` or `false`. If `false`, no developers will be able to subscribe to the Product.
- *Subscribe_Audience* must be `authenticated`, in which case the Product's Plans can be subscribed to by anybody who is registered through the Developer Portal, or `custom`, in which case the Product's Plans can be subscribed to by a specified group of users.
- The *Subscribe_Tag* variables are strings that contains any tags you want to attach to your Product. Each tag must be on a new line and preceded by a dash.
- *Subscribe_Organizations* specifies the organizations that can subscribe to the Product's Plans if *Subscribe_Audience* is set to `custom`. If *Subscribe_Audience* is not set to `custom`, omit it or set as `[]`. If *Subscribe_Audience* is `custom`, specify organizations in the following manner:

  ```
      orgs:
         - Organization 1
         - Organization 2
  ```

  where the *Organization* variables are the names of the organizations that are to be allowed to subscribe to the Product.
  Note: If a Product is to be available for subscription, it must already be visible. As a result, for the subscription audience to be `authenticated`, the view audience cannot be `custom`.

Results

You have completed the visibility section of your Product's YAML representation. It should have the following form:

```
visibility:
   view:
      enabled: View_Toggle
      type: View_Audience
      tags:
         - View_Tag_1
         - View_Tag_2
      orgs:
         - Organization_1
         - Organization_2

   subscribe:
      enabled: Subscribe_Toggle
      type: Subscribe_Audience
      tags:
         - Subscribe_Tag_1
         - Subscribe_Tag_2
      orgs:
         - Organization_1
         - Organization_2
```

where all variables are as described in previously in this topic. The indentation must be as in the example.

What to do next

You can also define the visibility of a Product at a Catalog or Space level. For more information, see Configuring Product visibility in a Catalog.

Related information

- Configuring Product visibility in a Catalog

Referencing the APIs for your Product

Detail the file paths for the APIs you want to include in your Product in IBM® API Connect.

About this task

Before an API can be included in a Plan, it must first be referenced in the APIs section of your Product description.

Procedure

Begin the APIs section and reference the APIs you want to include in your Product. The syntax that you use depends on which user interface you are using, as follows:

- API Designer:

```
apis:
  API_1_NameAPI_1_Version
    $ref: API_1_File_Path
  API_2_NameAPI_2_Version
    $ref: API_2_File_Path
```

- API Manager:

```
apis:
  API_1_NameAPI_1_Version
    name: 'API_1_Name:API_1_Version'
  API_2_NameAPI_2_Version
    name: 'API_2_Name:API_2_Version'
```

  where
  - the *API_n_Name* variables are the case-sensitive names of your APIs.
  - the *API_n_Version* variables are the versions of your APIs.
  - the *API_n_File_Path* variables are the file paths for the YAML files containing OpenAPI representations of your APIs.

The following example shows a complete sample APIs section:

```
apis:
  api11.0.0:
    name: 'api1:1.0.0'
  api21.0.0:
    name: 'api2:1.0.0'
  api31.0.0:
    name: 'api3:1.0.0'
```

For more information about creating OpenAPI definitions, see Creating an OpenAPI definition file.

The indentation must be as in the examples and the APIs must have been created before they can be referenced.

Results

You have referenced the APIs that are to be included in your Product. An example of a complete YAML representation of a Product can be found in An example YAML representation of a Product.

Describing Plans in your Product

Describe the Plans that you want to include in your IBM® API Connect Product and which APIs they will contain, as well as any rate limits that apply.

About this task

A Plan contains APIs and their operations. It can be used to implement rate limits and tailor visibility.

Note: If you are using more than one DataPower® server in a Gateway service, then to properly calculate API calls for rate limits the servers must be able to communicate with each other by using SLM peer groups, using either SLM unicast peering or SLM multicast peering depending on your network configuration. For more information, see SLM peering.
In addition, you can apply burst limits to your Plans, to prevent usage spikes that might damage infrastructure. Multiple burst limits can be set per Plan, at second and minute time intervals. You can also set multiple rate limits per Plan and per operation, at second, minute, hour, day, and week time intervals.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.
Two example Plan descriptions from a YAML representation of a Product can be found at the end of this topic. An example of a complete YAML representation of a Product can be found in An example YAML representation of a Product.

Procedure

To describe your Plans, include APIs in them, and set rate limits for Plans or specific operations, complete the following instructions:

1. Begin the Plans section with `plans:`
2. Under Plans, begin the description of your first Plan by providing a name, description, and specifying whether approval is required for subscription requests; use the following syntax:

```
plans:
  Plan_Name:
    title: Plan_Title
    description: Plan_Description
    approval: Approval_Toggle
```

   where:
   - *Plan_Name* is the name of the Plan. It must be a single word and contain only alphanumeric characters, and the - (dash) and _ (underscore) characters. The name is case-sensitive, and should be 20 characters or fewer so that it can be displayed in the API Manager user interface.
   - *Plan_Title* is the title of the Plan.Any string can be used, but the title should be kept short so that it can be displayed in the API Manager user interface.
   - *Plan_Description* is a description of your Plan.
   - *Approval_Toggle* must be either `true`, in which case approval is needed for subscription requests, or `false`, in which case subscriptions are automatically approved.
3. Optional: Under your Plan, add multiple burst and rate limits that will be shared across all the operations in the Plan; use the following syntax:
   Note: For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.

```
    rate-limits:
      Name:
        value: Rate_Limit
        hard-limit: Limit_Toggle
      Name:
        value: Rate_Limit
        hard-limit: Limit_Toggle
    burst-limits:
      Name:
        value: Burst_Limit
```

where:

- *Name* is the name of the limit.
- *Rate_Limit* is your rate limit. It can be for multiples of seconds, minutes, hours, days, or weeks, written as `second`, `minute`, `hour`, `day`, and `week` respectively; do not use the plural forms of the words. Use the syntax: **`1/2minute`**. If the time unit is singular, then it is not necessary to precede it with a number, for example, **`1/minute`**. If you do not want to apply a rate limit, set *Rate_Limit* as `unlimited`.
- *Limit_Toggle* must be `true` or `false`. If *true*, API calls by a developer will fail if the rate limit is exceeded. This step is not necessary if you have set *Rate_Limit* to `unlimited`.
- *Burst_Limit* is your burst limit. It can be for multiples of seconds or minutes, written as `second` or `minute`; do not use the plural forms of the words.

Note:

- Applying a rate limit at the Plan level creates a default rate limit that is shared across all the operations within the Plan. If you need to set specific rate limits for specific operations, you must set these within the operations themselves and these settings will override the setting at the Plan level.
- The test application that is used by the API Manager test tool is not subject to rate limits if you have enabled automatic subscriptions for the Catalog in which you are testing. For more information, see Working with Catalogs

4. Under your Plan, specify which APIs are to be included.
   Reference APIs by name and version, as follows:

```
    apis:
      API_1_nameAPI_1_version: {}
      API_2_nameAPI_2_version: {}
```

where

- the *API_n_name* variables are the case-sensitive names of your APIs.
- the *API_n_version* variables are the versions of your APIs.

5. Optional: If you want to include only a subset of an API's operations, list the operations that are to be included; use the following syntax:

```
    apis:
      API_nameAPI_version:
        operations:
          - operation: Operation_1_Verb
            path: Operation_1_Path
          - operation: Operation_2_Verb
            path: Operation_2_Path
```

where

- the *Operation_n_Path* variables are the paths of operations that is to be included. The dash is required for each new operation.
- the *Operation_n_Verb* variables are the appropriate REST verbs for the operations.

6. Optional: If you want to specify multiple rate limits for a single operation; use the following syntax:

```
    apis:
      API_nameAPI_version:
        operations:
          - operation: Operation_Verb
            path: Operation_Path
            rate-limits:
              Name:
                value: Operation_Limit
                hard-limit: Operation_Limit_Toggle
              Name:
                value: Operation_Limit
                hard-limit: Operation_Limit_Toggle
```

where:

- *Operation_Limit* is the rate limit that you want to apply to your operation. It can be for multiples of seconds, minutes, hours, days, or weeks, written as `second`, `minute`, `hour`, `day`, and `week` respectively; do not use the plural forms of the words. Use the syntax: **`1/2minute`**. If the time unit is singular, then it is not necessary to precede it with a number, for example, **`1/minute`**. If you do not want to apply a rate limit, set *Operation_Limit* as `unlimited`.
- *Operation_Limit_Toggle* must be `true` or `false`. If *true*, API calls by a developer will fail if the rate limit is exceeded. This step is not necessary if you have set *Operation_Limit* to `unlimited`.

Results

You have described the Plans that are to be included in your Product. Your Plans section should be similar to the following scenarios.

If you have enforced a rate limit for your Plan and not specified individual operations, your Plans section should have the following form:

```
plans:
  Plan_Name:
    title: Plan_Title
    description: Plan_Description
    approval: Approval_Toggle
    rate-limits:
      Name:
        value: Limit
        hard-limit: Limit_Toggle
    apis:
      API_1_nameAPI_1_version: {}
      API_2_nameAPI_2_version: {}
```

If you have enforced rate limits at the Plan level and want to include two operations, with a separate rate limit one for one of the operations, your Plans section should have the following form:

```
plans:
  Plan_Name:
    title: Plan_Title
    description: Plan_Description
    approval: Approval_Toggle
    rate-limits:
      Name:
        value: API_Limit
        hard-limit: API_Limit_Toggle
    burst-limits:
      Name:
        value: Burst_limit
    apis:
      API_nameAPI_version:
        operations:
          - operation: Operation_1_Verb
            path: Operation_1_Path
            rate-limits:
              Name:
                value: Operation_Limit
                hard-limit: Operation_Limit_Toggle
          - operation: Operation_2_Verb
            path: Operation_2_Path
```

In both examples, variables are as in the previous steps and the indentation must be as presented.

The following example shows a complete sample Plans section:

```
plans:
  default:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/hour
        hard-limit: false
  my-plan:
    title: my_plan
    rate-limits:
      Default rate-limit:
        value: 50/1hour
        hard-limit: false
    burst-limits:
      Default burst-limit:
        value: 10/1second
    apis:
      api21.0.0:
        operations:
          - operation: get
            path: /path2
      api31.0.0:
        operations:
          - operation: get
            path: /path3
            rate-limits:
              limit3:
                value: 10/1second
                hard-limit: true
              limit4:
                value: 100/1hour
                hard-limit: true
      api11.0.0: {}
```

An example YAML representation of a Product

Products in IBM® API Connect can be represented by using a YAML file in a similar fashion to how APIs can be represented by using OpenAPI.

The following code describes a complete Product, with sample values.

```
info:
  version: 1.0.0
  title: SampleProduct
  name: SampleProduct
  summary: This is a sample product
gateways:
  - datapower-gateway
product: 1.0.0
visibility:
  view:
    enabled: true
    type: public
    tags: []
    orgs: []
  subscribe:
    enabled: true
    type: authenticated
    tags: []
```

```
    orgs: []
plans:
  default:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/hour
        hard-limit: false
  newplan:
    title: NewPlan
    rate-limits:
      low:
        value: 10/1hour
        hard-limit: true
    burst-limits:
      Default burst-limit:
        value: 10/1second
apis:
  SampleAPI:
    name: 'Sampleapi:1.0.0'
```

Using `x-ibm-languages` to create multilingual API and Product documentation

Create multilingual API and Product documentation by using the **`x-ibm-languages`** extension in your API and Product OpenAPI definitions.

You can scale your API initiatives to a global user base, while still maintaining a single API definition. Translations are custom configured and controlled, so that they can be tailored to both your API documentation and the API consumer. The extensions that are used in API Connect are added directly to the YAML file as **`x-ibm-languages`**. These extensions are then used in the Developer Portal, so that whatever language the Developer Portal is set to reflects the translations that are contained in the API and Product definitions.

Add the following syntax into your API or Product YAML file at every point that you require some translated text:

```
x-ibm-languages:
  item_name:
    language_code: translated_text
```

Where:

- ***`item_name`*** is the name of the item that you want to translate, for example **`summary`**.
- ***`language_code`*** is the ISO code for the translation language. Supported languages with their ISO codes are listed in the following table.

  Table 1. List of supported language codes

Language	Code
Chinese, simplified	`zh_cn`
Chinese, traditional	`zh_tw`
Dutch	`nl`
English	`en`
French	`fr`
German	`de`
Italian	`it`
Japanese	`ja`
Korean	`ko`
Portuguese	`pt`
Spanish	`es`
Turkish	`tr`

- *translated_text* is the translated text that you want to be displayed for the item in the Developer Portal.

Note: The Developer Portal automatically assumes that the default language in the OpenAPI definition is English. If you want to use a different default language in the definition, you must provide both the English translation and the default language text in the **`x-ibm-languages`** extension sections of your OpenAPI definition, by using the following syntax:

```
x-ibm-languages:
  item_name:
    en: English_translated_text
    default_language_code: default_language_text
```

For an example of how to write an OpenAPI YAML file with French as the default language, see the Examples section.

Examples

An example API OpenAPI YAML file that contains the **`fr`** language extension, where English is the default language:

```
swagger: '2.0'
info:
  x-ibm-name: climbing-weather-api
  title: Climbing Weather API
  version: 1.0.0
  x-ibm-languages:
    title:
      fr: Climat d'escalade
```

```
schemes:
  - https
host: $(catalog.host)
consumes:
  - application/json
produces:
  - application/json
x-ibm-configuration:
  assembly:
    execute:
      - invoke:
          target-url: 'https://1234.com'
          title: 3 day forecast invocation
          cache-response: time-to-live
          cache-key: $(request.search)
  gateway: datapower-gateway
  enforced: true
  testable: true
  phase: realized
  cors:
    enabled: true
paths:
  /weather/forecast:
    get:
      summary: Retrieve the 3 day forecast for a location
      description: Retrieve the locations weather forecast descriptions for the next 3 days and nights

    rate-limits:
      100 Calls per day:
        hard-limit: true
        value: 100/1day
```

An example of how to write an OpenAPI YAML file with French as the default language:

```
info:
  name: climat-d-escalade
  title: Climat d'escalade
  version: 1.0.0
  x-ibm-languages:
    title:
      en: Climbing Weather API
      fr: Climat d'escalade
...
```

This example shows that both the default French language, and the English language translation, must be provided in the **x-ibm-languages** section.

- Expand your API Initiatives Globally with Multi-Lingual Support of API and Product Definitions

Using x-example to control the examples displayed in the Developer Portal

OpenAPI does not support the use of **example** attributes on parameters, only on request and response objects and their properties. To allow API Developers to be able to control the examples displayed in the portal you can use **x-example** in OpenAPI parameters.

In this example, you cannot use **example** as it isn't supported by the OpenAPI spec, but you can use **x-example**.

```
- name: city
  in: query
  required: false
  type: string
  maxLength: 50
  description: "Location"
  x-example: "New York"
```

An **example** attribute is honored where set and allowed by the spec. If **example** is not found, **default** is honored where set and allowed by the spec. An **x-example** attribute is honored if found, if not found, a random example to match the schema is generated.

If the spec allows you to use **example**, then you should use it in preference to **x-example**.

Using x-embedded-doc to add additional documentation to products and APIs

You can use **x-embedded-doc** to add additional documentation to a product or an API as part of their definition.

You can embed additional documentation pages within the api swagger documentation. These pages can be base64 encoded strings or markdown strings of the html content of the page. These pages show up in the navigation, on the left side, underneath the overview for that product or API, and above the paths. Any styling that is needed to theme the documentation can be included in the Developer Portal custom theme.

Embedded docs for products and APIs

You can embed documentation for individual products and APIs by specifying an additional **x-embedded-doc** object in the product or API specification.

Field name	Type	Description
name	**string**	Required, the name of the embedded document
title	**string**	Required, The display title of the embedded document
format	**string**	Optional, the format of the embedded document content value. Values are **b64html** or **md**. Default value is **md**.
content	**string**	The base64 encoded html of page, or, the markdown string.

Field name	Type	Description
docs	`x-embedded-doc`	Additional embedded documentation. If no content is specified for parent, then the first child is the content that is shown.

Hierarchies of documents are supported by nesting of further doc properties. Language support is available by using `x-ibm-languages`.

Examples

Documentation can be added to an api, by using the following JSON:

```
"x-embedded-doc": [
    {
      "name": "introduction",
      "title": "Introduction",
      "format": "md",
      "content": "# some markdown"
    },
    {
      "name": "concepts",
      "title": "Concepts",
      "format": "md",
      "content": "## more markdown"
    },
    {
        "name": "authentication",
        "title": "Authentication",
        "docs": [{
              "name": "auth_clientid_secret",
              "title": "Obtaining a Client ID and Secret",
              "format": "md",
              "content": "### even more markdown"
              },
              {
                "name": "auth_bearertoken",
                "title": "Getting and Using a Bearer Token",
                "format": "md",
                "content": "#### yet more markdown"
              }
              ]
    }
  ]
```

Alternatively, by using base 64 encoded HTML:

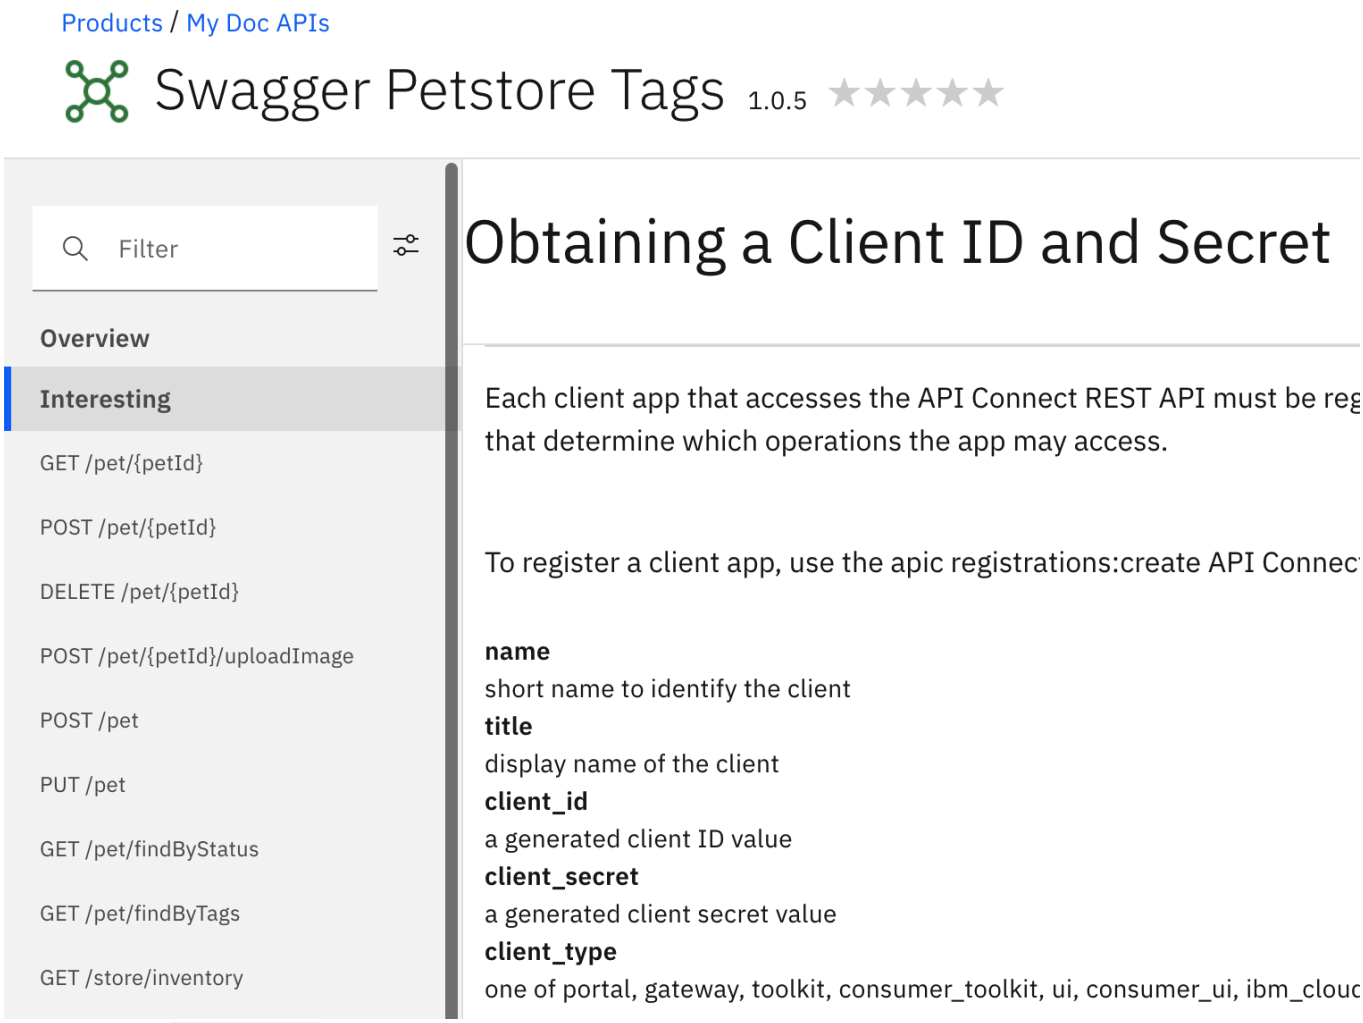
```
"x-embedded-doc": [
  {
    "name": "introduction",
    "title": "Introduction",
    "format": "b64html",
    "content": "PGFydGljbGUgaWQ9ImludHJvZHVjdGlvbiIgY2xhc3M...."
  },
  {
    "name": "concepts",
    "title": "Concepts",
    "format": "b64html",
    "content": "PGFydGljbGUgaWQ9ImNvbmNlcHRzIiBjbGFzcz0icGFnZSI....."
  },
  {
    "name": "authentication",
    "title": "Authentication",
    "docs": [{
            "name": "auth_clientid_secret",
            "title": "Obtaining a Client ID and Secret",
            "format": "b64html",
            "content": "PGFydGljbGUgaWQ9ImNsaWVudC1pZC1zZWNyZX....."
            },
            {
            "name": "auth_bearertoken",
            "title": "Getting and Using a Bearer Token",
            "format": "b64html",
            "content": "ICA8YXJ0aWNsZSBpZD0iYmVhcmVyLXRva2VuIiBjbGFz....."
            }
          ]
      }
]
```

Or mixed formats:

```
"x-embedded-doc": [
  {
    "name": "introduction",
    "title": "Introduction",
    "format": "b64html",
    "content": "PGFydGljbGUgaWQ9ImludHJvZHVjdGlvbiIgY2xhc3M...."
  },
  {
    "name": "concepts",
    "title": "Concepts",
    "format": "md",
    "content": "# some markdown"
  }
]
```

An example of some `x-embedded-doc` code and how it might render:

```
x-embedded-doc:
  - name: document
    title: Interesting
    format: b64html
    content: >-
      PGFydGljbGUgaWQ9ImNsaWVudC1pZ...=
securityDefinitions:
  api_key:
    type: apiKey
    in: header
    name: api_key
```



An example of some **x-embedded-doc** code into a product and how it might render:

```
x-embedded-doc:
  - name: introduction
    title: Introduction
    format: md
    content: >-
      ## Overview

      ### Philosophy

      Markdown is intended to be as easy-to-read and easy-to-write as is
      feasible. Compellingly facilitate 2.0 intellectual capital for
      cross-platform networks.  Dynamically incubate ethical sources after
      optimal technologies. Phosfluorescently restore global users via excellent
      niche markets. Credibly impact cross-media mindshare through strategic
      best practices. Synergistically impact interdependent web services rather
      than unique interfaces.

      Continually reintermediate enabled sources rather than professional
      architectures. Appropriately embrace viral collaboration and idea-sharing
      whereas granular solutions. Energistically revolutionize competitive
      paradigms vis-a-vis highly efficient models. Objectively incentivize
      enterprise customer service through compelling e-markets. Competently grow
      multifunctional e-markets with business methods of empowerment.

      Dramatically iterate equity invested scenarios and focused data.
      Compellingly reconceptualize next-generation deliverables rather than
      out-of-the-box architectures. Competently foster cross-unit web services
      with interactive innovation. Quickly revolutionize enabled communities and
      alternative content. Globally administrate resource maximizing
      deliverables whereas corporate e-business.
```

```
    Progressively develop maintainable leadership.
- name: concepts
  title: Concepts

- Using x-ibm-languages to create multilingual API and Product documentation

Using `x-pathalias` to give consistent URLs for products and APIs

You can use **`x-pathalias`** to assign a URL to a product or an API.

The information section of a YAML representation of a Product or API can include **`x-pathalias`**. This option can be useful as it allows the same URL to be used on different revisions of your product. It also allows the use of a vanity URL, which might better represent the branding of your site, or make the URL easier to pronounce.

In this example, you set an API called `Climbing weather API` in product `Weather watch` to have a URL of ***`portalURL`*`/product/weather/api/climbing`**.

Product information:

```
info:
  version: 1.0.0
  title: Weather watch
  name: weather-watch
  x-pathalias: weather
```

API information:

```
info:
  title: Climbing Weather API
  x-ibm-name: climbing-weather-api
  version: 1.0.0
  x-pathalias: climbing
```

Validating the YAML or JSON definition of an API or Product

You can validate a YAML or JSON definition by using the IBM® API Connect developer toolkit.

Before you begin

To complete the steps that are described in this topic, you must have installed the developer toolkit. For more information, see Installing the toolkit.

Procedure

To perform validation by using the developer toolkit, enter the following command:

```
apic validate filename
```

where *filename* is the file name of the API definition file you want to validate.

- Include `--product-only` to validate only a Product definition and not any APIs that it references.
- Include `--no-extensions` to validate only the default OpenAPI section of the API and none of its extensions.

Note:

- If the OpenAPI file that defines your API uses a **`$ref`** field to reference a fragment of OpenAPI code that is defined in a separate file, the **`$ref`** field is replaced with the contents of the target file before the draft API is created with the **apic drafts:validate** command. For more information, see Using $ref to reuse code fragments in your OpenAPI files.
- Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "**`(?`**" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col: 0)
400
```

Related concepts

- Creating an OpenAPI definition file

Creating and using API and Product definitions templates

You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form **`{{variable-name}}`** that are substituted with values when you create the API or Product definition.

Before you begin

To complete the steps that are described in this topic, you must have installed the IBM® API Connect developer toolkit. For more information, see Installing the toolkit.

Procedure

1. Create a Product or API definition template, either from scratch, or by copying one of the examples provided in API and Product definition template examples. The template file must have **`.hbs`** filename extension, and may contain any of the handlebars variables described in Template variables for API and Product definitions.
2. To create a Product or API definition from a template, enter the following command:

   ```
   apic create:[api | product] --template template_file --title [api_title | product_title] options
   ```

   where *template_file* is the template **`.hbs`** file to use, *api_title* or *product_title* is the title of the API or Product to create, and *options* is any additional command-line options. The path to the template file can be either an absolute path or relative to the location where the command is executed.

   When the Product or API definition is created, the value of each command-line option is substituted for the corresponding handlebars template variable. For example, the value of the required **`--title`** option is substituted for the **`info.title`** field in the template file. The command creates an API or Product definition YAML file with the name specified in the **`--name`** option. If you don't supply the **`--name`** option, the command derives the name of the API or Product YAML file from the specified title by down-casing the title and replacing spaces with dashes.

Working with global policies

Use global policies to configure policy assemblies that are called just before, or just after, each of your API assemblies is called, or when an error is thrown. You can upload global policies into each of the gateway services in your Catalogs, and then designate, for each gateway service, which global policy should be called before an API assembly is called, after an API assembly is called, or if an error occurs when an API assembly is called. The designated global policies are applied to all the APIs that are deployed to the associated gateway service.

Prerequisites

IBM® DataPower® Gateway version that is compatible with your deployed version of API Connect.

To complete the global policy management tasks described in this topic, you must be the owner of the provider organization, or be assigned a role that has the **Settings:Manage** permission. The pre-supplied Administrator role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Overview

For each of the gateway services in a Catalog, a global policy that you want to be called before any API assembly is called is designated as a *pre-request* global policy, and a global policy that you want to be called after any API assembly is called is designated as a *post-response* global policy. A policy that you want to be called when an error is thrown is called an *error* global policy. You can upload as many global policies into a gateway service as you want, but you can designate at most one global policy to be pre-request, one to be post-response, and one to be an error, at any one time.
Note:

- If you are using the DataPower Gateway (v5 compatible), there can be only one **proxy** policy across the combined pre-request, API, and post-response assembly flows.
- Catalog properties, as described in Creating and configuring Catalogs, and API properties, as described in Setting API properties, are not supported with global policies. Therefore, if you use such properties in a global policy, they are **not** replaced with the values specified in the API or Catalog property definitions.

A global policy is defined in a .yaml file. The global policy file specifies the policy assembly that you want to call. A global policy file has the following structure:

```
global-policy: 1.0.0

info:
    name: global_policy_name
    title: global_policy_title
    version: global_policy_version

gateways:
    - gateway_type

assembly:
    - policy_assembly_to_be_called
```

where *gateway_type* has the value **datapower-gateway** if you want to use the global policy in a DataPower Gateway (v5 compatible), and **datapower-api-gateway** if you want to use the global policy in a DataPower API Gateway. For more information on the different types of gateway, see API Connect gateway types.
Note: Error global policies are supported only by the DataPower API Gateway, not by the DataPower Gateway (v5 compatible).
The **assembly** section for a pre-request or post-response global policy can contain any valid API assembly flow. For more information, see the execute section.

The **assembly** section for an error global policy can only contain a **catch** extension in the assembly, an **execute** section is not valid. For details of the **catch** extension, see catch.

Sample global policy .yaml file for pre-request or post-reponse

```
global-policy: 1.0.0

info:
  name: sample-policy
  title: Sample Policy
  version: 2.0.0

gateways:
  - datapower-api-gateway

assembly:
  execute:
    - invoke:
        target-url: http://myhost.com/mytarget
        version: 2.0.0

  catch:
    - errors:
        - ConnectionError
      execute:
        - activity-log:
            title: activity-log
            content: activity
            error-content: payload
            version: 2.0.0
```

Sample error global policy .yaml file

Note: An error global policy .yaml file can contain only a **catch** extension in the assembly.

```
global-policy: 1.0.0

info:
  name: sample-error-policy
  title: Sample Error Policy
  version: 2.0.0

gateways:
  - datapower-api-gateway

assembly:
  catch:
    - errors:
        - ConnectionError
      execute:
        - activity-log:
            title: activity-log
            content: activity
            error-content: payload
            version: 2.0.0
    - errors:
        - SOAPError
      execute:
        - xslt:
            version: 2.0.0
            title: xslt
            input: true
            source: |-
              <!-- Placeholder -->
              <xsl:stylesheet xmlns:xsl=''/>
```

Logging in to the Management server

You work with global policies by using developer toolkit CLI commands. Before you can run the commands, you must log in to your management server from the CLI. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

Uploading a global policy to a gateway service

You upload a global policy to a gateway service by using the **apic global-policies:create** command. The command has the following format:

```
apic global-policies:create --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name --
server mgmt_endpoint_url --scope scope [--space space] filename
```

where:

- *catalog_name* is the value of the **name** property of the Catalog that contains the gateway service to which you want to upload the global policy.
- *gateway_service_name* is the value of the **name** property of the gateway service.
- *organization_name* is the value of the **name** property of the provider organization that contains the Catalog.
- *mgmt_endpoint_url* is the platform API endpoint URL.
- *scope* has one of the following values:
  - **catalog** if the Catalog does not have Spaces enabled.
  - **space** if the Catalog has Spaces enabled. If you specify **space** for the **--scope** parameter you must also supply the **--space** parameter to specify the Space that contains the gateway service.
- (optional) *space* is the name of the Space that contains the gateway service. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command.
- *filename* is the name of the global policy .yaml file that you want to upload.

Note: If Spaces are enabled in a Catalog, a global policy that you apply to one Space is applied to **all** Spaces; you cannot apply a global policy to an individual Space in the Catalog. Any subsequent updates are also applied to all Spaces.
You can confirm the global policies that have been uploaded by using the **apic global-policies:list-all** command, which has the following format:

```
apic global-policies:list-all --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name
--server mgmt_endpoint_url --scope scope [--space space]
```

For reference details of the **apic global-policies** commands, see apic global-policies.

Designating the pre-request global policy

To designate the pre-request policy for a gateway service, complete the following steps:

1. Write the URL of the required global policy to a .yaml file by using the following command:

   ```
   apic global-policies:get --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name
   --server mgmt_endpoint_url --scope scope [--space space] policy_name:policy_version --fields url
   ```

   where *policy_name*:*policy_version* specifies the name and version number of the required global policy, as defined in the global policy **.yaml** file that was originally uploaded to the gateway service.
   The value of the URL is written to a file called GlobalPolicy.yaml.

2. Edit the GlobalPolicy.yaml file and replace the string **url** with **global_policy_url**. The resulting file has the following format:

   ```
   global_policy_url: >-
     https://server_host_name/api/catalogs/catalog_id/configured-gateway-services/gateway_service_id/global-
   policies/policy_id
   ```

3. Designate the global policy to be the pre-request policy by using the following command:

   ```
   apic global-policy-prehooks:create --catalog catalog_name --configured-gateway-service gateway_service_name --org
   organization_name --server mgmt_endpoint_url --scope scope [--space space] GlobalPolicy.yaml
   ```

To replace the designated pre-request global policy with another policy, repeat steps 1 and 2, then use the **apic global-policy-prehooks:update** command. To remove the pre-request global policy designation, use the **apic global-policy-prehooks:delete** command.
For reference details of the **apic global-policy-prehooks** commands, see apic global-policy-prehooks.

By default, whenever an API is called, a series of policies, called the *preflow* policies, are invoked prior to the policy assembly configured in the API definition. However, by using a pre-request global policy you can, if required, fully customize the behavior of these policies, controlling if and when they are invoked, and with what customization. For more information, see Customizing the preflow policies.

Designating the post-response global policy

To designate the post-response policy for a gateway service, complete the following steps:

1. Write the URL of the required global policy to a .yaml file by using the following command:

   ```
   apic global-policies:get --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name
   --server mgmt_endpoint_url --scope scope [--space space] policy_name:policy_version --fields url
   ```

   where *policy_name*:*policy_version* specifies the name and version number of the required global policy, as defined in the global policy **.yaml** file that was originally uploaded to the gateway service.
   The value of the URL is written to a file called GlobalPolicy.yaml.

2. Edit the GlobalPolicy.yaml file and replace the string **url** with **global_policy_url**. The resulting file has the following format:

   ```
   global_policy_url: >-
     https://server_host_name/api/catalogs/catalog_id/configured-gateway-services/gateway_service_id/global-
   policies/policy_id
   ```

3. Designate the global policy to be the post-response policy by using the following command:

   ```
   apic global-policy-posthooks:create --catalog catalog_name --configured-gateway-service gateway_service_name --org
   organization_name --server mgmt_endpoint_url --scope scope [--space space] GlobalPolicy.yaml
   ```

To replace the designated post-response global policy with another policy, repeat steps 1 and 2, then use the **apic global-policy-posthooks:update** command. To remove the post-response global policy designation, use the **apic global-policy-posthooks:delete** command.
For reference details of the **apic global-policy-posthooks** commands, see apic global-policy-posthooks.

Designating the error global policy

The error global policy is applied to an error caught in the API pre-request, assembly, and post-response stages unless any of those stages has its own error rule defined for the same error, in which case that error rule takes priority.

To designate the error global policy for a gateway service, complete the following steps:

1. Write the URL of the required global policy to a .yaml file by using the following command:

   ```
   apic global-policies:get --catalog catalog_name --configured-gateway-service gateway_service_name --org organization_name
   --server mgmt_endpoint_url --scope scope [--space space] policy_name:policy_version --fields url
   ```

   where *policy_name*:*policy_version* specifies the name and version number of the required global policy, as defined in the global policy **.yaml** file that was originally uploaded to the gateway service.
   The value of the URL is written to a file called GlobalPolicy.yaml.

2. Edit the GlobalPolicy.yaml file and replace the string **url** with **global_policy_url**. The resulting file has the following format:

   ```
   global_policy_url: >-
     https://server_host_name/api/catalogs/catalog_id/configured-gateway-services/gateway_service_id/global-
   policies/policy_id
   ```

3. Designate the global policy to be the error policy by using the following command:

```
apic global-policy-errors:create --catalog catalog_name --configured-gateway-service gateway_service_name --org
organization_name --server mgmt_endpoint_url --scope scope [--space space] GlobalPolicy.yaml
```

To replace the designated error global policy with another policy, repeat steps 1 and 2, then use the **apic global-policy-errors:update** command. To remove the error global policy designation, use the **apic global-policy-errors:delete** command.

For reference details of the **apic global-policy-errors** commands, see apic global-policy-errors.

Customizing the preflow policies

By default, whenever an API is called, a series of policies, called the *preflow* policies, are invoked prior to the policy assembly configured in the API definition. However, by using a global policy you can, if required, fully customize the behavior of these policies, controlling if and when they are invoked, and with what customization.

Before you begin

- For details on how to configure and deploy a global policy, see Working with global policies.
- For details on how to avoid authentication errors on a WSDL action, see the IBM troubleshooting tech note, API Connect HTTP GET ?WSDL retrieval returns "401 - Unauthorized Invalid client id or secret".

Default preflow policies

The following preflow policies are invoked by default:

- **cors**: handles cross-origin resource sharing (CORS) requests for the API; invoked if CORS is enabled in the API definition settings.
- **wsdl**: handles WSDL requests.
- **html-page**: for a GraphQL API, if the GraphQL editor option is enabled, returns the GraphQL HTML page.
- **client-identification**: examines the API key credentials that are carried in the API request and matches the API Plan through which the target API is made available to the client.
- **ratelimit**: enforces the rate limit scheme that is configured for the matching API Plan. When the rate limit is reached, the request is rejected.
- **security**: performs the authentication and authorization checks that are required by the target API and operation. if the security requirement is not fulfilled, the request is rejected.

Configuring a global policy to customize the preflow policies

To customize the preflow policies, complete the following steps:

1. add the following property to the **info:** section of your global policy .yaml file:

   ```
   mode: mode_type
   ```

   Where ***mode_type*** is one of the following options:
   - **after-builtin** - this means that your preflow policies are applied after the default preflow policies.
   - **before-builtin** - this means that your preflow policies are applied before the default preflow policies.
   - **full-custom** - this means that you must explicitly add the preflow policies to the assembly of your global policy. You can, however, remove, reposition, or replace any of the preflow policies as required.
2. Configure the policies in your global policy assembly as required.
   An **after-builtin** global policy example:

   ```
   global-policy: 1.0.0
   info:
     name: foo-example
     title: foo-example
     version: 2.0.0
     mode: after-builtin
   gateways:
     - datapower-api-gateway
   assembly:
     execute:
       - set-variable:
           version: 2.0.0
           title: set-variable
           actions:
             - set: message.headers.X-Flexible-Preflow
               value: 'Hello reboot global policy 1 on catalog 1 this policy will be executed after all default builtins'
               type: string
   ```

   A **before-builtin** global policy example:

   ```
   global-policy: 1.0.0
   info:
     name: foo-example
     title: foo-example
     version: 2.0.0
     mode: before-builtin
   gateways:
     - datapower-api-gateway
   assembly:
     execute:
       - set-variable:
           version: 2.0.0
           title: set-variable
           actions:
             - set: message.headers.X-Flexible-Preflow
   ```

```
            value: 'Hello reboot global policy 1 on catalog 1 this policy will be executed before all default builtin
policies'
            type: string
```

A `full-custom` global policy example:

```
global-policy: 1.0.0
info:
  name: preflow-4-actions
  title: preflow-4-actions
  version: 2.0.0
  mode: full-custom
gateways:
  - datapower-api-gateway
assembly:
  execute:
    - cors:
        version: 2.0.0
        title: cors-in-preflow
    - wsdl:
        title: default-wsdl
    - html-page:
        title: html-page-in-preflow
        output: message
        version: 2.0.0
    - helloworld:
        version: 1.0.0
        title: helloworld
    - client-identification:
        version: 2.0.0
        title: ci-in-preflow
    - ratelimit:
        version: 2.0.0
        title: assembly-rt-in-preflow
        source: plan-default
    - security:
        version: 2.0.0
        title: sec-in-preflow
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - set: message.headers.X-Flexible-Preflow
            value: 'Hello reboot with 4 actions'
            type: string
```

3. Deploy your global policy as a pre-request global policy.

Reference

Reference information for developing your APIs in API Connect, including context variables, and template variables.

Note: For product-wide reference material, including command-line tool and REST APIs documentation, see Reference information for IBM® API Connect.

- **API Connect context variables**
  List of IBM API Connect context variables that you can reference when defining default parameter values in an assembly operation, or by using the `getContext()` function when defining a policy.
- **OAuth context variables**
  You can customize the OAuth security flow in a native OAuth provider by adding multiple OAuth policies to the assembly. Each OAuth policy takes input from context variables and writes output to context variables. By using these OAuth context variables you can manipulate the original request, and process the output from an OAuth policy.
- **Error cases supported by assembly catches**
  Several error cases that can be returned by the assembly are available to the catch function.
- **API and Product definition template examples**
  You can use template files when creating API and Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition. This topic provides the default Handlebar templates used by `apic` to create Products and APIs as examples you can use to copy and customize for your own use.
- **Template variables for API and Product definitions**
  You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form `{{variable-name}}` that are substituted with values when you create the API or Product definition.

Related information

- IBM API Connect overview

API Connect context variables

List of IBM® API Connect context variables that you can reference when defining default parameter values in an assembly operation, or by using the `getContext()` function when defining a policy.

The following tables are presented:

- General context variables.
- OAuth context variables - DataPower Gateway (v5 compatible).
- Application certificate context variables.
- API activity logging context variables.
- GraphQL context variables.

For more information about implementing an assembly component, see Including elements in your OpenAPI 2.0 API assembly, Including elements in your OpenAPI 2.0 API assembly, and for information about how to reference context variables in API Connect see Variable references in API Connect and Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

For more information about creating a user-defined policy, see Authoring policies.

General context variables

Note:

- For plan variables (such as **`plan.name`** or **`plan.version`**), plan information is available only when the requested operation requires identification and the client passes the authentication check.
- If you deploy your API to the DataPower® Gateway (v5 compatible) then, with the exception of client ID and client secret, the passing of form input as a parameter into an API is not supported. This restriction does not apply if you deploy your API to the DataPower API Gateway.

Table 1. API Connect context variables

Name	Description	Permission
API Gateway only **`api.catalog.id`**	The ID of the Catalog in which the API is published.	Read/write
API Gateway only **`api.catalog.name`**	The name of the Catalog in which the API is published.	Read/write
API Gateway only **`api.catalog.path`**	The path segment that represents this Catalog.	Read/write
`api.endpoint.address`	The address of the API Gateway endpoint.	Read/write
`api.endpoint.hostname`	The host name of the API Gateway endpoint, as requested by the application.	Read/write
API Gateway only **`api.id`**	The identifier of the API.	Read/write
`api.name`	The name of the API; this corresponds to the **`x-ibm-name`** field in the OpenAPI definition for the API.	Read/write
`api.operation.id`	The ID of the operation.	Read/write
`api.operation.path`	The path of the operation.	Read/write
`api.org.id`	The organization ID of the API provider.	Read/write
`api.org.name`	The organization short name of the API provider.	Read/write
**`api.properties.`*`propertyname`*	The name of a custom API property. Property values are Catalog specific. Note: • You have write permission to a custom property **only** from the user interface, **not** from GatewayScript. • To access a Catalog specific property value from GatewayScript, you must refer to the property by using the following syntax: **`apim-`*`catalog-name`*** where *catalog* is the name of the Catalog, and *name* is the property name. For example: **`var mypropertyvalue = $(apim-mycatalog-mypropertyname)`**	Read/write
`api.root`	The API base path.	Read/write
`api.type`	The API type; REST or SOAP.	Read/write
`api.version`	The version string of the API.	Read/write
`client.app.id`	The client ID or application key that is received on the request.	Read/write
API Gateway only **`client.app.lifecycle-state`**	The lifecycle status of the calling client application. The possible values are as follows: • **`DEVELOPMENT`** • **`PRODUCTION`** (default)	Read/write

Name	Description	Permission
API Gateway only `client.app.metadata.key`	The string value of an application metadata key, where *key* is the name of the key. You can add metadata keys to an application by using either the **apic apps:create** or the **apic apps:update** command; you include the metadata keys in the configuration file parameter that is passed to the command. For example: `apic apps:create myapp.yaml --server myserver.com --org myorg --catalog mycatalog --consumer-org mycorg` where myapp.yaml contains the following: `name: myapp` `title: My test application` `metadata:` `  key1: value1` `  key2: value2` `  key3: value3` `  key4: value4` `  key5: value5` You can then retrieve the value of a metadata key in an API assembly policy by using a context variable such as the following: `client.app.metadata.key3` Note that adding application metadata might impact gateway trans performance.	Read/write
`client.app.name`	The name of the application that is identified as having issued the request.	Read/write
`client.app.secret`	The client secret that is received in the request.	Read/write
`client.app.type`	The type of the client application that issued the request.	Read/write
`client.org.id`	The unique identification key of the organization that owns this application.	Read/write
`client.org.name`	The name of the organization that owns this application.	Read/write
API Gateway only `client.result`	The result of the client security policy, which is `SUCCESS` or `FAILURE`.	Read/write
API Gateway only `client.third_party.type`	The type of user registry used for third-party authentication of the extracted client credentials. The possible values are `LDAP` and `auth-url`.	Read/write
API Gateway only `client.third_party.headers`	The array of headers added to the request that was sent to that API authentication URL during third-party authentication.	Read/write
API Gateway only `client.third_party.response.authenticated`	The third-party authentication results. The possible values are as follows: • `true`: the authentication was successful. • `false`: the authentication failed.	Read/write
API Gateway only `client.third_party.response.user`	The user for third-party authentication.	Read/write
API Gateway only `client.title`	The title for the credentials that are received in the request.	Read/write
DataPower Gateway (v5 compatible) only `env.name`	The name of the Catalog in which the API is published.	Read/write
DataPower Gateway (v5 compatible) only `env.path`	The path segment that represents this Catalog.	Read/write
API Gateway only `error.message`	The message text for the error.	Read/write
API Gateway only `error.name`	The name of the error.	Read-only
API Gateway only `log`	The transaction data gathered in an assembly log action.	Read/write
`message.attachments`	The array of attachments in a multipart message.	Read/write
`message.attachments[].body`	The attachment payloads in a multipart message.	Read/write
`message.attachments[].headers`	The attachment headers in a multipart message.	Read/write
`message.body`	The payload of the request or response message. Note: The `message.body` context variable is not supported with `getContext()` function. Use the `getvariable()` function instead.	Read/write
`message.headers.name`	The value of the current named header of the message or of the current named header of the root part of a multipart message. The *name* segment is case-insensitive.	Read/write
API Gateway only `message.original.headers.name`	The value of the original named header of the HTTP message. When the assembly contains an invoke action, the value is automatically populated by the original named header of the response message from the invoked URL. The *name* segment is case-insensitive.	Read-only
API Gateway only `message.package.headers.name`	The value of the current named header of the multipart message. The *name* segment is case-insensitive.	Read/write
`message.status.code`	The HTTP status code of the response.	Read/write
`message.status.reason`	The HTTP reason phrase of the response.	Read/write

Name	Description	Permission
API Gateway only **message.variables.*name***	The value of a property in the message. For example, when **myvar** is the property in the message, you can retrieve the value of the **myvar** property by reading **message.variables.myvar**.	Read/write
plan.name	The name of the plan.	Read/write
plan.id	The unique identifier of the plan.	Read/write
plan.rate-limit	The rate limit of the plan, which is the number of API calls per time interval.	Read/write
API Gateway only **plan.rate-limit[index].hard-limit**	The hard limit setting for the rate limit scheme that is identified by **[index]**.	Read/write
API Gateway only **plan.rate-limit[index].value**	The value of the rate limit scheme that is identified by **[index]**. The syntax is **rate/interval**.	Read/write
plan.spaceId	The unique identifier of the space that the plan is contained within.	Read/write
plan.spaceName	The name of the space that the plan is contained within.	Read/write
plan.version	The version number of the plan.	Read/write
request.authorization	The parsed HTTP **authorization** header.	Read-only
request.body	The payload from the incoming request.	Read-only
request.content-type	Normalized content-type value.	Read-only
request.date	A date object that represents approximately when the request was received by the Gateway.	Read-only
request.headers.*name*	The value of the original named header of the HTTP request, or the value of the current named header of the root part of a multipart request. The *name* segment is case-insensitive. The request header can be modified only in preflow policies. For more information, see Customizing the preflow policies.	Read/write
API Gateway only **request.original.headers.*name***	The value of the original named header of the HTTP request. This variable is created only when the request header is modified. The *name* segment is case-insensitive.	Read-only
API Gateway only **request.package.headers.*name***	The value of the named header of the multipart request. The *name* segment is case-insensitive.	Read-only
API Gateway only **request.parameters**	You can obtain your incoming parameters from path and query parameters.	
API Gateway only **request.parameters.*name*.locations**	An array of strings that specify the parameter types associated with the parameter specified in name. The supported keywords for parameter types are as follows. **formData** The parameter is in the body as form data **header** The parameter is in the request header **path** The parameter is in the path **query** The parameter is in the query	Read-only
API Gateway only **request.parameters.*name*.values**	An array containing values of the parameter types associated with the parameter specified in name. For example, when the first value is **path** in **request.parameters.myparam.locations[]**, the first value in **request.parameters.myparam.values[]** is the array of path values associated with **myparam**. Request parameters can be modified only in preflow policies. For more information, see Customizing the preflow policies.	Read/write
API Gateway only **request.original.parameters.*name*.values**	An array containing the original values of the parameter types associated with the parameter specified in *name*. This variable is created only when a request parameter value is modified.	Read-only
request.path	The path section of the **request.uri** that starts with the base path of the API, including the '/' character that begins the base path.	Read-only
API Gateway only **request.protocol**	The protocol that is used to receive the request: **http** or **https**.	Read-only
request.querystring	The request query string without the leading question mark.	Read-only
request.search	The request query string with the leading question mark.	Read-only
request.uri	The full HTTP request URI from the application.	Read-only
request.verb	The HTTP verb of this request.	Read-only
API Gateway only **session.apiGateway**	The gateway that receives the request.	Read-only
API Gateway only **session.apiGatewayName**	The name of the API gateway as defined in the API Manager.	Read-only
API Gateway only **session.clientAddress**	The address of the client that sent the request.	Read-only
API Gateway only **session.domainName**	The name of the domain that the gateway belongs to.	Read-only

Name	Description	Permission
API Gateway only `session.globalTransactionID`	The global transaction ID in the logs.	Read-only
API Gateway only `session.localAddress`	The address of the gateway on the DataPower® Gateway.	Read-only
API Gateway only `session.timeStarted`	The time that the gateway started to process the request.	Read-only
API Gateway only `session.transactionID`	The transaction ID of the gateway request.	Read-only
`system.datetime`	Returns a string that represents the current date and time in the system time zone of the gateway.	Read-only
`system.time`	Returns a string that represents the current time in the system time zone of the gateway.	Read-only
`system.time.hour`	Returns a number 0 - 23 inclusive, representing the hour of the current time in the system time zone of the gateway.	Read-only
`system.time.minute`	Returns a number 0 - 59 inclusive representing the minute of the current time in the system time zone of the gateway.	Read-only
`system.time.seconds`	Returns a number 0 - 59 inclusive representing the seconds of the current time in the system time zone of the gateway.	Read-only
`system.date`	Returns a string that represents the current date in the system time zone of the gateway.	Read-only
`system.date.day-of-week`	Returns a number 1 - 7 (Monday to Sunday) inclusive representing the day of the week in the system time zone of the gateway.	Read-only
`system.date.day-of-month`	Returns a number 1 - 31 representing the day of the month in the system time zone of the gateway.	Read-only
`system.date.month`	Returns a number 1 - 12 representing the month in the system time zone of the gateway.	Read-only
`system.date.year`	Returns a four-digit number that represents the year in the system time zone of the gateway.	Read-only
`system.timezone`	Returns a system time zone ISO 8601 identifier for the gateway, which might include a sign, a two-digit hour, and minutes. For example, `-04:00`.	Read-only

OAuth context variables - DataPower Gateway (v5 compatible)

The OAuth context variables described in this section apply only to the DataPower Gateway (v5 compatible). For details of the OAuth context variables that apply to the DataPower API Gateway, see OAuth context variables.

Table 2. OAuth context variables (DataPower Gateway (v5 compatible)).
Note: Most OAuth context variables are available only when IBM API Connect is acting as the OAuth resource server. However, the `oauth.introspect` variables are also available when integrating with third party providers.

Name	Description
`oauth.access-token`	If the request is authenticated with OAuth, this variable contains the access token string.
`oauth.miscinfo`	This variable contains information explicitly included in the Authentication URL and Metadata URL headers. For more information, see Authenticate URL.
`oauth.not-after`	If the request is authenticated with OAuth, this variable contains the date when the token expires.
`oauth.not-before`	If the request is authenticated with OAuth, this variable contains the date when the token was issued.
`oauth.resource-owner`	If the request is authenticated with OAuth, this variable contains the name of the resource owner.
`oauth.scope`	If the request is authenticated with OAuth, this variable contains the scope of this access token.
`oauth.introspect.active`	Always available to introspection. Boolean value.
`oauth.introspect.response`	Always available to introspection. Shows the complete current response payload. Example payload value: `{"active":true, "client_id", "xxx-xxx", "token_type", "bearer", "scope":"neon"}`
Other variables might be available from the third party, in the form of: `oauth.introspect.<variable>`	Decoding the previous example payload, the following variables are made available for further processing. `oauth.introspect.client_id: xxx-xxx` `oauth.introspect.token_type: bearer` `oauth.introspect.scope: neon`

Application certificate context variables

The following table describes context variables that are available when a certificate is used to verify access to an API, although these will vary depending on the signature mechanism that is being used; for more information, see the Internet X.509 Public Key Infrastructure Certificate and CRL Profile specification.

Table 3. Application certificate context variables

Name	Description
`application.certificate.Base64`	Base64 format.
`application.certificate.fingerprint`	Fingerprint
`application.certificate.Version`	Version
`application.certificate.SerialNumber`	Serial number
`application.certificate.SignatureAlgorithm`	Signing algorithm
`application.certificate.Issuer`	The issuer of the certificate
`application.certificate.Subject`	Subject
`application.certificate.NotBefore`	Not valid before this date
`application.certificate.NotAfter`	Not valid after this date
`application.certificate.SubjectPublicKeyAlgorithm`	Algorithm for the subject public key
`application.certificate.SubjectPublicKeyBitLength`	Length for the subject public key

Name	Description
`application.certificate.KeyValue.type`	Various context variables that depend on the algorithm and key. The following are possible context variables: • `application.certificate.KeyValue.RSAKeyValue.Modulus` • `application.certificate.KeyValue.RSAKeyValue.Exponent`

API activity logging context variables

If activity logging is enabled for an API, a `log` context variable is created; the `log` context variable contains the data relating to an API execution event. On completion of API execution, the `log` context variable is written to an API event record that is stored for subsequent access by API analytics. For details of the fields contained in the `log` context variable, see API event record field reference.

The way in which you enable and configure activity logging depends on the type of gateway you are using, as follows:

- If you are using the DataPower API Gateway, you configure activity logging in the API configuration settings; see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0).
- If you are using the DataPower Gateway (v5 compatible), you configure activity logging by adding an Activity Log policy to the API assembly.

The activity logging configuration defines the default content of the `log` context variable, but you can modify it in an API assembly; for example:

- Add your own data values by using a Set Variable policy.
- Remove or redact data values by using a Redaction policy; see Redaction - DataPower API Gateway or Redaction - DataPower Gateway (v5 compatible).
- API Gateway only Modify or replace the `log` context variable by using a Log policy.

GraphQL context variables

The GraphQL query and response variables generated from API processing and assembly actions are stored in the API context in the `message.attributes.graphql` context variables.

Table 4. GraphQL context variables

Name	Description
`message.attributes.graphql`	The query and response attributes of the GraphQL message.
`message.attributes.graphql.query`	The attributes of a GraphQL query, including the query string, operation name, and variables.
`message.attributes.graphql.query.query`	The GraphQL query string.
`message.attributes.graphql.query.variables`	The map of GraphQL variables.
`message.attributes.graphql.query.operationName`	The name of the operation to execute.
`message.attributes.graphql.query.operationType`	The type of the operation to execute.
`message.attributes.graphql.request`	The attributes of the GraphQL request.
`message.attributes.graphql.request.fieldCost`	The weighted sum of the cost of all fields accessed in the query. The cost of each field access is configured in the schema. This count includes fields whose field costs are not set to 0.0.
`message.attributes.graphql.request.fieldCounts`	The maximum number of times that each field can be retrieved by the given query. This number is equal to the number of times that the resolver responsible for producing the value of the field is required to run. This count includes fields whose field costs are not set to 0.0.
`message.attributes.graphql.request.typeCost`	The weighted sum of the cost of all types retrieved in the query. The cost of each type is configured in the schema. This count includes types whose type costs are not set to 0.0.
`message.attributes.graphql.request.typeCounts`	The maximum number of times that a value of each type can be retrieved by the given query. This count includes types whose type costs are not set to 0.0.
`message.attributes.graphql.response.fieldCost`	The weighted sum of the cost of all fields in the response to the query. The cost of each field access is configured in the schema. If this sum cannot be calculated based on the analysis configuration in the request, the field cost is expressed as the maximum integer value that can be assigned.
`message.attributes.graphql.response.fieldCounts`	The number of times that each field was retrieved in the response to the query. This number is equal to the number of times that the resolver responsible for producing the value of the field is required to run. If this sum cannot be calculated based on the analysis configuration in the request, the field count is expressed as the maximum integer value that can be assigned.
`message.attributes.graphql.response.typeCost`	The weighted sum of the cost of all types in the response to the query. The cost of each type is configured in the schema. If this sum cannot be calculated based on the analysis configuration in the request, the type cost is expressed as the maximum integer value that can be assigned.
`message.attributes.graphql.response.typeCounts`	The number of times that a value of each type was contained in the response to the query. If this sum cannot be calculated based on the analysis configuration in the request, the type count is expressed as the maximum integer value that can be assigned.

Name	Description
`message.attributes.parse.GraphQLIntrospection`	The introspection type of the assembly GraphQL introspect action. When a GraphQL query is parsed, this context variable is populated with one of the following values: • `not-introspection` • `custom-introspection` • `default-introspection`

- Variable references in API Connect

OAuth context variables

You can customize the OAuth security flow in a native OAuth provider by adding multiple OAuth policies to the assembly. Each OAuth policy takes input from context variables and writes output to context variables. By using these OAuth context variables you can manipulate the original request, and process the output from an OAuth policy.

Note: The OAuth context variables described here apply only to the DataPower® API Gateway. For details of the OAuth context variables that apply to the DataPower Gateway (v5 compatible), see OAuth context variables - DataPower Gateway (v5 compatible).
There are two main types of OAuth context variables:

- Information variables, outputs of an OAuth policy.
- Processing variables, processed during the execution of an OAuth policy.

Information variables

These context variables are outputs of an OAuth policy. They are not used in the processing of the OAuth action.

`oauth.result`
: The result of the latest action; returns `SUCCESS` or `FAILURE`.

`oauth.settings.variable_name`
: Basic settings from the OAuth provider. The following context variables are available:

```
oauth.settings.allowed_scopes
oauth.settings.access_token_ttl
oauth.settings.authorization_code_ttl
oauth.settings.refresh_token_ttl
oauth.settings.refresh_token_limit
oauth.settings.maximum_consent_ttl
```

`oauth.executed_components[0].variable_name`
: The components that have executed in this transaction, with their result. If a failure occurs then the error and error description will be added. The following context variables are available:

```
oauth.executed_components[0].result
oauth.executed_components[0].type
oauth.executed_components[0].error_description
oauth.executed_components[0].error
```

The possible values for the `type` variable are as follows:

```
ValidateRequestComponent
GenerateAZCodeComponent
VerifyAZCodeComponent
VerifyRefreshTokenComponent
GenerateAccessTokenComponent
IntrospectTokenComponent
RevokeTokenComponent
CollectMetaDataComponent
```

The following example shows a corresponding JSON extract from the OAuth context:

```
"executed_components": [
  {
    "type": "ValidateRequestComponent",
    "result": "SUCCESS"
  },
  {
    "type": "GenerateAccessTokenComponent",
    "result": "SUCCESS"
  }
]
```

`oauth.verified_access_token.variable_name`
: The token that was verified in the security requirement for a native OAuth provider. The following context variables are available:

```
oauth.verified_access_token.access_token

oauth.verified_access_token.client_id
oauth.verified_access_token.consented_on
oauth.verified_access_token.consented_on_text
```

`oauth.verified_access_token.grant_type`
`oauth.verified_access_token.misc_info`
`oauth.verified_access_token.not_after`
`oauth.verified_access_token.not_after_text`
`oauth.verified_access_token.not_before`
`oauth.verified_access_token.not_before_text`
`oauth.verified_access_token.one_time_use`
`oauth.verified_access_token.resource_owner`
`oauth.verified_access_token.scope`

`oauth.third_party.`***`variable_name`***
The token that was verified in the security requirement for a third party OAuth provider. Provides the following information:

- The response headers from the external, third-party OAuth provider.
- The body of response from the external, third-party OAuth provider.
- Whether the response is cached. When cached, the value is **`true`**. When not cached, the value is **`false`**.

The following context variables are available:

`oauth.third_party.headers`
`oauth.third_party.response`
`oauth.third_party.cached`

`oauth.code.`***`variable_name`***
The code that was generated during the execution of a component of type **`GenerateAZCodeComponent`**. The following context variables are available:

`oauth.code.client_id`
`oauth.code.code`
`oauth.code.redirect_uri`
`oauth.code.resource_owner`
`oauth.code.scope`

`oauth.token.`***`variable_name`***
The token that was generated during the execution of a component of type **`GenerateAccessTokenComponent`**. The following context variables are available:

`oauth.token.token_type`
`oauth.token.access_token`
`oauth.token.scope`
`oauth.token.expires_in`
`oauth.token.consented_on`
`oauth.token.redirect_uri`
`oauth.token.resource_owner`
`oauth.token.client_id`
`oauth.token.refresh_token`
`oauth.token.refresh_token_expires_in`
`oauth.token.refresh_token_count`

`oauth.introspect.`***`variable_name`***
The token that was introspected during execution of a component of type **`IntrospectTokenComponent`**. The following context variables are available:

`oauth.introspect.active`
`oauth.introspect.scope`
`oauth.introspect.client_id`
`oauth.introspect.resource_owner`
`oauth.introspect.token_type`
`oauth.introspect.grant_type`
`oauth.introspect.ttl`
`oauth.introspect.expires`
`oauth.introspect.expires_text`
`oauth.introspect.iat`
`oauth.introspect.not_before`
`oauth.introspect.not_before_text`
`oauth.introspect.consented_on`
`oauth.introspect.consented_on_text`
`oauth.introspect.one_time_use`

`oauth.external_manager.`***`variable_name`***
Token management when using an external token manager. Provides the following information:

- The response headers from the external management server.
- The response JSON body from the external management server.
- When caching is enabled, whether the response is found in the cache or set in the cache. When caching is not enabled, that the response is not set in the cache.

The following context variables are available:

`oauth.external_manager.headers`
`oauth.external_manager.response`
`oauth.external_manager.cached`

Processing variables

These context variables are processed during the execution of an OAuth policy in your API assembly. If they are set prior to any OAuth policy then the value overrides what was sent in the request. They can also be modified between OAuth policies to manipulate the next component that executes. The following context variables are available:

`oauth.processing.assertion`
`oauth.processing.client_id`
`oauth.processing.client_secret`
`oauth.processing.grant_type`
`oauth.processing.redirect_uri`
`oauth.processing.scope`
`oauth.processing.response_type`
`oauth.processing.state`

```
oauth.processing.resource_owner
oauth.processing.refresh_token
oauth.processing.code
oauth.processing.token
oauth.processing.token_type_hint
oauth.processing.nonce
oauth.processing.max_age
oauth.processing.oidc_values_requested
oauth.processing.id_token_requested
oauth.processing.oidc_signing_algorithm
oauth.processing.code_challenge
oauth.processing.code_challenge_method
oauth.processing.code_verifier

oauth.processing.metadata.access_token
oauth.processing.metadata.payload
oauth.processing.metadata.azcode_miscinfo

oauth.processing.verified_code.client_id
oauth.processing.verified_code.resource_owner
oauth.processing.verified_code.misc_info
oauth.processing.verified_code.scope
oauth.processing.verified_code.is_verified
oauth.processing.verified_code.nonce

oauth.processing.verified_refresh_token.client_id
oauth.processing.verified_refresh_token.resource_owner
oauth.processing.verified_refresh_token.misc_info
oauth.processing.verified_refresh_token.scope
oauth.processing.verified_refresh_token.refresh_token_count
oauth.processing.verified_refresh_token.is_verified
oauth.processing.verified_refresh_token.one_time_use
oauth.processing.verified_refresh_token.grant_type
```

The following example shows the OpenAPI source code for a `gateway-script` policy that executes before an OAuth policy in your API assembly and adds a custom scope to the request:

```
// Add another custom scope to the request
let scope = context.get("request.parameters.scope.values[0]");
if (scope)
  context.set("oauth.processing.scope", scope + " custom");
```

The following example shows the OpenAPI source code for a `gateway-script` policy that between OAuth policies in your assembly and modifies the scope depending on the resource owner:

```
// Check resource owner and modify the scope
let owner = context.get("oauth.processing.resource_owner");
let scope = context.get("oauth.processing.scope");

if (owner === 'admin') {
    context.set("oauth.processing.scope", scope + " admin");
} else {
    context.set("oauth.processing.scope", scope + " customer");
}
```

Advanced scope context variables

The following context variables are used in OAuth advanced scope checking. They are populated by the values entered in the Endpoint and TLS Client Profile fields for the Application scope check and Owner scope check in the native OAuth provider configuration. Do not change these values as this might result in incorrect advanced scope operation.

For information on scope configuration, see Configuring scopes for a native OAuth provider. For information on advanced scope checking, see Scope.

```
oauth.advscope.app.url
oauth.advscope.app.tls-profile
oauth.advscope.own.url
oauth.advscope.own.tls-profile
```

Custom error context variables

These context variables are used to stop OAuth processing and specify the respective error details. They can be used before OAuth processing takes place.

```
oauth.custom_error.status.code
oauth.custom_error.status.reason
oauth.custom_error.message
oauth.custom_error.description
```

Error cases supported by assembly catches

Several error cases that can be returned by the assembly are available to the catch function.

ConnectionError

An error occurred while establishing a connection to another URL.

JavaScriptError
: An error occurred while executing JavaScript or GatewayScript in a policy.

PropertyError
: An error occurred due to an incorrect property during an invoke call or during the execution of a set-variable policy when an action was not set, add, or clear.

RedactionError
: An error occurred during the redaction of a field as part of a redact policy.

TransformError
: An error occurred during a transformation policy.

RuntimeError
: An otherwise unspecified error occurred.

BadRequestError
: An error occurred while trying to access the request. Beginning with Version 10, this is not supported by the default catch; to catch this condition, specify it in your catch definition.

SOAPError
: A SOAP Fault response was received as the result of a web service invoke request.

OperationError
: An invoke request received a response with an unsuccessful HTTP status code.

ValidateError
: An error occurred while trying to schema validate a message payload.

AssemblyRateLimitError
: The request exceeds the transaction count threshold specified in the API's Plan.

UnauthorizedError
: The API cannot be invoked based on the client ID and/or client secret provided, or id/secret were specified in the wrong location. Beginning with Version 10, this is not supported by the default catch; to catch this condition, specify it in your catch definition.

ForbiddenError
: The application making the API request has been disabled or is not active. Beginning with Version 10, this is not supported by the default catch; to catch this condition, specify it in your catch definition.

API and Product definition template examples

You can use template files when creating API and Product definitions. Template files are Handlebars templates containing variables of the form **`{{variable-name}}`** that are substituted with values when you create the API or Product definition. This topic provides the default Handlebar templates used by **`apic`** to create Products and APIs as examples you can use to copy and customize for your own use.

Default API definition template (OpenAPI 2.0)

The following example template, which is for an OpenAPI 2.0 API definition, is the default template that developer toolkit uses when you create an API definition. Copy this example template into your own template file (which must have the **`.hbs`** extension), then edit it for your purposes. Template variables are enclosed by double curly braces, for example **`{{name}}`**. For information on template variables, see Template variables for API and Product definitions. For more information on Handlebars, see https://handlebarsjs.com/.

/oauth2/token:

  post:
    consumes:
      - application/x-www-form-urlencoded
```

```
    produces:
      - application/json
    summary: Request Access Tokens
    description: |
      This endpoint allows requesting an access token following one of the flows below:
      - Authorization Code (exchange code for access token)
      - Client Credentials (2-legged, there isnt resource owner information)
      - Resource Owner Password Credentials (2-legged, client provides resource owner name and password)
      - Refresh Token (exchange refresh token for a new access code)

      The table below indicates the required parameters for each specific grant_type options.
      Empty cells indicate a parameter is ignored for that specific grant type.

      Client authentication:
      - Confidential clients should authenticate using HTTP Basic Authentication. Alternatively, they may post
        their client_id and client_secret information as a formData parameter.
      - Public clients should send their client_id as formData parameter.

      | grant_type           | code       | client_credentials | password    | refresh_token |
      |----------------------|------------|--------------------|-------------|---------------|
      | client_id            | required*  | required*          | required*   | required*     |
      | client_secret        | required*  | required*          | required*   | required*     |
      | code                 | required   |                    |             |               |
      | redirect_uri         | required   |                    |             |               |
      | username             |            |                    | required    |               |
      | password             |            |                    | required    |               |
      | scope                |            | optional           | optional    |               |
      | refresh_token        |            |                    |             | required      |

      The implicit grant requests, see /oauth2/authorize.

Template variables for API and Product definitions

You can use template files when creating OpenAPI 2.0 and OpenAPI 3.0 APIs, and when creating Product definitions. Template files are Handlebars templates containing variables of the form **{{variable-name}}** that are substituted with values when you create the API or Product definition.

Product definition variables

The following table describes the Handlebars template variables that can be used in a product definition file. For more information on Handlebars, see https://handlebarsjs.com/. Product definition template files must have a **.hbs** filename extension.

Table 1. Product definition Handlebars template variables

Variable	Type	Description
{{apis}}	Array of string	The APIs to which the product definition refers. After substitution, the array values become the values of **apis.routes[*n*].$ref** fields, for example: `apis:` `  'routes':` `  $ref: apidef.yaml` `  ...`
{{name}}	String	Value of **info.x-ibm-name** field.
{{title}}	String	Value of **info.title** field.
{{version}}	String	Value of **info.version** field.

API definition variables

The following table describes the Handlebars template variables that can be used in an API definition file. For more information on Handlebars, see https://handlebarsjs.com/. API definition template files must have a **.hbs** filename extension.

Table 2. API definition Handlebars template variables

Variable	Type	Description
{{basepath}}	String	Base path on which the API is served, which is relative to the **host**.
{{definitions}}	OpenAPI definitions objectconverted to a YAML string ("stringified").	For a LoopBack API, contains data types that can be consumed and produced by operations. These data types can be primitives, arrays or models.
{{definitionsObj}}	OpenAPI definitions objectconverted to a YAML string ("stringified").	For a LoopBack API, contains data types that can be consumed and produced by operations. These data types can be primitives, arrays or models.
{{hostname}}	String	Value of the **host** field.
{{name}}	String	Value of **info.x-ibm-name** field.
{{paths}}	OpenAPI paths object	For a LoopBack API, contains the relative paths to the individual endpoints. The path is appended to **{{basePath}}** to construct the full URL.
{{pathsObj}}	OpenAPI paths object	For a LoopBack API, contains the relative paths to the individual endpoints. The path is appended to **{{basePath}}** to construct the full URL.
{{schemes}}	Array of string	Transfer protocol of the API. Values must be one of: **"http"**,**"https"**, **"ws"**, or **"wss"**.
{{targeturl}}	String	Value of **x-ibm-configuration.assembly.execute[invoke]**. Default is **$(runtime-url)$(request.path)**.
{{title}}	String	Value of **info.title** field.
{{version}}	String	Value of **info.version** field.

Managing your APIs

You manage your APIs by using the API Manager user interface of IBM® API Connect. You can also analyze your API usage by using the analytics that are provided and socialize your APIs in a developer portal.

Why use APIs?

Whether you are a business user, an IT user, or an application developer, APIs are increasingly important to your business. You can use an API to publicize your company. The assets, data, or services of your company can be provided to external application developers to expand your enterprise and open new markets.

The API Manager UI provides a solution for companies to manage APIs for private internal APIs, and public external APIs. This on-premises offering provides the capabilities that are required so that you can externalize and manage your services as REST or SOAP APIs.

What do you need to know?

Depending on your role, you can complete different tasks relating to managing your API Catalogs and these are outlined in the documentation. Each task is covered in the order that they are executed.

Each task introduces new features of the API Manager UI as they become relevant to the Catalog that you are building.

For security reasons, your session times out after a period of inactivity.

Before you start, check that the browser you are using is supported and meets the required minimum levels; for details, open the Detailed system requirements for a specific product page, search for the IBM API Connect product, then select the required version.

The ways in which you can manage your APIs are described in the following subtopics:

- **API management checklist**
  A summary, with links, of the key tasks for managing APIs in IBM API Connect.
- **Activating your API Manager user account**
  Before you can access the API Manager user interface of IBM API Connect, you must activate the user account that your Cloud Manager administrator invited you to join.
- **Accessing the API Manager user interface**
  The IBM API Connect API Manager user interface provides a range of options for working with your APIs and Products, and managing security.
- **Searching for items in API Manager**
  Use the search feature in IBM API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.
- **Working with Catalogs**
  Products must be staged to a Catalog and then published; application developers are able to access the APIs in a Product by being members of consumer organizations to which the Product is made available. In API Connect, you can create multiple Catalogs. Catalogs are useful for separating Products and APIs for testing before you make them available to consumer organizations. The syndication feature in API Connect means that you can also publish a Product to a Space in a Catalog.
- **Using syndication in API Connect**
  With the API Connect syndication feature, you can partition your catalogs into *Spaces*. Each space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that space, enabling each team to manage their APIs independently.
- **Working with Products**
  In IBM API Connect, Plans and APIs are grouped together in Products.
- **Working with APIs**
  For a specific Product, you can work with the APIs that are contained in the Plans in that Product.
- **Working with Plans**
  After a Product has been published to a Catalog, you can work with the Plans in that Product.
- **Working with consumer organizations**
  Manage the consumer organizations that access your APIs and Plans when their users sign up to use the IBM API Connect Developer Portal.
- **Working with developer applications**
  You can work with the applications that have been registered in the Developer Portal associated with a Catalog.
- **Working with application subscriptions**
  You can work with the subscriptions to the Plans in all the Products in a specific Catalog. Plan subscriptions are created by application developers in the Developer Portal.
- **Security and authentication**
  In API Manager, you can use TLS profiles to secure the transmission of data between the management server and other API Connect subsystems and external services, and also configure user registries to securely authenticate your Catalogs and APIs.
- **API Analytics**
  You can use API Connect to filter, sort, and aggregate your API event data. You can present the results within correlated charts, tables, and maps to help you manage service levels, set quotas, establish controls, set up security policies, manage communities, and analyze trends.
- **Configuring API governance in the API Manager**
  How to add custom API governance rulesets to your API development process, to validate and enforce organizational governance policies and best practices in your provider organization.
- **Administering user access**
  If you have permission to administer users in IBM API Connect, you can add and delete users. After users are removed from an organization through deletion, the user account remains in API Manager.
- **Changing your API Manager password**
  You can change your API Manager password in IBM API Connect.
- **Resolving login problems by increasing HTTP header size**
  You can resolve login problems for the API Manager UI by increasing the maximum HTTP client header size.
- **Reviewing a gateway's processing status**
  Review the processing status for the Gateway services that are enabled in your API Connect Catalogs and Spaces.
- **Reference**
  Reference information for the API Manager component in IBM API Connect.

API management checklist

A summary, with links, of the key tasks for managing APIs in IBM® API Connect.

Task	Description
Activate your API Manager user account	To connect to a Management server using the API Manager user interface, you must be an owner or a member of a provider organization.
Log in to the API Manager user interface	After you have activated your account, you can log in to your Management server from the API Manager user interface.
Configure your Catalogs	APIs are published to a Catalog to make them available to application developers. The URLs for API calls, and for the Developer Portal, are specific to a particular Catalog. By default, a *sandbox* Catalog is provided for API testing, but you can create your own Catalogs; for example, a production Catalog for hosting APIs that are ready for full use.
Manage the membership of your Catalogs	You can add users to your Catalogs, and assign roles and permissions to control their level of access.
Configure API security	You can configure user registries of various types for authenticating API access, TLS profiles for securing data transmission over HTTPS, and OAuth providers for securing third-party website or application access to APIs.
Manage your Products	Move your Products through their lifecycle, from initially staging a Product to a Catalog, through to publishing to make the Product version available to your application developers, and to eventual retiring and archiving. You can also display analytics information, and control who can see or subscribe to your Products.
Analyze your API usage	You can use IBM API Connect to filter, sort, and aggregate your API event data. You can present the results within correlated charts, tables, and maps to help you manage service levels, set quotas, establish controls, set up security policies, manage communities, and analyze trends.
Manage user access to your provider organization	You can add users to your provider organization, remove users, and assign roles and permissions.
Partition your Catalogs into Spaces for syndication	With the syndication feature, you can partition your Catalogs into *Spaces*. Each Space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that Space, enabling each team to manage their APIs independently.

Activating your API Manager user account

Before you can access the API Manager user interface of IBM® API Connect, you must activate the user account that your Cloud Manager administrator invited you to join.

Before you begin

The Cloud Manager administrator invited you to join API Connect .

Procedure

1. Complete the following steps to create your API Manager account:

   If the Identity Provider uses LDAP
   : An invitation email with an activation link is sent. Click the activation link, or paste it in a browser, to log in directly with your user credentials. Upon authentication, the API Connect user record is updated from the backend identity provider.

   If the Identity Provider uses a local registry
   : An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your first name, last name and password. Passwords must have a minimum of 8 characters and contain characters from at least three of the four following categories:
     - Uppercase letters
     - Lowercase letters
     - Numbers
     - Special characters (for example: ! # $ %)

     Note:
     - The email address that you enter on the sign up page must match the email address to which the invitation email was sent, otherwise the account activation fails.
     - If you previously had an account that the administrator removed, and they are inviting you again, you must re-activate your account by using the Sign In option on the page, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail.

   If the Identity Provider uses an authentication URL
   : An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your credentials, which then become your user name and password. Upon authentication, the API Connect user record is updated from the backend identity provider.

If multiple user registries are available for selection on the sign up page, then make sure that the correct registry for your API Manager account is selected. You might need to ask your administrator which user registry is appropriate for your account.

For information on configuring user registries and making them available for API Manager login, see User registries overview and Selecting user registries for Cloud Manager and API Manager.

2. Click Sign up to complete your registration, then click Sign in to open the API Manager login page.

Results

You have created your API Connect account.

What to do next

Log in to the API Manager user interface and, depending on your role, start to work with Catalogs, consumer organizations, APIs and Products.
To access the API Manager login page in the future, use the following URL:

`https://host/manager`

where *host* is the fully qualified host name or IP address of the Management server.

Accessing the API Manager user interface

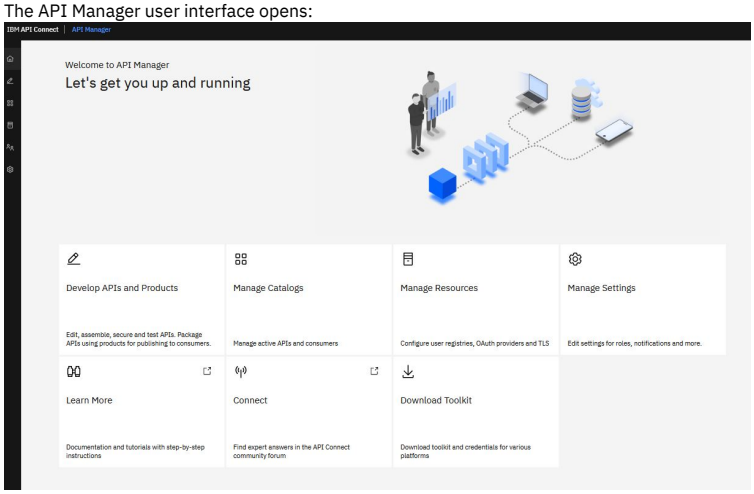
The IBM® API Connect API Manager user interface provides a range of options for working with your APIs and Products, and managing security.

To log in to the API Manager user interface, complete the following steps:

1. In a web browser, enter the following URL:

   `https://host/manager`

   where *host* is the fully qualified host name or IP address of the Management server.
2. If your cloud contains multiple user registries, then select the user registry that contains the login credentials for your API Manager account. You might need to ask your administrator which user registry is appropriate for your account.
   For information on configuring user registries and making them available for API Manager login, see User registries overview and Selecting user registries for Cloud Manager and API Manager.
3. Enter your user name and password, then click Sign in.
   The API Manager user interface opens:



Depending on your role, you can now start to work with Catalogs, consumer organizations, APIs and Products.

Searching for items in API Manager

Use the search feature in IBM® API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.

Search is available from any page in API Manager and can be accessed by typing in the search field in the page banner, or by clicking Search in the navigation list.

Using Search

The Search feature is available on all pages of the API Manager. To start searching, just type a string into the Search field and press Enter. Whenever you press Enter in the Search field, the Search page displays with results and additional options. If you press Enter in an empty Search field, or click Search in the navigation list, then the Search page displays a list all items. If you type a string before pressing Enter, the page displays the results from the corresponding search.

Search results include all items that contain the search string in a text field. For example, suppose you searched for "Crafted". The results might look like the following image, with items that don't match the search string exactly, but do include the string in a text field such as a title or a name.

By default, the search returns all types of items that contain the string. Sort results on a particular column by clicking the column header.

When you find an item you want to work with, click the . . . actions menu next to the item's "Modified" date to see what you can do. The list of possible actions depends on the item's type.

You can limit the search results by selecting an item type from the list that displays before the results. Click More to view additional types. If you select a type from the More menu, it replaces a type in the list.

If you want to refine the search further, click Options. On the Options panel, click Catalogs to Search and select which catalogs to search (the default is all catalogs). You can select up to 5 catalogs for a limited search.

You can also choose whether only exact matches (the complete string) are included in results, or items containing similar strings are also included.

Working with Catalogs

Products must be staged to a Catalog and then published; application developers are able to access the APIs in a Product by being members of consumer organizations to which the Product is made available. In API Connect, you can create multiple Catalogs. Catalogs are useful for separating Products and APIs for testing before you make them available to consumer organizations. The syndication feature in API Connect means that you can also publish a Product to a Space in a Catalog.

A Catalog is a staging target, and behaves as a logical partition of the gateway and the Developer Portal. The URL for API calls and the Developer Portal are specific to a particular Catalog. In a typical configuration, an API provider organization uses a development Catalog for testing APIs under development and a production Catalog for hosting APIs that are ready for full use. A common approach is to have a development cloud with a development Catalog, a few test Catalogs and a production cloud that might have its own test Catalog.

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a sub-catalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see Using syndication in API Connect.

Note:
Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: **`A user already exists with this email address`**.

For more information on using the Developer Portal, see Developer Portal: Socialize your APIs.

- **Creating and configuring catalogs**
  These instructions describe how to create and configure catalogs in IBM API Connect.
- **Configuring Product visibility in a Catalog or a Space**
  How to configure the visibility of Products at the Catalog or Space level.
- **Configuring sub paths for Developer Portal sites**
  You can increase the specificity of a IBM API Connect Developer Portal site URL by using sub paths.
- **Managing Catalog membership**
  Manage Catalog membership by adding new users to the Catalog and assigning roles to the users.
- **Importing a user-defined policy into a Catalog**
  You can make your user-defined policy available to API developers by importing it into an IBM API Connect Catalog, or a Space in a Catalog.
- **Importing an OpenAPI extension into a Catalog**
  You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An extension is imported into a Catalog, or a Space in a Catalog, then added to the API schema.
- **Retaining Version 5 vanity endpoint behavior in a Catalog**
  The behavior of vanity endpoints in a Catalog has changed in API Connect Version 10 compared with Version 5. However, you can modify your Catalog settings to retain the Version 5 behavior.

Creating and configuring catalogs

These instructions describe how to create and configure catalogs in IBM® API Connect.

Before you begin

You must have catalog create permissions to complete this task. For more information about permissions, see API Connect user roles.
Notes:

- As the user who creates the catalog, you are automatically the catalog owner and have all catalog permissions.
- If you configure a new user registry for authenticating users to the Developer Portal, you must also complete the onboarding section in the catalog, to make the registry available to Developer Portal users. See Step 15 for details.
- Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: `A user already exists with this email address`.

Procedure

To create and configure your catalog, complete the following steps:

1. Log in to API Manager and click Manage.
2. Create the catalog.
   You can create the catalog in either of the following ways:
   Specify the owner, then configure the catalog:
   a. Click Add > Create catalog.
   b. In the Catalog Owner field, select the owner of the catalog; by default, you are the owner. You can specify any user who is a member of the provider organization.
   c. Continue from step 3 to configure the catalog.
   Send an invitation email, with an activation link, to the intended catalog owner:
   a. Click Add > Invite catalog owner.
   b. Enter the email address of the catalog owner, then click Invite.
   c. On receipt of the email, the catalog owner must activate the catalog and configure it:
      i. Open the activation link, complete the sign up form, and sign in to the API Manager UI.
      ii. Click Manage Catalogs, click the catalog name that was provided on the sign up form, then click the Catalog settings tab.
      iii. Continue from step 6 to configure the catalog.
3. Enter the catalog Title. A Name is entered automatically and cannot be changed.
   Note: The value in the Name field is a single string that is used to identify the catalog in developer toolkit CLI commands. The Title is used for display; you can change the title but the name does not change.
   To view the CLI commands to manage catalogs, see apic catalogs.
4. Click Create.
   Your new catalog is displayed on the Manage page.
5. To continue to configure your catalog, select the catalog on the Manage page, then click the Catalog settings tab.
6. To configure the general settings for the catalog, click Overview, then proceed with the following steps:
   a. By default, the new catalog is a development catalog. To use the catalog in production, set the Production Mode slider control to the On position, then click Confirm.
   In a development catalog, all publish operations are forced, and any conflicts are resolved automatically. If you republish a previously published product version it is overwritten without warning, allowing you, for example, to repeatedly republish the same product version during testing. If spaces are enabled in a development catalog and you republish a previously published product version to a different space, it is removed from the previous space.

   A development catalog behaves the same as any other catalog with regard to requiring approval for staging and publishing actions, if the catalog has been configured to require approval.

   Note: In a production catalog, the following conditions apply:
   - You cannot publish a product to the catalog if there is already a product in the catalog with the same name and version. Instead, you must create a new version of the product for publication; see Creating a new version of your product . If spaces are enabled in a production catalog, you cannot publish a product with the same name and version to more than one space in the catalog.
   - If this new product contains one or more modified APIs, you **must** create new versions of the APIs for inclusion in the product; see Creating a new version of an API definition. If the product contains a modified API and there is already a published API of the same name and version, the changes will **not** be published.

   b. To enable the partition of this catalog into spaces, set the Spaces slider control to the On position, then click Confirm.
   For more information, see Using syndication in IBM API Connect.
   c. If the catalog is the default staging catalog, move the Default slider control to the On position, then click Confirm. Then, calls to APIs that are published to the catalog can use a shorter URL that does not include the catalog name.
   Note: You can enable Default only for one catalog. If another catalog is already set as the default catalog you will be unable to enable the setting on this catalog without first disabling the setting on the other catalog.
7. To transfer ownership of the catalog to a different user, click Overview, then proceed with the following steps:
   a. Click Edit.
   b. From the Select owner user drop-down menu, select the user who will become the new owner.
   c. If spaces are enabled in the catalog then to also have the ownership of all spaces in the catalog transferred to the new catalog owner, select Also transfer ownership of owned Spaces.
   d. Click Save when done.
   Note:
   - To have permission to change the catalog owner, you must be either the catalog owner, or the owner of the provider organization that contains the catalog.
   - When the ownership changes, the new owner is assigned administration privileges for the catalog, and the previous owner has their administration privileges removed. If required, you can restore the privileges to the previous owner as described in Managing Catalog membership.

- The ownership can be transferred only to a user who is already a member of the catalog. To transfer to a new user or another existing user, that user must previously have been added or invited to the catalog, as described in Managing Catalog membership.

8. To configure the gateway service settings for the catalog, click Gateway Services, then proceed with the following steps:
   Note: If spaces are enabled in the catalog then you configure the gateway settings for the spaces, **not** for the catalog as a whole.
   a. Click Edit.
   b. Select the gateway services that you want to use with this catalog.
      Gateway services are configured by the using the Cloud Manager UI. For details, see Registering a gateway service. If any catalog default gateway services have been configured, they will already be selected when you create a new catalog; see Configuring default gateway services for catalogs.
      The TYPE column indicates the gateway type for each gateway service listed, DataPower® Gateway (v5 compatible), DataPower API Gateway. For more information, see API Connect gateway types.
   c. Click Save to save your changes.

   You publish APIs by adding them to a product and then publishing the product to a catalog. To be able to publish products to a catalog, the catalog must be assigned at least one gateway service so that the APIs in the product are available to be called at a gateway service endpoint. You can assign more than one gateway service to a catalog, and they can be of mixed types, DataPower API Gateway and DataPower Gateway (v5 compatible).

   A product is gateway type specific, either DataPower API Gateway or DataPower Gateway (v5 compatible). By default, when you publish a product to a catalog, it is published to all the assigned gateway services of the same gateway type as the product, but you can choose to publish the product only to selected gateway services, of that type, at publish time; see Publishing a draft product for more information. The APIs in the product will be available to be called at all the specified gateway service endpoints.

   If you select two or more Gateway services then, for analytics data to be available in the Developer Portal for this catalog, the Gateway services must all be associated with the **same** analytics service. If the set of associated analytics services for the selected gateway services includes two or more different analytics services then the Developer Portal does **not** display analytics data. An analytics service is associated with a gateway service in the Cloud Manager user interface; see Associating an analytics service with a gateway service.
   Note: You can also configure the gateway service settings for the catalog by using the developer toolkit CLI; for details, see apic configured-gateway-services.
9. To specify the product lifecycle state changes for which you want to enforce approval, complete the following steps:
   a. Click Lifecycle Approvals in the catalog settings navigation pane, then click Edit.
   b. Select the required state changes, then click Save when done.
      For example, if you select Publish and leave the other check boxes cleared, approval is required when anyone attempts to publish a product, but no approval is required for any of the other lifecycle state changes.
      Note: Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   c. To allow the originator of a product lifecycle change to approve it themselves, move the Task self approval slider control to the On position.
      Note: In a development catalog, the originator of a product lifecycle change can **always** approve it themselves. In a production catalog, the originator of a product lifecycle change can approve it themselves only if the catalog setting Task self approval is enabled.
10. Click Save.
11. To configure the publish validations that are performed when a product is published, complete the following steps:
    a. Click Publish validations in the catalog settings navigation pane.
    b. Click Edit, and select or clear the validation check boxes as required.
       The following validation options can be selected:
       - Publishing APIs with empty paths is not allowed.
       - Validate custom policy schema in assembly.
       - Validate the references inside the API and perform additional OpenAPI validations.
       - Publishing APIs with duplicate base paths is not allowed.
12. Click Save.
13. To configure the permissions that each role in API Manager has, complete the following steps:
    a. Click Roles in the catalog settings navigation pane.
       To see the current permissions for a role, expand the role.
    b. Click the options icon ⋮ alongside the role that you want to work with, then click Edit.
    c. Select or clear the permissions check boxes as required.
       To ensure a role can manage user-defined policies, select Manage for the Settings permission.

       To grant a role the permission to approve a specific lifecycle state change, select the state change in the Product-Approval section.

       Note: You cannot remove a permission that has been assigned to the role at the provider organization level. However, you can add permissions that haven't been assigned at the provider organization level.
    d. Click Save when done.
14. To configure the default role permissions for consumer organizations that are created in this catalog, complete the following steps:
    a. Click Role Defaults in the catalog settings navigation pane.
       To see the current default permissions for a role, expand the role.
    b. Click the options icon ⋮ alongside the role that you want to work with, then click Edit.
    c. Select or clear the permissions check boxes as required.
    d. Click Save when done.
    e. To create a new role and assign default permissions to it, click Add, name the role and assign permissions, then click Save.
15. To manage the onboarding of API consumers into this catalog, complete the following steps:
    a. Click Onboarding in the catalog settings navigation pane.
    b. To select the registries that are used to authenticate users of the Developer Portal associated with this catalog, click Edit in the Catalog User Registries section, select the required registries, then click Save.
       For details on how to configure a user registry, see Authenticating by using your enterprise user registry.
       Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
    c. To set a default registry, click the options icon ⋮ alongside the required registry, then select Set default.
       When an API consumer signs up to the Developer Portal, the specified registry is used by default, with the option to select another registry.
    d. To allow API consumers to complete their own sign-up process to the Developer Portal, move the Self service onboarding slider control to the On position.

If this option is disabled, an API consumer cannot sign-up without an invitation from a consumer organization owner.

e. To require approval for all new self service onboarding to the Developer Portal, move the Self service onboarding approval slider control to the On position.
If this option is enabled, then any attempt by an API consumer to sign-up to the Developer Portal results in an approval request being sent. This request is displayed in the Task tab in the catalog for the associated Developer Portal, from where the request can be approved or declined.
Note that Self service onboarding approval is honored whenever a consumer organization is created. So, even if an API consumer has already been approved to access a Developer Portal with a specific consumer organization, if they then try to create another consumer organization in the same Developer Portal, their request will still go through the approval process.

Note: To enable self-service onboarding approval, you must also complete the following tasks:
- Configure the user registry to require the user's email address.
- Configure the OIDC apps to send the user's email address for approval.

f. To configure the ability for API consumers to invite collaborators and assign them to roles, click Edit in the Consumer invitation and roles section, select the options required, and click Save.

g. To configure the timeout for activation links that are sent in email invitations to application developers, click Edit in the Invitation Timeout section, specify the timeout length, then click Save.

h. To override the timeouts set by consumer organization invitations, enable the Override consumer organization's invitation timeout with catalog invitation timeout setting by moving the slider to the On position.
The catalog's own timeout setting will be used instead.

16. To specify the user registries that are used to secure access to APIs in this catalog, and to add the user registry to the Sandbox catalog, complete the following steps:
    a. Click the Catalog settings tab, and then select API User Registries.
    b. Click Edit and select the user registries you want to use.
    For details on how to configure a user registry, see Authenticating by using your enterprise user registry.
    c. Click Save when done.

    Note:
    - Only LDAP and Authentication URL registries can be used to secure access to APIs; therefore, only registries of these types are listed and available for selection.
    - If spaces are enabled in the catalog then you specify the user registries for the spaces, **not** for the catalog as a whole. If you specify a user registry in one space in a catalog, it is deployed to the gateway services across all spaces in that catalog.
    For more information about enabling and managing spaces, see Using syndication in API Connect

    .

17. To specify the OAuth Providers that can be used to secure access to APIs in this catalog, complete the following steps:
    Note:
    - If you want to specify an OAuth provider for a catalog, ensure that the Sandbox catalog is configured to use the same OAuth provider
    - Any resources that the OAuth provider references, such as API user registries or TLS client profiles, must also be enabled in the catalog
    - If spaces are enabled in the catalog then you specify the OAuth providers for the spaces, **not** for the catalog as a whole. If you specify an OAuth provider in one space in a catalog, it is deployed to the gateway services across all spaces in that catalog.
    For more information about enabling and managing spaces, see Using syndication in API Connect.

    a. Click OAuth Providers in the catalog settings navigation pane.
    b. Click Edit, then select the OAuth providers that you want to use.
    To configure an OAuth provider, see either Configuring a native OAuth provider using Cloud Manager or Configuring a native OAuth provider using API Manager.

    c. Click Save when done.

18. Optional: Configure vanity API endpoints for your catalog.
    For any API, there are two possible endpoints to consider:
    - The gateway endpoint at which the API is invoked.
    - The endpoint that is visible to the consumer in the Developer Portal.

    If you do not configure vanity endpoints, these two endpoints are the same, and point to the gateway endpoint at which an API is invoked.
    To have an endpoint visible to the consumer that is different to the gateway endpoint, you configure a vanity endpoint. A vanity endpoint represents the endpoint by which an API is known externally; that is, the endpoint that is published to the Developer Portal and is used by an application developer to invoke the API. The way in which the gateway endpoints for an API are determined depends on the OpenAPI version of the API, as follows:

    (OpenAPI 2.0): For any enforced API in API Connect, the gateway endpoint formats for the API are as follows:
    - If the OpenAPI definition has no `host` field, the API endpoint has the following format:

      `https://gateway_service_host/provider_organization/catalog/basepath`

    - If the OpenAPI definition has a `host` field (for example, `petstore.com`), the host is appended to the path after the *provider_organization*/*catalog* segments, and the API endpoint has the following format:

      `https://gateway_service_host/provider_organization/catalog/host_field_value/basepath`

      Note: This is a change in behavior from IBM API Connect Version 5.0, where the `host` field is not included in the API endpoint.

    In these endpoint URLs, the variables are as follows:
    - *gateway_service_host* is the host name of the gateway service on which the API is running.
    - *provider_organization* is the value of the `name` field of the provider organization that contains the catalog in which the API is published.
    - *catalog* is the value of the `name` field of the catalog in which the API is published.
    - *basepath* is the value of the `basepath` field in the OpenAPI definition for the API.
    - *host_field_value* is the value of the host field in the OpenAPI definition for the API.

    For details on configuring the host server URL in an OpenAPI 2.0 API definition, see Specifying the host for an API.

    API Gateway only **(OpenAPI 3.0):** If the API is enforced by the DataPower API Gateway, the value specified for the first `url` entry in the `servers` array in the OpenAPI definition of the API is used to determine the `basepath` element of the API endpoint, as follows:
    a. If a relative URL is specified for the server URL, that value is used as-is for the `basepath`, and the API endpoint has the following format:

      `https://gateway_service_host/provider_organization/catalog/basepath`

    b. If a full URL is specified for the server URL, the scheme (`http://` or `https://`) is ignored by the DataPower API Gateway, and the remaining host name and `basepath` are used to form the API endpoint as follows:

`https://gateway_service_host/provider_organization/catalog/host_name/basepath`

In these endpoint URLs, the variables are as follows:

- *gateway_service_host* is the host name of the gateway service on which the API is running.
- *provider_organization* is the value of the **name** field of the provider organization that contains the catalog in which the API is published.
- *catalog* is the value of the **name** field of the catalog in which the API is published.
- *host_name* is the value of the host name in the server URL.
- *basepath* is the value of the **basepath** derived from the server URL.

For details on configuring the server URL in an OpenAPI 3.0 API definition, see Defining servers for an API, Defining servers for a Path, and Defining servers for an operation.

Note: You can change your catalog settings to use the IBM API Connect Version 5.0 endpoint behavior, including support for a feature known as *host to catalog mapping*, whereby an API can be invoked without having to include the provider organization or catalog in the URL path; see Retaining Version 5 vanity endpoint behavior in a Catalog.

To configure vanity API endpoints, so that you can publish endpoints that are different to these gateway endpoints, complete the following steps:

a. Click API Endpoints in the catalog settings navigation pane. The Vanity API Endpoint page opens.
b. Click Edit.
c. To display the current API base endpoint settings, select Display vanity endpoint.
d. Select the required Preference setting. Choose one the following settings:
   - Catalog priority: Any host defined in the OpenAPI definition of the API is ignored and all API endpoints always point to the endpoints that you define here. For example, suppose you define a vanity API endpoint, with Catalog priority preference, to be **https://prod.acme.com/**. Then the API endpoint will be **https://prod.acme.com/*basepath***.
     The way in which the **basepath** is determined depends on the OpenAPI version of the API, as follows:
     - **(OpenAPI 2.0):** The **basepath** is taken from the **basepath** field in the OpenAPI definition.
     - API Gateway only **(OpenAPI 3.0):** The **basepath** is taken from the first **url** entry in the **servers** array in the OpenAPI definition, ignoring any scheme (**http://** or **https://**) and host name.
   - API priority: The host defined in the OpenAPI definition for the API takes precedence. For example, suppose you define a vanity API endpoint, with API priority preference, to be **https://api.acme.com/**. Then the following rules determine the endpoint that is used when an API is called:
     - If the OpenAPI definition has a host defined, **test.acme.com** for example, then that value is used to determine the API endpoint. For example: **https://test.acme.com/*basepath***.
     - If the OpenAPI definition has no host defined, the API endpoint will be **https://api.acme.com/*basepath***, as determined by the vanity API endpoint setting.

     The way in which any defined host is determined depends on the OpenAPI version of the API, as follows:
     - **(OpenAPI 2.0):** The host is taken from the **host** field in the OpenAPI definition.
     - API Gateway only **(OpenAPI 3.0):** The host is taken from the host name in the first **url** entry in the **servers** array in the OpenAPI definition.
e. Supply one or more endpoints, as follows:
   - If you selected Catalog priority, click Add to enter one or more endpoints URLs, and an optional summary for each. Any of the endpoint URLs can be used to invoke an API.
   - If you selected API priority, enter the endpoint URL, and an optional summary.

Note: After configuring your catalog to support your vanity URL, you must configure your external network to map the vanity endpoints to the corresponding gateway endpoints. This typically includes the following:

- A DNS mapping to ensure that the vanity host resolves to the gateway.
- Additional URL routing for the API as required.

For example, if your gateway has a default domain name of **apigw.dc.zone.mycompany.com** and an IP address of **29.12.141.150**, then the generic DNS configuration might look like:

```
api.acme.com. CNAME apigw.dc.zone.mycompany.com.
```

or

```
api.acme.com. A 29.12.141.150
```

Consult your network administrator and the DNS provider's documentation to do this configuration.

19. To configure the TLS client profiles that are used with this catalog, complete the following steps:
    Note: If spaces are enabled in the catalog then you configure the TLS client profiles for the spaces, **not** for the catalog as a whole. If you configure a TLS client profile in one space in a catalog, it is deployed to the gateway services across all spaces in that catalog.
    For more information about enabling and managing spaces, see Using syndication in API Connect.

    a. Click TLS Client Profiles in the catalog settings navigation pane.
    b. Click Edit, then select the TLS client profiles that you want to use with this catalog.
       For details on how to create a TLS client profile, see Creating a TLS client profile.
    c. Click Save when done.
20. To configure the Developer Portal, complete the following steps:
    a. Click Portal in the catalog settings navigation pane, then click Create.
    b. Select the portal service that you want to use with this catalog.
       Portal services are configured by using the Cloud Manager UI. For details, see Registering a portal service.
    c. Optionally, override the default generated portal URL.
       The URL must have the following format:

       `https://host_name.portal.com`

       where *host_name.portal.com* must resolve to the IP address of the Developer Portal machine.
       For example:

       `https://myhost.mydomain.com`

       Important:
       - The URL must be unique across all catalogs.
       - Mixed-case names are supported for resource names; however, portal endpoint URLs can support only lower-case. If a provider organization is created with a mixed-case name, you must edit the default-generated portal URL to make the provider organization name lower-case in the URL.

       To use sub paths in your site URL, see Sub paths for Developer Portal sites.

d. Select the portal service that you want to use with this catalog.
For more information on using the Developer Portal, see Developer Portal: Socialize your APIs.

e. Click Create to save your changes.

Note: The account profile for the owner of the catalog must have an email address specified to receive the creation notification, otherwise the Developer Portal creation operation will fail. To check whether your account profile has an email address, and specify a value, complete the following steps:

a. Click the User icon, and then select My Account.
b. Check the contents of the Email field, and specify a value if necessary, then click Save.

Note: If you want to edit the portal service or URL, or delete the portal site, return to this portal settings page, click the options icon, and click Edit or Delete.

21. To define catalog properties, complete the following steps:
    a. Click Properties in the catalog settings navigation pane, then click Create.
    b. Enter the property Name and Value, then click Create.

    The properties that you define can be referenced in any of the API definitions in this catalog. It is also possible to define properties that are specific to an API definition; see Setting API properties. For information on how to reference a property in an API definition, see Variable references in API Connect.
    Note:
    - If you define a catalog property of the same name as an API property, the API property takes precedence over the catalog property.
    - If you change the value of a catalog property, any API that references that property must be republished for it use the new value.
22. Optional: To configure the visibility of products that are published to a catalog or a space, see Configuring Product visibility in a Catalog or a Space.

What to do next

Import your own policies into the catalog. For details, see Importing a user-defined policy into a catalog.
Note: When you import a policy, its implementation is imported into all Gateway devices associated with the Gateway service that hosts the catalog. Additionally, API Connect modifies some object names and file locations to mark them with the appropriate catalog name and policy version.
For more information about how to create and manage user-defined policies, see User defined policies.

Configuring Product visibility in a Catalog or a Space

How to configure the visibility of Products at the Catalog or Space level.

Before you begin

To configure Product visibility, you must be assigned to a role that has the Settings > Manage permission for that Catalog or Space. For more information on assigning Catalog permissions to a role, see Creating and configuring catalogs.

Note: All references in this topic to a Catalog can also be applied to a Space in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.

About this task

When you create a draft Product, you typically define the visibility in the Product document; see Specifying the visibility of your Product, and Creating a draft Product for details. If you don't define any visibility settings in the draft Product, then the visibility defaults to the following settings:

```
visibility: {
    view: {
        enabled: true,
        type: 'public',
        orgs: []
    },
    subscribe: {
        enabled: true,
        type: 'authenticated',
        orgs: []
    }
}
```

When the Product is published, the visibility that is defined in the draft Product can be overridden by using the Products view within a Catalog in the API Manager UI; see Changing the availability of a Product for more information.
From IBM API Connect 10.0.5.1, you can also define a Catalog or Space setting to control the visibility of Products that are published to that Catalog or Space, as described in the following instructions. When this Catalog or Space setting is enabled, it can be used for the following two purposes:

- The setting can ensure that any Product published to that Catalog or Space, cannot have a visibility setting that exceeds the visibility level set at the Catalog or Space level.
- The setting can also be used as the default visibility setting for all Products that are published to that Catalog or Space. To use the setting as the default visibility, you must ensure that the Product doesn't have any visibility set during the publish, either saved in the Product document, or set during the publish itself.

Product visibility is picked up in the following order of precedence: Product override - Product document - Catalog or Space setting - default setting.

Note: You can also modify the Catalog or Space visibility settings by using the API Connect REST APIs; see the API Connect REST API documentation.

Procedure

To modify the Catalog or Space visibility settings by using the developer toolkit CLI, complete the following steps.

1. Log in to your API Connect Management server as a member of a provider organization, by using the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

Where:
- *mgmt_endpoint_url* is the platform API endpoint URL.
- *user_id* is the user ID that you want to log in with. The user ID must be a member of a provider organization. This is an ID that you could also use to log in to the API Manager user interface.
- *password* is the password that is associated with the supplied user ID.
- *identity_provider* is the identity provider that is used to authenticate the supplied user ID.

For example:

```
apic login --server platform-api.myserver.com --username myuser --password mypassword --realm provider/myldap
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details on how to log in to your management server from the CLI, see Logging in to the management server.

2. Define your visibility settings by creating a YAML file with the following structure:

```
allowed_product_visibility: {
    view: {
        enabled: true_or_false,
        type: 'visibility_type',
        org_urls: [],
        group_urls: []
    },
    subscribe: {
        enabled: false,
        type: 'authenticated'
    }
}
```

Where, in the `view` section of the `allowed_product_visibility` property:
- `enabled` - can be set to `true` or `false`. The default setting is `false`.
  If set to `true` then any Product that is published to that Catalog or Space can have only a visibility that is the same or more restrictive than is configured in the `type` setting. If no visibility is set in the Product document, then the Catalog or Space setting is used as the default for the publish. If you want to always use the Catalog or Space setting as the default, then you must ensure that a Product visibility is not set.
  Note: If you are creating draft Products, and no visibility is set, then the value from the `allowed_product_visibility` field in the Sandbox Catalog is used as the default.
  If set to `false`, the feature is disabled, and the Product visibility settings that are defined in the Product document are used.
- `type` - if `enabled` is set to `true`, then this property specifies the maximum visibility of the Products that are published to this Catalog or Space. Valid settings are:
  - `public` - the Products are visible to all users.
  - `authenticated` - the Products are visible only to users who have successfully authenticated.
  - `custom` - the Products are visible only to the consumer organizations and consumer organization groups that are specified in `org_urls` and `group_urls`.
- `org_urls` - if `type` is set to `custom`, then this property specifies the URLs of the consumer organizations that you want the Products to be visible to. Otherwise, leave empty.
- `group_urls` - if `type` is set to `custom`, then this property specifies the URLs of the consumer organization groups that you want the Products to be visible to. Otherwise, leave empty.

The `subscribe` section is blocked at the Catalog or Space level, and cannot be edited. Subscribability is defined by the Product visibility setting, and is always more restrictive than the `view` section. For more information, see Specifying the visibility of your Product.

3. Modify your Catalog settings by using the following command:

```
apic catalog-settings:update --server mgmt_endpoint_url --catalog catalog_name --org organization_name filename
```

Where *filename* is the name of the YAML file that you created in step 2.

Note: If Spaces are enabled for the Catalog, then the visibility settings must be set at the Space level by using the `--space` option.

4. Confirm your updated Catalog settings by using the following command:

```
apic catalog-settings:get --server mgmt_endpoint_url --catalog catalog_name --org organization_name --output -
```

Related tasks

- Creating and configuring catalogs

Configuring sub paths for Developer Portal sites

You can increase the specificity of a IBM® API Connect Developer Portal site URL by using sub paths.

By adding additional text to the URL of a Developer Portal site, you can create more site permutations for an organization. Developer Portal site URLs must be unique across all Catalogs.

Important:

- Sub paths are case-sensitive.
- The Developer Portal host name must contain only **lowercase** characters.

You can create a Developer Portal in the following format:

`https://host_name.portal.com/sub_path_1/sub_path_2/.../sub_path_n`

Where *sub_path* can be any text that you want to implement to specify your site URL. There is no limit to the number of sub paths that you can have for the first site that you want to create.
However, you must not create overlaps in the naming of your URLs. A URL of one site must not be able to be confused with pages belonging to another site. For example, if you create the following site URL:

`https://host_name.portal.com/bank/safe/dollar`

Then, you cannot have the following site URL permutations:

`https://host_name.portal.com/bank/safe`

or

`https://host_name.portal.com/bank/safe/dollar/cent`

However, you can lengthen or shorten a site URL if you change a single sub path value, or the *host_name.portal.com* value. For example, if you created the following site URL:

`https://host_name.portal.com/bank/safe/dollar`

Then, you can create the following site URL permutations:

`https://host_name.portal.com/bank/euro`

and

`https://host_name.portal.com/bank/euro/vault/cent`

Important: If you already have a site URL that ends in *sub_path* texts, you cannot create a new site URL with the sub path text at the start.
For example, if you create the following site URL:

`https://host_name.portal.com/bank`

then, you cannot create the following site URL:

`https://bank.host_name.portal.com`

Managing Catalog membership

Manage Catalog membership by adding new users to the Catalog and assigning roles to the users.

Before you begin

To manage Catalog members in the API Manager, you must be assigned to a role that has the Member > Manage permission for that Catalog. For more information on assigning Catalog permissions to a role, see Creating and configuring catalogs.

About this task

The Catalog owner can invite members of the provider organization work with the Catalog in the API Manager. The invited users are called "Catalog members" and are different from consumer users who are members of consumer organizations.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Members tab.
3. To add an existing user, click Add > Add member. To add a new user, click Add > Invite member.
   If you are using the Add member option, you can add any user who is already a member of another Catalog, or of a Space, in the provider organization, and is neither currently a member of this Catalog, nor the Catalog owner.
4. Enter the email address of a new user, or search for, and select, an existing user.
5. Select the roles that you want to assign to the user.
   For details of the roles and the default permissions assigned to them, see API Connect user roles. For details on how to create your own roles, see Creating custom roles.

   If Spaces are enabled in the Catalog, any role that you assign to the user at the Catalog level is assigned automatically to the user in all Spaces in that Catalog. Furthermore, if a user had originally been assigned a role only in a specific Space in a Catalog and you subsequently assign the user that role at the Catalog level, the Space specific role assignment is lost and the user now has that role in all Spaces in the catalog.
   Note: You can subsequently change the roles assigned to a user by selecting or clearing the appropriate check boxes alongside that user on the Members tab. If a user was originally added to the provider organization, rather than to the Catalog itself, the following conditions apply:

- Any role assigned to the user at the provider organization level is assigned automatically to the user in all Catalogs, and cannot be removed at the Catalog level.
  For details on adding a user to a provider organization, see Adding provider organization users and assigning roles.
- In the Catalog, the user has the permissions that are configured for the role at the Catalog level.
- Any role that hasn't been assigned to the user at the provider organization level can be assigned to the user at the Catalog level.

6. If you are adding an existing user, click Add. If you are adding a new user, click Invite.

Importing a user-defined policy into a Catalog

You can make your user-defined policy available to API developers by importing it into an IBM® API Connect Catalog, or a Space in a Catalog.

About this task

For instructions, see Defining, packaging, and publishing a catalog-scoped policy for the API Gateway.

Importing an OpenAPI extension into a Catalog

You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An extension is imported into a Catalog, or a Space in a Catalog, then added to the API schema.

Before you begin

You must possess Catalog edit permissions to complete this task.

About this task

This task describes how to import an OpenAPI extension into a Catalog by using the browser based API Manager user interface. Alternatively, you can use the developer toolkit CLI; see Working with OpenAPI extensions.

For an example of an extension schema file, see Referring to an extension in an API definition.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
3. Click the Catalog settings tab if you are working in a Catalog, or the Space settings tab if you are working in a Space.
4. Click Gateway services.
5. Alongside the Gateway service that you want to work with, click the options icon and then click View extensions.
6. Click Upload then upload the extension file as indicated, either by dragging and dropping the file, or by browsing and selecting it. The extension schema file will be either a JSON or YAML file.
7. Click Upload when done.

Results

The user-defined extension is now imported into a Catalog or Space, and can be used when developing an API by using the API editor in either the API Designer or the API Manager user interface.

What to do next

Add the OpenAPI extension to your APIs as required; see Adding an OpenAPI extension to an API.

Retaining Version 5 vanity endpoint behavior in a Catalog

The behavior of vanity endpoints in a Catalog has changed in API Connect Version 10 compared with Version 5. However, you can modify your Catalog settings to retain the Version 5 behavior.

About this task

A vanity endpoint represents the endpoint by which an API is known externally; that is, the endpoint that is published to the Developer Portal and is used by an application developer to invoke the API.

You can modify your Catalog settings to define vanity endpoints that retain the API Connect Version 5 behavior.

You can modify the Catalog settings in either of the following ways:

- Use the API Manager user interface.
- Use the developer toolkit CLI.

You can also use the API Connect REST APIs; see the API Connect REST API documentation.

Procedure

- To modify the Catalog settings to retain Version 5 vanity endpoint behavior by using the API Manager user interface, complete the following steps:
  1. Click API Endpoints in the Catalog settings navigation pane. The Vanity API Endpoint page opens.
  2. Click Edit, then select v5 legacy behavior.
  3. To use the API Connect URLs, select Use gateway URLs. To configure a vanity endpoint, select Display vanity endpoint then provide the following information:
     - Endpoint: The URL of your vanity endpoint.
     - Gateway Uri: The URL of the gateway service that is enabled in the Catalog and is associated with the vanity endpoint; select from the list provided.
     - Summary: An optional description of the vanity endpoint.
- To modify the Catalog settings to retain Version 5 vanity endpoint behavior by using the developer toolkit CLI, complete the following steps:
  1. Log in to your API Connect Management server as a member of a provider organization, by using the following command:

     ```
     apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
     ```

     where:
     - *mgmt_endpoint_url* is the platform API endpoint URL.
     - *user_id* is the user ID that you want to log in with. The user ID must be a member of a provider organization. This is an ID that you could also use to log in to the API Manager user interface.
     - *password* is the password associated with the supplied user ID.
     - *identity_provider* is the identity provider that is used to authenticate the supplied user ID.

     For example:

     ```
     apic login --server platform-api.myserver.com --username myuser --password mypassword --realm provider/myldap
     ```

     You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

     ```
     apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
     ```

     For example,

     ```
     apic identity-providers:list --scope provider --server myserver.com --fields title,realm
     total_results: 2
     results:
       - title: Cloud Manager User Registry
         realm: provider/default-idp-2
       - title: Corporate LDAP user registry
         realm: provider/corporate-ldap
     ```

     The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
     For full details on how to log in to your management server from the CLI, see Logging in to the management server.

  2. Define the configuration for your vanity endpoint by creating a YAML file with the following structure:

     ```
     legacy_endpoint_behavior: enabled
     v5_endpoint_substitution_behavior:
       base_endpoints:
         - endpoint: vanity_enpoint_url
           description: description
           gateway_service_url: gateway_service_url
       unenforced_api_base_endpoint: unenforced_api_base_endpoint
     ```

     where:

     - the `legacy_endpoint_behavior: enabled` setting specifies that the Catalog retains API Connect Version 5 behavior. A Catalog can support either Version 5 behavior or Version 10 behavior but not both.
     - *vanity_enpoint_url* is the URL of your vanity endpoint.
       Note: API Connect Version 5 supports only the host name in a vanity endpoint URL; a URL of the form `https://host_name/path` is not supported. Therefore the vanity endpoint URL that you supply here must contain only a host name; for example, `https://vanity.com`.
     - *description* (optional) is a description of your vanity endpoint.
     - *gateway_service_url* is the URL of the gateway service that is enabled in the Catalog and is associated with the vanity endpoint.
       Note: You can determine the gateway service URL by using the following command:

       ```
       apic configured-gateway-services:list --scope catalog --catalog catalog_name --server mgmt_endpoint_url --org organization_name
       ```

       where:
       - *gateway_service_name* is the name of the gateway service.
       - *catalog_name* is the name of the Catalog.
       - *organization_name* is the name of the provider organization that contains the Catalog.

       The command output lists all the gateway services that are enabled in the Catalog, together with their gateway service URLs.

     - *unenforced_api_base_endpoint* (optional) is a custom API URL that specifies the URL for APIs that are deployed to a third party gateway.

     Note: `base_endpoints:` is an array. You can configure multiple vanity endpoints by defining multiple `endpoint:` entries.
  3. Modify your Catalog settings by using the following command:

     ```
     apic catalog-settings:update --server mgmt_endpoint_url --catalog catalog_name --org organization_name filename
     ```

     where *filename* is the name of the YAML file that you created in step 2.

4. Confirm your updated Catalog settings by using the following command:

```
apic catalog-settings:get --server mgmt_endpoint_url --catalog catalog_name --org organization_name --output -
```

Using syndication in API Connect

With the API Connect syndication feature, you can partition your catalogs into *Spaces*. Each space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that space, enabling each team to manage their APIs independently.

When you stage or publish an API to a catalog that has spaces enabled, you specify the space within that catalog that you want to stage or publish to. However, application developers that access the Developer Portal for the catalog are unaware of the space partitioning of the catalog and see the APIs as a coordinated offering.

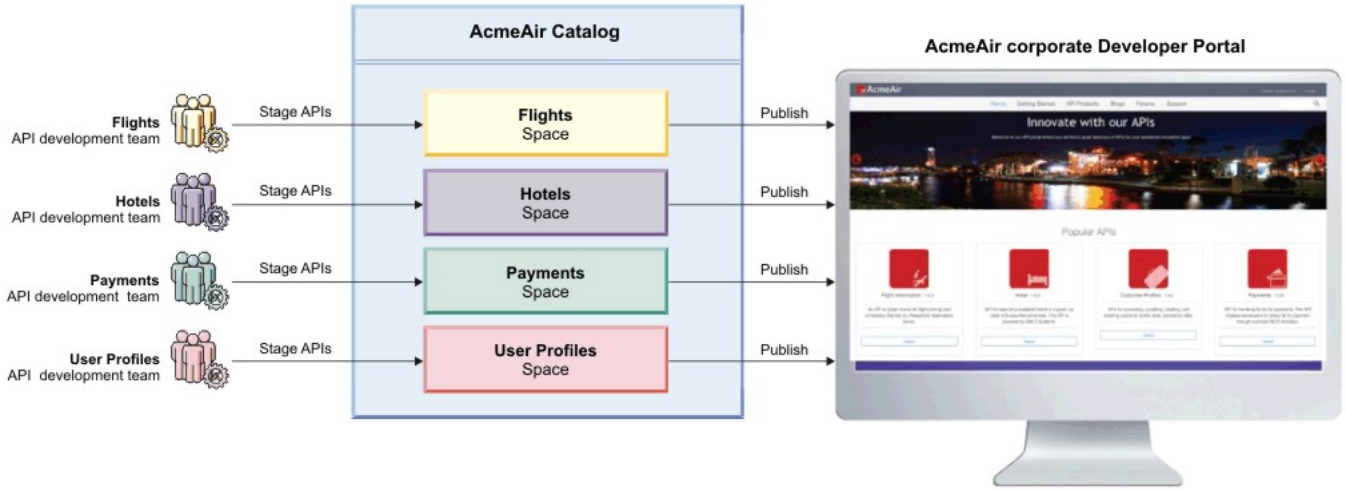
Each space has its own product lifecycle management, subscription approvals, and analytics data. You use space specific access control to restrict user access to each space; for example, a developer in the Flights team is able to stage APIs only to the Flights space.

Example

A travel company, AcmeAir, has separate API provider development teams for each of the following areas of their business:

- Flights
- Hotels
- Payments
- User Profiles

They have an AcmeAir corporate catalog, with its associated corporate Developer Portal. They partition their catalog into separate spaces, one for each development team.



Spaces are described in detail in the following sections:

- **Enabling Spaces in a Catalog**
  To use the syndication feature in IBM API Connect, you must enable Spaces in any Catalog in which you require syndication capabilities.
- **Creating, modifying, and deleting Spaces**
  You use the API Manager user interface to create a new Space in a Catalog, modify the configuration, and owner of a Space, and delete a Space from a Catalog.
- **Working with Spaces**
  If Spaces are enabled in an IBM API Connect Catalog, you can select a specific Space to work with in the API Manager user interface. This enables you to manage the Products and APIs that are specific to that Space, and control user access to the Space.

Enabling Spaces in a Catalog

To use the syndication feature in IBM® API Connect, you must enable Spaces in any Catalog in which you require syndication capabilities.

Before you begin

If Spaces are enabled for a Catalog, Products (and their associated APIs) can be published only to a Space within that Catalog. For information about publishing, see Staging a Product for publishing by using the API Designer, and see Publishing APIs for publishing by using the developer toolkit.

Note: You cannot enable Spaces in a Catalog to which one or more Products have already been staged or published. If the Catalog does contain staged or published Products, first complete the following steps for each Product in the Catalog:

1. Remove all staged Products.
2. Retire, then remove, all published Products.

After enabling Spaces, re-stage or re-publish Products, and re-create application subscriptions, as required.

About this task

By default, Spaces are disabled in a Catalog. You enable Spaces by modifying the Catalog settings. After Spaces are enabled for a Catalog, a default Space is automatically created that inherits all of the configuration settings from the Catalog.

Note: You can also enable Spaces by using the developer toolkit CLI; for details, see apic spaces.

Procedure

To enable Spaces in a Catalog, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Catalog settings tab.
3. Set the Spaces slider control to the On position.
4. In the Enable Spaces window, click Enable.

Results

Spaces are enabled for your Catalog, and a default Space is created that automatically inherits all of the configuration settings from the Catalog. The Catalog owner is also the owner of the default Space.

What to do next

You can modify Space settings, and create more Spaces; see Creating, modifying, and deleting Spaces and Working with Spaces for more information.

Creating, modifying, and deleting Spaces

You use the API Manager user interface to create a new Space in a Catalog, modify the configuration, and owner of a Space, and delete a Space from a Catalog.

Before you begin

Navigate to the Spaces page of the Catalog containing the Space you want to work with, by completing the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.

Note: You can also enable Spaces by using the developer toolkit CLI; for details, see apic spaces.

Procedure

- To create a new Space, complete the following steps:
  1. Click Add > Add a new Space.
  2. In the Space Details window, enter the Title of the Space and, optionally, a descriptive summary. A Name is entered automatically.
     Note: The value in the Name field is a single string that is used to identify the Space in developer toolkit CLI commands. The Title is used for display.
     To view the CLI commands to manage Spaces, see apic spaces.
  3. Click Create to create the Space.

  Note:
  - As the user who creates the Space, you are automatically the Space owner and have all Space permissions.
  - When you create a new Space, it does not automatically inherit all of the configuration settings from the Catalog. So you should check and modify the settings as necessary.
- To modify the details of a Space, complete the following steps:
  1. On the Spaces page, select the Space whose details you want to modify, then click Space settings.
  2. Use the options in the navigation pane to modify the details as required.
     The following types of resource can be enabled in a Space:
     - Gateway services
     - API user registries
     - OAuth providers
     - TLS client profiles

     Note:
     - If you enable a resource of any of the following types in one Space in a Catalog, it is deployed to the gateway services across all Spaces in that Catalog:
       - API user registries
       - OAuth providers
       - TLS client profiles
     - If you deploy any of the following types of resource to a gateway in a Space, it is actually deployed to the gateway at Catalog scope:
       - Custom policy
       - Global policy
       - Global policy pre-hook
       - Global policy post-hook
       - Gateway extension
- To change the owner of a Space, complete the following steps:
  1. On the Spaces page, select the Space whose details you want to modify.
  2. Click the Space settings tab to open the Space details page, then click Edit.
  3. From the Select owner user drop-down menu, select the user who will become the new owner.
  4. Click Save when done.

  Note:

- To have permission to change the Space owner, you must be either the Catalog owner, the Space owner, or the owner of the provider organization that contains the Space.
- When the ownership changes, the new owner is assigned administration privileges for the Space, and the previous owner has their administration privileges removed. If required, you can restore the privileges to the previous owner as described in Managing Space membership.
- The ownership can be transferred only to a user who is already a member of the Space or Catalog. To transfer to a new user or another existing user, that user must previously have been added or invited to the Space, as described in Managing Space membership, or to the Catalog, as described in Managing Catalog membership.

- To delete a Space, complete the following steps:
  1. On the Spaces page, click the Manage icon ⋮ for the Space that you want to delete.
  2. Click Delete, then click Confirm to confirm deletion.

  Note:
  - You cannot delete a Space to which one or more Products have been staged or published.
  - If there is only one Space in a Catalog, you cannot delete it, but you can disable Spaces for the Catalog.
    However, you cannot disable Spaces in a Catalog to which one or more Products have already been staged or published. If any of the Spaces in the Catalog do contain staged or published Products, first complete the following steps for the Products in each of the Spaces:
    1. Remove all staged Products.
    2. Retire, then remove, all published Products.

    Then, to disable Spaces for the Catalog, complete the following steps:
    1. Click the Catalog settings tab in the Catalog.
    2. Set the Spaces slider control to the Off position.

    After disabling Spaces, re-stage or re-publish Products, and re-create application subscriptions, as required.

Working with Spaces

If Spaces are enabled in an IBM® API Connect Catalog, you can select a specific Space to work with in the API Manager user interface. This enables you to manage the Products and APIs that are specific to that Space, and control user access to the Space.

Procedure

To work with a Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.

What to do next

For details of the Space management tasks, see the following subtopics:

- **Managing Products in a Space**
  If Spaces are enabled in an IBM API Connect Catalog, you can use the API Manager user interface to separately manage the Products that are staged or published to each Space.
- **Managing subscription requests in a Space**
  If Spaces are enabled in an IBM API Connect Catalog, you can approve, or deny, individual requests to subscribe to Plans in Products that are published to the Space.
- **Managing application subscriptions in a Space**
  If Spaces are enabled in an IBM API Connect Catalog, you can use the API Manager user interface to separately manage the application subscriptions to Plans in the Products that are published to a Space.
- **Managing Space membership**
  If Spaces are enabled in an IBM API Connect Catalog, you can manage the members within the Space. You manage Space membership by adding new users to the Space and assigning roles to the users.
- **Managing user access in a Space**
  If Spaces are enabled in an IBM API Connect Catalog, you can manage the access that users have within the Space. You manage access by specifying the permissions that are assigned to user roles.
- **Managing Gateways in a Space**
  If Spaces are enabled in a Catalog, you can separately control which Gateway services are used by each of the Spaces in the IBM API Connect Catalog.

Managing Products in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can use the API Manager user interface to separately manage the Products that are staged or published to each Space.

Before you begin

To manage Products in a Space in the API Manager UI, a user must be assigned a role that has the Products > Manage permission. For more information on assigning Space permissions to a role, see Managing user access in a Space.

Procedure

To manage the Products that are staged or published to a specific Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.

What to do next

For details of the management tasks that you can perform on the Products in the Space, see Working with Products.

Managing subscription requests in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can approve, or deny, individual requests to subscribe to Plans in Products that are published to the Space.

Before you begin

To manage Space subscription requests in the API Manager UI, a user must be assigned a role that has the Subscription Approvals > Manage permission. For more information on assigning Space permissions to a role, see Managing user access in a Space.

Procedure

To manage the subscription requests in a Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.
4. Click the Tasks tab.
   The Tasks page lists only the subscription requests for the selected Space.

What to do next

For details on how to manage approvals, see Approving Product lifecycle and subscription requests.

Managing application subscriptions in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can use the API Manager user interface to separately manage the application subscriptions to Plans in the Products that are published to a Space.

Before you begin

To manage application subscriptions in the API Manager UI, a user must be assigned a role that has the Subscriptions > Manage permission. For more information on assigning Space permissions to a role, see Managing user access in a Space.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.
4. In the navigation pane of the API Manager UI, click the Applications tab.
   All applications that have been registered in the Developer Portal associated with this Space are listed.
5. Click the options icon ⋮ alongside the application you want to work with, then click View Subscriptions.

What to do next

For details of the management tasks that you can perform on application subscriptions in a Space, see Working with application subscriptions.

Managing Space membership

If Spaces are enabled in an IBM® API Connect Catalog, you can manage the members within the Space. You manage Space membership by adding new users to the Space and assigning roles to the users.

Before you begin

To manage Space members in the API Manager UI, a user must be assigned a role that has the Child > Manage permission for the Catalog that contains the Space. For more information on assigning Space permissions to a role, see Managing user access in a Space.

About this task

Note: You can add the same user to two or more Spaces and assign different roles in each, allowing a user to have differing levels of access in different Spaces.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.
4. Click the Members tab.
5. To add an existing user, click Add > Add member. To add a new user, click Add > Invite member.
   If you are using the Add member option, you can add any user who is already a member of another Space, or of a Catalog, in the provider organization, and is neither currently a member of this Space, nor the Space owner.
6. Enter the email address of a new user, or search for, and select, an existing user.
7. Select the roles that you want to assign to the user.
   For details of the roles and the default permissions assigned to them, see API Connect user roles. For details on how to create your own roles, see Creating custom roles.

   If a user was originally added either to the provider organization, or to the Catalog that contains the Space, rather than to the Space itself, the following conditions apply:
   - Any role assigned to the user at the provider organization or Catalog level is assigned automatically to the user in all Spaces, and cannot be removed at the Space level.
     For details on adding a user to a provider organization, see Adding provider organization users and assigning roles.

     For details on adding a user to a Catalog, see Managing Catalog membership.
   - In the Space, the user has the permissions that are configured for the role at the Space level.
     For details on configuring role permissions for a Space, see Managing user access in a Space.
   - Any role that hasn't been assigned to the user at the provider organization or Catalog level can be assigned at the Space level

   Note: You can subsequently change the roles assigned to a user by selecting or clearing the appropriate check boxes alongside that user on the Members page.
8. If you are adding an existing user, click Add. If you are adding a new user, click Invite.

Managing user access in a Space

If Spaces are enabled in an IBM® API Connect Catalog, you can manage the access that users have within the Space. You manage access by specifying the permissions that are assigned to user roles.

Before you begin

To manage Space permissions in the API Manager UI, a user must be assigned a role that has the Child > Manage permission for the Catalog that contains the Space. For information on adding users to a Space and assigning user roles, see Managing Space membership.

Procedure

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.
4. Click the Space settings tab.
5. Click Roles, click the options icon ⋮ alongside the role whose permissions you want to modify, then click Edit.
6. Select the required permissions, then click Save.

Related tasks

- Creating custom roles

- API Connect user roles

Managing Gateways in a Space

If Spaces are enabled in a Catalog, you can separately control which Gateway services are used by each of the Spaces in the IBM® API Connect Catalog.

Before you begin

To manage Space Gateway settings in the API Manager UI, a user must be assigned a role that has the Child > Manage permission for the Catalog that contains the Space. For information on adding users to a Space and assigning user roles, see Managing Space membership.

About this task

Note: If Spaces are enabled in a Catalog then you configure the Gateway settings for each Space separately, **not** for the Catalog as a whole.

Procedure

To manage the Gateway settings for a Space, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Click the Spaces tab.
3. Select the space that you want to work with.
4. Click the Space settings tab.
5. Click Gateway services.
   The Gateway services that are currently enabled for the Space are listed.
6. To change the Gateway service configuration for the Space, click Edit, then select which Gateway services you want the Space to use.
7. Click Save to save your changes.

Related information

- Configuring the initial Gateway service

Working with Products

In IBM API Connect, Plans and APIs are grouped together in Products.

Information about managing Products in the API Manager UI can be found in the following topics.

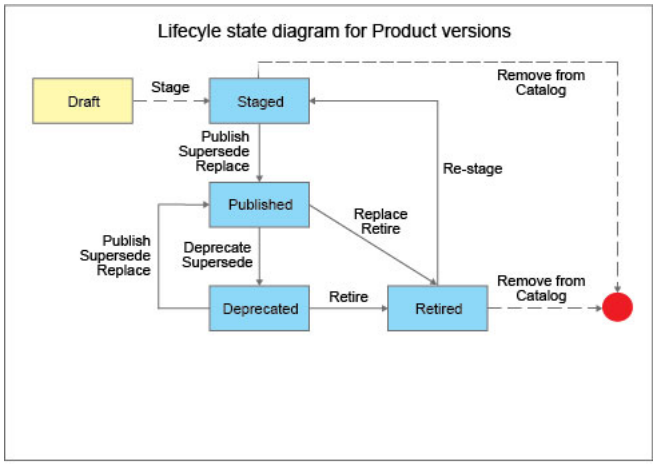
- **The Product lifecycle**
  When you manage your Product versions, you move them through a series of lifecycle states. From initially staging a Product version to a Catalog, through to publishing to make the Product version available to your application developers, and to eventual retiring and archiving. The syndication feature in IBM API Connect means that Product lifecycle states can also be managed within Spaces in the associated Catalog.
- **Monetizing your Products**
  In addition to offering free Plans for your customers to use your Products, you can also define Plans that automatically bill your customers who are using your Products in IBM API Connect.
- **Managing your Products**
  You can manage your products in API Manager by using the Products page of the associated catalog. In this view, you can move the products through their lifecycle, display analytics information, and control who can see or subscribe to the products. The syndication feature in IBM API Connect means that products can also be managed by using the Products tab of the associated space.

The Product lifecycle

When you manage your Product versions, you move them through a series of lifecycle states. From initially staging a Product version to a Catalog, through to publishing to make the Product version available to your application developers, and to eventual retiring and archiving. The syndication feature in IBM® API Connect means that Product lifecycle states can also be managed within Spaces in the associated Catalog.

Product lifecycle state diagram

The following diagram shows the possible lifecycle states for a Product version, and the Product management operations that move a Product version from one lifecycle state to another. For example, the Retire operation moves a Product version from the Published to the Retired state.



Note: The same Product lifecycle states apply irrespective of whether your Product is managed within a Catalog, or within a Space in a Catalog. For more information about the syndication feature, see Using syndication in API Connect.

If approval is required for a Product management operation, an approval request is sent and the Product version moves to the pending state. When the request is approved, the operation is completed and the Product version moves to the next lifecycle state. If approval is not required, the operation is completed immediately.
Note: Approval is not required for the following lifecycle state transitions:

- Retired to Staged.
- Deprecated to Published.

For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.
Note:

- Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
- Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
- You can view the history of Product lifecycle requests and approvals, by clicking the options icon ⋮ alongside the Product that you want to work with, and selecting View Approval History.

The following sections describe the various lifecycle states for a Product version.
Note: All references in this topic to a Catalog, can also be applied to a Space in a Catalog, unless specified otherwise.

Draft

The draft state for a Product or API is when a Product or API definition is not deployed and is not associated with any Catalog.

Staged

When you stage a Product, a copy of the Product version is deployed to the target Catalog. Staged is the initial state when you publish a Product. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers. For more information about staging a Product, see Staging a Product.

You stage a Product so that the appropriate approvals, internally within the organization, can be given for it to then be published. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests. For information on publishing a Product, see Publishing a Product.

Published

When you publish a Product, a fixed copy of the Product version is deployed to the target Catalog. The Product version is visible to, and subscribable by, the targeted developers or communities. When a Product is published in a Catalog, the visibility and subscription settings can be changed for the published version of that Product. Any further changes require a new version of the Product to be staged and published before they take effect.

If you replace a Published Product with a Staged or Deprecated Product, the replacement Product is published, and the replaced Product is retired.

If you supersede a Published Product with a Staged or Deprecated Product, the superseding Product is published, and the superseded Product is deprecated.

For more information about publishing a Product, see Publishing a Product.

Note: If you want to update a Product, you must republish it. The `products:update` command only updates a Product's metadata.

Deprecated

When you deprecate a Product, the Product version is visible only to developers whose applications are currently subscribed. No new subscriptions to the Plans in the Product are possible. For more information about deprecating Products, see Deprecating a Product.

A Product is also deprecated if you supersede it with another Product. For more information, see Superseding a Product with another Product.

Retired

When you retire a Product, the Product version can neither be viewed nor can its Plans be subscribed to, and all of the associated APIs are taken offline. For more information about retiring Products, see Retiring a Product.

A Product is also retired if you replace it with another Product. For more information, see Replacing a Product with another Product.

Monetizing your Products

In addition to offering free Plans for your customers to use your Products, you can also define Plans that automatically bill your customers who are using your Products in IBM® API Connect.

API Connect includes a subscription billing feature that allows API providers to define pricing Plans in their API Products, and monetize their API offerings. If a Product contains a pricing Plan, API consumers must enter their payment information into the Developer Portal before they can subscribe to that Plan.

API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product Plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.

You can define both free Plans and paid Plans within the same Product. To charge your customers more for greater access to your APIs, you can create multiple Plans with different tiers of prices and rate-limits. For example, an introductory Plan might have a low monthly price and restrictive rate-limiting, while a higher tier Plan might couple a higher monthly price with less restrictive rate limiting controls. Your customers can then select the Plan that is appropriate for their usage rates. As your customers have different needs for the use of your Products, so you can offer different levels of service. For example, a smaller customer might need a rate of only 5 API calls per hour, whereas a larger company might need a rate of 1000 API calls per hour. You can create the Plans that are appropriate for your customers, and they can subscribe to the service and pricing Plan that is appropriate for them.

Restriction: The following limitations apply to the subscription billing feature:

- Billing and monetization requirements vary by country, where IBM and the independent cloud billing provider, Stripe, cannot guarantee every country requirement is supported. Country requirements change, and are out of scope for this document. Some limitations on storing and passing fields to the Stripe billing provider might exist, when fields are unique to a subset of countries. For example, the passing of a billing address from API Connect to Stripe, which is required by some EU countries due to GDPR and taxation laws, is not currently supported.
- Two data center disaster recovery configurations including the optional billing microservice are not supported at this time.
- After a configured billing resource is in use by a Catalog, it might not be possible to remove it. Do not add your Stripe test keys to production Catalogs. If you want to prototype with your non-production Stripe keys, create a separate temporary Catalog.
- If an API consumer deletes their payment method, or their credit card expires, or their card is out of credit after they have initially subscribed and prepaid for their first month, there is no mechanism to alert the provider organization or suspend API access automatically in response. Provider organizations can monitor their Stripe dashboards for non-payment events and, if necessary, notify the consumer, suspend the application for that subscription, or cancel the API Connect subscription manually. The URL of the API Connect subscription is saved in the metadata of the Stripe subscription object, to assist in reverse lookups.
- Suspending an application does not automatically pause the billing cycles of the subscriptions for that application.
- You can republish a Product that includes billing only when the Catalog Production mode is set to On.

Though much of the procedure is the same for setting up a paid Plan and a free Plan, there are some extra actions that are needed before you can start defining paid Plans. See the following topics for more information:

1. First, you must configure a billing integration resource for your provider organization; see Adding a billing integration resource.
2. Before you can publish a Product Plan with pricing to a Catalog, you must add your billing integration resource to that Catalog; see Adding a billing integration resource to a Catalog.
3. Also before you can publish to a Catalog, an administrator must enable the Stripe payment method module in the Developer Portal for that Catalog; see Configuring Stripe in the Developer Portal.
4. After the Catalog and Developer Portal are configured, you can create Products that include pricing Plans; see Defining a Product with billing integration.

Note:

- Before you can create billing resources in provider organizations, the billing microservice must be enabled on your management system by your system administrator. See Configuring monetization on VMware and Configuring monetization on Kubernetes for more information.
- You can also create and manage billing integration resources by using the developer toolkit CLI. For more information, see Command-line tool reference for the developer toolkit.

Adding a billing integration resource

To enable the monetization of your Product Plans, you must add a billing integration resource in your IBM® API Connect provider organization that defines the configuration data needed to synchronize with an external subscription billing system.

Before you begin

To use Stripe as your credit card processing vendor, you must have port 443 open to HTTPS communication between the Stripe API and your Developer Portal management and the Management cluster servers. See Firewall requirements on Kubernetes and Firewall requirements on VMware for more information about this requirement.

Before you can create billing resources in provider organizations, the billing microservice must be enabled on your management system by your system administrator. See Configuring monetization on VMware and Configuring monetization on Kubernetes for more information.

You must either be the provider organization owner, or have `Settings: Manage` permissions, to complete this task.

You must have an account with Stripe to be able to complete this task. If you do not already have a Stripe account, you can set one up at: www.stripe.com.

About this task

API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product Plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system. When API consumers subscribe to Product Plans with billing in the Developer Portal, they set up automatic payments through a credit card registered with Stripe. To enable this billing process, you must first specify your Stripe account information by creating a billing integration resource. The subscription payment amount is processed from the account that is provided by the API consumer, and credited to the account that you provide as the API provider.

Important: Each Stripe account comes with two sets of API keys, one for testing, and one for production. Each set of API keys has a distinct namespace for Stripe objects. Test API keys cannot see objects created by production API keys, and vice versa. You cannot switch the API keys of one of your billing integrations with the keys from another account, or swap your test and production keys over, as that would prevent API Connect from resolving the Stripe objects that were created by using the old keys. If you want to use your Stripe test keys, you must create a separate Catalog for testing, and not add your Stripe test keys to production Catalogs.

Procedure

To create a billing integration resource, complete the following steps:

1. In the API Manager, click Resources.
2. Ensure that you are in the provider organization to which you want to add the billing integration.
3. Select Billing, and then click Add.
   The Add billing integration page for Stripe integration is displayed.
4. Enter a Title for your billing integration.
5. The Name is auto-generated based on the Title that you enter, and is a single string that can be used in developer toolkit CLI commands.
6. Enter the Publishable key and Secret key for your Stripe account.
   Refer to your Stripe dashboard to get your publishable key and secret key; see https://dashboard.stripe.com/apikeys.
7. Click Add to create your billing integration resource.

Results

Your new billing integration resource is listed in the table on the Billing dashboard. The table also displays the state of the job queue for the billing integration. Any issues with the job queue are displayed in this table. See Billing integration resource job queues for more information.

What to do next

To be able to publish monetized Product Plans, you must add the billing integration resource to your Catalog, and to the Sandbox Catalog. See Adding a billing integration resource to a Catalog for details.

- Troubleshooting your billing configuration

Billing integration resource job queues

Billing integration resources use job queues to manage the bulk Product lifecycle operations in IBM® API Connect.

Subscription billing systems such as Stripe, typically provide APIs that support updating a single resource at a time. However, IBM API Connect has Product lifecycle operations that can modify many resources in a single transaction, such as migrating a set of subscriptions from one Product to another Product. In order to bridge the mismatch between these two APIs, API Connect adds a job queue to each billing integration resource in your provider organization. Jobs on this queue are responsible for mapping bulk operations to a series of API calls against the subscription billing system. Jobs run one at a time, in the order that they were created. When a job completes it's deleted from the queue, and the next job runs. When all of the jobs in the queue complete running and the queue is empty, the data model of the subscription billing system should be up-to-date with the changes made in API Connect.

There are potential issues when moving this type of synchronization to background jobs. Network connectivity, outages at the billing provider, or rolling of the API keys of the billing system, could all cause the job queue to be blocked if the root issue does not resolve by itself in the span of an hour. If a job encounters an error, such as a network connectivity error, the job is retried up to five times over the course of 70 minutes, before changing the state of the job from Running to either Blocked or Failed. Only when the state of the head job is blocked or failed, will the Retry Blocked Jobs action appear in the options menu. So if an error is shown but the job is still attempting to run, you need to wait up to 70 minutes before the Retry Blocked Jobs action appears.

The job queue status can be viewed in the table on the Billing dashboard. The table lists any blocked jobs, and the error that is blocking them. If the error indicates that your API keys are no longer valid, you must update your billing resource to contain the correct values. After the root cause is resolved, you can click the ⋮ options menu on the row of the billing integration resource, and click Retry Blocked Jobs. This action retries the jobs on the job queue. After a few minutes the number of jobs should go down. Note that you can click the Refresh icon ↻ to refresh the results from the server.

- Monetizing your Products

Adding a billing integration resource to a Catalog

To be able to publish monetized Product Plans, you must add a billing integration resource to your Catalogs.

Before you begin

You must have created a billing integration resource. See Adding a billing integration resource for details.

You must either be the provider organization owner, or have `Settings: Manage` permissions, to complete this task.

About this task

Before you can publish any Products that include pricing Plans, you must add the billing integration resource to the Catalog where you will create the monetized Products. When API consumers subscribe to Product Plans with billing in the Developer Portal, they set up automatic payments through a credit card registered with Stripe. To enable this billing process, after you have specified your Stripe account in a billing integration resource, you must then apply that resource to your Catalogs. The subscription payment amount is processed from the account that is provided by the API consumer, and credited to the account that is provided in the billing integration resource.

Note:

- Before you can publish a monetized Product Plan to a Catalog, the Stripe payment method module in the Developer Portal must also be enabled; see Configuring Stripe in the Developer Portal.
- Each Stripe account comes with two sets of API keys, one for testing, and one for production. Each set of API keys has a distinct namespace for Stripe objects. Test API keys cannot see objects created by production API keys, and vice versa. You cannot switch the API keys of one of your billing integrations with the keys from another account, or swap your test and production keys over, as that would prevent API Connect from resolving the Stripe objects that were created by using the old keys. If you want to use your Stripe test keys, you must create a separate Catalog for testing, and not add your Stripe test keys to production Catalogs.

Procedure

To add a billing integration resource to a Catalog, complete the following steps:

1. In the API Manager, click Manage.
2. Select the Catalog tile on the Manage page that you want to update, then click the Catalog settings tab.
3. Select Billing, and then click Edit.
4. Select the billing integration resource that you want to apply to the Catalog, and click Save. You should apply only one billing integration resource to each production Catalog.
   The billing integration resource is now listed in the Billing section.
   Note: More than one billing resource can be applied to the Sandbox Catalog.

Results

The billing integration resource is added to the Catalog.

What to do next

The Stripe payment method module must be enabled in the Developer Portal for that Catalog; see Configuring Stripe in the Developer Portal for details.

After both the Catalog and the Developer Portal are configured, you can create Products with pricing Plans. See Defining a Product with billing integration for more information.

- Troubleshooting your billing configuration

Defining a Product with billing integration

To monetize your APIs, you must create Product Plans with pricing information that allow API consumers to subscribe to your Plans with integrated billing.

Before you begin

You must have a billing integration resource, and this resource must be added to the Catalog that you want to publish your Product to, as well as to the Sandbox Catalog. See Adding a billing integration resource, and Adding a billing integration resource to a Catalog for details.

Also, the Stripe payment method module must be enabled in the Developer Portal for the Catalog; see Configuring Stripe in the Developer Portal for details.

About this task

When you decide to charge customers to use your API Products, your customers have different requirements for the number of API calls that they are willing to pay for. You can solve this issue by defining Plans at different levels of service, and at different costs.

Within your Product, you can define free Plans as well as Plans that contain billing integration. The following instructions guide you through defining a Plan with pricing information. For more detailed information about creating Products, see Creating a draft Product and Editing a draft Product.

Important: Products that contain a billing integration cannot be re-staged into non-production Catalogs. To experiment with billing on the Sandbox Catalog, or any other non-production Catalogs, you must publish new versions of your monetized Product. This practice aligns with how you have to work with production Catalogs currently, as they also don't support the re-staging of existing versions of the same Product.

Procedure

To add pricing information to a Product Plan, complete the following steps:

1. In the API Manager, click Develop.
2. Select the Products tab.
3. Select the Product that you want to add billing integration to, or create a new draft Product by clicking Add > Product and following the wizard.
4. With the Product open and the Design tab selected, select Plans in the navigation menu.
5. In the Billing integration section, select the billing integration resource that you want to apply to the Product.
   In the Plans section, you can then either edit the Default Plan to add pricing information, or create a new Plan with pricing information.
6. If this is a new Plan, enter a Title, and if you require approval for someone to subscribe to this Plan also select the Approval checkbox.
7. In the Plan pricing section, complete the following steps to add the pricing information:
   a. Change the toggle to On for Plan pricing.
      The Plan pricing definition section is displayed.
   b. Optional: If you want to include any free trial days in your Plan, select Include free trial days, and then enter the number of trial days that a subscriber can use the Plan without charge, after which their billing cycle begins.
   c. Select the Currency for the billing process use.
   d. Enter the Price per month to bill the subscriber for.
      If the selected currency supports fractional units, enter the price including any fractional units, such as cents.
8. Optional: In the Plan rate limits section, set the rate limits by entering the number of calls that are allowed per unit of time.
   Remember that this rate limit applies only to this Plan. You can set multiple rate limits, at second, minute, hour, day, and week time intervals. You can override this Plan rate limit for specific endpoints if you prefer, adding a different rate limit or enabling unlimited calls to it. You can also create more Plans with different rate limits. For more information about rate limits, see Understanding rate limits for APIs and Plans.
9. Optional: Select the Hard limit checkbox if you want the gateway to reject any calls beyond the specified rate, rather than adding them to a queue to be resolved when the limits reset.
10. Optional: Add more burst limits, GraphQL limits, and assembly limits, as appropriate for your APIs.
11. Complete the Plan APIs section if you want to customize the APIs and operations that are available in this Plan.
12. If you want to add more Plans to the Product, repeat the process from Step 6.
13. Click Save to save the Product.

Results

Your Product with billing integration and a pricing Plan is listed in the Products dashboard of the Develop area. If your Product doesn't appear, click the Refresh icon to refresh the results from the server.

What to do next

Stage your Product to a Catalog. For more information, see Staging a draft Product.

Managing your Products

You can manage your products in API Manager by using the Products page of the associated catalog. In this view, you can move the products through their lifecycle, display analytics information, and control who can see or subscribe to the products. The syndication feature in IBM® API Connect means that products can also be managed by using the Products tab of the associated space.

Before you begin

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page.

For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

For more information about the product lifecycle, see The Product lifecycle.
For more information about the syndication feature, see Using syndication in API Connect.

For information on viewing analytics that can provide insight into product and API usage and performance, see API Analytics.

For information about product billing, see Monetizing your Products.

Procedure

To manage your product, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Expand a product to see details of the APIs and plans in that product.

   Manage options are also available, depending on the state of the product. To view the manage options, click the options icon and select the options that you require.
4. To manage the lifecycle of a version of a product, click the options icon alongside the product version, and select the required lifecycle action.
5. To set the migration target of a version of a product, click the options icon alongside the product version, and select Set migration target. In the Set migration target window, select the product that you want to set as the migration target, and select Next. Then map the migration source plans to the migration target plans, and click OK.
   Restriction: If the plan is part of a product that is contained within a space in the catalog, and the migration action is being made at the space level, the plan that you are migrating subscriptions from must be located in the same space as the plan you are migrating to. If the migration action is being made at the catalog level, subscriptions can be migrated across spaces. For more information about the Space feature, see Using syndication in API Connect.

- **Considerations when changing a Product lifecycle with billing integration**
  There are special considerations for lifecycle operations for Products that contain a billing integration in IBM API Connect.
- **Publishing a Product**
  APIs become accessible when a Product is published and made visible on the IBM API Connect Developer Portal for use by application developers. A Product can be published to selected communities of application developer organizations, and the Plans within the Product can be used to tailor access and visibility further.
- **Migrating application subscriptions to another Product**
  By using the Products view within a Catalog in API Manager, you can migrate application subscriptions between Products. The syndication feature in IBM API Connect means that you can also use the Products view within a Space in a Catalog to migrate application subscriptions.
- **Migrating application subscribers to new Product versions**
  When new versions of Products are created in IBM API Connect, there are a number of ways that subscribers can be moved to the Plans of the new Product.
- **Changing the availability of a Product**
  You can change the availability of a Product and the associated Plans by using the Products view within a Catalog in API Manager. The syndication feature in IBM API Connect means that you can also use the Products view within a Space in a Catalog to change the availability of a Product.
- **Deprecating a Product**
  You can deprecate a published Product by using the Manage Products page within a Catalog in API Manager. When you deprecate a Product, application developers that are already subscribed to the Product can continue to use it, but no new developers can subscribe to the Product. The syndication feature in IBM API Connect means that you can also use the Manage Products page within a Space in a Catalog to deprecate a published Product.
- **Retiring a Product**
  You can retire a published or deprecated Product by using the Manage Products page within a Catalog in API Manager. When a Product is retired, all associated APIs are taken offline, and any subscriptions are deleted. The syndication feature in IBM API Connect means that you can also use the Manage Products page within a Space in a Catalog to retire a Product.
- **Re-staging a Product**
  If a Product in a Catalog has been retired, you can re-stage the Product so that it can re-enter the Product lifecycle. A re-staged Product moves to the Staged state, from where it can be published. The syndication feature in IBM API Connect means that you can also re-stage a Product within a Space in a Catalog.
- **Working with the subscriptions in a Product**
  You can work with the subscriptions to the Plans in a specific Product. Plan subscriptions are created by application developers in the Developer Portal.
- **Updating the gateway services for a Product**
  When you stage or publish a draft Product to a Catalog, you specify the gateway services at which the APIs in the Product are to be made available. However, you can later update the selected gateway services after a Product has been stage or published.
- **Removing a Product from a Catalog**
  You can remove a Product from a specific Catalog by using the Products view within a Catalog in API Manager. The syndication feature in IBM API Connect means that you can also use the Products view within a Space to remove a Product from a Catalog.
- **Approving Product lifecycle and subscription requests**
  To approve or decline requests to change the lifecycle state of a Product, and requests by application developers to subscribe to a Plan, use the Tasks page in the Catalog that contains the associated Product in API Manager. The syndication feature in IBM API Connect means that you can also use the Tasks page within a Space in a Catalog to approve or decline requests.

Considerations when changing a Product lifecycle with billing integration

There are special considerations for lifecycle operations for Products that contain a billing integration in IBM® API Connect.

For example, if you release new versions of your Product that contain pricing changes, you will need to define the upgrade pathways for your existing subscribers. The following scenarios detail the special considerations for Product lifecycle changes:

Deprecating
: Preparing an existing Product to be removed from production. You can define a replacement Product by using the Set Migration Target option in the Catalog. API consumers will then see a Migrate this subscription message in the Developer Portal that they can click to upgrade their subscription to the migration target. If the upgrade target is a paid Plan, they must enter a payment method before upgrading. Upgrades by API consumers from a free Plan to a paid Plan are supported. For more information about deprecating Products, see Deprecating a Product.

Migrating
: Moving subscriptions from one Product to a different Product, and from a free Plan to a paid Plan, is not supported. Instead, see the superseding scenario.

Replacing
: Replacing a Product with a newer version of the same Product, and automatically upgrading all existing subscribers to the new Product. You must map which Plans from your new Product correspond to which Plans in your old Product. You cannot map a free Plan to a paid Plan in the replace operation. For more information about replacing Products, see Replacing a Product with another Product.

Retiring
: Removing a Product or Plan from production, and canceling all of the existing subscriptions and their billing cycles. For more information about retiring Products, see Retiring a Product.

Superseding
: Deprecating the old Product, and at the same time defining its migration target to a newer version of itself. Retaining the existing Product and Plan for subscribers who would like to keep it, but offering a different Product and Plan for the updated version of a Product. API consumers will then see a Migrate this subscription message in the Developer Portal that they can click to upgrade their subscription to the migration target. If the upgrade target is a paid Plan, they must enter a payment method before upgrading. Upgrades by API consumers from a free Plan to a paid Plan are supported. For more information about superseding Products, see Superseding a Product with another Product.

Note: You can use the Set Migration Target option in the Catalog on a Product that isn't being deprecated. For example, if you wanted to give customers the option to move to a different Product without affecting the original Product.
While these follow the same basic procedures that are described in Managing your Products for Products and Plans without billing, there are some considerations that only apply to Products that contain paid Plans.

You cannot migrate a customer directly from a free Plan to a Plan with billing

Customers who subscribe to Plans with billing must set up their billing information in the Developer Portal. If they subscribe only to free Plans, they don't have billing accounts.

There are two ways to migrate customers from a free Plan to a paid Plan:

- Supersede the free Product Plan and provide a migration target to a paid Product Plan. This deprecates the free Product Plan so no new users can subscribe to it, and gives the customer a Migrate this subscription message in the Developer Portal to move to the new Product Plan.
- Set a migration target to a paid Product Plan. In this case the free Product Plan is not deprecated, but it still gives the customer the Migrate this subscription message in the Developer Portal for moving to the new Product Plan. With this method, new customers can still subscribe to the free Product Plan.

Both of these methods require action from the customer before they move from the free Product Plan to the paid Product Plan.
Note: Free trial days do not apply to customers when they migrate. They are available only for new customers.

You must map the existing Plans to the new Plans when you supersede or replace a Product

When you replace or supersede a Plan with billing with another Plan, you must map the Plans from the Product that is being removed to the Plans that are in the new Product. It is convenient if there are the same number of Plans for each, but you can map more than one Plan from the existing Product to one Plan in the new Product.

Billing charges are prorated when subscriptions are migrated

When customers change their subscriptions to a Plan that has a different price, their next monthly invoice will contain prorated charges, depending on how long they spent on different billing Plans. For more information about how Stripe handles proration, see https://stripe.com/docs/billing/subscriptions/prorations.

Publishing a Product

APIs become accessible when a Product is published and made visible on the IBM® API Connect Developer Portal for use by application developers. A Product can be published to selected communities of application developer organizations, and the Plans within the Product can be used to tailor access and visibility further.

Before you begin

You must stage a Product before it can be published. For more information about staging Products, see Staging a Product.
Note: If you want to publish a LoopBack project, you must publish both the APIs (by publishing the Products that contain the APIs) and the associated applications so the project can be run. For more information about publishing LoopBack applications, see Publishing APIs and applications.
To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains

the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

A community is a collection of consumer organizations, used to control which organizations have access to Products and Plans without having to assign access on an individual basis. A Product can be published to selected communities, which means that only application developers within those organizations contained within the community can see the Product on the Developer Portal and obtain application keys to access it. A Product can alternatively be published to all communities. Communities are used to restrict the visibility and accessibility of APIs, for example to particular business partners, internal organizations, or other groups of application developers.

Note: If you want to update a Product, you must republish it. The `products:update` command only updates a Product's metadata.

Procedure

You can publish a product in any of the following ways:

- Publish a new Product.
- Replace a Product with another Product.
- Supersede a Product with another Product
  For details of the ways in which you can publish a Product, see the following subtopics:

- **Publishing a new Product**
  Publish a Product from within its containing Catalog in API Manager. The syndication feature in IBM API Connect means that you can also publish a Product from within its containing Space in a Catalog.
- **Replacing a Product with another Product**
  You can replace a published Product in IBM API Connect with another Product, and automatically migrate subscribers to the new Product, by using the API Manager.
- **Superseding a Product with another Product**
  You can supersede a published Product with another Product by using the API Manager.

Publishing a new Product

Publish a Product from within its containing Catalog in API Manager. The syndication feature in IBM® API Connect means that you can also publish a Product from within its containing Space in a Catalog.

Before you begin

The Product that you are publishing must be in the Staged or Deprecated state.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

If you publish a Product to a non-development Catalog, the Product that is published is an independent and fixed copy of the version of the Product that you chose to stage. Editing the Product through the Products page will not affect the published Product. For this reason, it is recommended that when you stage a Product, you then create a new version of the Product to edit in future, so as to avoid confusion regarding the properties of the published Product. For more information on creating new versions of your Product, see Creating a new version of your Product.

An exception is that if you publish a Product to a development Catalog, editing it through the Products page will enable you to re-stage and publish the same version of the Product. For information on how to create a development Catalog, see Creating and configuring Catalogs.

Although you can publish to a development Catalog, the development Catalog should be used only for testing purposes. Similarly, a Developer Portal created from a development Catalog must be used for testing purposes only, and not for production use. For more information on Catalogs, see Working with Catalogs.

Note: All references in this topic to a Catalog can also be applied to a Space in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.

Procedure

To publish a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click  Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.

3. Alongside the Product version that you want to work with, click the options icon and then click Publish.
   The Confirm Visibility Settings page opens.
4. Specify the following options:
   - The users that the Product is visible to
     You can choose Public users, Authenticated users, or Custom.
     - Custom - You can use the Type to add... field to search for organizations or communities that you want your Product to be visible to.
   - Who can subscribe to the Product
     You can add or remove one or more consumer organizations or communities.
     - Custom - You can use the Type to add... field to search for organizations or communities that you want to allow to subscribe to your Product.
5. Click Publish, then click Confirm to proceed with the publish operation.
   If approval is required to publish Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is published when the request is approved. If approval is not required, the Product version is published immediately, and moves to the Published state. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon alongside the Product that you want to work with, and selecting View Approval History.

Results

Your Product is in the Published state.

Your Product is published to your Catalog and available to your specified organizations or communities. Application developers within the groups you selected can see and use the APIs within the Product.
Any application developer requests to use your Product are displayed on the Approvals tab in the containing Catalog, where you can decline or accept the request.

Related tasks

- Deprecating a Product

Related information

- Staging a Product

Replacing a Product with another Product

You can replace a published Product in IBM® API Connect with another Product, and automatically migrate subscribers to the new Product, by using the API Manager.

Before you begin

The Product to be replaced must be in the Published state, and the replacement Product must be in the Staged, Published, or Deprecated state.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

When you replace a Product with another Product, the following actions are taken:

- The replacement Product is published.
- If the visibility and subscribability settings in the replacement Product are such that access is the same as, or less restrictive than, the original Product, the settings in the replacement Product are used. If the settings in the replacement Product are more restrictive, meaning that fewer consumer organizations can see or subscribe to the Product, the replace operation fails. For more information on visibility and subscribability settings, see Changing the availability of a Product.
- The subscribers to the original Product are migrated to the replacement Product.
  Note: Customers cannot be migrated automatically from a free Plan to a paid Plan. To move your customers from a free Plan to a paid Plan, you can supersede the product with a new product and set a migration target to the paid Plan. The customers then select a button to migrate and must enter their credit card information before the process is complete. For more information, see Considerations when changing a Product lifecycle with billing integration.
- The original Product is moved to the Retired state. Products in the Retired state are removed from the Developer Portal; they are no longer visible to the application developers, and any subscriptions to them are canceled. However, the Product can be staged again later if required.

Although you can publish to a development Catalog, the development Catalog should be used only for testing purposes. Similarly, a Developer Portal created from a development Catalog must be used for testing purposes only, and not for production use. For more information on Catalogs, see Working with Catalogs.

Note: All references in this topic to a Catalog, can also be applied to a Space in a Catalog, unless specified otherwise.

Procedure

To replace a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to replace, click the options icon, then click Replace.
   The Replace window opens.
4. Select the replacement Product, then click Next.
5. From the drop-down list, select which Plans from your new Product correspond to Plans in your old Product.
6. Click Replace.
   If approval is required to replace Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is replaced when the request is approved. If approval is not required, the Product is replaced immediately. For information on configuring product lifecycle approvals for a catalog, see Creating and configuring catalogs. For information on approving requests, see Approving product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon alongside the Product that you want to work with, and selecting View Approval History.

Results

Your new Product is in the Published state, and the original Product is in the Retired state.

Your new Product is published to your preferred organizations or communities. Application developers within the groups you selected can see and use the APIs within the Product.
Any application developer requests to use your Product are displayed on the Approvals tab in the containing Catalog, where you can decline or accept the request.

Superseding a Product with another Product

You can supersede a published Product with another Product by using the API Manager.

Before you begin

The Product to be superseded must be in the Published state. The superseding Product must be in the Staged, Published, or Deprecated state.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM® API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

When you supersede a Product with another Product, the following actions are taken:

- The superseding Product is published.
- If the visibility and subscribability settings in the superseding Product are such that access is the same as, or less restrictive than, the original Product, the settings in the superseding Product are used. If the settings in the superseding Product are such that access is more restrictive, meaning that fewer consumer organizations can see or subscribe to the Product, the supersede operation fails. For more information on visibility and subscribability settings, see Changing the availability of a Product.
- The original Product is moved to the Deprecated state.
- The application developers that are already subscribed to the now deprecated Product can continue to use it, but no new developers can subscribe to the Product. In the Developer Portal the application developers will see a Migrate this subscription message, which they can click to upgrade their subscription to the migration target.

- The deprecated product can be published again if required.

Although you can publish to a development Catalog, the development Catalog should be used only for testing purposes. Similarly, a Developer Portal created from a development Catalog must be used for testing purposes only, and not for production use. For more information on Catalogs, see Working with Catalogs.

Note: All references in this topic to a Catalog, can also be applied to a Space in a Catalog, unless specified otherwise.

Procedure

To supersede a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to supersede, click the options icon and then click Supersede.
4. Select the superseding Product and then click Next.
5. From the drop-down list, select which Plans from your new Product correspond to Plans in your old Product.
6. Click Supersede.
   If approval is required to supersede Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is superseded when the request is approved. If approval is not required, the Product is superseded immediately. For information on configuring product lifecycle approvals for a catalog, see Creating and configuring catalogs. For information on approving requests, see Approving product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon alongside the Product that you want to work with, and selecting View Approval History.

Results

Your superseding Product is in the Published state.

The Product that was superseded is in the Deprecated state.

Your superseding Product is published to your preferred organizations or communities. Application developers within the groups you selected can see and use the APIs within the Product. The original Product is deprecated.
Any application developer requests to use your Product are displayed on the Approvals tab in the containing Catalog, where you can decline or accept the request.

Existing customers remain subscribed to the deprecated product, and any billing cycles for subscriptions to paid plans continue uninterrupted. For more information, see Considerations when changing a Product lifecycle with billing integration.

Migrating application subscriptions to another Product

By using the Products view within a Catalog in API Manager, you can migrate application subscriptions between Products. The syndication feature in IBM® API Connect means that you can also use the Products view within a Space in a Catalog to migrate application subscriptions.

Before you begin

Your Product that you are migrating subscriptions from must be in one of the following states:

- Published
- Deprecated

To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for Products in the Catalog that contains the Product. If you have View permission for Products in this Catalog, you will have read-only access to the Product management page. For information on configuring Product management permissions for a Catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

Application developers initially subscribe their applications to one or more Plans in Products by using the Developer Portal. For more information, see Exploring APIs and Products in the Developer Portal. However, by using API Manager, for a chosen Product you can migrate one or more of its application subscriptions from one Plan to a Plan in another Product.

Procedure

To migrate Product subscriptions, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon and then click Migrate Subscriptions.
4. Select the Plan from which you want to migrate subscriptions, then click Next.
5. Select the subscriptions that you want to migrate, then click Next.
6. Select the Product that you want to migrate the subscriptions to, then click Next.
7. Select the Plan that you want to migrate the application subscriptions to, and then click Migrate.

Results

The target Product has the migrated subscriptions, and those subscriptions are removed from the Product from which they were migrated.

Related tasks

- Working with Spaces

Migrating application subscribers to new Product versions

When new versions of Products are created in IBM® API Connect, there are a number of ways that subscribers can be moved to the Plans of the new Product.

About this task

You can move users to the new Plans in different ways, depending on your Product strategy, by using the options icon alongside the Product in the associated Catalog in the API Manager UI.

Procedure

To automatically migrate all existing subscribers to a new Product, for example, when you are applying fixes to a Product:

- You should Replace the original version of the Product with a new version of the Product.
  - The replacement Product is Published.
  - The original Product is Retired.
  - The subscribers to the original Product are automatically migrated to the replacement Product.
    Note: Customers cannot be migrated automatically from a free Plan to a paid Plan. To move your customers from a free Plan to a paid Plan, you can supersede the product with a new product and set a migration target to the paid Plan. The customers then select a button to migrate and must enter their credit card information before the process is complete. For more information, see Considerations when changing a Product lifecycle with billing integration.

  For more information about replacing Products, see Replacing a Product with another Product.

To encourage subscribers to move to a new Product, and stop new users from subscribing to the original Product, for example, if an enhancement or new feature is added:

- You should Supersede the original version of the Product with a new version of the Product.
  - The superseding Product is Published.
  - The original Product is Deprecated.
  - The application developers that are already subscribed to the now deprecated Product can continue to use it, but no new developers can subscribe to the Product. In the Developer Portal the subscribers will see a Migrate this subscription message, which they can click to upgrade their subscription to the migration target.
  - If the migration target is a paid Plan, subscribers must enter a payment method before they can upgrade. Upgrades by subscribers from a free Plan to a paid Plan are supported.

  For more information about superseding Products, see Superseding a Product with another Product.

To prepare a Product to be removed from production, but leave the existing subscriptions as they are:

- You should Deprecate the original Product.
  - The Product is Deprecated.
  - The application developers that are already subscribed to the now deprecated Product can continue to use it, but no new developers can subscribe to the Product.
  - You can define a replacement Product by using the Set Migration Target option in the Catalog. Application developers will then see a Migrate this subscription message in the Developer Portal that they can click to upgrade their subscription to the migration target. If the upgrade target is a paid Plan, they must enter a payment method before upgrading. Upgrades by API consumers from a free Plan to a paid Plan are supported.

For more information about deprecating Products, see Deprecating a Product.

To give subscribers the option to move to a different Product, but without affecting the original Product:

- You can use the Set Migration Target option in the Catalog on a Product that isn't being deprecated or superseded. For more information, see Managing your Products.

Changing the availability of a Product

You can change the availability of a Product and the associated Plans by using the Products view within a Catalog in API Manager. The syndication feature in IBM® API Connect means that you can also use the Products view within a Space in a Catalog to change the availability of a Product.

Before you begin

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

Note: All references in this topic to a Catalog can also be applied to a Space in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.

Procedure

To change the availability of a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon, then click Edit visibility.
   The Visibility page opens.
4. In the Visibility section, specify the users that you want the Product to be visible to. You can choose Public to make the Product visible to all users, Authenticated to make the Product available to users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that you want the Product to be visible to.
   If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups that you want the Product to be visible to. For information about how to create and manage consumer organizations and consumer organization groups, see Working with consumer organizations.

   Use the Temporarily disable visibility check box to toggle whether the Product is or is not visible, without having to change other visibility settings.

5. In the Subscribability section, specify the users that can subscribe to the Plans in the Product. You can choose Authenticated to make the Plans in the Product subscribable by users who have successfully authenticated, or Custom to specify the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product.
   If you select Custom, use the Type to add organizations field to search for the consumer organizations and consumer organization groups that can subscribe to the Plans in the Product. If you selected custom visibility, only the consumer organizations and consumer organization groups selected there are available for adding to the custom subscribability list. For information about how to create and manage consumer organizations and consumer organization groups, see Working with consumer organizations.

   Use the Temporarily disable subscribability check box to toggle whether the Product can or cannot be subscribed to, without having to change other subscription settings.

6. Click Save when done.
   The Product version is configured with the modified availability settings.
   Note:
   - Changing who can view or subscribe to a Product does not affect the settings of the draft Product. The change applies only in the Catalog that was selected in Step 1.
   - Changing who can view or subscribe to a Product does not affect existing subscriptions.

Results

Your Product remains in the same lifecycle state, now with new availability settings.

Deprecating a Product

You can deprecate a published Product by using the Manage Products page within a Catalog in API Manager. When you deprecate a Product, application developers that are already subscribed to the Product can continue to use it, but no new developers can subscribe to the Product. The syndication feature in IBM® API Connect means that you can also use the Manage Products page within a Space in a Catalog to deprecate a published Product.

Before you begin

The Product that you are deprecating must be in the Published state.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

Procedure

To deprecate a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon, then click Deprecate.
   The Deprecate Product window opens.
4. Click Confirm to deprecate the Product.
   If approval is required to deprecate Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is deprecated when the request is approved. If approval is not required, the Product is deprecated immediately. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon alongside the Product that you want to work with, and selecting View Approval History.

Results

Your Product is in the Deprecated state.

Retiring a Product

You can retire a published or deprecated Product by using the Manage Products page within a Catalog in API Manager. When a Product is retired, all associated APIs are taken offline, and any subscriptions are deleted. The syndication feature in IBM® API Connect means that you can also use the Manage Products page within a Space in a Catalog to retire a Product.

Before you begin

The Product that you are retiring must be in the Published or Deprecated state.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

Procedure

To retire a Product, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon and then click Retire. The Retire Product window opens.
4. Click Confirm.
   If approval is required to retire Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is retired when the request is approved. If approval is not required, the Product is retired immediately. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.
   Note:
   - Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
   - Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
   - You can view the history of Product lifecycle requests and approvals, by clicking the options icon alongside the Product that you want to work with, and selecting View Approval History.

Results

Your Product is in the Retired state. It is also removed from the Developer Portal, is no longer visible to the application developers, and any subscriptions to it are deleted. You can stage the Product again later if required; for details, see Staging a Product.
If the Product has any monetized Plans, the billing cycles for any subscriptions are canceled as well. For more information, see Considerations when changing a Product lifecycle with billing integration.

Re-staging a Product

If a Product in a Catalog has been retired, you can re-stage the Product so that it can re-enter the Product lifecycle. A re-staged Product moves to the Staged state, from where it can be published. The syndication feature in IBM® API Connect means that you can also re-stage a Product within a Space in a Catalog.

Before you begin

The Product that you are re-staging must be in the Retired state.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

You stage a Product so that the appropriate approvals, internally within the organization, can be given for it to then be published. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests. For information on publishing a Product, see Publishing a Product.

Procedure

To re-stage a Product, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon and then click Re-stage. The Re-stage Product window opens.
4. Click Confirm.
   If approval is required to stage Products in this Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is re-staged when the request is approved. If approval is not required, the Product is re-staged immediately. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.

Note:

- Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
- Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
- You can view the history of Product lifecycle requests and approvals, by clicking the options icon ⋮ alongside the Product that you want to work with, and selecting View Approval History.

Results

Your Product is in the Staged state, from where it can be published; see Publishing a new Product.

Working with the subscriptions in a Product

You can work with the subscriptions to the Plans in a specific Product. Plan subscriptions are created by application developers in the Developer Portal.

Procedure

To work with the Plan subscriptions in a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. Alongside the Product version that you want to work with, click the options icon ⋮ and then click View Subscriptions.
   A window opens listing all subscriptions to the Plans in the selected Product.
4. Alongside the subscription that you want to work with, click the options icon ⋮.
   You can then select from the following options:
   - View Consumer Organization: a window opens listing the consumer organization that the subscribing application belongs to. If required, you can click the options icon ⋮ to work with the consumer organization For details of the available options, see Working with consumer organizations.
   - View Application: a window opens listing the subscribing application. If required, you can click the options icon ⋮ to work with the application. For details of the available options, see Working with developer applications.
   - View Plan: a window opens listing the Plan that the application is subscribed to. If required, you can click the options icon ⋮ to work with the Plan. For details of the available options, see Working with Plans.
   - View Product: a window opens listing the Product that contains the Plan that the application is subscribed to. If required, you can click the options icon ⋮ to work with the Product. For details of the available options, see Managing your Products.
5. To display the Client ID's for a particular Product subscription, click the information icon ⓘ in the Application column for the subscription that you require.

Updating the gateway services for a Product

When you stage or publish a draft Product to a Catalog, you specify the gateway services at which the APIs in the Product are to be made available. However, you can later update the selected gateway services after a Product has been stage or published.

Before you begin

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM® API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

About this task

When you stage or publish a draft Product to a Catalog, you can either choose to make the APIs in the Product available at all the gateway services that match the gateway service type of the Product, either DataPower® API Gateway or DataPower Gateway (v5 compatible), or can you select specific gateway services of that type. The APIs in the Product can then be called at those gateway service endpoints.

However, after a Product has been staged or published you can later update the gateway services to change the selections.

For more information on staging and publishing a Product, see Staging a draft Product and Publishing a draft Product.

For more information on the gateway service types, see API Connect gateway types.

Procedure

To update the gateway services for a Product, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon, then click Update gateway services.
   The Select Gateway Services window opens.
4. Select the required gateway services, then click Save.

Removing a Product from a Catalog

You can remove a Product from a specific Catalog by using the Products view within a Catalog in API Manager. The syndication feature in IBM® API Connect means that you can also use the Products view within a Space to remove a Product from a Catalog.

Before you begin

The Product that you are removing from the Catalog must be in the Staged or Retired state. For more information, see Staging a Product or Retiring a Product.

To complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the catalog that contains the product. If you have View permission for products, you have read-only access to the product management page. For information on configuring product management permissions for a catalog, see Creating and configuring catalogs.

The syndication feature in IBM API Connect means that products can be contained within a space in a catalog. In this case, to complete the product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Manage permission for products in the space that contains the product. For information on configuring product management permissions for a space, see Managing user access in a space.

Procedure

To remove a Product from a Catalog, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon, then click Delete.
   The Delete Product window opens.
4. Click Confirm to delete the Product.

Results

Your Product is removed from the Catalog. You can stage the Product again if required; for details, see Staging a Product.
If your Product was contained within a Space in a Catalog, your Product is removed from both the Space and the Catalog.

Approving Product lifecycle and subscription requests

To approve or decline requests to change the lifecycle state of a Product, and requests by application developers to subscribe to a Plan, use the Tasks page in the Catalog that contains the associated Product in API Manager. The syndication feature in IBM® API Connect means that you can also use the Tasks page within a Space in a Catalog to approve or decline requests.

Before you begin

To see lifecycle change requests for a Product, you must either be the owner of the API provider organization, or you must be assigned a user role that has permission to view or manage Products in the Catalog that contains the Product. For information on configuring Product management permissions for a Catalog, see Creating and configuring catalogs.

The syndication feature in API Connect means that Products can be contained within a Space in a Catalog. In this case, to see lifecycle change requests for a Product, you must either be the owner of the API provider organization, or you must be assigned a user role that has permission to view or manage Products in the Space that contains the Product. For information on configuring Product management permissions for a Space, see Managing user access in a Space.

About this task

If approvals for Product lifecycle changes are enabled for a Catalog, then an attempt to change the lifecycle state of a Product results in an approval request being sent. This request is displayed in the Tasks page in the Catalog, from where the request can be approved or declined. The authority to approve Product lifecycle state changes is restricted to users in specified roles. For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring catalogs.
Note:

- Approval for product lifecycle state changes in a catalog is disabled by default. You must explicitly enable the product lifecycle state changes that you want to enforce.
- Product lifecycle approvals can be configured only at the Catalog level. This feature is not available at the Space level.
- You can view the history of Product lifecycle requests and approvals, by clicking the options icon ⋮ alongside the Product that you want to work with, and selecting View Approval History.

If a Product is set to require approval for subscription by application developers, then an attempt by an application developer to subscribe to the Product results in an approval request being sent. This request is displayed in the Approvals tab in the Catalog that contains the associated Product in API Manager, from where the request can be approved or declined.

Procedure

To work with a Product lifecycle change request, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Click the Tasks tab, then locate the Product lifecycle change request that you want to deal with.
4. Click the Approve or Decline as required.
   Note: You can approve or decline lifecycle change requests only if you have a user role that has permission to approve Product publish requests in the Catalog in which the changes will take place.
   For information on configuring Product management permissions for a Catalog, see Creating and configuring catalogs.

To work with a subscription request, complete the following steps.

5. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
6. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
7. Click the Tasks tab, then locate the subscription requests that you want to deal with.
   Note: To see subscription approvals, you must either be the owner of the API provider organization, or you must be assigned a user role that has permission to view or approve subscription requests. For information on creating and assigning user roles, see Administering user access.
8. Click the Approve or Decline as required.
   Note: The options to approve or decline a subscription request are available only if you are assigned a user role that has permission to approve subscription requests. For information on configuring permissions for a Catalog, see Creating and configuring catalogs For information on assigning user roles, see Managing Catalog membership.

Results

For a subscription request, an email is sent confirming whether you approved or declined the request. For a request to change the lifecycle state of a Product, no email is sent.

Working with APIs

For a specific Product, you can work with the APIs that are contained in the Plans in that Product.

Procedure

To work with the APIs in a Product, complete the following steps:

1. List the Plans in the Product:
   a. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   b. If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
      i. Click the Spaces tab.
      ii. Select the space that you want to work with.
   c. If the Products page is not already displayed, click the Products tab.
   d. Alongside the Product version that you want to work with, click the options icon, then click View Plans.
   A window opens listing the Plans in the Product.
2. Alongside the required Plan, click View APIs.
   A window opens listing the APIs in the Plan.
3. Alongside the required API, click the options icon.
   You can then select from the following options:
   - Take Offline: if you take an API offline, the API is no longer available to be called. When required, you can make the API available again by selecting Online.
   - View Products: a window opens listing all the Products that contain the API. If required, you can click the options icon alongside a Product to work with that Product. For details of the available options, see Managing your Products.
   - View Plans: a window opens listing all Plans, across all Products, that contain the API. If required, you can click the options icon alongside a Plan to work with that Plan. For details of the available options, see Working with Plans.

Working with Plans

After a Product has been published to a Catalog, you can work with the Plans in that Product.

Before you begin

For details on configuring a Plan in a Product, see Editing a draft Product.

For details on Publishing a Product to a Catalog, see Publishing a Product.

To complete the tasks that are described in this topic, you must either be the owner of the API provider organization, or you must be assigned a role that has either the Product > Manage or the Product > View permission for the Catalog. For more information, see Adding provider organization users and assigning roles and Managing Catalog membership. For information on configuring Product management permissions for a Catalog, see Creating and configuring Catalogs.

Procedure

To work with Plans in a Catalog, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. If the product that you want to work with is contained within a space, select the required space by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   The Products page of the space opens, and all of the products available in that space are displayed.
3. Alongside the Product version that you want to work with, click the options icon and then click View Plans.
   A window opens listing all the Plans in the selected Product.
4. Alongside the Plan that you want to work with, click the options icon.
   You can then select from the following options:
   - View Product: a window opens listing the Product that contains the Plan. If required, you can click the options icon to work with the Product. For details of the available options, see Managing your Products.
   - View APIs: a window opens listing the APIs in the Plan. If required, you can click the options icon alongside an API to work with that API. For details of the available options, see Working with APIs.
   - View Subscriptions: a window opens listing the subscriptions to the Plan. If required, you can click the options icon alongside a subscription to work with that subscriptions. For details of the available options, see Working with application subscriptions.

Working with consumer organizations

Manage the consumer organizations that access your APIs and Plans when their users sign up to use the IBM® API Connect Developer Portal.

About this task

Application developers in consumer organizations access the Developer Portal and sign up to use the Plans in the Products you create in the API Manager. You can create more than one consumer organization and each organization has one owner. Application developers are added through the Developer Portal UI.

You can also create groups of consumer organizations. A consumer organization group is an efficient way of grouping application developers together to publish Products to, making it easier to control who has access to the Plans in the Products.

Use the following tasks to administer your consumer organizations and consumer organization groups:

- **Creating a consumer organization**
  If you have permission to manage developers, you can create new consumer organizations in a Catalog. consumer organizations contain the application developers that subscribe to use the APIs that are published to the Catalog
- **Editing a consumer organization**
  You can change the title of an IBM API Connect consumer organization, and also transfer ownership to a new organization owner.
- **Deleting a consumer organization**
  When you delete a consumer organization, all of the resources in that organization are removed from the cloud. However, the account of the organization owner remains in IBM API Connect.
- **Working with the applications in a consumer organization**
  You can work with the developer applications that have been registered in a consumer organization.
- **Working with the subscriptions in a consumer organization**
  You can work with the Plan subscriptions that have been created by the developer applications registered in a consumer organization.
- **Working with consumer organization groups**
  A *consumer organization group* is a collection of consumer organizations, and provides an efficient way of controlling who can see, and subscribe to, the APIs in your Products. By using a consumer organization group, you can define this access for all the developers in the organizations in that group in a single operation, rather than having to define access for the organizations separately.
- **Sending messages to consumer organization owners**
  You can send email messages to the owners of consumer organizations. You can also style the email to match your business theme.

Creating a consumer organization

If you have permission to manage developers, you can create new consumer organizations in a Catalog. consumer organizations contain the application developers that subscribe to use the APIs that are published to the Catalog

Before you begin

Your IBM® API Connect Developer Portal must be enabled to perform this task. For more information, see Creating and configuring Catalogs.
To complete this task, you must be defined as a member in a catalog or space (if spaces are enabled), and you must be assigned a role that has the Consumer-Org > Manage permission. For more information, see Adding provider organization users and assigning roles and Managing catalog membership.

About this task

You can create a consumer organization in either of the following ways:

- Invite a user to be a consumer organization owner, in which case they receive an invitation email with an activation link, and can complete the creation of the consumer organization and specify the title.
- Create the consumer organization yourself, specifying the owner and title. There are two ways you can specify the owner:
  - Specify the user ID of an existing user.
  - If you are using a Local User Registry, specify a new user ID; the user is added to the registry and becomes the owner of the consumer organization.

If Spaces are enabled in your Catalog, when you create a consumer organization, it is added to the Catalog and its Spaces. For more information about enabling Spaces, see Using syndication in API Connect.

Procedure

1. In the navigation pane of the API Manager UI, click  Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. To invite a user to be a consumer organization owner, complete the following steps:
   a. Click Add > Invite organization owner.
   b. Enter the email address of the organization owner.
   c. Click Invite.
   The new consumer organization is added to the list, and an email invitation is sent to the owner; by using the activation link, the owner specifies the title of the organization. The status is shown as `Pending` until the recipient of the email clicks the link in the email to complete the creation of their Developer Portal account, after which the status changes to `Enabled`.
5. To create the consumer organization yourself, complete the following steps:
   a. Click Add > Create organization.
   b. Enter the organization Title. A Name is entered automatically.
   The value in the Name field is a single string that is used to identify the consumer organization in developer toolkit CLI commands. The title is used for display.
   To view the CLI commands to manage consumer organizations, see apic consumer-orgs.
   c. Select the required user registry.

d. Specify the organization owner; complete one or other of the following steps, either to specify an existing user, or to create a new user:
- To specify the user ID of an existing API Connect user who is in the selected user registry, complete the following steps:
  - For the Type of user, select Existing.
  - In the Username field, enter the user ID of the organization owner
    After the consumer organization is created, the specified user can immediately log in to the Developer Portal associated with the Catalog.
- If you selected a Local User Registry, then to specify a new user ID, complete the following steps:
  - For the Type of user, select New User.
  - In the Username field, enter the new user ID.
  - Enter the Email, First Name, Last Name, and Password.
    After the consumer organization is created, the new user will have been added to the selected registry and can immediately log in to the Developer Portal associated with the Catalog, by using the specified user ID and password.

e. Click Create to complete the creation of the consumer organization.

Editing a consumer organization

You can change the title of an IBM® API Connect consumer organization, and also transfer ownership to a new organization owner.

Before you begin

To complete this task, you must be defined as a member in a catalog or space (if spaces are enabled), and you must be assigned a role that has the Consumer-Org >. Manage permission. For more information, see Adding provider organization users and assigning roles and Managing catalog membership.

About this task

If you transfer ownership, the new organization owner can be an existing user, or you can create a new user. When the ownership changes, the new owner is assigned administration privileges for the organization, and the previous owner has their administration privileges removed. If required, you can restore the privileges to the previous owner as described in Administering members and roles.

If Spaces are enabled in your Catalog, when you edit the details of a consumer organization, the updates are applied to the Catalog and its Spaces. For more information about enabling Spaces, see Using syndication in API Connect.

Procedure

To change the title of a consumer organization, or to transfer ownership to a new organization owner, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. Click the name of the consumer organization that you want to work with.
5. To change the title, enter a new title in the Title field, then click Save.
6. To transfer ownership, select the user registry for the consumer organization owner you want to transfer ownership to.
   The remaining procedure varies according to the type of the selected user registry, as follows:
   - Local User Registry
     - Select whether the user is an Existing user or a New User.
       - For an existing user, complete the following steps:
         - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
         - Click Save.
       - For a new user, complete the following steps:
         - Enter a unique user name for the new user.
         - Supply an email address, name details, and a password.
         - Click Save.
   - LDAP
     - Enter the name of a user that exists in the selected user registry.
     - Click Save.
   - Authentication URL and OIDC
     - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account. If the required organization owner has not previously been invited and activated their account, you must ensure they have been invited to the organization first.
     - Click Save.

Results

If the title of the consumer organization is changed, all application developers that are members of that consumer organization will see the title change reflected in the Developer Portal user interface.

Deleting a consumer organization

When you delete a consumer organization, all of the resources in that organization are removed from the cloud. However, the account of the organization owner remains in IBM® API Connect.

Before you begin

To complete this task, you must be defined as a member in a catalog or space (if spaces are enabled), and you must be assigned a role that has the Consumer-Org > Manage permission. For more information, see Adding provider organization users and assigning roles and Managing catalog membership.

Important: If you delete a consumer organization, client IDs and secrets associated with applications that were registered by users in the consumer organization can no longer be used to call APIs. However, the account of the organization owner remains in API Connect.

About this task

When you delete a consumer organization, it is removed permanently and users can no longer access that organization.
If Spaces are enabled in your Catalog, when you delete a consumer organization, it is deleted from the Catalog and its Spaces. For more information about enabling Spaces, see Using syndication in API Connect.

Procedure

To delete a consumer organization, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. Click the options icon alongside the consumer organization you want to work with, then click Delete.
5. Click Confirm to delete the consumer organization.
   Note: If the consumer organization is the only one specified in the custom visibility settings for a published Product, the deletion operation will fail. For more information, see Changing the availability of a Product.

Working with the applications in a consumer organization

You can work with the developer applications that have been registered in a consumer organization.

Procedure

To work with applications, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. Click the options icon for the consumer organization that you want to work with, then click View Applications.
   A window opens listing all the developer applications that have been registered in the consumer organization
5. To view and edit the details of an application, click the title of the application.
6. Further options are available by clicking the options icon alongside the application you want to work with. For details, see Working with developer applications.

Working with the subscriptions in a consumer organization

You can work with the Plan subscriptions that have been created by the developer applications registered in a consumer organization.

Procedure

To work with Plan subscriptions, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. Click the options icon for the consumer organization that you want to work with, then click View Subscriptions.

A window opens listing all the Plan subscriptions that have been created by the developer applications registered in the consumer organization. If required, you can click the options icon ⋮ alongside a subscription to work with that subscription. For details of the available options, see Working with application subscriptions.

Working with consumer organization groups

A *consumer organization group* is a collection of consumer organizations, and provides an efficient way of controlling who can see, and subscribe to, the APIs in your Products. By using a consumer organization group, you can define this access for all the developers in the organizations in that group in a single operation, rather than having to define access for the organizations separately.

About this task

A consumer organization group might represent particular business partners, internal organizations, or other groups of application developers.

When you create a Product, you can define which application developers can access the APIs in that Product. You can configure the following types of access:

- Visibility, which specifies the application developers who can see the APIs in the Developer Portal.
- Subscribability, which specifies the application developers who can create subscribe to use the APIs.

You configure this access by selecting the required consumer organizations, and Consumer organization groups. You can also change the visibility and subscribability settings for a Product after it has been published. For more information, see Creating a draft Product and Changing the availability of a Product.

Procedure

To work with consumer organization groups, you first navigate to the Consumer organization groups page. You then create new groups, send an email to the owners of the consumer organizations in a group, and edit or delete existing groups.

- Navigating to the required consumer organization groups page.
  1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
  2. If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
     a. Click the Spaces tab.
     b. Select the space that you want to work with.
  3. Click the Consumers tab, then click Manage Groups.
- Creating a consumer organization group.
  1. Click Add.
  2. Enter a Title for the new group and, optionally, a Summary. A Name is entered automatically. The title is used for display.
  3. Use the Search orgs/groups field to search for, and select, the consumer organizations that you want to add to the group.
     Note: To prevent excessive search results lists, only the first 10 matches are displayed when you begin typing in the field; lengthen your search string to shorten the list for locating the required consumer organization.
  4. Click Save to create the group.
- Editing a consumer organization group.
  1. Click the options icon ⋮ for the consumer organization group that you want to work with, then click Edit.
  2. Make the required updates, then click Save.

  Note: If you remove a consumer organization from a group, and that group is specified in the custom visibility settings for a Product, applications in that consumer organization can no longer subscribe to the Product. However, any existing subscriptions are not affected. For information on managing visibility and subscribability settings, see Editing a draft Product.
- Deleting a consumer organization group.
  1. Click the options icon ⋮ for the consumer organization group that you want to work with, then click Delete.
  2. Click Confirm to delete the group.
- Sending an email to the owners of the consumer organizations in a consumer group
  1. Click the options icon ⋮ for the consumer organization group that you want to work with, then click Message owners.
     The Send message window opens, and the email addresses of the consumer organization owners are displayed as the recipients.
  2. Enter the subject of the message in the Subject field.
  3. Enter the content of the message in the Message field, then click Send.

Sending messages to consumer organization owners

You can send email messages to the owners of consumer organizations. You can also style the email to match your business theme.

Before you begin

To complete this task, you must be defined as a member in a catalog or space (if spaces are enabled), and you must be assigned a role that has the Consumer-Org >. Manage permission. For more information, see Adding provider organization users and assigning roles and Managing catalog membership.

Email messages contain a sender name and address that's based on a hierarchical search of the configured sender details in API Connect. Depending on the email being sent, the search can start at the Space level, and then go through the Catalog, Provider Organization, and the Cloud Manager levels. The sender details that are used will be the first set of configured details found during this hierarchical search. To view which search path API Connect takes when looking for the sender details for each notification template, see tbc.

Note: You can also send email messages by using the developer toolkit CLI, or by using the API Connect REST APIs. See API development and management commands, or API Connect REST APIs, for more information.

Procedure

To send a message, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. In the navigation pane of the API Manager UI, click the Consumers tab.
4. You can either send a message to the owner of a specific consumer organization, or to the owners of multiple selected consumer organizations.
   - To send a message to the owner of a specific consumer organization, click the options icon ⋮ alongside the consumer organization you want to work with, then click Message owner. The Send Message window opens, and the email address of the consumer organization owner is displayed as the recipient.
   - To send a message to the owners of multiple selected consumer organizations, complete the following steps:
     - Click the options icon ⋮ alongside the Add button, then click Message owners.
     - Select the required consumer organizations, then click Next. The Send Message window opens, and the email addresses of the selected consumer organization owners are displayed as the recipients.
5. Enter the subject of the message in the Subject field.
6. Select the Content type that you want to use for the entering the content of the message, from HTML, PlainText, or Both. The default content type is PlainText.
   An edit window for the selected content type is displayed, or both edit windows are displayed if Both is selected.
   For HTML content, only the tags and their attributes that are shown in the following table are allowed.

Table 1. List of allowed HTML tags and their attributes

HTML tag	Attribute
`<a>`	`"class", "href", "hreflang", "style"`
`<em>`	`"class", "style"`
`<strong>`	`"class", "style"`
`<cite>`	`"class", "style"`
`<blockquote>`	`"class", "cite", "style"`
`<code>`	`"class", "style"`
`<ul>`	`"class", "type", "style"`
`<ol>`	`"class", "start", "type", "style"`
`<li>`	`"class", "style"`
`<dl>`	`"class", "style"`
`<dt>`	`"class", "style"`
`<dd>`	`"class", "style"`
`<h1>`	`"class", "id", "style"`
`<h2>`	`"class", "id", "style"`
`<h3>`	`"class", "id", "style"`
`<h4>`	`"class", "id", "style"`
`<h5>`	`"class", "id", "style"`
`<h6>`	`"class", "id", "style"`
`<p>`	`"class", "style"`
`<div>`	`"class", "style"`
` `	`"class", "style"`
`<span>`	`"class", "style"`
`<img>`	`"class", "src", "alt", "data-entity-type", "data-entity-uuid", "data-align", "data-caption", "width", "height", "style"`
`<table>`	`"class", "id", "style"`
`<tr>`	`"class", "id", "style"`
`<td>`	`"class", "id", "style"`

   If an HTML tag that is not allowed is used in a notification, the tag and its contents are displayed in the email as plain text.
   Images can be used by adding a `<img src="https://path/to/image.png"/>` tag in the template. The `src` attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images, they must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.
7. Enter the content of the message.
8. Click Send.

Working with developer applications

You can work with the applications that have been registered in the Developer Portal associated with a Catalog.

Procedure

To work with developer applications, complete the following steps.

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. Click the Applications tab.
   All applications that have been registered in the Developer Portal associated with this Catalog are listed.
4. To view and edit the details of an application, click the title of the application.

5. Further options are available by clicking the options icon ⋮ alongside the application you want to work with, as follows:
   - Client ID: lists the Client IDs for the application. You can add new client ID/client secret credentials; you can copy the client secret only at creation time. An option is provided for deleting any of the credentials from the application.
   - Create Subscription: subscribe the application to a Plan in a Product; select the required Plan and Product, then click Create Subscription.
   - View Subscriptions: a window opens listing summary details of all the Plan subscriptions for the application. If required, you can click the options icon ⋮ alongside a subscription to work with that subscriptions. For details of the available options, see Working with application subscriptions.
   - View Consumer Organization: a window opens listing the consumer organization that the application belongs to. If required, you can click the options icon ⋮ to work with the consumer organization. For details of the available options, see Working with consumer organizations.

Working with application subscriptions

You can work with the subscriptions to the Plans in all the Products in a specific Catalog. Plan subscriptions are created by application developers in the Developer Portal.

Procedure

To work with application subscriptions, complete the following steps:

1. In the navigation pane of the API Manager UI, click Manage, then select the catalog that you want to work with.
   The Products page of the catalog opens, and all of the products available in that catalog are displayed.
2. Optional: If spaces are enabled in the catalog, select the space that you want to work with by completing the following steps:
   a. Click the Spaces tab.
   b. Select the space that you want to work with.
   For more information about enabling spaces, see Using syndication in API Connect.
3. Click the Subscriptions tab.
   A window opens listing all subscriptions to the Plans in all the Products in the Catalog.
4. Alongside the subscription that you want to work with, click the options icon ⋮.
   You can then select from the following options:
   - View Consumer Organization: a window opens listing the consumer organization that the subscribing application belongs to. If required, you can click the options icon ⋮ to work with the consumer organization For details of the available options, see Working with consumer organizations.
   - View Application: a window opens listing the subscribing application. If required, you can click the options icon ⋮ to work with the application. For details of the available options, see Working with developer applications.
   - View Plan: a window opens listing the Plan that the application is subscribed to. If required, you can click the options icon ⋮ to work with the Plan. For details of the available options, see Working with Plans.
   - View Product: a window opens listing the Product that contains the Plan that the application is subscribed to. If required, you can click the options icon ⋮ to work with the Product. For details of the available options, see Managing your Products.

Security and authentication

In API Manager, you can use TLS profiles to secure the transmission of data between the management server and other API Connect subsystems and external services, and also configure user registries to securely authenticate your Catalogs and APIs.

For details of authentication in IBM API Connect, see the following subtopics:

- **Creating a TLS client profile**
  In the IBM API Connect API Manager interface, TLS profiles are used to secure transmission of data between the management server and other API Connect subsystems and external services. TLS and SSL certificates guarantee that information you submit will not be stolen or tampered with. In this topic, you learn how to create a TLS profile in API Manager.
- **Authenticating by using your enterprise user registry**
  IBM API Connect supports a variety of user registry types for authenticating users and securing APIs.
- **Configuring a native OAuth provider**
  Native OAuth providers are configured and managed by you within your cloud.
- **Configuring a third-party OAuth provider**
  Enter the secure endpoints to provide OAuth authentication from a third party.
- **OAuth concepts for API Connect**
  OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information.

Creating a TLS client profile

In the IBM® API Connect API Manager interface, TLS profiles are used to secure transmission of data between the management server and other API Connect subsystems and external services. TLS and SSL certificates guarantee that information you submit will not be stolen or tampered with. In this topic, you learn how to create a TLS profile in API Manager.

Before you begin

One of the following roles is required to configure TLS Profiles:

- Organization Administrator
- Owner
- Custom role with the `Settings: Manage` permissions

About this task

API Connect supports the use of TLS and SSL certificates, but does not itself produce strong encryption keys or manage your encryption keys. Encryption keys should be created and managed according to your own procedures. For more information, see Viewing certificate details and adding certificates to a keystore or truststore and Generating a PKCS#12 file for Certificate Authority.

Note: If you update a TLS profile that is associated with a Gateway service, the updates are not automatically propagated to Gateway servers. For instructions on configuring the toolkit command-line tool to use TLS certificates when connecting to API Manager, see Configuring the command-line tool to use TLS certificates.

Procedure

To create a TLS profile, complete the following steps:

1. In the API Manager, click Resources.
2. Select TLS.
3. Click Create in the TLS Client Profile table.
4. Enter the fields to configure the TLS Client Profile:

Field	Description
Title (required)	Enter a Title for the profile. The title is displayed on the screen.
Name (required)	The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage a TLS Client Profile, see apic tls-client-profiles. Important: The name of the TLS Client Profile as saved on the DataPower® Gateway, depending on the gateway type, is as follows: • DataPower API Gateway: `provider-org-name_catalog-name_tlsp-tls-profile-nameV1.0.0` • DataPower Gateway (v5 compatible): `provider-org-name-tls-profile-nameV1.0.0` where • *tls-profile-name* is the value of the auto-generated Name field for the TLS client profile in API Connect. • *provider-org-name* is the name of the provider organization containing the TLS client profile. • *catalog-name* is the name of the catalog, in that provider organization, containing the TLS client profile.
Version (required)	Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, *MyProfile 1.0* and *MyProfile 1.1*.
Summary (optional)	Enter a description of the profile.
Protocols (required)	Select one or more supported TLS protocol versions. The default is 1.2.
Server Connection (optional)	Specify whether to support weak or insecure credentials. • Allow insecure server connections - Insecure server connections may result from self-signed certificates, expired or corrupted certificates, or certificates from an unknown or untrusted source. Check this box to allow the connection to proceed with an insecure connection. The default is to not allow insecure server connections. • Support Server Name Indication (SNI) - Check this box to enable SNI. SNI allows support for multiple certificates presented on the same IP address using different host names. The client profile sends the name of a virtual domain as part of the TLS negotiation. The default is to enable SNI.
Keystore (optional)	A Keystore is a repository containing public and private key pairs. Select the keystore where you will store the certificates for the profile. Default keystores are provided, and you can also create your own.
Truststore (optional)	A Truststore is a repository containing verified public keys, which are usually obtained from a third-party certificate authority. Truststores provide list of certificates to verify a peer's certificate. If used in a TLSServerProfile, a truststore is used when mutual authentication is enabled. Select a truststore for the profile. Default truststores are provided, and you can also create your own.
Ciphers (required)	Cipher suites are encryption/decryption algorithms used to secure HTTPs communication within the API Connect ecosystem. Select the ciphers that the profile supports. Note: The TLS 1.3 ciphers are clearly indicated. If you select TLS version 1.3 as one of the protocols for the profile but do not select any TLS 1.3 ciphers, **all** the TLS 1.3 ciphers are added to the list of ciphers supported by the profile. If you do not select TLS version 1.3 but select one or more TLS 1.3 ciphers, those ciphers are **not** added to the list of ciphers supported by the profile.

5. Click Save.

- **Creating a Keystore**
  Keystores contain matched pairs of public certificates and private keys used to confirm identity and encrypt/decrypt data transmission over HTTPS.
- **Creating a Truststore**
  Truststores are repositories containing trusted certificates with verified public keys. The certificates in the truststore are usually obtained from a third-party certificate authority (CA).
- **Generating a PKCS#12 file for Certificate Authority**
  PKCS#12 (P12) files define an archive file format for storing cryptographic objects as a single file. API Connect supports the P12 file format for uploading a keystore and truststore. The keystore should contain both a private and public key along with intermediate CA certificates.
- **Generating a self-signed certificate using OpenSSL**
  OpenSSL is an open source implementation of the SSL and TLS protocols. It provides the transport layer security over the normal communications layer, allowing it to be intertwined with many network applications and services.
- **Viewing certificate details and adding certificates to a keystore or truststore**
  You can view details for the certificates in an existing keystore or truststore and add additional certificates. You might need add certificates when a certificate or

PKCS #12 (P12) file expires.
- **Defining elliptic curve cryptographic schemes for a TLS client profile**
  You define the elliptic curve cryptographic schemes for a TLS client profile by using the developer toolkit CLI.

Creating a Keystore

Keystores contain matched pairs of public certificates and private keys used to confirm identity and encrypt/decrypt data transmission over HTTPS.

Before you begin

API Manager supports and uses TLS certificates, but does not produce strong encryption keys or manage your encryption keys. Encryption keys are generated and managed according to your own procedures. For more information, see Generating a PKCS#12 file for Certificate Authority and Generating a self-signed certificate using OpenSSL.

One of the following roles is required to configure Keystores:

- Organization Administrator
- Owner
- Custom role with the `Settings: Manage` permissions

About this task

API Connect includes pre-configured Keystores which may be used for testing purposes. For production environments, we suggest creating a new, secure Keystore.

Procedure

Perform the following steps to create a TLS Client profile:

1. In the API Manager, click  Resources.
2. Select TLS.
3. Click Create in the Keystore table.

Field	Description
Title (required)	Enter a Title for the Keystore. The title is displayed on the screen.
Name (required)	The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage keystores, see apic keystores.
Summary (optional)	Enter a brief description.
Private Key & Public Key: Step 1: Upload private key	Upload the file containing the private key certificate. If necessary, you can click Browse to locate the file. If the file contains both the private and public keys, upload it in Step 1. Private and public keys are always uploaded in pairs, either in a single file or separate files.
Private key password (optional)	Enter the password for the private key if it has a password.
Private Key & Public Key: Step 2: Upload public key	If the public key is contained in a separate file, upload it in Step 2. Private and Public keys are always uploaded in pairs, either in a single file or separate files.

4. Click Save.
   Note: After they have been uploaded, private keys cannot be downloaded from API Connect.

- Creating a Truststore
- Generating a PKCS#12 file for Certificate Authority

Creating a Truststore

Truststores are repositories containing trusted certificates with verified public keys. The certificates in the truststore are usually obtained from a third-party certificate authority (CA).

Before you begin

One of the following roles is required to configure truststores:

- Organization Administrator
- Owner
- Custom role with the `Settings: Manage` permissions

About this task

API Manager supports and uses TLS certificates, but does not produce strong encryption keys or manage your encryption keys. Encryption keys are generated and managed according to your own procedures. For more information, see Generating a PKCS#12 file for Certificate Authority and Generating a self-signed certificate using OpenSSL.

API Connect includes pre-configured Truststores which may be used for testing purposes. For production environments, we suggest creating a new, secure Truststore.

Procedure

1. In the API Manager, click Resources.
2. Select TLS.
3. Click Create in the Truststore table.

Field	
Title (required)	Enter a Title for the Truststore. The title is displayed on the screen.
Name (required)	The Name is auto-generated. The value in the Name field is a single string that can be used in developer toolkit CLI commands. To view the CLI commands to manage truststores, see apic truststores.
Summary (optional)	Enter a brief description.
Public Keys	Upload the file containing the public key certificate. If necessary you can click Browse to locate the file.

4. Click Save.

Related tasks

- Creating a TLS client profile
- Creating a Keystore

Generating a PKCS#12 file for Certificate Authority

PKCS#12 (P12) files define an archive file format for storing cryptographic objects as a single file. API Connect supports the P12 file format for uploading a keystore and truststore. The keystore should contain both a private and public key along with intermediate CA certificates.

Before you begin

One of the following roles is required to add a key to a keystore or truststore:

- Organization Administrator
- Owner
- Custom role with the `Settings: Manage` permissions

Before you can generate a P12 file, you must have a private key (for example: key.pem), a signed certificate by a Certificate Authority (for example certificate.pem) and one or more certificates from the CA authority (known as *intermediate CA certificates*).
Note: If your certificate file contains more than one certificate, you must manually split the file and create a single file for each entry. Each entry must be bound by the following markers:

```
-----BEGIN CERTIFICATE-----

-----END CERTIFICATE-------
```

Procedure

1. If you have intermediate certificates from your CA, concatenate them into a single .pem file to build your **caChain**. Be sure to enter a new line following each certificate's data.

```
cat ca1.pem ca2.pem ca3.pem > caChain.pem
cat caChain.pem
-----BEGIN CERTIFICATE-----
MIIEpjCCA46gAwIBAgIQEOd26KZabjd+BQMG1Dw16jANBgkqhkiG9w0BAQUFADCB
...
lQX7CkTJn6lAJUsyEa8H/gjVQnHp4VOLFR/dKgeVcCRvZF7Tt5AuiyHY
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
MIIEPDCCAySgAwIBAgIQSEus8arH1xND0aJ0NUmXJTANBgkqhkiG9w0BAQUFADBv
...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
MIIENjCCAx6gAwIBAgIBATANBgkqhkiG9w0BAQUFADBvMQswCQYDVQQGEwJTRTEU
...
-----END CERTIFICATE-----
```

2. Create the P12 file including the private key, the signed certificate and the CA file you created in step 1, if applicable. Omit the **-CAfile** option if you don't have CA certificates to include.
   The following command uses OpenSSL, an open source implementation of the SSL and TLS protocols.

```
openssl pkcs12 -inkey key.pem -in certificate.pem -export -out certificate.p12 -CAfile caChain.pem -chain
```

   Once the certificate file is created, it can be uploaded to a keystore.
3. Once the certificate file is created, it can be uploaded to a Truststore. In the API Manager, click

4. Select TLS.
5. Click Create in the Keystore table.
6. Create a Keystore and upload the certificate file following the instructions at Creating a Keystore.
   Notes:
   - API Connect supports only the P12 (PKCS12) format file for the present certificate.
   - Your P12 file must contain the private key, the public certificate from the Certificate Authority, and all intermediate certificates used for signing.
   - Your P12 file can contain a maximum of 10 intermediate certificates.
7. Click Save.

Results

Your P12 file is generated and ready to upload.

What to do next

Upload your P12 file to IBM® API Connect. For more information, see Creating a TLS client profile.

Generating a self-signed certificate using OpenSSL

OpenSSL is an open source implementation of the SSL and TLS protocols. It provides the transport layer security over the normal communications layer, allowing it to be intertwined with many network applications and services.

Before you begin

One of the following roles is required to complete this task:

- Organization Administrator
- Owner
- Custom role with the `Settings: Manage` permissions

About this task

This topic tells you how to generate a self-signed SSL certificate request using the OpenSSL toolkit to enable HTTPS connections.

Procedure

To generate a self-signed SSL certificate using the OpenSSL, complete the following steps:

1. Write down the Common Name (CN) for your SSL Certificate. The CN is the fully qualified name for the system that uses the certificate. For static DNS, use the hostname or IP address set in your Gateway Cluster (for example. **`192.16.183.131`** or **`dp1.acme.com`**).
2. Run the following OpenSSL command to generate your private key and public certificate. Answer the questions and enter the Common Name when prompted.

   ```
   openssl req -newkey rsa:2048 -nodes -keyout key.pem -x509 -days 365 -out certificate.pem
   ```

3. Review the created certificate:

   ```
   openssl x509 -text -noout -in certificate.pem
   ```

4. Combine your key and certificate in a PKCS#12 (P12) bundle:

   ```
   openssl pkcs12 -inkey key.pem -in certificate.pem -export -out certificate.p12
   ```

5. Validate your P2 file.

   ```
   openssl pkcs12 -in certificate.p12 -noout -info
   ```

   Once the certificate file is created, it can be uploaded to a keystore.
6. In the API Manager, click  Resources.
7. Select TLS.
8. Click Create in the Keystore table.
9. Create a Keystore and upload the certificate file following the instructions at Creating a Keystore.
   Note:
   - API Connect supports only the P12 (PKCS12) format file for the present certificate.
   - Your P12 file must contain the private key, the public certificate from the Certificate Authority, and all intermediate certificates used for signing.
   - Your P12 file can contain a maximum of 10 intermediate certificates.
10. Click Save.

Related tasks

Viewing certificate details and adding certificates to a keystore or truststore

You can view details for the certificates in an existing keystore or truststore and add additional certificates. You might need add certificates when a certificate or PKCS #12 (P12) file expires.

Before you begin

One of the following roles is required to edit Keystores and Truststores:

- Organization Administrator
- Owner
- Custom role with the `Settings: Manage` permissions

About this task

API Connect includes pre-configured Keystores and Truststores which can be used for testing purposes. For production environments, we suggest creating a new, secure Keystore or Truststore. From an existing Keystore or Truststore, you can edit the title, view the details of the certificates, and add new certificates.

Procedure

To work with existing Keystores and Truststores:

1. In the API Manager, click  Resources.
2. Select TLS.
3. Click the name of the keystore or truststore.
4. Edit the name and summary if needed.
5. The Subject, Finger Print, and Expiration date is shown for each certificate in the keystore or truststore. Click > to view the certificate details.
6. Add additional private and/or public keys if needed.
7. Click Save.
   Note: After they have been uploaded, private keys cannot be downloaded from API Connect.

Defining elliptic curve cryptographic schemes for a TLS client profile

You define the elliptic curve cryptographic schemes for a TLS client profile by using the developer toolkit CLI.

About this task

To define elliptic curve cryptographic schemes for a TLS client profile, you include **`elliptic_curve_auto_negotiation`** and **`elliptic_curve`** properties in a YAML file definition for the TLS client profile. The **`elliptic_curve`** property lists the required elliptic curve cryptographic schemes. For example:

```
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - secp521r1
  - secp384r1
  - prime256v1
```

You then use the developer toolkit CLI to create the TLS client profile in API Connect.

When **`elliptic_curve_auto_negotiation`** is set to **`true`**, the system negotiates the Elliptic-curve Diffie-Hellman (ECDH) key agreement automatically with its peer, and any **`elliptic_curve`** property settings are ignored.

The following example shows a complete YAML file for a TLS client profile:

```
type: tls_client_profile
name: my-tls-client-profile
version: 1.0.0
title: My TLS client profile
protocols:
  - tls_v1.2
ciphers:
  - ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - sect163k1
insecure_server_connections: false
server_name_indication: true
```

Note:

- The **`elliptic_curve_auto_negotiation`** option is not supported by any of the API Connect gateway types. If the TLS client profile is targeted for an API Connect gateway; this setting is ignored by the gateway.
- The elliptic curve cryptographic schemes shown in each row of the following table are equivalent. However, API Connect recognizes only one or the other depending on how the TLS profile is used, as indicated in the table.

Table 1.

API enforcement on the gateway	API Connect server access security
secp192r1	prime192v1
secp256r1	prime256v1

Therefore, if you want to use either of these schemes and are unsure whether you are targeting the TLS client profile to the API Connect gateway for API enforcement, whether you are using it to secure user access to the API Connect servers, or whether it will be used for both purposes, specify both equivalent schemes; API Connect will simply ignore the non-relevant scheme. For example:

```
elliptic_curve:
        .
        .
        .
  - secp256r1
  - prime256v1
        .
        .
        .
```

Procedure

To create a TLS client profile with elliptic curve cryptographic schemes defined. complete the following steps:

1. Create a YAML file definition for your TLS client profile, with the required **elliptic_curve** property.
2. Log in to the management server from the developer toolkit CLI. Log in either as a member of the cloud administration organization or as a member of a provider organization, depending on where you want to create the TLS client profile. For details, see Logging in to a management server.
3. Create the TLS client profile by using the following command:

   ```
   apic tls-client-profiles:create --server mgmt_endpoint_url --org organization_name tls_client_profile_yaml_file
   ```

   where:
   - *mgmt_endpoint_url* is the platform API endpoint URL, and is the same as that which was used when you logged in at step 2.
   - *organization_name* is either **admin**, for the cloud administration organization, or the name of your provider organization, and is the same as that which was used when you logged in at step 2.
   - *tls_client_profile_yaml_file* is the name of the YAML file that contains the definition for your TLS client profile.

   Note: When you install IBM® API Connect, the API Connect gateway has a pre-supplied default TLS client profile that is used for API enforcement if you do not configure a TLS client profile; you cannot configure this default TLS client profile on the gateway.
   For reference details of all the **apic tls-client-profiles** commands, see apic tls-client-profiles.

   You can also complete the operations described in this topic by using the API Connect REST APIs; see the API Connect REST API documentation.

Authenticating by using your enterprise user registry

IBM® API Connect supports a variety of user registry types for authenticating users and securing APIs.

You can use your enterprise user registry for authentication in API Connect if it is of one of the following types:

LDAP directory
: If your user registry uses Lightweight Directory Access Protocol (LDAP), you can use it in API Connect for both user authentication and API security.

Authentication URL User Registry
: You can configure a non-LDAP user registry by using an authentication URL user registry. An authentication URL user registry enables integration with third-party authentication providers. You can use an authentication URL user registry in API Connect for both user authentication and API security.

Local User Registry
: You can authenticate users with a local user registry. A local user registry is an internal registry stored within API Connect.

OpenID Connect
: You can authenticate users through an identity provider that supports the OpenID Connect (OIDC) authentication protocol.

- **Working with user registries**
  To secure the APIs that are published to your IBM API Connect Catalogs, you authenticate with user registries.
- **Modifying the configuration details for a user registry**
  You modify the configuration details for a user registry by using the User Registries page in the API Manager user interface of IBM API Connect.
- **Password lockout criteria**
  You can be locked out of your account if you attempt to log in and fail consecutively.

Related tasks

- Working with user registries

Working with user registries

To secure the APIs that are published to your IBM® API Connect Catalogs, you authenticate with user registries.

About this task

Create user registry resources to secure your APIs, and authenticate with users.

Procedure

To configure a user registry, complete the following steps:

1. In the API Manager user interface, select Resources.
2. On the Resources page, select User Registries > Create.
3. Select the tile for the user registry type you want, and continue to the instructions for configuring user authentication for your selection.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

   Authentication URL User Registry
   : For more information, see Creating an Authentication URL user registry.

   Custom user registry
   : For more information, see Creating an organization-specific custom user registry.

   LDAP User Registry
   : For more information, see Creating an LDAP user registry in API Manager.

   Local User Registry
   : For more information, see Creating a Local User Registry

   OIDC User Registry
   : For more information, see Creating an OIDC user registry.

Results

The user registry information is added to API Manager.

What to do next

You can now use API Manager to chart and manage your Catalogs.

- **Creating an Authentication URL user registry**
  An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.
- **Creating an organization-specific custom user registry**
  You can configure an organization-specific custom user registry to provide user authentication for the Developer Portal.
- **Creating an LDAP user registry in API Manager**
  You can use the API Manager UI to configure an organization-specific LDAP user registry to provide user authentication and onboarding for the Developer Portal. APIs can also be secured with an LDAP user registry.
- **Creating a Local User Registry**
  A Local User Registry (LUR) can be created to provide user authentication for API Manager.
- **Creating an OIDC user registry**
  Create an organization-specific OIDC user registry when multi-factor authentication (MFA) is required.

Creating an Authentication URL user registry

An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.

About this task

This topic describes how to create a new Authentication URL user registry as a Resource in your organization. After the user registry is created, the user registry must be added to the Sandbox catalog.

One of the following roles is required to configure user registries:

- Administrator
- Organization Owner
- Custom role with the `Settings: Manage` permissions

Note:
API Connect issues an HTTP **`GET`** call to the Authentication URL endpoint, sending the user's credential. The following example shows a call made to an Authentication URL identity provider with an endpoint defined as **`https://myauthurl.example.com/user/authenticate`**:

```
GET /user/authenticate HTTP/1.1
 Host: myauthurl.example.com
 Authorization: Basic c3Bvb246Zm9yaw=
```

If the Authentication URL endpoint returns an HTTP status code of **`200`**, the user authenticates successfully. An HTTP status code other than **`200`** indicates a failed login attempt. API Connect forwards any HTTP Header starting with **`X-`** (with the exception of **`X-Client-Certificate`**), and Cookie to the Authentication URL identity provider, to aid the authentication decision; for example:

```
GET /user/authenticate HTTP/1.1
 Host: myauthurl.example.com
 Authorization: Basic c3Bvb246Zm9yaw=
 X-Forwarded-For: 8.8.9.9
 X-Custom-Header-From-Customer: special
 Cookie: MyCookie=VGhpc0lzV2lja2VkQW1hemluZw==
```

When a user is presented with the form for completing their API Connect user registration, which fields are pre-populated depends on which fields are returned in the response from the Authentication URL identity provider. If any of the following fields are returned, they will be pre-populated in the registration form:

- `username`
- `email`
- `first_name`
- `last_name`

If the `username` field is not returned, the registration form displays the user name that was provided by the user. The pre-population capability requires that the response from the Authentication URL identity provider satisfies the following conditions:

- The `Content-Type` must be `application/json`.
- The response body format must be JSON.

A sample response is as follows:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache

{
  "username":"myuser",
  "email":"myuser@example.com",
  "first_name":"My",
  "last_name":"User"
}
```

Procedure

1. In the API Manager, click  Resources.
2. Select User Registries to see the list of current user registries in your organization.
3. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. Select Authentication URL User Registry and enter the following parameters:

Field	Description
Title (required)	Enter a descriptive name to use on the screen.
Name (required)	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see apic user-registries.
Summary (optional)	Enter a brief description.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the `Title` of the User Registries when rendering them at the login page, rather than the `Display Name`.
URL (required)	Enter the URL for the authentication service. When establishing authentication, API Connect makes a GET call to the URL. The call includes the user name and password it has collected from the user in its authorization header. Either `200 OK` or `401 Unauthorized` will be returned.
TLS Client Profile (optional)	Select a TLS Client Profile to allow secure authentication with a specific web server.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend Authentication URL server: • **Only** select Case sensitive if your backend server supports case-sensitivity. • Do **not** select Case sensitive if your backend server does not support case-sensitivity. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

5. Click Save.
6. Add the user registry to the Sandbox catalog. See Creating and configuring Catalogs.

Results

The user registry can be used for Basic Authentication in the Security Definition for an API. For more information, see Creating a basic authentication security definition.

Creating an organization-specific custom user registry

You can configure an organization-specific custom user registry to provide user authentication for the Developer Portal.

Before you begin

Custom user registries can be used for authenticating users to the Developer Portal, but cannot be used to secure APIs.

To configure a custom user registry as a resource in API Manager, the external user directory must be created and available to use with your API Connect ecosystem.

Also, a custom user registry definition for your external user registry must already have been created on the Cloud Manager, as you will need the information from this definition to set up the custom user registry. See Configuring a shared custom user registry for information.

One of the following roles is required to configure a custom user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create a custom user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific user registry can be used for authenticating Developer Portal users in a specific provider organization. While a shared user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure an organization-specific custom user registry. If you want to create a shared registry, see Configuring a shared custom user registry for more information.
Note:

- You can also create and manage custom user registries by using the API Connect REST APIs; see the API Connect REST API documentation.

You can use the following instructions to create a writable or a read-only custom user registry.

API Connect provides two methods for creating a custom user registry in the API Manager, as described in the following sections:

- Creating a custom user registry by using the API Manager UI
- Creating a custom user registry by using the developer toolkit CLI

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

Creating a custom user registry by using the API Manager UI

You configure a custom user registry by creating a new custom user registry resource, which references the custom user registry type that is defined in the Cloud Manager. To make the custom user registry available to the Developer Portal for user authentication, you must enable the registry in the associated Catalog. When the custom user registry is used for authentication, API Connect makes a REST call to the endpoint of your external registry, as defined in the custom user registry type.

Creating a custom user registry resource

Use the following instructions to create a new custom user registry resource in the API Manager UI.

1. Click Create in the User Registries section of Resources.
2. Click the Custom user registry tile.
3. Enter the following information:

Property	Description
Custom type	The name of the custom user registry type. For example, *my-custom-user-registry-type*. Use the drop-down arrow to select different custom user registry types. The custom user registry type is defined in the Cloud Manager.
Title	A descriptive name to display in the UI.
Name	The name of the custom user registry. This name is auto-generated, and is used in CLI commands.
Summary	A brief description of the custom user registry.
Endpoint	Optional endpoint information.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend server: • **Only** select Case sensitive if your backend server supports case-sensitivity. • Do **not** select Case sensitive if your backend server does not support case-sensitivity. Note: • The Developer Portal does not support case sensitive usernames. • After at least one user has been onboarded into the registry, you cannot change this setting.
User registry managed	Determines whether API Connect manages your user registry. Valid values are: • **`true`** - select the checkbox • **`false`** - clear the checkbox
User managed	Determines whether your user registry is writable or not. Select the checkbox to set to **`true`** for writable. Clear the checkbox for the non-writable option.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.

Property	Description
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Create. The new user registry is displayed in the User registries list.

Adding your custom user registry to the Developer Portal login

To make the custom user registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Catalog settings > Onboarding. In the Catalog User Registries section, click Edit, select the custom user registry, and click Save. For more information, see Creating and configuring Catalogs.

Creating a custom user registry by using the developer toolkit CLI

You configure an organization-specific custom user registry by creating a new custom user registry resource that references the integration document that exists on the Cloud Manager. You use developer toolkit CLI commands to create the custom user registry, and to make the registry available to the Developer Portal, you must enable the registry in the associated Catalog. When the custom user registry is used for authentication, API Connect makes a REST call to the endpoint of your external registry, as defined in the integration document.

Logging in to the management server CLI

Before you can define the custom user registry configuration, you must log in to your management server from the developer toolkit CLI as a member of a provider organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the login command, see Logging in to a management server.

For more information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Defining your custom user registry

You define the configuration of your custom user registry in a `custom_config_file.yaml` file, as shown in the following example.

```
name: 'custom_registry_name'
title: 'display_title'
registry_type: 'custom_user_registry'
integration_url: custom_integration_url
case_sensitive: true_or_false
user_managed: true_or_false
user_registry_managed: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
 - name: provider_name
   title: 'provider_title'
configuration:
  custom_config1: 'value1'
  customize: true
```

The registry properties that are common to each authentication method are described in the following table:

Property	Description
`name`	The name of the custom user registry. This name is used in the CLI commands.
`title`	A descriptive name to display in a graphical user interface.
`registry_type`	The registry type that is configured in the `name` property in the integration document, for example `custom_user_registry`.
`integration_url`	The custom integration URL in your API Connect configuration. You can determine the custom integration URL by using the following CLI command: `apic integrations:list --server mgmt_endpoint_url --subcollection user-registry`

Property	Description
`case_sensitive`	Determines whether your user registry is case-sensitive. Valid values are: • `true` • `false` To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** set `case_sensitive` to `true` if your backend LDAP server supports case-sensitivity. • Set `case_sensitive` to `false` if your backend LDAP server does not support case-sensitivity. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
`user_managed`	Determines whether your user registry is writable or not. Must be set to `true` for writable. Set to `false` if you don't want the registry to be writable.
`user_registry_managed`	Determines whether API Connect manages your user registry. Valid values are: • `true` • `false`
`email_required`	Determines whether an email address is required as part of the user onboarding process. Valid values are: • `true` • `false` If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
`email_unique_if_exist`	Determines whether email addresses must be unique within the user registry. Valid values are: • `true` • `false` Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
`identity_providers`	An array containing the details of your custom server, where: • `name` - is the name of the custom server and is the name that is used in CLI commands • `title` - is the display name of the custom server
`configuration`	The user-defined configuration based on the `configuration_schema` that is defined in the integration document.

Save your ***`custom_config_file`*`.yaml`** so it can be accessed by the **`user-registries:create`** command in the following section.

Creating your custom user registry

To create your organization-specific custom user registry, run the following CLI command:

`apic user-registries:create --server` ***`mgmt_endpoint_url`*** **`--org`** ***`organization_name custom_config_file`*****`.yaml`**

where:

- ***`mgmt_endpoint_url`*** is the platform API endpoint URL.
- **`--org`** ***`organization_name`*** means that the registry will be created in your provider organization.
- ***`custom_config_file`*** is the name of the YAML file that defines the configuration of your custom user registry.

On completion of the registry creation, the command displays the following summary details:

`registry_name registry_url`

The ***`registry_name`*** is derived from the **`name`** property in the custom user registry YAML file. The ***`registry_url`*** is the URL with which the custom registry resource can be accessed.
Your organization-specific user registry is now created; see the following section for instructions on how to make the registry available to users.

Configuring your custom user registry in a Catalog

To make your custom user registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your custom user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   `apic user-registries:list --server` ***`mgmt_endpoint_url`*** **`--org`** ***`organization_name`***

2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   `apic configured-catalog-user-registries:create --server` ***`mgmt_endpoint_url`*** **`--org`** ***`organization_name`*** **`--catalog`** ***`catalog_name`*** **`-`**

   where *catalog_name* is the value of the `name` property of the required Catalog. The command returns

   `Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin`

3. Enter the following data, followed by a new line:

   `user_registry_url:` ***`custom_registry_url`***

   where ***`custom_registry_url`*** is the URL of your custom user registry, obtained in step 1.

4. Press `CTRL D` to terminate the input.

Creating an LDAP user registry in API Manager

You can use the API Manager UI to configure an organization-specific LDAP user registry to provide user authentication and onboarding for the Developer Portal. APIs can also be secured with an LDAP user registry.

Before you begin

To configure an LDAP user registry as a resource in API Manager, the LDAP directory must be created and populated for use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, or for securing a Catalog to authenticate Developer Portal users.

Important: If you are using an LDAP registry to secure APIs, the STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.
One of the following roles is required to configure an LDAP user registry:

- Organization Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for authenticating Developer Portal users in a specific provider organization. While a shared LDAP user registry can be used across the Cloud Manager, the API Manager, and the Developer Portal components in your environment.

This topic describes how to configure an organization-specific LDAP user registry. If you want to create a shared registry, see Configuring an LDAP user registry in the Cloud Manager for more information.
Note:

- You can also create and manage LDAP user registries by using the developer toolkit CLI. For more information, see Using the CLI to create an organization-specific LDAP user registry.
- The API Connect REST APIs can also be used to create and manage LDAP user registries; see the API Connect REST API documentation.
- If you are using the DataPower® API Gateway, LDAP group authentication is not supported.
- You can map external LDAP groups to API Connect user roles to enable greater control of user access, but this configuration can be done only by using the developer toolkit CLI; see Using the CLI to create an organization-specific LDAP user registry for details.

You create an LDAP user registry by configuring a set of properties in the API Manager UI. If you want to enable writable LDAP, you must complete the Attribute Mapping section by selecting the User Managed checkbox, and providing the mapping of your source LDAP attribute names to the target API Connect values. You can also change a registry to be read-only again by clearing the User Managed checkbox. To make the registry available to the Developer Portal, you must define the registry for consumer onboarding in the associated Catalog. To secure APIs with an LDAP registry, you must configure security definitions.

For general information about authenticating with LDAP, see LDAP authentication.

Procedure

Follow these steps to configure a new LDAP user registry as a Resource in the API Manager UI.

Note: If you are using an **`Active Directory`**, you must indicate this by using the property **`"directory_type": "ad"`** in the LDAP config.

1. In the API Manager, click  Resources.
2. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
3. Select LDAP User Registry for the user registry type, and enter the following information:

Field	Description
Title	Enter a descriptive name to display on the screen.
Name	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see apic user-registries.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the **`Title`** of the User Registries when rendering them at the login page, rather than the **`Display Name`**.
Summary (optional)	Enter a brief description.
Address	Enter the IP address or host name of the LDAP server.

Field	Description
Port	Enter the Port number that API Connect can use to communicate with the LDAP registry. For example, `389`.
Select a TLS Client Profile (optional)	Select the TLS Client Profile that the LDAP server requires.
Select a protocol version	Select the version number for the LDAP protocol that you are using.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** select Case sensitive if your backend LDAP server supports case-sensitivity. • Do **not** select Case sensitive if your backend LDAP server does not support case-sensitivity. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Next and enter the authentication information, which will vary depending on the selected Authentication Method. The choices are:
   - Compose DN - Select this format if you can compose the user LDAP Distinguished Name (DN) from the user name. For example, **`uid=<username>,ou=People,dc=company,dc=com`** is a DN format that can be composed from the user name. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, Compose DN is not supported with the DataPower API Gateway.
   - Compose UPN - Select this format if your LDAP directory supports binding with User Principal Names such as **`john@acme.com`**. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator.
     Note: The Admin Bind DN and Admin Bind Password are not used with this authentication method.
   - Search DN - Select this format if you cannot compose the user LDAP Distinguished Name from the user name; for example, if the base DNs of the users are different. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.

   For all of the authentication methods:

   If you are creating an LDAP registry to authenticate users of an API, you can specify an LDAP authorization group to restrict API access. To be able to call an API that is secured by the LDAP registry, a user must successfully authenticate with their LDAP user ID and password **and** they must be a member of the specified authorization group. The authorization group can be a Static Group or Dynamic Group. A static group is one in which the individual members of the group are explicitly listed. A dynamic group is one which is defined according to the set of attributes that the group members share in common.

5. For authentication method Compose DN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Prefix	Specify the prefix to the DN. For example `(uid=`.
Suffix	Specify the suffix to the DN. For example `)`.
Base DN (optional)	Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN.
Use group authentication (optional)	Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.

6. For authentication method Compose UPN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Suffix	Enter the domain part of the user principal name. For example, `@acme.com`.
Use group authentication (optional)	Enter the Filter condition for the group.

7. For authentication method Search DN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the Distinguished Name of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Prefix	Specify the prefix to the DN. For example `(uid=`.
Suffix	Specify the suffix to the DN. For example `)`.
Base DN (optional)	Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN.
Use group authentication (optional)	Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.

8. Optional: Click Test configuration to test the settings for your LDAP user registry. Enter valid credentials to ensure that you can access the LDAP database.
9. Optional: If you want to make your LDAP user registry writable, select the User Managed checkbox in the Attribute Mapping section, and provide the mapping of your source LDAP attribute names to the target API Connect values. Click Add to add each name/value pair, specified as follows:

- LDAP ATTRIBUTE NAME - is the name of the source LDAP attribute.
- API CONNECT VALUE - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.

The default user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`, as shown in the following example:

LDAP ATTRIBUTE NAME	API CONNECT VALUE
`dn`	`uid=[username],ou=users,dc=company,dc=com`
`cn`	`[first_name] [last_name]`
`sn`	`[last_name]`
`mail`	`[email]`
`userPassword`	`[password]`

You must ensure that you enter the correct attribute mapping values for your LDAP configuration, to enable API Connect to access the LDAP database. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.

10. Click Create.
    Your new LDAP registry is shown in the list of User Registries on the Resources page.

What to do next

If you want to make the LDAP user registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Click the relevant Catalog, then click Settings > Onboarding. In the Catalog User Registries section, click Edit, select the user registry, and click Save. For more information, see Creating and configuring catalogs .

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see Creating a basic authentication security definition.
- To use for authentication in the User Security configuration for a native OAuth provider, see Configuring user security for a native OAuth provider.

- **Using the CLI to create an organization-specific LDAP user registry**
  You can use the developer toolkit CLI to configure an organization-specific LDAP user registry to provide user authentication for the Developer Portal. APIs can also be secured with an LDAP user registry.

Using the CLI to create an organization-specific LDAP user registry

You can use the developer toolkit CLI to configure an organization-specific LDAP user registry to provide user authentication for the Developer Portal. APIs can also be secured with an LDAP user registry.

Before you begin

To configure an LDAP user registry as a resource in API Manager, the LDAP directory must be created and available to use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, or for securing a Catalog to authenticate Developer Portal users.

Important: If you are using an LDAP registry to secure APIs, The STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.
Note: If you are using an **`Active Directory`**, you must indicate this by using the property **`"directory_type": "ad"`** in the LDAP config.
One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for onboarding and authenticating Developer Portal users in a specific provider organization. While a shared LDAP user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure an organization-specific LDAP user registry. If you want to create a shared registry, see Using the CLI to configure a shared LDAP user registry for more information.
Note:

- You can also create organization-specific LDAP user registries by using the API Manager UI; for more information see Creating an LDAP user registry in API Manager.
- In addition, you can create and manage LDAP user registries by using the API Connect REST APIs; see the API Connect REST API documentation.
- If you are using the DataPower® API Gateway, LDAP group authentication is not supported.
- You can map external LDAP groups to API Connect user roles to enable more control of user authorization by using the developer toolkit CLI. The following instructions explain how to set the **`external_group_mapping_enabled`** configuration on your LDAP user registry resource. For information about how to set external role mapping on your API Connect user roles, see Configuring LDAP group mapping on Cloud Manager user roles.

You create an LDAP user registry by first defining the registry details in a configuration file. You then use a developer toolkit CLI command to create the registry, passing the configuration file as a parameter. To make the registry available to the Developer Portal, you must enable the registry in the associated Catalog. To secure APIs with an LDAP registry, you must configure security definitions. You can use the following instructions to create a writable or a read-only LDAP user registry.

For general information about authenticating with LDAP, see LDAP authentication.

Logging in to the management server CLI

Before you can define the LDAP user registry configuration, you must log in to your management server from the developer toolkit CLI as a member of a provider organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the login command, see Logging in to a management server.

For more information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Defining your LDAP configuration

You define the configuration of your LDAP user registry in an *`ldap_config_file`*`.yaml` file, as shown in the following example. Note that the actual contents of your YAML file will vary depending on the authentication method of your LDAP server, and this is explained in the following tables.
Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.

```
name: registry_name
title: "display_title"
integration_url: LDAP_integration_url
user_managed: true_or_false
user_registry_managed: false

external_group_mapping_enabled: true_or_false
case_sensitive: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
 - name: provider_name
   title: provider_title
endpoint:
  endpoint: "ldap_server_url_and_port"
configuration:
  authentication_method: authentication_method
  authenticated_bind: "true_or_false"
  admin_dn: "admin_dn"
  admin_password: admin_password
  search_dn_base: "search_dn_base"
  search_dn_scope: search_dn_scope
  search_dn_filter_prefix: prefix
  search_dn_filter_suffix: suffix
  attribute_mapping:
    dn: "distinguished_name"
    cn: "common_name"
    sn: "last_name"
    mail: "email_address"
    userPassword: "password"
```

The registry properties that are common to each authentication method are described in the following table:

Property	Description
`name`	The name of the registry. This name is used in CLI commands.
`title`	A descriptive name to display in a graphical user interface.
`integration_url`	The LDAP integration URL in your API Connect configuration. You can determine the LDAP integration URL by using the following CLI command: `apic integrations:list --server mgmt_endpoint_url --subcollection user-registry`
`user_managed`	Determines whether your user registry is writable or not. Must be set to `true` for writable LDAP. You can change this setting to `false` if you don't want the registry to be writable; see the Switching your LDAP registry between writable and read-only section at the end of this topic for details. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
`user_registry_managed`	Must be set to `false` for LDAP. Determines whether API Connect manages your user registry. Only LUR registries are managed by API Connect.

Property	Description
`external_group_mapping_enabled`	Determines whether your user registry supports LDAP group mapping. Valid values are: • `true` • `false` The default value is `false`.
`case_sensitive`	Determines whether your user registry is case-sensitive. Valid values are: • `true` • `false` To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** set `case_sensitive` to `true` if your backend LDAP server supports case-sensitivity. • Set `case_sensitive` to `false` if your backend LDAP server does not support case-sensitivity. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
`email_required`	Determines whether an email address is required as part of the user onboarding process. Valid values are: • `true` • `false` If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
`email_unique_if_exist`	Determines whether email addresses must be unique within the user registry. Valid values are: • `true` • `false` Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
`identity_providers`	An array containing the details of your LDAP server, where: • `name` - is the name of the LDAP server and is the name that is used in CLI commands • `title` - is the display name of the LDAP server
`endpoint`	The endpoint of your LDAP server, made up of the url and port, for example: `"ldap://server.com:389"`
`tls_profile`	Optionally set the TLS Client Profile that the LDAP server requires.
`protocol_version`	Optionally set the version number for the LDAP protocol that you are using. Valid values are: • `2` • `3` Defaults to `3` if not explicitly set.

The properties in the configuration section will vary depending on the selected authentication method. The three authentication methods are:

- `compose_dn` - Set this format if you can compose the user LDAP Distinguished Name (DN) from the user name. For example, `uid=<username>,ou=People,dc=company,dc=com` is a DN format that can be composed from the user name. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, `compose_dn` is not supported with the DataPower API Gateway.
- `compose_upn` - Set this format if your LDAP directory supports binding with User Principal Names such as `john@acme.com`. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator.
  Note: The Admin Bind DN and Admin Bind Password are not used with this authentication method.
- `search_dn` - Select this format if you cannot compose the user LDAP Distinguished Name from the user name; for example, if the base DNs of the users are different. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.

For authentication method `compose_dn`, set the following configuration properties:

Properties	Description
`authentication_method`	`compose_dn`
`authenticated_bind`	The bind method. Valid values are: • `"true"` - authenticated bind • `"false"` - anonymous bind If specific permissions are not needed to search the registry, select `"false"`. If specific permissions are necessary, select `"true"`.
`admin_dn`	If `authenticated_bind` is set to `"true"`, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: `"cn=admin,dc=company,dc=com"`
`admin_password`	If `authenticated_bind` is set to `"true"`, enter the user password for the `admin_dn`.
`search_dn_base`	Optionally set a base DN, for example: `"dc=company,dc=com"`
`bind_prefix`	Set the prefix to the DN, for example: `(uid=`

Properties	Description
bind_suffix	Set the suffix to the DN, for example: **)**
attribute_mapping	If **user_managed** is set to **true**, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows: ***ldap_registry_attribute_name*: "*apic_ldap_attribute_value*"** Where: • *ldap_registry_attribute_name* - is the name of the source LDAP attribute • *apic_ldap_attribute_value* - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in **[ ]** with the value that the user supplies when signing up. The user profile properties that API Connect requires during user registration are **username**, **first_name**, **last_name**, **email**, and **password**. The following extract shows an example of an attribute mapping: **attribute_mapping:** **dn: "uid=[username],ou=users,dc=company,dc=com"** **cn: "[first_name] [last_name]"** **sn: "[last_name]"** **mail: "[email]"** **userPassword: "[password]"**

For authentication method **compose_upn**, set the following configuration properties:

Properties	Description
authentication_method	**compose_upn**
authenticated_bind	The bind method. Valid values are: • **"true"** - authenticated bind • **"false"** - anonymous bind If specific permissions are not needed to search the registry, select **"false"**. If specific permissions are necessary, select **"true"**.
admin_dn	If **authenticated_bind** is set to **"true"**, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: **"cn=admin,dc=company,dc=com"**
admin_password	If **authenticated_bind** is set to **"true"**, enter the user password for the **admin_dn**.
bind_suffix	Enter the domain part of the user principal name. For example: **@acme.com**
attribute_mapping	If **user_managed** is set to **true**, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows: ***ldap_registry_attribute_name*: "*apic_ldap_attribute_value*"** Where: • *ldap_registry_attribute_name* - is the name of the source LDAP attribute • *apic_ldap_attribute_value* - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in **[ ]** with the value that the user supplies when signing up. The user profile properties that API Connect requires during user registration are **username**, **first_name**, **last_name**, **email**, and **password**. The following extract shows an example of an attribute mapping: **attribute_mapping:** **dn: "uid=[username],ou=users,dc=company,dc=com"** **cn: "[first_name] [last_name]"** **sn: "[last_name]"** **mail: "[email]"** **userPassword: "[password]"**

For authentication method **search_dn**, set the following configuration properties:

Property	Description
authentication_method	**search_dn**
authenticated_bind	The bind method. Valid values are: • **"true"** - authenticated bind • **"false"** - anonymous bind If specific permissions are not needed to search the registry, select **"false"**. If specific permissions are necessary, select **"true"**.
admin_dn	If **authenticated_bind** is set to **"true"**, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: **"cn=admin,dc=company,dc=com"**
admin_password	If **authenticated_bind** is set to **"true"**, enter the user password for the **admin_dn**.
search_dn_base	Optionally set a base DN, for example: **"dc=company,dc=com"**

Property	Description
`search_dn_scope`	Optionally set the search DN scope. The scope determines which part of the directory information tree is examined. Possible values are: • `base` • `one` • `sub`
`search_dn_filter_prefix`	Set the prefix to the DN, for example: `(uid=`
`search_dn_filter_suffix`	Set the suffix to the DN, for example: `)`
`attribute_mapping`	If `user_managed` is set to `true`, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows: `ldap_registry_attribute_name: "apic_ldap_attribute_value"` Where: • *ldap_registry_attribute_name* - is the name of the source LDAP attribute • *apic_ldap_attribute_value* - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up. The user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`. The following extract shows an example of an attribute mapping: `attribute_mapping:` `  dn: "uid=[username],ou=users,dc=company,dc=com"` `  cn: "[first_name] [last_name]"` `  sn: "[last_name]"` `  mail: "[email]"` `  userPassword: "[password]"`

Save your `ldap_config_file.yaml` so it can be accessed by the `user-registries:create` command in the following section. See the Example section for an example configuration file.

Creating your LDAP user registry

To create your organization-specific LDAP user registry, run the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org organization_name ldap_config_file.yaml
```

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.
- *organization_name* is the value of the `name` property of your provider organization.
- *ldap_config_file* is the name of the YAML file that defines the configuration of your LDAP user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

The *registry_name* is derived from the `name` property in the configuration YAML file. The *registry_url* is the URL with which the registry resource can be accessed.
Your LDAP user registry is now created; see the following section for instructions on how to make the registry available in the Developer Portal.

Configuring your LDAP registry in a Catalog

If you want to make your LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org organization_name
   ```

2. Log in to the management server as a member of a provider organization; enter the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *catalog_name* is the value of the `name` property of the required Catalog. The command returns

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

4. Enter the following data, followed by a new line:

   ```
   user_registry_url: ldap_registry_url
   ```

   where *ldap_registry_url* is the URL of your LDAP registry, obtained in step 1.
5. Press **CTRL D** to terminate the input.

Switching your LDAP registry between writable and read-only

After an LDAP user registry has been created, it can be switched between writable and read-only by updating the **user_managed** property in the registry configuration. Complete the following steps.

1. Determine the name or ID of the LDAP user registry that you want to update, by running the following command (or you can use the summary from the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org organization_name
   ```

   The command returns a list of all the user registries for that organization, shown by name followed by their registry URL. The registry ID is located at the end of the URL, for example **https://company.com/api/user-registries/x-x-x-x-x/*registry_id***.
2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic user-registries:update --server mgmt_endpoint_url --org organization_name registry_name_or_id -
   ```

   where ***registry_name_or_id*** is the name or ID of the LDAP user registry that you want to update (as determined in the previous step). The command returns:

   ```
   Reading USER_REGISTRY_FILE arg from stdin
   ```

3. Enter the following data, followed by a new line:

   ```
   user_managed: true_or_false
   ```

   where **true** makes the registry writable, and **false** makes the registry read-only.
4. Press **CTRL D** to terminate the input.

Note that if you are changing your registry from read-only to writable, you must also set the **attribute_mapping** configuration, as described in the previous registry property tables.

Using an LDAP user registry to secure APIs

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see Creating a basic authentication security definition.
- To use for authentication in the User Security configuration for a native OAuth provider, see Configuring user security for a native OAuth provider.

For details of all the **apic user-registries** and **apic configured-catalog-user-registries** commands, see apic user-registries and apic configured-catalog-user-registries.

Example

The following example shows a configuration file that uses the Search DN authentication method for setting up writable LDAP:

```
name: sdn-ldap
title: "SDN LDAP User Registry"
integration_url: https://mycompany.com/api/cloud/integrations/user-registry/xxx-xxx-xxx
user_managed: true
user_registry_managed: false

case_sensitive: false
identity_providers:
  - name: ldap
    title: "SDN LDAP Identity Provider"
endpoint:
  endpoint: "ldap://mycompany.com:389"
configuration:
  authentication_method: search_dn
  authenticated_bind: "true"
  admin_dn: "cn=admin,dc=company,dc=com"
  admin_password: xxxx
  search_dn_base: "dc=company,dc=com"
  search_dn_scope: sub
  search_dn_filter_prefix: (uid=
  search_dn_filter_suffix: )
  attribute_mapping:
    dn: "uid=[username],ou=users,dc=company,dc=com"
    cn: "[first_name] [last_name]"
    sn: "[last_name]"
    mail: "[email]"
    userPassword: "[password]"
```

Creating a Local User Registry

A Local User Registry (LUR) can be created to provide user authentication for API Manager.

About this task

Local User Registries (LURs) are the default user registries included in API Connect. LURs are local databases included with API Connect. Two default LURs are installed and configured during installation of API Connect. They cannot be deleted. The default Admin user account is stored in the Provider LUR.

You can use API Manager to create additional Local User Registries for use with your provider organization.

One of the following roles is required to configure user registries:

- Administrator
- Organization Owner
- Custom role with the `Settings: Manage` permissions

Procedure

Follow these steps to configure a new LUR:

1. In the API Manager, click  Resources.
2. Select User Registries to see the list of current user registries in your organization.
3. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. Select Local User Registry as the type for the user registry and enter the following information:

Field	Description
Title (required)	Enter a descriptive name for use on the screen.
Name (required)	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see apic user-registries.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the **`Title`** of the User Registries when rendering them at the login page, rather than the **`Display Name`**.
Summary (optional)	Enter a brief description.
Case sensitive	Select this setting if user names are case-sensitive. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. For new Local User Registries, this setting is always selected; so if email addresses are contained in the user record, they must be unique. However, for existing Local User Registries this setting can be edited. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

5. Click Save.
6. Add the user registry to the Sandbox Catalog. See Creating and configuring Catalogs.

Results

The user registry can be used for Basic Authentication in the Security Definition for an API. For more information, see Creating a basic authentication security definition.

Creating an OIDC user registry

Create an organization-specific OIDC user registry when multi-factor authentication (MFA) is required.

You can create an OIDC user registry that is specific to a provider organization, or that is shared and available to all the provider organizations in your API Connect environment. An organization-specific OIDC user registry is used for onboarding and authenticating Developer Portal users, while a shared OIDC user registry can be used

for onboarding and authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to create an organization-specific registry. For information on how to create a shared registry, see Configuring an OIDC user registry.

Important: If you are using Twitter as your OIDC provider, API Connect supports only the OAuth 1.0a method, so your Twitter application must be configured to use OAuth 1.0a. Other OIDC providers support OAuth 2.0.
API Connect provides two methods for creating an OIDC user registry in API Designer, as described in the following sections:

- Using the UI to create an OIDC user registry
- Using the CLI to create an OIDC user registry

Using the UI to create an OIDC user registry

Use the API Designer user interface to create an organization-specific OIDC user registry when multi-factor authentication (MFA) is required.

1. In the API Designer navigation pane, click Resources.
2. Click User Registries.
3. Click Create and select OIDC User Registry.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. On the Create OIDC User Registry page, use the fields in each of the following sections to configure the registry settings, and then click Create.
   Many of the registry settings are preconfigured to simplify the configuration steps.

Provider Type
: Use the settings in Table 1 to define the provider type.

Table 1. Provider Type settings

Field	Description
Provider Type	OIDC provider. Select one of the following supported OIDC providers: • Facebook • GitHub • Google • LinkedIn • Slack • Twitter • Windows Live • Standard OIDC (default value allows you to specify another provider)
Title	Provide a descriptive name for display purposes.
Name	Automatically generated. This name is used in CLI commands to reference the registry. For details of the CLI commands for managing user registries, see the apic user-registries topic in the Command Line tool reference section of this documentation.
Summary	Provide a brief description of the new registry.
Email required	Select this check box if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this check box if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

Provider Endpoint
: Automatically generated for most supported providers. In the Authorization Endpoint field, type the URL of the provider's authorization endpoint.

Token Endpoint
: Fill in the settings as described in Table 2.

Table 2. Token Endpoint settings

Field	Description
URL	Preconfigured for most of the supported OIDC providers. Type the URL of the provider's token endpoint.
TLS	Select the TLS Client Profile for the token endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

UserInfo Endpoint
: Fill in the settings as described in Table 3.

Table 3. UserInfo Endpoint settings

Field	Description
URL	Preconfigured for most of the supported OIDC providers. Type the URL of the provider's userinfo endpoint.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

JWKS Endpoint
: Fill in the settings as described in Table 4.

Table 4. JWKS Endpoint settings

Field	Description
URL	Type the URL of the read-only endpoint that contains the public keys' information in JWKS format.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

Logout
: Fill in the settings as described in Table 5.

Table 5. Logout

Field	Description

Field	Description
Logout redirect	Optionally, give a logout redirect URL, allowing APIC to initiate an https 302 redirect to the configured endpoint. Note: When the Developer Portal uses this feature, it does not retain control afterwards. Instead, the content is presented from the redirected endpoint.

Client Information

Fill in the settings as described in Table 6.

Table 6. Client Information settings

Field	Description
Client ID	Provide the client ID of the application that is registered with the selected OIDC provider.
Client Secret	Provide the client secret of the application that is registered with the selected OIDC provider.
Response Type	Preconfigured for most of the supported OIDC providers. Specify the data type of the response that will be received from the OIDC provider.
Scopes	Preconfigured for most of the supported OIDC providers. Specify the access scope for the OIDC provider.
Client Authentication Method	Preconfigured for most of the supported OIDC providers. Select the authentication method to be used with the OIDC provider. Options are: • HTTP Basic authentication schema • Data encoded form body

Additional Support

Optional. Select the additional security parameters described in Table 7.

Table 7. Additional security options

Security parameter	Setting name for CLI	Description
NONCE	`nonce`	Enable the NONCE extension to prevent compromised requests from being used again (replayed).
Proof Key for Code Exchange (PKCE)	`pkce`	Enable the PKCE extension to allow public clients to mitigate the threat of having the authorization code intercepted.

Advanced Features

Optional. Select the advanced features described in Table 8.

Table 8. Advanced features

Feature / UI Label	Setting name for CLI	Description
Auto onboard	`auto_onboard`	Allow users to executes calls to APIs without logging in first, provided they present a valid token issued by the OIDC provider. Note: Does not apply to consumer organizations.
Always use the userinfo endpoint	`userinfo`	Configures the OIDC user registry to always fetch user data from the userinfo endpoint, if populated.
Use Portal as Endpoint for external OIDC provider traffic	`proxy_redirect`	When authenticating users, redirect the external OIDC provider to communicate with the Developer Portal instead of API Manager.
Return third-party access token	`proxy_access_token`	Include the third-party OIDC access token in the response. Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an ERR_HTTP2_PROTOCOL_ERROR or ERR_CONNECTION_CLOSED error.
Return third-party id_token	`proxy_id_token`	Include the third-party OIDC id_token in the response. Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an ERR_HTTP2_PROTOCOL_ERROR or ERR_CONNECTION_CLOSED error.
Token Relay	`token_relay`	Allow `access_token/refresh_token` to send in 302 redirect for logout
Userinfo POST	`post_userinfo`	If supported by your OIDC provider, by using HTTP POST method when contacting userinfo endpoint. Note: Not all OIDC providers support POST. Ensure that your OIDC provider supports this before you enable the feature.
Use IBM APIC token expiration setting from cloud	`override_provider_ttl`	Override the OIDC provider's token expiration setting with the access token and refresh token expiration settings that are configured in API Connect. For information on configuring the access token and refresh token expiration settings in API Connect, see Configuring timeouts for access tokens and refresh tokens.
Disable hash verification (CLI only)	`disable_hash_verification`	Disable `at_hash`, `c_hash`

User Mapping

Fill in the settings as described in Table 9.

Note:

The User Mapping fields are preconfigured for most of the supported OIDC providers to minimize potential errors; use care when changing the settings. For the Standard OIDC option, contact your OIDC provider to obtain the details of the fields.

Table 9. User mapping settings

Field	Description
Username	The name of the field in the response token that contains the user's user name. Note: The username field must be unique for this OIDC registry, because it identifies the user in the system and cannot be changed.
Email	The name of the field in the response token that contains the user's email address.
First name	The name of the field in the response token that contains the user's given name.
Last name	The name of the field in the response token that contains the user's surname.

Redirect URI
: The Redirect URI section lists the endpoints to which the OIDC authorization server will redirect the authorization code. There is one endpoint for each API Connect organization type: Cloud administration, Provider organization, and Consumer organization. The redirect endpoint is required when a user registers their application with the OIDC provider. For example, if this OIDC user registry is used by a provider organization, the user must register the provider organization's redirect endpoint with the OIDC provider. These read-only fields are provided for you to copy the endpoint values as required.

Enabling the OIDC user registry

Complete the following steps to enable the new user registry for a specific catalog in the Developer Portal. Repeat this procedure for each catalog that will use the new registry.

1. On the navigation pane, click  Manage.
2. Select the catalog for which you will enable the new OIDC user registry.
3. On the navigation pane, click the Catalog settings tab.
4. On the Settings page, click Onboarding.
5. On the Onboarding page, click Edit in the Catalog User Registries section.
6. On the Edit User Registry page, select the new OIDC user registry to enable for your catalog.
7. Click Save.

Using the CLI to create an OIDC user registry

Use the developer toolkit CLI to create an organization-specific OIDC user registry when multi-factor authentication (MFA) is required.

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the Catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
You configure an OIDC user registry by first defining the registry details in a configuration file. You then use a CLI command to create the registry, passing the configuration file as parameter. To make the registry available to the Developer Portal, you must enable the registry in the associated catalog.
Note:

- An OIDC registry, in common with a Local User Registry, cannot be used to secure APIs on the gateway.
- Because the interaction with the third party OIDC provider is handled by the Management server, the Management server is the application from the point of view of the third party OIDC provider. Your OIDC redirection endpoint, which is used by authorization server to send the token to the Management server, must be accessible to the OIDC provider through your firewall. When you register your application with the third party OIDC provider, you are required to supply the associated OIDC redirect URI, `https://consumer.mycompany.com/consumer-api/oauth2/redirect` for example. However, this information is not available until you have created your OIDC user registry in API Connect. You must therefore first register your application without this information, then update it later, as detailed in the instructions on this page.

Logging in to the Management server

Before you can create an OIDC user registry, you must log in to your management server from the CLI. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

Defining your OIDC registry configuration

Define the configuration of your OIDC user registry in a YAML file. At a minimum, the YAML file must include the settings from the following list. For additional settings, see the tables provided with the UI version of the procedure in this topic.

```
title: registry_title
integration_url: oidc_integration_url
case_sensitive: case_sensitivity_setting
email_required: true_or_false
email_unique_if_exist: true_or_false
configuration:
  client_id: 'app_client_id'
  client_secret: 'my-client-secret'
  provider_type: oidc_provider_type
```

where:

- *registry_title* is your chosen descriptive title for the user registry.
- *oidc_integration_url* is the OIDC integration URL in your API Connect configuration. You can determine the OIDC integration URL by using the following CLI command:

```
apic integrations:list --server mgmt_endpoint_url --subcollection user-registry
```

- *case_sensitivity_setting* determines whether your user registry is case-sensitive. Valid values are:
  - `true`
  - `false`

  To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on the backend OIDC provider:
  - Only set `case_sensitive` to `true` if the backend OIDC provider supports case-sensitivity.
  - Set `case_sensitive` to `false` if the backend OIDC provider does not support case-sensitivity.

  Note: After at least one user has been added to the registry, you cannot change this setting.
- *email_required* determines whether an email address is required as part of the user onboarding process. Valid values are:
  - `true`
  - `false`

  If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding.
  Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
- *email_unique_if_exist* determines whether email addresses must be unique within the user registry. Valid values are:
  - `true`
  - `false`

  Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
- *app_client_id* is the client ID of the application that is registered with the OIDC server, and must be in string format.
- *my-client-secret* is the client secret of the application that is registered with the OIDC server, and must be in string format.
- *oidc_provider_type* is the type of OIDC provider; specify one of the following values:
  - `facebook`
  - `github`
  - `google`
  - `linkedin`
  - `slack`
  - `twitter`
  - `windows_live`
  - `standard`

    Use the `standard` provider type for any OIDC provider that is compliant with the OIDC standard.
    Note: If the provider type is `standard`, you must include the following additional properties in the `configuration` section of your YAML file:

    ```
    authorization_endpoint: 'oidc_auth_endpoint'
    token_endpoint:
      endpoint: 'oidc_token_endpoint'
    ```

    where:
    - *oidc_auth_endpoint* is the authorization endpoint on the OIDC server, and must be in string format.
    - *oidc_token_endpoint* is the token endpoint on the OIDC server, and must be in string format.

Default OIDC configurations

For each OIDC provider type, API Connect assumes a default configuration, but you can override the default configuration properties in your YAML file. The default configurations are as follows:

- Facebook

```
authorization_endpoint: 'https://www.facebook.com/v3.1/dialog/oauth'
token_endpoint:
  endpoint: 'https://graph.facebook.com/v3.1/oauth/access_token'
userinfo_endpoint:
  endpoint: 'https://graph.facebook.com/me'
scope: email public_profile
field_mapping:
  username: email
  email: email
  last_name: last_name
  first_name: first_name
```

- GitHub

```
authorization_endpoint: 'https://github.com/login/oauth/authorize'
token_endpoint:
  endpoint: 'https://github.com/login/oauth/access_token'
userinfo_endpoint:
  endpoint: 'https://api.github.com/user'
scope: 'read:user user:email'
field_mapping:
  username: login
  email: email
  last_name: name
  first_name: name
```

- Google

```
authorization_endpoint: 'https://accounts.google.com/o/oauth2/v2/auth'
token_endpoint:
  endpoint: 'https://www.googleapis.com/oauth2/v4/token'
scope: openid profile email
field_mapping:
  username: email
  email: email
  last_name: family_name
  first_name: given_name
```

- Linkedin

```
authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'
token_endpoint:
  endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'
userinfo_endpoint:
  endpoint: 'https://api.linkedin.com/v1/people/~:(id,first-name,last-name,picture-url,public-profile-url,email-address)?
format=json'
scope: r_basicprofile r_emailaddress
field_mapping:
  username: emailAddress
  email: emailAddress
  last_name: lastName
  first_name: firstName
credential_location: form_body
```

- Slack

```
authorization_endpoint: 'https://slack.com/oauth/authorize'
token_endpoint:
  endpoint: 'https://slack.com/api/oauth.access'
userinfo_endpoint:
  endpoint: 'https://slack.com/api/users.identity'
scope: identity.basic identity.email
field_mapping:
  username: user.email
  email: user.email
  last_name: user.name
  first_name: user.name
```

- Twitter

```
request_endpoint: https://api.twitter.com/oauth/request_token'
authorization_endpoint: https://api.twitter.com/oauth/authenticate'
token_endpoint:
    endpoint: 'https://api.twitter.com/oauth/access_token'
userinfo_endpoint:
    endpoint: 'https://api.twitter.com/1.1/account/verify_credentials.json'
oauth_signature_method: 'HMAC-SHA1'
field_mapping:
    email: email
    first_name: name
    last_name: name
    username: screen_name
```

- Windows Live

```
authorization_endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/authorize'
token_endpoint:
  endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/token'
scope: openid offline_access profile email
field_mapping:
  email: email
  username: preferred_username
  first_name: name
  last_name: name
```

- Standard

```
response_type: code
scope: openid
field_mapping:
  username: sub
  email: email
  last_name: family_name
  first_name: given_name
credential_location: auth_header
```

  Although this is the default configuration for the **standard** provider type, you should contact your OIDC provider to obtain the details of the fields that you need to define.

Creating your OIDC user registry

To create your OIDC user registry, use the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org organization_name oidc_config_file
```

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.
- *organization_name* is the value of the **name** property of your provider organization.
- *oidc_config_file* is the name of the YAML file that defines the configuration of your OIDC user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

By default, the *registry_name* is derived from the **title** property in the configuration YAML file but you can override this by including a **name** property in the file. The *registry_url* is an internal URL that API Connect assigns to the registry.
After you have created your OIDC user registry, you must update your application registration with the third party OIDC provider to include the OIDC redirect URI; you can obtain this information by using the following command, which displays the details of the registry in the command window:

```
apic user-registries:get --server mgmt_endpoint_url --org organization_name registry_name --output -
```

The required **oidc_redirect_uri** value is in the **consumer:** section; for example:

```
consumer:
  oidc_redirect_uri: https://consumer.mycompany.com/consumer-api/oauth2/redirect
```

Enabling your OIDC registry in a Catalog

To make your OIDC registry available for onboarding and authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your OIDC user registry by using the following command:

   ```
   apic user-registries:list --server mgmt_endpoint_url --org organization_name
   ```

2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *catalog_name* is the value of the `name` property of the required Catalog. The command returns

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

3. Enter the following data, followed by a new line:

   ```
   user_registry_url: oidc_registry_url
   ```

   where *oidc_registry_url* is the URL of your OIDC registry, obtained in step 1.
4. Press `CTRL D` to terminate the input.

For details of all the **`apic user-registries`** and **`apic configured-catalog-user-registries`** commands, see apic user-registries and apic configured-catalog-user-registries.

You can also complete the operations described in this topic by using the API Connect REST APIs; see the API Connect REST API documentation.

Modifying the configuration details for a user registry

You modify the configuration details for a user registry by using the User Registries page in the API Manager user interface of IBM® API Connect.

About this task

If you want to authenticate an API Connect Catalog with a user registry that is not yet defined in API Connect, you define the registry when you configure the Catalog; for details, see Working with user registries.
Note: User registries shared from the Cloud Manager cannot be edited.
To modify the configuration details for a user registry that is already defined, you use the User Registries page.

Procedure

To modify the configuration details for a user registry, complete the following steps:

1. In the API Manager, click Resources, and then select User Registries.
2. On the User Registries page, click the options icon for the user registry that you want to edit, then click Edit.
   The details of the registry are displayed.
3. Modify the configuration details as required, then click Save to save your changes.

Password lockout criteria

You can be locked out of your account if you attempt to log in and fail consecutively.

Note: Account lock out applies only for local user registries.
The length of time that you are locked out of using the account is based on the number of consecutive attempts that you fail. The length of time increases as the number of consecutive failed attempts increases.

For example, you can be locked out for 15 seconds if you have five consecutive failed attempts, or 32 minutes for 12 consecutive failed attempts.
Note: External user registries, such as LDAP, might enforce their own lockout criteria.

Configuring a native OAuth provider

Native OAuth providers are configured and managed by you within your cloud.

About this task

A native OAuth provider object provides settings for OAuth processing operations such as generating and validating OAuth tokens. An OAuth provider object is referenced by an OAuth security definition to protect an API. When a native OAuth provider is used, the OAuth operations are performed natively by API Connect.

Every OAuth provider object has a backing API. Your configuration here automatically updates the OpenAPI document of the API. You can edit the OpenAPI document directly by navigating to the Resources > OAuth Providers page, selecting your OAuth provider, then clicking API Editor.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example:

- If you change the name of auto generated assembly actions in the source code, the assembly will be prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the **`oauth-provider-settings-ref`** field in each OAuth assembly action.

When a published API references an OAuth provider object, the backing API is automatically made available in the gateway.

Token requests and client_id checks:
If you are calling an OAuth endpoint, the sequence of **`client_id`** checks in the token request is as follows:

1. Check both body and query.
   - If found in only the body, validate and return a **`200`** or appropriate return code.
   - If found in only the query, return a **`wrong location`** error.
   - If found in both the body and the query, return a **`more than one location`** error.
2. When not found in the body or the query, check the **`Authorization`** header.
   - If found in this header, validate and return a **`200`** or appropriate return code.
3. Not found, return the appropriate error and code.

The best location for the **`client_id`** is in the request body.
One of the following roles is required to configure a native OAuth provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

Note:

- The OAuth provider logs analytics data for failure cases, but does not log successful cases. Activity log policies that call for logging of analytics data upon success do not apply for the OAuth provider.
- You must ensure the OAuth Provider is configured in the Sandbox Catalog before using the OAuth Provider in a non-Sandbox Catalog.

Procedure

1. In the API Manager, click Resources.
2. Click OAuth Providers > Add > Native OAuth provider.
   a. Complete the following parameters for the first screen, then click Next.

Field	Description
Title	Enter a title for the native OAuth provider.
Name	This field is auto-populated by the system.
Description (optional)	Enter a brief description.
Base path (optional)	The base path is the URL segment of the API that is shared by all operations in the API. It does not include the host name or any additional segments for paths or operations. The base path must be unique for a given catalog. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
Gateway Type	Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For information about types of gateways, see API Connect gateway types. OAuth Providers apply to one gateway type.

   b. In the next screen, enter the following additional configuration parameters, then click Next.

Field	Description
Authorize Path	`/oauth2/authorize/` is the standard OAuth endpoint to login to account
Token Path	`/oauth2/token/` is the standard OAuth endpoint to exchange code for access token.
Supported grant types	• Implicit - An access token is returned immediately without an extra authorization code exchange step. • Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." Does not require User Security. • Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code." • Resource owner - Password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients. • API Gateway only Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token.
Supported client types	• Confidential - Client can maintain secure credentials on a secure server • Public - Client credentials are not secure.

   c. Enter the scopes in the next screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

Field	Description
sample_scope_1	Scope for token
additional scopes	Scope for token

   d. Enter the parameters for User Security in the next screen. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User Security is not required for the Application grant type. Click Next when done.

Field	Description

Field	Description
Identity Extraction	Determines how the user credential is extracted: • Basic Authentication - HTTP basic authentication (requires no additional configuration) • Default HTML Form - Use default login form for user name and password • API Gateway only Context variable - Specify which variable contains the user name and password. API Connect OAuth context variables as listed here API Connect context variables Note: DataPower API Gateway only. Not available for DataPower Gateway (v5 compatible). • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML login form for user security. • Redirect - Enter an endpoint to redirect to a third-party identity provider. For more information, see Authenticating and authorizing through a redirect URL. • API Gateway only Disabled - do not collect the user credential Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint **must** maintain the order of the query parameters before the `state_nonce` query parameter, otherwise the authorization fails.
Authentication	Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL User Registry. For a DataPower API Gateway, you have the option to disable authentication with a user registry.
Authorization	The following methods for extracting the user credential are available: • Authenticated - Authorize authenticated users automatically. • Default HTML Form - Use default HTML form to authorize. • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML authorization form for user security. • API Gateway only Disabled - Disable authorization.

3. Review the Summary for the native OAuth provider configuration.
4. Click Back to make changes.
5. Click Finish to save the basic configurations and to proceed to the Advanced Parameters for a native OAuth Provider.

Results

You can use the OAuth Provider to secure the APIs in catalog.

- **Configuring basic settings for a native OAuth provider**
  You can update the identification details and basic configuration settings for a native OAuth provider.
- **Configuring scopes for a native OAuth provider**
  Access tokens contain authorization for specific scopes.
- **Configuring user security for a native OAuth provider**
  Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.
- **Configuring tokens for a native OAuth provider**
  Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.
- **Configuring token management and revocation for a native OAuth provider**
  Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.
- **Configuring introspection for a native OAuth provider**
  Define an introspection path to allow the metadata for an access token to be examined.
- **Configuring metadata for a native OAuth provider**
  Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- **Configuring the OIDC parameters for a native OAuth provider**
  Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.
- **Editing a native OAuth provider by using the API Editor**
  You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

Configuring basic settings for a native OAuth provider

You can update the identification details and basic configuration settings for a native OAuth provider.

About this task

One of the following roles is required to configure the basic settings for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the basis settings pages for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the basic settings for an existing native OAuth provider. If you want to update the basic settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. To modify the identification details, click Info in the sidebar menu, then update the following fields as required:

Field	Description
Title	Enter a title for the native OAuth provider.
Name	This field is auto-populated by the system.
Description (optional)	Enter a brief description.
Base path (optional)	The base path is the URL segment of the API that is shared by all operations in the API. It does not include the host name or any additional segments for paths or operations. The base path must be unique for a given catalog. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.

2. To modify the basic configuration settings, click Configuration in the sidebar menu, then update the following fields as required:

Field	Description
Authorize Path	`/oauth2/authorize/` is the standard OAuth endpoint to login to account
Token Path	`/oauth2/token/` is the standard OAuth endpoint to exchange code for access token.
Supported grant types	• Implicit - An access token is returned immediately without an extra authorization code exchange step. • Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." Does not require User Security. • Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code." • Resource owner - Password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients. • API Gateway only Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token. Tip: Selecting only the Resource owner - JWT grant type when defining a native OAuth provider in the user interface is not supported and results in an invalid configuration. To avoid this problem, additionally select either the Access code or the Resource owner - Password grant type. Note: If you plan to configure OpenID Connect (OIDC) for a native OAuth provider, you must include at least one of the following grant types: Implicit, Access code.
Supported client types	• Confidential - Client can maintain secure credentials on a secure server • Public - Client credentials are not secure.

DataPower Gateway (v5 compatible) only Note: If the gateway type is DataPower® Gateway (v5 compatible) and, when the native OAuth provider was created, only the Application grant type was selected, you cannot add further grant types until you configure the user security settings. In particular, you must specify the user registry for authenticating application users. To configure the user security settings, complete the following steps:

a. Click User Security in the sidebar menu, then click Edit.
b. Update the user security settings as required; for more details, see Configuring user security for a native OAuth provider.
c. Click Save when done.

3. Click Save when done.

Configuring scopes for a native OAuth provider

Access tokens contain authorization for specific scopes.

About this task

The client applications can request only the scopes or a subset of the scopes that you define here. The scopes are included in the access tokens that are generated from the provider. When an OAuth protected API is invoked, the gateway checks the scopes carried in the access tokens against the list of allowed scopes in the security definition for the API to determine whether to grant access.

In addition, you can enforce advanced scope checks. The advanced scope check URLs are invoked after application authentication or after user authentication based on which URLs are configured. The final scope permission that is granted by the access token is the result of all scope checks.

Per IETF RFC 6749, the value of the scope parameter is a list of space-delimited, case-sensitive strings. For more information, see The OAuth 2.0 Authorization Framework.

One of the following roles is required to configure scopes for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the scope settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the scope settings for an existing native OAuth provider. If you want to update the scope settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click Scopes in the sidebar menu. The currently configured scopes are listed. Review and update the scopes as required.

Field	Description
sample_scope_1	Scope for token
additional scopes	Scope for token

In the Default scopes section, select the default scopes to be used if the API request doesn't contain any scopes. If no default scope is defined, and the request doesn't contain a scope, an invalid scope error is returned for the request.

If the user authorization method is set to Default HTML Form in the User Security settings, all scopes specified here are added automatically to the authorization consent form.

2. Advanced scope check before token generation. This setting specifies the scope check endpoint where additional scope verification is performed in addition to the basic scopes. The advanced scope check URLs are invoked after application authentication or after owner authentication based on which URLs are configured. The scopes are included in the token and will overwrite any previous scopes.

Field	Description
Application scope check	Allow extra verification by running a scope check from an endpoint. Enter the endpoint and an optional TLS Profile to use for an application scope check.
Owner scope check	Further refine the scope with an additional check. Enter the endpoint and an optional TLS Profile to use for an owner scope check.

For more information about scope, see Scope

3. Advanced scope check after token generation. This setting specifies an additional scope check at the API consumer level to verify compliance with the scope requirements of the API.

Field	Description
Enabled	Select the check box to enable the advanced scope check after token validation. Enter an optional default validator endpoint.
Use endpoint from API	Select the check box to use the endpoint from the API, or clear the check box to override the endpoint from the API.

For more information about scope, see Scope

4. Click Save when done.

Results

You can use the OAuth Provider with these scopes to secure the APIs in catalog.

Configuring user security for a native OAuth provider

Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.

About this task

User security authenticates the user. It is required for the Implicit, Access code, and Resource owner - Password grant types. It is not used for the Application or Resource owner - JWT grant types.

One of the following roles is required to configure user security for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the user security settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the user security settings for an existing native OAuth provider. If you want to update the user security settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click User Security in the sidebar menu.
2. Specify the following parameters for User Security. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User Security is not required for the Application or Resource owner - JWT grant types. Click Next when done.

Field	Description
Identity Extraction	Determines how the user credential is extracted: • Basic Authentication - HTTP basic authentication (requires no additional configuration) • Default HTML Form - Use default login form for user name and password • API Gateway only Context variable - Specify which variable contains the user name and password. API Connect OAuth context variables as listed here API Connect context variables • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML login form for user security. • Redirect - Enter an endpoint to redirect to a third-party identity provider. For more information, see Authenticating and authorizing through a redirect URL. • API Gateway only Disabled - do not collect the user credential Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint **must** maintain the order of the query parameters before the `state_nonce` query parameter, otherwise the authorization fails.
Authentication	Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL User Registry.

Field	Description
Authorization	Various methods may be used to authorize application users. For a DataPower® API Gateway, the following methods for extracting the user credential are available: • Authenticated - Authorize authenticated users automatically. • Default HTML Form - Use default HTML form to authorize. If you select the Default HTML Form method, all scopes that are specified in the Scopes settings are added automatically to the authorization consent form. • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. • API Gateway only Disabled - Disable authorization.

3. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in catalog.

Configuring tokens for a native OAuth provider

Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.

About this task

Access tokens are granted to the client application to allow the application to access resources on behalf of the application user. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or more narrow scope. You can also specify how long the consent given by the combination of any number of access and refresh token remains valid.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the token settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the token settings for an existing native OAuth provider. If you want to update the token settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click Tokens in the sidebar menu.
2. Define the settings to configure tokens.

Field	Description
Access tokens time to live	Enter the expiration time period in seconds for access tokens.
API Gateway only One time use access token	Click the check box to enable one time use for the access token. Access tokens are multiple use by default which allows them to be used for multiple requests. When one time use is enabled, the access token will be consumed after one use. The OAuth flow will need to be repeated to obtain another access token. Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: • Configuring token management and revocation for a native OAuth provider (Cloud Manager) • Configuring token management and revocation for a native OAuth provider (API Manager)
Refresh tokens	Click the check box to enable Refresh tokens. Set the Count to limit the number of times a refresh token can be issued. Set the Refresh Token Time to Live value to determine the time to live, or expiration time period, for each refresh token in seconds.
One time use refresh token	Clear the check box to disable one time use for the refresh tokens. Refresh tokens are one time use by default which allows them to be used one time only to generate an access token and a new refresh token. When refresh token one time use is disabled then the refresh token count is limited to one and the refresh token can be used multiple times to generate new access tokens, however, another refresh token will not be generated unless the initial OAuth flow (Authorization Code or Password) is repeated. Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: • Configuring token management and revocation for a native OAuth provider (Cloud Manager) • Configuring token management and revocation for a native OAuth provider (API Manager)
Maximum consent	Click the check box to enable Maximum consent and enter the Maximum Consent Time to Live value in seconds. This is the time to live, or expiration time period, for all tokens, both access and refresh.
API Gateway only Token secret	Click the check box to select the Shared Secret which was configured for the gateway. If no Shared Secret was entered in the Gateway Configuration, then enter an key name and key value to use as the token secret.

Field	Description
API Gateway only Proof Key for Code Exchange	Proof Key for Code Exchange (PKCE) is a method to protect OAuth 2.0 public clients from an authorization code interception attack when they use Authorization Code grant requests. You can enable this extension when deploying with the DataPower® API Gateway. For more information, see RFC 7636. Select the options for your OAuth Providers: • Enable proof key for code exchange If selected, enforces PKCE when submitted in Authorization Code grant requests. • Always required If selected, requires PKCE in all Authorization Code grant requests. • Allow plain Select this check box to allow the plain challenge method in Authorization Code grant requests.

3. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in a catalog.

Configuring token management and revocation for a native OAuth provider

Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.

About this task

Token management enables you to prevent replay attacks by configuring token revocation. API Connect supports token revocation using a native gateway (DataPower) or a third party endpoint. For a native gateway, quota enforcement is used to manage tokens. For a third party endpoint, a URL to an external service is used to manage tokens.

For more information, see the IETF RFC 7009 OAuth 2.0 Token Revocation.

One of the following roles is required to configure token management and revocation for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the token management settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the token management settings for an existing native OAuth provider. If you want to update the token management settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Select Token Management in the sidebar menu.
2. Enable token management by selecting the check box.
3. From the Type list, select either Native or External. Native points to DataPower as the token storage location; External points to a revocation URL for token storage.
   Note: If you are using the API Manager user interface then, for the External option to be available, you must be using DataPower® API Gateway Version 10.0.1.0 or later, and the gateway service must be enabled in the Sandbox Catalog; for details on how to enable a gateway service in a Catalog, see Creating and configuring Catalogs
4. For Native, select one or both of the Resource owner revocation path and Client revocation path.
   - Resource owner revocation path - Uses the standard OAuth revocation path to allow the resource owner (end user) to revoke the application permission.
   - Client revocation path - Uses the standard OAuth revocation path to allow the client (application) to revoke a single token when the application closes.

   For more information about managing tokens with the Native DataPower Gateway, see Token management with the native DataPower Gateway.
5. For External, the settings depend on the gateway type, as follows:
   DataPower API Gateway:
   - Endpoint - the URL of the external management endpoint.
   - TLS Client Profile (optional) - the TLS client profile to secure connections.
   - Security - how to secure connections. The only supported method is basic authentication.
   - Basic authentication username (optional) - the user name for authentication.
   - Basic authentication password (optional) - the password for authentication.
   - Basic authentication request header name (optional) - the request header that contains the authentication string; if you supply both a request header name and user name/password, the request header authentication method is used.
   - Custom header pattern (optional) - the name pattern of the headers to use for sending additional information to the external management service.
   - Cache type - the cache type to control whether and how to cache positive responses. If you select Time to live, specify how long to keep responses in the cache; the default value is 900 seconds.
   - Fail on error - if selected, processing is stopped if the connection to the external management service fails.

   Note: For details of the JSON format that is required when exchanging messages with the external management service, see JSON format to exchange messages with the external management service.
   DataPower Gateway (v5 compatible):
   - Endpoint - Enter the URL to an external web server that contains information about access or refresh tokens. API Connect calls the URL to determine if the associated token can be trusted. The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing. For more information see Token revocation.

- TLS Client Profile - Select a TLS profile to verify the external endpoint.

6. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in a catalog.

Configuring introspection for a native OAuth provider

Define an introspection path to allow the metadata for an access token to be examined.

About this task

Token introspection allows an authorized holder of an access token to examine the contents of tokens using an introspection path. The access token to introspect must be obtained through the native OAuth provider. Introspection provides context for the token by allowing an authorized protected resource to query the authorization server to determine the set of metadata for a given token. The metadata includes whether or not the token is currently active, the scopes assigned to the token, and the authorization context in which the token was granted (including who authorized the token and which client it was issued to). API Connect token introspection conforms to IETF RFC 7662. See OAuth 2.0 Token Introspection.

One of the following roles is required to enable introspection for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the introspection settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the introspection settings for an existing native OAuth provider. If you want to update the introspection settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click Introspection in the sidebar menu.
2. Select the check box to enable Introspection. The OAuth standard path for introspection, /oauth2/introspect is automatically entered. This path will be used when another entity inspects the token contents.
3. Click Save when done.

Results

Tokens will be queried using the /oauth2/introspect path. You can use the OAuth Provider to secure the APIs in a catalog.

Configuring metadata for a native OAuth provider

Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

About this task

Configure an Authentication URL or an External URL from which custom metadata is collected for inclusion in the token. The metadata is either stored inside the access token or it is sent along with the access token to the client application. For more information about how the metadata is collected, see OAuth external URL and authentication URL.

Following are examples of metadata that can be included with the access token:

- Metadata about the authenticated resource owner
- Grant type that was used to obtain the token
- A confirmation code to be provided to the client application

One of the following roles is required to configure metadata collection for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can select the metadata settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the metadata settings for an existing native OAuth provider. If you want to update the metadata settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click Metadata in the sidebar menu.
2. Select Collect metadata to enable metadata collection.
3. The Authentication URL user registry is selected by default and is required. For more information about the Authentication URL, see Authentication URL user registry.
4. Select the External URL to collect metadata from an external URL. Enter the endpoint and an option TLS Client Profile.
5. API Gateway only If required, override the default Header name token value. The value of this header, if returned in the response from the OAuth endpoint, is placed in the response payload and indicated as `metadata`.
6. API Gateway only If required, override the default Header name payload value. The value of this header, if returned in the response from the OAuth endpoint, is placed within the access token and indicated as `miscinfo`.
7. Save the OAuth Provider.
8. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in a catalog.

Configuring the OIDC parameters for a native OAuth provider

Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.

About this task

When you enable OpenID connect, a template is provided for generating ID tokens along with access tokens and the required assembly policies are automatically created. You can customize the policies to suit your needs in the API Editor. The sample key provided is for test purposes only and is used to sign the JWT token.

One of the following roles is required to configure an OIDC template for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the System > Manage permissions

Note: You can configure OIDC parameters only if the selected grant types for the native OAuth provider include at least one of the Implicit or Access code grant types; see Configuring basic settings for a native OAuth provider.
You can select the OIDC settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the OIDC settings for an existing native OAuth provider. If you want to update the OIDC settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click OpenID Connect in the sidebar menu.
2. Select the initial check box to configure an OIDC Template. Enter the following parameters:

Field	Description
API Gateway only Support hybrid response types (optional)	Select the response types for the OpenID Connect hybrid flow to be supported by this OAuth provider.
DataPower Gateway (v5 compatible) only ID token issuer	Descriptive text to indicate the source of the key.
DataPower Gateway (v5 compatible) only ID token signing key	Specify the JSON Web Key (JWK) to be used to sign the ID token.
DataPower Gateway (v5 compatible) only ID token signing algorithm	Select the algorithm used to sign the token.

3. Click Save when done. You can edit the policies by using the API Editor.

Results

You can use the OAuth Provider to secure the APIs in a catalog.

Editing a native OAuth provider by using the API Editor

You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

About this task

If you have configured an OIDC template, you can customize it in API Editor. In the API Editor, the Source tab allows you to edit the code for the configuration using a text editor. The API Assemble tab provides a graphical drag-and-drop editor (identical to the one in API Manager) that allows you to add additional elements to the assembly for the OAuth Provider.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example:

- If you change the name of auto generated assembly actions in the source code, the assembly will be prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the `oauth-provider-settings-ref` field in each OAuth assembly action.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

You can modify the native OAuth provider configuration by selecting the API Editor page immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the configuration for an existing native OAuth provider. If you want to update the configuration for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. Click API Editor in the sidebar menu.
2. In the Source tab, view and edit the policies to customize the behavior for the OAuth provider.
3. In the API Assemble tab, use the drag and drop editor to add additional policies to the OIDC behavior.
   Note: If you add a policy that references a TLS profile, an **invoke** policy for example, then when you publish an API that uses this OAuth provider, you must ensure that the TLS profile is enabled for the Catalog to which you publish the API. For details on how to enable a TLS profile in a Catalog, see Creating and configuring Catalogs.
4. Save the edits.
5. Click Save when done.

Results

You can use the OAuth Provider to secure the APIs in a catalog.

Configuring a third-party OAuth provider

Enter the secure endpoints to provide OAuth authentication from a third party.

About this task

One of the following roles is required to configure OAuth Providers:

- Organization Administrator
- Owner
- Custom role with the Settings > Manage permissions

Procedure

1. In the API Manager, click Resources.
2. Select OAuth Providers > Add > Third party OAuth Provider.
   a. Complete the following parameters for the first screen and click Next.

Field	Description
Title	Enter a descriptive title for the gateway service. This title will be displayed on the screen.
Name	This field is auto-populated by the system and used as the internal field name.
Supported grant types	Select from the following options: • Implicit: An access token is returned immediately without an extra authorization code exchange step. • Application: Application to application. Corresponds to the OAuth grant type Client Credentials. Does not require User Security. • Access code: An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type Authorization Code. • Resource owner - Password: The user's username and password are exchanged directly for an access token, so can only be used by first-party clients. • API Gateway only Resource owner - JWT: a JSON Web Token (JWT) Bearer Token is used as a means for requesting an OAuth 2.0 access token, and for client authentication, as defined by the JSON Web Token (JWT) Profile for OAuth 2.0 Client Authentication and Authorization Grants.
Gateway type	Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For information about types of gateways, see API Connect gateway types. OAuth Providers apply to one gateway type.

   b. Specify configuration settings for the endpoints.

Field	Description
Authorization URL	An authorization URL where the resource owner grants authorization to the client application to access a protected resource. Example: `https://example.com/oauth2/authorize`

Field	Description
Token URL	A token request URL where the client application exchanges an authorization grant for an access token. Example: `https://example.com/oauth2/token`
Introspect URL	The introspection URL is where the API gateway validates the access tokens that are issued by the third party provider. Example: `https://example.com/oauth2/introspect` For more information on integrating third party OAuth providers for introspection, see OAuth introspection for third-party OAuth providers.
API Gateway only Introspect cache type	The cache type determines how long responses from the third party provider are cached, if at all. Select one of the following options: • No cache (default): Responses are not cached. • Protocol: Defined by the `cache-control` header in the provider response. • Time to live: Defined by the provider.
API Gateway only Cache Time to Live	The length of time, in seconds, for which provider responses are cached, if the Introspect cache type is set to Time to live. The default value is 900.
TLS Profile (optional)	Select an optional TLS profile for communicating with the third party provider.
Security	Default is Basic Authentication.
Basic authentication request header name	The `x-introspect-basic-authorization-header` is available to provide a user-configured HTTP Basic authorization header.
API Gateway only Basic authentication username (optional)	The default user name for HTTP Basic authentication.
API Gateway only Basic authentication password (optional)	The default password for HTTP Basic authentication.
API Gateway only Token validation	Specifies the method used to determine the success of the introspection request that is sent to the third party service to validate the provided token. Select one of the following options: • Connected: The query is successful if the status return code is `200`. • Active (default): The query is successful if the status return code is `200` and the response JSON body includes the property `active: true`.
API Gateway only Custom header pattern (optional)	A regular expression for request headers that are to be passed to the third-party provider; for example, `x-Introspect-*`.
API Gateway only Authorization header pass through	Select this check box if you want to retain the `Authorization` header for a bearer token. The default behavior is to remove this header.

c. Enter the scopes in the third screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

Field	Description
sample_scope_1	Scope for token
sample_scope_2	Scope for token
additional scopes	Scope for token

d. Review the settings on the Summary panel.

3. Click Save and Edit to complete the configuration.

OAuth concepts for API Connect

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information.

Note: In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- **OAuth user scenario**
  Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.
- **OAuth introspection for third-party OAuth providers**
  OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by IBM API Connect. IBM API Connect can use this feature along with the mentioned provider to protect access to the API.
- **OAuth external URL and authentication URL**
  You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- **Scope**
  Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.
- **Tokens**
  Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.
- **Authentication URL user registry**
  You can use an Authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides additional metadata to be embedded in the token.

- **Custom forms for user security**
  You can create custom forms for the authorization and identity extraction phase of OAuth.
- **Securing an API with a JSON Web Token**
  There are two methods to secure your API with a JSON Web Token. You can use the **jwt-generate** command, or you can use a token that has been generated external to IBM API Connect.
- **Troubleshooting OAuth**
  You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

OAuth user scenario

Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.

Scenario overview

In this scenario, Alice is a user of an application. Alice can grant permission for an application to access specific information about Alice in a third-party system that is using OAuth. Depending on the type of OAuth that is supported by the target service, Alice does not enter her user name and password into the application. Instead, the application receives an access token that represents her credentials (user name and password). The application can now access the information about Alice in the target system.

For example, Alice maintains a list of books that she reads on a service that is provided by mybooks.com. Following the purchase of a smartphone, Alice installs an application on her new phone to display the book details. The phone application wants to call an API provided by mybooks.com, which can access the information. The mybooks.com API is secured by using the OAuth protocol.

To access the book details, the application must complete a two-step process:

1. The application must first obtain permission from Alice.
2. The application then uses that permission to call the target service and obtain the list of books.

In the first step, the application typically directs Alice to the provider of the target service, mybooks.com. Alice provides her user name and password, and gives permission for the application to access her information. It is important that Alice trusts that she is providing her credentials to the provider of the target service and not to an untrusted proxy application. For example, by checking that the security certificate of the website where Alice enters her credentials matches what Alice expects from the provider of the target service.

The result of this step is the access token that the application can use to call the API. The application then generates the appropriately formatted OAuth request. For example, the Authorization header, or HTTP query parameters, which includes the access token, consumer key, and signature method that are required by OAuth. This OAuth request is used to invoke the API proxy operation.

Scenario within API Connect

No changes to the definition of your API operation are required to support this scenario.

1. Alice grants permission for the application to access her information *before* the invocation of the API.
2. When the application provides the Authorization header, or query parameters, containing the OAuth details about the call to the operation endpoint, the header is automatically passed through to the target service without any additional configuration.

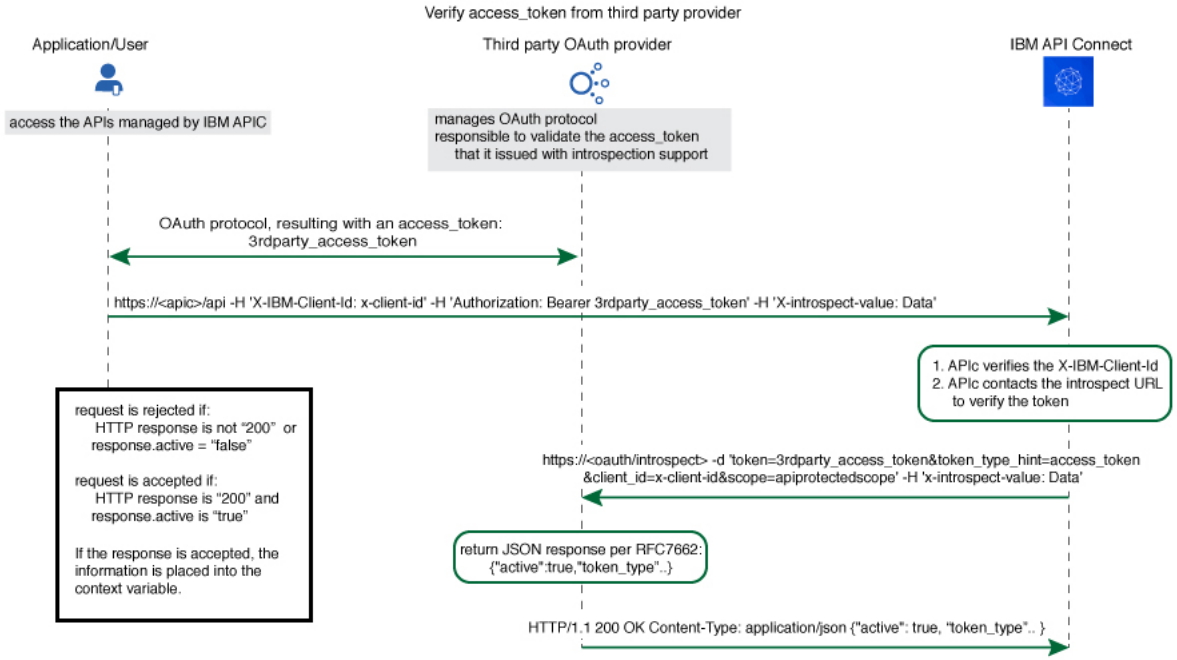
OAuth introspection for third-party OAuth providers

OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by IBM API Connect. IBM® API Connect can use this feature along with the mentioned provider to protect access to the API.

You can use API Connect to protect an API that is secured by using the third-party OAuth access token in accordance with Introspection specification as defined in RFC 7662. In addition to the specification, the **`x-Introspect-`** header is provided to pass other content to the third party as you require.

Authentication information can be carried in the request by configuring a basic authentication request header.

The following sequence diagram depicts the overall flow of request and response. The purpose of this diagram is only to provide a general visualization of the nature of the flow; for the precise details, refer to the explanatory information after the diagram.



The Introspect URL is configured in the Third Party OAuth provider configuration. See Configuring a third-party OAuth provider.

When an API is protected by a third-party OAuth provider, API Connect will extract the bearer token and issue an HTTP POST request to the endpoint specified in the Introspect URL field.

The GET request is protected by API Connect with this feature.

You can use a header prefix to pass information to the third-party provider. The header prefix can include a regular expression and specifies the name pattern of the headers to use for sending additional information, such as **`x-introspect-*`**.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
Authorization: Bearer tGzv3JOkF0XG5Qx2TlKWIA
x-IBM-Client-Id: xxx-xxx
```

However, if you want to use a different header prefix, specify the required value in the Custom header pattern field in the third party OAuth provider configuration. For third-party OAuth provider configuration details, see Configuring a third-party OAuth provider. The Custom header pattern feature is available only with the DataPower® API Gateway, if you are using the DataPower Gateway (v5 compatible) the header prefix must be **`x-Introspect-`**.

API Connect will issue this POST request to the introspection endpoint specified in **`x-tokenIntrospect`**, as illustrated in the code sample:

```
POST /oauth/introspectURL HTTP/1.1
Host: apiconnect.ibm.com
Content-Type: application/x-www-form-urlencoded
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
token_type_hint=access_token&token=tGzv3JOkF0XG5Qx2TlKWIA
```

The third party OAuth/OIDC provider will respond with `HTTP 200` indicating the request was successful and that payload contains the token information. API Connect honors the active claim as defined in the RFC specification.

If the value of the active claim is `true`, the token is treated as valid.

```
HTTP/1.1 200 OK
 Content-Type: application/json;charset=UTF-8
 Cache-Control: no-store
 Pragma: no-cache

 { "active":true,
    "token_type":"bearer",
    "client_id":"xxx-xxx",
    "username":"John Smith",
    ...
 }
```

If the value of the active claim is `false`, the token is treated as invalid.

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache

{
  "active":false
}
```

A response code other than **`HTTP 200`** indicates failure to process the request.

When the OAuth token is valid and active, context variables are populated with information from the introspect JSON response. For more information, see API Connect context variables.

When contacting the introspection endpoint, API Connect uses **`client_id`**/**`appId`** and **`client_secret`**/**`appSecret`** to construct the HTTP Basic authorization header.

By default, if **`x-introspect-basic-authorization-header`** exists in the request, the value is used for the HTTP Basic authentication header when the introspection endpoint is contacted. API Connect verifies that the HTTP Basic authentication header value is Base64 encoded before it is sent, and encodes it if necessary as shown in the following example. If the header is already encoded, it is sent without modification.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-introspect-basic-authorization-header: user:password
```

API Connect issues the following:

```
POST ..
Authorization: Basic M3JkLXBhcnR5LWNsaWVudF9pZDozcmQtcGFydHlfY2xpZW50X3NlY3JldA==token_type_hint=access_token&token= ..
```

If you are using the DataPower API Gateway, you can specify your own value for the HTTP Basic authentication header by providing the required value in the Basic authentication request header name field in the third party OAuth provider configuration. The following rules determine what authentication data is passed to the introspection endpoint:

- If there is a basic authentication header in the request, the specified credentials are used. The value must be either a string in the format ***`user:password`***, or the Base64 encoded equivalent; API Connect will Base64 encode the value if necessary before sending the request to the introspection endpoint.
- If there is no basic authentication header in the request but there are values specified in the Basic authentication username and Basic authentication password fields in the third party OAuth provider configuration, those values are used.
- If there is no basic authentication header in the request, and user name and password details are not supplied in the third party OAuth provider configuration, but **`client_id`** and **`client_secret`** values are supplied in the body of the request, these are used.
- Otherwise, an error is returned.

For third-party OAuth provider configuration details, see Configuring a third-party OAuth provider.
If either, or both, of scope and **`scope validate url`** are configured, and if the response is an active token with a scope claim from the third-party OAuth Provider introspection endpoint, API Connect will further enforce the scope validation in the following order:

1. If **`scope`** is configured for the OAuth API protection, verify the third-party scope against the scope that is configured.
2. If **`scope validation url`** is configured, verify the third-party scope against the scope validation URL.
3. If the third-party OAuth provider introspection endpoint does not return a scope, the Gateway will not check the scope defined in the security definition of the API where the third-party OAuth provider resource is used. For details on configuring an OAuth security definition in an API, see Creating an OAuth security definition.

For more information, see Scope.

DataPower Gateway (v5 compatible) only By default the API Connect client ID and scope are sent to the third party OAuth provider. You can suppress this behavior in either of the following ways:

- Supply a **`suppress-parameters`** header as follows:

  `suppress-parameters: client_id`

  `suppress-parameters: scope`

  or

  `suppress-parameters: client_id scope`

  depending on which parameters you want to suppress.
- Define an API property called **`suppress-parameters`** in the API definition itself, with one of the following string values:

  `client_id`

  `scope`

  or

  `client_id scope`

  depending on which parameters you want to suppress. For information on how to define API properties, see Setting API properties.

OAuth external URL and authentication URL

You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

Including custom metadata in a token

In many scenarios, custom metadata needs to be included during the access token generation process. The metadata is either stored inside the access token or it is sent along with the access token to the client application. The client application can then send that access token, or the metadata in the payload, in a subsequent request to IBM® API Connect where the metadata is retrieved, validated, or sent to the downstream systems as required.

Examples include, but are not limited to:

- When resource owners are authenticated, metadata about the authenticated resource owner needs to be stored within the access token.
- The grant type that was used to obtain the token is another example of metadata stored within the access token.
- A confirmation code that needs to be sent to the client application along with access token is stored as metadata within the access token.

Configuring External URL or Authentication URL in API Connect to obtain metadata

Metadata can be set by using either or both of the following URLs:

- External URL - When you call the External URL, an HTTP GET request is sent and API Connect expects an HTTP 200 OK along with an optional set of the specified response headers.
- Authentication URL - When you call the Authentication URL, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.
  See: Authentication URL.

The External URL endpoint is entered in the Metadata section when you configure an OAuth Provider in the Cloud Manager or API Manager UI.

Use the following HTTP headers in the response, depending on the type of gateway you are using:

- DataPower® API Gateway:

  `X-API-OAUTH-METADATA-FOR-PAYLOAD`

  `X-API-OAUTH-METADATA-FOR-ACCESSTOKEN`

  Note: These are the default header names for the DataPower API Gateway but you can override them; see Configuring metadata for a native OAuth provider.
- DataPower Gateway (v5 compatible):

  `API-OAUTH-METADATA-FOR-PAYLOAD`

  `API-OAUTH-METADATA-FOR-ACCESSTOKEN`

The response header value from **`X-API-OAUTH-METADATA-FOR-PAYLOAD`** or **`API-OAUTH-METADATA-FOR-PAYLOAD`** is placed in the response payload and indicated as **`metadata`**.

The response header value from **`X-API-OAUTH-METADATA-FOR-ACCESSTOKEN`** or **`API-OAUTH-METADATA-FOR-ACCESSTOKEN`** is placed within the access token and indicated as **`miscinfo`**.

The two metadata response headers are case insensitive and you must escape any special characters in the string value content.

An example response payload that contains metadata along with the access token:

```
{
"token_type":  "bearer",
"access_token":  "AAEkNzhjDHYyyYy...cL0Mv6ctl37w7ZU",
"metadata":  "m:metadata-for-payload_content"
"expires_in":  3600,
"scope":  "read",
"refresh_token":  "AAEnj5SynCMybF...oEZ6JjxYax_HdNg",
}
```

This example output from the token introspection endpoint shows the contents of the access token with **`"miscinfo"`** containing the metadata information.

```
{
"active":  true,
"token_type":  "bearer",
"client_id":  "78c2f10f-799a-4e1f-8e0a-098634997a35",
"username":  "Fred Smith",
"sub":  "fred",
"exp":  1479850049,
"expstr":  "2016-11-22T21:27:29Z",
"iat":  1479846449,
"nbf":  1479846449,
"nbfstr":  2016-11-22T20:27:29Z",
"scope":  "read",
"miscinfo":  "m:metadata-for-accesstoken_content",
"client_name":  "MobileApp"
}
```

Input to the External URL

The following request headers are sent to the External URL.
Note: Any existing metadata values that were previously sent from the Authentication URL are also sent in the two request headers **`x-existing-metadata-for-payload`** and **`x-existing-metadata-for-access-token`**. The Metadata URL can make use of this information to create a new set of metadata values.
The two request headers that are sent to the Metadata URL are displayed in bold text.

```
X-existing-metadata-for-payload     payload-from-auth-url
X-existing-metadata-for-access-token     token-from-auth-url
X-URI-in     /org/env/miscinfo/oauth2/token (the URL that was sent to APIConnect for this particular token request)
X-METHOD-in     POST
X-POST-Body-in     client_id=client_id&grant_type=password&scope=read&username=name&password=password
X-X-Client-IP     IP_address
X-X-Global-Transaction-ID     ID_number
...
```

Note: If you are using the DataPower API Gateway rather than the DataPower Gateway (v5 compatible), the **`X-POST-Body-in`** header is not supported.

Retrieving Metadata in API Connect

As described in the previous example scenarios, the metadata can be retrieved from the access token in the Application API and sent to the downstream systems. Retrieval can be done in the API assembly, which is secured to accept tokens in the security definitions.

In the resource API that accepts an access token, the **`miscinfo`** field can be accessed in the Assembly with the **`oauth.miscinfo`** context variable, as in the example.

```
apim.setvariable('message.body',apim.getvariable('oauth.miscinfo'));
```

You can also use token introspection to look at the contents of the access token.

Refresh tokens and metadata

The Authentication URL (if configured for authentication) is invoked first, during authentication of the resource owner. The External URL is invoked as the last step, just before the generation of the access token. The only exception is when access tokens are generated from a refresh token. In cases where refresh tokens are used to generate new access tokens, the External URL is not invoked. The metadata from the refresh token is retained and then copied into the newly generated access token.

Identifying the source of the metadata

The metadata is prefixed with keywords to indicate whether it originated from the External URL or the Authentication URL.

- Metadata from the External URL is prefixed with `m:`
- Metadata from the Authentication URL is prefixed with `a:`

Note: When revocation is enabled, some internal details are also stored in the `miscinfo` field, in brackets within the access token as shown in the following example:

```
"miscinfo": "[tlsprofile@https://api-revoke-url:443/server/revocation-url]m:metadata-for-accesstoken_content"
```

Maximum size of the metadata

Metadata for the access token cannot exceed 512 bytes.

Metadata for the payload does not have a specific size restriction, except for when you use the Authorization code grant type. These restrictions are described in following sections.

Characters are not allowed in metadata in certain scenarios

When you use the Authorization code grant type, or when a consent form is used for implicit grant type, there is a temporary state or code where the metadata from the authentication URL is stored. API Connect internally uses two prefixes - `!ma` and `!mp` to differentiate between payload and token metadata received from the Authentication URL and store them internally in the temporary state/code. Hence these specific character sequences - `!ma` and `!mp` should not be used as the metadata itself.

Grant types and metadata

The OAuth grant types described in the following sections include `authorization code (access code)`, `implicit`, and `client credentials (application)`.

Authorization code grant type

- When metadata is included from an Authentication URL for an Authorization code grant type, as it is a three legged flow, both the content and the payload are stored within the `dp-state` and carried on to the authorization code and to the access token. Note that around 10 characters are used internally to differentiate between the metadata for payload and metadata for the access token when stored in the `dp-state`. In addition, if revocation is enabled, that will also be part of the token metadata. Hence the combined size of the token metadata, the payload metadata (including the 10 characters of internal data), and internal revocation details, cannot exceed 512 bytes in total.

  If the overall size of the metadata exceeds 512 bytes, then the access token generation succeeds, but the metadata fields contain an error message of "`metadata too large`" as shown in the example.

  ```
  "metadata":"m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-payload]"
  "miscinfo":"[r:gateway]m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-token]"
  ```

  This size restriction can be overcome when the metadata is sent from the Metadata URL and not from the Authentication URL, because the metadata is not stored in `dp-state` or in the authorization code.

  Example of the `authorization code (access code)` grant type:

  ```
  $ curl -k -d
  "grant_type=authorization_code&code=$mycode&client_id=$myid&scope=scope_introspect&redirect_uri="
  https://9.70.153.90/fei/sb/introspectp1/oauth2/token
  { "token_type":"bearer",
  "access_token":"AAEkOThlZDhhNjYtYTQ1ZS00YTMzLWE0N2QtZmE2OGZkMzQ0NzQ20ZN5Tl_TqYFeIfB7BFf6HFgibEoOjWXXEA84oFsWuE4NY-
  RRZVdnGSaXAIYJz7s5vczfk5EV-BIb_6P_lYKm3ahrfhR5kI3sPO0uADEoseIP5-O9anUpEM5yhsayXvZbJ_6VDYz-hyXSJHTNqVj-
  PHBialoRkBD5qca6kO0fV2M", "metadata":"a:[Authorization Code-Test-auth-url-payload]", "expires_in":3600,
  "scope":"scope_introspect", "refresh_token":"AAFAg1EVMbwicr_L0fTZ4q6HZ-
  RcQygniXFC9zbSKO4wd3hcniC4KQX21X0fL2c8cnmzCZgws8xxLzNyfjQhUJNGl5C1GbIe3dwhXJdiWA0Go-
  dduhVtCbG26sJRRXyYrMeRxWnJsylBETPI8HQEN4a_D7fmxKcTVRZBvq86byg95qe1ZKyERi0Lhxdd_O4Nvss" }
  ```

  ```
  $ curl -k -H "X-IBM-Client-Id: $myid" -H "X-IBM-Client-Secret: $mysecret" -d
  "token_type_hint=access_token&token=$mytoken" https://9.70.153.90/fei/sb/introspectp1/oauth2/introspect
  { "active":true, "token_type":"bearer", "client_id":"98ed8a66-a45e-4a33-a47d-fa68fd344746", "username":"anyuser",
  "sub":"anyuser", "exp":1484766368, "expstr":"2017-01-18T19:06:08Z", "iat":1484762768, "nbf":1484762768,
  "nbfstr":"2017-01-18T18:06:08Z", "scope":"scope_introspect", "miscinfo":"[r:gateway]a:[Authorization Code-Test-auth-
  url-token]", "client_name":"oauth_app" }
  ```

Implicit grant type

- When implicit grant type is used, the access token and the metadata are returned in the `location` header as a fragment, as you see in the example.

```
< Location:

```

Client credentials grant type
: Authentication URL will not be invoked when using client credentials grant type, as there is no resource owner. The metadata from Authentication URL is not available for this grant type. However, content returned from Metadata URL will be included as metadata.

Behavior when retrieving metadata with both an External URL and an Authentication URL

If an External URL is configured and a connection to the external server is successful, the response headers overwrite any existing metadata obtained from the Authentication URL to become the final value. Therefore, you must carefully examine the incoming request headers and create appropriate response headers from the External URL.

If an External URL is configured, but the connection to the External URL fails, then a failure message of "`error on metadata url`" is written for metadata in both the payload and the access token.

If an External URL is configured and the connection is successful, but the remote server does not send any of the specified HTTP response headers, a blank value is written for metadata in both the payload and the access token.
Attention: An External URL overwrites existing values from Authentication URL. This includes blank values.
If no External URL is configured, the metadata that is obtained from the Authorization URL is retained as the final value.

Scope

Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.

In IBM® API Connect, scopes have no inherent meaning. Instead, scopes are defined in the OAuth Provider so that an application can request an access token that is valid for one or more of the scopes. In the secured API, scopes are listed as requirements for an access token to be considered valid. All scopes that are listed by the security definition for the API must be granted by the access token.
Note:

- An OAuth Provider must have at least one scope.
- An OAuth token will not be granted unless a default scope is configured at the provider, or one or more predefined scopes are included in the grant request.
- If no default scope is defined, and the request does not contain a scope, an invalid scope error is returned for the request.

OAuth provider

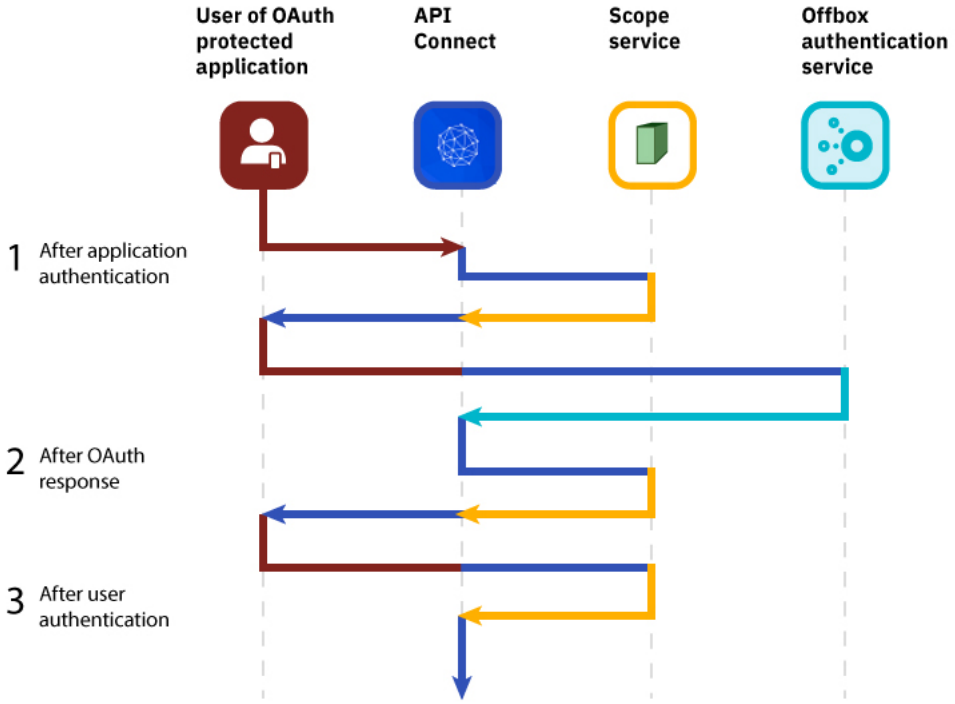
To provide more refined support for the OAuth scope handling, API Connect allows the Authentication URL user registry extension to modify the scope value.

When you define an OAuth provider, the Advanced scope check extensions provide the flexibility to check and override allowed scopes. The optional extensions are Application scope check and Owner scope check.

The scope that is eventually received by the application is determined by the interactions that are described in the three following paragraphs. Scope processing follows the sequence of items 1, 2, and 3 in the following list, offering three opportunities to override the scope value. Figure 1 provides an overview of the process.

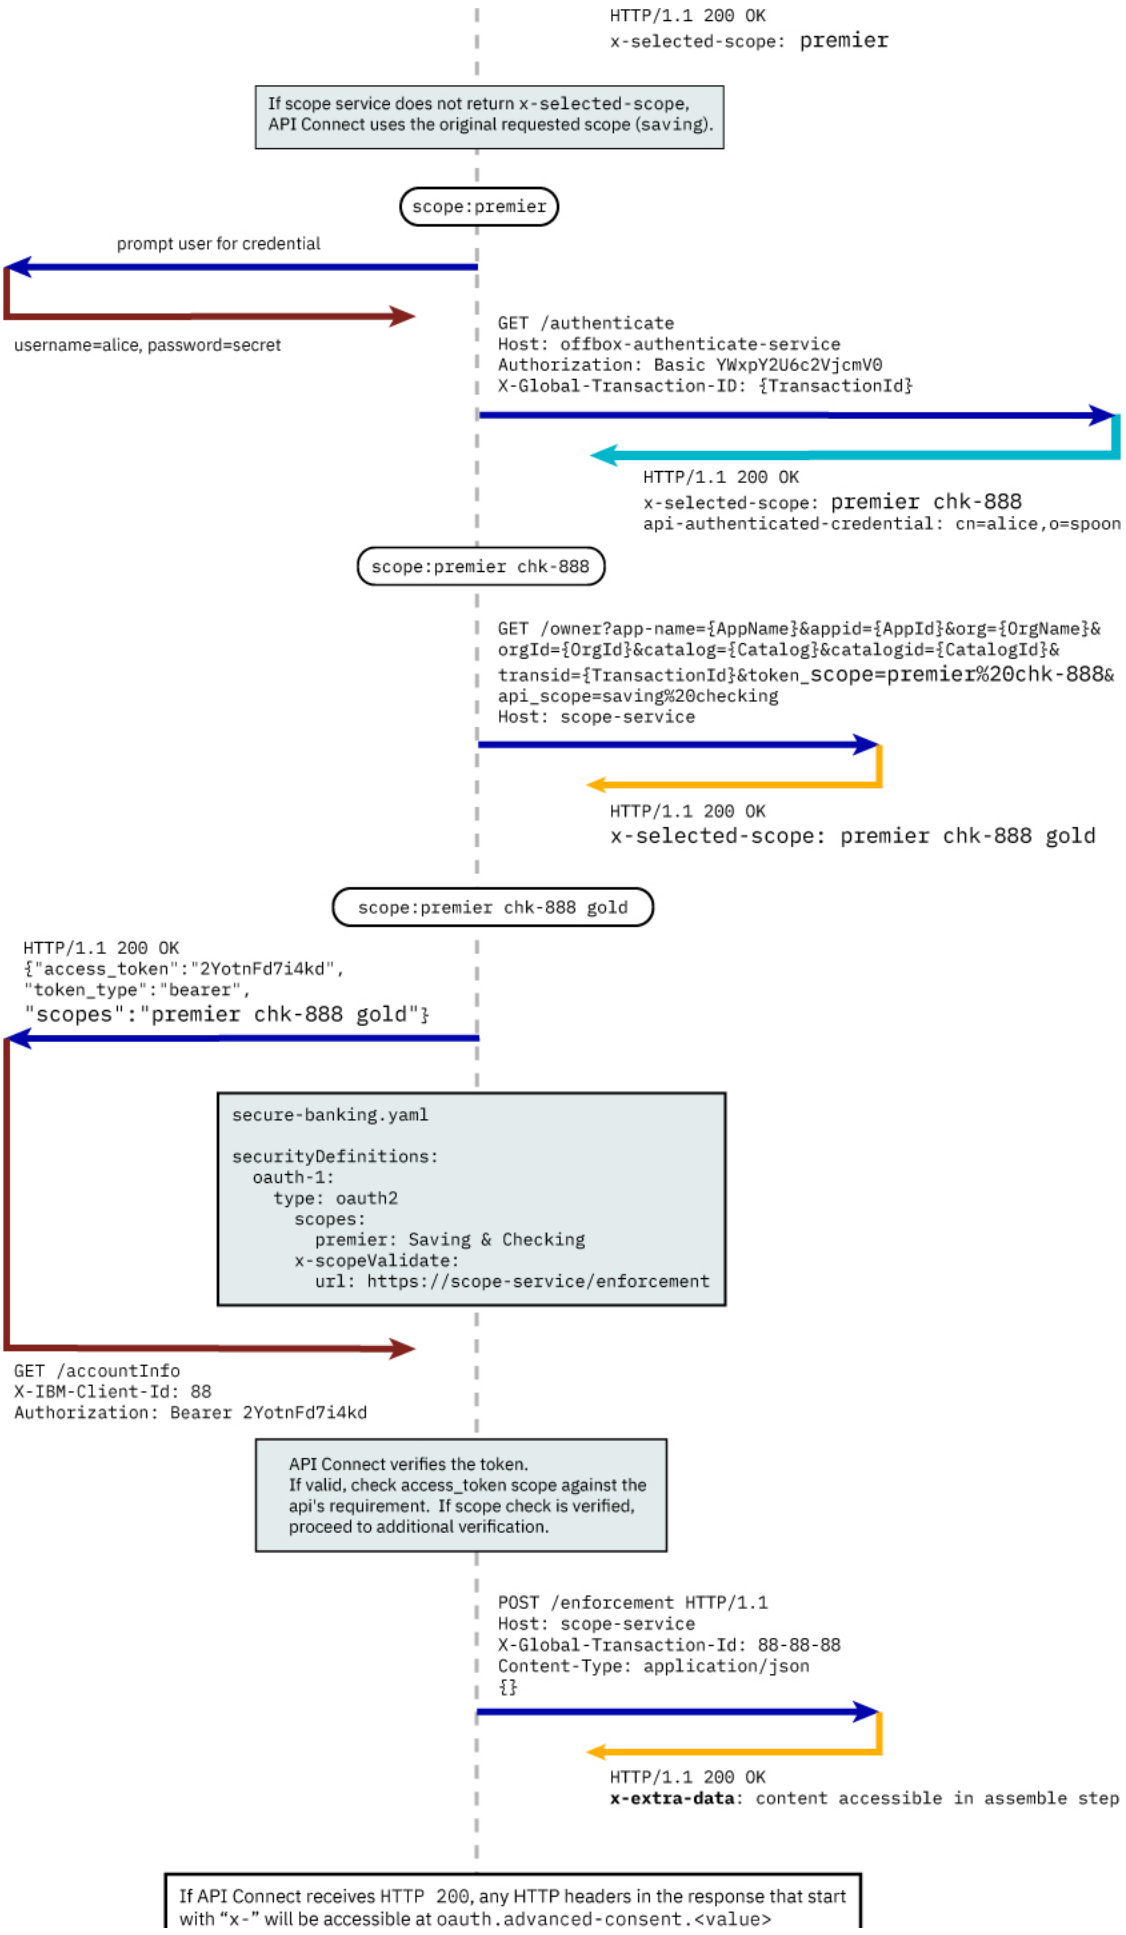
1. After the application successfully authenticates, and if OAuth Native provider > Advanced scope check > Application scope check is configured, API Connect makes a call to allow extra verification and uses the contents of **`x-selected-scope`** to override the scope value that was initially requested by the application. When Application scope check is enabled, the HTTP response header **`x-selected-scope`** must be present, or the call fails.
2. If OAuth Native provider > User Security > Authentication is configured to authenticate application users using an Authentication URL, then API Connect makes a call, as documented in Authentication URL user registry. When the response code is `HTTP 200`, and the response header **`x-selected-scope`** is present, the value that is configured in **`x-selected-scope`** is used as the new scope value, overriding both what the application already requested and what was provided in the Application scope check described in paragraph 1. In the response header, **`x-selected-scope`** is an optional element.
3. After the user successfully authenticates, and if OAuth Native provider > Advanced scope check > Owner scope check is enabled and configured with a valid URL, API Connect makes a call to allow the content of **`x-selected-scope`** to refine the scope value. When Owner scope check is enabled, the HTTP response header **`x-selected-scope`** must be present, or the call fails.

Figure 1. OAuth advanced scope overview



The final scope permission that is granted by the access token is the result of the flow described in items 1, 2, and 3. Figure 2 shows a more detailed view of the transaction flow with examples that show when **`x-selected-scope`** provides a new scope value.

Figure 2. OAuth advanced scope detail



HTTP/1.1 200 OK
x-selected-scope: premier
If scope service does not return x-selected-scope, API Connect uses the original requested scope (saving).
scope:premier
prompt user for credential
username=alice, password=secret
GET /authenticate
Host: offbox-authenticate-service
Authorization: Basic YWxpY2U6c2VjcmV0
X-Global-Transaction-ID: {TransactionId}
HTTP/1.1 200 OK
x-selected-scope: premier chk-888
api-authenticated-credential: cn=alice,o=spoon
scope:premier chk-888
GET /owner?app-name={AppName}&appid={AppId}&org={OrgName}&
orgId={OrgId}&catalog={Catalog}&catalogid={CatalogId}&
transid={TransactionId}&token_scope=premier%20chk-888&
api_scope=saving%20checking
Host: scope-service
HTTP/1.1 200 OK
x-selected-scope: premier chk-888 gold
scope:premier chk-888 gold
HTTP/1.1 200 OK
{"access_token":"2YotnFd7i4kd",
"token_type":"bearer",
"scopes":"premier chk-888 gold"}
secure-banking.yaml
securityDefinitions:
oauth-1:
type: oauth2
scopes:
premier: Saving & Checking
x-scopeValidate:
url: https://scope-service/enforcement
GET /accountInfo
X-IBM-Client-Id: 88
Authorization: Bearer 2YotnFd7i4kd
API Connect verifies the token.
If valid, check access_token scope against the api's requirement. If scope check is verified, proceed to additional verification.
POST /enforcement HTTP/1.1
Host: scope-service
X-Global-Transaction-Id: 88-88-88
Content-Type: application/json
{}
HTTP/1.1 200 OK
x-extra-data: content accessible in assemble step
If API Connect receives HTTP 200, any HTTP headers in the response that start with "x-" will be accessible at oauth.advanced-consent.<value>

For the above example, `x-extra-data` is accessible at `oauth.advanced-consent.x-extra-data`.
If other than `HTTP 200` is returned, it has the same effect as if the access token does not contain neccesary permissions to access the resource.

Consumer API enforcement

Standard scope validation
To access the API /getaccount the application must send a **GET** request with an access token that contains the scope, or scopes, defined in the OAuth provider. If the request doesn't contain a scope, you must specify a default scope to use. If no default scope is defined, and the request doesn't contain a scope, an invalid scope error is returned for the request.

```
GET /getaccount
HTTP/1.1
Host: server.example.com
X-IBM-Client-Id: 8888-8888-8888
Authorization: Bearer AAEkNjVkOWIyYjgtOWY5ZS00YWQwLWIyYzktZ
```

The following application OpenAPI file secure-banking.yaml defines the scope, or scopes, that must exist in the token to be granted access to the API /getaccount.

```
secure-banking.yaml

securityDefinitions:
   scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
security:
  - scope-only:
      - checking
  - scope-only:
      - saving
      - mutual
```

In the examples, the access token **AAEkNjVkOWIyYjgtOWY5ZS00YWQwLWIyYzktZ** is able to access the API because it contains one, or a combination of **scope-only** that is defined in secure-banking.yaml such as:

- **checking**
- **saving mutual**
- **checking saving mutual**

Advanced Scope Check
Administrators can enable an additional scope check by configuring the consumer API property Advanced Scope Check URL that becomes **x-scopeValidate** as shown in the following OpenAPI file example.

```
securityDefinitions:
  advanced-scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
    x-scopeValidate:
      url: 'https://advanced-scope-check.bk.com/validate-scope'
      tls-profile: 'ssl-client'
```

After API Connect successfully verifies the access token against any scope requirement, API Connect will make an **HTTP POST** request to the **x-scopeValidate** endpoint similar to the following example. Response code `HTTP 200` from the endpoint indicates a success. Any other response code, or a connection error, is treated as a permission error for the token.

```
     POST /validate-scope?app-name=..&appid=..&org=..&orgid=..&catalog=..&catalogid=..&transid=..
HTTP/1.1
     Host: advanced-scope-check.bk.com
     Content-Type: application/json

   {"context-root" : checking,
    "resource" : accountinfo,
    "method" : GET,
    "api-scope-required" : [jointaccount],
    "access_token" : {"client_id" : "2cd71759-1003-4a1e-becb-0474d73455f3",
                      "not_after" : 174364070,
                      "not_after_text" : "2017-07-11T02:27:50Z",
                      "not_before" : 174360470,
                      "not_before_text" : "2017-07-11T01:27:50Z",
                      "grant_type" : "code",
                      "consented_on" : 1499736470,
                      "consented_on_text" : "2059-07-11T01:27:50Z",
                      "resource_owner" : "cn=spoon,email=spoon@poon.com",
                      "scope" : "jointaccount mutual",
                      "miscinfo" : "[r:gateway]"
                     }
}
```

An example of successful response follows.

```
HTTP/1.1 200 OK
Cache-Control: no-store
Pragma: no-cache
X-Custom-For-Assemble-Process: audit
```

Any HTTP response header that begins with "**x-**" is kept as the context variable **oauth.advanced-consent**. Based on the example successful response, **X-Custom-For-Assemble-Process: audit** becomes `oauth.advanced-consent.x-custom-for-assemble-process`, and can be accessed in the assemble step.

Additional validation options
You can optionally use additional fields for validation:

Request Header
: Defines the regular expression to match against **request** headers. Matching headers are included in the request to the advanced scope validation endpoint.

Response Context Variable
: Defines the regular expression to match against **response** headers. Matching headers are saved as context variables in the format **oauth.advanced-consent.***.

Related information

- IETF RFC 6749

Tokens

Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.

This section contains information regarding token management, including refreshing and revoking tokens, redirecting, and managing tokens with the DataPower Gateway.

- **Refresh tokens**
  If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.
- **Token revocation**
  In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.
- **Authenticating and authorizing through a redirect URL**
  You can use a service that is hosted externally from IBM API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.
- **Token management with the DataPower Gateway (v5 compatible)**
  API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.
- **Token management with the DataPower API Gateway**
  API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

Refresh tokens

If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.

When you are using OAuth authentication, API requests must include a valid access token, by using the Authorization HTTP header. Access tokens that are issued by the IBM® API Connect Token Endpoint are valid for 3600 seconds (1 hour) by default, as indicated by the expires_in property that is returned on the token request. The following code block shows an example API request with an Authorization header:

```
GET /bankingApi/accountSummary?client_id=32427ce5-bb7c-48a7-9de3-4bb629091103
HTTP/1.1
Accept: application/json
Host: api.ibm.com
Authorization: Bearer AAEFYy1hbGxlhdS5nVX4x6iTL2sb3ymBivQb...
```

After an access token expires, if the option is enabled in the OAuth provider configuration Tokens > Refresh tokens screen, the application uses refresh tokens. Each refresh token is valid for approximately 31 days after it is issued (or for the Time to Live time period specified) and can be used only once to request a new access token. Along with the new access token, a new refresh token is also returned. For details on how to enable refresh tokens, see Configuring a native OAuth provider.

If the access token is expired and the application does not have a refresh token, it must restart the OAuth exchange by using the choice of Grant Type(s) allowed by the OAuth provider.

Token revocation

In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.

Token revocation using an external third party service

This topic describes token revocation using a third party, external service. This option is configured in the Native OAuth provider, using the Token Management > Type = Third party screen. The revocation URL is an endpoint that links to an external service which contains information about access or refresh tokens. API Connect is involved in the initial creation and validation of tokens. When an OAuth revocation URL is present, API Connect calls the URL to determine if the associated token can be trusted.

The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing.

Examples

A number of revocation examples follow. The first shows a sample fetch request and the response from a remote revocation URL.

GET request and response

In this example, an API Gateway server issues a GET request to the Revocation URL and receives a result. It shows that different resource owners (Laura and Emily) can revoke all tokens when using the same application (client ID).

Request:

```
<?xml version="1.0" encoding="UTF-8"?>
GET <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Accept: application/xml; text/xml
```

Response:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>

<!--
Access Tokens and/or Refresh Tokens that are revoked can be individually listed.
To keep this list small, please only include access tokens and refresh tokens that are valid.
For access tokens, any token older than 20 minutes is no longer valid.
For refresh tokens, any token older than 44700 minutes is no longer valid.
-->

<token type="access">AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1...</token>
<token type="refresh">fZaRlVbnPSc1UGTjCRdq4mPbOosD2+aZIKbJ6bTeW...</token>

<!--
If a resource owner has revoked all tokens issued to a given application, please
list them as shown here.
-->

<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">laura</resource-owner>
<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">emily</resource-owner>

</oauth-revocation>
```

POST request and response

The next example shows a post request and response.

Request:

```
POST <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Content-Type: application/xml

<?xmlversion="1.0" encoding="UTF-8"?>
<token>
   <token_type>bearer</token_type>
   <access_token>AAENYy1hbGwtcmVmcmVzaOfNeQKX8ZeojsBY9v0FI7/OerQvzKHq...</access_token>
   <expires_in>3600</expires_in>
   <scope>3600</scope>
   <resource-owner>alice</resource-owner>
   <client_id>83d9cdcd-ba72-4d00-abae-005da8da5fb1</client_id>
</token>
```

Response:

```
HTTP/1.1 200 OK
```

Provide token information on revocation request

In this example, the application calls an API and passes a bearer token. In response, the Gateway fetches the revocation URL and provides information on the token being verified.

Gateway:

```
GET  <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Alternatively, the same process occurs when using a refresh token to issue a new access token. The application sends a refresh request to the token service. The Gateway then fetches the revocation URL, providing information on the refresh token being verified.

Gateway:

```
GET  <revocationURL>GET  HTTP/1.1
refresh-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
```

```
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Note: If you are using a third party OAuth provider then, for API Calls with bearer tokens, when Introspect URL is enabled on the API, the revocation URL is not applicable. Instead, the third party endpoint must validate the token and also check for revocation before returning a `200 OK` response to the Gateway.

Revoking tokens issued to Alice up to and including a specific date

On May 1st, Alice loses her phone and needs to reset her password. As a result, the token provider wants to revoke every token issued before Alice lost her phone. In this example, the Gateway sends a `GET` request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-05-01T09:30:10Z">alice</resource-owner>
<oauth-revocation>
```

Revoking all tokens issued up to and including a specific date

Under certain catastrophic conditions, you may need to revoke all tokens issued up to and including a specific date, for example, May 1st. In this example, the Gateway sends a `GET` request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <everytoken before="2015-05-01T09:30:10Z" />
<oauth-revocation>
```

Putting it all together

The following shows the examples contained in this topic executed in a single action:

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
HTTP/1.1 200 OK
Content-Type: application/xml
Cache-Control: public, max-age=120
Date: Fri, 08 May 2015 21:49:03 GMT

<?xml version-"1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-04-08T09:30:10Z">mary</resource-owner>
  <resource-owner before="2015-04-12T09:30:10Z">john</resource-owner>
  <resource-owner before="2015-04-13T09:30:10Z">kevin</resource-owner>
  <resource-owner before="2015-04-01T09:30:10Z">alice</resource-owner>
<oauth-revocation>
```

Notes:

- In the previous example, there are no entries older than one month in the response (the maximum life of a refresh token).
- Each response is cached for up to two minutes according to response's directive.
- The `before` attribute uses the `xs:dateTime` syntax.

Authenticating and authorizing through a redirect URL

You can use a service that is hosted externally from IBM® API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.

Before you begin

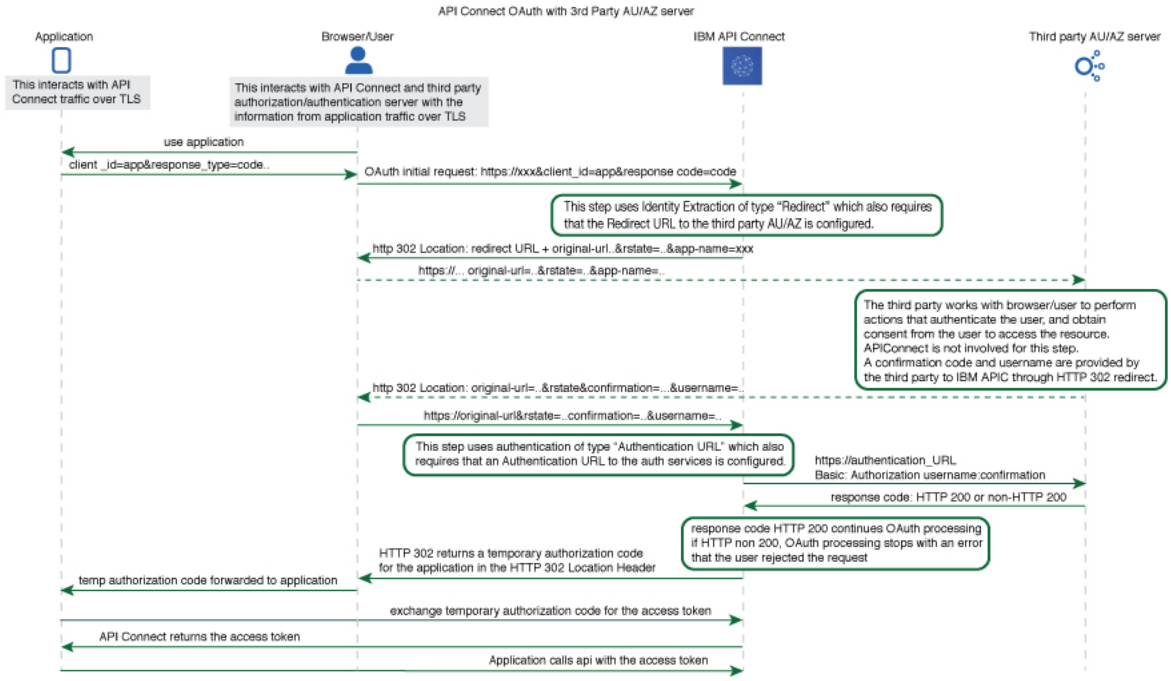
To complete this task, you will need to either create or have created an OAuth security definition that uses Implicit grant type or Access Code (Authorization Code) grant type. For more information, see Creating an OAuth security definition.

About this task

If you use methods for authentication that are not supported by API Connect, you can redirect users to a suitable URL at which they can authenticate. The user is then returned to the OAuth process after authentication and authorization have been confirmed.

The following illustration indicates the transaction flow for third party authentication.

Figure 1. Third party authentication (AU) and authorization (AZ) transaction flow



1. The application initiates a request to access an API protected with a third-party entity. API Connect redirects the application with an **`HTTP 302`** redirect based on **`identity extraction -> redirect -> redirect-url`**, for user authentication (and optional authorization).
2. The application communicates directly with the third-party entity to gather user identity. API Connect is not involved in this communication. After the third-party entity finishes processing authentication (and optional authorization), it returns an **`HTTP 302`** redirect that uses the **`original-url`** from the request, with the username and confirmation code appended.
3. API Connect receives the request that includes the username and confirmation code, and communicates with the authentication URL, based on **`authentication -> x-ibm-authentication-url`**, to confirm user identity before the request is completed.
4. An **`HTTP 200`** response from the third-party entity allows API Connect to continue the OAuth 2.0 request process as if the owner is authenticated. The request is then processed according to the **`grants`** type.
   - **`- accessCode`** returns a temporary code to the application.
   - **`- implicit`** returns the access token to the application.

   For any response other than HTTP 200, the request fails with a statement added to the error log.

Procedure

To create an external form, and to indicate the URL to which API Connect will redirect users, complete the following instructions:

1. Create your service for authentication and authorization. You will use the URL of the landing page of this service as your redirect URL.
   a. To include elements in your form that are provided by API Connect, use the following query parameters from the URL that your user is redirected to.
   Note: With the exception of **`original-url`**, none of these parameters are included in the URL automatically; you must add them as required.

   app-name
   : The name of the application requesting access, as provided through the Developer Portal.

   appid
   : The id of the application requesting access.

   catalog
   : The name of the catalog where the product is being used by the application.

   catalogid
   : The id of the catalog where the product is being used by the application.

   catalogtitle
   : User-friendly display name for the catalog.

   org
   : The name of the consumer organization that hosts the application.

   orgid
   : The id of the consumer organization that hosts the application.

   orgtitle
   : User-friendly display name for the organization.

   original-url

The original URL that the user was directed to by the application, including query parameters from the original URL that are necessary for standard OAuth 2.0 requests. You can include these parameters in your service to provide information to the user. Additionally the state_nonce is appended. The state_nonce is a hash code generated by API Connect for verification purposes. The URL is URL-encoded and should be decoded before further use, the **`state_nonce`** should remain unchanged.

provider
: The name of the API provider organization.

providerid
: The id of the API provider organization.

providertitle
: User-friendly display name for the provider organization.

requested-scope
: [optional] If Application Scope check is enabled and replaces the **`scope`** from the initial application request, this field holds the **`scope`** value from the initial application request, and the new replacement scope value is put into **`original-url`**.

transid
: transaction id used in the GW for the transaction which trigger this call

The URL to which the user is sent to when they are redirected to your page has the following form:

```
Redirect_URL?original-url=Original_URL&state_nonce=R_State&app-name=Application_Name
```

where all variables are as described previously. The Redirect URL does not have a size limit enforced by API Connect.

b. Create the stages of authentication, authorization, and any intermediate stages that you require to take place before you allow access to the application. Upon completion of these stages, redirect the user to the *Original_URL* and append a user name, their confirmation code, and the application name to be evaluated for access grant or denial by API Connect. The confirmation code does not have a size limit enforced by API Connect.
Original URL requires the following form:

```
Original_URL&username=User_Name&confirmation=Confirmation_Code
```

where all variables are as described previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtqlB7LDkq4gjlD3SHKglCbnYdHs/bMz2Y=&username=spoon&confirmation=12345678
```

c. To send your own error responses after the authentication and authorization service, redirect the user to the *Original_URL* and append an error code. You can also append a user name. Use the following form:

```
Original_URL&username=User_Name&error=Error_Response
```

where *Error_Response* is the message you wish to send and all other variables are described as previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtqlB7LDkq4gjlD3SHKglCbnYdHs/bMz2Y=&username=User&error=access_denied
```

2. Create a service to validate the confirmation code and user name. API Connect makes a GET call to your authentication URL after the user is redirected back to the authorization URL. When the call is made, it includes in its authorization header the user name and confirmation code you supplied previously. Confirm that these are correct and respond with an HTTP success code such as `200 OK` if you want to allow access, or non-`200 HTTP` response code, such as `401 Unauthorized` to deny access.
3. In your OAuth provider configuration, supply the redirect URL that is used in Step 1 and the authentication URL that is used in Step 2.
For more information on configuring an OAuth Provider, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Token management with the DataPower Gateway (v5 compatible)

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

In order to manage tokens with the DataPower® Gateway (v5 compatible), you must set the Token Management Type to Native in your Native OAuth provider configuration. See Configuring token management and revocation for a native OAuth provider when using Cloud Manager or Configuring token management and revocation for a native OAuth provider when using API Manager.

Also, the DataPower quota enforcement server must be enabled on the DataPower Gateway to use the distributed cache to manage tokens. See Quota enforcement.

When distributed cache support is enabled, replay protection is provided across the gateway cluster through the quota enforcement server. This support ensures that the same token cannot be reused across the members of the quota enforcement peer group.

Important:
If you have a cluster of DataPower Gateway servers, the OAuth data synchronization behavior across the servers depends on whether or not you enable revocation:

- If you enable revocation, API Connect uses the DataPower quota enforcement server, and OAuth data is synchronized across the servers. If an access token is obtained from one server, the OAuth data synchronization ensures that the same authorization code cannot be used to obtain an access code from another server. You must ensure that the DataPower quota enforcement server is configured.
- If you disable revocation, API Connect does **not** use the DataPower quota enforcement server and OAuth data does not synchronize across the cluster of DataPower Gateway servers. Therefore, to prevent the same authorization code being used to obtain an access code from more than one server you must configure DataPower to synchronize OAuth data across the servers, by using the DataPower Gateway console.

To configure DataPower to synchronize OAuth data, ensure that the DataPower quota enforcement server is configured. For more information, see Configuring the quota enforcement server.

Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user `cn=spoon,o=ibm` with username `spoon` and password `spoon` using a registered administration application of `5287fe53-8747-438a-8262-681ec75b79c5`.

- Request:

```
GET /oauth2/issued
HTTP/1.1
       Host: apic.ibm.com
       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
       Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK

Content-Type: application/json;charset=UTF-8

Cache-Control: no-store

Pragma: no-cache

[

{

"clientId": "5287fe53-8747-438a-8262-681ec75b79c5", => same client id as request

} => delete second item

]
```

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client-id=a8746323-9825-a842-8736-abd8202356ac8

HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: a8746323-9825-a842-8736-abd8202356ac8 => same client id as delete request

x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7

Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

    { "status": "success" }
```

Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to /oauth2/revoke, which supports OAuth 2.0 IETF RFC 7009. An HTTP POST operation that an application can send to this API to revoke either an **access_token**, or **refresh_token** with **token_type_hint** as shown in the following examples:

Revoke **access_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

    Host: apic.ibm.com

       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
      Content-Type: application/x-www-form-urlencoded

      token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn94lSWX14xuR....
```

- Response:

```
HTTP/1.1 200 OK
      Content-Type: application/json;charset=UTF-8
      Cache-Control: private, no-store, no-cache, must-revalidate
      Pragma: no-cache

    { "status": "success" }
```

Revoke **refresh_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

    Host: apic.ibm.com

       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
      Content-Type: application/x-www-form-urlencoded

      token_type_hint=refresh_token&token=........
```

- Response:

```
HTTP/1.1 200 OK
      Content-Type: application/json;charset=UTF-8
      Cache-Control: private, no-store, no-cache, must-revalidate
      Pragma: no-cache

    { "status": "success" }
```

Token management with the DataPower API Gateway

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

Note: The steps described in this topic are required if you are using the DataPower® OVA or appliance version of the gateway. For the API Connect supplied Kubernetes deployment, the API Security Token Manager is preconfigured provided that, in the gateway service custom resource file, v5 compatibility mode is disabled and the token management service is enabled:

```
      .
      .
      .
spec:
      .
      .
      .
  apicGatewayServiceV5CompatibilityMode: false
  tokenManagementService:
    enabled: true
      .
      .
      .
```

For more information, see Installing the DataPower Gateway subsystem.
In order to manage tokens with the DataPower API Gateway, you must set the Token Management Type to Native in your Native OAuth provider configuration. See Configuring token management and revocation for a native OAuth provider when using Cloud Manager or Configuring token management and revocation for a native OAuth

provider when using API Manager.

Note: This setting is also required when you use a third-party OAuth provider and **`Introspect cache type`** is set to **`protocol`** or **`Time to live`**.
For token management with the DataPower API Gateway, you must configure the API Security Token Manager on the gateway. Complete the following steps:

1. Log in to the DataPower administration console, selecting apiconnect for the domain, and WebGUI for the Graphical Interface.
2. In the search box, enter API Security Token Manager, then click on the API Security Token Manager link that displays in the search results.
3. For the Administrative state, select enabled.
4. Click the + icon alongside the Gateway Peering field to create a new gateway peering object.
5. Provide a Name and a Local address.
6. In the Local port and Monitor port fields, provide values that aren't already in use by services for the Local address.
7. Ensure that Peer group mode is selected.
8. Alongside the Peers field, use the add button and accompanying field to add at least two peers, to ensure that quorum is achieved.
9. If the Enable SSL option is selected, select a value for the Identification credentials.
10. For Persistence location, select a setting other than memory.
11. When done, click Apply.
12. Repeat steps 1 to 11 for each DataPower API Gateway in the peer group.
13. When done, click Apply, then click Save Configuration to save your changes.

For more information, see Defining the API security token manager and Creating a gateway peering instance.

Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user **`cn=spoon,o=ibm`** with username **`spoon`** and password **`spoon`** using a registered administration application of **`5287fe53-8747-438a-8262-681ec75b79c5`**.

- Request:

```
GET /oauth2/issued
HTTP/1.1
       Host: apic.ibm.com
       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
       Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK

Content-Type: application/json;charset=UTF-8

Cache-Control: no-store

Pragma: no-cache

"catalogTitle": "For public",

"catalogId": "5887803de4b06e6998c4b2d3"

} => delete second item

]
```

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client-id=a8746323-9825-a842-8736-abd8202356ac8

HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: a8746323-9825-a842-8736-abd8202356ac8 => same client id as delete request

x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7

Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

    { "status": "success" }
```

Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to /oauth2/revoke, which supports OAuth 2.0 IETF RFC 7009. An HTTP POST operation that an application can send to this API to revoke either an `access_token`, or `refresh_token` with `token_type_hint` as shown in the following examples:

Revoke `access_token`

- Request:

```
POST /oauth2/revoke
HTTP/1.1

   Host: apic.ibm.com

      x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
      x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
     Content-Type: application/x-www-form-urlencoded

     token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn94lSWX14xuR....
```

- Response:

```
HTTP/1.1 200 OK
     Content-Type: application/json;charset=UTF-8
     Cache-Control: private, no-store, no-cache, must-revalidate
     Pragma: no-cache

    { "status": "success" }
```

Revoke `refresh_token`

- Request:

```
POST /oauth2/revoke
HTTP/1.1

   Host: apic.ibm.com

      x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
      x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
     Content-Type: application/x-www-form-urlencoded

     token_type_hint=refresh_token&token=........
```

- Response:

```
HTTP/1.1 200 OK
     Content-Type: application/json;charset=UTF-8
     Cache-Control: private, no-store, no-cache, must-revalidate
     Pragma: no-cache

    { "status": "success" }
```

Authentication URL user registry

You can use an Authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides additional metadata to be embedded in the token.

This support can optionally enable any of the following:

- Providing the authenticated credential to IBM® API Connect. For example, the user logs-in with user name: `spoon`, and password: `fork`. When the user is authenticated, the credential becomes **`cn=spoon,o=eatery`**. The credential is kept in the OAuth **access_token** to represent the user.
- Providing metadata support. Allow extra metadata to be stored in the **`access_token`**.
- Overriding the **`scope`** that the application receives after a successful OAuth protocol processing. By responding with a specific header, the Authentication URL endpoint can replace the **`scope`** value that the application receives. For example, you can provide a specific resource owner an account number within the **`scope`** header response for use in future processing steps.

When you call the Authentication URL user registry, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.

The following response from the REST authentication service indicates that user authentication is successful and that API Connect will use **`cn=spoon,o=eatery`** as the user identity.

```
HTTP/1.1 200 OK
Server: example.org
X-API-Authenticated-Credential: cn=spoon,o=eatery
```

For information on how to configure a User Security policy in an API assembly for use with an Authentication URL user registry, see User Security policy.

For an example of an OAuth provider configuration that uses an Authentication URL user registry, see Example - using multiple OAuth policies in an OAuth provider assembly.

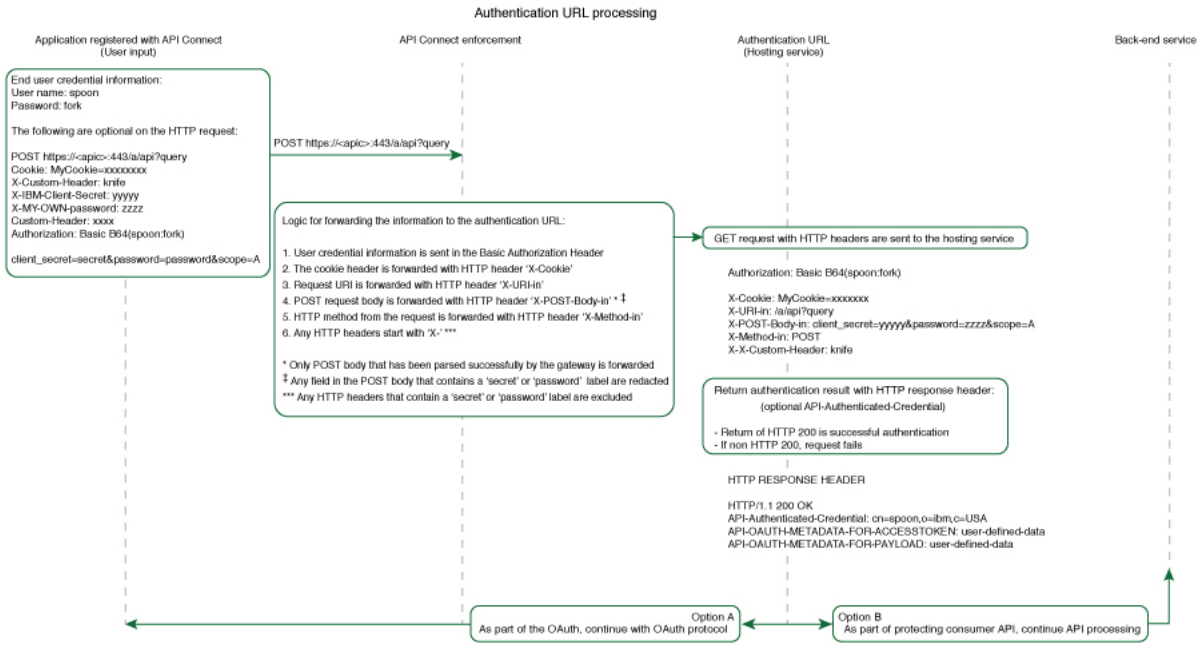
API Connect considers any non-200 HTTP response code a failed user authentication attempt.

When an Authentication URL user registry is invoked, two HTTP response headers are available that include metadata in the access token or the response payload that contains the access token. For more information, see OAuth external URL and authentication URL. The two metadata response headers are:

```
API-OAUTH-METADATA-FOR-ACCESSTOKEN
API-OAUTH-METADATA-FOR-PAYLOAD
```

When an Authentication URL is invoked, an HTTP response header is available to override the requested **`scope`** from the application. For more information, see Scope. The response header is:

```
x-selected-scope
```



If you are using the DataPower® API Gateway rather than the DataPower Gateway (v5 compatible), this diagram is provided for guidance only and is not fully accurate for this release.

Custom forms for user security

You can create custom forms for the authorization and identity extraction phase of OAuth.

About this task

The Native OAuth provider configuration provides the capability for requiring additional authentication and authorization steps for user security. Custom HTML forms may be created to extract the identity of the user and to authorize the user. This capability applies to Implicit, Resource owner password, and Access code grant types.

- **Creating a custom HTML login form for user security**
  Custom HTML forms can be created for user security during the identity extraction stage in OAuth.
- **Creating a custom HTML authorization form for user security**
  Custom HTML forms can be created for user security during the authorization stage in OAuth.

Creating a custom HTML login form for user security

Custom HTML forms can be created for user security during the identity extraction stage in OAuth.

Before you begin

The Native OAuth provider configuration includes Identity Extraction when using the Implicit, Access code, or Resource owner password grant types. You have the option to select how to extract the user credential and one of the choices is Custom HTML Form. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager. For more information, see Configuring a native OAuth provider. This topic describes how to create the Custom HTML form for identity extraction.

About this task

During three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user is presented with a form for signing in to the service provided by the API. You can present a custom form or a default form. Your custom form must fulfill certain requirements.

Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

Procedure

To create a custom sign-in form for your Native OAuth provider, complete the following steps:

1. Create a well formed XHTML document that will be parsed and transformed by API Connect to inject hidden fields.
2. For your XHTML form, set the method as `POST`, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.
   For example:

   ```
   <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
   ```

3. Create a text input field that is named `username` and create a password input field named `password`.
4. Add the line `<EI-INJECT-HIDDEN-INPUT-FIELDS>`. This third element is a placeholder that API Connect replaces with input fields to complement the user-submitted data.
5. Create a button to initiate the sign-in process.
   For example:

   ```
   <button
   id="_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.apionprem.doc_oauth_custom_login_form_2_login
   _button" type="submit" name="login" value="true">Log in</button>
   ```

6. Optional: Add text that is displayed the first time that the user visits the sign-in page. Use the tag `<EI-LOGINFIRSTTIME>` for the text that you want to display.
7. Optional: Add text that appears when the user is returned to the sign-in page if they fail to authenticate. Use the tag `<EI-LOGINFAILED>` for the text that you want to display.
8. Optional: Have an error message displayed when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<EI-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the end user.
9. Optional: You can add elements that are loaded from external sources, such as images or JavaScript.
10. Insert spacing and other features as you require. Completing Steps 1 through to 8 results in a form similar to the following example:

```
<html lang="en" xml:lang="en">
  <head><meta http-equiv="Content-Type" content="text/html; charset=UTF-8"/></head>
  <body>
    <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
      <h1>Please sign in</h1>
      <p>Username </p>
      <p ><input type="text" name="username" required="required" /> </p>
      <p>Password </p>
      <p ><input type="password" name="password" required="required" /> </p>
      <EI-INJECT-HIDDEN-INPUT-FIELDS/>
      <p > <button
id="_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.apionprem.doc_oauth_custom_login_form_2_login
_button" type="submit" name="login" value="true">Log in</button> </p>

      <EI-LOGINFIRSTTIME>
        <p>If you have forgotten your user name or password, contact your system administrator.</p>
      </EI-LOGINFIRSTTIME>

      <EI-LOGINFAILED>
        <p >At least one of your entries does not match our records.
          If you have forgotten your user name or password, contact your system administrator.</p>
      </EI-LOGINFAILED>

      <EI-INTERNAL-CUSTOM-FORM-ERROR/>

    </form>
  </body>
</html>
```

11. Make your form available at a URL of your choice.
12. If you have not already done so, configure your Native OAuth provider to use a Custom HTML form for identity extraction and provide the URL at which your form is available. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

- Configuring API security

Creating a custom HTML authorization form for user security

Custom HTML forms can be created for user security during the authorization stage in OAuth.

Before you begin

The Native OAuth provider configuration includes user authorization when using the Implicit, Access code, or Resource owner password grant types. You have the option to select how to authorize application users and one of the choices is Custom HTML Form. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager. This topic describes how to create the Custom HTML form for authorization.

About this task

During three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user is presented with a form through which they grant permission to an application to access their data through the API on their behalf. You can present a custom form or a default form. Your custom form must fulfill certain requirements.
Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

Procedure

To create a custom authorization form for your Native OAuth provider, complete the following steps:

1. Create a well-formed XHTML document. This will be parsed and transformed by API Connect to inject hidden fields.
2. For your XHTML form, set the method as `POST`, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.
   For example:

   ```
   <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
   ```

3. Add the line `<AZ-INJECT-HIDDEN-INPUT-FIELDS/>`. This line is a placeholder that API Connect will replace with input fields necessary for the completion of the OAuth process.
4. Create two buttons with the following code so that the user can grant or deny permission. Edit the text to suit your preferences.

   ```
   <button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
   <button class="submit" type="submit" name="approve" value="true">Allow Access</button>
   ```

5. Optional: Display an error message when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<AZ-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the end user.
6. Optional: You can add to the form HTML elements that will load features from external sources, such as images or JavaScript.
   For example, `<script src="http://www.example.com/example.js" />`
7. Insert spacing and additional elements as you require. Completing Steps 1 through to 6 results in a form similar to the following example:

   ```
   <html lang="en" xml:lang="en">
     <head><title>Request for permission</title></head>
     <body class="customconsent">
       <div>
         <div>
           <form method="post" enctype="application/x-www-form-urlencoded" action="authorize">
             <AZ-INJECT-HIDDEN-INPUT-FIELDS/>
             <p>Greeting..</p><DISPLAY-RESOURCE-OWNER/>
             <p>This app </p><OAUTH-APPLICATION-NAME/><p> would like to access your data.</p>
             <div>
               <button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
               <button class="submit" type="submit" name="approve" value="true">Allow Access</button>
             </div>
           </form>
         </div>
         <AZ-INTERNAL-CUSTOM-FORM-ERROR/>
       </div>
     </body>
   </html>
   ```

8. Make your form available at a URL of your choice.
9. If you have not already done so, configure your Native OAuth provider to use a Custom HTML Form for authorization for User Security. Provide the URL as the endpoint at which your form is available. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Securing an API with a JSON Web Token

There are two methods to secure your API with a JSON Web Token. You can use the **jwt-generate** command, or you can use a token that has been generated external to IBM® API Connect.

About this task

JSON Web Token (JWT) is an OAuth 2.0 compliant method of authentication that can be useful to secure your API in API Connect.

You can secure your API with a JSON Web Token by using either of the following methods:

- Generate a token through the **jwt-generate** command, and then augment the response payload with your generated token replacing the `id` token.
- Use a token that was generated outside of API Connect and include it into the response payload, by using the metadata URL.

Procedure

Create a **jwt-generate** policy in the assembly.

a. In API Manager, open the Assembly tab.
b. Add a jwt-generate policy to the assembly for the API.

Troubleshooting OAuth

You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

You can use the following links to go to the topics:

- OAuth 2.0 support in the developer portal test tool
- OAuth requires quorum in a multi-node cluster

OAuth 2.0 support in the developer portal test tool

OAuth 2.0 support is exposed as an API through the provider OpenAPI definition. You can use the test tool that is included with API Connect to test the OAuth 2.0 configuration. For more information, see Testing an API using the Developer Portal test tool.

OAuth requires quorum in a multi-node cluster

In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

API Analytics

You can use API Connect to filter, sort, and aggregate your API event data. You can present the results within correlated charts, tables, and maps to help you manage service levels, set quotas, establish controls, set up security policies, manage communities, and analyze trends.

API analytics is built on the OpenSearch open source real-time distributed search and analytics engine.

The content of the API event data depends on the logging policy that is set for the operation. For more information about the fields that are displayed in an API event record, see API event record field reference. For information about how to configure your logging preferences for API events, see activity-log policy and Including elements in your assembly.

- **Catalogs, spaces, and analytics**
  Understand how syndication and the use of catalogs and spaces affects the use of the features in API Connect analytics.
- **Accessing analytics**
  Analytics data is displayed in dashboards in the API Manager UI. Dashboards are scoped at the provider organization, catalog, and space level. To access analytics data at the cloud scope, use the Cloud Manager UI. Analytics data is also accessible by using the Toolkit CLI and REST API.

Catalogs, spaces, and analytics

Understand how syndication and the use of catalogs and spaces affects the use of the features in API Connect analytics.

The data for analytics is collated from API events that are logged when API operations are invoked. Analytics data for an API is scoped to the catalog or space where that API resides, and is only included in search results (and thus, visualizations and dashboards) for the owning catalog or space.

Access to the analytics data, and to the analytics functions in the API Manager user interface, can be managed through the use of catalogs and spaces, and the roles and permissions that are assigned to the users (or *members*) of the provider organization.

The cloud admin user can view aggregated analytics data for all catalogs, spaces, in all provider organizations, in the admin UI.

Catalogs, spaces, and permissions

Catalogs act as deployment targets through which APIs (in their containing plans and products) are staged and published to consumer organizations. API Manager users in the provider organization can be assigned the following access to the analytics component for a catalog:

- A role that has the Analytics > View permission for a catalog: These users can view the analytics data generated for the APIs in the catalog within *dashboards*, export dashboard data in its raw format or as event records, and apply filters to the data shown within the dashboards.
- A role that has the Analytics > Manage permission for a catalog: This is a legacy permission and has the same permissions as the View permission.

The IBM® API Connect syndication feature provides a way for you to partition a catalog into multiple deployment targets (or *spaces*) through which separate groupings of APIs (in their containing plans and products) can be staged and published. Each space can be allocated to a separate group of users who need to manage their products independently, and the analytics data in each space is scoped to those products only. API Manager users in the provider organization can be assigned the following access to the analytics component for a space:

- A role that has the Analytics > View permission for a space: These users can view the analytics data generated for the APIs in the space within dashboards, export dashboard data in its raw format, and apply filters to the data shown within the dashboards.
- A role that has the Analytics > Manage permission for a catalog: This is a legacy permission and has the same permissions as the View permission.

For more information about assigning catalog or space permissions to a role, see Managing Catalog membership and Managing Space membership.

For more information about the default API Manager roles and permissions, see API Connect user roles.

Accessing analytics

Analytics data is displayed in dashboards in the API Manager UI. Dashboards are scoped at the provider organization, catalog, and space level. To access analytics data at the cloud scope, use the Cloud Manager UI. Analytics data is also accessible by using the Toolkit CLI and REST API.

The ability to access analytics data at a catalog or space level depends on your assigned roles and permissions. For more information about catalogs and spaces, see Working with Catalogs and Using syndication in API Connect.

To access analytics data from the API Manager UI, select the Analytics tab when viewing a catalog. For more information about the analytics data viewable from the API Manager UI, see Accessing analytics from the API Manager UI.
Restriction: If the visualizations in your dashboards are empty or display no recent data, a possible reason might be that access to analytics data within API Connect is deactivated. Contact your administrator for confirmation.
To export your analytics data, see Export your analytics data.

To use the toolkit CLI or REST API to access your analytics data, see:

- Analytics CLI.
- Analytics REST API.

Configuring API governance in the API Manager

How to add custom API governance rulesets to your API development process, to validate and enforce organizational governance policies and best practices in your provider organization.

Before you begin

Before you can create API governance rulesets, the API governance optional add-on must be enabled on your management subsystem by your system administrator. See Enabling API governance on Kubernetes, and Enabling API governance on VMware for more information. If API governance is enabled in your deployment, the API governance resource is displayed on the Resources page in the API Manager.

The API governance service is available to all user roles.

About this task

API governance is an optional add-on to IBM® API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process. You configure API governance by creating one or more custom rulesets that contain a collection of rules that can then be used to check Swagger, OpenAPI, and AsyncAPI documents. API governance contains the following types of rulesets:

- Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization.
- Global rulesets - these are pre-configured IBM and Spectral rulesets that contain the rules that are shared with your provider organization, and cannot be edited.

API governance in IBM API Connect is based on the open-source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

Note:

- API governance in IBM API Connect only supports the creation of custom rulesets that contain rules that use the built-in Spectral core functions, as defined in https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions. The use of custom functions, for example rules that use functions that you have created yourself in JavaScript files, is not supported.
- Some of the Spectral rules within the Global rulesets contain the property `recommended: false`, which means that those rules are ignored during validation. However, if you create a new ruleset from one of these rulesets by using the Save as new ruleset option, the `recommended` property isn't transferred to the new ruleset. Therefore all of the rules will be used in the validation, unless you delete those rules from the ruleset. The Spectral ruleset names are prefixed by spectral-.
- You can also configure API governance rulesets in the Cloud Manager. For more information, see Configuring API governance in the Cloud Manager.

You can complete this task only by using the API Manager UI.

You can configure API governance rulesets by using the following methods:

- Create a new ruleset.
- Import a ruleset.

Procedure

- To create a new ruleset, complete the following steps.
  1. In the API Manager, click Resources.
  2. In the Resources navigation menu, select API governance.
  3. In the Provider organization rulesets section, click Add > Create from scratch.
     The Create provider organization ruleset wizard opens.
  4. Provide the following Ruleset info details.

Property label	Required	Description	Data type
Title	Yes	A short descriptive name for the ruleset. This name is displayed in the list of global rulesets.	String
Name	Yes	A short machine name for the ruleset. Can contain only alpha-numeric characters, underscores (_), and hyphens (-).	String
Version	Yes	The version number is pre-populated with 1.0.0 and cannot be edited.	String
Description	No	An optional description of the ruleset.	String

  5. Click Next, and then add an initial rule to your ruleset.
  6. Provide the following Rule info details.

Property label	Required	Description	Data type
Title	Yes	A short descriptive name for the rule.	String
Name	Yes	A short machine name for the rule. Can contain only alpha-numeric characters, underscores (_), and hyphens (-).	String
Description	Yes	A description of the rule.	String
Message	No	Provide a message to help users understand what the goal of the rule is. If no message is provided, the value of the Description property is used for the message output of the validation scan.	String
Severity	Yes	Select a severity level from the following options: • error • warn • info • hint • off error is selected by default.	String

  7. In the Given section, specify one or more values for the parts of the API document to target. To add more values, click Add. Values must be written in JSONPath.
  8. In the Then section, specify the function type and options that will be used to evaluate the target values in the API document. Write this section in YAML syntax.
     In the following example, for a Given value of `$` (which means root level of the document), the Then section uses the Spectral core `truthy` function to check that the `info.contact` property value is not `false`, `""`, `0`, `null`, or `undefined`.

```
- field: info.contact
  function: truthy
```

     The Then section can also contain a list of functions to be applied to the Given part of the document. In the following example, for a Given value of `$.info.version` (which refers to the `version` property inside the `info` property at the root level of the document), the Then section uses both the `truthy` function, and the Spectral core `pattern` function that checks that the `info.value` matches the regex expression that is given by `functionOptions.match`.

```
- function: truthy
- function: pattern
  functionOptions:
    match: "^[0-9]+.[0-9]+.[0-9]+(-[a-z0-9+.-]+)?"
```

     For a complete list of the Spectral core functions that you can use in your custom rules, along with examples of these functions, see https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions.
  9. Click Create to create your draft ruleset.
     Your draft ruleset opens in design form view. Note that you can switch to the OpenAPI YAML source view by clicking the Source icon </>. To return to the design form view, click the Form icon.
  10. You now have the following options:
      - You can continue to edit your ruleset. For example, you can add more rules by clicking the Create rule icon alongside Rules in the navigation pane. Remember to click Save when you finish editing.
      - If you don't want to edit your ruleset further now, click API governance in the breadcrumb trail to return to the API governance overview page.
- To import an existing ruleset, complete the following steps. Remember that the rules in your imported ruleset can contain only built-in Spectral core functions, as defined in https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions.

1. In the API Manager, click Resources.
2. In the Resources navigation menu, select API governance.
3. In the Provider organization rulesets section, click Add > Import.
   The Import ruleset wizard opens.
4. Drag a file into the Upload file box, or click in the Upload file box to select a file to upload. The maximum file size is 100 kb, and the supported file types are YAML, YML, and JSON.
5. Click Next.
6. Edit the Ruleset info details as required, and click Import.
   Your draft ruleset opens in design form view. Note that you can switch to the OpenAPI YAML source view by clicking the Source icon </>. To return to the design form view, click the Form icon.
7. You now have the following options:
   - You can continue to edit your ruleset. For example, you can add more rules by clicking the Create rule icon alongside Rules in the navigation pane. Remember to click Save when you finish editing.
   - If you don't want to edit your ruleset further now, click API governance in the breadcrumb trail to return to the API governance overview page.

Results

Your draft ruleset is now listed in the table of Provider organization rulesets.

What to do next

You can validate the ruleset against an API by clicking Validate, selecting the rules that you want to validate, and one or more APIs, then clicking Validate. The results of the validation are displayed in a scorecard.

When you finish editing your ruleset, you can publish it to your provider organization. Click the options menu icon either next to the ruleset that you want to publish, or from within the ruleset viewer. Select Publish, and then click Publish again to confirm. The status of your ruleset changes from Draft to Published, and can now be used by API developers to validate their APIs. For more information, see Validating an API document by using API governance.

Note:

- After a ruleset is published, the ruleset information and rules can no longer be edited. If you need to update this information, you must create a new version by clicking the options menu icon either next to the ruleset that you want to edit, or from within the ruleset viewer, and selecting Save as new ruleset.
- **The API governance ruleset lifecycle in the API Manager**
  When you manage your custom API governance rulesets in the API Manager UI, you move them through a series of lifecycle states. From initially creating a draft ruleset, through to publishing to make the ruleset available to your API developers, to creating new versions, and to eventual archiving.

The API governance ruleset lifecycle in the API Manager

When you manage your custom API governance rulesets in the API Manager UI, you move them through a series of lifecycle states. From initially creating a draft ruleset, through to publishing to make the ruleset available to your API developers, to creating new versions, and to eventual archiving.

The following sections describe the various lifecycle states for a custom API governance ruleset.

Note:

- Approval is not required for any of the lifecycle state transitions.
- Global rulesets are pre-configured rulesets that contain the rules that are shared with your provider organization, and cannot be edited. These rulesets are always in the Published state.

Draft

The draft state for a ruleset is when the ruleset is not published, and isn't visible to your provider organization. The ruleset can continue to be edited, and its Status is shown as Draft.

Published

When you publish a ruleset, it is made visible to your provider organization, and cannot be changed. The ruleset Status is shown as Published. Any changes to the ruleset require a new version to be created by using the Save as new ruleset option.

Archived

When you archive a ruleset, it becomes a ready-only, fixed version of the ruleset that cannot be used for validation by your provider organization. The ruleset Status is shown as Archived.
Note: If you cannot see your Archived ruleset, ensure that the Edit filters option on the ruleset table is set to include Archived.
You can restore archived rulesets by using the Restore option, after which the Status returns to Published.

Also, you can delete Archived rulesets by using the Delete option.

Administering user access

If you have permission to administer users in IBM® API Connect, you can add and delete users. After users are removed from an organization through deletion, the user account remains in API Manager.

About this task

You can also authorize users to perform different roles within your organization. To make any changes to the users that can access your organizations, use the followings tasks:

- **Setting the expiration for invitations**
  Set a time-out for invitations to expire.
- **Configuring notifications**
  Specify the sender name and email address to use for email notifications. You can preview the templates and customize the text if required. You can also style the notifications to match your business theme.
- **Viewing your user information**
  You can view the users that can access your IBM API Connect organization.
- **Adding provider organization users and assigning roles**
  If you have the permissions that are required to edit users in API Connect, you can add users to your provider organization, remove users, assign roles and perform other user administration tasks.
- **Creating custom roles**
  If you have permission to edit roles in IBM API Connect, you can create custom roles, and assign permissions, in a provider organization. You can create as many custom roles as you want.
- **Removing a user from a provider organization**
  If you have permission to edit users, you can remove a user from a provider organization.
- **Configuring LDAP group mappings on API Manager user roles**
  As an API Manager administrator, you can configure LDAP group mapping on API Connect roles in a provider organization by using the developer toolkit CLI.

Setting the expiration for invitations

Set a time-out for invitations to expire.

About this task

Invitations contain a link, which expires after the specified the timeout.

Procedure

1. In API Manager, click  Settings.
2. In the Settings navigation list, click Onboarding, then click Edit.
3. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
4. Click Save.

Configuring notifications

Specify the sender name and email address to use for email notifications. You can preview the templates and customize the text if required. You can also style the notifications to match your business theme.

About this task

The API Manager emails are sent automatically when certain system events occur. The email templates are organized by scope, as explained in Table 1.

Table 1. Notification scopes

Scope	Events that trigger the notification
catalog	Activities related to Catalogs; such as application life cycle events, invitations to catalogs, product approvals, and subscription approvals.
consumer	Activities to consumer applications and subscription requests in the Developer Portal, invitations to Consumer organizations, and password reset requests for Developer Portal accounts.
provider	Invitations.
space	Invitations.

Email notifications contain a sender name and address that's based on a hierarchical search of the configured sender details in API Connect. Depending on the email template being sent, the search can start at the Space level, and then go through the Catalog, Provider Organization, and the Cloud Manager levels. The sender details that are used will be the first set of configured details found during this hierarchical search. To view which search path API Connect takes when looking for the sender details for each notification template, see Configuring sender details for email notifications.

One of the following roles is required to configure email notifications:

- Administrator
- Owner
- A custom role with the `Settings:Manage` permission

Note: You can also customize notifications by using the developer toolkit CLI, or by using the API Connect REST APIs. See API development and management commands, or API Connect REST APIs, for more information.

Procedure

1. In API Manager, click Settings.
2. In the Settings navigation list, click Notifications, then click Edit.
3. Specify a sender by entering a Name and Email address, then click Save.
   To configure sender details at the Space or Catalog levels, you must use the developer toolkit CLI. For more information, see Configuring sender details for email notifications.
4. Optional: To enable template customization, move the Customize notification templates slider to the On position.
   Note: You can reload all the default notifications, as configured by a cloud administrator, by disabling and re-enabling template customization. However, doing so will overwrite any customizations that have been made. For more information on customizing notifications as a cloud administrator, see Customizing email notification templates.
5. To preview the text for a template, select Preview from the options menu alongside the template name.
6. To edit the text for the template, either click the template name, or select Edit in the options menu alongside the template name.
   When a template is opened, an attempt is made to get the language from the browser setting, but if this isn't possible the template defaults to English.

   The text includes variables; for example, **{{catalog}}**. The notification text is based on Handlebars syntax. Most variables are enclosed in double curly braces **{{ }}**, but can be enclosed in triple curly braces **{{{ }}}** to disable HTML escaping, when the variable is a URL link for example. For more information on Handlebars, see https://handlebarsjs.com/.

   To obtain the complete list of variables that are available for a particular notification template, complete the following steps:
   a. Log in to the management server from the command line as a member of a provider organization; for details, see Logging in to a management server. You can use the same management server URL, user name, and password in the login command that you use to log in to the API Manager user interface.
   b. Enter the following command:

   ```
   apic notification-templates:get template_name --server mgmt_endpoint_url --scope org --org provider_organization --subcollection template_scope --fields variables --output -
   ```

   where:
   - *template_name* is the name of the required notification template, as displayed in the Template column in the user interface.
   - *template_scope* is the scope name displayed in the Scope column alongside that template.
   - *provider_organization* is the value of the **name** field for your provider organization.

   For example:

   ```
   apic notification-templates:get member-invitation --server https://myserver.com --scope org --org myorg --subcollection catalog --fields variables --output -
   ```

   The variables that are available for the template are displayed, for example:

   ```
   variables:
     - org
     - catalog
     - activationLink
     - expiresAt
     - originator
     - originatorFirstName
     - originatorLastName
     - originatorEmail
     - username
     - email
     - firstName
     - lastName
   ```

   The **--output -** parameter causes the command output to be written to the command line. You can specify **--output** ***filepath*** to have the output written to a .yaml file at the specified location, or omit it altogether to have a file written to the current folder.
7. To view and edit the notification template in a different language, select one of the following supported languages from the View template in drop-down list:
   - Chinese (Simplified)
   - Chinese (Traditional)
   - Czech
   - Dutch
   - English (US English)
   - French
   - German
   - Italian
   - Japanese
   - Korean
   - Polish
   - Portuguese
   - Russian
   - Spanish
   - Turkish
8. Edit the Subject as required.
9. Select the Content type that you want to use for the template, from HTML, PlainText, or Both. The default content type is PlainText.
   An edit window for the selected content type is displayed, or both edit windows are displayed if Both is selected.
10. Edit the body of the template as required.
    For HTML content, only the tags and their attributes that are shown in the following table are allowed.

Table 2. List of allowed HTML tags and their attributes

HTML tag	Attribute
<a>	"class", "href", "hreflang", "style"
	"class", "style"
	"class", "style"
<cite>	"class", "style"

HTML tag	Attribute
`<blockquote>`	`"class", "cite", "style"`
`<code>`	`"class", "style"`
`<ul>`	`"class", "type", "style"`
`<ol>`	`"class", "start", "type", "style"`
`<li>`	`"class", "style"`
`<dl>`	`"class", "style"`
`<dt>`	`"class", "style"`
`<dd>`	`"class", "style"`
`<h1>`	`"class", "id", "style"`
`<h2>`	`"class", "id", "style"`
`<h3>`	`"class", "id", "style"`
`<h4>`	`"class", "id", "style"`
`<h5>`	`"class", "id", "style"`
`<h6>`	`"class", "id", "style"`
`<p>`	`"class", "style"`
`<div>`	`"class", "style"`
` `	`"class", "style"`
`<span>`	`"class", "style"`
`<img>`	`"class", "src", "alt", "data-entity-type", "data-entity-uuid", "data-align", "data-caption", "width", "height", "style"`
`<table>`	`"class", "id", "style"`
`<tr>`	`"class", "id", "style"`
`<td>`	`"class", "id", "style"`

If an HTML tag that is not allowed is used in a notification, the tag and its contents are displayed in the email as plain text.
Images can be used by adding a **`<img src="https://path/to/image.png"/>`** tag in the template. The **`src`** attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images, they must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.

11. Click Save when done.
    Note: Edits made to a template are saved only for the specific language version that is edited.

- **Configuring sender details for email notifications**
  Understand how the hierarchical search works for the email notification sender details, and how you can configure sender details at the Space and Catalog level.

Configuring sender details for email notifications

Understand how the hierarchical search works for the email notification sender details, and how you can configure sender details at the Space and Catalog level.

Before you begin

One of the following roles is required to configure sender details for email notifications:

- Administrator
- Owner
- A custom role with the **`Cloud settings:Manage`** or **`Settings:Manage`** permission

For more information about the notification templates, their scope, and how to customize them, see Configuring notifications at the Provider Organization level, and Customizing email notification templates at the Cloud Manager level.

About this task

Email notifications are sent automatically by API Connect when certain system events occur. These notifications contain a sender name and address that's based on a hierarchical search of the configured sender details in API Connect. Depending on the email template that's being sent, the search can start at the Space level, the Catalog level, the Provider Organization level, or the Cloud level. The sender details that are used are the first set of configured details that are found during the hierarchical search.
The following table shows the starting point for the sender details hierarchical search for each email template, ordered by the scope of the template, where:

- Cloud: emails are sent from the details that are configured in the Settings > Notifications section of the Cloud Manager.
- Org: the search for sender details starts at the Provider Organization level; if not available, the Cloud details are used.
- Catalog: the search for sender details starts at the Catalog level; if not available, the Org details are used, and if they're not available, the Cloud details are used.
- Space: the search for sender details starts at the Space level; if not available, the Catalog details are used, if they're not available, the Org details are used, and if they're not available, the Cloud details are used.
- Space or Catalog: in these cases the search starts at the Space level, or at the Catalog level, depending on the user that made the request, as shown in the following list:
  - When the product lifecycle change is started by a user in a Space, the search for sender details starts at the Space level.
  - When the product lifecycle change is started by a user in a Catalog, the search for sender details starts at the Catalog level.
  - When the product lifecycle change is approved by a user in a Space, the search for sender details starts at the Space level.
  - When the product lifecycle change is approved by a user in a Catalog, the search for sender details starts at the Catalog level.

Table 1. Starting point for the sender details search for each email template

Scope	Template name	Email subject	Sender details
admin	mail-server-test-connection	Test message from IBM® API Connect.	Cloud
admin	member-invitation	Invitation to an admin organization in IBM API Connect.	Cloud
admin	password-changed	Password changed for your user account in IBM API Connect.	Cloud

Scope	Template name	Email subject	Sender details
admin	password-reset	Password reset request for your user account in IBM API Connect.	Cloud
provider	invitation	Invitation to create an API provider organization in IBM API Connect.	Cloud
provider	member-invitation	Invitation to an API provider organization in IBM API Connect.	Org
catalog	app-lifecycle-cancelled	Request withdrawn to *{{action}}* app *{{appName}}*.	Catalog
catalog	app-lifecycle-request	Request for approval to *{{action}}* app *{{appName}}*.	Catalog
catalog	invitation	Invitation to create an API catalog in IBM API Connect.	Org
catalog	member-invitation	Invitation to an API catalog in IBM API Connect.	Catalog
catalog	task-consumer-onboard-request	Consumer onboarding request in the *{{catalog}}* developer portal.	Catalog
catalog	task-product-lifecycle-approved	Request approved to *{{action}}* API product in catalog *{{catalog}}*.	Space or Catalog
catalog	task-product-lifecycle-cancelled	Request withdrawn to *{{action}}* an API product in the *{{catalog}}* catalog.	Space or Catalog
catalog	task-product-lifecycle-denied	Request denied to *{{action}}* API product in catalog *{{catalog}}*.	Space or Catalog
catalog	task-product-lifecycle-pending	Request received to *{{action}}* API product in catalog *{{catalog}}*.	Space or Catalog
catalog	task-product-lifecycle-request	Request for approval to *{{action}}* an API product in the *{{catalog}}* catalog.	Space or Catalog
catalog	task-subscription-cancelled	Request withdrawn to subscribe to an API product in the *{{catalog}}* catalog.	Catalog
catalog	task-subscription-request	Request for approval to subscribe to an API product in the *{{catalog}}* catalog.	Catalog
space	invitation	Invitation to create an API space in IBM API Connect.	Catalog
space	member-invitation	Invitation to an API space in IBM API Connect.	Space
consumer	account-approved	*{{catalogTitle}}* developer portal account registration is approved.	Catalog
consumer	account-denied	*{{catalogTitle}}* developer portal account registration is denied.	Catalog
consumer	account-pending-approval	*{{catalogTitle}}* developer portal account registration pending approval.	Catalog
consumer	app-lifecycle-approved	Request approved to *{{action}}* app *{{appName}}*.	Catalog
consumer	app-lifecycle-denied	Request denied to *{{action}}* app *{{appName}}*.	Catalog
consumer	app-lifecycle-pending	Request received to *{{action}}* app *{{appName}}*.	Catalog
consumer	app-reinstated	*{{appName}}* app reinstated in the *{{consumerOrg}}* developer portal.	Catalog
consumer	app-suspended	*{{appName}}* app suspended in the *{{consumerOrg}}* developer portal.	Catalog
consumer	invitation	Invitation to create an API consumer organization in the *{{catalog}}* developer portal.	Catalog
consumer	member-invitation	Invitation to an API consumer organization in the *{{catalog}}* developer portal.	Catalog
consumer	password-changed	Password changed for your user account in *{{portalTitle}}* developer portal.	Catalog
consumer	password-reset	Password reset request for your *{{catalog}}* developer portal account.	Catalog
consumer	sign-up	*{{catalogTitle}}* developer portal account registration.	Catalog
consumer	task-subscription-approved	API subscription request approved for app *{{appName}}*.	Catalog
consumer	task-subscription-denied	API subscription request denied for app *{{appName}}*.	Catalog
consumer	task-subscription-pending	API subscription request received for app *{{appName}}*.	Catalog

The sender address details can be configured at four levels: Cloud, Provider Organization, Catalog, and Space, and you can set a different sender address for each Provider Organization, Catalog, or Space, as required. The sender address for the Cloud can be configured in the Cloud Manager UI; see Setting up notifications for details. The sender address for the Provider Organization can be configured in the API Manager UI; see Configuring notifications for details. However, the sender address for Catalogs and Spaces can be configured only by using the toolkit CLI, as explained in the following steps.

Procedure

1. Log in to the management server from the command line as a member of a provider organization; for more information, see Logging in to a management server. You can use the same management server URL, username, and password in the login command that you use to log in to the API Manager user interface.
2. To update the sender address details for a Space, run the following commands.
   a. Run the **apic space-settings:get** command to read the current Space settings and output them to a json file. For example:

      ```
      apic space-settings:get --server my_mgt_server --org my_provider_org --catalog my_catalog --space my_space --format
      json
      ```

      Where:
      - ***my_mgt_server*** is your management server endpoint or URL.
      - ***my_provider_org*** is the name of your Provider Organization.
      - ***my_catalog*** is the name of your Catalog.
      - ***my_space*** is the name of your Space.

   b. Make a copy of the output file that you can then use to update the settings, for example:

      ```
      cp space-setting.json space-setting-update.json
      ```

   c. Edit the copied settings file to update the **email_sender** block. For example:

      ```
      vi space-setting-update.json
      ...
        "email_sender": {
          "custom": true,
          "name": "NO REPLY: space sender name",
          "address": "space_sender_email@nomail.com"
        },
      ...
      ```

      Where:
      - **custom** must be changed from the default setting of **false** to **true**.
      - the **name** line must be added to the file, and the ***space sender name*** details completed.
      - the **address** line must be added to the file, and the ***space_sender_email@nomail.com*** address details completed.

      Note: Ignore all of the other configuration details that are contained in this settings file.

   d. Run the **space-settings:update** command to update the Space settings with the new sender address details. For example:

```
apic space-settings:update --server my_mgt_server --org my_provider_org --catalog my_catalog --space my_space space-setting-update.json
```

Where *space-setting-update.json* is the name of your updated settings file.

3. To update the sender address details for a Catalog, run the following commands.
   a. Run the `apic catalog-settings:get` command to read the current Catalog settings and output them to a json file. For example:

   ```
   apic catalog-settings:get --server my_mgt_server --org my_provider_org --catalog my_catalog --format json
   ```

   Where:
   - *my_mgt_server* is your management server endpoint or URL.
   - *my_provider_org* is the name of your Provider Organization.
   - *my_catalog* is the name of your Catalog.

   b. Make a copy of the output file that you can then use to update the settings, for example:

   ```
   cp catalog-setting.json catalog-setting-update.json
   ```

   c. Edit the copied settings file to update the `email_sender` block. For example:

   ```
   vi catalog-setting-update.json
   ...
     "email_sender": {
       "custom": true,
       "name": "NO REPLY: catalog sender name",
       "address": "catalog_sender_email@nomail.com"
     },
   ...
   ```

   Where:
   - `custom` must be changed from the default setting of `false` to `true`.
   - `name` line must be added to the file, and the *catalog sender name* details completed.
   - `address` line must be added to the file, and the *catalog_sender_email@nomail.com* address details completed.

   Note: Ignore all of the other configuration details that are contained in this settings file.

   d. Run the `catalog-settings:update` command to update the Catalog settings with the new sender address details. For example:

   ```
   apic catalog-settings:update --server my_mgt_server --org my_provider_org --catalog my_catalog catalog-setting-update.json
   ```

   Where *catalog-setting-update.json* is the name of your updated settings file.

Results

You now understand how the hierarchical search works for the sender details for each email template, and can update the sender details at the Space and Catalog level as required.

Viewing your user information

You can view the users that can access your IBM® API Connect organization.

Procedure

To view your organization user information, complete the following steps:

In the navigation pane of the API Manager user interface, click Members.

What to do next

You can modify your user accounts; see Adding provider organization users and assigning roles. You can create custom roles; see Creating custom roles.

Adding provider organization users and assigning roles

If you have the permissions that are required to edit users in API Connect, you can add users to your provider organization, remove users, assign roles and perform other user administration tasks.

About this task

There are two ways to add a user:

- Invite member - send an invitation email with an activation link that enables the user to complete the addition operation.
- Add member - specify the user and add them as a member of the provider organization immediately.

Procedure

- To send an email invitation to a new user to register as a member of the provider organization, complete the following steps:
  1. In the navigation pane of the API Manager user interface, click Members.

2. Click Add > Invite member.
3. Enter the email address of the user.
4. Select the roles that you want to assign to the user.
5. Click Invite.

- To specify the user and add them as a member of the Admin organization immediately, complete the following steps:
  1. In the navigation pane of the API Manager user interface, click Members.
  2. Click Add > Add member.
  3. Select the required user registry.
     Note: For a user registry to be available in the selection list, one of the following conditions must be satisfied:
     - The visibility of the user registry is set to Public.
     - The visibility of the user registry is set to Custom, and the specified list of provider organizations includes the one to which you are adding the user.

     For more information, see Setting visibility for a user registry.
     The remaining procedure varies according to the type of the selected user registry, as follows:
     - Local User Registry
       - Select whether the user is an Existing user or a New User.
         - For an existing user, complete the following steps:
           - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
           - Select the roles that you want to assign to the user, then click Add. The user is added and their membership is immediately enabled. The specified user can log in to the API Manager user interface.
         - For a new user, complete the following steps:
           - Enter a unique user name for the new user.
           - Supply an email address, name details, and a password.
           - Select the roles that you want to assign to the user, then click Add. The user account is created, and the user membership is immediately enabled. The specified user can log in to the API Manager user interface.
     - LDAP
       - Enter the name of a user that exists in the selected user registry.
       - Select the roles that you want to assign to the user, then click Add. The user is added, and the user membership is immediately enabled. The specified user can log in to the API Manager user interface with their LDAP user name.
     - Authentication URL and OIDC
       - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
       - Select the roles that you want to assign to the user, then click Add. The user is added, and the user membership is immediately enabled. The specified user can log in to the API Manager user interface.

Results

The user is added to the list of provider organization members. If an email invitation was sent, the status is shown as `Pending` until the recipient of the email clicks the link in the email to complete the creation of their account, after which the status changes to `Enabled`.

What to do next

The new user can access the API Manager user interface. The user's authorization within API Manager is defined by the roles that are assigned to them.

Related tasks

- Creating custom roles

Creating custom roles

If you have permission to edit roles in IBM® API Connect, you can create custom roles, and assign permissions, in a provider organization. You can create as many custom roles as you want.

About this task

You create custom roles at the provider organization level; those roles are inherited by the Catalogs and Spaces in the provider organization. You can assign permissions at the provider organization, Catalog or Space level.

For a description of the permissions, and details of the default user roles and default permissions assigned to those roles, see API Connect user roles.

Note: In API Manager, the Organization Owner role has full access and cannot be edited or deleted. All other roles, including custom roles, can be deleted. If you delete a role, users lose that role. If a user loses that role, their account remains in API Manager, enabling you to add a role to the user at a future date.

Procedure

To create a custom role, complete the following steps:

1. In the navigation pane of the API Manager user interface, click Settings
2. Click Roles, then click Add.
   The Create a Role page opens.
3. Enter a role Title and an optional Summary. A Name is entered automatically.
   Note: The value in the Name field is a single string that is used to identify the role in developer toolkit CLI commands. The Title is used for display.
   To view the CLI commands to manage roles, see apic roles.
4. Use the check boxes to assign permissions to the new role.
5. When you are finished, click Save.

6. To delete a role, click the options icon ⋮ alongside the role that you want to delete, click Delete, then click Delete again to confirm the role deletion.
   Note:
   - You can create and delete a role only at the provider organization level. You cannot create or delete a role at the Catalog level. Nor can you create or delete a role at the Space level.
     You can, however, assign Catalog-specific permissions to the role; for details, see Creating and configuring Catalogs. You can also assign Space-specific permissions; for details, see Managing user access in a Space; for more information on Spaces, see Using syndication in API Connect.
   - If you assign Product-Drafts or Api-Drafts permissions to the role, these permissions are not inherited by the role in a Catalog or Space. These permissions apply to working with draft Products and APIs in a provider organization and are not relevant in a Catalog or Space.

Results

The custom role is created and assigned the permissions that you selected.

What to do next

Assign the custom role to a user.

Removing a user from a provider organization

If you have permission to edit users, you can remove a user from a provider organization.

About this task

After you have removed the user from your IBM® API Connect provider organization, their resources are deleted and the user cannot access any of the organization's artifacts.
Note: The user account of the deleted user remains in the associated API Connect user registry. The user can still log in to the API Manager user interface but only information links are available; there is no access to view or manage any resources.
If you later invite the same user again, they can re-activate their account. If you are using a Local User Registry, the user must re-activate their account by using the Sign In option, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail. For details on how to invite a user to join your organization, see Adding provider organization users and assigning roles.

Procedure

To remove a user from a provider organization complete the following steps:

1. In the navigation pane of the API Manager user interface, click Members.
2. Alongside the user that you want to delete, click the options icon ⋮, click Delete, the click Delete again to confirm the user deletion.
   Note: You cannot delete the owner of a provider organization.

Results

The user is removed from the provider organization, and the user account remains in API Manager.

Configuring LDAP group mappings on API Manager user roles

As an API Manager administrator, you can configure LDAP group mapping on API Connect roles in a provider organization by using the developer toolkit CLI.

Before you begin

You must have an LDAP user registry resource in the API Manager that has the **`external_group_mapping_enabled`** configuration set to **`true`**. See Using the CLI to create an organization-specific LDAP user registry for information.

One of the following roles is required to edit roles:

- Administrator
- Owner
- Custom role with the `Settings: manage` permissions

Note: The provider organization roles apply only to API Manager users. If you want to apply LDAP group mapping to Cloud Manager users, see Configuring LDAP group mapping on Cloud Manager user roles. LDAP group mapping cannot be applied to Developer Portal users.

About this task

You can map external LDAP groups to the API Connect preconfigured user roles (except for the Owner and Member roles), as well as to any custom user roles, to reflect your business needs.

Notes:

- After LDAP group mapping is enabled on a role, user onboarding always honors the group mappings.

- Once on-boarded, user membership in API Connect is valid throughout the login period (`access_token_ttl`), irrespective of any changes in the external LDAP registry. Membership is updated only on the next login, when the LDAP information is fetched and refreshed.
- One or more API Connect roles can be mapped to one or more LDAP groups, and one or more LDAP groups can be mapped to a role.
- When multiple LDAP groups are mapped to a single role, it means that a user from any one of the LDAP groups can logon to API Connect.
- If a user is removed from the external LDAP user registry, to ensure quick removal from API Connect you must also delete the user membership in API Connect.
- In API Manager you can map roles at the provider organization, Catalog and, if appropriate, Space level. However, you can only map roles at the child level of Catalog, and then the Catalog's child level of Space, if the parent level also has group mapping defined. Mapping at a child level overrides the mapping for the same role at the parent level. For example:
  If the Administrator Role at the provider organization level is mapped to the LDAP group of `cn=APIC-Administrators,ou=ibmgroups,o=ibm.com`, and the Administrator Role at a Catalog level is mapped to the LDAP group of `cn=APIC-Developers,ou=ibmgroups,o=ibm.com`, then any user that is added as a Catalog member must belong to the `cn=APIC-Developers,ou=ibmgroups,o=ibm.com` group. Note that provider organization level members that belong to the `cn=APIC-Administrators,ou=ibmgroups,o=ibm.com` group can still access the Catalog due to inheritance.

You can configure LDAP group mappings using one of the following methods:

- Using the UI to configure LDAP group mappings
- Using the CLI to configure LDAP group mappings

Using the UI to configure LDAP group mappings

Use the API Manager UI to configure LDAP group mappings.

Procedure

1. Login to the API Manager as a user with the appropriate permissions.
2. Click Settings > Roles > Add a new Role or edit existing role .
3. Select the following settings:
   - Enable external group mapping - select to enable external group mapping for this role.
   - LDAP user Registry - LDAP user registry list which has external group mapping enabled. User must select one of the LDAP user registry from this list.
   - LDAP group names - add one or more LDAP group names that you want to map to the user role.
   - User group prefix - add the prefix for the LDAP user group.
   - User group suffix - add the suffix for the LDAP user group.
4. Save your changes.

Results

The role is updated with the LDAP group mapping information. Users can now log on to the API Manager, and automatically be assigned the correct access permissions for their role.

Using the CLI to configure LDAP group mappings

Use the toolkit CLI to configure LDAP group mappings.

About this task

For detailed information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Procedure

Perform the following steps to map external LDAP groups to API Manager user roles.

1. Log in to the management server CLI.
   Before you can update the role configuration, you must log in to your management server from the developer toolkit CLI as a member of a provider organization. Use the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   where *`mgmt_endpoint_url`* is the platform API endpoint URL.
   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the login command, see Logging in to a management server.

2. Run the following command to get the URL of the LDAP user registry resource in the API Manager that you want to map the user roles to:

   ```
   apic user-registries:get  ldap_user_registry --org organization_name --server mgmt_endpoint_url --output -
   ```

   where:
   - *`ldap_user_registry`* is the name or ID of your LDAP user registry resource.
   - *`organization_name`* is the value of the `name` property of your provider organization.

- *mgmt_endpoint_url* is the platform API endpoint URL.

This command outputs the configuration details of your LDAP user registry, and the **url:** is shown at the end of the list, for example:

```
type: user_registry
api_version: 2.0.0
id: 35e75bad-1d89-4a65-a70f-xxxxxx
name: ldap
title: LDAP
integration_url: >-
  https://server.com/api/cloud/integrations/user-registry/147b5fb1-e88e-41e3-90e9-xxxxxx
registry_type: ldap
user_managed: false
user_registry_managed: false
external_group_mapping_enabled: true
...
url: >-
  https://server.com/api/user-registries/3d58ce7e-16a8-493b-9684-xxxxxx/35e75bad-1d89-4a65-a70f-xxxxxx
```

3. Create a role yaml file that contains the following LDAP group mapping configuration properties:

```
external_group_mapping:
  user_registry_url: https://server.com/api/user-registries/3d58ce7e-16a8-493b-9684-xxxxxx/35e75bad-1d89-4a65-a70f-xxxxxx
  ldap_groups:
    - 'cn=apic-administrators,ou=ibmgroups,o=ibm.com'
    - 'cn=apic-developers,ou=ibmgroups,o=ibm.com'
  user_group_filter_prefix: (&(uniquemember=
  user_group_filter_suffix: )(objectClass=groupOfUniqueNames))
```

   Where:
   - **user_registry_url** is the URL of your LDAP user registry resource from Step #task_apim_role_mapping__ldap_url.
   - **ldap_groups** is a list of the LDAP group names that you want to map to the user role.
   - **user_group_filter_prefix** is the prefix for the LDAP user group.
   - **user_group_filter_suffix** is the suffix for the LDAP user group.
4. Run the following command to update the user role with the **external_group_mapping** configuration properties:

```
apic roles:update role_name --scope org --org organization_name --server mgmt_endpoint_url mapping_properties_file
```

   Where:
   - *role_name* is the name of the user role that you want to add the LDAP group mapping to.
   - **--scope** is the organization level that you want the update to apply to. Valid values are:
     - **org** to apply the mapping at the provider organization level.
     - **catalog** to apply the mapping at the Catalog level.
     - **space** to apply the mapping at the Space level.
   - *organization_name* is the value of the **name** property of your provider organization.
   - *mgmt_endpoint_url* is the platform API endpoint URL.
   - *mapping_properties_file* is the name of your mapping properties file from Step #task_apim_role_mapping__role_file, for example **role_mapping_file.yaml**.

   If you prefer to enter the configuration properties interactively on the command line, you can substitute the *mapping_properties_file* for a terminating hyphen character **-**, and enter the information manually, followed by pressing **CTRL D** to terminate the input.
   If you want to create a custom role that includes LDAP group mapping, you can include the **external_group_mapping** configuration section in the **role_file**, and then create the new role by using the **apic roles:create** command.

For more information about the **apic roles** commands, see **apic roles** in the CLI reference section.

Results

The role is updated with the LDAP group mapping information. Users can now log on to the API Manager, and automatically be assigned the correct access permissions for their role.

Changing your API Manager password

You can change your API Manager password in IBM® API Connect.

Procedure

To change your password, complete the following steps:

1. Log in to the API Manager user interface.
2. Click the User icon then click My Account.
3. In the Change password section, enter your current password and your new password, and confirm the new password.
   Passwords must satisfy the following requirements:

   - Cannot be re-used for at least 8 password cycles
   - Cannot contain more than 2 consecutive repeating characters
   - Must include at least 8 characters
   - Must include 1 or more characters from at least 2 of the following categories:
     - Lowercase letters
     - Uppercase letters
     - Numbers

- Special characters – only the following special characters are allowed:

```
!
\"
#
$
%
&
\
(
)
*
+
,
-
.
/
:
;
<
=
>
?
@
[
\\
]
^
_
`
{
|
}
~
```

4. Click Change Password.

Results

Your password is changed.

Resolving login problems by increasing HTTP header size

You can resolve login problems for the API Manager UI by increasing the maximum HTTP client header size.

About this task

Login attempts to the user interface might fail with error **`502 (Bad Gateway)`**. This error can occur when logging in from a browser that has a large number of cookies. The error occurs because size of the login request exceeds the maximum HTTP client header size.

The maximum HTTP client header size is limited for security reasons. To workaround this issue, you can clear the browser cache and cookies, or open an incognito window from the browser, and then retry the login.

Alternatively, you can increase the maximum HTTP client header size. Use caution when increasing the maximum size because larger headers can raise a security risk to your system.

Procedure

1. **SSH** to your management system or appliance.
2. Enter the following commands:

```
kubectl get deployment -n namespace  | grep apim-v2
kubectl edit deployment -n namespace apiconnect-apim-v2-deployment
```

3. In the **env** section of the deployment configuration, change **`--max-http-header-size=12000`** to a larger value that works for your environment. For example:

```
 - name: NODE_OPTIONS
          value: --max-old-space-size=8094 --max-http-header-size=16000
```

4. Save the updated configuration.
5. Run `kubectl get pod -n namespace` a few times until the new `apiconnect-apim-v2` pod is up and running.

API Gateway only

Reviewing a gateway's processing status

Review the processing status for the Gateway services that are enabled in your API Connect Catalogs and Spaces.

About this task

Sometimes you might want to check the status of an API event that is being processed by the gateway. For example, you might want to ensure that a Product was published before and is available on the gateway before you invoke one of its APIs. Or perhaps it appears that API events are being processed too slowly and you want to see if all of the events for a particular gateway service are affected. You can review a gateway's processing status to see the which events were sent for processing and which events are still waiting in the queue.

Notes:

- You can only obtain processing status information for the DataPower® API Gateway. This feature is not supported for the DataPower Gateway (v5 compatible) service.
- Processing information is collected for each Catalog. If you view information for a particular Space, the display shows the results for the entire Catalog instead.

Procedure

1. Open the Gateway services page:
   a. Log in to API Manager.
   b. In the navigation pane, click Manage.
   c. Select a Catalog.
   d. Click the Catalog settings tab.
   e. On the Settings page, click Gateway services.
   A list of all of the gateway services for the selected Catalog, including all of its Spaces, displays the gateway type and its endpoint URL. In addition, a status icon displays for each service name to provide a quick indication of that service's current status:
   - Normal: Between 0 and 10 events are waiting to be processed
   - Increased: Between 10 and 20 events are waiting to be processed
   - High: More than 20 events are waiting to be processed

   You can view details about a service's status to gain insight into possible issues.
2. On the Gateway services page, click ⋮ next to a service and select View gateway processing status.
   The Gateway processing status page displays a list of the events that were sent to the gateway. For each event, you can see the following information:
   - Event type: The action performed by the event; for example, subscribing to a product, deleting an application, or creating a new consumer organization.
   - Category: The feature area affected by the event; for example, subscriptions, applications, or consumer organizations.
   - Time: The time when the event was processed by the gateway service.
   - Status: The current event's processing status; for example, Queued (not yet sent for processing), Sent (but not processed yet), or Processed (complete). The number of events in the Queued and Sent states determine the status level for the service.

   The display includes events that were not processed yet, as well as the last event processed. If a particular event is not listed as Sent or Queued, then that event was already processed.

Reference

API gateway response codes

When an API is called, different HTTP status codes are returned by the gateway to indicate whether the request was successfully completed.

The response codes used in IBM® API Connect correspond to the registered HTTP status codes that are typically generated to provide informational (1xx), successful (2xx), redirection (3xx), client error (4xx), or server error (5xx) responses, as described at https://tools.ietf.org/html/rfc7231#section-6 and Hypertext Transfer Protocol (HTTP) Status Code Registry.

In API Connect, successful responses vary depending on the API being called. Other response codes can also be generated, depending on the implementation of the assembly and the response from the external systems. The standard reasons listed for the registered HTTP status codes are considered adequate for most responses that are returned; these response codes and their causes are therefore not listed here.

In certain cases, a client or server error response code can be caused by a condition that is specific to API Connect. The following table contains a list of these error response codes and identifies possible causes for these codes being returned. For some error codes, multiple causes are possible.

Table 1. Error codes and their causes

Error Code	Cause
401 Unauthorized	• The required client identification has not been successfully provided. • User authentication failed or did not take place.

Error Code	Cause
403 Forbidden	• The application is not registered with the plan that is used. • The application is not active. • User authentication failed because multiple client IDs provided.
404 Not Found	• Information for the provider organization or environment was not found. • The API URL was not found in the organization or environment.
405 Method Not Allowed	The API URL was found, but no operation was found that supports the requested HTTP verb.
406 Not Acceptable	The API cannot produce any responses that are supported by the application.
429 Too Many Requests	The rate limit has been exceeded for the plan or operation being used.
500 Internal Server Error	An error occurred while executing this request.
503 Service Unavailable	The status of an API was switched from online to offline, making the API unavailable across all Products in which it is contained. For more information, see Managing your Products in the API Manager UI and Managing API Products using the developer toolkit.

Troubleshooting your billing configuration

Some issues can occur when you are setting up billing integration in IBM® API Connect.

You can use the following links to browse the issues:

1. My customer payment is not completing with Stripe, but the Product is still being accessed.
2. My Product with billing is returning an error when I try to configure it with my Stripe account.
3. My customer previously had a Stripe subscription to a Product but can't access its billing details.

My customer payment is not completing with Stripe, but the Product is still being accessed.

When payment issues occur with the credit card payment provider, the credit card subscription is canceled, but the API Connect subscription is not canceled. You can disable an application until the payment issues are resolved by completing the following steps:

1. Navigate to the Settings page in the dashboard of your Stripe account.
2. In the Billing section navigate to the Subscriptions and emails page.
3. In the Manage failed payments section, change the Subscription status to If all retries for a payment fail, mark the subscription as unpaid.
4. Navigate to the Subscriptions page, and when the subscription has moved into the unpaid state open the subscription in the Stripe dashboard.
5. In the Metadata section, copy the subscription_url value.
6. Use the developer toolkit CLI, and the UUID from the subscription_url, to set the state of the application or subscription to disabled.

My Product with billing is returning an error when I try to configure it with my Stripe account.

The most common cause of this is that your Developer Portal cluster servers or your Management cluster servers cannot communicate with Stripe.
To resolve this, ensure that the Stripe API is enabled with HTTPS communication with your Management cluster servers and the Developer Portal on port 443. See Firewall requirements on Kubernetes and Firewall requirements on VMware for more information about this requirement.

Other causes might be issues with the subscription billing service, network stability, or the API keys might have been rolled and not updated in API Connect and the Developer Portal.

My customer previously had a Stripe subscription to a Product but can't access its billing details.

There is more than one possible cause and resolution for this situation.

- The credit card transaction might not be completing correctly. If this situation happens, the subscription might be canceled with Stripe, but the API Connect subscription is not canceled. For instructions about how to disable a subscription, see My customer payment is not completing with Stripe, but the Product is still being accessed.
- A recent change to a Product with billing might have triggered an action that was not completed correctly. Seemingly minor changes to the Product can start a number of actions that can overload a server. For example, when you replace a version of the Product with a new version, it starts an update to the Stripe server for every account that is subscribed to that Product. If the action fails to complete, the Plan's subscription status might not be reflected correctly with Stripe.
  You can identify this situation by viewing the Billing dashboard in the Resources section of the API Manager. The table displays the state of the job queue for the billing integration resource, and any issues with the job queue are displayed here. For more information about the job queue, and how to retry blocked jobs, see Billing integration resource job queues.

Authoring policies

With the on-premise offering, you can control specific processing features in the Gateway server of IBM® API Connect by creating user-defined policies.

IBM API Connect enables organizations to easily promote business services as APIs to internal and external developer communities. API developers can rapidly create, proxy, assemble, and secure APIs through the API Designer user interface (UI). The API Designer assembly feature allows API developers to create complex REST or SOAP API operations that transform data, perform multiple service calls, aggregate data, and apply policies.

A policy is a piece of configuration that controls a specific aspect of processing in the IBM DataPower® Gateway server during the handling of an API invocation at run time. IBM API Connect provides a number of different types of policies, but you can also create user-defined policies to provide more processing control.

When would you need a user-defined policy?

A user-defined policy enables you to control extra processing features in the Gateway server, such as security, or routing of requests. The user-defined policies feature is available only with the on-premise offering of IBM API Connect.

Create a user-defined policy in IBM API Connect when you need to augment the actions or activities that are performed by the API gateway. For example, you might want to perform the following operations:

- Implement your own proprietary logic for dynamic routing of requests.
- Enforce extra security constraints to your API.
- Make accessible an extra capability that is provided in DataPower that is not yet accessible in the IBM API Connect policy catalog.

Note: For best results, do not try to update your existing user-defined policies, because those are already in use by your APIs. Instead, create a new version of the policy that you want to update, and then modify the API assembly to use the newer version of the policy.
See the following topics for more information about user-defined policies, and how to create and import them into IBM API Connect:

- **Authoring policies for the DataPower Gateway (v5 compatible)**
  A user-defined policy for the DataPower Gateway (v5 compatible) consists of a package that contains a YAML definition file that describes the policy, together with the policy implementation files. You import the package into one or more Catalogs in your IBM API Connect environment to make the policy available to APIs that are published to those Catalogs.
- **Authoring policies for the DataPower API Gateway**
  A user-defined policy for the DataPower API Gateway consists of a package containing configuration details that define the actions of the policy. You publish the package to the DataPower API Gateway to make it available to APIs that are deployed there.

DataPower Gateway (v5 compatible) only

Authoring policies for the DataPower Gateway (v5 compatible)

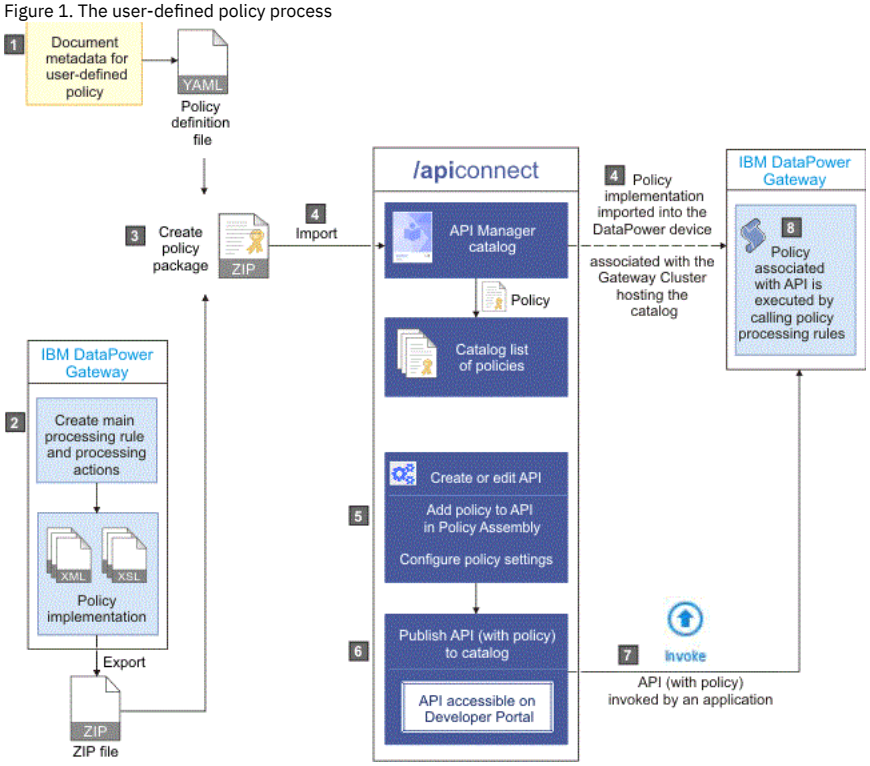
A user-defined policy for the DataPower® Gateway (v5 compatible) consists of a package that contains a YAML definition file that describes the policy, together with the policy implementation files. You import the package into one or more Catalogs in your IBM® API Connect environment to make the policy available to APIs that are published to those Catalogs.

How do user-defined policies work?

A user-defined policy is implemented as a DataPower processing rule. After a policy is imported into an IBM API Connect Catalog, the policy is available to be placed into an assembly flow of an enforced API. When the API is published, and invoked by an application, the API Gateway executes all policies that are associated with this API. An API Gateway that is running in DataPower calls the IBM DataPower Gateway processing rules that those policies implement.

The following diagram provides an overview of how to create and execute a user-defined policy in IBM API Connect.

Figure 1. The user-defined policy process



For details on how to define and deploy user-defined policies for the DataPower Gateway (v5 compatible), see the following subtopics:

- **Describing your policy**
  Describe your user-defined policy by creating a definition file in YAML format to document metadata about the policy.
- **Creating a new user-defined policy**
  Create a user-defined policy by configuring a policy definition file and its implementation, and then packaging the policy and importing it into IBM API Connect.

DataPower Gateway (v5 compatible) only

Describing your policy

Describe your user-defined policy by creating a definition file in YAML format to document metadata about the policy.

About this task

A policy YAML file contains the following sections:

- A specification version.
- An information section.
- An attach section.
- A properties section.
- A gateways section.

You can create a policy YAML file by using any editor of your choice. Both .yaml and .yml file extensions are supported, but the use of the .yaml file extension is recommended by yaml.org.

Note: All keys and enumeration values that are specified in this topic are case-sensitive.

Procedure

The following steps describe how to construct a policy YAML file.

1. Set the specification version by adding the following line to the beginning of the file: `policy: 1.0.0`.
2. Complete the information section with details about the policy by using the following syntax:

```
info:
  title: Title of policy
  name: shortnameofpolicy
  version: 1.0.0
  description: An example policy
  contact:
    name: name1
    url: url1
    email: email1
```

   where:
   - `title` is the title of the policy. Any string can be used, but the title should be kept short so that it can be displayed in the API Manager user interface.
   - `name` is the short name for the policy and must contain only alphanumeric characters, the - (dash) character, and the _ (underscore) character (blank spaces are not supported). The name is case-sensitive, and should be 20 characters or less so that it can be displayed in the API Manager user interface. In the example, the name is shown as `<policy-name>`.
     Important: The policy short name must be different from the OpenAPI names of the built-in policies, otherwise it will cause a policy conflict in the API assembly definition. For a list of the OpenAPI built-in policy names, see execute. Also, consider including an appropriate unique prefix or suffix string in the short names of your user-defined policies to prevent possible name conflicts with future built-in policies.
     Note: The `name:` property must be identical to the Node.js module name.
   - `version` is the version number of the policy. This is a reserved property.
     Tip: The *version.release.modification* version numbering scheme is recommended, for example *1.0.0*.
     Note: The `info.version` in policy.yaml must match the `version` indicated in package.json.
   - `description` (optional) is a short description of the policy.
   - `contact` (optional) is the contact information for the policy, where:
     - `name` (string) is the identifying name of the contact person or organization.
     - `url` (string) is the URL that points to the contact information.
     - `email` (string) is the email address of the contact person or organization.
3. Complete the attach section by specifying which type of API flow the policy can be attached to.

```
attach:
 - rest
 - soap
```

   where:
   - `rest` indicates that this policy can be attached to a REST API flow.
   - `soap` indicates that this policy can be attached to a SOAP API flow.

   The attach section must contain at least one API flow type. If a policy can be attached to both API flow types, they must both be indicated in the attach section.
4. Complete the properties section by defining a JSON schema (based on JSON Schema Specification Draft 4, but rendered in YAML format) that contains the list of properties the policy will declare as required input. These properties are presented to the API author at development time, when the properties can be configured or mapped to values as required.

The JSON schema defines a root object that contains the following JSON properties:

- `type`
- `properties`
- `required`

The syntax and definition of these properties matches the JSON schema definition. The following code block shows an example of a simple schema that defines one required property (*a_property*):

```
properties:
  $schema: "http://json-schema.org/draft-04/schema#"
  type: object
  properties:
    a_property:
    label: a label
    description: a description
    type: a type
  required:
    - a_property
```

The root *type* of the schema must be an `object`, as shown in the example schema. You can define zero or more properties in the schema. Required properties are declared by using the `required` parameter, as shown in the example schema. The policy will not be accessible in the API Manager assembly editor, unless all the required properties have values. Each property is an object with the following items:

- `label` is a short name for the property and is displayed in the Name column of the API Manager assembly editor.
- `description` is a short description for the property and is displayed in the Description column of the API Manager assembly editor.
- `type` must be one of the following primitives that are supported:
  - *integer*
  - *number*
  - *string*
  - *boolean* (this primitive is shown as a check box in the assembly editor)
  - *array*
- `default` (optional) specifies a default value for the property.
- `enum` (for properties with a `type` of *string*) is an array of valid values.

5. In your gateways section, specify that the policy is for the DataPower® Gateway.
   Enter the following code:

```
gateways:
  - datapower-gateway
```

6. Save the new policy as a YAML file using the value of the `name` property (in the `info` section) as the file's name.
   Required: To ensure a successful import, the YAML file must use the name specified in the policy's `name` property.

Results

You have created a user-defined policy definition YAML file that documents metadata about your policy.

Example

The following code block shows an example of a policy definition file that contains all the supported primitives. This policy must be saved as sampleimpl.yaml to ensure that it can be imported into API Connect.

```
policy: 1.0.0

info:
  title: Sample Policy
  name: sampleimpl
  version: 1.0.1
  description: This is a sample policy.
  contact:
    name: Steve Product Manager
    url: http://developer.acme.com/contacturl
    email: steve-product-manager@someemailservice.com

attach:
  - rest
  - soap

properties:
  $schema: "http://json-schema.org/draft-04/schema#"
  type: object
  properties:
    samplestring:
      label: String Property
      description: Sample string property
      type: string
    sampleboolean:
      label: Boolean Property
      description: Sample boolean property
      type: boolean
    sampleinteger:
      label: Integer Property
      description: Sample integer property
      type: integer
    samplenumber:
      label: Number Property
      description: Sample number property
      type: number
    samplestringwithenum:
      label: Enum Property
      description: Sample string enum property
```

```
      enum:
        - one
        - two
        - three
      default: one
      type: string
    samplearray:
      label: Array of properties
      description: Sample array of properties
      type: array
      items:
        type: object
        properties:
          string:
            label: String Property
            description: Sample string property in array
            type: string
          boolean:
            label: Boolean Property
            description: Sample boolean property in array
            type: boolean
        required:
          - string
  required:
    - samplestring
    - sampleboolean
    - sampleinteger
    - samplenumber
    - samplearray

gateways:
  - datapower-gateway
```

In the following code block, an example of a policy definition file for modifying message payload is shown.

```
policy: 1.0.0

DataPower Gateway (v5 compatible) only

Implementing your policy

Create an implementation for your user-defined policy by using DataPower® processing rules and actions.

Before you begin

You must create a policy YAML file before you create an implementation. For more information, see Describing your policy.

You can create an implementation for your policy by using the usual tools available to IBM® DataPower Gateway developers. However, the DataPower user interface is typically the tool that is used to create processing rules and actions.
Note: You must be skilled in DataPower tooling and concepts, before you can create a policy implementation.
In order for your processing actions to work well under the API Gateway configuration, and also to enable the use of contextual information that is relevant to the processing actions, a library of functions and templates is available that you can use to assist you in writing the XSLT or GatewayScript transformations. This library provides the following mechanisms:

- Access to input property values (input from the assembly editor).
- Access to context values (the API Gateway runtime context).
- Access to the runtime payload message and media-type.
- Ability to modify the payload message.
- Ability to end the policy execution with an error.

About this task

You create an implementation for your user-defined policy in the IBM DataPower Gateway. The implementation must adhere to the following conventions:

1. You must create a main processing rule, and this rule will be the starting point for the policy. The rule name must start with the name of the policy (the value of the **`name`** property in the "info" section of the policy YAML file), followed by -main; for example *checkmembership-main*.
2. There are no restrictions on what actions the processing rule can execute, on condition that the rule adheres to the naming convention in point 1. and the instructions that are detailed in this topic.
3. The names of the processing actions and all other objects also must start with the name of the user-defined policy (the value of the **`name`** property in the "info" section of the policy YAML file).
4. If your processing rule runs transformation actions that use XSLT or GatewayScript files, these files must be stored in the following location: local://policy/*<policy-name>*.
5. If you have certificate and key files that must be stored in the cert: folder, the names of these files also must start with the name of the user-defined policy (as defined in the policy YAML file).
6. If your policy is using GatewayScript transformations, your policy code must require **`apim.custom.js`**, for example:

   ```
   var apic = require('local://isp/policy/apim.custom.js');
   ```

The following steps describe how to create an implementation for your user-defined policy:

- Create a main processing rule.
- Create one or more processing actions:
  - Configure access to input properties.
  - Configure access to the runtime context.
  - Configure access to the input payload.
  - Configure access to the HTTP headers.
  - Modify the payload in XSLT or gatewayscript.
  - Configure the implementation to produce error information.
  - Set variables.
- Export your policy implementation.

.

Procedure

1. Create a main processing rule that is called *<policy-name>*-main where *<policy-name>* is the name of your user-defined policy (the value of the **`name`** property in the "info" section of the policy YAML file).
   Note: You must specify the following processing rule settings:
   - Rule direction: Both Directions
   - Non-XML Processing: on
2. Create one or more processing actions.
   Each processing action should have a unique name and must start with the name of the user-defined policy (as defined in the policy YAML file).

Note: Different processing actions in DataPower might require different releases of the DataPower firmware. When using the GatewayScript actions, the minimum DataPower firmware that should be used is version 7.2.0.
The following processing actions are available:

- Configure access to the input properties in XSLT (`policyProperties`), or in GatewayScript (`apic.getPolicyProperty`).
  If required by the properties that are defined in the policy YAML file, when the policy is attached to an API the API developer must enter the input settings or variables for a particular property. This function provides the mechanism to retrieve these input settings or variables at run time. For an example code snippet, see Access to input properties code snippet.

- Configure access to the runtime context in XSLT (`getContext`), or in GatewayScript (`apic.getContext`).
  When an API is invoked, runtime information about the request can be accessed by using a user-defined policy, and this information is known as the runtime context. The function `getContext` provides the mechanism to access this runtime context. For an example code snippet, see Access to runtime context code snippet. For a complete list of context variables, see API Gateway context variables.

- Configure access to the input payload in XSLT (`payloadRead`), or in GatewayScript (`apic.readInput(callback)`).
  Some policies require access to the input message or payload that is provided by the application. Accessing the input message or payload during an assembly flow can be difficult, as this information might change as the policies and the assembly steps run. This function provides a mechanism to get the correct input message or payload at the time of policy execution. For an example code snippet, see Access to input payload code snippet.

  This function returns an XML node-set that contains the payload of the request. If the payload is in JSON format, a JSONx node-set is returned that can then be manipulated within an XSLT or GatewayScript stylesheet. If the payload is not in JSON or XML format, the node-set that is returned is empty.

  Note: The `payloadType()` function can be called to determine what type of payload (XML or JSONx) will be returned by the `payloadRead()` or the `apic.readInput(callback)` function.
- Configure access to the HTTP headers in XSLT (`getContext`), or in GatewayScript (`apic.getContext`).
  The HTTP header information of a request can be retrieved from the request context. The HTTP header names are normalized to lowercase. The function `getContext()` provides the mechanism to access the HTTP header information. For an example code snippet, see Access to HTTP headers code snippet.

  Note: Access or modification of HTTP headers by using DataPower extensions, such as `dp:set-request-header`, is not advisable, as such actions might yield unexpected results when the policy is combined with other policies and assembly steps.
- Modify the payload in XSLT or GatewayScript.
  When a policy implementation is required to change a payload message, you must configure the DataPower Transform Processing Action to set the Output context field to *OUTPUT* (referred to as the *OUTPUT* named context).

  The output must be an XML node-set, which represents an XML or SOAP message, or a JSON message by using JSONx. To assist the API Gateway policy framework to accept the new or transformed message, call the `apim-output` template. For an example code snippet, see Modify the payload code snippet.

  Note: The modify the payload processing action works only with a proxy task. An HTTP or web service task always overwrites the output of a policy implementation.
- Configure the implementation to produce error information.
  If you require your policy implementation to produce error information when there is a failure, you must configure the implementation by calling the error template. For an example code snippet, see Configure error information code snippet.

- Set variables.
  Use the `setVariable` template to set a runtime variable to a specified string value. This value can then be retrieved by using the function `getVariable()`, or by mapping the value into a step. For an example code snippet, see Set variables code snippet.

3. Export your policy implementation from DataPower.
   From the DataPower user interface, export the objects and files that are referenced by your main processing rule as a compressed file. No other objects or files should be exported. The following file list is an example configuration of an export from DataPower:

```
Archive: checkmembership.zip

11819    11-19-2014 22:53 dp-aux/basetypes.xml
3028207  11-19-2014 22:53 dp-aux/drMgmt.xml
6456     11-19-2014 22:53 dp-aux/map-dmz.xsl
7299     11-19-2014 22:53 dp-aux/management.xsl
23130    11-19-2014 22:53 dp-aux/SchemaUtil.xsl
216003   11-19-2014 22:53 dp-aux/clixform.xsl
5284     11-19-2014 22:53 local/policy/checkmembership/check.xsl
5061     11-19-2014 22:53 export.xml
```

   The example shows the exported configuration file (export.xml) that contains all the processing actions and DataPower objects, the referenced files, and the DataPower configuration schemas that are created by using the configuration export in the DataPower user interface.

Results

You have created an implementation for your user-defined policy and exported this implementation from the DataPower user interface.

What to do next

Create a user-defined policy package that can then be imported into IBM API Connect. For details, see Packaging and importing your policies into IBM API Connect.

Related concepts

- Authoring policies

Related information

- IBM DataPower Gateway

DataPower Gateway (v5 compatible) only

Packaging and importing your policies into IBM API Connect

Make your user-defined policy available to API developers by packaging it and importing it into an IBM® API Connect Catalog.

Before you begin

Before you can package a user-defined policy and import it into IBM API Connect, you must complete the following tasks:

1. Describe your policy in a YAML file.
2. Implement your policy by using DataPower processing rules and actions.

Procedure

To package and import your user-defined policy, complete the following steps:

1. Create a .zip file that contains the following folder structure:

   ```
   <policy-name>.yaml
   implementation/
                policy-name.zip
   ```

   where
   - *<policy-name>*.yaml is your policy definition file. The YAML file must use the name that is specified in its `name` property.
   - implementation/*policy-name*.zip is your policy implementation for a policy that is deployed to the DataPower Gateway. The policy implementation file contains the DataPower processing rules and actions that were exported from DataPower in step 2.

   The name of the .zip file must start with the name of the user-defined policy (as defined in the policy YAML file). If the implementation requires certificate and key files, these files must be added to the implementation directory.

   Note: Your package .zip file must contain a .zip policy implementation file.
2. Use the API Manager user interface to import your policy into a Catalog. For more information, see Importing a user-defined policy into a Catalog.
   Note:
   - You must import your user-defined policy into every Catalog in API Manager that you require your policy to run in.
   - For the policy to be displayed on the palette in the API assembly editor, you must import the user-defined policy into the Sandbox Catalog.

What to do next

Make your user-defined policy package accessible to the API Designer UI. To display user-defined policies in the API Designer UI, edit the .apiconnect/config file to point to the directory containing the policy.yaml file. You can edit the global config file (~/.apiconnect/config) or a project-specific config file (~/ProjectA/.apiconnect/config). Follow these steps:

1. Create one or more directories to hold your policy.yaml files that are accessible to Node.js, and copy the user-defined policy package into this directory. For example, create directories named /ProjectA/Policies and /ProjectB/Policies.
2. Extract the policy package so that the folder structure is visible, for example *policy*.yaml and implementation/*policy-name*.zip. The file containing the custom policies must be named policy.yaml.
3. Add the `userPolicies: [ ]` array object to the config file in ~/*ProjectA*/.apiconnect/ or ~/.apiconnect/, and edit the array object so it contains the absolute path to the director(ies) containing the policy.yaml file.
   Following is an example of an ~/.apiconnect/config file showing the userPolicies entry pointing to the directory containing the policy.yaml file:

   ```
   apim_server: us.apiconnect.ibmcloud.com
   us.apiconnect.ibmcloud.com.meta:
    formFactor: BLUEMIX_PUBLIC
    serverCapabilities:
       authTypes:
         - basic
         - token
    toolkit:
       version_recommended: 2.1.30
       version_minimum: 2.1.30
   catalog: >-
     apic-catalog://us.apiconnect.ibmcloud.com/orgs/sampleorg-myspace2/catalogs/sb
   app: >-
     apic-app://us.apiconnect.ibmcloud.com/orgs/sampleorg-myspace2/apps/acme-bank
   userPolicies:
     - /ProjectA/Policies
   ```

   Note:
   - The `userPolicies: []` array object contains a list of absolute paths to the policy director(ies). The values can point to a parent location, for example `userPolicies: ["~/mypolicies"]`. Alternatively, each policy location can be specified in the array, for example `userPolicies: ["~/mypolicies/policya", ~/mypolicies/policyb"]`. However, do not use both of these approaches in the same directory. For example, do not create policies in a directory structure like this ~/mypolicies, ~/mypolicies/policya, and ~/mypolicies/policyb.
4. Open the API Designer UI. The user-defined policy is available on the policy assembly palette, and you can add the policy to your API definition.

Note: If you are using GatewayScript, you must include the following command:

```
var apic = require(./apim.custom.js);
```

where *apic* is the common name used for the GatewayScript examples in this topic. However, *apic* could be any given name of your choice, for example you could use:

```
var apim = require(./apim.custom.js);
```

and then you would start your calls with `apim`.

Access to input properties code snippet

The following code block shows an example of how to access the input properties by using the XSLT `policyProperties()` function. The example defines a property that is named `a_property`, which is declared as an integer value, but is retrieved in XSLT as text.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/>

  <xsl:template match="/">
    <xsl:variable name="p" select="apim:policyProperties()" />
    <xsl:message>
      The value of my input property is
      <xsl:value-of select="$p/a_property" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, you must call the function:

```
apic.getPolicyProperty(propertyName)
```

where ***propertyName*** is the name of the input property that you want to access. If the input property name is blank, the action will return all input properties.

Access to runtime context code snippet

The following code block shows an example of how to access the runtime context by using the XSLT `getContext()` function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/>

  <xsl:template match="/">
    <xsl:variable name="client-id" select="apim:getContext('client.app.id')" />
    <xsl:message>
      The calling application is
      <xsl:value-of select="$client-id" />
    </xsl:message>
  </xsl:template>
```

```
</xsl:stylesheet>
```

If you are using GatewayScript, you must call the function:

```
apic.getContext(varName)
```

where ***varName*** is the name of the context variable that you want to access.
For a complete list of context variables, see API Gateway context variables.

Access to input payload code snippet

The following code block shows an example of how to access the input payload by using the XSLT **payloadRead()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/>

  <xsl:template match="/">
    <xsl:variable name="input" select="apim:payloadRead()" />
    <xsl:message>
      The input payload is
      <xsl:copy-of select="$input" />
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

If you are using GatewayScript, you must call the function:

```
apic.readInput(callback)
```

A callback is required because the actual payload read is asynchronous. The callback method is called when the payload is ready.
This function returns an XML node-set that contains the payload of the request. If the payload is in JSON format, a JSONx node-set is returned that can then be manipulated within an XSLT or GatewayScript stylesheet. If the payload is not in JSON or XML format, the node-set that is returned is empty.
The following example shows how to use the **payloadType()** function to determine what type of payload (XML or JSONx) will be returned by the XSLT **payloadRead()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/>

  <xsl:template match="/">
    <xsl:variable name="payloadType" select="apim:payloadType()" />
    <xsl:message>
      <xsl:text>Payload type is [</xsl:text>
      <xsl:value-of select="$payloadType" />
      <xsl:text>]</xsl:text>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

Access to HTTP headers code snippet

The following code block shows an example of how to access the HTTP headers in XSLT by using the **getContext()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/>

  <xsl:template match="/">
    <xsl:variable name="content-type" select="apim:getContext('request.headers.content-type')" />
    <xsl:message>
      The request content type is
      <xsl:value-of select="$content-type" />
    </xsl:message>
  </xsl:template>
```

```
</xsl:stylesheet>
```

If you are using GatewayScript, you must call the function:

```
apic.getContext(request.headers.headerName)
```

where ***headerName*** maps to the name of the header you want to access.
Note: Access or modification of HTTP headers by using DataPower® extensions, such as **dp:set-request-header**, is not advisable, as such actions might yield unexpected results when the policy is combined with other policies and assembly steps.

Modify the payload code snippet

The output from a user-defined policy must be an XML node-set, which represents an XML or SOAP message, or a JSON message by using JSONx. The following code block shows an example of how to modify the payload in XSLT. To assist the API Gateway policy framework to accept the new or transformed message, call the **apim-output** template, as shown in the following example.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:apim="http://www.ibm.com/apimanagement"
  xmlns:jsonx="http://www.ibm.com/xmlns/prod/2009/jsonx">

  <!-- Contains the APIM functions -->
  <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/>

  <xsl:template match="/">
    <!-- Creates a JSON document (empty object is for simplicity) -->
    <jsonx:object>
    </jsonx:object>

    <!-- Indicates the media type of the output being produced -->

    <xsl:call-template name="apim:output">
      <xsl:with-param name="mediaType" select="'application/json'" />
    </xsl:call-template>
  </xsl:template>

</xsl:stylesheet>
```

where **mediaType**:

- **'application/json'** is when the output is written in JSONx format.
- **'application/xml'** is when the output is written in XML format.

If you are using GatewayScript, you must call the function:

```
apic.output(mediaType)
```

where ***mediaType*** is:

- **application/json** is when the output is written in JSONx format.
- **application/xml** is when the output is written in XML format.

Specifying the media type allows the next steps in the assembly flow to understand how to process the new payload.

Tip: The output from a user-defined policy must be XML or JSONx. JSONx is an IBM standard format to represent JSON as XML. One way to convert output GatewayScript JSON data into JSONx, is to add a **Convert Query Params to XML** action to follow the GatewayScript action within the same policy rule. The **Convert Query Params to XML** action must have an **Input Conversion** with the **Default Encoding** set to **JSON**. The output from the GatewayScript action must be the input for the **Convert Query Params to XML** action for JSONx to be produced.

Configure error information code snippet

The following XSLT code block shows an example of how to configure the policy implementation to produce error information by calling the **apim-error** template.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:apim="http://www.ibm.com/apimanagement">

  <!-- Contains the APIM functions -->
  <xsl:include
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/>

  <!-- Indicates this policy has a failure and provides
       additional information for the client application -->
  <xsl:template match="/">
    <xsl:call-template name="apim:error">
      <xsl:with-param name="httpCode" select="'401'" />
      <xsl:with-param name="httpReasonPhrase" select="'Unauthorized'" />
      <xsl:with-param name="errorMessage" select="'Please select a Plan'" />
    </xsl:call-template>
  </xsl:template>

</xsl:stylesheet>
```

where:

- **httpCode** is the code of the required error message.
- **httpReasonPhrase** is the reason for the error.
- **errorMessage** is the suggested action for the user.

If you are using GatewayScript, you must call the template:

```
apic.error(name, httpCode, httpReasonPhrase, message)
```

where:

- **name** is the name of the error.
- **httpCode** is the code of the required error message.
- **httpReasonPhrase** is the reason for the error.
- **message** is the suggested action for the user.

Set variables code snippet

The following XSLT code block shows an example of how to set a runtime variable to a specified string value by calling the **setVariable** template.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/>

  <xsl:template match="/">
    <xsl:call-template name="apim:setVariable">
      <xsl:with-param name="varName" select="'serviceEndpoint'" />
      <xsl:with-param name="value" select="'https://endpoint.host.com/data'" />
    </xsl:call-template>
    <xsl:message>
      <xsl:text>Variable [</xsl:text>
      <xsl:value-of select="'serviceEndpoint'" />
      <xsl:text>] set to [</xsl:text>
      <xsl:value-of select="'https://endpoint.host.com/data'" />
      <xsl:text>]</xsl:text>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

where:

- **varName** is the name of the runtime variable that you want to set a value to.
- **value** is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the **value** as **$(request.headers.content-type)**.

If you are using GatewayScript, you must call the template:

```
apic.setvariable(varName, varValue, action)
```

where:

- **varName** is the name of the runtime variable that you want to set a value to, or that you want to add or clear.
- **varValue** is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the **varValue** as **request.headers.content-type**. This property is only required when **set** or **add** is specified as the action.
- **action** is the action that you want to apply to the variable. Valid options are:
  - **set**
  - **add**
  - **clear**

  If no option is set, the default option of **set** is applied.

The following XSLT example shows how to retrieve the value of a runtime variable by using the **getVariable()** function.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:dp="http://www.datapower.com/extensions"
  xmlns:func="http://exslt.org/functions"
  xmlns:apim="http://www.ibm.com/apimanagement" extension-element-prefixes="dp func apim">

  <!-- Contains the APIM functions -->
  <xsl:import
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.policy.doc_local:_isp_policy_apim.custom.xsl"
/>

  <xsl:template match="/">
    <xsl:variable name="varValue" select="apim:getVariable('serviceEndpoint')" />
    <xsl:message>
      <xsl:text>Variable [</xsl:text>
      <xsl:value-of select="'serviceEndpoint'" />
```

```
      <xsl:text>] = [</xsl:text>
      <xsl:value-of select="$varValue" />
      <xsl:text>]</xsl:text>
    </xsl:message>
  </xsl:template>

</xsl:stylesheet>
```

where

- **varValue** is the name of the runtime variable that you want to retrieve a value for.

If you are using GatewayScript, you must call the function:

```
apic.getvariable(varName)
```

where ***varName*** is the name of the runtime variable that you want to retrieve a value for.

API Gateway only

Authoring policies for the DataPower API Gateway

A user-defined policy for the DataPower® API Gateway consists of a package containing configuration details that define the actions of the policy. You publish the package to the DataPower API Gateway to make it available to APIs that are deployed there.

There are two types of user-defined policies, *Catalog scoped* user-defined policies and *global scoped* user-defined policies:

Catalog-scoped user-defined policies
: Catalog-scoped user-defined policies are available to APIs only in the Catalogs that you specify. Use a Catalog scoped user-defined policy if you want to limit the availability of your policy on a Catalog specific basis. The possible actions of a Catalog scoped user-defined policy are limited to the API Connect built-in assembly policies. For more information, see Defining, packaging, and publishing a catalog-scoped policy for the API Gateway.

Global-scoped user-defined policies
: Global-scoped user-defined policies are available to APIs in every Catalog in every provider organization. Use a global scoped user-defined policy in the following situations:

  - You want to make your policy available everywhere rather than limiting its availability to specific Catalogs.
  - Your policy uses a DataPower implementation, where configuration changes are made directly on the DataPower API Gateway.

  For more information, see Defining, packaging, and publishing a global-scoped policy for the API Gateway.

- **Defining, packaging, and publishing a catalog-scoped policy for the API Gateway**
  Create a catalog-scoped, user-defined policy that can be used in API assemblies within the catalog where the policy is published.
- **Defining, packaging, and publishing a global-scoped policy for the API Gateway**
  Create a global-scoped, user-defined policy that is available to APIs in any of the catalogs in any provider organization.

Defining, packaging, and publishing a catalog-scoped policy for the API Gateway

Create a catalog-scoped, user-defined policy that can be used in API assemblies within the catalog where the policy is published.

About this task

When a catalog-scoped policy is published, you can only use it in the API Assembler's Policy palette for APIs contained within the same catalog where the policy was published. Complete the following tasks to define, package, and publish the catalog-scoped policy.

Tip: During this task, you will create several zip files. On Mac OS X, run the **zip** command on the command line with the following flags:

```
-x ".DS_Store" -x "__MACOSX"
```

Including the flags prevents the auto-generated .DS_Store and __MACOSX files from being added to the zip.

- **Structure of the catalog-scoped user-defined policy YAML file**
  Review the required structure of the YAML file that contains your catalog-scoped user-defined policy.

Step 1: Define a catalog-scoped policy for API Gateway

Use the DataPower Web GUI to define a new policy that can be used in API assemblies within the catalog where the policy is published.

Procedure

1. Log in to the DataPower Web GUI.
2. Create a new "test" domain and then switch to it.
   This test domain will be used as a "sandbox" to build and export the custom policies.

3. Navigate to Assembly Function and create a new object:
   a. Name the object ***<org-name>_<catalogname>_udp-<policyname>_<version>***.
      Example: "testorg_stagecatalog_udp-testpolicy_1.0.0". Use the same name for all of the objects that you create in this task.
      Note: This naming convention specifies the provider organization and catalog where the policy will be available, as well as the policy's name and version.
   b. Under the "Assembly" property, create a new Assembly.
   c. Under the new Assembly, create a new Rule.
   d. Under the new Rule, create a new API Action.
   e. Optionally add an implementation file for the new Action.
      For example, an XSLT Action requires an XSL file. Create the file in the using the following path and name (where "udp" refers to user-defined policy:

      local:///*<udp-name>*/*<udp-name>*.*<file-extension>*

   f. Click Apply and then save all of the new objects.
4. Export the new user-defined policy.
   a. Navigate to the newly created Assembly Function.
   b. Click Export to export the new user-defined policy to a file named *<policyname>*_*<version>*.zip.
   c. Open the exported *<policyname>*_*<version>*.zip file and confirm that all referenced files are included.
   d. Delete the dp-aux folder from the zip.
      This optional folder requires a lot of storage space and might cause a problem when you package and publish the new policy in the next task.

Step 2: Package and publish a catalog-scoped policy for API Gateway

Decide how you want the new catalog-scoped policy to be managed, and then publish it to make it available to API assemblies within a particular catalog.

About this task

Be sure to complete Step 1: Define a catalog-scoped policy for API Gateway before attempting to package and publish the new policy.

There are two methods for packaging and publishing a user-defined policy, based on how you want the policy to be managed:

- Step 2, Option A: Package and publish a catalog-scoped policy directly in the DataPower configuration
- Step 2, Option B: Package and publish a catalog-scoped policy as a gateway extension that API Connect manages

Step 2, Option A: Package and publish a catalog-scoped policy directly in the DataPower configuration

Package and publish a catalog-scoped policy so it can be stored directly on the DataPower API Gateway.

About this task

When you store a catalog-scoped policy on the DataPower API Gateway, the policy exists in the gateway's startup domain configuration and will be unaffected by the API Manager lifecycle. If you want to store the catalog-scoped policy directly on DataPower, you do not need to package it for API Manager. Instead, complete the following steps.

Procedure

1. Import the custom policy created in Step 1: Define a catalog-scoped policy for API Gateway to the application domain for every DataPower node in the cluster.
2. Proceed to Step 3: Create and publish a policy.yaml file, where you will create a file that describes the new policy so that API Manager can support it.

Step 2, Option B: Package and publish a catalog-scoped policy as a gateway extension that API Connect manages

Package and publish a catalog-scoped policy as a gateway extension in API Connect.

Before you begin

The xml-manager must be enabled on the default domain of every gateway that will have a gateway-extension published to it.

About this task

When you publish a catalog-scoped policy as a gateway extension in API Connect, it is subject to the API Manager lifecycle. The individual assembly functions will not be added to the API Connect Gateway Service (only global-scoped policies are added to the service).

Procedure

1. Rename the *<policyname>*_*<version>*.zip file (that you created in Step 1: Define a catalog-scoped policy for API Gateway) to *<org-name>*_*<cat-name>*_*<policyname>*_*<version>*.zip.
   The new file name indicates the provider organization and the catalog where the policy will be used.

2. Create a gateway-extension manifest.json file as explained in Gateway extensions manifest.
   The manifest contains one or more entries. The following example contains a sample entry for the new catalog-scoped policy and references the new policy filename.

```
{
    "filename": "<org-name>_<cat-name>_<policyname>_<version>.zip",
    "deploy": "immediate",
```

```
            "type": "dp-import",
        },
```

3. Create a new zip file called gateway-extension.zip that contains the following files:
   - manifest.json
   - *<org-name>_<cat-name>_<policyname>_<version>*.zip
4. Publish the new gateway extension using the API Conref Toolkit or the Cloud Manager UI:
   - API Connect Toolkit:
     Use the **apic gateway-extensions:create** command to publish the gateway extension as explained in the **apic gateway-extensions** topic.
   - Cloud Manager UI:
     Complete the following steps to publish the gateway extension from Cloud Manager:
     - Log in to Cloud Manager.
     - Click Topology > ⋮ > Configure gateway extensions > Upload gateway-extension.zip file and upload your new gateway-extension.zip file.
5. Verify that the new catalog-scoped policy is available in the API Assembler's Policy palette.
   a. Log in to API Manager and open the Catalog where you published the new catalog-scoped policy.
   b. Create an API.
   c. Open the API Assembler page and view the Policy palette; verify that your new catalog-scoped policy displays and can be added to the API.

Step 3: Create and publish a policy.yaml file

Create a file that describes the properties of the catalog-scoped policy, and then publish it to make it accessible to API Manager.

Procedure

1. Create a YAML file that describes the new catalog-scoped policy.
   a. Create a file named *<policyname>*.yaml.
   b. Paste the following content into the new file:

```
attach:
- rest
- soap
policy: 1.0.0
info:
  title: <policyname>
  name: <policyname>
  version: 1.0.0
  description: <description-here>
properties:
  $schema: 'http://json-schema.org/draft-04/schema#'
  type: object
  properties:
    exampleProperty:
      label: Test Property
      description: Enter any value
      type: string
    exampleProperty2:
      label: Another Test Property
      description: Enter any value
      type: string
  required:
    - exampleProperty2
gateways:
- datapower-api-gateway
```

   c. Modify the content as needed to correctly describe your new catalog-scoped policy.
   For more information, see Structure of the catalog-scoped user-defined policy YAML file.
   d. Save and close the file.
2. Create a new zip file called *<policyname>*.zip that contains the new YAML file.
3. Publish the new policy using either the API Connect Toolkit or the API Manager:
   - API Connect Toolkit:
     Use the **apic policies:create** command to publish the gateway extension as explained in the **apic policies:create** topic.
   - API Manager:
     Complete the following steps to publish the new policy:
     - Log in to API Manager.
     - Click Manage Catalogs > Select Catalog > Gateways > *selected_gateway* > ⋮ > View policies and upload your new policy.zip file.
4. Verify that the new catalog-scoped policy is available in the API Assembler's Policy palette.
   a. In API Manager, select the Catalog where you published the new catalog-scoped policy.
   b. Create an API.
   c. Click ⚙ (next to Save) and for the Target Catalog, select the catalog where you published the new policy.
   d. Save the API.
   e. Open the API Assembler page and view the Policy palette; verify that your new catalog-scoped policy displays and can be added to the API.

Structure of the catalog-scoped user-defined policy YAML file

Review the required structure of the YAML file that contains your catalog-scoped user-defined policy.

The .yaml file for a catalog-scoped user-defined policy contains the following sections:

- Specification version
- Information
- Attach
- Gateways
- Properties
- Assembly section

Specification version

Set the specification version by adding the following line to the beginning of the file:

```
policy: 1.0.0
```

Information

Complete the information section with details about the policy by using the following syntax:

```
info:
  title: Title of policy
  name: shortnameofpolicy
  version: 1.0.0
  description: An example policy
  contact:
    name: name1
    url: url1
    email: email1
```

where:

- **title** is the title of the policy. Any string can be used, but the title should be kept short so that it can be displayed in the API Manager user interface.
- **name** is the short name for the policy. Must be a single word, and contain only alphanumeric characters, and the - (dash) and _ (underscore) characters. The name is case-sensitive, and should be 20 characters or less so that it can be displayed in the API Manager user interface.
  Important: The policy short name must be different from the OpenAPI names of the built-in policies, otherwise it will cause a policy conflict in the API assembly definition. For a list of the OpenAPI built-in policy names, see execute. Also, consider including an appropriate unique prefix or suffix string in the short names of your user-defined policy to prevent possible name conflicts with future built-in policies.
  Note: The **name:** property must be identical to the Node.js module name.
- **version** is the version number of the policy. This is a reserved property.
  Tip: The *version.release.modification* version numbering scheme is recommended, for example *1.0.0*.
  Note: The **info.version** in policy.yaml must match the **version** indicated in package.json.
- **description** (optional) is a short description of the policy.
- **contact** (optional) is the contact information for the policy, where:
  - **name** (string) is the identifying name of the contact person or organization.
  - **url** (string) is the URL that points to the contact information.
  - **email** (string) is the email address of the contact person or organization.

For example:

```
info:
  title: Custom Invoke Policy
  name: custom-invoke
  version: 1.0.0
  description: Invokes httpbin
  contact:
    name: IBM DataPower Samples
    url: 'https://github.com/ibm-datapower/'
    email: steve-product-manager@ibm.com
```

Attach

Complete the attach section by specifying which types of API flow the policy can be attached to.

- **rest** indicates that this policy can be attached to a REST API flow.
- **soap** indicates that this policy can be attached to a SOAP API flow.

The attach section must contain at least one API flow type. If a policy can be attached to both API flow types, they must both be indicated in the attach section.

For example:

```
attach:
  - rest
  - soap
```

Gateways

Specify the DataPower® API Gateway, as follows:

```
gateways:
  - datapower-api-gateway
```

Properties

Complete the properties section by defining a JSON schema (based on JSON Schema Specification Draft 4, but rendered in YAML format) that contains the list of properties the policy will declare as required input. These properties are presented to the API author at development time, when the properties can be configured or mapped to values as required. The JSON schema defines a root object that contains the following JSON properties:

- `type`
- `properties`
- `required`

The syntax and definition of these properties matches the JSON schema definition. The following code block shows an example of a simple schema that defines one required property (*a_property*):

```
properties:
  $schema: "http://json-schema.org/draft-04/schema#"
  type: object
  properties:
    a_property:
    label: a label
    description: a description
    type: a type
  required:
    - a_property
```

The root *type* of the schema must be an `object`, as shown in the example schema. You can define zero or more properties in the schema. Required properties are declared by using the `required` parameter, as shown in the example schema. The policy will not be accessible in the API Manager assembly editor, unless all the required properties have values. Each property is an object with the following items:

- `label` is a short name for the property and is displayed in the Name column of the API Manager assembly editor.
- `description` is a short description for the property and is displayed in the Description column of the API Manager assembly editor.
- `type` must be one of the following primitives that are supported:
  - *integer*
  - *number*
  - *string*
  - *boolean* (this primitive is shown as a check box in the assembly editor)
  - *array*
- `default` (optional) specifies a default value for the property.
- `enum` (for properties with a `type` of *string*) is an array of valid values.

For example:

```
properties:
  $schema: 'http://json-schema.org/draft-04/schema#'
  type: object
  properties:
    test:
      label: Test Property
      description: Enter any value
      type: string
  required:
    - test
```

Assembly section

The assembly section defines the assembly policy flow that will be activated when the user-defined policy is invoked. For example:

```
assembly:
  execute:
    - invoke:
        version: 2.0.0
        title: custom-invoke
        header-control:
          type: blacklist
          values: []
        parameter-control:
          type: whitelist
          values: []
        timeout: 60
        verb: keep
        cache-response: protocol
        cache-ttl: 900
        stop-on-error: []
        target-url: 'http://httpbin.org/headers'
```

You can determine the correct content of this section in either of the following ways:

- Define the assembly flow by using the graphical assembly editor in either the API Designer or API Designer user interface, then copy the `assembly:` section from the Source tab. For more information on defining an assembly flow in the user interface, see The Assemble view and API policies and logic constructs.
- Code the policies in the `execute:` subsection of the `assembly:` section by hand; for details, see execute.

The assembly section can contain only the API Connect built-in policies. However, you can include a gatewayscript policy that references native DataPower configuration.

Defining, packaging, and publishing a global-scoped policy for the API Gateway

Create a global-scoped, user-defined policy that is available to APIs in any of the catalogs in any provider organization.

About this task

When a global-scoped policy is published, you can use it in the API Assembler's Policy palette for APIs in any catalog belonging to any provider organization. Complete the following tasks to define, package, and publish the global-scoped policy.

Tip: During this task, you will create several zip files. On Mac OS X, run the **zip** command on the command line with the following flags:

```
-x ".DS_Store" -x "__MACOSX"
```

Including the flags prevents the auto-generated .DS_Store and __MACOSX files from being added to the zip.

Step 1: Define a global-scoped policy for API Gateway

Use the DataPower Web GUI to define a new policy that can be used in API assemblies in all catalogs belonging to all provider organizations.

Procedure

1. Log in to the DataPower Web GUI.
2. Create a new "test" domain and then switch to it.
   This test domain will be used as a "sandbox" to build and export the custom policies.
3. Navigate to Assembly Function and create a new object:
   a. Name the object ***<policyname>_<version>***.
      Example: "testpolicy_1.0.0". Use the same name for all of the objects that you create in this task. Because the policy will be available in all provider organizations and catalogs, there is no need to specify that information in the object name.
   b. Under the "Assembly" property, create a new Assembly.
   c. Under the new Assembly, create a new Rule.
   d. Under the new Rule, create a new API Action.
   e. Optionally add an implementation file for the new Action.
      For example, an XSLT Action requires an XSL file. Create the file in the using the following path and name (where "udp" refers to user-defined policy:

      local:///*<udp-name>*/*<udp-name>*.*<file-extension>*

   f. Click Apply and then save all of the new objects.
4. Export the new user-defined policy.
   a. Navigate to the newly created Assembly Function.
   b. Click Export to export the new user-defined policy to a file named *<policyname>*_*<version>*.zip.
   c. Open the exported *<policyname>*_*<version>*.zip file and confirm that all referenced files are included.
   d. Delete the dp-aux folder from the zip.
      This optional folder requires a lot of storage space and might cause a problem when you package and publish the new policy in the next task.

Step 2: Package and publish a global-scoped policy for API Gateway

Decide how you want the new global-scoped policy to be managed, and then publish it to make it available to API assemblies.

About this task

Be sure to complete the steps in Step 1: Define a global-scoped policy for API Gateway before attempting to package and publish the new global-scoped policy. There are two methods for packaging and publishing a user-defined policy, based on how you want the policy to be managed:

- Step 2, Option A: Package and publish a global-scoped policy directly in the DataPower configuration
- Step 2, Option B: Package and publish a global-scoped policy as a gateway extension that API Connect manages

Step 2, Option A: Package and publish a global-scoped policy directly in the DataPower configuration

Package and publish a global-scoped policy so it can be stored directly on the DataPower API Gateway.

About this task

When you store a global-scoped policy on the DataPower API Gateway, the policy exists in the gateway's startup domain configuration and will be unaffected by the API Manager lifecycle.

Procedure

1. Import the *<policyname>*_*<version>*.zip file containing the new global-scoped policy to the application domain for every DataPower node in the cluster.
   Complete the following steps on every DataPower node in the cluster--if you omit a node, then the policy will not be available in the API Assembly's Policy palette.
   a. On the DataPower node, navigate to the API Connect Gateway Service object.
   b. Under the "User-defined policies" property, add a new Assembly Function by importing the *<policyname>*_*<version>*.zip file containing your new global-scoped policy.
   c. Click Apply, and then Save.
2. Verify that the new global-scoped policy is available in the API Assembler's Policy palette.
   a. Log in to API Manager.
   b. Create an API.
   c. Open the API Assembler page and view the Policy palette; verify that your new global-scoped policy displays and can be added to the API.

Step 2, Option B: Package and publish a global-scoped policy as a gateway extension that API Connect manages

Package and publish a global-scoped policy as a gateway extension in API Connect.

Before you begin

The xml-manager must be enabled on the default domain of every gateway that will have a gateway-extension published to it.

About this task

When you publish a global-scoped policy as a gateway extension in API Connect, it is subject to the API Manager lifecycle.

Procedure

1. Make a copy of the *<policyname>_<version>*.zip file containing your new global-scoped policy and remove the ***<version>*** number from the file name.
   This name change ensures that the relative path of the file meets the requirement to match the following regular expression: **`implementation\/[\w_-]+\.zip`**.
   You can retain the copy of the file with its original name for tracking purposes.

2. Create a local folder named implementation and store the renamed zip file in that folder.
3. Create a YAML file that describes the new global-scoped policy.
   a. Create a file named *<policyname>*.yaml.
   b. Paste the following content into the new file:

   ```
   policy: 1.0.0
   info:
     title: <policyname>
     name: <policyname>
     version: 1.0.0
     description: <description-here>
   ```

   Only the **`policy`** and **`info`** sections are needed in the *<policyname>*.yaml for this task.

   c. Save and close the file.
4. Create a new zip file called *<policyname>_<version>*.zip that contains the following files:
   - The implementation folder
   - *<policyname>*.yaml
5. Create a gateway-extension manifest.json file as explained in Gateway extensions manifest.
   The manifest contains one or more entries. The following example contains a sample entry for the new global-scoped policy and references the original policy *<policyname>_<version>*.zip file that you created in Step 1: Define a global-scoped policy for API Gateway:

   ```
   {
       "filename": "<policyname>_<version>.zip",
       "deploy": "immediate",
       "type": "user-defined-policy",
   },
   ```

6. Create a new zip file called gateway-extension.zip that contains the following files:
   - manifest.json
   - *<policyname>_<version>*.zip
     This is the file that you created in step 4 of this task (it contains the implementation folder and the *<policyname>*.yaml file).

7. Publish the new gateway extension using one of the following methods:
   - API Connect Toolkit:
     Use the **`apic gateway-extensions:create`** command to publish the gateway extension as explained in the **`apic gateway-extensions`** topic.

   - Cloud Manager UI:
     Complete the following steps to publish the gateway extension from Cloud Manager:

     - Log in to Cloud Manager.
     - Click Topology > ⋮ > Configure gateway extensions and upload your new gateway-extension.zip file.
8. Verify that the new global-scoped policy is available in the API Assembler's Policy palette.
   a. Log in to API Manager.
   b. Create an API.
   c. Open the API Assembler page and view the Policy palette; verify that your new global-scoped policy displays and can be added to the API.

Developer Portal: socialize your APIs

The Developer Portal serves as a comprehensive platform for facilitating API sharing with application developers.

In addition to allowing application developers to find and subscribe to APIs, the Developer Portal provides additional features including forums, blogs, comments, and ratings, together with an administrative interface for customizing the Developer Portal to your brand and theme. See the following topics for more information.

Using the Developer Portal
: As well as enabling application developers to find and use your APIs, the Developer Portal also provides features such as API analytics, forums, blogs, and rating facilities.

Configuring the Developer Portal site
: Customize the look and feel of the Developer Portal site, and brand it for your organization.

Concepts in the Developer Portal
: Understand the various concepts and terminology that are referenced throughout the Developer Portal.

Getting started configuring the Developer Portal site
: A quick start guide to configuring your Developer Portal site.

Developer Portal tutorials
: Guided examples that take you through some of the most common user scenarios, as well as some of the more complex areas.

- **Using the Developer Portal**
  As well as enabling application developers to find and use your APIs, the Developer Portal also provides features such as API analytics, forums, blogs, and rating facilities.
- **Configuring the Developer Portal site**
  Customize the look and feel of your Developer Portal site, and brand it for your organization.
- **Managing the Developer Portal by using the toolkit CLI**
  You can perform operations on your Developer Portal by using the API Connect toolkit CLI.

  Tutorials for using the Developer Portal.

Using the Developer Portal

As well as enabling application developers to find and use your APIs, the Developer Portal also provides features such as API analytics, forums, blogs, and rating facilities.

The Developer Portal is a convenient place to share APIs with application developers. After a Developer Portal has been enabled through the API Manager, and one or more API Products have been published, application developers can browse and use the APIs. Typically, a Developer Portal is customized to fit the corporate branding and design requirements of a particular organization. For more information about configuring a Developer Portal site, see Configuring the Developer Portal site. However, when the Developer Portal is first enabled it can be used as is, for example for test and development purposes, or for internal use only.

The following topics provide information about the main API consumer concepts in the Developer Portal, and how an application developer can navigate the default site. However, bear in mind that the actual consumer experience might be very different depending on how the site is configured. For tutorials guiding you through enabling a Developer Portal site, and navigating and using APIs as an application developer, see Tutorial: Creating the Developer Portal and Tutorial: Creating Accounts and Applications on the Developer Portal.

- **Logging in to the Developer Portal with the CLI as a consumer**
  Use the toolkit CLI to log in to the Developer Portal as a consumer.
- **Exploring APIs and Products in the Developer Portal**
  As an application developer, you can browse, test, and subscribe to APIs in the Developer Portal by exploring the available API Products.
- **Applications in the Developer Portal**
  You can view, edit, configure, and create applications in the Developer Portal.
- **Analytics in the Developer Portal**
  You can view analytics for APIs in the Developer Portal at the application and organization levels. This information is displayed in dashboard views that show the analytics metrics in the form of *visualizations* (represented as charts).
- **Consumer organizations in the Developer Portal**
  Consumer organizations provide a way of grouping application developers together. You can add, remove, and configure Consumer organizations in the Developer Portal.
- **User accounts, passwords, and support in the Developer Portal**
  You can change general elements such as user accounts and passwords in the Developer Portal.

Logging in to the Developer Portal with the CLI as a consumer

Use the toolkit CLI to log in to the Developer Portal as a consumer.

Before you begin

To log in as a consumer, you must have created a developer account in the Developer Portal as explained in the following tutorial: Tutorial: Creating Accounts and Applications on the Developer Portal.

About this task

You can use the toolkit CLI to log in to the Developer Portal as a consumer to view it and test how it behaves for your customers.

Procedure

1. Set up the toolkit as explained in Installing the toolkit.
2. Determine the name of your identity provider.
   When you log in from the CLI, you must provide the name of the realm (identity provider) that hosts your API Connect user account. f you don't know the name of your account's realm, look it up now:

   In the CLI, run the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
   ```

For example:

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

In the response, each **title** indicates the name of a user registry (you might belong to more than one registry); you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. The default API Manager Local User Registry for logging in as a member of a provider organization is **default-idp-2**.

3. In the toolkit CLI, run the following command to log in to the Developer Portal:
   Command syntax:

```
apic login --mode consumer -s <consumer-api-server> -u <username> -p <password> -r consumer:<org>:<catalog>/<realm>
```

   Where:
   - ***<consumer-api-server>*** is the URL of the Developer Portal that your consumers will use to log in.
   - ***<username>*** is your API Connect username.
   - ***<password>*** is the password that corresponds to your API Connect username.
   - ***<org>*** is the name of the provider organization to which your API Connect account belongs.
   - ***<catalog>*** is the name of the Catalog that hosts the Developer Portal where you are logging in.
   - ***<realm>*** is the name of the identity provider that hosts your API Connect user account.

   Example:

```
apic login --mode consumer --server consumer.9a6e-88fa49bc.eu-gb.apiconnect.cloud.ibm.com -u my_username -p Bluemix123 -r
consumer:frankenstein:om-portal/om-portal-idp

Logged into consumer.9a6e-88fb51bc.eu-gb.apiconnect.cloud.ibm.com successfully
```

Exploring APIs and Products in the Developer Portal

As an application developer, you can browse, test, and subscribe to APIs in the Developer Portal by exploring the available API Products.

Browsing available APIs

In API Connect API providers package their APIs into Products to offer one or more APIs to application developers. The providers then use Plans to control access to APIs and to manage API usage. Products are packages that contain both the APIs and the accompanying Plans.
From the Developer Portal home screen, click API Products to browse the available products. You can then select a Product to explore the available Plans and APIs further, including viewing API code snippets, and request and response examples.
Note: If you have an account on the Developer Portal, you can specify a default programming language for the code snippets to display in by editing the Code Snippet Language in your account settings.

Subscribing to a Plan

A Plan is a collection of API operations or subsets of operations from one or more APIs. In order to subscribe to a Plan, you must have an account on the Developer Portal and have created an App. For more information, see User accounts, passwords, and support in the Developer Portal and Applications in the Developer Portal. Rate limits specify how many requests an App is allowed to make during a specified time interval. A Plan can have a shared rate limit for all the operations, or each operation can have a different rate limit. In addition, Plans can have multiple rate limits set per Plan and per operation, at second, minute, hour, day, and week time intervals. Plans can also have burst limits to prevent usage spikes that might damage infrastructure. Multiple burst limits can be set per Plan, at second and minute time intervals.

After you have identified the Plan that you want to use, click Subscribe and then select the App that you want to use with this Plan. If the Plan is not restricted, you can use it immediately. If the Plan is restricted, the subscription is shown as Pending Approval, and you cannot use the requested Plan until the administrator approves your request.

You cannot subscribe to a monetized Plan without first adding your payment information to your Consumer organization. You can register your payment information by editing the Billing tab for your Consumer organization. Note: you must either be the Consumer organization owner, or have `Settings: Manage` permissions for your organization to be able to edit the billing information. Consumer organizations can have at most one payment method. You can delete your payment method and add a different method, for example if your credit card expires. If you change your subscription to a Plan that has a different pricing structure, the subscription billing system will add a prorated amount to the next invoice of your subscription billing cycle.

Testing an API

You can test an API in the Developer Portal by using the interactive API document test tool. If the API operation that you want to test doesn't require a client ID, then you can use the test tool without the need to log in. For more information, see Testing an API by using the Developer Portal test tool.

Calling an API in your application

When you have subscribed to a Plan and you begin coding your application, you must retrieve the operation URL in order to call the API. You can retrieve the operation URL from the API overview page. For more information, see Calling an API.

- **How to use a URL to navigate directly to a Product or API in the Developer Portal**
  You can navigate to a specific Product or API in the Developer Portal by using ***x-ibm-name:version*** in the URL.
- **Testing an API by using the Developer Portal test tool**
  You can test the behavior of an API without the need to write any code by using the Developer Portal test tool. You provide the necessary API parameters within the test tool and click Invoke to see the response.
- **Calling an API**
  When you have a selected a Plan and you begin coding your application, you must retrieve the operation URL to call the API.

How to use a URL to navigate directly to a Product or API in the Developer Portal

You can navigate to a specific Product or API in the Developer Portal by using ***x-ibm-name:version*** in the URL.

To find a Product or API in the Developer Portal you typically navigate there by searching in the UI, clicking on the relevant Product, and then selecting the API. However, if you know the ***x-ibm-name:version*** of your Product or API, you can insert that information into the URL to go there directly.

To navigate directly to a specific API, use the following URL syntax:

portal.site.url*/productselect/*api_x-ibm-name*:*version

For example:

https://my.portal.com/myorg/sandbox/productselect/petstore-header-clientid:1.0.0

To navigate directly to a specific Product, use the following URL syntax:

portal.site.url*/product/*product_x-ibm-name*:*version

For example:

https://my.portal.com/myorg/sandbox/product/my-product:1.0.0

To navigate directly to a specific API within a specific Product, use the following URL syntax:

portal.site.url*/product/*product_x-ibm-name*:*version*/api/*api_x-ibm-name*:*version

For example:

https://my.portal.com/myorg/sandbox/product/my-product:1.0.0/api/petstore-header-clientid:1.0.0

Testing an API by using the Developer Portal test tool

You can test the behavior of an API without the need to write any code by using the Developer Portal test tool. You provide the necessary API parameters within the test tool and click Invoke to see the response.

Before you begin

To use the Developer Portal test tool with an API that requires an App client ID, you must first complete the following tasks:

- Create an App. For more information, see Registering an application.
- Subscribe to a Plan that contains the API that you want to test. For more information, see Exploring APIs and Products in the Developer Portal.

About this task

The Developer Portal test tool is an interactive API document test tool. If the operation that you want to test does not require a client ID, then you can use Developer Portal test tool without the need to sign in. However, if the operation that you want to interact with requires a client ID, then you must sign in to the Developer Portal first.

Using the Developer Portal test tool is subject to the rate limit that is applied to an operation or Plan. For example, if an operation has a rate limit of 10 requests per minute and you invoke the operation, the number of requests that can be made is reduced to nine. The limitations are triggered every time that you click invoke within the minute interval. This caveat affects the quota of the App that is selected to use with the Developer Portal test tool, but it does not affect the quota of the other Apps that are using the same operation or Plan.

To test an API in the Developer Portal, the Allow this API to be tested check box must be selected in the API Manager. For more information, see Creating API definitions.

Restriction:

- There are security mechanisms that prevent you using the Developer Portal test tool to test an Implicit or Authorization Code grant type in an OAuth provider API. Other grant types in the same OAuth provider API **can** be tested. If your OAuth provider allows those actions to function correctly from the test tool, you can disable this option. For more information, see Disabling test tool restrictions.
- You cannot use the Developer Portal test tool with suspended applications.
- You can only test an unenforced API if **testable=true**, and if the existing API implements CORS and is using HTTPS.

Note: GraphQL APIs can be tested from the Developer Portal user interface. However, not all authentication methods are supported. You must use one of the following authentication methods:

- Unsecured
- Client ID, passed in the header
- Client ID and secret, passed in the header

Also, **cost** metrics are not supported, and rate limits specific to GraphQL are not listed in Product plans.

Procedure

1. To use the Developer Portal test tool with an API that does not require the client ID of an App, complete the following steps:
   a. Click API Products.
      All of the APIs that can be used by application developers are displayed.
   b. Click the name of the API that you want to test.
   c. Select an operation and then select Try It.
   d. Click Try this operation.
   e. Supply the values for required headers or parameters.
   f. If the operation is secured with Basic Authentication, supply the credentials.
   g. Click Send Request.

The result is displayed in the Response Body field. You can continue to test different parameter values as necessary.
Note:
The first time that you click Try It, you might be presented with a security error. Copy the URL from the Request URL field, open it in a browser window, and accept the security certificate. You are not presented with the security error again.

Also, for performance reasons, if the payload is large, more than 1500 DOM highlighted elements, you get the response, but it is not pretty printed.

2. To use the Developer Portal test tool with an API that does require the client ID of an App, complete the following steps:
   a. Sign in to the Developer Portal.
   b. If you have not already done so, you must create an App so that you can test an API that requires a client ID. For more information, see Registering an application.
   c. Ensure that your App is subscribed to the Plan that contains the API that you want to test. For more information, see Exploring APIs and Products in the Developer Portal.
   d. Click API Products.
   All of the APIs that can be used by application developers are displayed.
   e. Click the *API* that you want to test.
   f. Select the **`Provide credentials for Client ID (API Key)`** operation and then select Try It.
   The API Key Identification window displays.
   g. Use the Register an application in order to select a client ID drop-down list to select an App to test the API with.
   h. Click Save credentials.
   i. If a client secret is required, enter the value in the Client Secret field.
   j. Find the operation that you want to test, then click Try It.
   k. Supply the required parameters and values.
   l. If the operation is secured with Basic Authentication, supply the credentials.
   m. Click Send.
   The result is displayed in the Response section. You can continue to test different field values as necessary.
   Note: The first time that you click Invoke, you might be presented with a security error. Click the link that is provided to accept the security certificate. You are not presented with the security error again.

Related tasks

- Calling an API by using CORS

Calling an API

When you have a selected a Plan and you begin coding your application, you must retrieve the operation URL to call the API.

About this task

Be aware of the following points when you call APIs in IBM® API Connect:

- In the HTTP response message for status code 200 the reason phrase is replaced with `OK`.
- API error messages are displayed in English only.

Procedure

To retrieve the operation URL, complete the following steps:

1. Click API Products, then select a product.
2. Click the API that you want to work with.
   The API overview page opens.
3. Select the operation you need and then copy the endpoint.
   This is the URL that the application calls, and its structure is defined:

Type of API	URL
REST APIs	**`https://`*`host`*`/org/catalog/api/operation`**
SOAP APIs	**`https://`*`host`*`/org/catalog/api`** for all operations in the WSDL.

   where:
   - *host* is the fully qualified host name of your gateway cluster.
   - *org* is the URL path of your organization.
   - *catalog* is the name of your Catalog.
   - *api* is the name of your API.
   - *operation* is the URL path of your operation.
4. Take note of any parameters, the request body, and the response body. Code your application to create the expected requests and handle the expected responses.

Depending on the Identify your application using setting for the API, you might have to provide a client ID, or client ID and client secret. To do this, complete the following steps:

5. To find the client ID, complete the following steps:
   a. Click Apps, then click the application name that you want to work with.
   b. Select the Show check box for Client ID.
   The client ID is displayed.
   c. Provide the client ID with the header parameter &client_id=
   For example, the URL used in the API might be:

   `https://`*`host`*`/org/catalog/api/quote?loanAmount=``20000`

   but when you call it with a client ID of *1234*, change the URL to:

```
https://host/org/catalog/api/quote?loanAmount=20000&client_id=1234
```

Note: API Gateway only A client ID is generated automatically by API Connect when you register an application. However, if you specify a customized client ID, by using the CLI or REST API, then the length must not exceed 512 bytes, otherwise the gateway will reject the API request and return a `401` error.

6. The client secret is produced when you register an application. Provide the client secret with the query parameter &client_secret=. If you did not note the client secret when you registered the application, you must reset it; for information, see Managing applications.

The client ID, or client ID and secret can be logged along with the URL. Web servers usually log the URL in their access logs, which would give away the client secret. If you do not want to expose your client ID or secret in the URL, complete the following steps.

7. For the client ID, set the header, `X-IBM-Client-Id`, as part of the HTTP message that the application sends when it calls the API.
   An example URL statement might be:

   ```
   curl --header "X-IBM-Client-Id: 1234" https://host/org/catalog/api/quote?loanAmount=20000
   ```

   Note: API Gateway only A client ID is generated automatically by API Connect when you register an application. However, if you specify a customized client ID, by using the CLI or REST API, then the length must not exceed 512 bytes, otherwise the gateway will reject the API request and return a `401` error.
8. For the client secret, set the header, `X-IBM-Client-Secret`, as part of the HTTP message that the application sends when it calls the API.
   For example, the URL would be:

   ```
   https://host/org/catalog/api/quote?loanAmount=20000
   ```

   and set the following HTTP headers:

   ```
   X-IBM-Client-Id=1234
   X-IBM-Client-Secret=ABCD
   ```

What to do next

Monitor the API and application usage. For more information, see Managing applications.

- **Calling an API by using CORS**
  CORS (cross origin resource sharing) is a technique that allows calls to be made from code that is running in a browser to a third-party server (such as APIs running on an API Connect). These calls are, by default, not allowed as per the same origin security policy that is applied to the browser sandbox. Without CORS support, web developers are required to use more complex techniques such as server-side proxies.

Calling an API by using CORS

CORS (cross origin resource sharing) is a technique that allows calls to be made from code that is running in a browser to a third-party server (such as APIs running on an API Connect). These calls are, by default, not allowed as per the same origin security policy that is applied to the browser sandbox. Without CORS support, web developers are required to use more complex techniques such as server-side proxies.

About this task

Note: CORS support is available only on the DataPower® API Gateway.
API Connect Gateway servers support CORS to make it as easy as possible for web developers to use APIs within their web applications.
CORS is supported in the following browsers:

- Chrome 3+
- Firefox 3.5+
- Internet Explorer V11, or later
- Opera 12+
- Safari 4+

A CORS enabled browser automatically sends either a simple CORS request, consisting of the original request with the addition of the `Origin` header, or a preflight request followed by a simple CORS request.

An example CORS preflight request is as follows:

```
OPTIONS /org/env/api/resourceHTTP/1.1
User-Agent: useragent details
Access-Control-Request-Method: GET
Access-Control-Request-Headers: header names
Host: x.xx.xxx.xx
Origin: https://example.com
Accept: */*
```

You do not need to create CORS requests yourself, other than for testing or troubleshooting purposes.

A CORS response is received from the gateway; for example:

```
HTTP/1.1 200 OK
X-Backside-Transport: FAIL FAIL
Connection: Keep-Alive
Transfer-Encoding: chunked
Access-Control-Allow-Origin: https://example.com
Access-Control-Allow-Credentials: true
Access-Control-Allow-Headers:accept, accept-language, content-type, x-ibm-client-id
Access-Control-Allow-Methods: methods allowed on the resource
Vary: Origin
```

Applications in the Developer Portal

You can view, edit, configure, and create applications in the Developer Portal.

Before you can subscribe to a Plan that contains the API or APIs that you want to use, you must first register an application by creating an App. You can create more than one App, and these Apps can be edited and deleted as required.

To learn about applications in the Developer Portal, use the following topic links.

- **Registering an application**
  Before you can use an API, you must register your application to the Developer Portal.
- **Managing applications**
  You can show or reset a client ID for an application, verify or reset a client secret, and view the details of the APIs in the application. You can also unsubscribe from a Plan that the application is subscribed to.
- **Editing an application**
  You can edit applications in the Developer Portal. If a user has the correct permissions, they can edit the content of any application in their organization.
- **Deleting an application**
  You can delete applications in the Developer Portal.
- **Changing an application image**
  You can change the image for an application in the Developer Portal.
- **Verifying an application client secret**
  You can verify an application client secret in the Developer Portal

Registering an application

Before you can use an API, you must register your application to the Developer Portal.

About this task

When you register an application, you are provided with a client ID and client secret for the application. You must supply the client ID when you call an API that requires you to identify your application by using a client ID, or a client ID and client secret.

You can, optionally, add further client ID/client secret pairs to an application, any of which can be used to identify the application when calling an API.

Procedure

To register an application, complete the following steps:

1. Click Apps.
   The Apps page opens.
2. Click Create new app.
3. Optional: Specify a URL in the Application OAuth Redirect URL(s) field.
   You can specify multiple OAuth redirect URLs by clicking Add another item. If only one redirect URL is specified, and the application does not provide the **`redirect_uri`** in the OAuth request, then API Connect automatically uses the one redirect URL specified. However, if more than one redirect URL is specified, then the application must provide the **`redirect_uri`** in the OAuth request, or the OAuth request is rejected.
4. Click Submit.
   Your application is displayed.
5. The client secret is hidden; click the Show check boxes, make a note of your client secret because it is displayed only once.
   You must supply the client secret when you call an API that requires you to identify your application by using a client ID and client secret.
   Note: The client secret cannot be retrieved. If you forget it, you must reset it.
6. Optional: In the Certificate field, paste the public X509 certificate for your application, in PEM format.
   The Certificate field is available only if the APIs that have been published to the Developer Portal include at least one API that has been secured with TLS mutual authentication. You must complete this field if you want to call an API that has been secured with TLS mutual authentication. For more information, see Composing a REST API definition.

   These certificates are sent to the management server and to the gateway, and are used for certificate verification when the application calls an API that has been secured with TLS mutual authentication.

   Important: When you paste the certificate, ensure that it contains no line breaks, and that the **`(-----BEGIN CERTIFICATE-----)`** prefix and **`(-----END CERTIFICATE----)`** suffix are removed.
7. Optional: The client ID is hidden, to display the client ID for your application, click Subscriptions, then select the Show check box for Client ID.
   The client ID is displayed and can be hidden again by clearing the check box.
8. Optional: To verify your client secret, click Subscriptions, then click Verify, enter your client secret in the Secret field, then click Submit.
   You have confirmed whether your client secret is correct or incorrect.
9. To add an additional client ID and client secret to the application, complete the following steps:
   a. Click Subscriptions.
   b. Click Add alongside Credentials.
      The "Add new application credentials" window opens.
   c. Enter a name and an optional summary, and click Submit.
   d. Select the Show Client ID or Show Client Secret check box to display the client ID or client secret for the new credentials.
   e. To add a description to a set of client credentials, or to change the current description, click Update alongside the required credentials.
   f. To remove a set of client credentials from the application, click Delete alongside the required credentials.

   If you add additional credentials to an application, any of the associated client ID/client secret pairs can be used to identify the application when calling an API.
   Note: If you add two or more sets of client credentials to an application, OAuth tokens are not shared between them; each client credential set uses a different OAuth token.

10. To add an image, click Upload image from the application overflow menu.
    A new window opens; click Browse, select an image from your directory, and click Submit.
11. Optional: To change the URL that authenticated OAuth flows for this application should be redirected to, click Edit from the application overflow menu, then enter a URL in the Application OAuth Redirect URL(s) field.
12. Optional: To change the application name or description, click the Edit from the application overflow menu.

Results

Your application is registered.

What to do next

Select a Plan to use with your application, see Exploring APIs and Products in the Developer Portal.

- IBM API Connect overview
- Creating an API key security definition

Managing applications

You can show or reset a client ID for an application, verify or reset a client secret, and view the details of the APIs in the application. You can also unsubscribe from a Plan that the application is subscribed to.

About this task

On the application details page, you can display and reset a client ID and client secret. You might want to reset a client secret if it is compromised or you forget it. A client secret is only displayed once, so after you reveal it for the first time at a time of your choosing, you can use this window to verify that what you have is correct or reset it if necessary.

You can, optionally, add further client ID/client secret pairs to an application, any of which can be used to identify the application when calling an API.

Procedure

To manage an application, complete the following steps:

1. Click Apps.
   The Apps page opens.
2. Select the application that you want to work with from the displayed list.
3. Click Subscriptions.
4. The client ID is hidden; to display the client ID, select the Show check box. The client ID is displayed, and can be hidden again by clearing the Show check box.
5. To reset your client ID, click Reset.
   Warning: API calls made by the application with the existing client ID will fail.
6. If the client secret is compromised or you forget it, click Reset to generate a new value for the client secret.
7. If you are unsure whether the value that you have for the client secret is correct, you can click Verify, enter the value, and click Submit to confirm whether or not it is correct.
8. To add an additional client ID and client secret to the application, complete the following steps:
   a. Click Subscriptions.
   b. Click Add alongside Credentials.
      The "Add new application credentials" window opens.
   c. Enter a name and an optional summary, and click Submit.
   d. Select the Show Client ID or Show Client Secret check box to display the client ID or client secret for the new credentials.
   e. To add a description to a set of client credentials, or to change the current description, click Update alongside the required credentials.
   f. To remove a set of client credentials from the application, click Delete alongside the required credentials.

   If you add additional credentials to an application, any of the associated client ID/client secret pairs can be used to identify the application when calling an API.
   Note: If you add two or more sets of client credentials to an application, OAuth tokens are not shared between them; each client credential set uses a different OAuth token.
9. To view more details about an individual API, click the API name.
   The operations are listed.
10. To unsubscribe from a Plan, click Unsubscribe alongside the Plan name.

Related information

- IBM API Connect overview

Editing an application

You can edit applications in the Developer Portal. If a user has the correct permissions, they can edit the content of any application in their organization.

Procedure

1. From the Developer Portal home page, click Apps.
2. Select the target application.
3. Click Edit from the application overflow menu.
4. Make any required changes, then click Submit.

Deleting an application

You can delete applications in the Developer Portal.

Procedure

1. From the Developer Portal home page, click Apps.
2. Select the required application.
3. Click Delete from the application overflow menu.
4. Click Delete again to confirm.

Changing an application image

You can change the image for an application in the Developer Portal.

Procedure

1. From the Developer Portal home page, click Apps.
2. Select the required application.
3. Click Upload image from the application overflow menu.
4. Browse for the target image, then click Submit.
   You can remove the image by clicking Remove.

Verifying an application client secret

You can verify an application client secret in the Developer Portal

Procedure

1. From the Developer Portal home page, click Apps.
2. Select the target application.
3. Click Subscriptions.
4. Click Verify for the client secret.
5. Enter your secret string and click Submit.
   You receive a notification saying whether or not the secret that you entered is correct.

Analytics in the Developer Portal

You can view analytics for APIs in the Developer Portal at the application and organization levels. This information is displayed in dashboard views that show the analytics metrics in the form of *visualizations* (represented as charts).

Restriction:

- If the Catalog that is associated with this Developer Portal has two or more gateway services enabled then, for analytics data to be available, the gateway services must all be associated with the **same** analytics service. If the set of associated analytics services for the gateway services includes two or more different analytics services then the Developer Portal does **not** display analytics data. An analytics service is associated with a gateway service in the Cloud Manager user interface; see Associating an analytics service with a gateway service.
- If the visualizations in your dashboard views display no data, show data only for a time period in the past, or the Dashboard tab does not show up, a possible reason might be that access to analytics data within API Connect has been switched off. Contact your API provider for confirmation.

Use the following topic links to learn how to access the various analytics available to you in the Developer Portal:

- **Application analytics in the Developer Portal**
  From the Developer Portal, you can view interactive analytic information about all of the APIs used by an application.
- **Organization analytics in the Developer Portal**
  From the Developer Portal, you can view interactive analytic information about all of the APIs within an organization.

Application analytics in the Developer Portal

From the Developer Portal, you can view interactive analytic information about all of the APIs used by an application.

About this task

All members of the consumer organization can view analytics information relating to APIs used by an application.

Procedure

1. Click Apps from the Developer Portal dashboard.
2. Click the name of the application for which you want to view analytic information.
   From the Dashboard tab, you can see your application analytics including, API Stats, Total Calls, and Total Errors.

Organization analytics in the Developer Portal

From the Developer Portal, you can view interactive analytic information about all of the APIs within an organization.

About this task

All members of the consumer organization can view analytics information relating to the APIs that are used within an organization.

Procedure

1. Click your userName from the Developer Portal dashboard.
2. From the drop-down menu, select My organization.
3. Click the Analytics tab.
   From the Analytics tab, you can see your organization analytics including, API Stats, Total Calls, and Total Errors.

Consumer organizations in the Developer Portal

Consumer organizations provide a way of grouping application developers together. You can add, remove, and configure Consumer organizations in the Developer Portal.

Developer Portal users must be a member of at least one Consumer organization. A Consumer organization can have multiple members and multiple applications. Members must register an application before they can subscribe to an API. A Consumer organization owns all the applications that are created within it. The members do not own any applications. As long as there is one member of a Consumer organization, all applications continue unchanged.

Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: `A user already exists with this email address`.
To learn more about Consumer organizations in the Developer Portal, see the following topics.

- **Adding a Consumer organization from within the Developer Portal**
  You can create a new Consumer organization from within your user account in the Developer Portal. The new Consumer organization appears also in the API Manager UI after it is created.
- **Editing the name of a Consumer organization**
  You can edit the name of your Consumer organization from within the Developer Portal.
- **Switching Consumer organizations**
  You can switch from one Consumer organization to another in the Developer Portal.
- **Adding users to a Consumer organization**
  If the API Provider organization administrator has granted you permission to collaborate, you can invite users to join your Consumer organization. Those organization members can then access the Developer Portal and use the APIs that have been made available to the Consumer organization.
- **Removing a user from a Consumer organization**
  You can remove a developer from a Consumer organization in the Developer Portal.
- **Changing the ownership of a Consumer organization**
  You can change the ownership of a Consumer organization in the Developer Portal.
- **Deleting a Consumer organization**
  You can delete a Consumer organization in the Developer Portal.

Adding a Consumer organization from within the Developer Portal

You can create a new Consumer organization from within your user account in the Developer Portal. The new Consumer organization appears also in the API Manager UI after it is created.

Procedure

1. Sign in to your user account in the Developer Portal.
2. Click the arrow next to your Consumer organization name on the Developer Portal home page.
3. Select Create organization from the drop-down menu.
4. In the Organization Title field, type the name of the new Consumer organization, then click Submit.

Results

Your new Consumer organization is created, and you can switch to it by clicking on its name in the Organization drop-down menu on the home page.

Editing the name of a Consumer organization

You can edit the name of your Consumer organization from within the Developer Portal.

Procedure

1. Sign in to your user account in the Developer Portal.
2. Click the arrow next to your Consumer organization name on the Developer Portal home page, and click My organization.
3. In the Manage tab, click the vertical ellipsis Manage organization icon, and click Edit organization.
4. Enter the new name for your Consumer organization in the Organization Title field, and then click Submit.
   You changed the name of your Consumer organization.

Switching Consumer organizations

You can switch from one Consumer organization to another in the Developer Portal.

Procedure

1. If you are a member of more than one Consumer organization, click the menu of Consumer organizations in the Developer Portal home page.
2. Select the Consumer organization that you want to switch to, and ensure that any applications you register are registered to the correct catalog.

Adding users to a Consumer organization

If the API Provider organization administrator has granted you permission to collaborate, you can invite users to join your Consumer organization. Those organization members can then access the Developer Portal and use the APIs that have been made available to the Consumer organization.

About this task

Depending on the permissions enabled by the Provider organization administrator, members can view applications and application activity, create and edit applications, manage client keys and subscribe to API Plans, or perform all activities.
Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: **`A user already exists with this email address`**.

Procedure

To invite users to join your Consumer organization, complete the following steps.

Note: The ability to invite users is only visible if the API Provider organization administrator has granted you permission to collaborate.

1. Sign in to your user account in the Developer Portal.
2. Click the arrow next to your Consumer organization name on the Developer Portal home page, and click My organization.
   The organization page is displayed.
3. On the Manage tab, select Invite.
4. Enter the email address of the new user in the Email field.
5. Under the Assign Roles heading, use the radio buttons to select a role for the new user, the roles are:
   - **Administrator**-- Can administer the Consumer organization, including invite new members, and can create, and edit applications, manage client keys, and subscribe to API Plans.
   - **Developer**-- Can create and edit applications, manage client keys, and subscribe to API Plans.
   - **Viewer**-- Can only view applications and application activity.

   For full details of the permissions that are assigned to the Developer Portal roles, see API Connect user roles.
6. Click Submit.
   An invitation is sent to the new user.

Results

The user is added to the Consumer organization list of members, and they are sent an email inviting them to join the organization. The user must click the link that is provided in the email to activate their account, and complete the setup.

Removing a user from a Consumer organization

You can remove a developer from a Consumer organization in the Developer Portal.

Before you begin

You must be the owner of your Consumer organization and have previously added the developer you wish to remove from the organization.
Note that removing a user from a Consumer organization does not delete their user account, it only removes them from that organization.

Procedure

1. Click your user name in the Developer Portal home page.
2. Click My organization in the menu.
3. Click Remove user for the user you want to remove.

Changing the ownership of a Consumer organization

You can change the ownership of a Consumer organization in the Developer Portal.

Before you begin

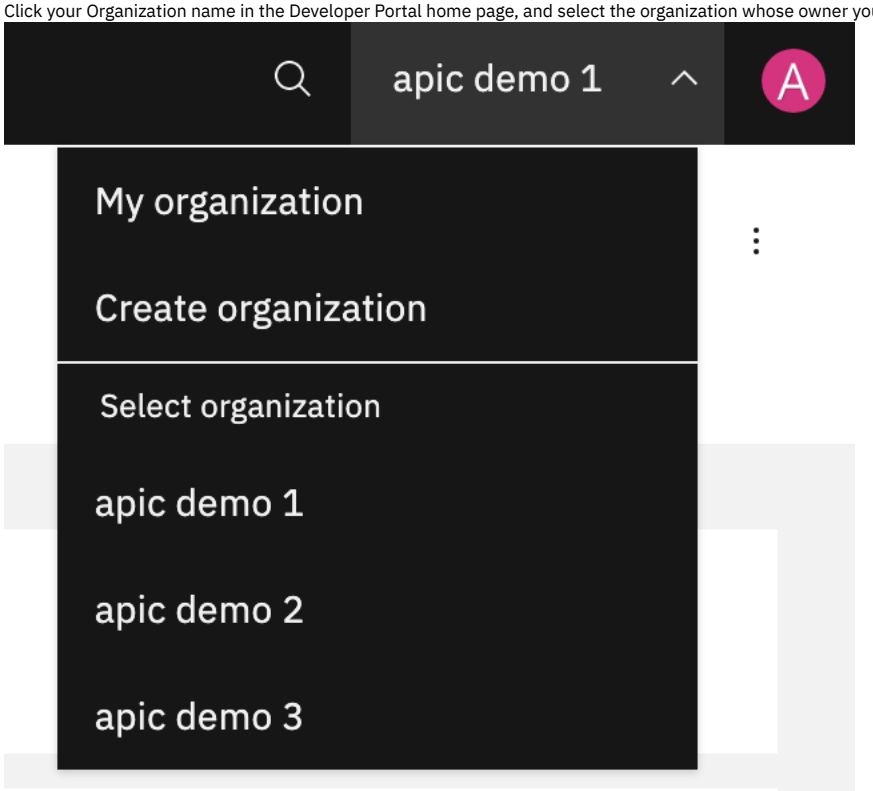
You can change the ownership of a Consumer organization only if you are the owner of that organization. The user that you transfer ownership to must already be a member of the organization. To have an account on a Developer Portal, you must be a member of at least one Consumer organization.

About this task

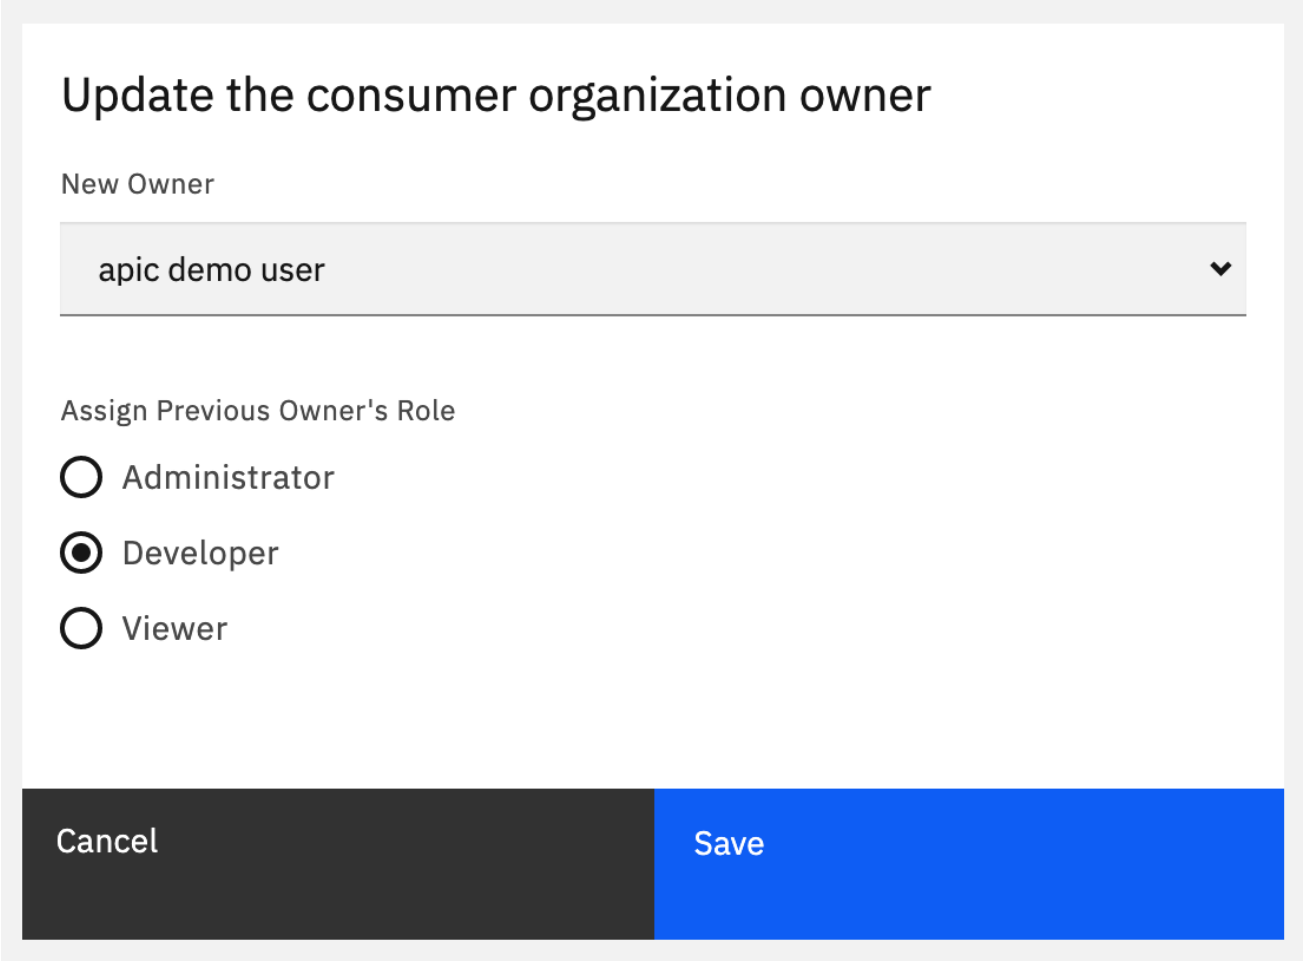
Transferring the ownership of a Consumer organization to another organization member, changes your role in that organization to App Developer.

Procedure

1. Click your Organization name in the Developer Portal home page, and select the organization whose owner you want to change by using the drop-down arrow.



2. Click your Organization name in the Developer Portal home page, and select My organization.
3. Click the options icon, ⋮ and select Change ownership.



4. Select the **New Owner** by using the drop-down arrow.
5. Use the radio buttons to **Assign Previous Owner's Role**, then click Submit.

Results

You successfully transferred ownership of a Consumer organization in the Developer Portal.

Deleting a Consumer organization

You can delete a Consumer organization in the Developer Portal.

Before you begin

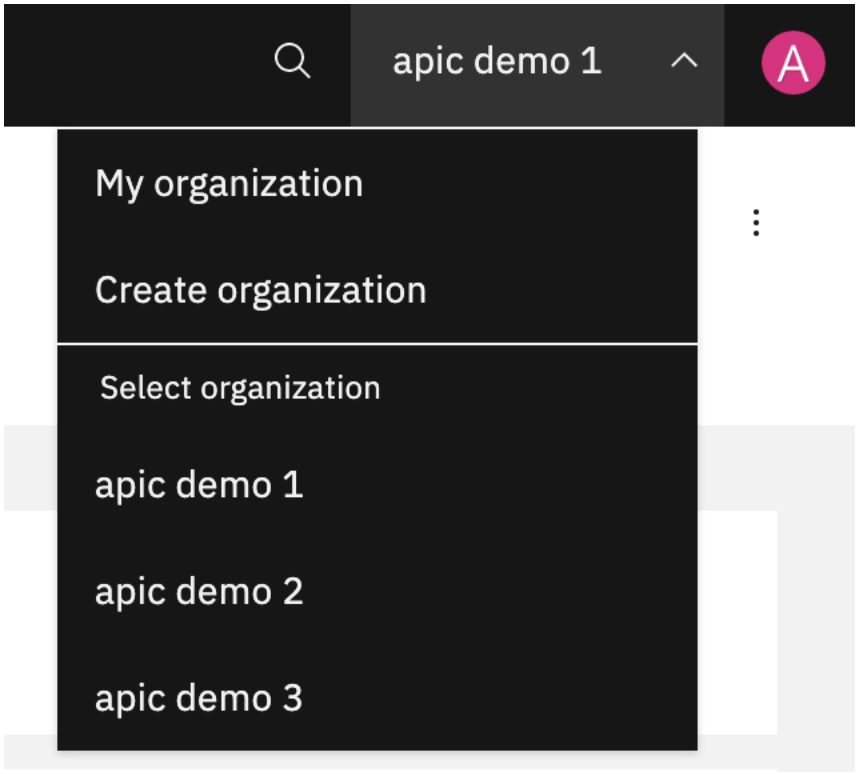
You can delete a Consumer organization only if you are the owner of that organization. To have an account on a Developer Portal, you must be a member of at least one Consumer organization. Therefore, if you are a member of only one Consumer organization, to delete that organization you must first either join or create another Consumer organization, or you can delete your whole developer account. For more information, see Deleting your developer account.

About this task

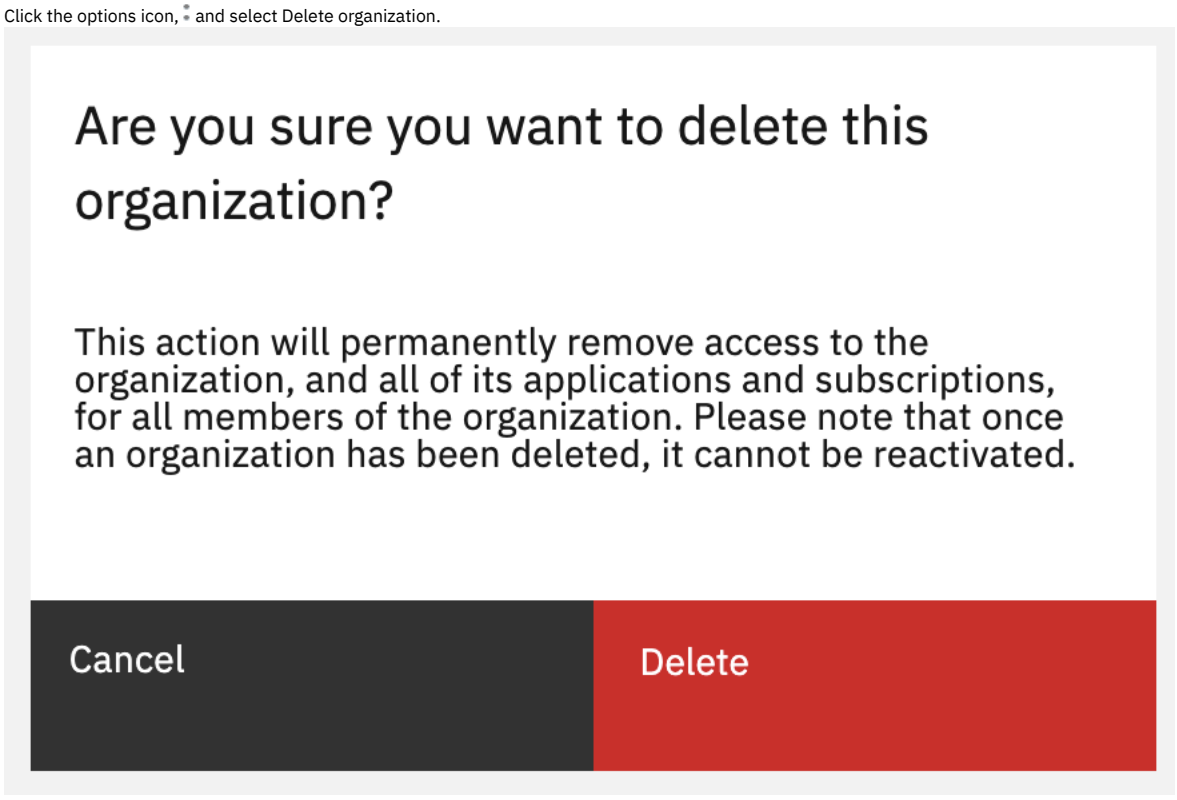
Deleting a Consumer organization in the Developer Portal permanently removes access to the organization, and all of its applications and subscriptions, for all members of the organization. Consider carefully the impact on any members of your Consumer organizations before you delete the organization. Any users that were members of only the deleted organization, must create a new Consumer organization when they next logon to the Developer Portal.
Important: When an organization is deleted, it cannot be reactivated. You might want to consider changing the ownership of a Consumer organization, rather than deleting it. For more information, see Changing the ownership of a Consumer organization.

Procedure

1. Click your Organization name in the Developer Portal home page, and select the organization that you want to delete by using the drop-down arrow.
   You must be in more than one Consumer organization.



2. Click your Organization name in the Developer Portal home page, and select My organization.
3. Click the options icon, ⋮ and select Delete organization.



4. Click Delete.

Results

You permanently deleted a Consumer organization in the Developer Portal.

User accounts, passwords, and support in the Developer Portal

You can change general elements such as user accounts and passwords in the Developer Portal.

Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: `A user already exists with this email address`.
To learn about general user features of the Developer Portal, see the following topics:

- **Creating a new developer account**
  You can create new developer accounts, and their associated Consumer organizations, in the Developer Portal.
- **Changing your account settings**
  You can edit your user account settings in the Developer Portal, such as changing your name, password, time zone, and language settings.
- **Deleting your developer account**
  You can delete your account in the Developer Portal.

Creating a new developer account

You can create new developer accounts, and their associated Consumer organizations, in the Developer Portal.

Before you begin

You need to provide an email address to create a new account. That email address must be a valid email address, and the domain that is used is required to have a valid MX record that is determined by DNS. You can disable the security module that checks that the email domain has a DNS record.

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Extend > Disable module.
4. In the search bar enter **`check_dns`**, then select the check_dns module and click Disable.
5. Click Disable to confirm that you want to disable the module.

About this task

In order to use the Developer Portal, you must have a developer account, and be a member of at least one Consumer organization. When you create a developer account, a Consumer organization is created at the same time. You can be an owner, and a member of, multiple Consumer organizations. For more information about Consumer organizations, see Consumer organizations in the Developer Portal.
Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: `A user already exists with this email address`.

Procedure

1. From the Developer Portal home page, click Create account.
2. Populate the available fields with the details of the developer account and Consumer organization that you want to create.
3. Click Sign up.
   The email address that you provided for the new developer account is sent an email that contains an activation link for the new developer account. Use this link to activate your new account.

Changing your account settings

You can edit your user account settings in the Developer Portal, such as changing your name, password, time zone, and language settings.

About this task

You can edit various details about your user account, for example, change your password, update your code snippet language, change your time zone, select your preferred site language, and select an avatar.

Procedure

1. Click your user name in the Developer Portal home page, and click My account.
2. To update your password, click Change Password, and update the fields as required.
3. To update other elements of your account, such as your name, time zone, and language, click Edit and update the fields as required.
4. Click Save to save your changes.

Deleting your developer account

You can delete your account in the Developer Portal.

Before you begin

You must be the owner of the developer account that you want to delete, and you must not own more than one Consumer organization. If you do own more than one Consumer organization, you must either change the ownership of those organizations, or delete them, before you can delete your account. If you own only one Consumer organization, when you delete your account the Consumer organization is deleted at the same time as your account.

About this task

When you delete your account, any Consumer organizations that you own must also be deleted or transferred to new owners. If there are other members in a Consumer organization that you delete, these members will no longer have access to that organization, or any of its applications and subscriptions. Consider carefully the impact on any members of your Consumer organizations before you delete your account. For more information, see Deleting a Consumer organization.
Important: When an organization has been deleted, it cannot be reactivated. You might want to consider changing the ownership of your Consumer organizations before you delete your account. For more information, see Changing the ownership of a Consumer organization.

Procedure

1. Click your user name in the Developer Portal home page, and select My account.
2. Click the Edit tab.
3. Click Delete account.
4. Click Delete to confirm deletion of the account.
   This action deletes your developer account and, if you own a Consumer organization, this organization is also deleted.

Results

You successfully deleted your developer account in the Developer Portal.

Configuring the Developer Portal site

Customize the look and feel of your Developer Portal site, and brand it for your organization.

In IBM® API Connect Version 10 the Developer Portal is based on the open source Drupal 10 content management system, and consequently it is almost infinitely customizable. What an individual user is able to configure, depends on the role the user has been assigned, and the associated permissions of that role. A user can be assigned one of four Developer Portal roles:

Authenticated user
: An authenticated user is, typically, an application developer, and can perform all of the actions that are described in the Using the Developer Portal section.

Forum Moderator, Content Author, or Administrator
: In addition to performing all of the tasks that an Authenticated user role can, a Forum Moderator, Content Author, or Administrator role have additional permissions related to configuring the Developer Portal site. For more information, see Working with roles in the Developer Portal.
  Note: By default, the Developer Portal administration operations are available only if you have Administrator access.

Before you start to configure your Developer Portal site, you should familiarize yourself with the various concepts and terminology that is referenced throughout the Developer Portal. See Concepts in the Developer Portal.

When you are ready to start configuring your Developer Portal site, see Getting started configuring the Developer Portal site for a quick start guide on customization. There is also a tutorial that you can follow that takes you through an example customization scenario; see Tutorial: Creating a custom theme for the Developer Portal.

If you are migrating from Version 5 to Version 10, see Migrating your Developer Portal from Version 5 to Version 10 for guidance about how to transfer any specific customizations, such as custom modules and themes, from the Drupal 7 baseline to the Drupal 10 baseline.

In addition to the previous options, Developer Portal configuration operations are described in detail in the following sections:

Appearance
: Control and configure the general appearance of your Developer Portal site by setting and configuring a default theme.
  Important: Editing API Connect themes, modules, or Drupal core on the filesystem is not permitted or supported. For more information, see Creating a sub-theme and Extend.

Content
: Control multiple content entities in the Developer Portal, including the customization and restriction of specific content.

Structure
: Control the layout of the Developer Portal, such as configuring the front page, adding and changing blocks, and displaying Products and APIs in categories.

Configuration
: As an administrator, you can control multiple aspects of the Developer Portal configuration, including managing security and general configuration tasks.

People
: You can manage and customize the user experience in the Developer Portal, by altering permissions and assigning roles to specific users.

Forums
: Create and control forums in the Developer Portal.

Reports
: You can view reports about the general configuration and status of your Developer Portal site.

Extend
: You can extend the Developer Portal by creating and installing custom modules, or installing additional Drupal contributed modules.

Concepts in the Developer Portal

The Developer Portal is built on Drupal 9, an open source content management technology. A good understanding of Drupal concepts and terminology enhances your ability to work with the Developer Portal.

In Drupal, most content on the website is treated as variations on the concept of a **node**. Node types, such as static pages, blog posts, and news items, are all stored in the same way. The navigation structure of the site is designed separately by editing **menus**, **views**, and **blocks**. Finally, the **theme** of the system controls the overall appearance of the site to visitors. Access to these depends on the permissions that your role possesses. These are explained more fully in the following sections.

Nodes

A node is a set of individual related content such as a page, a poll, an article, a forum topic, or a blog post. For example, when you create a blog post, and definite the body text, you also define its title, content, author link, creation date, and taxonomy . Some of these elements are shown by the theme layer when the node is displayed, and some elements are metadata that control where and when the node is displayed at all. Each set of content in a Developer Portal site is a node. You can apply new features or changes to all content of a single node type.

Fields

A field is somewhere that you can add extra metadata to a node. The following types of data are examples of fields:

- Title
- Body
- Comment body
- Tags
- Image

You can create different types of fields, and they can be defined at the content-type level for content items and comments, at the vocabulary level for taxonomy terms, and at the site level for user accounts. Field types are defined by modules, and managed by the Field module. In addition, other modules might enable fields to be defined for their data.

Content types

A content type is a predefined collection of fields. Content types define the default fields that content editors use to add content in a Developer Portal site, and help structure the authoring and developing of content. Content types can be displayed in the Developer Portal. You can control which content types, and the order and format that they are displayed, in the Developer Portal.

Themes

You can use themes to control the overall appearance of your Developer Portal site. You can modify the appearance of the theme in following ways:

1. Extend the code of an existing theme.
2. Identify and use a theme that is provided by the Drupal community or a third-party website, and modify the theme settings.
3. Create a complete custom theme from scratch.

However, you cannot directly edit the API Connect theme as editing is not supported. Any edited versions of these files are overwritten when a fix pack or iFix is installed. So, the way to create a custom theme is to create a custom subtheme of the standard API Connect theme that the Developer Portal uses by default. A subtheme inherits all of the settings of its parent theme, apart from the settings that are overridden. For more information, see Creating a sub-theme.

Most themes use the Twig template engine for PHP.

Regions

The specific areas of a Developer Portal site in which content can be placed. Regions are customized and styled in the theme.

Blocks

Blocks are boxes of content that can be displayed in regions on your Developer Portal page. Blocks can be made available to your Developer Portal site by enabling specific modules. After a block is created, its appearance can be modified. You can also define which Developer Portal page or pages blocks appear on. Some modules can provide multiple blocks when they are enabled, while other modules might not define new blocks. For more information, see Adding and changing the blocks displayed on Developer Portal pages.

Modules

Modules are similar to the concept of plug-ins, in that they extend the core functions of the Developer Portal site. A set of modules is implemented by default with the Drupal core, and there are extra modules that can be enabled to extend the default functions. You can find and add more modules to your Developer Portal site from the internet. For more information, see Extend.

Views

You can use views to manipulate the content that is displayed on a page, block, and other visual elements in the Developer Portal site. Views can be used along with content types to format the appearance of your site to your specification. For more information, see Using the Views module in the Developer Portal.

Pages

Pages are used by the features that can modify the appearance of the Developer Portal to customize the appearance of your Developer Portal site. Pages can be customized to be as specific as you require, and can be configured to satisfy the context of the situation that they are used in.

Users

After you log in to the Developer Portal site, you have a user record in the Developer Portal database. User ID 1 is always reserved for the administrator account. Regardless of whether other user accounts are using remote authentication such as LDAP, the administrator account is always a local account to enable administration of the Developer Portal site. For more information, see People.

Roles

A role is a collection of permissions that define the actions that a user can do in the Developer Portal site. Users can be given one or more roles. By default, a user that is logged in to the Developer Portal is in the Authenticated role. Other roles that can be assigned to a user include:

- Administrator
- Forum Moderator
- Content Author

You can also create new custom roles. For more information, see Working with roles in the Developer Portal.

Permissions

Permissions define the actions that a user can or cannot do in a Developer Portal site. Permissions are additive. If a permission that enables a user to do an action is not assigned, the user cannot do the action. If a user has multiple roles, and any of them contain a specific permission, the user is able to do that action. There are also permissions that have security implications, and you are recommended to assign those permissions to trusted roles. For more information, see Controlling access to Developer Portal content.

Templates

Template files define how the output of a particular component can look. They are formatted as Twig template files. The following are examples of where you can use templates:

- html.html.twig - the template for Developer Portal HTML pages
- page.html.twig - the body of Developer Portal HTML page
- node.html.twig - the template for all of the content nodes
- comment.html.twig - the template for all of the comment nodes
- search-result.html.twig - the template for search results
- node--product.html.twig - the template for nodes that use the Product content type
- node--product--teaser.html.twig - the template for the previews for the Product content type

For more information about overriding templates in the Developer Portal, see Applying a modified content type template.

Getting started configuring the Developer Portal site

A quick start guide to the main tasks involved in configuring the Developer Portal to your brand or theme.

The Developer Portal is based on the open source Drupal 9 content management software, and consequently is almost completely customizable. The following sections take you through the most common tasks to get started with branding the Developer Portal to your organizational requirements, including links to the related topics in the main table of contents. Many more customizing options are described in the main table of contents, and the best way of finding help with a specific customization in this content, is to use the documentation search bar.
Important:
All of the customizations that are detailed in this topic are preserved when you update to new versions of API Connect. Drupal updates, as well as new functionality, defect fixes, and security updates, are made available through API Connect update packages as determined by IBM. These update packages can be applied by upgrading your deployment; see the upgrade instructions for your platform in Installing and maintaining your IBM API Connect cloud. To find out what update packages are available, select your product on IBM Fix Central.

Directly editing any API Connect themes, modules, or Drupal core on the file system is not permitted or supported, as edited versions of these files are overwritten when an update package is installed. Customizations must be done by using the proper mechanisms as described in this topic, such as custom modules and themes, and not by directly editing the source.

For more information about the API Connect support policy, see IBM® API Connect Support Lifecycle Policy.

- Create a custom theme
- Changing the page layout
- Changing the front page
- Advanced theme development
- Custom modules
- Hiding the admin login form

- What to do next - exploring the main configuration content

Create a custom theme

If you want your Developer Portal to have your corporate branding and style, you need to create a custom theme. Themes are composed primarily of Cascading Style Sheets (CSS) files, although they can include much more; see Advanced theme development.

Directly editing the API Connect theme is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed. The way to create a custom theme is to create a custom sub-theme of the standard API Connect theme that the Developer Portal uses by default. A sub-theme inherits the parent theme's resources, and this means that your custom sub-theme CSS file needs to contain only the changes or overrides that you want to make from the default theme. The CSS file can contain as little or as many updates as you like.

For more information, see Creating a sub-theme. You can also follow a tutorial that takes you through how to use the theme generator, customize a theme, and install a custom theme; see Tutorial: Creating a custom theme for the Developer Portal.

While experience with Drupal is beneficial, the only skill you really need to create a sub-theme is CSS.

Changing the page layout

While the theme defines *regions* of the page, such as a footer, or sidebar first, the page layout is defined by configuring which blocks appear in which regions. Blocks are controlled by using the Structure > Block layout options on the Developer Portal administrator dashboard. You can then further limit those blocks to show only on specific pages, or show on all pages except certain ones, to show only for certain roles, or for certain languages, and more.

For information about how to configure the page layout, see Adding and changing the blocks displayed on Developer Portal pages.

Changing the page layout is done entirely in the Developer Portal UI as an Administrator.

Changing the front page

The front page is a special case and does not use the blocks system that is mentioned previously. Instead, you configure it from the Structure > Pages options on the Developer Portal administrator dashboard.

For information about how to configure the front page, see Configuring the front page.

Further options that you might want to consider when designing your front page include:

- Change the banner block content or image: Changing the front page banner block.
- Display featured API Products by creating a featured content block: Changing the front page Featured Content block.
- Create custom blocks with your own HTML content: Adding and changing the blocks displayed on Developer Portal pages.
- Set up the social block to include your organization Twitter feed: Integrating Twitter data into the social block.
- Add a carousel to the front page to display a series of images: Implementing an image carousel.

Again, changing the front page is done entirely in the Developer Portal UI as an Administrator.

Advanced theme development

The DOM structure for specific blocks and parts of the page is controlled by templates. These templates are Twig files that define the actual HTML output for a particular piece of content. You can override a Twig template by copying the original template into the templates folder of your custom sub-theme, and then editing the template to your specification. The Developer Portal then uses your template in preference to the original one. For more information, see Applying a modified content type template.

Modifying Twig templates allows very fine-grained control over the structure of pages. However, it also means you might miss new features and defect fixes that are made to the original templates, as your Developer Portal is using your overrides instead of the originals. So, if you override a template, it is your responsibility to check the templates in the latest API Connect releases, and to ensure that any equivalent changes that are needed to your overrides to maintain functional equivalence are made.

If you're developing custom templates, knowledge of Twig templating language, Drupal, HTML, and CSS is recommended.

Custom modules

If you need to modify the functional behavior of the Developer Portal, then you can create a custom module to do so. Drupal has an extensible programmatic API that is built around a system of *hooks*. By using these hooks in your custom modules you can change what happens when, for example, forms are displayed, forms are submitted, or make extra variables available to custom templates, and other options.

For more information on writing custom modules, see Extend. You can also follow a tutorial that includes using a custom module, see Tutorial: Adding validation to a field on the sign-up form.

Custom modules are written in PHP, and so Drupal experience and PHP knowledge are very beneficial.

Hiding the admin login form

If your Developer Portal is public facing, you might want to hide the admin registry as an option on the login form. You can do this simply from the administrator dashboard, by clicking Configuration > System > IBM API Connect, and selecting Hide the admin registry on the login form. For more information, see Hiding the admin registry on the login form.

What to do next - exploring the main configuration content

There are an almost infinite number of configuration options available to you on the Developer Portal. Explore the following sections to find out more:

- Appearance - control general appearance elements, and learn how to create a custom theme.
- Content - add, configure, and control content elements, such as meta tags, custom pages, custom content types, and adding content to an API or Product.

- Structure - control how the content in your Portal is displayed, for example configuring the front page, changing block display, and using the Views module.
- Configuration - configure content moderation, perform general configuration tasks, and manage Developer Portal security.
- People - create and customize site configuration roles, control access to sites and to content, and create internal Consumer organizations to allow customization of specific API properties.
- Forums - create and control forums.
- Reports - list of available reports about the general configuration and status of your site.
- Extend - introduction to and instructions for creating custom modules, including information about developing in PHP, and how to use hooks in custom modules.
- Developer Portal tutorials - guided examples taking you through the simple and the more complex areas of configuration.

Appearance

Control and configure the general appearance of your Developer Portal site by setting and configuring a default theme.

To learn how to control the appearance of your Developer Portal site, use the following topic links.

- **Controlling general appearance elements in the Developer Portal**
  You can control general appearance aspects of the Developer Portal.
- **Adding custom JavaScript to a custom theme**
  To increase customization of the Developer Portal, you can add custom JavaScript to custom themes that you install.
- **Applying a modified content type template**
  You can apply a modified content type template to override a default content type template in the Developer Portal. For example, you can override the product content type template to change its layout.
- **Creating a sub-theme**
  Create a custom theme for your Developer Portal site by generating and configuring a sub-theme. A sub-theme is a theme that inherits all the resources of a specified parent theme. You can then override specific resources to configure your required customizations.
- **Installing additional themes**
  You can install additional themes in the Developer Portal.
- **Deleting themes**
  You can delete a theme from your Developer Portal site.

Controlling general appearance elements in the Developer Portal

You can control general appearance aspects of the Developer Portal.

To learn how to control general aspects of the Developer Portal appearance, use the following topic links:

- **Changing the shortcut icon**
  You can change the shortcut icon, or favicon, in the Developer Portal.
- **Changing the site email address**
  You can change the site email address in the Developer Portal.
- **Changing the site logo**
  You can change the site logo for your Developer Portal.
- **Changing the site name or site slogan**
  You can change the site name, or the site slogan, for your Developer Portal.
- **Changing the visibility of site branding**
  You can toggle the visibility of your site branding elements for your Developer Portal.

Changing the shortcut icon

You can change the shortcut icon, or favicon, in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

The shortcut icon, or favicon, is displayed in the address bar or bookmarks of most browsers. Drupal provides a default favicon, the water drop logo, but if you want to make your Developer Portal stand out, you should provide your own.
The default Drupal favicon is 32 pixels high by 32 pixels wide. As a favicon is displayed only in the address bar and favorites (bookmarks) list, any favicon that you create should be similarly small.

Procedure

To change the shortcut icon, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Appearance in the administrator dashboard.
3. Click Settings for the default theme.
4. Click Favicon in the Override Global Settings section.
5. Deselect the Use the favicon supplied by the theme check box.

6. Provide a path to a custom icon on the server by entering it in the Path to custom icon field. Alternatively, you can browse for, and upload, a favicon image under the Upload favicon image subheading.
7. Click Save configuration.
   Note: If the changes don't appear immediately in your browser, clear your browser's cache and reload the page. If you've bookmarked the site, you may need to delete the bookmark and then create it again, so the new favicon is used.

Results

You have changed the favicon for the site.

Changing the site email address

You can change the site email address in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To change the site email address, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. Under the System heading, click Basic site settings.
4. In the SITE DETAILS section, enter the new site email address in the Email address field.
5. Click Save configuration.

Results

You changed the email address for the site.

Changing the site logo

You can change the site logo for your Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To change the site logo, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Appearance in the administrator dashboard.
3. Click Settings for the default theme.
4. Click Logo image in the Override Global Settings section.
5. Deselect the Use the logo supplied by the theme check box.
6. Provide a path to your custom logo by completing the Path to custom logo field. Alternatively, you can browse and upload a logo image under the Upload logo image subheading.
7. Click Save configuration.
   Note: If the changes don't appear immediately in your browser, clear your browser's cache and reload the page.

Results

You changed the site logo for your Developer Portal. How the site logo is used depends on the settings for your theme.

Changing the site name or site slogan

You can change the site name, or the site slogan, for your Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

The site name is used to identify the site and can be displayed in browsers. You can also set a site slogan for your theme.

Procedure

To change the site name or site slogan, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration > System > Basic site settings in the administrator dashboard.
3. In the SITE DETAILS section, enter the new site name in the Site name field, or enter a new slogan in the Slogan field.
4. Click Save configuration.

Results

The site name or site slogan is updated. How the site name and the site slogan are used depends on the settings for your site theme. For more information, see Changing the visibility of site branding.

Changing the visibility of site branding

You can toggle the visibility of your site branding elements for your Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

The site branding block includes the site logo, name, and slogan. You can choose which of these branding elements you want to be displayed in this block.

Procedure

To change the visibility of your site branding elements, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure > Block layout in the administrator dashboard.
3. Find the Site branding block in the Navigation section, and click Configure.
4. In the TOGGLE BRANDING ELEMENTS section, use the check boxes to select which branding elements you want to be visible.
5. Click Save block to save your changes.

Results

You changed the visibility of your site branding elements. How these elements are used depends on the settings for your theme.

Adding custom JavaScript to a custom theme

To increase customization of the Developer Portal, you can add custom JavaScript to custom themes that you install.

Procedure

1. Add your JavaScript file to your theme. For example, in a sub-directory named js and the file `myfilename.js`.
2. Add the JavaScript file to your theme, by editing your {custom_theme}.libraries.yml file and adding in the JavaScript file.
   An example of the JavaScript file:

   ```
   myfile:
     js:
       js/myfilename.js: {}
   ```

3. Add the following code to your theme's .info.yml file:

   ```
   libraries:
   - {custom_theme}/myfile
   ```

   Note: You must replace `{custom_theme}` with your theme name. Also, both files must reference `myfile`.
4. Zip up the directory and upload it to your portal site. For more information, see Installing additional themes.

Applying a modified content type template

You can apply a modified content type template to override a default content type template in the Developer Portal. For example, you can override the product content type template to change its layout.

Before you begin

You must have administrator access to complete this task.

You must also have a custom sub-theme, and a copy of an existing template that you want to update. For information about how to create a sub-theme, see Creating a sub-theme.

To obtain a copy of an existing template, you can download a copy from the following locations on GitHub:

- https://github.com/ibm-apiconnect/devportal/tree/master/ibm_apim/templates
- https://github.com/ibm-apiconnect/devportal/tree/master/apic_api/templates
- https://github.com/ibm-apiconnect/devportal/tree/master/apic_app/templates
- https://github.com/ibm-apiconnect/devportal/tree/master/product/templates
- https://github.com/ibm-apiconnect/devportal/tree/master/consumerorg/templates

Note that you must copy the template to your sub-theme, and then modify the content. Do not modify the content that is stored on GitHub.

About this task

You can override the Developer Portal core templates by creating a custom sub-theme, and then adding your modified templates to the sub-theme folder. A sub-theme inherits all of the settings of its parent theme, apart from the settings that are overridden, such as by applying modified templates. After you have applied a modified content types template, these changes take precedence over the default content types template. The Developer Portal templates are formatted as Twig template files. The following levels are examples of where you can use templates:

- html.html.twig - the template for Developer Portal HTML pages
- page.html.twig - the body of Developer Portal HTML page
- node.html.twig - the template for all of the content nodes
- comment.html.twig - the template for all of the comment nodes
- search-result.html.twig - the template for search results
- node--product.html.twig - the template for nodes that use the Product content type
- node--product--teaser.html.twig - the template for the previews for the Product content type

For more information about Twig templates, see Working with Twig templates and Debugging Twig templates on the Drupal documentation website.
Modifying Twig templates allows very fine-grained control over the structure of pages. However, it also means you might miss new features and defect fixes that are made to the original templates, as your Developer Portal is using your overrides instead of the originals. So, if you override a template, it is your responsibility to check the templates in the latest API Connect releases, and to ensure that any equivalent changes that are needed to your overrides to maintain functional equivalence are made.

Important:
Directly editing any API Connect theme files is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.

Procedure

To override a default content type template:

1. Apply the modifications that you require to the default template that you obtained.
   Warning: Although the ability to override templates is supported, if you override a template they are your responsibility. Templates can be from multiple sources and compatibility with an earlier version is not ensured. You must check the templates in the latest API Connect release to check whether you need to make equivalent changes to your overrides to maintain functional equivalence.
2. Create a directory in your custom sub-theme, and name it templates.
3. Add your modified template to the templates directory.
   Note: The modified template file name must be identical to the original name of the template file that it is overriding.
4. Log in to the Developer Portal UI as an administrator.
5. If the administrator dashboard is not displayed, click Manage to display it.
6. Install your custom sub-theme onto the Developer Portal by clicking Appearance > Install new theme on the administrator dashboard.
7. Click Choose file, select your sub-theme, and then click Install.
8. Click Install newly added theme, find your new theme in the list of Uninstalled themes, and click Install and set as default to set your new custom sub-theme as the default theme for your site.
   Your new theme, which contains the modified template file, is now set as the default theme, and is listed in the Installed themes section.

Results

You successfully modified and applied a template to override a default content type template in the Developer Portal.

Creating a sub-theme

Create a custom theme for your Developer Portal site by generating and configuring a sub-theme. A sub-theme is a theme that inherits all the resources of a specified parent theme. You can then override specific resources to configure your required customizations.

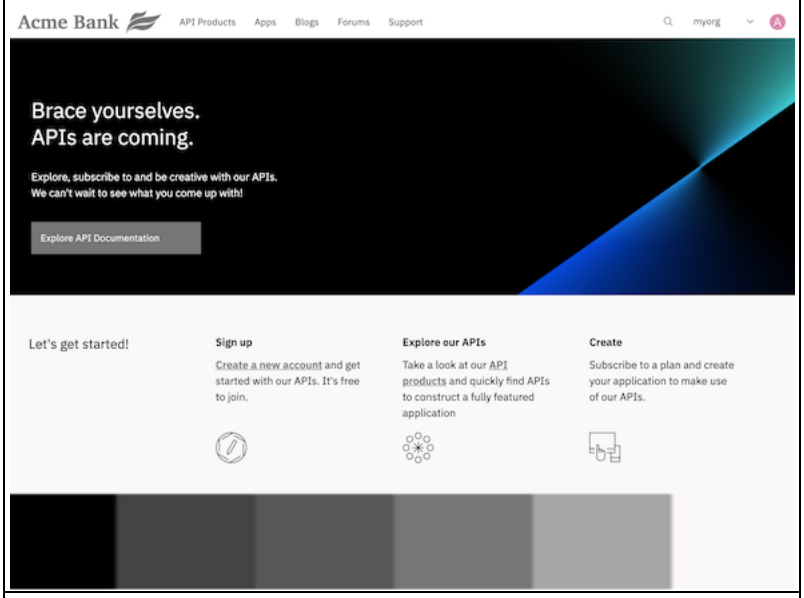
Before you begin

You must have administrator access to complete this task.

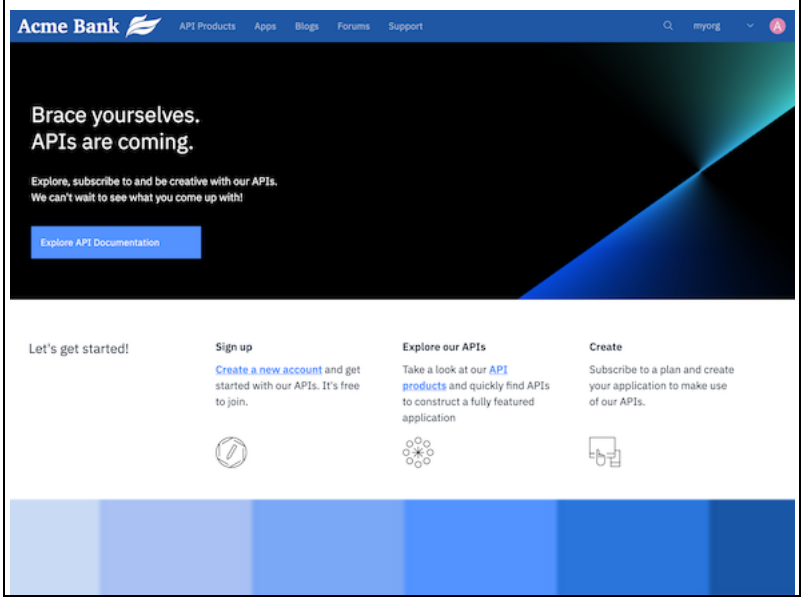
About this task

Directly editing the API Connect theme isn't permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed. So, the way to create a custom theme is to create a custom sub-theme of the standard API Connect theme that the Developer Portal uses by default. You can also create a sub-theme that is based on one of the following color templates:

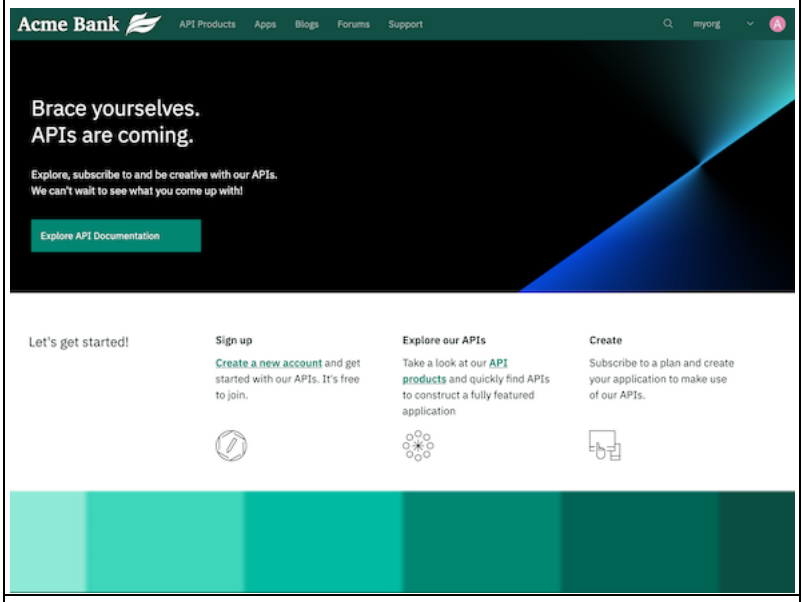
Business Mono



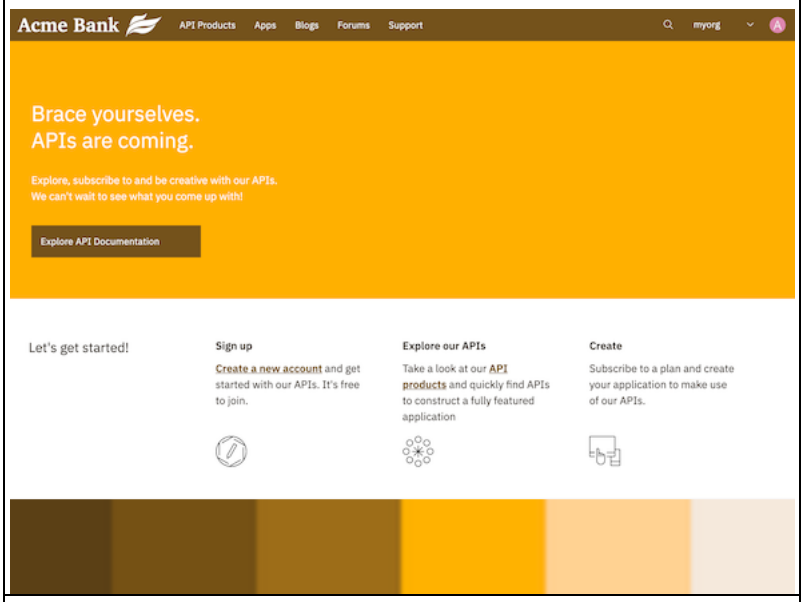
Sapphire Blue



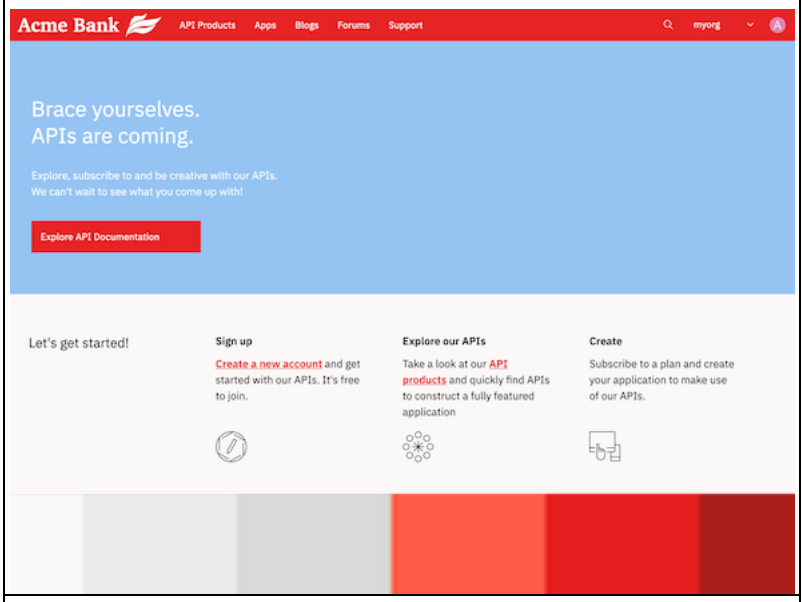
Emerald Green



Golden Brown



Ruby Red



Selecting a color template provides you with a base theme that you can build on more easily to produce your required site branding and styling.
Create a sub-theme by using the theme generator in the Developer Portal UI, customize the appearance as required, and then upload the compressed file back onto the site.

Important:

- You're not permitted to include any IBM® API Connect code within any custom themes that you create. Also, directly editing any API Connect themes on the file system is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.
- All custom development is your responsibility. Although the use of custom themes is supported, IBM API Connect do not provide support in their development or modification.

For a guided example on creating a sub-theme, see Tutorial: Creating a custom theme for the Developer Portal. In this example, you create a sub-theme, and then customize the styling by editing the overrides.css file.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. On the administrator dashboard, click Appearance > Generate sub-theme.
   The Generate sub-theme page is displayed.
3. Enter a Sub-theme name, and select the Sub-theme type that you would like to use. The name can contain only lowercase characters a - z, and numerals 1 - 9.
   - CSS - Cascading Style Sheets; the language that is used to describe how to display the HTML elements in the theme.
   - SCSS - Sass CSS; a superset of CSS. SCSS contains all the features of CSS, but is extended to include the features of Sass as well. However, SCSS must be compiled into CSS before it can be installed and used in the Developer Portal.
4. Select the template to base your sub-theme on:
   - Default - the standard connect_theme that the Developer Portal is based on.
   - Business Mono - a black and white color theme.
   - Sapphire Blue - a blue color theme.
   - Emerald Green - a green color theme.
   - Golden Brown - a brown color theme.
   - Ruby Red - a red color theme.
5. Click Generate.
   Your sub-theme is available to download from the Generate sub-theme page.
6. Click your new sub-theme and save it to your preferred location.
7. Extract the resources from the sub-theme file, and then edit the specific resources to configure the customizations that you require.
   Define your theme by creating metadata in the *your_theme_name*.info.yml file. You can then customize the appearance of your theme by configuring the overrides.css file. For detailed information about how to customize themes, see Theming Drupal.
8. After you have completed your customizations, compress the sub-theme resources back into the .zip file.
   Note that the following file extensions are also supported: tar, tgz, gz, and bz2.
9. Install your new sub-theme onto the Developer Portal by clicking Appearance > Install new theme.
10. Click Choose file, select your sub-theme, and then click Install.
11. Click Install newly added theme, find your new theme in the list of Uninstalled themes, and click Install and set as default to set your new custom sub-theme as the default theme for your site.
    Your new theme is now set as the default theme, and is listed in the Installed themes section.

Results

You created and installed a new sub-theme for your Developer Portal site.

What to do next

You can edit the display settings for your new theme, by clicking Settings next to your theme.

Related information

- Tutorial: Creating a custom theme for the Developer Portal

Installing additional themes

You can install additional themes in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To install additional themes, complete the following steps:

1. Click Appearance in the administrator dashboard.
2. Click + Install new theme.
3. You can enter a path to the theme in the Install from a URL field. Alternatively, you can upload a theme under the Upload a module or theme archive to install heading.
4. Click Install.
5. Click Enable newly added themes.

6. Click Enable and set default for the theme that you want to be displayed in the Developer Portal.
   Your theme is displayed in the Developer Portal when you navigate to the home page.

Deleting themes

You can delete a theme from your Developer Portal site.

Before you begin

You must have administrator access to complete this task.

About this task

If you have a custom theme which is disabled, you can remove it from the Developer Portal. Deleting a theme is useful if you have identified a theme that you do not want to use again.

Procedure

1. Click Appearance from the administrator dashboard.
2. Identify the custom theme that you want to delete, and ensure that it is disabled.
3. Click Delete against the theme.
   The theme is now deleted from your Developer Portal site.

Results

You deleted a disabled theme in the Developer Portal.

Content

Control multiple content entities in the Developer Portal, including the customization and restriction of specific content.

A *content entity* is an item of content data, which can consist of text, HTML markup, images, attached files, and other data that is intended to be displayed to site visitors. Content entities can be defined by the core software or by modules. Content entities are grouped into *entity types*, which have different purposes and are displayed in different ways on the site. Most entity types are also divided into *entity sub-types*, which are divisions within an entity type to allow for smaller variations in how the entities are used and displayed.

The Developer Portal site contains the following content entity types:

- API
- Application
- Article
- Basic page
- Blog post
- Book page
- Consumer Organization
- FAQ
- Forum Topic
- Product

Within content entity items the data is stored in individual *fields*, each of which holds one type of data, such as formatted or plain text, images or other files, or dates. Field types can be defined by the core software or by modules.

Fields can be added by an administrator on content entity sub-types, so that all the entity items of a given entity sub-type have the same collection of fields available. When you create or edit entity items, you are specifying the values for the fields on the entity item.

To learn how to configure the content entities of your Developer Portal site, use the following topic links.

- **Adding content elements in the Developer Portal**
  You can add content elements in the Developer Portal.
- **Configuring and restricting content in the Developer Portal**
  You can configure and restrict certain content elements in the Developer Portal.
- **Turning content on or off in the Developer Portal**
  You can turn certain content elements on or off in the Developer Portal

Adding content elements in the Developer Portal

You can add content elements in the Developer Portal.

To learn how to add various content elements in the Developer Portal, use the following topic links:

- **Adding and configuring meta tags**
  You can customize the Developer Portal by adding and configuring meta tags.
- **Adding custom pages**
  You can create custom pages within the Developer Portal. You can add a basic page for static content, or an article for news content.
- **Integrating Twitter data into the social block**
  You can retrieve and integrate data from a Twitter account of interest and display it into a social block in a Developer Portal site.
- **Adding content in multiple languages**
  You can create content in multiple languages in the Developer Portal.
- **Adding custom pages to APIs and Products**
  After you create a custom page in the Developer Portal, you can add a link to the new page to any APIs and Products that exist in the Developer Portal.
- **Adding new frequently asked questions**
  You can add new FAQs to the Developer Portal.
- **Applying an image to an API or Product**
  You can apply an image to an API or a Product in the Developer Portal.
- **Attaching a documentation file to APIs**
  You can attach a file to APIs in the Developer Portal, and display them as documentation attachments. You can attach multiple files to APIs.
- **Configuring blogs**
  You can post new blog entries in the Developer Portal, and configure them to suit your requirements. You can also turn blogs off.
- **Configuring the taxonomy menu block**
  To display your tag hierarchy in the Developer Portal, you must configure the taxonomy menu block.
- **Customizing the URL alias for a specific API or Product page**
  You can customize the URL of an API or Product page from the default alias that they are assigned.
- **Embedding multimedia in site content**
  You can embed multimedia elements in site content in the Developer Portal.
- **Linking from one piece of site content to another**
  You can link from one piece of site content to another in the Developer Portal.
- **Linking to social media sites**
  You can link to social media sites from the Developer Portal. You can configure where and how these links are displayed and which sites you want to link to.
- **Managing tags in the Developer Portal**
  These instructions show you how to add new tags to your taxonomy, and how to manage the tag hierarchy in the Developer Portal. You can use tags to classify your Developer Portal content.
- **Posting a poll**
  You can post a poll in the Developer Portal.
- **Adding images to site content**
  You can add .jpg, .png and .gif images to your site content in the Developer Portal.

Adding and configuring meta tags

You can customize the Developer Portal by adding and configuring meta tags.

Before you begin

You must have administrator access to complete this task.

About this task

Meta tags provide preview information that is displayed for a link to a website. The preview information can include images, descriptions, tags, and links. Meta tags are used when you link to external website, for example Facebook, Twitter, and Slack.

You can see which entities have the meta tag form available on their respective edit pages by default, and can be configured, Configuration > Search and metadata > Metatags > Settings:

- CONTENT
  - API
  - APPLICATION
  - ARTICLE
  - BLOG POST
  - BOOK PAGE
  - CONSUMER ORGANIZATION
  - FAQ
  - FORUM TOPIC
  - BASIC PAGE
  - PRODUCT
- TAXONOMY TERM
  - FORUMS
  - TAGS
- USER
  - USER

Procedure

1. In the administrator dashboard, click Extend > Update, then click List.
2. Enter `meta tag` in the Filter list field.
3. Select the check boxes for the Meta tags you want to enable, click Enable.

- **Disabling external search engine indexing**
  If you do not want your Developer Portal site content to be indexed by external search engines, then you can disable the indexing.

Disabling external search engine indexing

If you do not want your Developer Portal site content to be indexed by external search engines, then you can disable the indexing.

Before you begin

You must have administrator or content author access to complete this task.

About this task

By disabling the external search indexing, you can increase the confidentiality of your content and restrict its exposure.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. On the administrator dashboard, click Configuration.
3. In the SEARCH AND METADATA section, click Metatag.
4. Click Edit for the GLOBAL type.
5. Expand the ADVANCED section and, in the Robots section, select Prevents search engines from indexing this page.
6. Click Save.

Results

You have disabled external search engine indexing.

Adding custom pages

You can create custom pages within the Developer Portal. You can add a basic page for static content, or an article for news content.

Before you begin

You must have administrator or content author access to complete this task.

About this task

Use basic pages for your static content, such as an "About us" page. Typically, a basic page is used for static content that can be linked into the main navigation bar, although this is not a requirement. Use articles for time-sensitive content, like news, press releases, or blog posts.

Procedure

To add custom pages, complete the following steps.

1. Log in to the Developer Portal as an administrator or content author.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. In the administrator dashboard, click Content.
4. Click +Add content, then click either Basic page or Article, depending on the type of content you want to display.
5. Enter a page title, select the language, and enter the content.
6. Specify the remaining page options as required.
   If you want your new page to be linked to from a menu, you must complete the Menu settings section.
7. Optional: Click Edit summary and specify a summary page description.
8. Click Save to publish the new page immediately. If you don't want to publish the new page immediately, ensure that you deselect Published before saving.

Results

You added a new custom page to the Developer Portal. You can edit the page after it is created by clicking Edit for the custom page.

Integrating Twitter data into the social block

You can retrieve and integrate data from a Twitter account of interest and display it into a social block in a Developer Portal site.

Before you begin

You must have administrator access to complete this task.

You must have a Twitter App for the Twitter account of interest. The Twitter App contains information that is used to configure the social block. For information on creating Twitter Apps, see https://apps.twitter.com/.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. On the administrator dashboard, click Configuration.
3. In the WEB SERVICES section, click IBM Social Block settings.
4. Using the information from your Twitter App, enter the Consumer Key, Consumer Secret, Access Token, and Token Secret in the corresponding fields.
5. Click Save configuration.
   Twitter data from a Twitter account of interest has been integrated with the Developer Portal, and is displayed on the social block of the site.

- **Editing the social block**
  After you have integrated Twitter data into the Developer Portal social block, you can edit the content, appearance, and functionality of the social block.

Editing the social block

After you have integrated Twitter data into the Developer Portal social block, you can edit the content, appearance, and functionality of the social block.

Before you begin

You must have administrator access to complete this task.

You must have Twitter data integrated into the Developer Portal social block. For more information, see Integrating Twitter data into the social block.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. On the administrator dashboard, click Structure > Pages.
3. Click Edit next to the Welcome page (or next to the page that contains the social block that you want to edit).
4. From the Variants navigation tree, select Panels > Content, and click Edit next to the Social Block.
   The Edit block window is displayed.
5. Edit the social block by configuring any of the following options:

   Title
   : Update the title as required.

   Number of tiles to display
   : Configure the number of tiles that you want to display on the social block by entering a number in the Number of tiles to display field. The default number of tiles that are displayed on the social block is 9, and there is a limit of 100 tiles.

   FORUM
   : Use the check boxes to specify the forum topics that you want to display.

   Get tweets from
   : From the Get tweets from drop-down list, select whether you want to display Twitter data from users or a search term.

   Twitter search parameter
   : Enter the Twitter search parameter.

   Types of tweets to display
   : Select the types of tweets that you want to display from the drop-down list. You can select to display tweets, or tweets and replies.

6. After you have configured the social block, click Update block.
   Your social block is configured, and the configurations are implemented when you return to the home page.

Adding content in multiple languages

You can create content in multiple languages in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

About this task

You can provide custom pages in multiple languages to your APIs and Products to improve your customer experience and understanding. By default, multiple languages are enabled in the Developer Portal.

Note: In API Designer, translations for APIs and products must be done within a document. For more information, see Using `x-ibm-languages` to create multilingual API and Product documentation.

Procedure

1. Log in to the Developer Portal as an administrator or content author.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Content.

4. If you are creating a new page to be translated, click +Add content.
    a. Click Basic page, then select type, for example **`Basic page`**.
    b. Enter a title for your custom page in the Title field.
    c. Enter your information in the Body field.
    d. Click Save.
    e. Click Translate.
    f. Click Add for the language you want to translate.
    g. Provide the language content.
    h. Click Save (this translation).
5. If you are translating an existing page, find the page that you want to update in the list.
    a. Click Translate from the drop-down list for the page.
    b. Click Add for the language you want to translate.
    c. Provide the language content.
    d. Click Save (this translation).

Results

You successfully created a translated version of your content.

Adding custom pages to APIs and Products

After you create a custom page in the Developer Portal, you can add a link to the new page to any APIs and Products that exist in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

You must have an API or Product to add the custom page to.

About this task

You can add custom pages to your APIs and Products to provide further information on their use and value.

For example, you can create a custom documentation page on the implementation of an API in a specific circumstance, and add this custom documentation page to the API.

Procedure

1. Log in to the Developer Portal as an administrator or content author.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Content, then click +Add content.
4. Click Basic page.
   The Create Basic page window is displayed.
5. Enter a title for your custom page in the Title field.
6. Enter your information of interest in the Body field.
7. If you want to add the custom page to a specific Product, enter the Product name in the Link to one or more specific Products field. As you type into this field, a list of available Products is displayed for you to select. You can add more Products by clicking Add another item. If you want to add the custom page to all Products, select the Link to all Products check box.
8. If you want to add the custom page to a specific API, select the APIs tab, and then enter the API name in the Link to one or more specific APIs field. As you type into this field, a list of available APIs is displayed for you to select. You can add more APIs by clicking Add another item. If you want to add the custom page to all APIs, select the Link to all APIs check box.
9. Optional: Configure the additional settings of the custom page to your specification.
10. Click Save.

Results

Your custom page is created and linked to the APIs or Products that you have specified. You can edit the page after it is created, and update the APIs and Products that it is linked to, by clicking Edit for the custom page.

Adding new frequently asked questions

You can add new FAQs to the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

About this task

To add new FAQs, you create a new FAQ node and add questions and answers to that node. Each FAQ node represents an FAQ topic, and each topic can contain multiple questions and answers.

Procedure

To add new FAQs, complete the following steps:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Content in the administrator dashboard.
4. Click +Add content.
5. Click FAQ.
   The Create FAQ page displays.
6. Provide a Title for the new FAQ topic.
7. Enter the question in the Question field, and enter the answer in the Answer field.
8. Optional: If you have more content for this FAQ topic, click Add another item and complete the Question and Answer fields. Repeat this step as required.
9. Click Save to save your new FAQ topic.
   Your new FAQ topic is displayed in the Support section of the Developer Portal.

Results

You successfully added new FAQs to the Developer Portal.

What to do next

You can edit the current content of FAQs by clicking Content in the administrator dashboard, finding the FAQ content that you want to edit, and clicking Edit against that FAQ.

Applying an image to an API or Product

You can apply an image to an API or a Product in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To add an image to an API or Product, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. Click Edit next to the API or Product that you want to edit.
4. Under the Image heading, click Choose File to select an image.
5. Click Save and keep published, to publish the updated content,or select Save and unpublish if you want to publish the updated content later.
   You have added a new picture to the selected API or Product.

Attaching a documentation file to APIs

You can attach a file to APIs in the Developer Portal, and display them as documentation attachments. You can attach multiple files to APIs.

Before you begin

You must have administrator or content author access to complete this task.

About this task

You can attach only one file at a time. The default file upload size limit applies to the files that you want to attach, and you can attach up to 10 files to an API by default.
Note: You can change the default limit for the number of files that you want to attach.
An administrator can configure the types of file that are uploaded, and the number of files that a user can upload.

The following file types can be uploaded:

- txt doc pdf
- xls ppt pptx
- docx xlsx rtf
- odt ods odp md json
- yaml tgz tar zip

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. Click Edit next to the API you want to attach the file to.
4. In the Documentation section, click Browse and identify the file that you want to upload, then click Open.
5. Click Upload, then click Save.
6. Optional: Clear the Display checkbox for the file if you want to upload and attach the file to the API, but not show it in the Developer Portal.
7. Optional: Enter a description for your file in the Description field. This description can be used as the label of the link to the file.
8. Optional: If you uploaded multiple files, you can use the drag handle next to the file name to rearrange them.

Results

You successfully attached a documentation file to your API.

Configuring blogs

You can post new blog entries in the Developer Portal, and configure them to suit your requirements. You can also turn blogs off.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To post a new blog entry, complete the following steps:

- If the administrator dashboard is not displayed, click Manage to display it.
- Click Content in the administrator dashboard.
- Click Add content.
- Click Blog post.
- Fill in the Title and Body fields.
- Click Save and keep published, to publish the updated content,or select Save and unpublish if you want to publish the updated content later.
  You have posted a new blog entry.

To configure a blog post, complete the following steps:

- If the administrator dashboard is not displayed, click Manage to display it.
- Click Content in the administrator dashboard.
- Click Edit next to the blog post that you want to configure.
- You can configure the selected blog from this view.
- Click Save and keep published, to publish the updated content,or select Save and unpublish if you want to publish the updated content later.
  You have configured the selected blog post.

Configuring the taxonomy menu block

To display your tag hierarchy in the Developer Portal, you must configure the taxonomy menu block.

Before you begin

You must have administrator or content author access to complete this task.

About this task

Along with controlling how your tag hierarchy is displayed through configuring your taxonomy menu block, you can configure options for the taxonomy tree. The following options can be configured for your taxonomy menu block:

- Vocabulary
- Parent option
- Depth
- Node options and content
- Region settings
- Visibility settings

Important: The taxonomy block will appear after configuration only if there are tags for it to display.

Procedure

1. In the Administrator dashboard, click Structure > Blocks.
2. Click configure for the Taxonomy Menu Block (Tags) block.
3. Configure the options that are available for your taxonomy menu block.
4. When you have configured your taxonomy menu block, click Save block.
   You have configured your taxonomy menu block, and your tag hierarchy is displayed based on your configurations.

Customizing the URL alias for a specific API or Product page

You can customize the URL of an API or Product page from the default alias that they are assigned.

Before you begin

You must have administrator or content author access to complete this task.

About this task

Creating a custom URL, or path, alias is useful if you want to make the URL relevant to the API or Product page.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. On the administrator dashboard, click Content.
3. Identify the API or Product page that you want to customize the URL alias for, and click Edit.
4. In the Path Alias text field, enter the custom URL alias that you want to assign your API or Product page.
   Note: All Path Alias must be unique, and can contain only the following characters: [A-Za-z0-9_-.].
5. Click Save to publish the updated content.

Results

You have applied a custom URL alias for your specified API or Product page, and it is displayed in the URL of your browser when the API or Product page is selected. Depending on whether it is added to an API or a Product page, the application of the Path Alias differs. For example, if you add `my_new_path_alias`, you will have:

- `<my_site_url>/api/my_new_path_alias` for an API
- `<my_site_url>/product/my_new_path_alias` for a Product

Embedding multimedia in site content

You can embed multimedia elements in site content in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To embed multimedia in site content, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. Under the TITLE heading, click the title of the required content.
4. Click the Edit tab.
5. Use the Insert Media Embed icon  in the in the WYSIWYG editor to embed multimedia in the content.
   Note: The Insert Media Embed icon is available only if you have selected Full HTML mode.
6. Click Save and keep published to publish the new page immediately, or select Save and unpublish if you want to publish the page later.
   You have embedded multimedia in the selected site content.

Linking from one piece of site content to another

You can link from one piece of site content to another in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To link from one piece of site content to another, complete the following steps:

1. Click Content in the administrator dashboard.
2. Under the TITLE heading, click the title of the required content.
3. Select the Edit tab.

4. Use the Link to content icon  in the WYSIWYG editor.
5. Click Save.
   You have linked the selected site content to another site content element.

Linking to social media sites

You can link to social media sites from the Developer Portal. You can configure where and how these links are displayed and which sites you want to link to.

Before you begin

You must have administrator access to complete this task.

Procedure

1. Click Structure in the administrator dashboard.
2. Click Blocks.
3. Under the Disabled heading, locate the Follow site block.
4. Select the location for your social media block from the drop-down list for Follow Site in the REGION column.
   The Follow Site block will appear under the heading that corresponds to the region you selected in the REGION drop-down list.
5. Required: Click Save blocks before you begin configuring your new block.
6. Click configure for the Follow Site block.
7. In the Block title field, type the name of your block.
8. Under the Default block title heading, select one of the following leading text options for your block using the radio buttons for each option:
   - "Follow *your.portal.site* on"
   - "Follow me on"
   - "Follow us on"
9. Use the User pages check box to decide whether you want your block to display on your user's profile pages.
10. Use the Alignment and Icon Style drop-down lists to adjust the appearance of your block.
11. Click Save block.
12. Click Configuration in the administrator dashboard.
13. Under the WEB SERVICES heading, click Follow.
14. Type the URL under the URL heading for each of the social media sites you want your users to access. The following is an example of a link to the @ibmapiconnect twitter handle:

    ```
    https://twitter.com/ibmapiconnect
    ```

15. Click Submit.

Managing tags in the Developer Portal

These instructions show you how to add new tags to your taxonomy, and how to manage the tag hierarchy in the Developer Portal. You can use tags to classify your Developer Portal content.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To manage your tags, complete the following steps

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure > Taxonomy > Tags in the administrator dashboard.
   The List window for Tags is displayed.
3. You can add new terms, delete, and reorganize terms from this view.
   a. To add a new term, click Add term, define the new term, then click Save.
   b. To delete a term, select Delete from the OPERATIONS menu next to the term that you want to delete. Then click Delete to confirm.
   c. To reorganize terms, ensure that the row weights are hidden by clicking Hide row weights if necessary, then use the drag-and-drop handles to manage the tag hierarchy. Terms can be dragged to organize a parent grouping hierarchy. Then click Save.

- **Tagging APIs based on their lifecycle phase**
  In the Developer Portal, you can have APIs automatically tagged with their lifecycle phase; realized, identified, or specified.

Related tasks

- Editing tags for a specific item

Tagging APIs based on their lifecycle phase

In the Developer Portal, you can have APIs automatically tagged with their lifecycle phase; realized, identified, or specified.

Before you begin

You must have administrator or content author access to complete this task.

About this task

APIs are tagged in the API Manager with a lifecycle phase as follows:

- Realized (default) - The API is in the implementation phase.
- Identified - The API is in the early conceptual phase and is neither fully designed nor implemented.
- Specified - The API has been fully designed and passed an internal milestone, but has not yet been implemented.

You can configure the Developer Portal to tag APIs with their lifecycle phase automatically.

Procedure

Tagging APIs with their phase is disabled by default. To enable the function:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. On the administrator dashboard, click Configuration.
3. In the SYSTEM section, click IBM API Connect.
4. Select Automatically tag APIs with their phase, and then click Save configuration.

What to do next

You can manage the tag hierarchy of your APIs. For more information, see Managing tags in the Developer Portal.

Posting a poll

You can post a poll in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To post a poll, complete the following steps:

1. Click Content in the administrator dashboard.
2. Click Add content.
3. Click Poll.
4. Enter the poll question in the Poll question field.
5. Under the Choice heading, add answers to the available fields as choices.
6. From the Poll duration drop-down menu, select a time limit for the poll.
7. Click Save.
   You have posted a poll.

What to do next

See Editing sample content to learn how to add a links to your poll to sample content.

Adding images to site content

You can add .jpg, .png and .gif images to your site content in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To upload images for use in site content, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. Under the TITLE heading, click the title of the required content.
4. Click the EDIT tab.

5. Use the Image icon  in the in the WYSIWYG editor to add an image.
6. Click Save and keep published to publish the new page immediately, or select Save and unpublish if you want to publish the page later.

Configuring and restricting content in the Developer Portal

You can configure and restrict certain content elements in the Developer Portal.

To learn how to configure and restrict content in the Developer Portal, use the following topic links:

- **Creating content types**
  Content types define default fields for editors to add content on your Developer Portal site and are the building blocks for authoring content. You can control which content types are available
- **Configuring documentation upload limitations**
  You can attach documentation to an API by uploading it in the Developer Portal. You can configure the API content type to place limitations on the uploaded documentation.
- **Configuring image upload limitations**
  You can attach an image file to an API by uploading it in the Developer Portal. You can configure the API content type to place limitations on the uploaded image files.
- **Configuring the appearance of ratings in the Developer Portal**
  You can configure the appearance of ratings in the Developer Portal.
- **Customizing the privacy policy statement**
  You can define and customize a privacy policy statement that sets out the privacy conditions of your Developer Portal site. The privacy policy can be linked to from the cookie compliance banner.
- **Customizing the terms of use statement**
  You can define and customize a terms of use statement that sets out the terms and conditions that your users must accept to use your Developer Portal site.
- **Editing a site comment**
  You can edit site comments in the Developer Portal.
- **Editing sample content**
  You can edit sample content, such as basic pages, in the Developer Portal.
- **Editing tags for a specific item**
  You can edit tags for a specific item in the Developer Portal.

Creating content types

Content types define default fields for editors to add content on your Developer Portal site and are the building blocks for authoring content. You can control which content types are available

Before you begin

You must have administrator access to complete this task.

About this task

After you create your content type, it is added to the following list of default content types that are present in the Developer Portal:

- API
- Application
- Article
- Basic page
- Blog post
- Book page
- Consumer organization
- Forum topic
- Product

The content type that you create, and the default content types, can be edited and configured further to your specifications.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Content types.
4. Click +Add content type.
5. Enter a name for your content type in the Name field.
6. Optional: Enter the text that you want to appear on the Add new content page, in the Description field.
7. Enter a title field label for your content type in the Title field label field.
8. Optional: Configure any of the following options for your content type:
   - Submission form settings
   - Publishing options
   - Language settings
   - Display settings

- Menu settings

9. After you have configured your content type to your specifications, click Save and manage fields.
   You have created a new content type.

What to do next

You can add fields to your new content type; see Adding fields to content types.

- **Adding fields to content types**
  Fields can be added to content types in the Developer Portal for customization, and to add functionality.

Adding fields to content types

Fields can be added to content types in the Developer Portal for customization, and to add functionality.

Before you begin

You must have administrator access to complete this task.

About this task

You can specify the type of data that a field can store, and the form element to edit the data with. The type of form element that is available is dependent on the type of data that your field stores.

Note: You can specify the number of values that a field can store, including an unlimited amount. You can configure the value after the field is created. Reducing the number of values that can be stored after the field is created might lead to data loss.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Content types, and identify the content type that you want to add a field to.
4. Click Manage fields for the content type, then click Add field.
5. Select a field type or select an existing field to reuse, then enter a label for your field in the Label field.
   The label that you specify for your field is displayed in the UI.
6. Optional: If you want to edit the machine name that is automatically created based on your label, click Edit and enter the new name.
   You cannot change the machine name after the field is created.
7. Click Save and continue.
8. Modify the field type specific settings as required, then click Save field settings.
   You have added a field to your content type.

Configuring documentation upload limitations

You can attach documentation to an API by uploading it in the Developer Portal. You can configure the API content type to place limitations on the uploaded documentation.

Before you begin

You must have administrator access to complete this task.

About this task

The set of configurable limitations that you can place on uploading documentation is different to the set of limitations that you can place on uploading images.

The file size limit that is applied when you upload documentation is also different to the limit that is applied when you upload images.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structurein the administrator dashboard.
3. Click Content types.
4. For the API content type, click Manage fields.
5. For the Documentation field, click Edit.
6. Configure the type of files that are allowed to be uploaded in the Allowed file extensions field.
7. Enter the file size upload limit in the Maximum upload size field.
   The default size is 10MB, while the maximum upload size possible is 64MB.
8. Click Save settings.
   You have configured the documentation upload limitations.

Configuring image upload limitations

You can attach an image file to an API by uploading it in the Developer Portal. You can configure the API content type to place limitations on the uploaded image files.

Before you begin

You must have administrator access to complete this task.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structurein the administrator dashboard.
3. Click Content types.
4. For the API content type, click Manage fields.
5. For the Image field, click Edit.
6. Configure the type of image files that are allowed to be uploaded in the Allowed file extensions field.
7. Specify the maximum and minimum allowed image sizes in the Maximum image resolution and Minimum image resolution fields.
8. Enter the file size upload limit in the Maximum upload size field.
   The default size is 2MB, while the maximum upload size possible is 64MB.
9. Click Save settings.
   You have configured the image upload limitations.

Configuring the appearance of ratings in the Developer Portal

You can configure the appearance of ratings in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

You can configure the appearance of ratings for only the following content types in the Developer Portal:

- APIs
- Applications
- Products

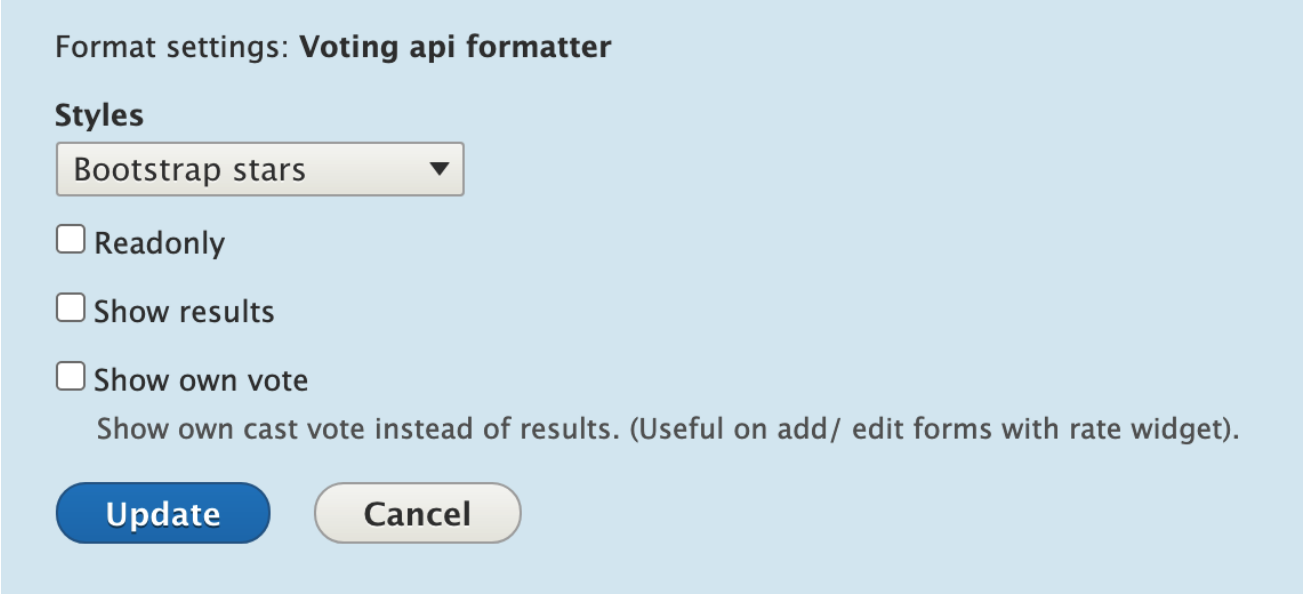
Note: The Applications and Products content types rating functionality is set to hidden by default.

Procedure

These following steps describe how to customize the rating on a selected API, Application, or Product. To ensure that the configured rating is also displayed in the list view of APIs, Applications, or Products, then you must repeat these steps on the Teaser tab in the Manage Display window:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Content types.
4. Select Manage display from the list in OPERATIONS column, next to the required content type.

5. Click the Settings icon , then select the style you require, then click Update.



6. Click Save. You have configured the appearance of the ratings feature for the required content type.

Customizing the privacy policy statement

You can define and customize a privacy policy statement that sets out the privacy conditions of your Developer Portal site. The privacy policy can be linked to from the cookie compliance banner.

Before you begin

You must have administrator access to complete this task.

Procedure

To define or customize a privacy policy, complete the following steps:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Content, then enter `privacy` into the title search filter, and click Filter.
   The Privacy Policy content item is displayed in the list of content.
4. Click Edit next to the Privacy Policy content item.
5. Update the content as required. For example, you can complete the following tasks:
   a. Edit the text of the privacy policy statement.
   b. Set the display settings.
   c. Link the content to Products and APIs.
   d. Enter an explanation of the changes that have been made to the privacy policy since the last version.
6. Click Save to save your changes.

Results

The privacy policy statement is successfully updated.

What to do next

You can set your cookie compliance banner to link to your updated privacy policy. For more information, see Enabling a cookie compliance banner.

Related tasks

- Enabling a cookie compliance banner
- Customizing the terms of use statement

Customizing the terms of use statement

You can define and customize a terms of use statement that sets out the terms and conditions that your users must accept to use your Developer Portal site.

Before you begin

You must have administrator access to complete this task.

Procedure

To define or customize a terms of use statement, complete the following steps:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Content, then enter `terms` into the title search filter, and click Filter.
   The Terms of use content item is displayed in the list of content.
4. Click Edit next to the Terms of use content item.
5. Update the content as required. For example, you can complete the following tasks:
   a. Edit the text of the terms of use statement.
   b. Set the display settings.
   c. Link the content to Products and APIs.
   d. Enter an explanation of the changes that have been made to the terms of use since the last version.
6. Click Save to save your changes.

Results

The terms of use statement is successfully updated.

What to do next

You can force new users to accept the terms and conditions on the Developer Portal. For more information, see Forcing new users to accept terms and conditions.

Related tasks

- Enabling a cookie compliance banner
- Customizing the privacy policy statement

Editing a site comment

You can edit site comments in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To edit a site comment, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. Click the Comments tab.
4. In the OPERATIONS column, click Edit alongside the comment that you want to edit.
5. Edit the content of the comment as required.
6. Click Save.
   You have edited the selected comment.

Editing sample content

You can edit sample content, such as basic pages, in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To edit sample content, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. In the OPERATIONS column, click Edit alongside the content item that you want to edit.
4. Edit the sample content of the selected element as required.

5. Click Save and keep published, to publish the updated content,or select Save and unpublish if you want to publish the updated content later.

Editing tags for a specific item

You can edit tags for a specific item in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

You must have some tags that are available to apply to your content; see Managing tags in the Developer Portal.

Procedure

To edit tags for a specific item, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. In the list of content items, click Edit alongside the content item that you want to update.
4. In the Tags section, select the required tag.
5. To add another tag, click Add another item, then select the required tag.
6. If you want to publish the updated content, ensure the Published check box is selected. Deselect the check box if you want to publish the updated content later.
7. Click Save.

Turning content on or off in the Developer Portal

You can turn certain content elements on or off in the Developer Portal

To learn how to turn content on or off in the Developer Portal, use the following topic links:

- **Deleting a site comment**
  You can delete site comments in the Developer Portal.
- **Deleting blocks**
  You can delete blocks in the Developer Portal.
- **Disabling blogs**
  You can disable blogs on your Developer Portal.
- **Deleting forums from the front page**
  You can delete the help information on forums from the front page of your Developer Portal.
- **Turning comments for specific content types on or off in the Developer Portal**
  You can turn the comments for specific content types on or off in the Developer Portal.
- **Turning comments off for an individual item**
  You can turn off comments for individual items within a content type.
- **Turning off ratings for specific content types in the Developer Portal**
  You can turn off ratings for specific content types in the Developer Portal by hiding the ratings field.
- **Turning the ability to tag specific content types off in the Developer Portal**
  You can turn the ability to tag specific content types on or off in the Developer Portal.

Deleting a site comment

You can delete site comments in the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

Procedure

To delete a site comment, complete the following steps

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. Click the Comments tab.
4. From the UPDATE OPTIONS list, select Delete the selected comments.
5. Select the comments that you want to delete, then click Update.
   The confirmation screen displays.
6. Click Delete comments.

You have deleted the selected comments.

Deleting blocks

You can delete blocks in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Pages.
4. In the OPERATIONS column, find the welcome page row and select Edit from the drop-down list.
5. Expand Panels, then click Content.
6. In the OPERATIONS column, find the block that you want to delete and select Delete for the drop-down list
7. Click Delete to confirm, then click Update and save.

Disabling blogs

You can disable blogs on your Developer Portal.

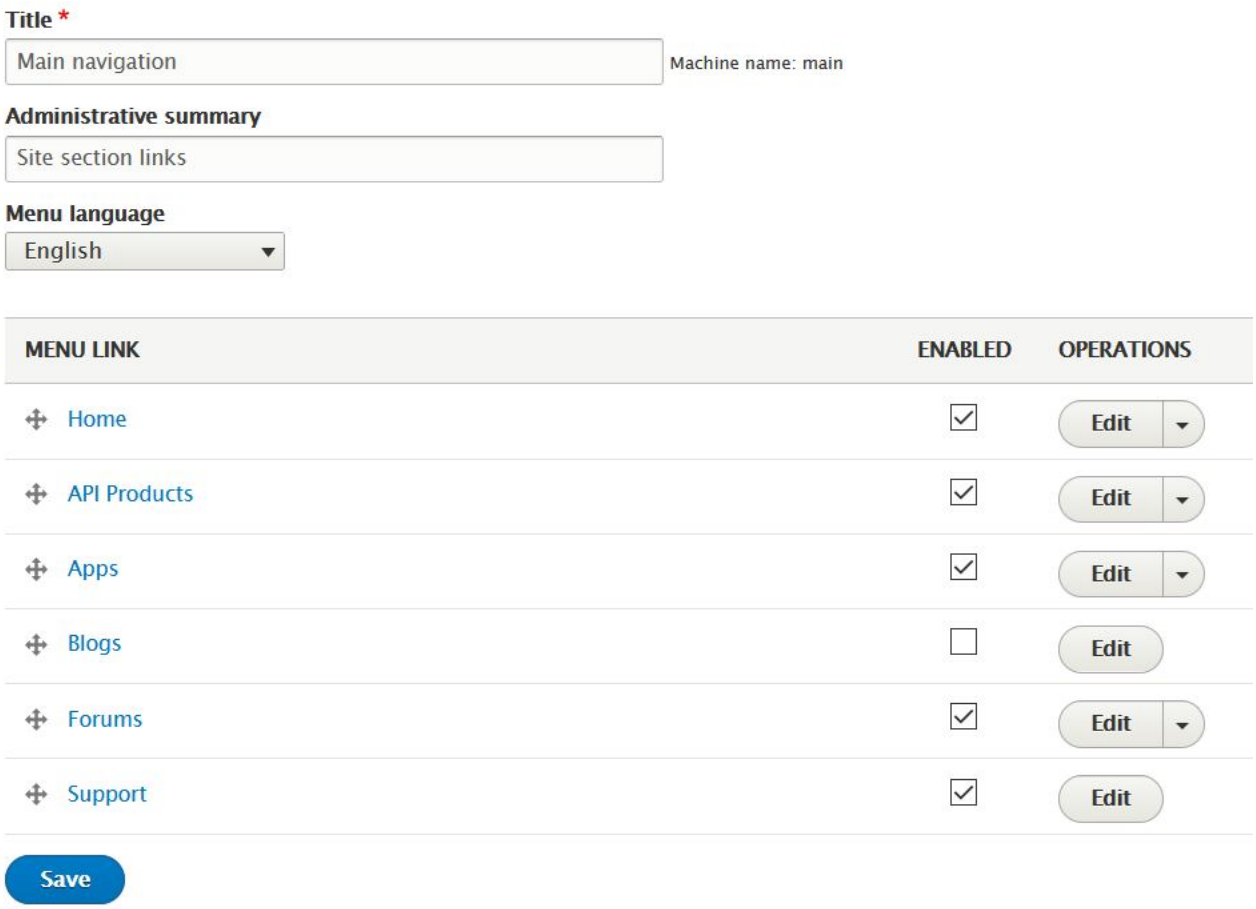
Before you begin

You must have administrator access to complete this task.

Before any changes are made, **`Blogs`** show as an option on the front page like this:

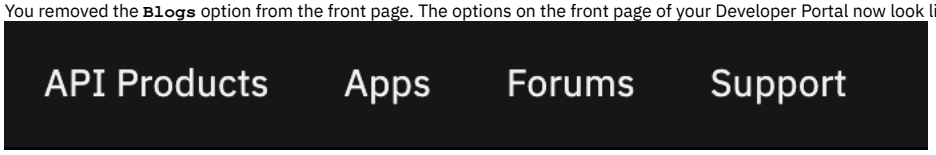
Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure > Menus from the administrator dashboard.
3. In the OPERATIONS column, click Edit menu for **`Main navigation`**.
4. Clear Enabled for the **`Blogs Menu link`**, then click Save.



Results

You removed the **Blogs** option from the front page. The options on the front page of your Developer Portal now look like this:



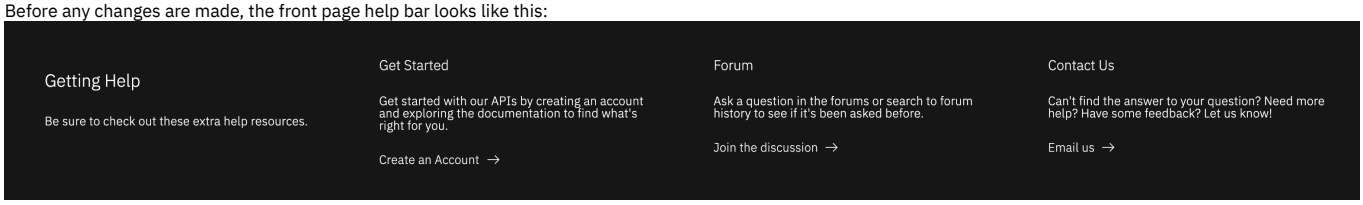
Deleting forums from the front page

You can delete the help information on forums from the front page of your Developer Portal.

Before you begin

You must have administrator access to complete this task.

Before any changes are made, the front page help bar looks like this:



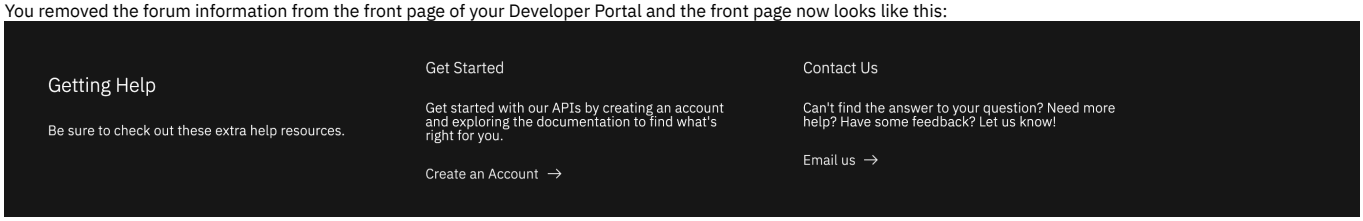
Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Block layout > Custom block library.
4. In Block description, enter `Get help`, then click Apply.

5. In the OPERATIONS column, click Edit for **`Get Help`**.
6. In the **`Body`** section, delete the forum information, then click Save.

Results

You removed the forum information from the front page of your Developer Portal and the front page now looks like this:



Turning comments for specific content types on or off in the Developer Portal

You can turn the comments for specific content types on or off in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To turn comments for specific content types on or off in the Developer Portal, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Content types.
4. In the OPERATIONS column, click Manage fields for the required content type.
5. In the OPERATIONS column, click Edit for the Comments field.
   Note:
   - If there is no Comments field, you can enable commenting for the selected content type by adding one as follows:
     - Click Add field.
     - From the Add a new field list, select Comments.
     - Enter a field label, then click Save and continue.
     - Select the required comment type, then click Save field settings.
   - You can completely disable commenting for the selected content type, and permanently remove all current comments, by selecting Delete.
6. Select the required option in the DEFAULT VALUE section.
   a. To allow commenting, select Open.
   b. To keep existing comments but disallow further commenting, select Closed.
   c. To hide all comments, select Hidden.
7. When done, click Save settings.

Turning comments off for an individual item

You can turn off comments for individual items within a content type.

Before you begin

Users with edit permission for the selected content type can perform this task.

Procedure

To turn off comments for a single item, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. In the OPERATIONS column, click Edit for the required content item.
4. Click Comment settings in the side pane.
5. Select Closed to turn comments off for the selected item.

6. Click Save.

Turning off ratings for specific content types in the Developer Portal

You can turn off ratings for specific content types in the Developer Portal by hiding the ratings field.

Before you begin

You must have administrator access to complete this task.

Procedure

To turn off ratings for specific content types in the Developer Portal, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Content types.
4. In the OPERATIONS column for the required content type, select Manage fields from the drop-down list.
5. Click on the Manage form display tab. In the FIELD list, select Rating and drag and drop it into the Disabled section, then click Save.
6. Click on the Manage display tab. Content items are displayed by using different view modes, such as Default, Card, and Teaser, and these modes are shown at the beginning of the Manage display page. For each view mode that is applicable to the content type you're editing, click the mode, and in the FIELD list select Rating, and drag and drop it into the Disabled section.
7. Click Save.

Turning the ability to tag specific content types off in the Developer Portal

You can turn the ability to tag specific content types on or off in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To turn the ability to tag specific content types on or off in the Developer Portal, complete the following steps:

1. Click Structure in the administrator dashboard.
2. Click Content types.
3. Click Manage fields next to the required content type.
4. From the Tags field, click Edit.
5. Click Delete, then confirm the Delete as the action cannot be undone.
   You have turned the ability to tag specific content types off.

Structure

Control the layout of the Developer Portal, such as configuring the front page, adding and changing blocks, and displaying Products and APIs in categories.

To learn how to control the layout of the content on your Developer Portal site, use the following topic links.

- **Configuring the front page**
  You can configure the Developer Portal front page.
- **Adding a menu**
  You can add a menu to the Developer Portal, and define the items that are included in the menu.
- **Adding and changing the blocks displayed on Developer Portal pages**
  You can add new blocks, and modify the existing blocks that are displayed on Developer Portal pages.
- **Changing the front page banner block**
  You can change the front page banner content and image that is displayed on the home page when a user first logs in to the Developer Portal.
- **Changing the front page Featured Content block**
  You can display featured Products or APIs on the front page of your Developer Portal by configuring the Featured Content block.
- **Changing the items in the main menu**
  You can change the items in the main menu that is displayed on all pages in the Developer Portal.
- **Changing the ratings display**
  You can change the appearance of the content ratings in the Developer Portal.
- **Displaying APIs and Products in categories**
  You can create taxonomies in the Developer Portal, which dictate the categorization of APIs and Products, and how they are displayed. The taxonomies that you define can be used by API developers to categorize APIs and Products in YAML files.
- **Implementing an image carousel**
  You can customize your Developer Portal home page to display images in a carousel. The image carousel provides your Developer Portal home page with a continuous slide show that is customized to your specifications.

- **Making your application's image public**
  You might want to display your application's image in an oauth authentication page to reassure customers that they are authenticating the correct application in the Developer Portal. That authentication uses a URL to the image that is stored on the Developer Portal. However, by default, those images are private unless you are logged in, which doesn't work if you want to display it in an oauth page. The solution is for the admin to change the **`application_image`** field to use public instead of private.
- **Providing navigation by tag hierarchy**
  You can provide the ability for users in the Developer Portal to navigate by using tag hierarchy.
- **Using the Views module in the Developer Portal**
  By using the Views module, you can fetch content from your Developer Portal site, and present it to users in different formats such as lists, graphs, and tables.

Configuring the front page

You can configure the Developer Portal front page.

Before you begin

You must have administrator access to complete this task.

About this task

Create a customized welcome page for your users. Note that blocks that are placed on the front page of the Developer Portal are visible to all users, regardless of whether the blocks have access restrictions placed on them. The visibility of blocks to all users also extends to the Featured Content block.

Procedure

To configure the front page, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure, then click Pages.
3. Alongside the welcome entry, click Edit.
4. Use the options provided to configure the front page.
   Here you can edit the page information, access, and configuration of the welcome page.
5. Click Update and save to save your changes.

What to do next

You can create a custom page. For more information, see Creating custom pages.

- **Disabling blogs**
  You can disable blogs on your Developer Portal.
- **Deleting forums from the front page**
  You can delete the help information on forums from the front page of your Developer Portal.

Related tasks

- Changing the front page banner block
- Changing the front page Featured Content block

Disabling blogs

You can disable blogs on your Developer Portal.

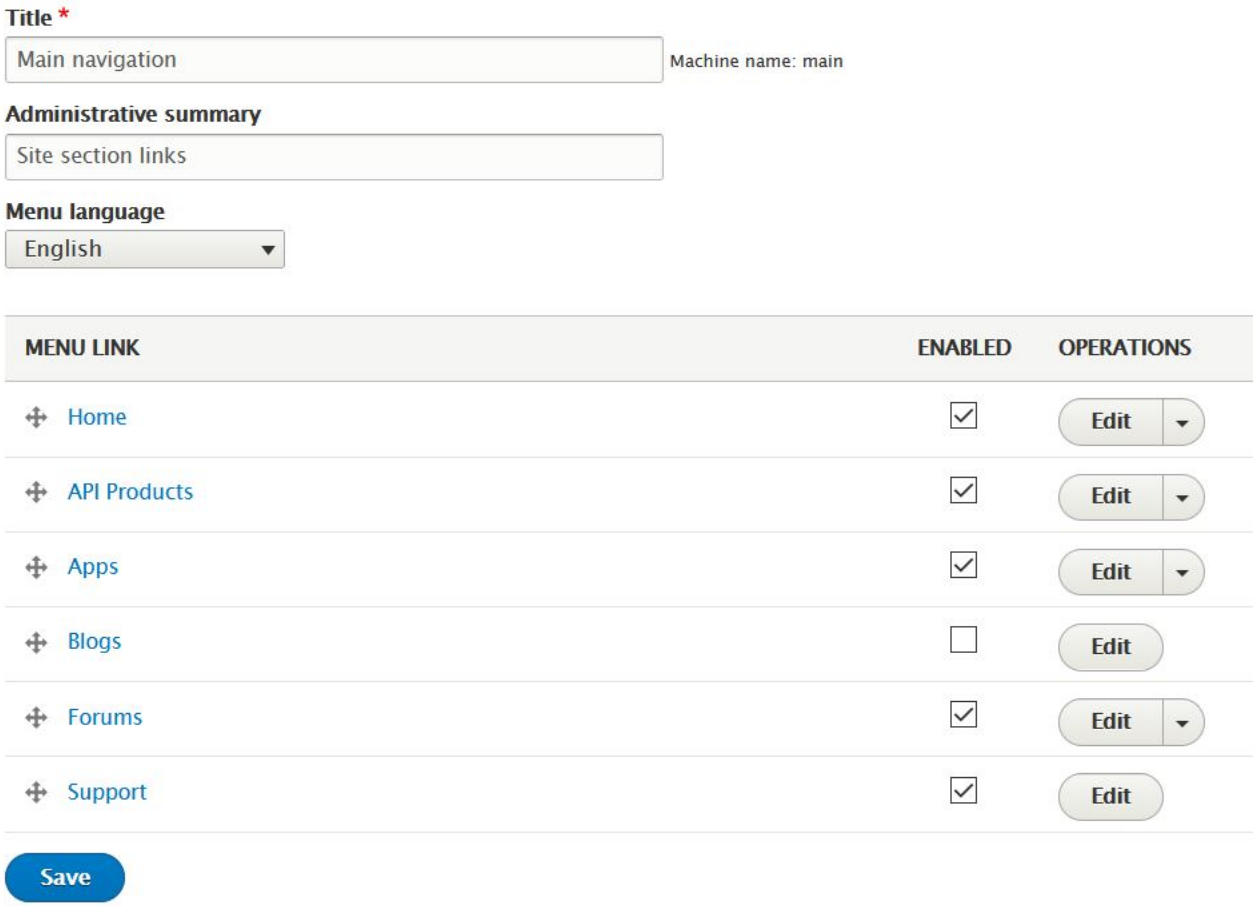
Before you begin

You must have administrator access to complete this task.

Before any changes are made, **`Blogs`** show as an option on the front page like this:

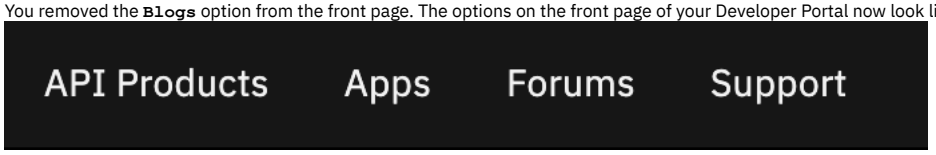
Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure > Menus from the administrator dashboard.
3. In the OPERATIONS column, click Edit menu for **`Main navigation`**.
4. Clear Enabled for the **`Blogs Menu link`**, then click Save.



Results

You removed the **`Blogs`** option from the front page. The options on the front page of your Developer Portal now look like this:



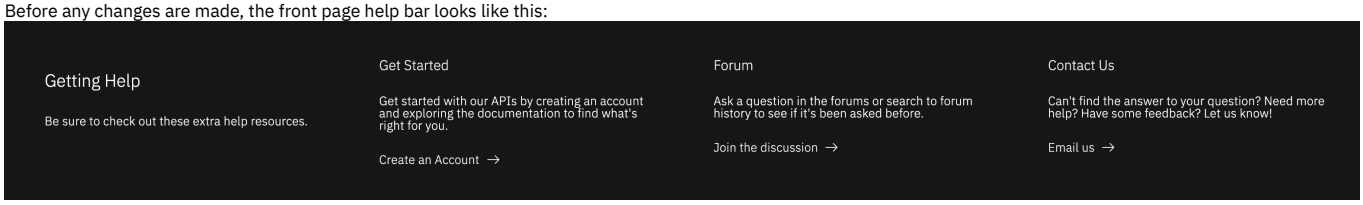
Deleting forums from the front page

You can delete the help information on forums from the front page of your Developer Portal.

Before you begin

You must have administrator access to complete this task.

Before any changes are made, the front page help bar looks like this:



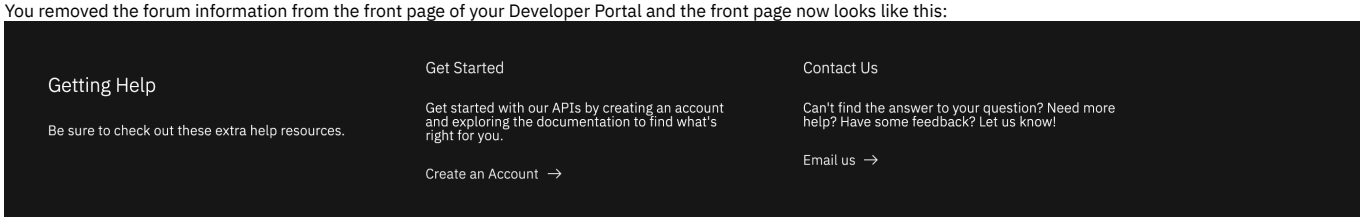
Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Block layout > Custom block library.
4. In Block description, enter `Get help`, then click Apply.

5. In the OPERATIONS column, click Edit for **`Get Help`**.
6. In the **`Body`** section, delete the forum information, then click Save.

Results

You removed the forum information from the front page of your Developer Portal and the front page now looks like this:



Adding a menu

You can add a menu to the Developer Portal, and define the items that are included in the menu.

Before you begin

You must have administrator access to complete this task.

Procedure

To add a menu, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure > Menus.
3. Click Add menu, provide a title, and an optional summary and menu language, and click Save.
4. To add items to your menu, click Add link, and configure the menu link details that you require.
5. Click Save to save your changes.
   A new block for your menu is created automatically, and your menu is now in the **`Menus`** list.

What to do next

You can use block configuration options to control which pages your menu is displayed on, and where it is positioned. You can use your menu with, or instead of, other menus available within the site. For more information, see Changing the blocks displayed on Developer Portal pages.

You can also update an existing menu, or change your menu. For more information, see Changing the items in the main menu.

Adding and changing the blocks displayed on Developer Portal pages

You can add new blocks, and modify the existing blocks that are displayed on Developer Portal pages.

Before you begin

You must have administrator access to complete this task.

About this task

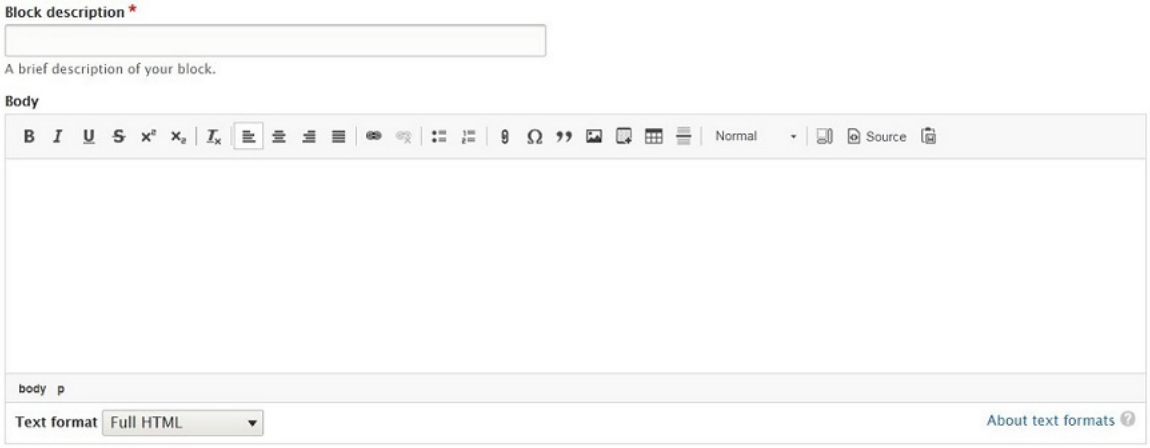
Blocks are boxes of content that are rendered into an area, or region, of a page. The content can be custom HTML, Github Markdown, or plain text, and you can specify the appearance, size, position, and also configure which pages a block appears on by editing its visibility settings. You can also modify an existing block to change its appearance, size, position, and visibility.

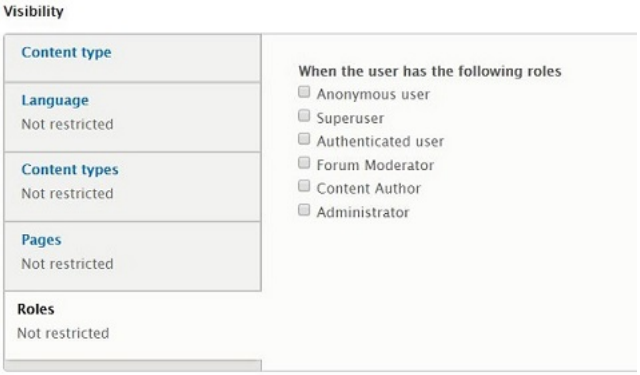
- Add a new block
- Edit the content of an existing block
- Modify the layout or visibility of an existing block

Procedure

To add a new basic block, complete the following steps.

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure, then click Block layout.
   All of the blocks that are in the system are displayed by theme. From the Block layout page you can assign blocks to a region, and control the order of the blocks within the region. Blocks are positioned on a per-theme basis, so if you enable more than one theme on your site, you can place blocks differently for each theme.
3. Click Place block > Add custom block.
   The Add custom block page is displayed.
4. Complete the Block description field.
5. Enter the content that you require for your block into the Body section.
   You can set the text format to Full HTML, Basic HTML, Restricted HTML, or Github Markdown. You can use the edit icons in the Body section to configure your content. Click the Source icon 

   to enter code source, such as HTML.
   


6. Click Save.
   The new custom block is saved and the Configure block page is displayed.
7. Complete the block Title field.
8. In the Visibility section, specify how you want the block to be displayed.
   You can specify the content types, configure the language settings, restrict the block to show only on pages that display specific content types, set which pages the block is displayed on, and restrict which user roles the block is visible to.
   


9. In the Region section, select the region where the block should be displayed.
10. Click Save block.
    The new custom block is added to your Developer Portal site.

To edit the content of an existing block, from the Block layout page complete the following steps.

11. Click the Custom block library tab (or select Structure > Block layout > Custom block library from the administrator dashboard).
12. Click Edit alongside the required block.
13. Change the block description and body content as required.
14. Click Save to save your changes.

To modify the layout or visibility settings of an existing block, from the Block layout page complete the following steps.

15. To change the region in which a block is positioned, select the required Region from the drop-down list next to the required block.
16. To change the vertical sort-order of a block within a region, drag the block to the required position.
17. To edit the visibility settings of an existing block, click Configure from the Operations drop-down menu next to the required block.
18. To enable or disable an existing block, select Enable or Disable from the Operations drop-down menu next to the required block.
19. Click Save blocks to save your changes.

Changing the front page banner block

You can change the front page banner content and image that is displayed on the home page when a user first logs in to the Developer Portal.

Before you begin

You must have administrator or content author access to complete this task.

About this task

You can change the front page banner by editing the Welcome Banner block in the custom block library.

Procedure

To change the front page banner block, complete the following steps.

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure > Block layout.
3. Select the Custom block library tab.
4. Click edit against the Welcome Banner block entry.
   The Edit Basic block Welcome Banner page is displayed.
5. Edit the Body section with the content and image that you require.
   You can set the text format to Full HTML, Basic HTML, Restricted HTML, or Github Markdown. You can use the edit icons in the Body section to configure your content. Click the Source icon 

   to view and edit the code source, such as HTML.
6. Configure the language and translation settings as required.
7. Click Save to save your changes.

Results

You successfully updated the front page banner block.

Related tasks

- Configuring the front page
- Adding and changing the blocks displayed on Developer Portal pages

Changing the front page Featured Content block

You can display featured Products or APIs on the front page of your Developer Portal by configuring the Featured Content block.

Before you begin

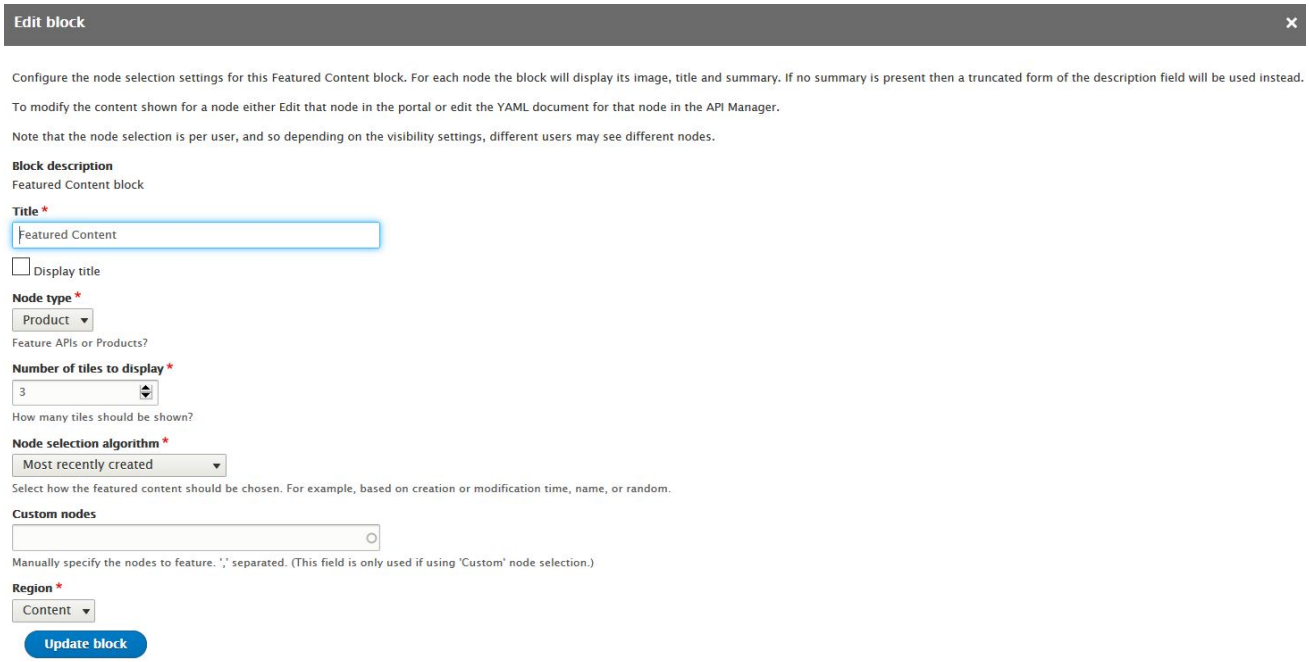
You must have administrator access to complete this task.

About this task

You can configure the Featured Content block on the front page of your Developer Portal. By default this block displays a list of the most recently created Products, but you can configure the block to display Products or APIs, and select how the featured content is chosen.

Procedure

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Structure > Pages.
4. Click Edit against the welcome page.
   The edit menu for the Welcome page is displayed.
5. Select Panels > Content from the navigation column, and then click Edit against the Featured Content block.
   The Edit block page for the Featured Content block is displayed.



6. Configure the Feature Content block as required.
   You can choose to display the title or not, select whether to use Products or APIs, for your node type. You can choose how many tiles to display, and select which algorithm is used to select the node. If you start typing in the **`Custom nodes`** field, you can choose from the options you are given.
7. Click Update block, then Update and save, to save your changes.

Results

You successfully configured the Featured Content block on the front page of your Developer Portal.

Changing the items in the main menu

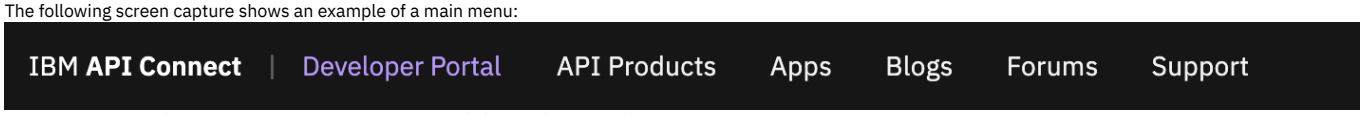
You can change the items in the main menu that is displayed on all pages in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

The following screen capture shows an example of a main menu:

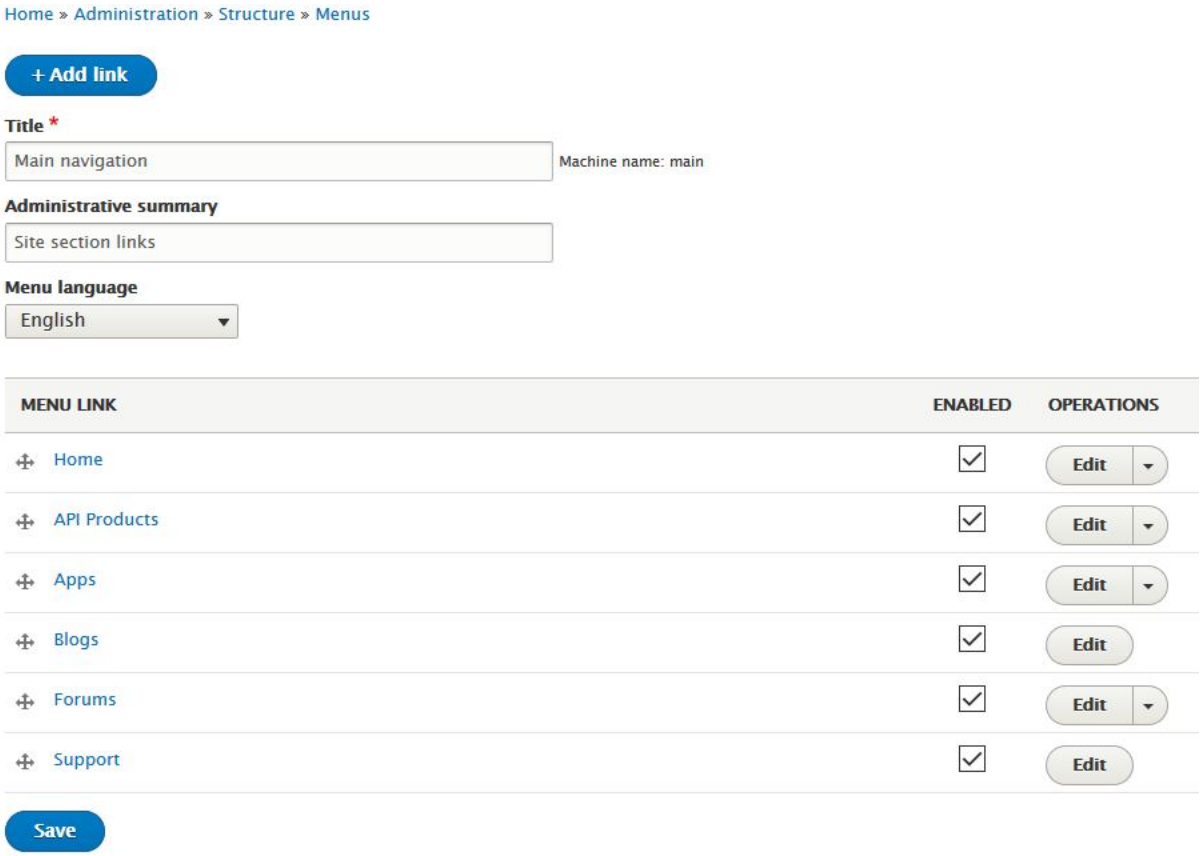


However, you can add new menu items, remove items, and change the item order.

Procedure

To change the items in the main menu, complete the following steps:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Structure > Menus > Main navigation.



4. Use the options provided to change the menu items.
5. Click Save to save your changes.

Changing the ratings display

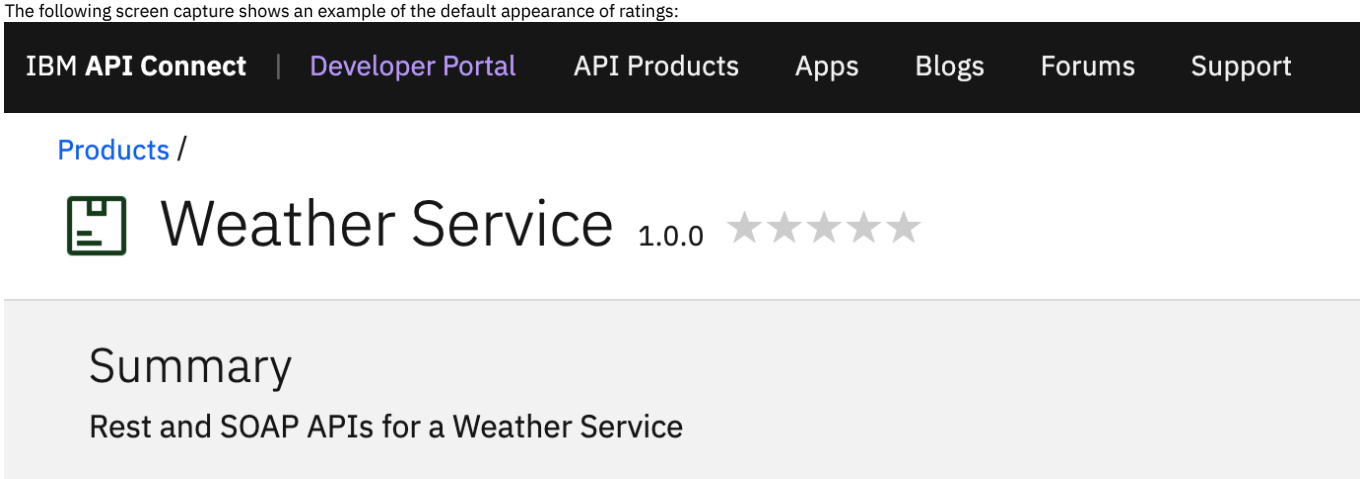
You can change the appearance of the content ratings in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

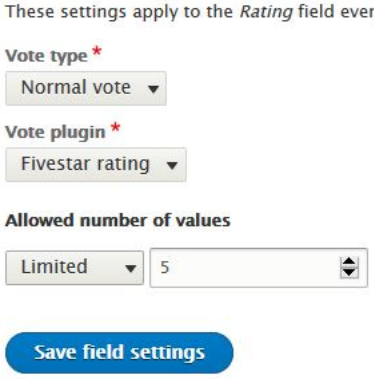
The following screen capture shows an example of the default appearance of ratings:



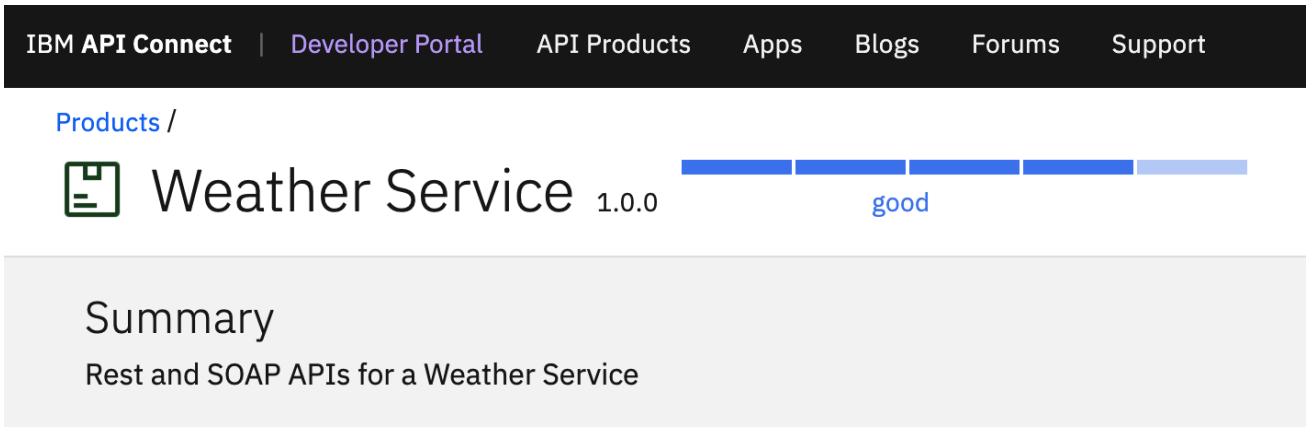
You can change this display if you want to.

Procedure

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Structure > Content types.
4. Click the Manage fields drop-down against the content type you want to change, for example **`Product`**.
5. Click Edit on the **`Rating`** row. Then, select the Field settings tab.



6. Change the style settings as required and click Save field settings.
   Here is an example of an alternative Ratings style:



Results

You successfully changed the ratings display for a content type in your Developer Portal.
Note: There are different view modes, and the settings would need to be changed for each view mode for each content type.

Displaying APIs and Products in categories

You can create taxonomies in the Developer Portal, which dictate the categorization of APIs and Products, and how they are displayed. The taxonomies that you define can be used by API developers to categorize APIs and Products in YAML files.

You might want to create taxonomies to control which set of APIs and products can and cannot be used in the Developer Portal.

By default, all taxonomies must be created in the Developer Portal. For more information, see Managing tags in the Developer Portal.

After you create your taxonomies for your APIs and Products, API developers can assign content to those taxonomies manually in the Developer Portal, or by using categories in YAML files.

However, if you create categories for your APIs and Products in the API Designer or API Manager UI, you can have your APIs and Products that are displayed in those categories in the Developer Portal. For more information about how to create categories for your APIs and Products in the API Designer or API Manager UI, see Organizing your Products into categories. For information about how to have your APIs and Products that are displayed in those categories in the Developer Portal, see Enabling dynamic category creation.

You can add more Developer Portal taxonomies to the categories that are defined in the API Designer or API Manager UI.

You can also provide the ability for users in the Developer Portal to navigate by using tag hierarchy. For more information, see Providing navigation by tag hierarchy.

- **Enabling dynamic category creation**
  You can display APIs and Products in pre-defined categories in the Developer Portal. You can define the categories that the APIs and Products are displayed in, in the API Designer or API Manager UI.

Enabling dynamic category creation

You can display APIs and Products in pre-defined categories in the Developer Portal. You can define the categories that the APIs and Products are displayed in, in the API Designer or API Manager UI.

Before you begin

You must have administrator access to complete this task.

Your APIs and Products must be categorized in the API Designer or API Manager UI, and they must be published. For more information, see Organizing your APIs into categories and Organizing your Products into categories.

About this task

By organizing your APIs and Products into categories, you can provide a hierarchical display for your APIs and Products in the Developer Portal.
Note: Organizing APIs and Products into a hierarchical view in the API Manager UI is different from tagging in the Developer Portal.
The categories that are defined in the API Designer or API Manager UI can be overridden by creating taxonomies in the Developer Portal. For more information, see Displaying APIs and Products in categories.

Procedure

1. To enable the Developer Portal to display the categories for your APIs and Products:
   a. On the administrator dashboard, click Configuration > System > IBM API Developer Portal.
   b. In the Categories section, select the Create taxonomies for categories if they do not already exist check box.
   c. Click Save configuration.
2. To enable the Developer Portal to display the change to the categories you made in step 1, you must republish your APIs and products.

Results

You enabled the Developer Portal to display the categories that you defined for your APIs and Products. You can see the categories that you defined, including the number of APIs and Products that are in each category, by selecting your APIs and Products in the Developer Portal.

Implementing an image carousel

You can customize your Developer Portal home page to display images in a carousel. The image carousel provides your Developer Portal home page with a continuous slide show that is customized to your specifications.

Before you begin

You must have administrator access to complete this task.

About this task

By implementing an image carousel, you can replace the default welcome banner or any previously set images.

Procedure

1. Create a content type of Image for your carousel.
   a. Click Structure > Content types > Add content type.
   b. Enter the name of your content type in the Name field.
      For example, *Slide show picture*.
   c. Optional: Specify the description of your content type in the Description field.
      For example, *A picture to display in the slideshow*.
   d. Click Save and manage fields for your newly created content type.
   e. Click Add field.
   f. Select Image for Add a new field, and enter a label for your field.
      For example, *slide image*.
   g. Click Save and continue.
      The Field settings page for your new field is displayed.
   h. In the DEFAULT IMAGE section, click Choose file to assign the image that you want as your default image for your slide show if no other images are found.
   i. Optional: Complete the Alternative text and Title fields.
   j. Click Save field settings.
   k. In the Manage fields tab for your newly created content type of *Slide show picture*, delete the `Body` field by clicking Delete on the OPERATIONS drop-down menu. Click Delete again to confirm.
2. Upload the images that you want to appear in your carousel.
   a. Click Content > Add content, then click the content type that you added in step 1.
   b. Enter a title for your image in the Title field.
      For example, if you had an image of a lighthouse, you can label the content as *Lighthouse*.
   c. Click Choose file under Slide image and select an image for your slide show. Complete the Alternative text field with some text to use when the image cannot be loaded.
   d. Click Save.
   e. Repeat sub-steps 2.a to 2.d until you are satisfied with the content of the slides for your carousel.
3. Create a view for your carousel.
   a. Click Structure > Views > Add new view.
   b. Complete View name.

For example, Slide show.
c. Select the Create a block check box in the BLOCK SETTINGS section.
d. Select Slick Carousel for the display format.
e. Enter the number of slides you have for your carousel in the Items per block field, then click Save and edit.
The Edit page for your slide show view is displayed.
f. Click the title of the view and enter `<none>` into the text field. Click Apply.
g. In the FIELDS section click Add, select the check box for slide image, and click Add and configure fields.
h. Ensure the check box for Create a label is not selected, and click Apply.
i. In the FIELDS section, click Content: Title > Remove.
j. In the FORMAT section, click Settings for Slick Carousel, and then set Skin Main to Default.
k. Scroll down to the CAPTION FIELDS section, and select the Content: slide image and Override main optionset check boxes.
l. In the OVERRIDABLE OPTIONS section, select the Autoplay, Dots, and Draggable check boxes.
m. Click Apply.
n. In the FILTER CRITERIA section, click Content: Published > Remove.
o. Click Save to save the Slide show view.
4. Configure your home page to host the carousel.
a. Click Structure, then click Pages.
b. Click edit for the welcome page, then click content in the Panels section.
c. To remove the current welcome banner, click the down-arrow under the OPERATIONS column for the Welcome Banner, and select Delete. Click Delete again to confirm.
d. To add your carousel, click Add new block and select the slide show view you created in step 3. Deselect Display title and click Add block.
e. Click Update and save.

Results

Your Developer Portal front page now has a slide show carousel.

Making your application's image public

You might want to display your application's image in an oauth authentication page to reassure customers that they are authenticating the correct application in the Developer Portal. That authentication uses a URL to the image that is stored on the Developer Portal. However, by default, those images are private unless you are logged in, which doesn't work if you want to display it in an oauth page. The solution is for the admin to change the **`application_image`** field to use public instead of private.

Before you begin

You must have administrator access to complete this task.

About this task

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Structure > Content types > Application > Manage fields
4. Navigate to the Image label, then in the **`Edit`** drop down, select **`storage settings`**.
5. Click **`Public files`** for **`Upload destination`**.
6. Click **`Save field settings`**.

Providing navigation by tag hierarchy

You can provide the ability for users in the Developer Portal to navigate by using tag hierarchy.

Before you begin

You must have administrator access to complete this task.

About this task

The Categories block provides the ability to navigate by tag hierarchy. The Categories block is disabled by default, so you need to enable the block and then configure it to your requirements.

Procedure

To provide navigation by tag hierarchy, complete the following steps:

1. Click Extend, in the filter box enter `Hierarchical Taxonomy Menu`.
2. Select **`Hierarchical Taxonomy Menu`**, then click Enable.
3. Click Structure > Block layout.
All of the blocks in the connect_theme are displayed.
4. Scroll to the region that you want to add the block to, for example Collapse right, click Place block.
5. Find the **`Hierarchical Taxonomy Menu`** block in the list and click Place block.
6. Complete any configuration tasks that you require for the **`Collapse right`** block, including selecting the correct taxonomy to use and indicating what pages to display the block on.

7. Click Save block to save your changes.
   You can add new blocks, and modify the existing blocks that are displayed on Developer Portal pages. For more information, see Adding and changing the blocks displayed on Developer Portal pages.

Using the Views module in the Developer Portal

By using the Views module, you can fetch content from your Developer Portal site, and present it to users in different formats such as lists, graphs, and tables.

The Views module is a powerful SQL query builder that can access almost all the information in your Developer Portal site database and display it in any format.

There are many uses cases for views, but the following list shows some of the common ones:

- You want to display some of the content differently, such as Products, APIs, and applications.
- You want to display a block with the five most recent posts of some kind.
- You want to change the way that articles are displayed.
- You want to provide an unread forum posts list.
- You want to provide a monthly archive of posts.

For information about how to create a view in the Developer Portal, see the following topic. You can also follow a tutorial about creating a custom sort order view; see Tutorial: Using a custom weighting sort order on the product list page.

- **Creating views in the Developer Portal**
  You can create new views in the Developer Portal, such as content lists of Products, APIs, and applications, by using the Views module.
- **Configuring the search results view in the Developer Portal**
  You can configure the way that the search results are displayed in the Developer Portal.
- **Configuring the default number of items in a view list in the Developer Portal**
  You can configure the default number of items that are displayed in a view list in the Developer Portal.

Creating views in the Developer Portal

You can create new views in the Developer Portal, such as content lists of Products, APIs, and applications, by using the Views module.

Before you begin

You must have administrator access to complete this task.

About this task

Creating views in the Developer Portal enables you to control the presentation of specific content for users. For more information about views, see Using the Views module in the Developer Portal.

Procedure

To create a view, complete the following steps.

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Structure > Views > Add new view.
   The Add view page is displayed.
4. Complete the View name and, optionally, the Description.
5. Complete the VIEW SETTINGS section with details of what you want your view to show, and how you want it to be sorted.
   For example, to create a view of APIs that are sorted by title, select Show `Content`, of type `API`, and sorted by `Title`.
6. Select whether to Create a page, Create a block, or both, for your view.
   A page is a full-screen page in the Developer Portal. Whereas a block would be a site block that you can then place on whatever pages you want to show a smaller view of the content, for example the 10 newest APIs.
7. Complete the options that you require for your view. For example, the display format, the number of items per page or block, whether to include a pager, whether to create a menu link, and whether to include an RSS feed.
8. Click Save and edit.
   Your new view opens in the Edit tab.
9. Refine your view further.
   Here you can further modify the display of your view or add new displays. More options include formatting of the view, what fields to include in a table or grid format, filtering and sorting criteria, add header or footer details, as well as advanced options around contextual filters, relationships, and behavior when there are no results to display. The Edit tab also includes a preview area, so you can check your view before publishing.
10. Click Save to make your changes permanent.
    When saved, your new view is visible in the Structure > Views pane.

Results

You created a new view in the Developer Portal.

Configuring the search results view in the Developer Portal

You can configure the way that the search results are displayed in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

In the Developer Portal, the search results are displayed as a view, and so you can control the presentation of this search content. For more information about views, see Using the Views module in the Developer Portal.

Procedure

To configure the search results view, complete the following steps.

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Structure > Views.
   The list of views is displayed.
4. Find the Search content view in the list, and click Edit.
5. Edit the Search content view settings as required.
   Here you can modify the display of the view or add new displays. For example, you can configure the formatting of the view, the filtering and sorting criteria, add header or footer details, as well as more advanced options around contextual filters, relationships, and behavior when there are no results to display. There is also a preview area so you can check the view before publishing.
6. Click Save to make your changes permanent.

Results

You updated the view of the search results in the Developer Portal.

What to do next

You can configure the search index and server that are used to generate the search results. For more information, see Configuring search indexes and servers.

- Drupal Views module

Configuring the default number of items in a view list in the Developer Portal

You can configure the default number of items that are displayed in a view list in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

In the Developer Portal, you can manage how many items in a list are shown for each page on a view. For more information about views, see Using the Views module in the Developer Portal.

Procedure

To configure the search results view, complete the following steps.

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Structure > Views.
   The list of views is displayed.
4. In the list, find the view name that you want to update, for example, Products, then click Edit.
5. Click Pager.
6. Select Display a specified number of items, click Apply.

7. Set the Items per page as required, click Apply.
8. Click Save to make your changes permanent.

Results

You updated the default number of items in a view of the search results in the Developer Portal.

What to do next

The Views module is a powerful SQL query builder that can access almost all the information in your Developer Portal site database and display it in any format. For more information, see Using the Views module in the Developer Portal.

Configuration

As an administrator, you can control multiple aspects of the Developer Portal configuration, including managing security and general configuration tasks.

To learn how to configure specific aspects of your Developer Portal site, use the following section links.

- **Configuring content moderation**
  By configuring content moderation, you can configure a review and approval process for content types in the Developer Portal. You can specify which roles can perform which actions by assigning them the appropriate permissions.
- **General configuration tasks**
  You can perform general configuration tasks in the Developer Portal as an administrator.
- **Managing Developer Portal security**
  You can manage multiple security elements in the Developer Portal.

Configuring content moderation

By configuring content moderation, you can configure a review and approval process for content types in the Developer Portal. You can specify which roles can perform which actions by assigning them the appropriate permissions.

Before you begin

An example use case for configuring content moderation would be for a professional documentation writer to review an APIs documentation before it is published on the Developer Portal. They might, for example, notify the API Developer of typographical errors, suggest improvements to operation descriptions, or attach an image file. Edits might then be made before the documentation was republished to the API and then published to the Developer Portal.

You must have a Developer Portal enabled, and you must have administrator access to complete this task.

About this task

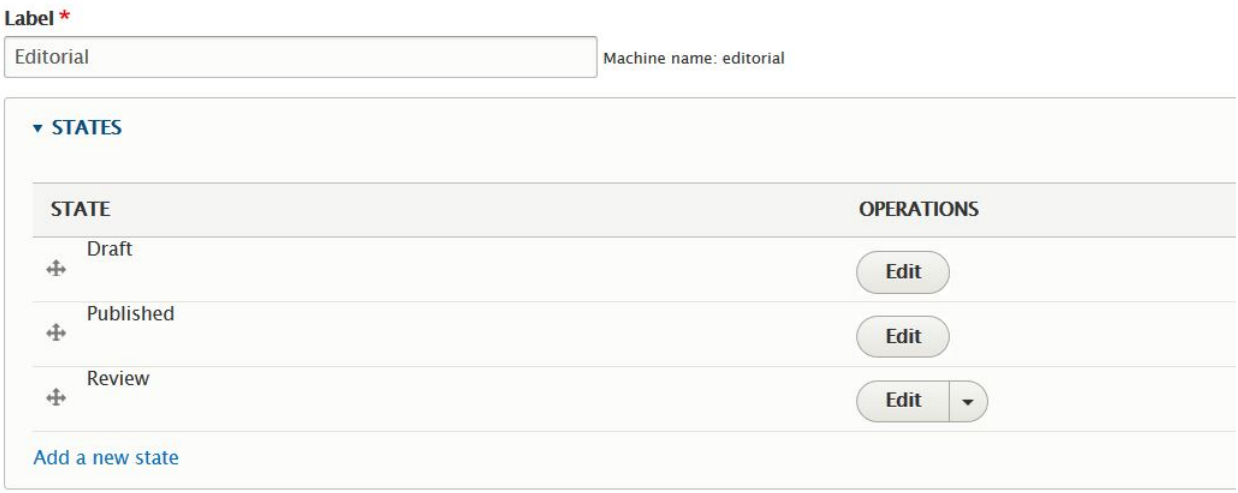
By using content moderation, you can configure the workflow of your Developer Portal site so that you can moderate content types, such as APIs and Products. However, you cannot moderate Consumer organizations or applications.

Procedure

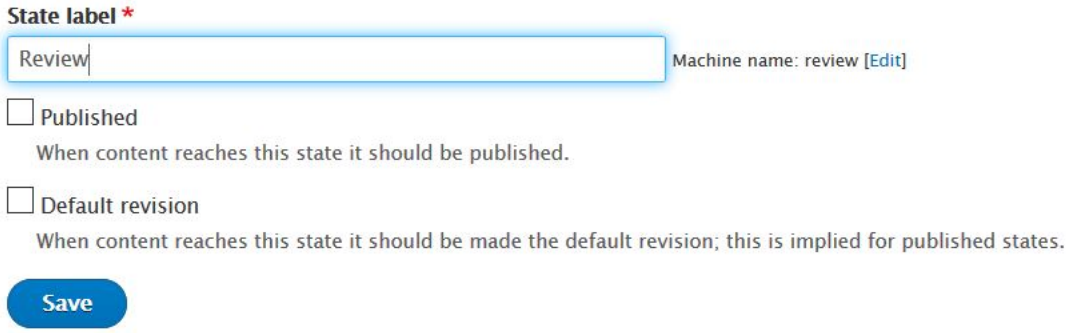
1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Enable the required modules:
   a. On the administrator dashboard, click Extend.
   b. In the search bar enter **`workflows`**, then select the Workflows module and click Enable.
   c. In the search bar enter **`content moderation`**, then select the Content Moderation module and click Enable.
4. Navigate to Configuration > Workflow > Workflows
5. Check that **`Editorial`** is listed as a workflow. If it isn't listed:
   a. Click **`+ Add workflow`**.

   b. Enter **`Editorial`** as the label.
   c. Select the workflow type **`Content moderation`**.
   d. Click **`Save`**.
6. Set up the workflow:
   a. Click **`Edit`** on the **`Editorial`** workflow.

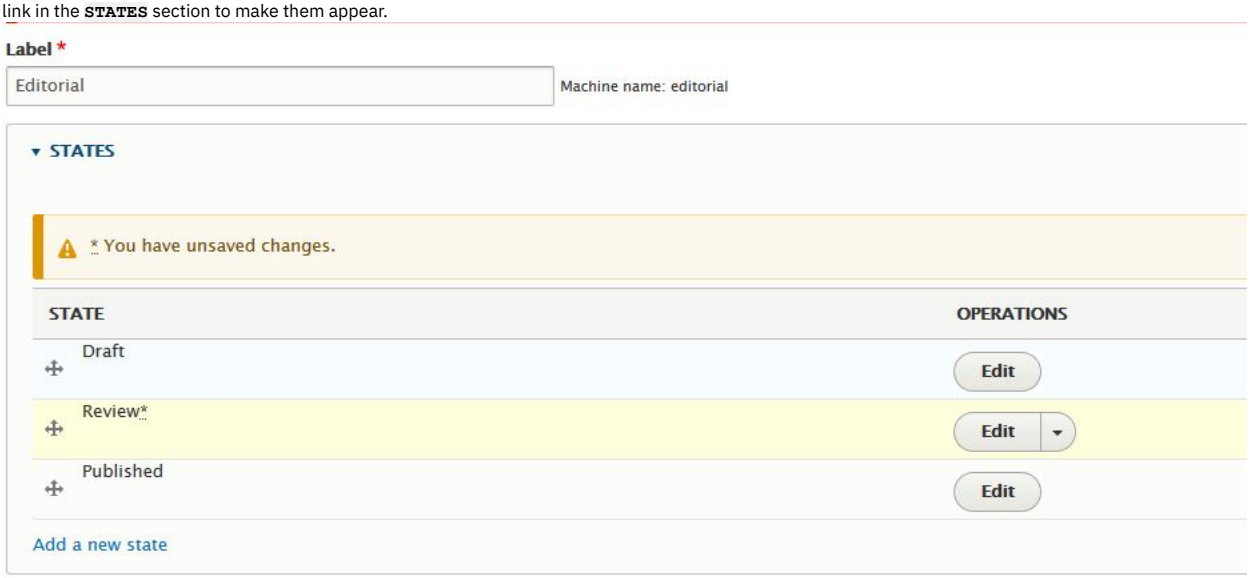
b. Click the **Add a new state** link.



c. Enter the value **Review** in the **State label** field, leave the **Published** and **Default revision** check boxes cleared then click Save.



d. Drag the **review** state to between the **Draft** and **Published** states then click 'Save'. If the drag handles are not visible, then click the **Hide row weights** link in the **STATES** section to make them appear.



e. Click the **Add a new transition** link.
f. Enter the value **Review** in the **Transition Label** field, tick the **Draft** check box in the **From** section and click **Review** in the **To** section then click Save.
g. Drag the **Review** transition to between the **Create New Draft** and **Publish** transitions, then click Save.
h. Click the **Edit** operation on the **Create New Draft** transition.
i. In the **From** check box list, untick **Published** and tick **Review** then click Save.
j. Click the **Edit** operation on the **Publish** transition.
k. In the **From** check box list, untick **Draft** and tick **Review** then click Save.
l. Click **Select** for the **Content types** item in the **THIS WORKFLOW APPLIES TO** section.
m. Select the **Product** content type then click Save.

7. Set up the permission schema for the workflow:
   a. Click People > Roles > Add a new role.
   b. In the **Role Name** field, enter the value **Editor** then click Save.
   c. Drag the **Editor** role to between the **Content Author** and **Administrator** roles then click Save.

d. Click the Permissions tab and scroll down to the **Content Moderation** permission section.
e. For the EDITOR role, select all the permissions in the **Content Moderation** section.
f. For the CONTENT AUTHOR role, select the permissions **Editorial workflow: Use Create New Draft transition**, **View any unpublished content**, and **View the latest version** then click Save permissions.
g. Ensure that the EDITOR and CONTENT AUTHOR roles have the permission **Use the administration toolbar**.

8. Assign the permissions to users in the portal. If you do not already have some registered users in your portal, create a new consumer organization and invite two new users to it.
   a. Click People.
   b. Tick the check box next to one of the users in the list, but not the admin user, then from the **Action** drop-down select **Add the Content Author role to the selected user(s)** then click **Apply to selected items**.
   c. Tick the check box next to another one of the users in the list, but not the admin user, then from the **Action** drop-down select **Add the Editor role to the selected user(s)** then click **Apply to selected items**.

Results

You successfully configured content moderation on your Developer Portal. You can now use the API manager user interface to publish a product to the portal, and transition the product from draft to review state.

- **Editing, reviewing, and publishing moderated content**
  If you have published content from API Manager UI to your Developer Portal or created content within the Developer Portal, you can edit and review the content through the Moderated content page before you publish it in the Developer Portal.

Editing, reviewing, and publishing moderated content

If you have published content from API Manager UI to your Developer Portal or created content within the Developer Portal, you can edit and review the content through the Moderated content page before you publish it in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

You must have content that is published to the Developer Portal from the API Manager UI.

Your role must have the necessary permissions that enable you to perform the tasks. For more information on assigning the necessary tasks, see Configuring content moderation.

About this task

In addition to editing content through the content moderation page, you can specify whether the content needs further review, or even publish the content if you have the permission.

Procedure

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. On the administrator dashboard, click Content.
4. Click the Moderated content tab.
5. If you have the necessary permissions to edit your content type, for example, you are a **Content author**:
   a. Click the Title of the content type that you want to edit, then click the Edit.
   b. Edit your content to your specification, then click Save.
      You are redirected to the **View** tab.
   c. When you have finished editing your content type on the **edit** tab, ensure that the **Review** state is selected from the **Change to** drop down, then click Save.
6. If you have the necessary permissions to review and publish your content type, for example, you are a **Reviewer**:
   a. On the administrator dashboard, click Content.
      The content page is displayed listing all content.
   b. Click the Moderated content tab.
   c. Click the Title of the content type that you want to review.
   d. Optional: If the content that you are reviewing requires editing, click Edit, apply the changes to your content type, then click Save.
      You are redirected to the View tab.

Results

You edited, reviewed, and published your draft content type.

General configuration tasks

You can perform general configuration tasks in the Developer Portal as an administrator.

To learn how to configure specific aspects of your Developer Portal site, use the following topic links.

- **Adding a page load progress indicator**
  You can extend your Developer Portal site by adding a page load progress indicator. This option might be useful on servers that have a slow connection to the API Manager, or for customers that are using OIDC and have slow response times from their OIDC provider.
- **Adding custom fields to user records**
  You can add custom fields to user records in the Developer Portal.
- **Checking the site status report**
  You can check the site status report in the Developer Portal.
- **Clearing the server caches**
  You can clear the server caches from within the Developer Portal.
- **Configuring a proxy**
  You can configure the proxy settings in your Developer Portal.
- **Configuring Stripe in the Developer Portal**
  You can offer free use of your Product Plans to your API consumers, or you can offer Products with paid Plans. To enable API consumers to subscribe to Products with paid Plans, you must first configure the Stripe payment method in your Developer Portal.
- **Configuring cron to run scheduled tasks**
  You can configure cron to run scheduled tasks in the Developer Portal.
- **Configuring search indexes and servers**
  You can configure search indexes and servers in the Developer Portal by using the Search API module.
- **Configuring the date and time**
  You can configure the date and time in the Developer Portal.
- **Configuring the notifications event log settings**
  You can configure the settings of the notifications event log for the activity feed on your Developer Portal.
- **Configuring the settings of a Consumer organization**
  You can configure the settings of your Consumer organization from within your Developer Portal. The default settings allow users to delete their accounts and organizations, create more consumer organizations, rename their organization, and change the owner of their organization.
- **Configuring the site default timezone**
  You can configure the site default timezone in the Developer Portal.
- **Configuring the site error handling**
  You can configure the site error handling in the Developer Portal.
- **Configuring which buttons are displayed in the WYSIWYG rich text editor**
  You can configure which buttons are displayed in the WYSIWYG rich text editor in the Developer Portal.
- **Configuring which languages are available**
  You can configure which languages are available in the Developer Portal.
- **Customizing user account settings**
  You can customize the user account options that are displayed to users when they register and use the Developer Portal.
- **Disabling languages**
  You can extend your Developer Portal site by managing which languages are available for use on the site.
- **Disabling test tool restrictions**
  The default OAuth provider contains security mechanisms that prevent the ability to obtain authorization tokens in the Developer Portal test tool when you use Implicit or Authorization Code grant types. If your OAuth provider allows those actions to function correctly from the test tool, you can disable this option.
- **Enabling a cookie compliance banner**
  You can add a cookie compliance banner to your Developer Portal site by configuring the EU Cookie Compliance module.
- **Enabling code languages for code snippets**
  You can specify the languages that code snippets for APIs can be displayed in.
- **Enabling code snippets for SOAP APIs**
  By default, code snippets are only shown for REST APIs. You can enable code snippets for SOAP APIs.
- **Forcing new users to accept terms and conditions**
  You can extend your Developer Portal site by forcing new users to accept the terms and conditions before they are able to create accounts.
- **Hiding the admin registry on the login form**
  You can hide the admin registry as an option on the login form. The use case for this option might be a public facing Developer Portal where you want to remove the admin access from customer view.
- **Hiding the certificate in the header for APIs secured with mutual TLS**
  You can hide the certificate in the header for APIs secured with mutual TLS. By default, the **`x-client-certificate`** header is shown in an API when mutual TLS is configured. You can choose to turn off this option in your Developer Portal.
- **Importing and exporting taxonomies**
  You can import and export taxonomies in the Developer Portal.
- **Restricting access by IP address**
  You can restrict access to a role or a user by IP address in the Developer Portal.
- **Restricting or preventing access from search engines**
  You can restrict or prevent access to your Developer Portal from search engines. You might want to control the access if you have a development or test site.
- **Toggling the site in and out of maintenance mode**
  You can put the Developer Portal site into maintenance mode for short periods of time. During maintenance mode, only an administrator is able to access the site, and all other users who enter the site URL get a maintenance message set by the administrator.
- **Viewing available updates**
  You can view available updates in the Developer Portal.

Adding a page load progress indicator

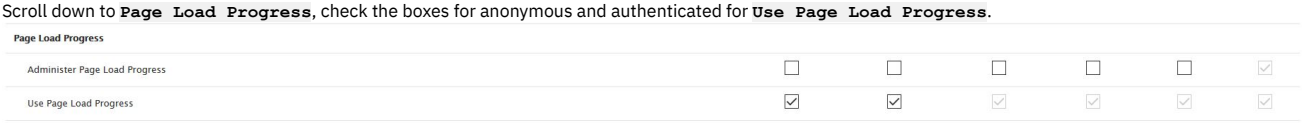
You can extend your Developer Portal site by adding a page load progress indicator. This option might be useful on servers that have a slow connection to the API Manager, or for customers that are using OIDC and have slow response times from their OIDC provider.

Before you begin

You must have administrator access to complete this task.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. In the administrator dashboard, click Extend.
   The List tab for the Extend page opens, and the list of installed modules is displayed. The list shows all the modules that are installed. The enabled modules are displayed with a selected check box. The disabled modules are displayed without a selected check box.
3. Enter `page_load_progress` into the search filter.
   The **`Page Load Progress`** content item is displayed in the list of content.
4. By default, the **`Page Load Progress`** module is enabled. However, if not, select the check box and click Enable.
   You have now enabled the default settings for the **`Page Load Progress`** module.
5. To change the default settings for the module, navigate to Configuration > User interface > Page Load Progress.
6. Decide which settings you want to change, for example, **`Time to wait before locking the screen`**, and click Save.
   Note: Changing the settings does not apply to the OIDC buttons. If it is enabled, the OIDC buttons use the page load process indicator, but do not allow any configuration.
7. To enable the permissions, navigate to People > Permissions.
8. Scroll down to **`Page Load Progress`**, check the boxes for anonymous and authenticated for **`Use Page Load Progress`**.



9. Click Save permissions.

Results

You successfully enabled the **`Page Load Progress`**. Now, the page loading spinner is automatically added to the login and register forms for OIDC buttons.

What to do next

You can customize the appearance of the modal page and spinner in CSS in a custom theme.

Adding custom fields to user records

You can add custom fields to user records in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

Any data that is added to a custom field for user records will remain in the Developer Portal database.

Procedure

1. In the administrator dashboard, click Configuration > People > Account settings.
2. Click the MANAGE FIELDS tab.
3. Click Add field.
4. Specify the type of data that your field can store by selecting the type from the Add a new field list.
5. Enter a label for your field in the Label field.
6. Optional: If you want to edit the machine name that is automatically created based on your label, click Edit and enter the new name.
7. Click Save and continue.
8. Configure any additional values for the new field then click Save field settings.
   You have added a custom field to your user record.

What to do next

You can configure the contents of your custom field depending on what type of data you specified it could store.

Checking the site status report

You can check the site status report in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To check the site status report, complete the following steps:

1. Click Reports in the administrator dashboard.
2. Click Status report.
3. You can review information relating to the site status report from this view.

Clearing the server caches

You can clear the server caches from within the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

1. In the administrator dashboard, click Configuration, then in the Development section, click Performance.
2. Click Clear all caches.
   You have cleared the server caches, and a message will be displayed stating: `Caches cleared`.

Configuring a proxy

You can configure the proxy settings in your Developer Portal.

Before you begin

You must have administrator access to complete this task.

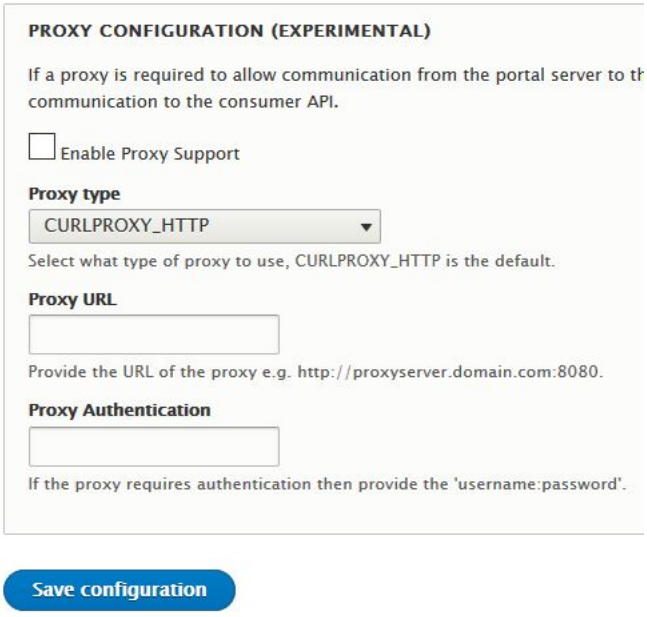
About this task

The Developer Portal communicates with the management server by way of the consumer and product APIs. For a Developer Portal that is deployed externally to the management server zone, and does not have access to the consumer and product APIs, a proxy can be used.

Procedure

To configure a proxy to use for communicating with management server APIs, complete the following steps:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Configuration > System > IBM API Connect in the administrator dashboard.
4. To configure a proxy, select **`Enable Proxy Support`**, and make the required changes.



5. When your changes are complete, click Save configuration.

Results

You successfully configured a proxy on your Developer Portal.

Configuring Stripe in the Developer Portal

You can offer free use of your Product Plans to your API consumers, or you can offer Products with paid Plans. To enable API consumers to subscribe to Products with paid Plans, you must first configure the Stripe payment method in your Developer Portal.

Before you begin

You must have administrator access to complete this task.

To use Stripe as your credit card processing vendor, you must have port 443 open to HTTPS communication between the Stripe API and your Developer Portal management and the Management cluster servers. See Firewall requirements on Kubernetes and Firewall requirements on VMware for more information about this requirement.

The billing microservice must be enabled on your management system by your system administrator. See Configuring monetization on VMware and Configuring monetization on Kubernetes for more information.

Billing integration support must be configured in the API Manager. For more information, see Monetizing your Products.

About this task

API Connect includes a subscription billing feature that allows API providers to define pricing Plans in their API Products, and monetize their API offerings. If a Product contains a pricing Plan, API consumers must enter their payment information into the Developer Portal before they can subscribe to that Plan.

API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product Plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.

Support is provided for Stripe in the Developer Portal, but before API consumers can enter their payment information, you need to configure the Stripe billing support in every Developer Portal where you will offer paid Plans. After this support is configured, API consumers can provide their payment information, and then subscribe to the paid Plans. Complete the following instructions to enable the APIC Monetization Stripe Integration module, and then configure your Stripe API credentials.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. In the administrator dashboard, click Extend.
   The List tab for the Extend page opens, and the list of installed modules is displayed. The list shows all the modules that are installed. The enabled modules are displayed with a selected checkbox. The disabled modules are displayed without a selected checkbox.
3. Enter `stripe` into the search filter.
   The **`ibm_stripe_payment_method`** module called APIC Monetization Stripe Integration is displayed in the list of contents.
4. Select APIC Monetization Stripe Integration and click Enable.
   The default settings for the **`ibm_stripe_payment_method`** module are now enabled.
5. In the administrator dashboard, click Configuration > System > IBM API Developer Portal Billing.
   The IBM API Developer Portal Billing Settings page is displayed.
6. Change the drop-down option to be the newly enabled APIC Monetization Stripe Integration (ibm_stripe_payment_method) as the module to use to create payment methods for the Stripe billing provider. Click Save configuration.
7. In the administrator dashboard, click Configuration > System > IBM APIC Stripe Integration, and enter your Stripe API credentials. These credentials must match the Stripe API credentials for the billing integration resource that is attached to the Catalog for this Developer Portal.
   Refer to your Stripe dashboard to get your publishable key and secret key; see https://dashboard.stripe.com/apikeys.
   Note: Each Stripe account comes with two sets of API keys, one for testing, and one for production. Each set of API keys has a distinct namespace for Stripe objects. Test API keys cannot see objects created by production API keys, and vice versa. You cannot switch the API keys of one of your billing integrations with the keys from another account, or swap your test and production keys over, as that would prevent API Connect from resolving the Stripe objects that were created by using the old keys. If you want to use your Stripe test keys, you must create a separate Catalog for testing, and not add your Stripe test keys to production Catalogs.
8. Click Save integration.

Results

You successfully configured the Stripe payment method in the Developer Portal. API consumers can now add a payment method to their consumer organization, so that they can subscribe to Products with paid Plans.

What to do next

After both the Catalog and the Developer Portal are configured, you can create Products with pricing Plans. See Defining a Product with billing integration for more information.

- Monetizing your Products
- Considerations when changing a Product lifecycle with billing

Configuring cron to run scheduled tasks

You can configure cron to run scheduled tasks in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To configure cron to run scheduled tasks, complete the following steps:

1. Click Configuration in the administrator dashboard.
2. Under the SYSTEM heading, click Cron.
3. Use the drop-down list for the module you want to configure and select Edit.
4. From the Run cron every drop-down menu, select the frequency of cron runs for this module.
5. Click Save.
   You have configured cron to run scheduled tasks.

Configuring search indexes and servers

You can configure search indexes and servers in the Developer Portal by using the Search API module.

Before you begin

You must have administrator access to complete this task.

About this task

The Search API module provides a generic framework for search capabilities within the Developer Portal, and you can customize the default database server and content index setup that is provided. By default, the search in the Developer Portal runs over the entire OpenAPI and WSDL documentation. It is not possible to restrict the search to specific sections of an Open API or WSDL document. The search can be configured to include any custom fields that were added to the Developer Portal, but it does not include any attached files.
The search results page is a view in the Developer Portal, and so it can also be configured. For more information, see Configuring the search results view in the Developer Portal.

Procedure

To configure the default database server and content index settings, complete the following steps.

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Configuration > Search and metadata > Search API in the administrator dashboard.
4. To configure the server settings, click Edit against the Database Server and make the required changes. For example:
   - Server name; the displayed name for the server.
   - Description; a description of the server.
   - CONFIGURE DATABASE BACKEND; the minimum number of characters a word must consist of to be indexed, and whether to search on parts of a word. However, wildcard searching can make searches on large sites very slow.
   - AUTOCOMPLETE SETTINGS; how suggestions are computed when autocompletion is used.
5. To configure the index settings, click Edit against the Default content index and make the required changes. For example:
   - Index name; the displayed name for the index.
   - Data sources; the data sources of the items to be stored in the index.
   - CONFIGURE THE DATASOURCE; for each data source, set which bundles of content should be indexed, and in which languages.
   - Server; the server that the index should use.
   - Description; a description for the index.
   - INDEX OPTIONS; whether the index is read only, whether to index new or updated items immediately, and setting how many items to index when indexing items during a cron run.
6. When your changes are complete, click Save.
   The View page of the updated default database server or default content index is displayed.

Results

You successfully configured the search indexes and servers in the Developer Portal.

What to do next

You can configure how searches are displayed by editing the Search content view. For more information, see Configuring the search results view in the Developer Portal.

- Search API module

Configuring the date and time

You can configure the date and time in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To configure the date and time, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. Under the Regional and language heading, click Date and time formats.
4. Click Edit for the format you want to change.
5. Change the settings of the format then click Save format.
   You have configured the date and time.

Configuring the notifications event log settings

You can configure the settings of the notifications event log for the activity feed on your Developer Portal.

About this task

The Developer Portal includes an activity feed that shows Consumer organization users the details of events that occur on the organization, such as application creation, subscriptions, and so on. This activity feed is displayed by default on the navigation bar of the organization, and as an additional tab on the organization page and the application page.

The default number of days that events are kept for is 30. You can edit this setting in the IBM APIC Notifications Settings page of your Developer Portal, as described in the following instructions.

Procedure

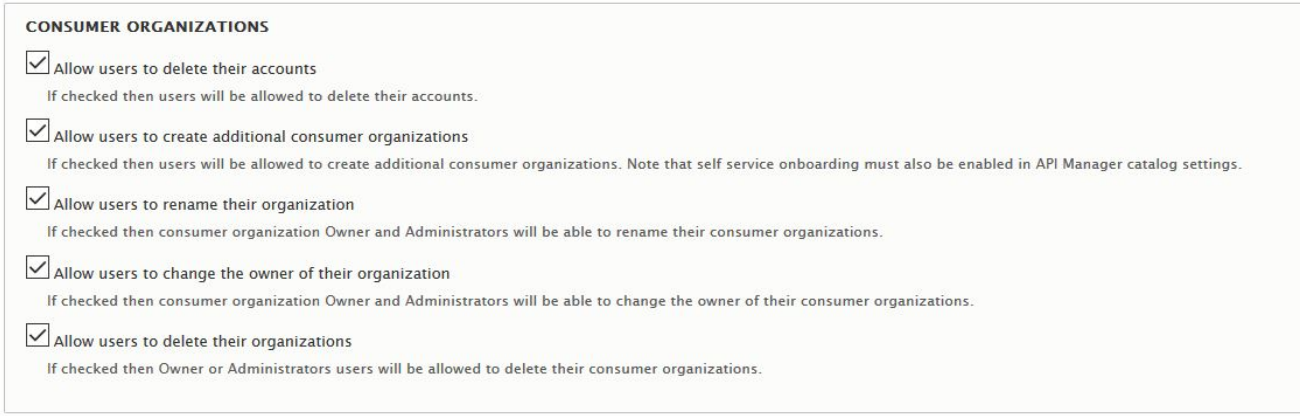
1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Configuration > System > IBM APIC Notifications Settings.
   The IBM APIC Activity Feed Settings page is displayed.
4. Enter the required number of days to keep events for in the Retention Days field.
5. Click Save configuration.

Configuring the settings of a Consumer organization

You can configure the settings of your Consumer organization from within your Developer Portal. The default settings allow users to delete their accounts and organizations, create more consumer organizations, rename their organization, and change the owner of their organization.

Procedure

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Configuration > System > IBM API Connect.
4. Scroll down to **CONSUMER ORGANIZATIONS**.



5. Clear which ever options you want to change, click Save configuration.

Configuring the site default timezone

You can configure the site default timezone in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To configure which languages are available, complete the following steps:

1. Click Configuration in the administrator dashboard.
2. Under the REGIONAL AND LANGUAGE heading, click Regional settings.
3. From the Default Time Zone drop-down menu, select the default time zone.
4. Click Save configuration.
   You have configured the default time zone.

Configuring the site error handling

You can configure the site error handling in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To configure the site error handling, complete the following steps:

1. Click Configuration in the administrator dashboard.
2. Under the DEVELOPMENT heading, click Logging and errors.
3. You can review and configure all information relating to site error handling from this view.
   Note: On a production system, set Logging and errors to **none**, to avoid any security issues.
4. Click Save configuration.
   You have configured the site error handling.

Configuring which buttons are displayed in the WYSIWYG rich text editor

You can configure which buttons are displayed in the WYSIWYG rich text editor in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To configure which buttons are displayed in the WYSIWYG rich text editor, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration > Content authoring > Text formats and editors.
3. Click Configure for the Full HTML profile.
4. In the **TOOLBAR CONFIGURATION** section, edit the buttons that you want to expose.
5. Click Save configuration.
   You have configured the editor buttons that are displayed in the WYSIWYG rich text editor.

Configuring which languages are available

You can configure which languages are available in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To configure which languages are available, complete the following steps:

1. Click Configuration in the administrator dashboard.
2. Under the REGIONAL AND LANGUAGE heading, click Languages.
3. Under the DEFAULT heading, select the radio button for the language you want to set as default.
4. To add a new language, click +Add language. Use the drop-down menu to select the language you want to add.
5. Click Save configuration.
   You have configured the languages that are available.
6. You can also provide your own translations, for strings of the website that are not translated, from the User interface translation view, under Configuration > Regional and Language in the administrator dashboard.

Results

You have configured the available languages for the Developer Portal.
Note: Multilingual API and Product documentation can be created by using an **x-ibm-languages** extension directly in the OpenAPI definition. For more information, see Using **x-ibm-languages** to create multilingual API and Product documentation.

Customizing user account settings

You can customize the user account options that are displayed to users when they register and use the Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

You can change what fields users of the Developer Portal see when they register to use the site, when they log in, and when they view their user account profile. For instance, you can change the field order display, hide fields, and add custom fields.
As an example, the Consumer organization field is a required entry field when a user creates an account on the Developer Portal. However, you can configure this field to be hidden, in which case the field is automatically completed with a default entry of **firstname lastname** of the new user instead.

Procedure

To customize the user account settings, complete the following steps.

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Configuration > People > Account settings in the administrator dashboard.
   The Account settings page is displayed.
4. From the Settings tab you can edit the following options:
   a. CONTACT SETTINGS; enable or disable the personal contact form for new users.
   b. PASSWORD RESET TIMEOUT; set the timeout in seconds for one-time login links. This setting applies only to the admin user of the Developer Portal.
   c. ANONYMOUS USERS; set the name to be used to indicate anonymous users.
   d. ADIMINISTRATOR ROLE; assign the administrator role that is automatically given new permissions whenever a new module is enabled. The default is Superuser.
      Note: The Superuser role has the highest level of permissions in the Developer Portal. This role bypasses all content access control, which means that users that have a Superuser role can see all of the site content. For more information, see Working with roles in the Developer Portal.
   e. LANGUAGE SETTINGS; enable or disable translation.
   f. REGISTRATION AND CANCELLATION; enable or disable the password strength indicator, and set the action to take when a user account is canceled.
   g. Notification email address; set the email address to use as the from address for all account notifications.
   h. Emails; edit the emails that are sent when an account is blocked or canceled, or when a new password is requested.
   i. Click Save configuration to save your updates.
5. Click the Manage fields tab to customize the fields that are available for storing user data.

Here you can edit the settings for current fields, delete fields, and add new fields. Remember to save any updates that you make.

6. Click the Manage form display tab to configure how the user forms are displayed.
   a. Click the Default form mode to configure how the form fields display when a user profile is being edited.
   b. Click the Register form mode to configure how the form fields display when a new user creates an account.
      For each user form mode you can edit the field settings, enable and disable fields, and drag the fields to change their display order. You can also manage the form modes.
      For example, to hide the Consumer organization field when a new user creates an account, click the Register form mode, and drag the Consumer organization into the Disabled section.
   c. Click Save to save your updates.
7. Click the Manage display tab to configure how fields are displayed on a user profile page.
   You can edit the field settings, enable and disable fields, and drag the fields to change their display order. You can also manage the display view modes. Remember to save any updates that you make.
8. Click the Translate account settings tab to configure the language options for the user account settings. Remember to save any updates that you make.

Results

You successfully customized the user account settings in the Developer Portal.

- Configuring CAPTCHA

Disabling languages

You can extend your Developer Portal site by managing which languages are available for use on the site.

Before you begin

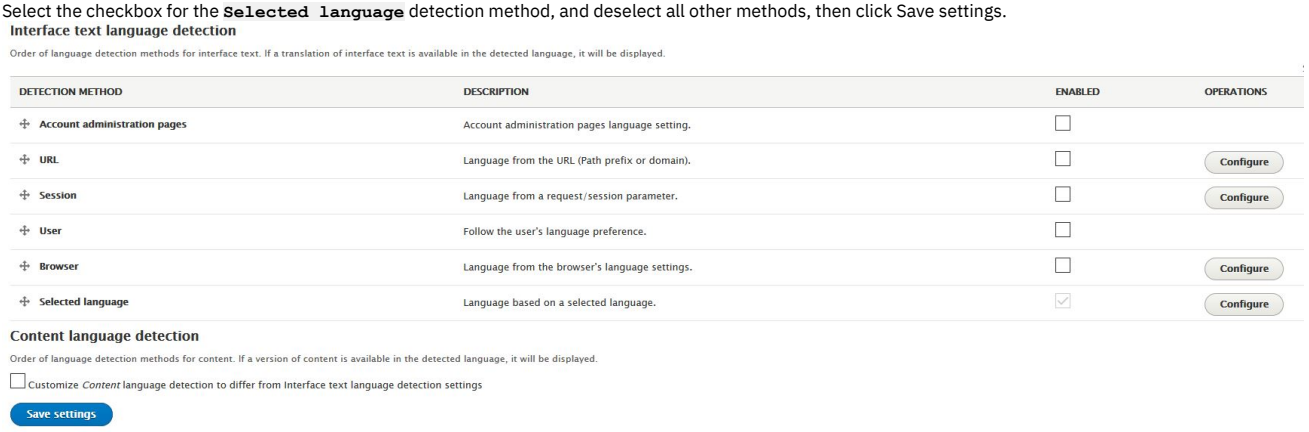
You must have administrator access to complete this task.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.

To disable all languages apart from English.

2. Navigate to Configuration > Regional and language > Languages > Detection and selection.
3. Select the checkbox for the **`Selected language`** detection method, and deselect all other methods, then click Save settings.

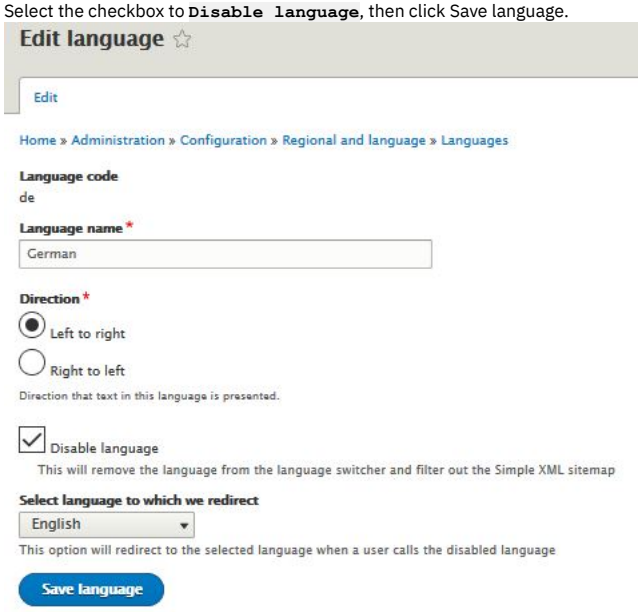


To disable one or more languages.

4. In the administrator dashboard, click Extend.
   The List tab for the Extend page opens, and the list of installed modules is displayed. The list shows all the modules that are installed. The enabled modules are displayed with a selected checkbox. The disabled modules are displayed without a selected checkbox.
5. Enter `disable language` into the search filter.
   The Disable Language content item is displayed in the list of content.
6. Select the checkbox for the **`Disable Language`** module, and click Enable.
7. Navigate to Configuration > Regional and language > Languages > Detection and selection.
8. Select the checkbox to enable URL, and click Save settings.

9. Navigate to Configuration > Regional and language > Languages.
10. Click Edit on the language that you want to disable.

11. Select the checkbox to **`Disable language`**, then click Save language.



Results

You successfully disabled your chosen language.

Disabling test tool restrictions

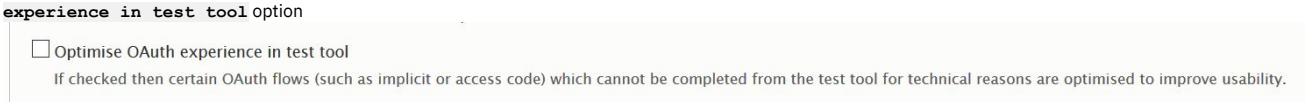
The default OAuth provider contains security mechanisms that prevent the ability to obtain authorization tokens in the Developer Portal test tool when you use Implicit or Authorization Code grant types. If your OAuth provider allows those actions to function correctly from the test tool, you can disable this option.

Before you begin

You must have administrator access to complete this task.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. In the administrator dashboard, click Configuration > System > IBM API Connect.
3. In the **`CONFIGURATION`** section, deselect the **`Optimise OAuth experience in test tool`** option



4. Click Save configuration.

Results

You successfully disabled the **`Optimise OAuth experience in test tool`** option. You can now use the Developer Portal test tool to test an Implicit or Authorization Code grant type in an OAuth provider API, if your OAuth provider allows those actions to function correctly from the test tool.

What to do next

You can enable the **`Optimise OAuth experience in test tool`** option by repeating the task but selecting the option and then clicking Save configuration.

Enabling a cookie compliance banner

You can add a cookie compliance banner to your Developer Portal site by configuring the EU Cookie Compliance module.

Before you begin

You must have administrator access to complete this task.

About this task

The EU Cookie Compliance module provides a customizable pop-up notification that informs visitors to your site that cookies are being used. The notification enables your site visitors to find out more about cookies, and to decide not to browse the site if they disagree with using cookies. You can also provide a link from your cookie compliance banner to an internal or external privacy policy. For more information about configuring an internal privacy policy, see Customizing the privacy policy statement.
The EU Cookie Compliance module is enabled by default. The following instructions show you how to configure the notification.

Procedure

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Configuration > System > EU Cookie Compliance.
   The Settings tab of the EU Cookie Compliance page is displayed.
4. In the SETTINGS section select Enable banner, otherwise the notification does not display.
5. In the PRIVACY POLICY section, edit the Privacy policy link field to provide a link to your privacy policy or other page that explains cookies to your site visitors. The default link is `/privacy`, which links to the Privacy Policy content that is configured within the Developer Portal. For more information, see Customizing the privacy policy statement.
   External links should start with `http://` or `https://`. For example:

   ```
   https://example.com/privacy
   ```

6. Configure the remaining options as required. For example, you can change the wording, and edit the display size and color.
7. Click Save configuration to save your updates.

Results

You successfully enabled a cookie compliance banner on your Developer Portal site. New visitors to your site are now prompted to accept cookies.

Related tasks

- Customizing the terms of use statement
- Customizing the privacy policy statement

Enabling code languages for code snippets

You can specify the languages that code snippets for APIs can be displayed in.

Before you begin

You must have administrator access to complete this task.

Procedure

1. On the administrator dashboard, click Configuration > System > IBM API Connect.
2. In the API Code Snippets section, select the check boxes for the languages that you want to make available for the code snippets to be displayed in.
3. Click Save configuration.
   The languages that you have enabled are displayed as options for your code snippets.

Enabling code snippets for SOAP APIs

By default, code snippets are only shown for REST APIs. You can enable code snippets for SOAP APIs.

Before you begin

You must have administrator access to complete this task.

About this task

Code snippets for SOAP APIs use raw HTTP, and do not use any SOAP libraries.

Procedure

1. On the administrator dashboard, click Configuration > System > IBM API Connect.
2. In the API Code Snippets section, select the Display code snippets for SOAP APIs as well as REST APIs check box.
3. Click Save configuration.
   The languages that you have enabled are displayed as options for your code snippets.

Forcing new users to accept terms and conditions

You can extend your Developer Portal site by forcing new users to accept the terms and conditions before they are able to create accounts.

Before you begin

You must have administrator access to complete this task.

Note: From IBM® API Connect Version 10.0.4.0, the **Legal** module is included in the list of core Developer Portal modules. The **Terms of use** module is still available in the Developer Portal, but the **Legal** module provides more configuration options.

About this task

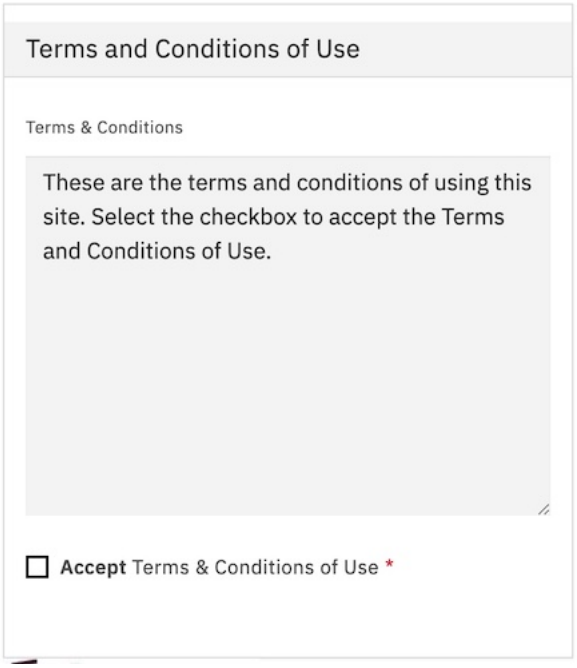
Use the following instructions to enable and configure the **Legal** module for your site terms and conditions.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. In the administrator dashboard, click Extend.
   The List tab for the Extend page opens, and the list of installed modules is displayed. The list shows all the modules that are installed. The enabled modules are displayed with a selected check box. The disabled modules are displayed without a selected check box.
3. Enter `legal` into the search filter.
   The Legal content item is displayed in the list of content.
4. Select the check box for the **Legal** module, and click Enable.
5. Navigate to Configuration > People > Legal.
6. Enter your Terms & Conditions statement, and select the Text format that you require.
7. Click Save configuration.

Results

You successfully enabled the **Legal** module. Now, when a user tries to create an account on your Developer Portal site, they must agree to the terms and conditions as a part of the registration.



What to do next

You can edit the terms and conditions page by navigating to Configuration > People > Legal, and making the changes that you require. You can disable the use of terms and conditions during site registration by deleting the terms and conditions content, and then disabling the **Legal** module.

If you prefer to use the **Terms of use** module, you can enable the module, and then navigate to Configuration > People > Terms of use, and select the page that contains your site terms and conditions, for example **Terms of use (1)**. For information about how to customize the statement, see Customizing the terms of use statement. The terms are displayed when you create an account and also from the link in the site footer. You can disable the use of terms and conditions during site registration by disabling the module.

- Drupal Legal module

Hiding the admin registry on the login form

You can hide the admin registry as an option on the login form. The use case for this option might be a public facing Developer Portal where you want to remove the admin access from customer view.

Before you begin

You must have administrator access to complete this task.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. On the administrator dashboard, click Configuration > System > IBM API Developer Portal.
3. In the Configuration section, select the check box for **`Hide the admin registry on the login form`**.
4. Click Save configuration.
   The **`Hide the admin registry on the login form`** configuration is saved.

What to do next

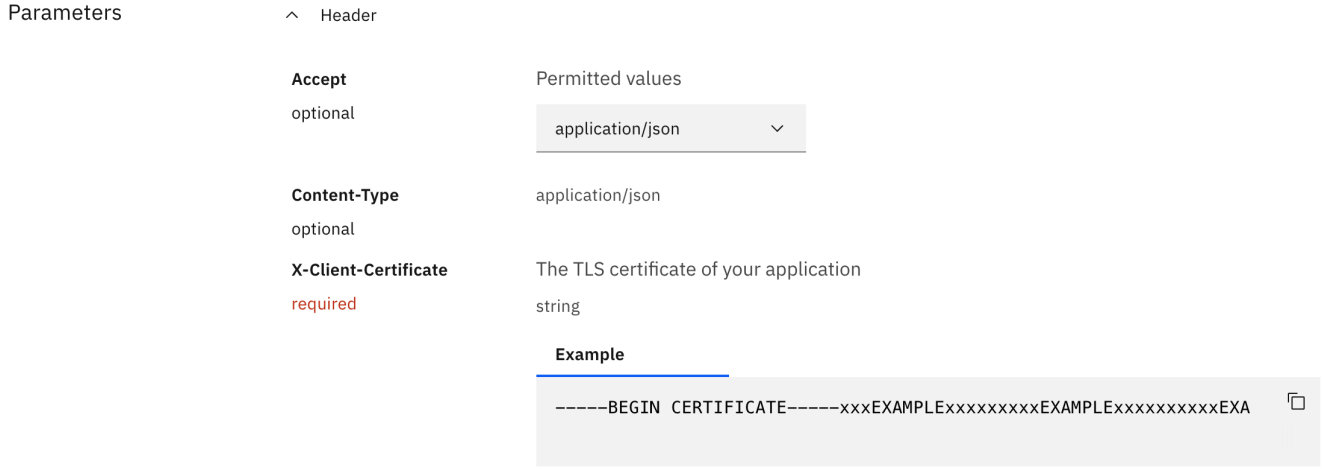
The admin registry is no longer shown on the login form. However, it is still accessible directly. The user can navigate to **`<site_url>/user/login?registry_url=/admin`**.

Hiding the certificate in the header for APIs secured with mutual TLS

You can hide the certificate in the header for APIs secured with mutual TLS. By default, the **`x-client-certificate`** header is shown in an API when mutual TLS is configured. You can choose to turn off this option in your Developer Portal.

Before you begin

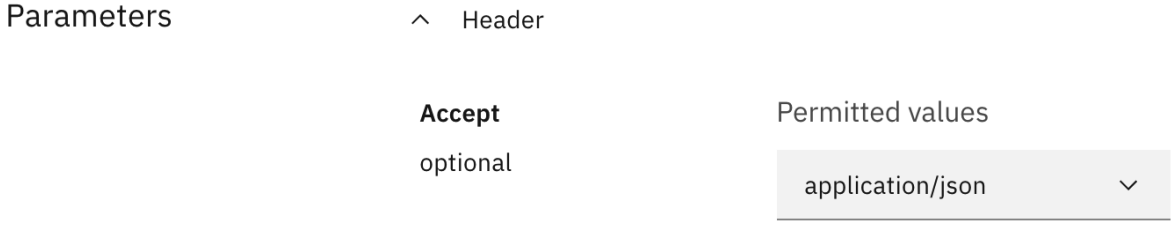
The parameters for the example API showing the certificate.



You must have administrator access to complete this task.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. On the administrator dashboard, click Configuration > System > IBM API Developer Portal.
3. In the Configuration section, deselect the checkbox for **`Show certificate in header for APIs secured with mutual TLS.`**
4. Click Save configuration.
   The **`Show certificate in header for APIs secured with mutual TLS.`** configuration is saved.
   The parameters for the example API now not showing the certificate:



Importing and exporting taxonomies

You can import and export taxonomies in the Developer Portal.

Before you begin

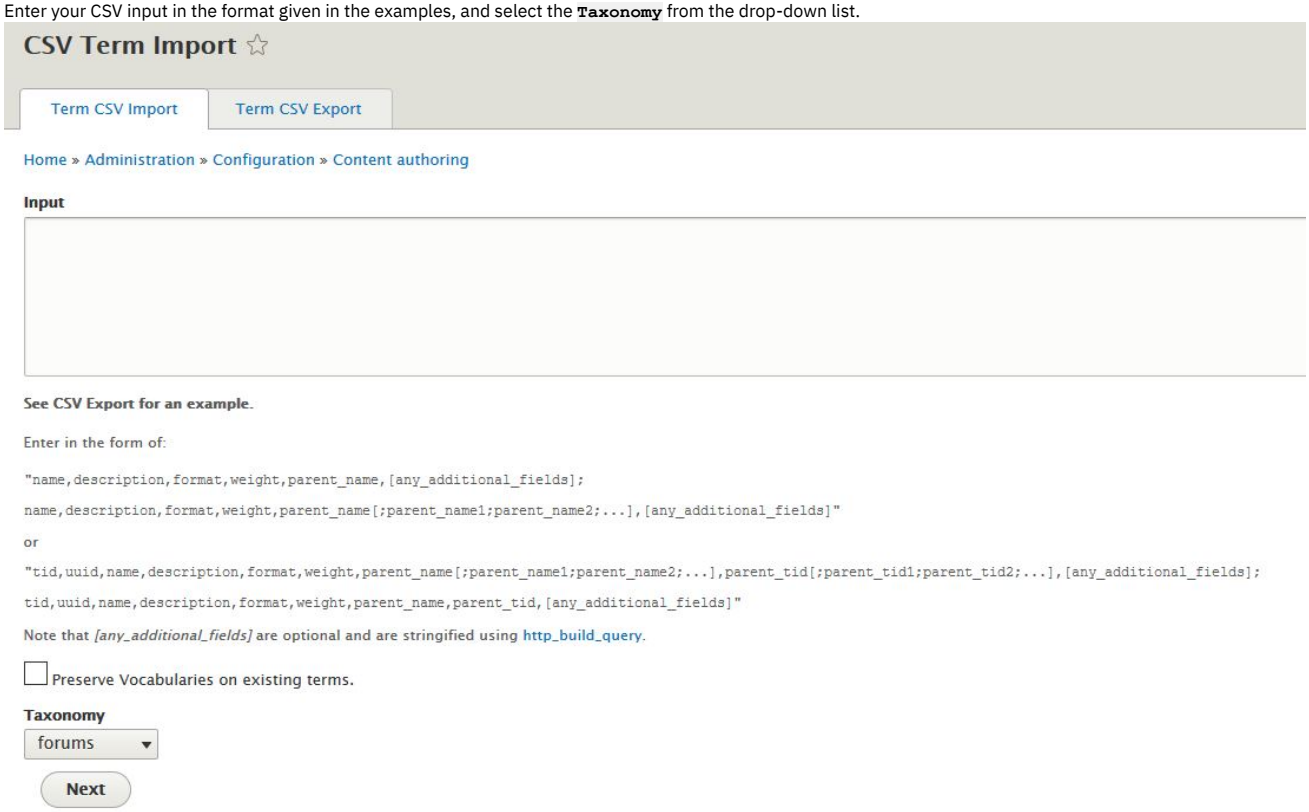
You must have administrator access to complete this task.

Procedure

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. In the administrator dashboard, click Configuration > Content authoring > Term CSV Export/Import.
4. Select Term CSV Import, or Term CSV Export.

For Term CSV Import

5. Enter your CSV input in the format given in the examples, and select the **`Taxonomy`** from the drop-down list.



6. Click Next.
7. Click Import.

For Term CSV Export

8. Select the **`Taxonomy`** from the drop-down list, and check any other options that you want.

9. Click Export.

Results

You successfully imported or exported a taxonomy.

Restricting access by IP address

You can restrict access to a role or a user by IP address in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

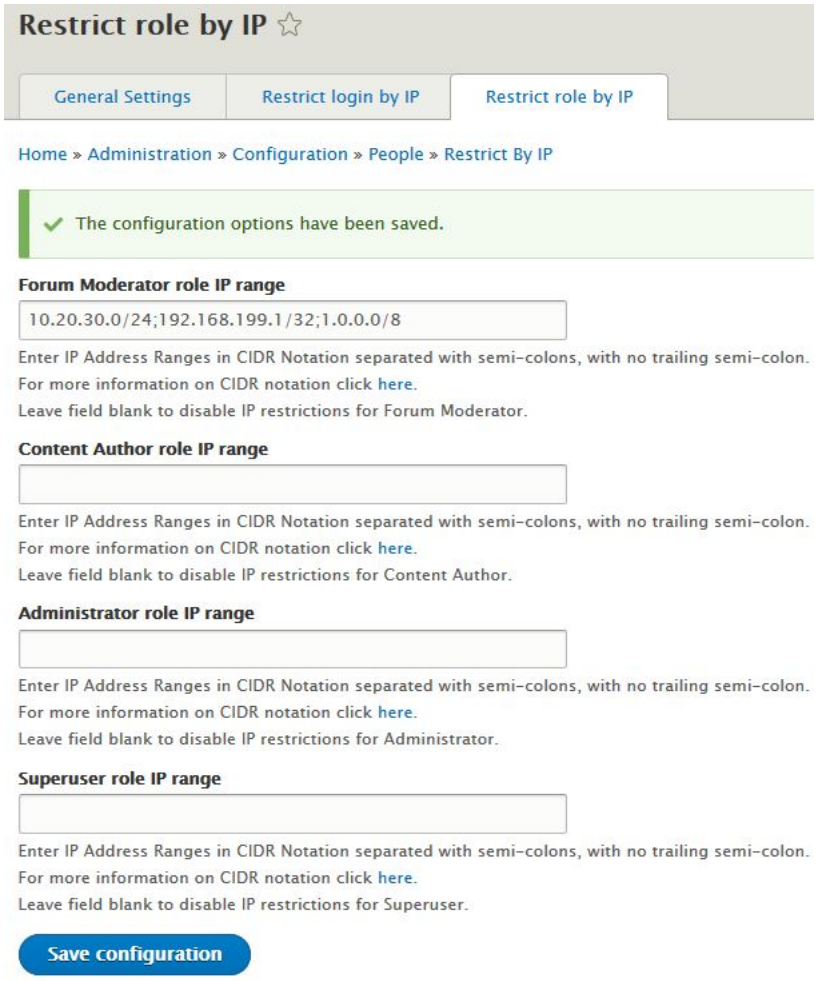
About this task

By restricting access to a role by IP address, that role is unavailable to users outside of the IP address ranges that you define. If a role restriction is triggered, the user's session is unaffected, but the restricted role is no longer available to the user. Role restriction affects only the availability of the restricted role to users. Role restrictions are available for all roles, except `anonymous user` and `authenticated user`.

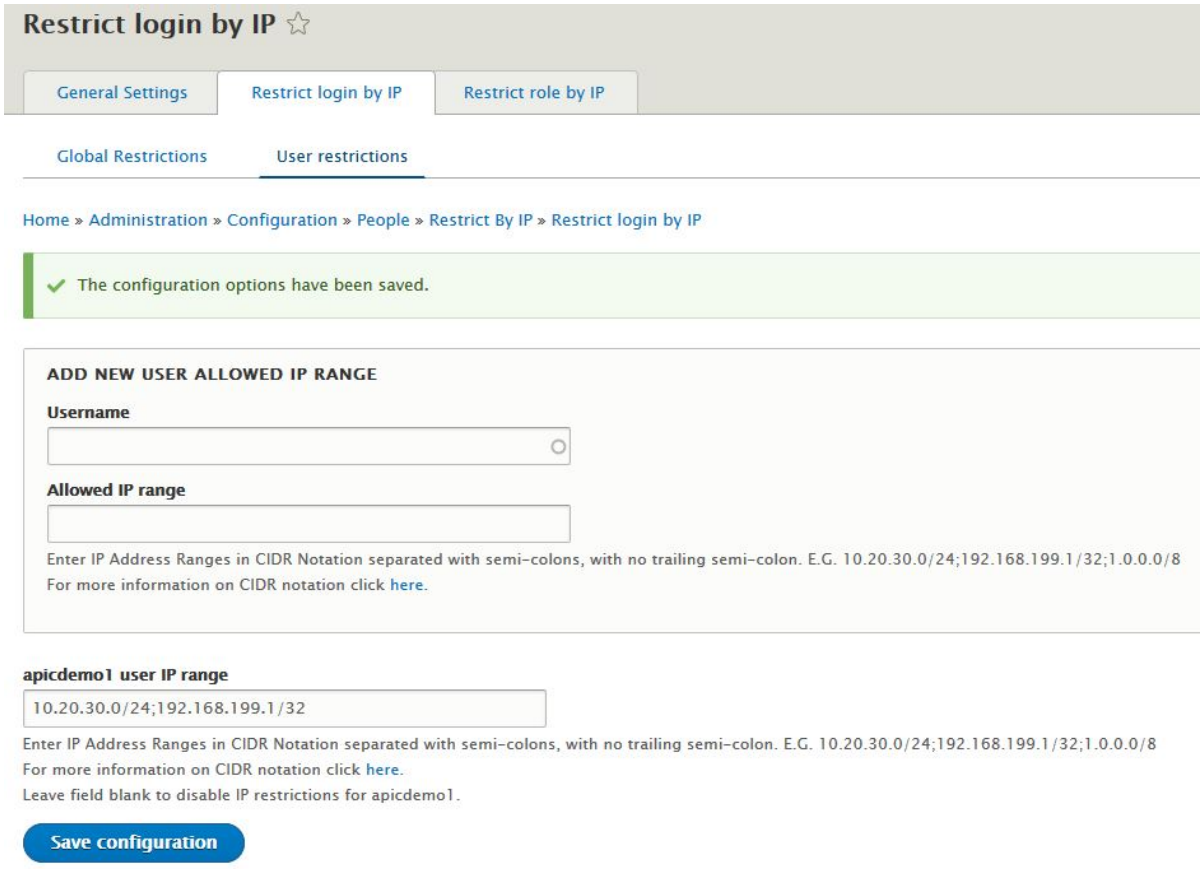
By restricting login access of a user by IP address, the user is unable to log in outside of the IP address ranges that you define. You can also specify global IP address ranges, which apply to all users. IP restrictions are checked on every page load. If a user restriction is triggered by an attempt at logging in being denied, then the user is logged out and sent to the 'error page' that is specified by the site administrator.
Note: IP address ranges must be entered in CIDR notation that is separated with semi-colons and no trailing semi-colon. For more information on CIDR notation, see CIDR format.

Procedure

1. In the Developer Portal, click Configuration > People > Restrict by IP, then click **`Restrict log in by IP`**.
2. On the **`Global restrictions`** tab, enter the address of the page to which the user is redirected to if they are not allowed to log in, in the Login denied error page.
3. Select one of the following options:
   - To restrict access to a role by IP address, complete the following steps:
     - Click Restrict role by IP.
     - Decide which role you want to restrict, the roles that you can restrict include Administrator, Content Author, and Forum Moderator.
     - Enter the IP address range (in CIDR notation) that you do not want to restrict log in for in the field for that role, for example, Forum Moderator role IP range.
     - Click Save configuration.



- To restrict login access of a user by IP address, complete the following steps:
  - Click Restrict login by IP, then click **`User restrictions`**.
  - In the **`ADD NEW USER ALLOWED IP RANGE`** section, enter a user name in the **`Username`** field.
  - Enter an IP address Range (in CIDR notation), that you do not want to restrict log in for in the **`Allowed IP range`** field.
  - Click Save configuration. Your new log in restriction can be seen after the **`ADD NEW USER ALLOWED IP RANGE`** section.



- To restrict login for all users, complete the following steps:
  - Click Restrict login by IP, then click **`Global restrictions tab`**.
  - Enter the global IP address ranges (in CIDR notation) in the Restrict global login to allowed IP range field.
  - Click Save configuration.

4. To remove an IP restriction, delete the value that is associated with the restriction, then click Save configuration.

Restricting or preventing access from search engines

You can restrict or prevent access to your Developer Portal from search engines. You might want to control the access if you have a development or test site.

Before you begin

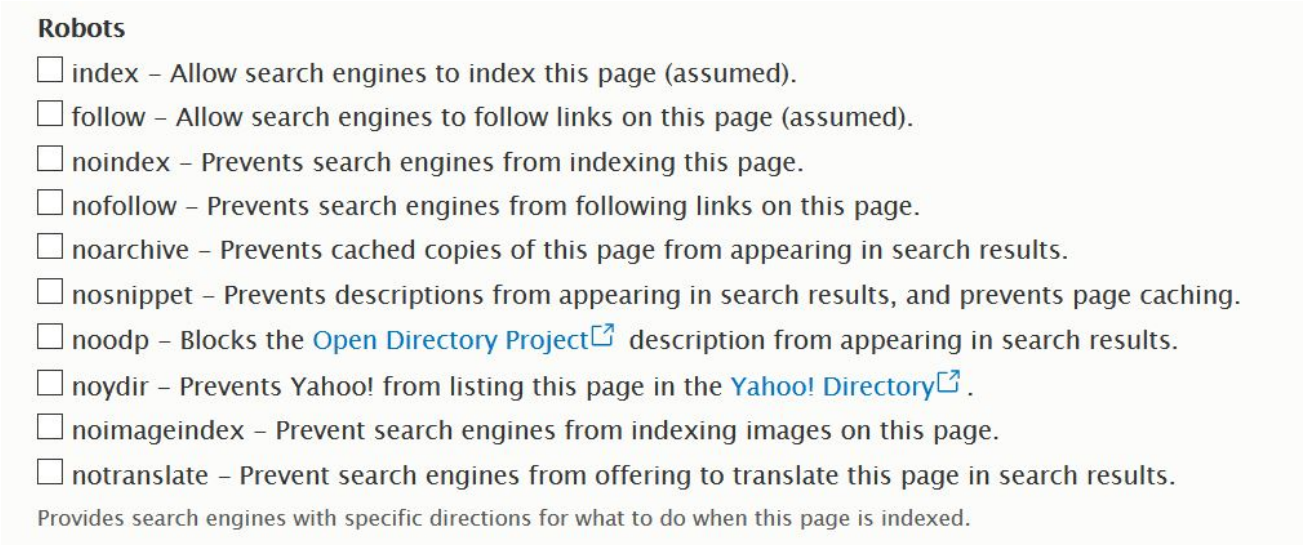
You must have administrator access to complete this task.

About this task

You might have a development or test Developer Portal site on the internet, but do not want them to be indexed by Google, or other search engines, making them visible to your customers. Google explicitly advises not to use **`robots.txt`** as a blocking mechanism. A correct solution is to control access by using Metatag.

Procedure

1. In the Developer Portal, click Configuration > Search and metadata > Metatag.
2. On the **`Global restrictions`** tab, click Edit.
3. In the Advanced section, select the meta tags that you want to use to restrict or prevent the access:



4. Click Save.

Toggling the site in and out of maintenance mode

You can put the Developer Portal site into maintenance mode for short periods of time. During maintenance mode, only an administrator is able to access the site, and all other users who enter the site URL get a maintenance message set by the administrator.

Before you begin

You must have administrator access to complete this task.

Important:

- Maintenance mode is designed for short-term site maintenance; it is not meant for long-term usage. While a site is in maintenance mode, the database is not updated with new content from API Manager. As soon as the maintenance tasks are finished, you must take the site out of maintenance mode.
- Do not log out of the Developer Portal while the site is in maintenance mode, as you will not be able to log back in to the UI. In this case, maintenance mode can be turned off only by using the toolkit CLI; see the following instructions for details.

Procedure

To put the site into maintenance mode, complete the following steps.

1. Click Configuration in the administrator dashboard.
2. Under the DEVELOPMENT heading, click Maintenance mode.
3. Select the Put site into maintenance mode checkbox.
4. Enter a site message, or leave the default site maintenance text.
   This message is what will be seen by users who visit the site while it is in maintenance mode.
5. Click Save configuration.
   Your site is now in maintenance mode.

To take the site out of maintenance mode, complete one of the following steps.

6. If you remained logged in to the site as the admin user during the maintenance period, you can use the Developer Portal UI to disable maintenance mode:
   a. Click Configuration in the administrator dashboard.
   b. Under the DEVELOPMENT heading, click Maintenance mode.
   c. Clear the Put site into maintenance mode checkbox .
      Your site is now available to users, and out of maintenance mode.
7. If you're no longer logged in to the site, you can use the toolkit CLI to disable maintenance mode:
   a. Log in to the toolkit CLI as a Provider org:

      ```
      apic login --server management_server --realm provider/identity_provider --username provider_username --password
      provider_password
      ```

      You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

      ```
      apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
      ```

      For example,

      ```
      apic identity-providers:list --scope provider --server myserver.com --fields title,realm
      total_results: 2
      results:
        - title: Cloud Manager User Registry
          realm: provider/default-idp-2
      ```

```
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

b. Run the following command to disable maintenance mode on your Developer Portal:

```
apic --mode portaladmin drupal-state:set --server management_server --org orgid/name --catalog catalogid/name --
state_key system.maintenance_mode  --input_format integer --state_value 0
```

Where:

- ***management_server*** is the endpoint URL of your management server (required).
- ***catalogid/name*** is the ID or name of the catalog that your site belongs to (required).
- ***orgid/name*** is the ID or name of the provider organization that the catalog belongs to (required).
- **--state_key** is the name of the state key (required). Must be set to **system.maintenance_mode**.
- **--input_format** is the input format of the value of the state key. Must be set to **integer** for configuring the maintenance mode.
- **--state_value** is the value to assign to the state key (required). Set to **0** to disable maintenance mode.

For example, to disable maintenance mode for a Developer Portal in the **myOrg** organization, and in the **dev** catalog:

```
apic --mode portaladmin drupal-state:set --server my.management.server.com --org myOrg --catalog dev --state_key
system.maintenance_mode  --input_format integer --state_value 0
Successfully set state system.maintenance_mode to the value of 0.
```

Your site is now available to users, and out of maintenance mode.

What to do next

You can use the toolkit CLI to enable, and disable, maintenance mode. For more information, see the scenario How to enable and disable maintenance mode on your Developer Portal.

Viewing available updates

You can view available updates in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To view available updates, complete the following steps:

1. Click Reports in the administrator dashboard.
2. Click Available updates.
3. You can see what updates are available from this view. However, updates can be applied only by applying the latest available API Connect release; see Upgrading in a Kubernetes environment, or Upgrading in a VMware environment, for more information.

Managing Developer Portal security

You can manage multiple security elements in the Developer Portal.

- **Configuring CAPTCHA**
  You can add a CAPTCHA challenge to any of your Developer Portal pages to protect your site from spam.
- **Configuring reCAPTCHA**
  You can configure reCAPTCHA on your Developer Portal site to provide more protection from spam and abuse.
- **Configuring session timeout and limit**
  You can specify session timeout settings to control when a user is automatically logged out of the Developer Portal. You can also restrict the number of sessions a single user has available to them.
- **Configuring the timeout length for the password reset link**
  You can configure the timeout length for the one-time password reset link that is sent from the Developer Portal to the admin user account.
- **Configuring your site password policy**
  You can configure your site password policy to define the constraints that are applied to the passwords of your Developer Portal users.

- **Disabling CORS warnings**
  You can disable cross-origin resource sharing (CORS) warnings for unenforced APIs in the Developer Portal.
- **Disabling live testing of APIs**
  You can disable live testing of APIs in the Developer Portal to restrict exposure of an API.
- **How to enable penetration testing, and information about Developer Portal cookies**
  Many security features are available in the Developer Portal, but if you need to do a penetration test of your Developer Portal site, some of these features might block the scan that is required as part of the testing. This topic provides guidance on the security features that you might need to disable to allow penetration testing of your site, as well as information about Developer Portal cookies.
- **How to manage IP security in the Developer Portal**
  The Developer Portal offers the ability to perform various IP address security measures, such as adding and removing specific IP addresses from the banned IP address list, automatically banning client IP addresses by using the Drupal Perimeter Defence module, or managing login security by using flood control.
- **Managing banned IP addresses**
  You can ban specific IP addresses from accessing your Developer Portal site.
- **Using flood control for login security**
  You can configure login security for your Developer Portal by using flood control.
- **Login security**
  You can configure the login security for your Developer Portal at an IP and user level. You can also configure login security for Developer Portal contact forms.
- **Using the Security kit**
  You can improve the security of your website by configuring various options that are available in the Security Kit module, in the Developer Portal.
- **Using Honeypot for spam protection**
  Honeypot protection provides security mechanisms to protect your Developer Portal site from form submission by spam bots. If spam bot activity is detected, form submission is blocked.

Configuring CAPTCHA

You can add a CAPTCHA challenge to any of your Developer Portal pages to protect your site from spam.

Before you begin

You must have administrator access to complete this task.

About this task

The types of CAPTCHA challenges that are available include Image and Math based CAPTCHAs. Both types of CAPTCHA challenges are configurable in the CAPTCHA dialog box. By default, your Developer Portal site is configured with the Image based CAPTCHA challenge enabled.
You can also configure reCAPTCHA on your site. For more information, see Configuring reCAPTCHA.

Procedure

To configure CAPTCHAS, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the PEOPLE section, click CAPTCHA module settings.
   The CAPTCHA settings window opens.
4. Use the CAPTCHA configuration options provided as required. For example, you can complete the following tasks:
   a. Specify the CAPTCHA challenge type.
   b. Specify which forms must include a CAPTCHA challenge.
   c. Add a description to the CAPTCHA.
   d. Enable CAPTCHA statistics.
5. Click Save configuration to save your changes.

Configuring reCAPTCHA

You can configure reCAPTCHA on your Developer Portal site to provide more protection from spam and abuse.

Before you begin

You must have administrator access to complete this task.

About this task

reCAPTCHA is a CAPTCHA-like system that is designed to establish that a computer user is human. The types of reCAPTCHA that are available include Checkbox, Invisible, and Android.
Note: To use reCAPTCHA the administrator of your Developer Portal is required to sign up to Google's reCAPTCHA API, and your portal server must have internet access.

Procedure

To configure reCAPTCHA, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.

2. Click Configuration > People > CAPTCHA module settings > reCAPTCHA in the administrator dashboard.
   The reCAPTCHA settings window opens.
3. In the GENERAL SETTINGS section, click register for reCAPTCHA.
   The Google registration site for reCAPTCHA is displayed.
4. Follow the instructions on Google to register your Developer Portal site, and obtain the Site key and Secret key.
5. Return to the reCAPTCHA settings window in the Developer Portal, and enter the Site key and Secret key that you obtained from Google into the GENERAL SETTINGS section.
6. Optional: Update the WIDGET SETTINGS section as required.
7. Click Save configuration to save your changes.
8. Click the CAPTCHA Settings tab, and in the FORM PROTECTION section change the Default challenge type to reCAPTCHA (from module reCAPTCHA).
9. Click Save configuration.

Results

The reCAPTCHA module is now enabled on your Developer Portal site.

- Configuring CAPTCHA

Configuring session timeout and limit

You can specify session timeout settings to control when a user is automatically logged out of the Developer Portal. You can also restrict the number of sessions a single user has available to them.

Before you begin

You must have administrator access to complete this task.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. To manage the automated logout settings, complete the following steps:
   a. Click Configuration in the administrator dashboard.
   b. In the PEOPLE section, click Automated logout settings.
      Note: You must check **`Enforce auto logout on admin pages`** for **`autologout`** to apply when navigating the admin areas of the site.

      

   c. Use the session timeout configuration options provided as required. For example, you can complete the following tasks:
      - Specify the length of inactivity time, in seconds, before a user is automatically logged out.
      - Specify session timeout values for individual user roles.
        Note: The default session timeout is 30 minutes.
      - Provide a redirection URL at logout.
      - Provide session expiry message texts.
   d. Click Save configuration to save your changes.
3. To restrict the number of sessions available to a user, complete the following steps:
   a. Click Configuration in the administrator dashboard.
   b. In the PEOPLE section, click Session limit.
   c. Specify the default maximum number of sessions for a user by entering the number into the Default maximum number of active sessions field.
   d. Select the required action from the When the session limit is exceeded options.
   e. From the Logged out message severity list, select the severity of the message that the user receives when they are logged out.
   f. Optionally, in the ROLE LIMITS section, specify separate session limits for each role.
   g. Click Save configuration to save your changes.

Configuring the timeout length for the password reset link

You can configure the timeout length for the one-time password reset link that is sent from the Developer Portal to the admin user account.

Before you begin

You must have administrator access to complete this task.

About this task

By completing the steps in this task, you are configuring the timeout length for the one-time password reset link that is sent to the admin user account by the Developer Portal.

Note:

- Setting the password reset timeout length in the Developer Portal affects only the admin user account.
- You are not affecting the user activation or password reset links that are used by any other identification provider type in API Manager.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the PEOPLE section, click Account settings.
   The Account settings window opens.
4. In the Account settings window, navigate to the PASSWORD RESET TIMEOUT section.
5. Enter your required value for the timeout in the Password Reset Timeout field.
   Note: The timeout value is specified in seconds, and is 86400 seconds by default.
6. Click Save configuration.
   You have configured the timeout length for the one-time link that is sent from the Developer Portal for the admin user account.

Configuring your site password policy

You can configure your site password policy to define the constraints that are applied to the passwords of your Developer Portal users.

Before you begin

You must have administrator access to complete this task.

About this task

Any passwords that are stored in the API Manager must comply with the API Manager password policy. You can configure your password policy to be the same as or stricter than the API Manager password policy.

Procedure

To configure your site password policy, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the SECURITY section, click Password Policy.
   The Password Policies page opens.
4. In the OPERATIONS column for the default password policy, click Edit.
   Note: You can create a new password policy by clicking Add Policy; this allows you to apply different password policy settings to different roles. If you need only a single password policy, just configure the pre-supplied default policy.
5. Click Next.
   The Configure Constraints page opens.
6. Configure the password constraints as required.
   a. To configure a constraint, click Edit in the OPERATIONS column for the required constraint.
   b. To delete a constraint, select Delete in the OPERATIONS column.
   c. To add a constraint, select the required constraint type from the drop-down list, then click Configure Constraint Settings.
   d. When you are done, click Next.
      The Apply to Roles page opens.
7. Select the roles to which the password policy settings are to be applied. then click Finish.

Disabling CORS warnings

You can disable cross-origin resource sharing (CORS) warnings for unenforced APIs in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

By disabling the CORS warnings, users will not receive further warnings regarding the usage of unenforced APIs.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the SYSTEM section, click IBM API Connect.
4. Ensure that the Display CORS warnings for unenforced APIs check box is cleared.
5. Click Save Configuration.

You have disabled CORS warnings in the Developer Portal. To enable CORS warnings, repeat the steps and ensure that the Display CORS warnings for unenforced APIs check box is selected.

Disabling live testing of APIs

You can disable live testing of APIs in the Developer Portal to restrict exposure of an API.

Before you begin

You must have administrator access to complete this task.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the SYSTEM section, click IBM API Connect.
4. Ensure that the Allow live testing of APIs check box is cleared.
5. Click Save configuration.
   You have disabled live testing of APIs. To enable live testing of APIs, repeat the steps and ensure that the Allow live testing of APIs check box is selected.

How to enable penetration testing, and information about Developer Portal cookies

Many security features are available in the Developer Portal, but if you need to do a penetration test of your Developer Portal site, some of these features might block the scan that is required as part of the testing. This topic provides guidance on the security features that you might need to disable to allow penetration testing of your site, as well as information about Developer Portal cookies.

Penetration testing, or pen testing, is the practice of testing a computer system, network, or web application for potential security vulnerabilities that an attacker might exploit. For certain elements of your pen testing, you might want to disable some of the security features that block scanning of the Developer Portal. The following sections describe the security features in the Developer Portal that you might need to disable. The actual requirements depend on your Developer Portal configuration, and on the type of pen testing that you are running. Note also the final section, which discusses testing for Distributed Denial of Service attacks.
Important:

- If you run a pen test, and you give the automated test tool the admin credentials, the tool submits all of the administration configuration forms as well, and this action is likely to break the Portal site configuration. Best practice is to use different credentials for the testing.
- If you disable security modules, and then run security scans, your Portal site configuration might be broken by the scanning process. Before running any security testing, ensure that you have a valid backup of your Portal site.
- If your Portal site configuration is broken by the security testing, then you must delete the Portal site from the API Manager Catalog settings and re-create it, or restore it from a backup.
  For information about restoring your site, see the appropriate topic for your environment:
  - Backing up and restoring the Developer Portal in a Kubernetes environment
  - Backing up and restoring the Developer Portal on OpenShift and Cloud Pak for Integration
  - Backing up and restoring the Developer Portal in a VMware environment
- Note that disabling of security modules makes it highly likely that you will find issues that are not actually vulnerabilities, because you have disabled the modules that are designed to protect against these vulnerabilities. Therefore, any issue that is found in these circumstances must be replicated in an environment without the security modules disabled, before contacting IBM Support.
- Do not use the **`Enforced`** mode of the **`Content Security Policy`**, this mode is not supported and can break core Developer Portal functionality such as API rendering and the content editor. The **`Content Security Policy`** must be in **`Report only`** mode.

Note: You might need to disable the **`Honeypot`** module to allow your penetration test to run. For more information, see Using Honeypot for spam protection.
This topic contains the following sections:

CAPTCHA and reCAPTCHA verifications

CAPTCHA and reCAPTCHA verifications are a type of challenge-response test that are used in web applications to check whether the user is human. By default, your Developer Portal site is configured with an Image based CAPTURE challenge enabled, but you can also configure a Math based CAPTCHA challenge, and Checkbox, Invisible, and Android reCAPTCHA challenges. If you need to disable these verifications before pen testing, see the following instructions.

To disable the CAPTCHA and reCAPTCHA verifications, you must disable the modules as follows:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Extend > Disable module.
4. Search through the list of modules, and select the check boxes next to the Image CAPTCHA and reCAPTCHA modules.
5. Click Disable, and click Disable again to confirm.
6. On the Disable tab, select the check box next to the CAPTCHA module, and click Disable. The display shows the forms that the CAPTCHA configuration is removed from.
7. Click Disable again to confirm. Note that the modules must be disabled in this order.

The CAPTCHA and reCAPTCHA modules are now disabled, and you can complete your pen testing. After pen testing, you can enable the modules again by clicking Extend on the administrator dashboard, selecting the check box for each module in the List tab, and clicking Enable.

Drupal Perimeter Defense module

The Drupal Perimeter Defense module (machine name: perimeter) immediately bans the IP addresses of those users that send suspicious requests to your site, so any pen testing scans would be blocked. This module is enabled by default on the Developer Portal. For more information about the module, see the Drupal documentation Drupal Perimeter Defense module.

If you need to disable the Drupal Perimeter Defense module before pen testing, see the following instructions:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Extend > Disable module.
4. Search through the list of modules, and select the check box next to the Drupal Perimeter Defense module.
5. Click Disable, and click Disable again to confirm.

The Drupal Perimeter Defense module is now disabled, and you can complete your pen testing. After pen testing, you can enable the module again by clicking Extend on the administrator dashboard, selecting the check box next to the Drupal Perimeter Defense module in the List tab, and clicking Enable.

Login Security module

The Login Security module (machine name: login_security) enables the site administrator to improve the security options in the login operation of your Developer Portal site. For example, controlling the number of invalid login attempts before blocking users, and denying access by IP address. This module is enabled by default on the Developer Portal. For more information about the module, see the Drupal documentation Login Security module.

If you need to disable these security options before pen testing, you need to manually modify the configuration of your security options according to your requirements. For example, you might need to change the number of login attempts that are allowed before a user or IP address is blocked. To configure the security options, see the following instructions:

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. On the administrator dashboard, click Configuration > People > Login Security.
4. In the Login Security window, update the security options according to your requirements.
5. Click Save configuration to save your updates.

The Login Security options are now updated, and you can complete your pen testing. After pen testing, you can reconfigure your security options in the Login Security window.

Developer Portal cookies

Cookies are small text files that are placed on a computer by websites when they are visited. The Developer Portal uses cookies that remain on the computer for varying times. Some cookies expire at the end of each session, and some remain longer to enhance the user experience in the future. The list here explains the cookies that are used by the Developer Portal, and why they are used.
Note: Any load balancer that sits in front of the Developer Portal must be a transparent proxy that enables all cookies returned by the Developer Portal to pass through to the browser.

Drupal session identifier cookie
: This is the main cookie that all of the Developer Portal sites have, and it stores the session identification. The session cookie is named in the format SSESS*UUID*, where *UUID* is a randomly generated unique string of characters for that session, and this is the session token itself. The session cookie is always marked with the following flags as instructions to the browser client:

  - **`Secure`** - means that the cookie is sent only over a secure connection (that is, over TLS).
  - **`HttpOnly`** - means that the browser adds this cookie on outbound requests only, and not provide the value to client side javascript.

session_store.id cookie
: This cookie is used to store information on where a user is in the subscription flow, and any options that they selected, if they haven't yet signed in, so the Developer Portal can redirect them back there later. The session_store.id cookie is also marked with the **`Secure`** and **`HttpOnly`** flags, and it does not contain any confidential information.

Drupal.visitor.startSubscriptionWizard cookie
: This cookie is used to store information on where a user started in the subscription flow if they haven't yet signed in, so the Developer Portal can redirect them back there later. The Drupal.visitor.startSubscriptionWizard cookie is also marked with the **`Secure`** and **`HttpOnly`** flags, and it does not contain any confidential information.

portal_web cookie
: This cookie is used to achieve session persistence, which it does by ensuring that web traffic between the user and the Developer Portal is correctly routed to the server. The portal_web cookie is used for both HTTP and HTTPS communications, so that routing is meaningful irrespective of the transfer protocol, and ensuring consistent behavior if the switching of protocols is required. The cookie contains only a hash of the pod that served the traffic to maintain session persistence, and does not contain any confidential information. The cookie is provided by the Portal ingress. This cookie is not marked as **`Secure`** or **`HttpOnly`**, as the Kubernetes ingress does not yet support these attributes.

Other cookies
: In addition to the cookies listed previously, there are other (usually temporary) cookies that might be created depending on the configuration options of your Developer Portal site. For example, if the site uses OAuth for authentication, then during the OAuth token activation flow a JSON Web Token is sent to the browser. This token is stored in a cookie for a limited lifetime. This action is part of the normal function of an OAuth flow. As the creation of these other cookies depends on your particular Developer Portal configuration, we cannot provide a complete list of cookies here.

Should I test the Developer Portal for vulnerability to Distributed Denial of Service attacks?

When you run penetration testing, it's important to understand that individual systems are not responsible for (nor capable of dealing with) Distributed Denial of Service (DDoS) attacks. DDoS attacks are launched by huge numbers of external computers simultaneously, with a goal of using up all of the resources of a system, and thereby

denying service to legitimate users. These kinds of attacks are usually defended against at the level of the network and edge gateways, and information about how to protect against them is out of the scope of this topic. Although the Developer Portal does have some capabilities, including the modules mentioned previously, for potentially mitigating some of the effects of a DDoS attack, do not rely on these capabilities as the first line of defense; rather they are designed to assist in dealing only with any elements of an attack that might have gotten through the outer network layers of protection.

How to manage IP security in the Developer Portal

The Developer Portal offers the ability to perform various IP address security measures, such as adding and removing specific IP addresses from the banned IP address list, automatically banning client IP addresses by using the Drupal Perimeter Defence module, or managing login security by using flood control.

See the following links for information about how to manage IP security in the Developer Portal:

- Enable and disable IP security
- Correctly passing through client IP addresses
- Managing banned IP addresses

Enable and disable IP security

The ability to enable or disable IP security related actions can be controlled at the Portal service level by using the Developer Portal CLI command **`ip-security-enabled`**. When IP security is enabled, modules such as the Drupal Perimeter Defence module, or flood control, will block client IP addresses suspected of malicious behavior, as expected. When IP security is disabled, all IP related security is switched off. For example, the perimeter module won't block client IP addresses when IP security is disabled. You might want to turn off IP security if you are performing penetration tests, or if you cannot pass through the client IP address from your external load balancer. For more information, see Using the ip-security-enabled command.

Correctly passing through client IP addresses

In order to correctly use modules that make use of client IP banning, such as the Drupal Perimeter Defence module, you must ensure that any external load balancer that fronts the Portal cluster passes through the client IP address. This can be achieved by passing the client IP address through in an **`'x-forwarded-for'`** header, or by making use of the proxy protocol (provided both the load balancer and the ingress controller are compatible with the proxy protocol, and have the protocol enabled). Failure to correctly pass through the client IP address, results in the load balancer IP address being blocked when a client attempts to send a suspicious request to the portal.

If you are fronting the Portal cluster with an HAProxy setup acting as the load balancer, then you can make use of the proxy protocol by adding the **`send-proxy`** directive to the end of the Portal server declarations in the HAProxy configuration file, for example:

```
server portal0 portal_host:port check send-proxy
```

You must restart the HAProxy for the change to take effect. Note that if your load balancer IP address has already been blocked, you will need to remove the blocked IP address from the banned list by using the **`security`** command in theDeveloper Portal CLI, see Using the security command.

If you find your load balancers are being banned by Portal's IP Security modules, then you might need to configure your system's ingresses to send the **`'x-forwarded-for'`** headers. For instance, the default behavior of the **`nginx-ingress-controller`** is to ignore the inbound **`'x-forwarded-for'`** header and construct a new one. To configure the **`nginx-ingress-controller`** to pass through the inbound **`'x-forwarded-for'`** header you need to add the following to the **`nginx-ingress-controller`** config map:

```
data:
 compute-full-forwarded-for: "true"
 use-forwarded-headers: "true"
```

For more information about the Drupal Perimeter Defence module, see Drupal Perimeter Defense module.

Managing banned IP addresses

You can manage banned IP addresses for a particular site by using the administrator dashboard for a particular Developer Portal site. For more information, see Managing banned IP addresses.

Related concepts

- How to enable penetration testing, and information about Developer Portal cookies

Related tasks

- Disabling modules
- Login security
- Blocking and unblocking specific users
- Managing banned IP addresses

Managing banned IP addresses

You can ban specific IP addresses from accessing your Developer Portal site.

Before you begin

You must have administrator access to complete this task.

Procedure

To manage banned IP addresses, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the PEOPLE section, click IP address bans.
   The IP address bans window opens.
4. You can complete the following tasks:
   a. To ban an IP address, enter the address in the IP address field, then click Add.
      The address is added to the BANNED IP ADDRESSES list.
   b. To remove an IP address from the banned list, click Delete alongside the required address.

   Note:
   - There is automatic login "flood" protection built into the Developer Portal. This feature means that an excess of login attempts from the same IP address in one hour will cause that IP to be temporarily banned. For more information, see Using flood control for login security.
   - You can also clear banned user/IP addresses by using the Developer Portal CLI command `security:clear-bans`. For more information, see Using the security command.

Using flood control for login security

You can configure login security for your Developer Portal by using flood control.

Before you begin

You must have administrator access to complete this task.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Navigate to Configuration > System > Flood Control.
3. Enter values in the following fields in the LOGIN SETTINGS section according to your requirements:
   - Failed IP login limit (min 1) - the number of failed login attempts from the same client IP.
   - Failed IP login window in seconds (0 = Off) - the time window, in seconds, for the number of failed login attempts from the same client IP.
   - Failed User login limit (min 1) - the number of failed login attempts from a user.
   - Failed User login window in seconds (0 = Off) - the time window, in seconds, for the number of failed login attempts from a user.
4. Enter values in the following fields in the CONTACT FORM section according to your requirements:
   - Emails sent limit - the number of emails that can be sent.
   - Emails sent window in seconds - the time window, in seconds, for the number of emails that can be sent.
5. Click Save configuration.

What to do next

To unblock a user, see Blocking and unblocking specific users. To unblock an IP address, see Managing banned IP addresses.

Login security

You can configure the login security for your Developer Portal at an IP and user level. You can also configure login security for Developer Portal contact forms.

Before you begin

Important: The Login Security module is being removed from future releases. It has been replaced by Flood Control. Existing users of the Login security module should configure Flood Control with the same limits and time windows as specified here. For more information, see Using flood control for login security.
You must have administrator access to complete this task.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the PEOPLE section, click Login Security.
4. Enter values in the following fields in the GENERAL SETTINGS section according to your requirements:
   - Track time - the time window to check for security violations.
   - User - the number of login failures before blocking a user.
   - Soft host - the number of login failures before soft blocking a host. The host can still browse the site as an anonymous user.
   - Host - the number of login failures before hard blocking a host. The host cannot access the site at all.
   - Attack detection - the number of login failures before warning about an ongoing attack.
5. Select the check boxes that satisfy your notification requirements in the NOTIFICATION section:
   - Disable login failure error message
   - Notify the user about the number of remaining login attempts
   - Display last login timestamp
   - Display last access timestamp
6. Optional: Edit the EMAIL FOR ONGOING ATTACK DETECTION section.
7. Optional: Edit the EMAIL FOR BLOCKED ACCOUNT section.
8. Optional: You can edit the notification texts that are displayed by configuring the following options:
   - Failed login attempt
   - Banned host (soft IP ban)
   - Banned host (hard IP ban)
   - Blocked user by uid
9. After you have configured your login security options, click Save configuration.

What to do next

To unblock a user, see Blocking and unblocking specific users. To unblock an IP address, see Managing banned IP addresses.

Using the Security kit

You can improve the security of your website by configuring various options that are available in the Security Kit module, in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

The Security Kit module provides your website with various options to mitigate risks of common web application vulnerabilities like Cross-site Scripting, Cross-site Request Forgery and Clickjacking. It also has some options to improve your SSL/TLS security.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the SYSTEM section, click Security Kit settings.
4. In the Security Kit module, configure the security settings for your website as required.
5. When you are done, click Save configuration.

Using Honeypot for spam protection

Honeypot protection provides security mechanisms to protect your Developer Portal site from form submission by spam bots. If spam bot activity is detected, form submission is blocked.

Before you begin

You must have administrator access to complete this task.

About this task

Honeypot protection provides the following security mechanisms:

- A hidden field, unseen by users, is added to the form. If a value has been entered in the field when the form is submitted then this indicates that the form was completed by a spam bot, and the submission is blocked. You can specify the name of the hidden field.
- If the form is submitted before a specified time has elapsed (five seconds by default), it is assumed that this is too short a time for a human to have completed the form, and the submission is blocked. You can specify the time length.

Honeypot protection is provided by the Honeypot module, which is enabled by default.

Note: If you want to carry out automated testing of your Developer Portal, you might need to disable the Honeypot module, because Honeyspot spam protection is designed specifically to block automated Developer Portal usage. For details on how to disable a module, see Disabling modules.

Procedure

To configure Honeypot for spam protection in the Developer Portal, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. In the CONTENT AUTHORING section, click Honeypot configuration.
4. Specify the forms that you want to protect with Honeypot.
   a. To enable Honeypot protection for all the forms on your Developer Portal site, select Protect all forms with Honeypot.
   b. To choose which forms you want to protect with Honeypot, clear the Protect all forms with Honeypot check box, then select the required forms in the HONEYPOT ENABLED FORMS section.

   By default, Honeypot protection is enabled for all user management forms and all comment forms.
5. To have details of all blocked form submissions written to the log file, select Log blocked form submissions.
6. In the Honeypot element name field, specify the name of the hidden form field.
   The default field name is url. You need to change the value if your form already has a field of the same name. For the most effective protection, use a generic field name; for example, email, homepage, or link.
7. In the Honeypot time limit field, specify the number of seconds that must elapse before it is assumed that a form is being submitted by a human rather than a spam bot. If the form is submitted before this time has elapsed then the submission is blocked.
   The default value is five seconds.
8. When done, click Save configuration.

People

You can manage and customize the user experience in the Developer Portal, by altering permissions and assigning roles to specific users.

To learn how to configure the user experience for your Developer Portal site, use the following section links.

- **Blocking and unblocking specific users**
  You can block and unblock specific users in the Developer Portal.
- **Controlling access to Developer Portal content**
  In IBM® API Connect, you can restrict access to content for Consumer organizations through an access content list. However, you can also assign permissions in the Developer Portal that override the access content list, and allow users to access and edit all of the content for Products, APIs, and Applications.
- **Creating a developer account to customize API properties**
  You can allow specific users in the Developer Portal to customize the properties for certain APIs, including APIs that are not viewable by the administrator, or other customizable features, by creating an internal Consumer organization.
- **Email Subscribers**
  As a site administrator, you can use the email subscribers wizard to send messages to your Developer Portal community.
- **How to style the Developer Portal emails**
  You can apply a theme to the HTML emails that are sent by the Developer Portal by using CSS and templating.
- **Working with roles in the Developer Portal**
  As a site administrator, you can create and customize site configuration roles in the Developer Portal.

Blocking and unblocking specific users

You can block and unblock specific users in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To block or unblock a specific user, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click People in the administrator dashboard.
   A list of users is displayed.
3. Select the check box next to the target user.
4. From the drop-down list under Action, select Block the selected user(s) or Unblock the selected user(s).
5. Click Apply to selected items.
   You have blocked or unblocked specific users from the Developer Portal.
   Note: If a user reports that they are unable to login, but they do not appear as blocked, then it might be that they have been blocked by Flood Control. To unblock such users, select Configuration > System > Flood unblock. You can configure your Flood Control settings; see Using flood control for login security for more information.

Controlling access to Developer Portal content

In IBM® API Connect, you can restrict access to content for Consumer organizations through an access content list. However, you can also assign permissions in the Developer Portal that override the access content list, and allow users to access and edit all of the content for Products, APIs, and Applications.

Before you begin

You must have administrator access to complete this task.

About this task

A user with a Content Author role is a curator of content for the Developer Portal. A Content Author user can perform the following actions:

- Set taxonomies on the content
- Provide custom icons for content
- Upload additional documentation files
- Create documentation pages in the Developer Portal.

By default, Content Author users are assigned the following user permissions:

Edit any Product content
: The user can access and edit all of the Products available in the Catalog that the Developer Portal is associated with. The user can also access APIs that belong to those Products.

Edit any API content
: The user can access and edit all of the APIs that are available in the Catalog, but not the Products with which they are associated. (Note that this permission is a subset of Edit any Product content; as Content Author users are assigned both permissions they can access and edit all of the Products and the associated APIs that are available.)

The Edit any Application permission grants the user access to all of the Applications that are in the Developer Portal, but is not assigned to any user or role by default.
Note: There are security implications if you grant the Edit any Application permission, and it should be assigned only to trusted roles.
A user can configure, attach, and upload content if they are assigned the appropriate permissions.

Procedure

To check and assign permissions that grant users access to all content, proceed with one of the following options:

- Assign a user to the Content Author role. For more information, see Assigning users to a role.
- Create a custom role, to which you can add the relevant permissions and add users to your new custom role. For more information, see Creating a new role, Assigning permissions to a role, and Assigning users to a role.

Creating a developer account to customize API properties

You can allow specific users in the Developer Portal to customize the properties for certain APIs, including APIs that are not viewable by the administrator, or other customizable features, by creating an internal Consumer organization.

Before you begin

You must have administrator access to complete this task.

About this task

Every user in the Developer Portal must be a member of a Consumer organization. To enable additional users to be editors of particular content in the Developer Portal, you can create an internal Consumer organization. You can then invite these additional editors to this organization, and assign them a specific role that grants certain editing permissions. For example, the following API properties can be customized by any member of the new Consumer organization that have been assigned the Administrator or Content Author role:

- Image uploading
- Tag assignment
- File attachment
- Custom field editing

Procedure

To create a new Consumer organization within the Developer Portal, complete the following steps:

1. Log in to the Developer Portal as an administrator or Content Author.
2. Click the arrow next to `your_organization_name` from the Developer Portal home page, and select Create organization.
3. In the Organization Title field, type the name of the organization that you want, then click Submit.

To invite the editor users to your new organization, complete the following steps:

4. Switch to your newly created organization by clicking the arrow next to `your_current_organization_name`, and select your new organization name from the list.
5. Click the arrow next to `your_new_organization_name` and select My organization.

Your new organization page is displayed.

6. For each new user, click Invite, complete their Email details, and click Submit. Note that you can leave the default role of Developer selected and then change the role later, or you can select the Administrator role now. However, be aware that an administrator is able to perform any task within the Developer Portal that does not involve the creation of APIs, Products, and Apps. You should be careful to ensure that only trusted users are given this access and level of control of your site. Each new user will receive an invitation email, and they need to click on the link in the email to activate their Developer Portal account.

To assign the required permissions to the users of your organization, you must log in as an administrator and complete the following steps:

7. Log in to the Developer Portal as an administrator.
8. If the administrator dashboard is not displayed, click Manage to display it.
9. Click People on the administrator dashboard.
10. Select the check box for the user, or users, to whom you want to give new permissions.
11. Under the Action heading, select the relevant role from the drop-down list.
    For example, selecting Add the Content Author role to the selected user(s) means they can edit images and content within the Developer Portal.
12. Click Apply to selected items to update the roles.

What to do next

If you want specific Products or APIs to be customized by the editor users, you must ensure that the relevant Products are visible to the internal Consumer organization that you have created. For more information on how to make a plan visible in API Manager, see Changing the availability of a Product.
Note that you can also create new roles and assign specific permissions to those roles. For more information, see Creating a new role and Assigning permissions to a role.

Email Subscribers

As a site administrator, you can use the email subscribers wizard to send messages to your Developer Portal community.

You can email all the subscribers of a specific API, plan, product, or all registered consumer organizations. For each consumer organization, you can select whether to email just the owner or all of the members. Each recipient receives an individual email.

You can use the wizard to specify context-specific tokens in the email subject and body. The tokens available and their replacement values depend on which flow is selected, for example, API, plan, product, or all.

- **Emailing all subscribers**
  As a site administrator, you can use the email `All users` wizard to email all the subscribers of all the consumer organizations on your Developer Portal.
- **Emailing api subscribers**
  As a site administrator, you can use the email `API subscribers` wizard to send messages to all subscribers of all product plans that contain a specific API on your Developer Portal.
- **Emailing plan subscribers**
  As a site administrator, you can use the email `Plan subscribers` wizard to send messages to all subscribers of a chosen plan that belongs to a specific product on your Developer Portal.
- **Emailing product subscribers**
  As a site administrator, you can use the email `Product subscribers` wizard to send messages to all subscribers of any plan for a specific product in your Developer Portal.
- **Token reference**
  You can use the email subscribers wizard to specify context-specific tokens in the email subject and body. The tokens available and their replacement values depend on which flow is selected, for example, API, plan, product, or all.

Emailing all subscribers

As a site administrator, you can use the email `All users` wizard to email all the subscribers of all the consumer organizations on your Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

You can use the `All users` wizard to send messages to all consumer organizations. You can select whether to email just the owner, or all of the members of the consumer organizations. Each recipient receives an individual email.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Navigate to People > Email subscribers.
3. Select `All users`, and click Save.
4. Select the role of the recipients that you want to send the email to, then click Next.
   - Owners - sends the email to the relevant consumer organization owners.
   - Members - sends the email to all members of the relevant consumer organizations.

5. Enter the content of the email, subject, and body, and set the Text Format of the email:
   - Basic HTML
   - Plain text
6. Expand the REPLACEMENTS drop-down, and click Browse available tokens to view which tokens can be added to the subject and body fields for replacement. You can select a token to use by either typing it directly, or by clicking in the subject or body field. You are then given a list of available tokens, and you can insert the token that you want. For a reference list of tokens, see Token reference.
7. Expand the ADDITIONAL EMAIL OPTIONS drop-down to configure any additional settings:
   - **`Priority`**: Set the priority of the email. Many email programs ignore a priority setting.
   - **`Request receipt`**: Request a read receipt from your emails. Many email programs ignore these requests so it is not a definitive indication of how many people read your email.
   - **`Additional headers`**: Set any additional headers to be sent with the email.
8. Use the remaining check boxes to configure what messages are to be sent and how:
   - Send the message directly by using the Batch API. This option sends the emails directly by the Batch API. If not selected, then the emails are added to the spool and sent out by cron.
   - Send a copy of all messages to the sender. Because emails might contain context-specific tokens, a new email is generated for each recipient with the correct token replacement. This option sends a copy of all generated emails to the sender.
   - Send a copy of the original message to the sender. This option sends a single copy of the original email, subject, and body, without the replacement of any specified tokens.
9. Click Next.
10. Confirm that the email is ready to send, then click Next.
11. If you chose to send the emails by the Batch API, you see a progress page that indicates how many emails were sent. You are then redirected to a summary page that shows the total number of emails that were sent.
    If you chose to spool the delivery of the emails, you are redirected to the summary page that shows the total number of emails that are spooled.
12. Click Finish.

Results

You successfully sent an email to all members, or all of the owners of each consumer organization on your Developer Portal.

Emailing api subscribers

As a site administrator, you can use the email **`API subscribers`** wizard to send messages to all subscribers of all product plans that contain a specific API on your Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

You can use the email **`API subscribers`** wizard to send messages to all subscribers of all product plans that contain a specific API in your Developer Portal community. For each consumer org, you can select whether to email just the owner or all members. Each recipient receives an individual email.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Navigate to People > Email subscribers.
3. Select **`API subscribers`**, and click Save.
4. In the text box, enter the name of the API whose subscribers you want to email. If you start typing in the text box, you can choose from the options that you are given. Click Next.
5. Select the role of the recipients that you want to send the email to, then click Next.
   - Owners - sends the email to the relevant consumer organization owners.
   - Members - sends the email to all members of the relevant consumer organizations.
6. Enter the content of the email, subject, and body, and set the Text Format of the email:
   - Basic HTML
   - Plain text
7. Expand the REPLACEMENTS drop-down, and click Browse available tokens to view which tokens can be added to the subject and body fields for replacement. You can select a token to use by either typing it directly, or by clicking in the subject or body field. You are then given a list of available tokens, and you can insert the token that you want. For a reference list of tokens, see Token reference.
8. Expand the ADDITIONAL EMAIL OPTIONS drop-down to configure any additional settings:
   - **`Priority`**: Set the priority of the email. Many email programs ignore a priority setting.
   - **`Request receipt`**: Request a read receipt from your emails. Many email programs ignore these requests so it is not a definitive indication of how many people read your email.
   - **`Additional headers`**: Set any additional headers to be sent with the email.
9. Use the remaining check boxes to configure what messages are to be sent and how:
   - Send the message directly by using the Batch API. This option sends the emails directly by the Batch API. If not selected, then the emails are added to the spool and sent out by cron.
   - Send a copy of all messages to the sender. Because emails might contain context-specific tokens, a new email is generated for each recipient with the correct token replacement. This option sends a copy of all generated emails to the sender.
   - Send a copy of the original message to the sender. This option sends a single copy of the original email, subject, and body, without the replacement of any specified tokens.
10. Click Next.

11. Confirm that the email is ready to send, then click Next.
12. If you chose to send the emails by the Batch API, you see a progress page that indicates how many emails were sent. You are then redirected to a summary page that shows the total number of emails that were sent.
    If you chose to spool the delivery of the emails, you are redirected to the summary page that shows the total number of emails that are spooled.
13. Click Finish.

Results

You successfully sent an email to all members or all owners of each consumer org that contained a subscription to all product plans that contain the chosen API on your Developer Portal.

Emailing plan subscribers

As a site administrator, you can use the email **`Plan subscribers`** wizard to send messages to all subscribers of a chosen plan that belongs to a specific product on your Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

You can use the email **`Plan subscribers`** wizard to send messages to all subscribers of a chosen plan that belongs to a specific product on your Developer Portal community. For each consumer org, you can select whether to email just the owner or all members. Each recipient receives an individual email.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Navigate to People > Email subscribers.
3. Select **`Plan subscribers`**, and click Save.
4. In the text box, enter the name of the product whose subscribers you want to email. If you start typing in the text box, you can choose from the options that you are given. Click Next.
5. Select the name of the plan whose subscribers you want to email. Click Next.
6. Select the role of the recipients that you want to send the email to, then click Next.
   - Owners - sends the email to the relevant consumer organization owners.
   - Members - sends the email to all members of the relevant consumer organizations.
7. Enter the content of the email, subject, and body, and set the Text Format of the email:
   - Basic HTML
   - Plain text
8. Expand the REPLACEMENTS drop-down, and click Browse available tokens to view which tokens can be added to the subject and body fields for replacement. You can select a token to use by either typing it directly, or by clicking in the subject or body field. You are then given a list of available tokens, and you can insert the token that you want. For a reference list of tokens, see Token reference.
9. Expand the ADDITIONAL EMAIL OPTIONS drop-down to configure any additional settings:
   - **`Priority`**: Set the priority of the email. Many email programs ignore a priority setting.
   - **`Request receipt`**: Request a read receipt from your emails. Many email programs ignore these requests so it is not a definitive indication of how many people read your email.
   - **`Additional headers`**: Set any additional headers to be sent with the email.
10. Use the remaining check boxes to configure what messages are to be sent and how:
    - Send the message directly by using the Batch API. This option sends the emails directly by the Batch API. If not selected, then the emails are added to the spool and sent out by cron.
    - Send a copy of all messages to the sender. Because emails might contain context-specific tokens, a new email is generated for each recipient with the correct token replacement. This option sends a copy of all generated emails to the sender.
    - Send a copy of the original message to the sender. This option sends a single copy of the original email, subject, and body, without the replacement of any specified tokens.
11. Click Next.
12. Confirm that the email is ready to send, then click Next.
13. If you chose to send the emails by the Batch API, you see a progress page that indicates how many emails were sent. You are then redirected to a summary page that shows the total number of emails that were sent.
    If you chose to spool the delivery of the emails, you are redirected to the summary page that shows the total number of emails that are spooled.
14. Click Finish.

Results

You successfully sent an email to all members or all owners of each consumer org that contained a subscription to the chosen plan within the chosen product, on your Developer Portal.

Emailing product subscribers

As a site administrator, you can use the email **`Product subscribers`** wizard to send messages to all subscribers of any plan for a specific product in your Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

You can use the email **`Product subscribers`** wizard to send messages to all subscribers of any plan for a specific product in your Developer Portal community. For each consumer org, you can select whether to email just the owner or all members. Each recipient receives an individual email.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Navigate to People > Email subscribers.
3. Select **`Product subscribers`**, and click Save.
4. In the text box, enter the name of the product whose subscribers you want to email. If you start typing in the text box, you can choose from the options that you are given. Click Next.
5. Select the role of the recipients that you want to send the email to, then click Next.
   - Owners - sends the email to the relevant consumer organization owners.
   - Members - sends the email to all members of the relevant consumer organizations.
6. Enter the content of the email, subject, and body, and set the Text Format of the email:
   - Basic HTML
   - Plain text
7. Expand the REPLACEMENTS drop-down, and click Browse available tokens to view which tokens can be added to the subject and body fields for replacement. You can select a token to use by either typing it directly, or by clicking in the subject or body field. You are then given a list of available tokens, and you can insert the token that you want. For a reference list of tokens, see Token reference.
8. Expand the ADDITIONAL EMAIL OPTIONS drop-down to configure any additional settings:
   - **`Priority`**: Set the priority of the email. Many email programs ignore a priority setting.
   - **`Request receipt`**: Request a read receipt from your emails. Many email programs ignore these requests so it is not a definitive indication of how many people read your email.
   - **`Additional headers`**: Set any additional headers to be sent with the email.
9. Use the remaining check boxes to configure what messages are to be sent and how:
   - Send the message directly by using the Batch API. This option sends the emails directly by the Batch API. If not selected, then the emails are added to the spool and sent out by cron.
   - Send a copy of all messages to the sender. Because emails might contain context-specific tokens, a new email is generated for each recipient with the correct token replacement. This option sends a copy of all generated emails to the sender.
   - Send a copy of the original message to the sender. This option sends a single copy of the original email, subject, and body, without the replacement of any specified tokens.
10. Click Next.
11. Confirm that the email is ready to send, then click Next.
12. If you chose to send the emails by the Batch API, you see a progress page that indicates how many emails were sent. You are then redirected to a summary page that shows the total number of emails that were sent.
    If you chose to spool the delivery of the emails, you are redirected to the summary page that shows the total number of emails that are spooled.
13. Click Finish.

Results

You successfully sent an email to all members or all owners of each consumer org that contained a subscription to any plan within the chosen product on your Developer Portal.

Token reference

You can use the email subscribers wizard to specify context-specific tokens in the email subject and body. The tokens available and their replacement values depend on which flow is selected, for example, API, plan, product, or all.

Application Tokens

Tokens that are related to an individual Application.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
Description	`[application:description]`	The description that is given to the application.	✓	✓	✓	
Enabled	`[application:enabled]`	The state that the application is in.	✓	✓	✓	
ID	`[application:id]`	The ID of the application.	✓	✓	✓	
Image URL	`[application:image_url]`	The URL of the image for the application.	✓	✓	✓	
Lifecycle State	`[application:lifecycle_state]`	The lifecycle state of the application.	✓	✓	✓	
Name	`[application:name]`	The name of the application.	✓	✓	✓	

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
Title	`[application:title]`	The title of the application.	✓	✓	✓	

Consumer Organization Tokens

Tokens that are related to the individual consumer organization.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
ID	`[consumer-org:id]`	The ID of the consumer organization.	✓	✓	✓	✓
Name	`[consumer-org:name]`	The name of the consumer organization.	✓	✓	✓	✓
Title	`[consumer-org:title]`	The title of the consumer organization.	✓	✓	✓	✓

Product Tokens

Tokens that are related to an individual product.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
APIs	`[product:apis]`	A comma separated list of APIs (name:version) within the product.	✓	✓	✓	
ID	`[product:id]`	The ID of the product.	✓	✓	✓	
Image URL	`[product:image_url]`	The URL of the image for the product.	✓	✓	✓	
Name	`[product:name]`	The name of the product.	✓	✓	✓	
Plans	`[product:plans]`	A comma separated list of plan names within the product.	✓	✓	✓	
State	`[product:state]`	The state of the product.	✓	✓	✓	
Title	`[product:title]`	The title of the product.	✓	✓	✓	

Plan Tokens

Tokens that are related to an individual product plan.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
Approval required	`[product-plan:approval]`	Whether the plan requires approval or not.		✓		
Description	`[product-plan:description]`	The description of the plan.		✓		
Name	`[product-plan:name]`	The name of a given plan within the product.		✓		
Rate limits	`[product-plan:rate-limits]`	A comma separated list of rate limit name value pairs that the plan contains.		✓		
Title	`[product-plan:title]`	The title of the plan.		✓		

API Tokens

Tokens that are related to an individual API.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
ID	`[api:id]`	The ID of the API.			✓	
Image URL	`[api:image_url]`	The URL of the image for the API.			✓	
Name	`[api:name]`	The name of the API.			✓	
OAI Version	`[api:oai_version]`	The OAI version of the API.			✓	
Protocol	`[api:protocol]`	The protocol of the API.			✓	
State	`[api:state]`	The current state the API is in.			✓	
Title	`[api:title]`	The title of the API.			✓	
Version	`[api:version]`	The version of the API.			✓	

User Tokens

Tokens that are related to the individual user account of the recipient.

Name	Token	Description	Product Subscribers	Plan Subscribers	API Subscribers	All Users
Account Name	`[user:account-name]`	The login name of the user account.	✓	✓	✓	✓
Created	`[user:created]`	The date the user account was created.	✓	✓	✓>	✓
Display Name	`[user:display-name]`	The display name of the user account.	✓	✓	✓	✓
Email	`[user:mail]`	The email address of the user account.	✓	✓	✓	✓
First Name	`[user:first_name]`	The first name of the user.	✓	✓	✓	✓

Short format	`[current-date:short]`	A date in 'short' format. (01/08/2021 - 14:19)	✓	✓	✓	✓
Time-since	`[current-date:since]`	A date in 'time-since' format. (6 minutes)	✓	✓	✓	✓

How to style the Developer Portal emails

You can apply a theme to the HTML emails that are sent by the Developer Portal by using CSS and templating.

Before you begin

You must have administrator access to complete this task.

You must have a custom theme. For information about how to create a custom theme, see Creating a sub-theme.

About this task

You can apply custom styling to the HTML content of the emails that are sent by the Developer Portal, such as the emails that are sent by the Email subscribers wizard. The custom styling consists of two parts: editing a twig template and, optionally, also editing a CSS file in your custom theme. See the following instructions for details. Note: These instructions apply only to emails that are sent by the Developer Portal. These instructions don't apply to the consumer invitation, activation, and password reset emails, as these emails are sent by the API Manager. For information about how to style API Manager emails, see Configuring notifications and Sending messages to consumer organization owners.

Procedure

1. Download the ibm-apic-mail-message.html.twig template from https://github.com/ibm-apiconnect/devportal/tree/master/ibm_apim/ibm_apic_mail/templates, and save it to your custom theme templates directory.
2. Edit the ibm-apic-mail-message.html.twig template to fit your custom theme.
   You can add styles directly into this twig template, or you can add them to the css/mail.css file in your custom theme, which will mean that they are automatically included in the HTML email content that is sent.

   If you are using an SCSS theme that has been generated by the Developer Portal theme generator, then you can put the custom SCSS mail styles into the mail-overrides.scss file. These styles will then be compiled into the mail.css file.

   Note: If you are using an older theme that was generated before API Connect Version 10.0.4.0, then the theme won't contain the mail theme support. However, you can workaround this by generating a new sub-theme with the same name, copying the overrides.css, or overrides.scss, as appropriate, logo.png, and *.theme files from the old theme into the new sub-theme, and then compress and install the new sub-theme as usual. (See Creating a sub-theme for details.)
3. Define a standard set of classes in the ibm-apic-mail-message.html.twig template that the Developer Portal administrators can use.
   The twig template lists the variables that can be used within it. The HTML **<body>** element is the actual content of the email message as defined within Drupal. For example, that content could be the information that's entered in the WYSIWYG editor of the Email subscribers wizard. Note that the HTML content in the WYSIWYG editor is more restricted for security reasons, for example, it's not possible to use inline styles in the HTML content in the editor. However, it is possible to use CSS class names, and then define the class in the mail.css file, which is then included in the emails. Therefore, it's recommended that you define a standard set of classes that the Developer Portal administrators can use when they're creating emails.

4. Optional: Add images to the ibm-apic-mail-message.html.twig template.
   Images can be used by adding a **** reference in the twig template. The **src** attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images, they must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.

   Note: The **logo** will be automatically set to the fully qualified URL for the site logo image.
5. Compress all of your sub-theme resources back into a .zip file, and install into the Developer Portal. See Installing additional themes for details.

What to do next

It is possible to have multiple email templates. For example for different modules, where one template could be used for the emails that are sent by the contact module, and another template for the emails that are sent by the Email subscribers wizard. This more advanced configuration can be done by using the module and key attributes, and is explained within the twig template itself. Essentially, you create a twig template that's called ibm-apic-mail-message.contact.html.twig, for example, to override the default template for only the contact module. Then the most specific template for a module is used by the Developer Portal, before falling back on the more general template.

Related tasks

- Creating a sub-theme
- Installing additional themes
- Applying a modified content type template

Working with roles in the Developer Portal

As a site administrator, you can create and customize site configuration roles in the Developer Portal.

Rather than assigning individual permissions to each user, permissions are assigned to roles, and then roles are assigned to users. Using roles gives administrators greater control over permissions, and makes it easy to assign and remove roles when necessary.

Administrators can assign the following site configuration roles to users in the Developer Portal:

Superuser
: The Superuser role has the highest level of permissions in the Developer Portal, and is the role that is assigned by default to the admin user, in addition to the Administrator role, when they enable a Developer Portal site in the API Manager. This role bypasses all content access control, which means that users that have a Superuser role can see all of the site content. This level of access can lead to some unexpected behavior when they access content such as their Consumer organizations and their applications. Careful consideration should be given before you assign users to a Superuser role.

Administrator

An Administrator can use the administrator dashboard to customize and configure the Developer Portal. An Administrator is able to perform any task within the Developer Portal that does not involve the creation of APIs, Products, and Apps.

Content Author
: A Content Author is a curator of content for the Developer Portal. A Content Author can perform the following actions:

  - Set taxonomies on the content.
  - Provide custom icons for content.
  - Upload additional documentation files.
  - Create documentation pages in the Developer Portal.

Forum Moderator
: A Forum Moderator can moderate the content of a forum in the Developer Portal.

Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: `A user already exists with this email address`.
To learn how to create and customize roles in the Developer Portal, use the following topic links:

- **Creating administrator users for the Developer Portal**
  You can create additional administrator users for an Developer Portal.
- **Assigning users to a role**
  Assign users to one or more roles in the Developer Portal to enable role specific permissions.
- **Assigning permissions to a role**
  You can assign permissions to a new role in the Developer Portal, and update the permissions for current roles.
- **Creating a new role**
  You can create a new role within the Developer Portal.

Creating administrator users for the Developer Portal

You can create additional administrator users for an Developer Portal.

Before you begin

You must have administrator access to complete this task.

About this task

After you enable a Developer Portal site in the API Manager, you are sent an email that contains a one-time log in link for the Developer Portal site Admin user. The Admin user can administer the Content Management System (CMS) capabilities of the Developer Portal. For more information about enabling a site, see Creating and configuring Catalogs.

However, you can also create additional administrative roles for users from within the Developer Portal by assigning the role to users that have access to the Developer Portal. A user with an Administrator role can use the administrator dashboard to customize and configure the Developer Portal. An Administrator is able to perform any task within the Developer Portal that does not involve the creation of APIs, Products, and Apps. You should be careful to ensure that only trusted users are given this access and level of control of your site.

Procedure

To create additional administrative users, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click People in the administrator dashboard.
3. Select the List tab.
4. Select the check boxes for the target users.
5. From the drop-down list under the Action heading, select Add the Administrator role to the selected user(s).
6. Click Apply to selected items.

Results

You have assigned the selected users to the Administrator role.

Assigning users to a role

Assign users to one or more roles in the Developer Portal to enable role specific permissions.

Before you begin

You must have administrator access to complete this task.

Procedure

To assign users to a role, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click People in the administrator dashboard.
3. Select the List tab.
4. Select the check boxes for the target users.
5. From the drop-down list under the Action heading, select the role that you want to assign.
6. Click Apply to selected items.

Results

You have assigned the selected users to the required role.

Assigning permissions to a role

You can assign permissions to a new role in the Developer Portal, and update the permissions for current roles.

Before you begin

You must have administrator access to complete this task.

Procedure

To assign or update permissions for a role, complete the following steps:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click People in the administrator dashboard.
3. Select the Permissions tab.
4. Assign a permission to a role, by selecting the check box in the relevant column for the permission that you want to assign.
5. Click Save permissions.

Results

You have assigned permissions to the target role.

Creating a new role

You can create a new role within the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To create a new role, complete the following steps:

1. Click People in the administrator dashboard.
2. Select the Roles tab.
3. Click Add role.
4. Enter a name for the new role in Role name, and click Save.
5. Your new role is displayed in the list of roles. You can drag any of the roles to re-order them. It's recommended to order roles from least permissive (for example, Anonymous user) to most permissive (for example, Administrator user). Users who aren't logged in have the Anonymous user role. Users who are logged in have the Authenticated user role, plus any other roles granted to their user account.

Results

You have created a new role in the Developer Portal.

What to do next

The new role is created with the same permissions as an Authenticated user role. You can click the Permissions tab and edit the permissions as required.

Forums

Create and control forums in the Developer Portal.

The Developer Portal lets you create threaded discussion boards, called forums, on your site. To learn how to configure forums, use the following topic links.

- **Creating a new forum**
  You can create a new forum in the Developer Portal.
- **Creating new forum containers**
  You can create new forum containers in the Developer Portal.
- **Configuring the creation of new forums for each API**
  You can choose whether or not to automatically create a new forum when an API is created in the Developer Portal.
- **Locking forum topics**
  You can lock forum topics in the Developer Portal.
- **Marking content in a forum as sticky**
  You can mark content in a forum as sticky in the Developer Portal.
- **Removing forum posts**
  You can remove forum posts in the Developer Portal.
- **Turning off forums in the Developer Portal**
  You can turn off forums in the Developer Portal by disabling the Forum module. This action prevents users from viewing, and contributing to, forums.

Creating a new forum

You can create a new forum in the Developer Portal.

Before you begin

You must have administrator or Forum moderator access to complete this task.

Procedure

To create a new forum, complete the following tasks:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Forums.
4. Click Add forum.
5. Fill in the Name and Description fields for the new forum.
6. From the Parent drop-down list, select the hierarchical position of the new forum.
7. Click Save. You have created a new forum.

Creating new forum containers

You can create new forum containers in the Developer Portal.

Before you begin

You must have administrator or Forum moderator access to complete this task.

Procedure

To create a new forum containers, complete the following tasks:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Structure in the administrator dashboard.
3. Click Forums.
4. Click Add container.
5. Fill in the Name and Description fields for the new forum container.
6. From the Parent drop-down list, select the hierarchical position of the new forum container.
7. Click Save. You have created a new forum container.

Configuring the creation of new forums for each API

You can choose whether or not to automatically create a new forum when an API is created in the Developer Portal.

Before you begin

You must have administrator access to complete this task.

Procedure

To configure the creation of new forums for each API, complete the following tasks:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Configuration in the administrator dashboard.
3. Under the SYSTEM heading, click IBM API Connect.
4. Select or clear the Automatically create a forum per API check box to turn the feature on or off.
5. Click Save configuration.
   You have configured the creation of new forums for each API.

Locking forum topics

You can lock forum topics in the Developer Portal.

Before you begin

You must have administrator or Forum moderator access to complete this task.

Procedure

To lock forum topics, complete the following tasks:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. Click Edit for the forum topic that you want to lock.
4. Click Comment settings. The view expands.
5. Select Closed .
6. Keeping the Published selected, click Save.
   You have disallowed any further replies and marked the topic as locked.

Marking content in a forum as sticky

You can mark content in a forum as sticky in the Developer Portal.

Before you begin

You must have administrator or Forum moderator access to complete this task.

Procedure

To mark content in a forum as sticky, complete the following tasks:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. From the Action drop-down menu, select Make content sticky.
4. Select the check boxes next to the forum topics that you want to make sticky.
5. Click Apply to selected items.
   You made the selected forum content sticky.

Removing forum posts

You can remove forum posts in the Developer Portal.

Before you begin

You must have administrator or Forum moderator access to complete this task.

Procedure

To remove forum posts, complete the following tasks:

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Click Content in the administrator dashboard.
3. From the Action drop-down menu, select Delete content.
4. Select the check boxes next to the forum posts that you want to remove.
5. Click Apply to selected items.
   You removed the selected forum posts.

Turning off forums in the Developer Portal

You can turn off forums in the Developer Portal by disabling the Forum module. This action prevents users from viewing, and contributing to, forums.

Before you begin

You must have administrator access to complete this task.

About this task

To turn off forums, you must first remove all Forums terms, and then you can disable the Forum module.

Procedure

To turn off forums, complete the following steps.

1. If the administrator dashboard is not displayed, click Manage to display it.
2. Delete all Forums terms by completing the following steps:
    a. Click Structure > Taxonomy > Forums in the administrator dashboard.
    The list of Forums terms is displayed.
    b. For each item in the list of terms, select Delete from the drop-down list in the OPERATIONS column, and then click Delete again to confirm.
    All of the Forums terms are deleted.
3. Disable the Forum module by completing the following steps:
    a. Click Extend > Disable module in the administrator dashboard.
    b. Select the Forum module, then click Disable.
    c. The display then shows a list of forum configuration that will also be removed if the Forum module is disabled. Click Disable again to confirm that you agree to this removal.

Results

You successfully turned off forums in the Developer Portal.
If you want, you can enable the Forum module again by clicking Extend, selecting the Forum module on the List tab, and clicking Enable.

Reports

You can view reports about the general configuration and status of your Developer Portal site.

Use the Reports section in the Developer Portal to view information about the following areas:

Available updates
: Status report about available updates for your installed modules and themes.

Node Type Count
: Status report about how much of each content type there is in your portal site, and whether it is published or not. It can also provide totals of how many users there are of each role.

Available translation updates
: Status report about available interface translations for your installed modules and themes.

Field list
: Overview of fields on all entity types.

Status report
: Short overview of your site's parameters, as well as any problems detected with your installation.

Views plugins
: Overview of the plugins that are used in all views.

Extend

You can extend the Developer Portal by creating and installing custom modules, or installing additional Drupal contributed modules.

Modules provide functionality to your site, and the *core modules* that are included in the standard Developer Portal installation, provide all of the basic functions that most sites need. However, some of the core modules are not enabled by default, so you might want to examine the module list under the Extend menu of your site, to see whether the functionality you require is available from a core module before starting to investigate custom and contributed modules. If you still require additional custom or contributed modules, consider the following topics to help you create and implement modules consistently.
Note: The Developer Portal contains a Rules framework for event based actions. Some of those actions and triggers might exhibit unexpected behavior. A workaround is to create a custom module instead, because the same events and actions are possible there.

- **Custom module development: an introduction to Drupal tools for PHP development**
  Some guidance about the Drupal tools and environment considerations when developing in PHP, to help when writing custom modules to extend your Developer Portal functionality.
- **Custom module development: background and prerequisites**
  You can create custom modules in the Developer Portal to extend functionality. The following information provides a getting started developer guide to custom module development.

- **Custom module development: creating a module skeleton**
  You can extend your Developer Portal site by creating custom modules. The starting point for a new module is to create a module skeleton.
- **Custom module development: using hooks**
  You can use hooks in custom modules to alter the behavior of Drupal core or other modules in your Developer Portal.
- **Installing custom modules**
  You can extend your Developer Portal site by installing custom modules that you created, and also installing contributed modules from the Drupal community.
- **Deleting custom modules**
  You can delete custom modules from your Developer Portal if you want to remove them entirely from your site.
- **Disabling modules**
  You can disable an entire module in the Developer Portal if you want to improve performance, or remove functionality.
- **Using Developer Portal metadata on API Manager**
  For content created or updated after Version 10.0.1.0, the Developer Portal propagates more metadata to API Manager for `consumerorgs`, `users`, and `applications`.
- **Using a custom module for payment method creation**
  You can offer free use of your products to your customers or you can configure your Developer Portal to bill your customers when they use your products. You can use a custom module to configure creation of payment methods.

Custom module development: an introduction to Drupal tools for PHP development

Some guidance about the Drupal tools and environment considerations when developing in PHP, to help when writing custom modules to extend your Developer Portal functionality.

The following sections provide an overview of the key automation tools and environment considerations for PHP development in the Developer Portal. For a complete list of Drupal tools, see Development tools overview on Drupal.org, however, note that you are not permitted to access the shell inside the Developer Portal containers. Important:

- You are not permitted to include any IBM® API Connect modules within any custom modules that you create. Also, directly editing any API Connect themes, modules, included modules, or Drupal core on the file system is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.
- All custom development is your responsibility. Although the use of custom modules and themes is supported, IBM API Connect do not provide support in their development or modification.

Devel, Devel Generate Kint, and Webprofiler development modules

The Devel, Devel Generate Kint, and Webprofiler modules are all packaged within the Devel module. These modules provide the following development support:

- *Devel* - Helper functions for Drupal developers.
- *Devel Generate Kint* - Accelerate development of your site or module by quickly generating nodes, comments, terms, users, and more.
- *Kint* - Pretty print of variables with `kint($my_var)`.
- *Webprofiler* - Port of the Symfony WebProfiler Bundle as a Drupal module.

For more information, see Devel module on drupal.org, and Devel on drupalship.org.

Admin Toolbar module

The Admin Toolbar module improves the default Drupal Toolbar by transforming it into a drop-down menu, providing fast access to the administration pages. It also adds extra links to the Drupal icon on the admin toolbar to development tools such as flush all caches, run cron, and run updates.

For more information, see Admin toolbar module on drupal.org.

Examples for developers project

The Examples for Developers project aims to provide high-quality, well-documented API examples for a broad range of Drupal core functionality.

The project contains many modules that illustrate best practices for implementing Drupal core APIs. For example there are examples for Block, Cache, Config and Content Entity, Cron, Database API, Email, Events, Form API, Field, Field Permission, File, Hooks, Javascript, Node Type, Page, Pager, PHPUnit, Plugin Type, Queue, Simple Test, Stream Wrapper, Table Sort, Testing, and Tour.

For more information, see Examples for developers project on drupal.org.

Coding standards

The Drupal Coding Standards apply to code within Drupal and its contributed modules. For more information, see Coding standards on drupal.org.

Related tasks

- Installing custom modules

Related information

- Drupal tools for developers

Custom module development: background and prerequisites

You can create custom modules in the Developer Portal to extend functionality. The following information provides a getting started developer guide to custom module development.

Custom modules are written in PHP, which is an open source server-side scripting language that is used for creating dynamic web pages. For general information on the Drupal tools for PHP development, see Custom module development: an introduction to Drupal tools for PHP development.

The following sections provide an overview of custom module development, with links to learn more about the required development languages and concepts. Creating custom modules affects the source of your Developer Portal site, so it is recommended that you gain Drupal experience and PHP knowledge before you start creating modules.

Important:

- You are not permitted to include any IBM® API Connect modules within any custom modules that you create. Also, directly editing any API Connect themes, modules, included modules, or Drupal core on the file system is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.
- All custom development is your responsibility. Although the use of custom modules and themes is supported, IBM API Connect do not provide support in their development or modification.

Object-Oriented Programming (OOP)

OOP is established as best practice for development, so ensure your knowledge of OOP is good. The PHP documentation on Classes and Objects is a good place to start. For a general overview of PHP best practices, see PHP The Right Way. The following resources are also helpful:

- Object-oriented programming (on Wikipedia)
- Object Oriented Programming with PHP (on phpro.org)
- Object-Oriented PHP for Beginners (on tutsplus.com)
- Object Oriented Programming in PHP (on tutorialspoint.com)

Drupal also uses some common design patterns, so you need to ensure you have a basic understanding of these. See the following pattern resources:

- The Factory Pattern (on phptherightway.com), and Late Static Bindings (on php.net)
- Software design pattern (on Wikipedia)
- Programming Foundations: Design Patterns (on lynda.com)

PHP namespaces

You must be familiar with the concept of namespaces in PHP. In most cases, the Drupal code is namespaced based on the module that code belongs to.

For example, the namespace for **`block.module`** is:

```
namespace Drupal\block;
```

When you create Drupal modules, it is important to consider that PHP has a global namespace, and that function names must be unique. You are recommended to prefix the name of any methods with the module name.

For example, if you have a module that is named **`custom_module`**, a **`create`** method within it is called **`custom_module_create()`**.

For more information about namespaces, see the following resources:

- Drupal namespace standards (on drupal.org)
- How to use PHP namespaces (on sitepoint.com)
- PHP Namespaces (on php.net)

Dependency injection

It is important that you have a baseline understanding of dependency injection. Drupal makes heavy use of this concept, so you will need this understanding to be able to access and make use of many of the core APIs.

To find out more about dependency injection, see Dependency Injection (on phptherightway.com), as well as the additional articles that are linked to on that page. See also Services and dependency injection in Drupal (on drupal.org).

Symfony

Symfony is a set of reusable PHP components and a PHP framework for web projects. Drupal borrows from this framework in order to reduce code duplication across various PHP projects. Much of the code that Drupal uses to handle routing, sessions, and the services container, amongst other things, is borrowed from Symfony.

To understand how Symfony works, see the Symfony Documentation on symfony.com.

Other useful resources

- Drupal API Annotations - list of the different annotation types that Drupal uses for plugin discovery, and to provide additional context/meta-data for the code that's being executed.
- Plugin API overview - overview about how plugins are used in Drupal.
- Tools are available for checking your custom modules, such as drupal_check on GitHub, which checks Drupal code for deprecations.

Related tasks

Related information

- Creating custom modules

Custom module development: creating a module skeleton

You can extend your Developer Portal site by creating custom modules. The starting point for a new module is to create a module skeleton.

Before you begin

You must have administrator access to complete this task.

You must also have experience in Drupal and PHP development. For more information, see Custom module development: an introduction to Drupal tools for PHP development and Custom module development: background and prerequisites.

Important:

- You are not permitted to include any IBM® API Connect modules within any custom modules that you create. Also, directly editing any API Connect themes, modules, included modules, or Drupal core on the file system is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.
- All custom development is your responsibility. Although the use of custom modules and themes is supported, IBM API Connect do not provide support in their development or modification.

About this task

Every custom module creation starts with creating an .info.yml file. This file, or module skeleton, is used to store the metadata about the custom theme. After the module skeleton is created, the module can be installed onto your site by using the Extend menu on the administrator dashboard of the Developer Portal UI. However, without any module specific code, your site won't be affected.
The following instructions guide you through creating a custom module skeleton. What to do next in your custom module creation depends on what you want your module to do. Options are shown at the end of this task.

Procedure

1. Choose a short name, also known as a machine name, for your custom module.
   The machine name is used in several files and functions in your module, as well as by Drupal core to programmatically refer to your module. The name must conform to the following rules:
   - It must start with a letter.
   - It must contain only lowercase letters and underscores. (Note that if uppercase letters are used in the name, Drupal won't recognize any hook implementations in your module.)
   - It must not contain any spaces.
   - It must be unique within your Developer Portal site.
   - It should not be any of the following reserved terms: **`src`**, **`lib`**, **`vendor`**, **`assets`**, **`css`**, **`files`**, **`images`**, **`js`**, **`misc`**, **`templates`**, **`includes`**, **`fixtures`**, **`Drupal`**.
2. Create a module folder in a location of your choice, for example, /modules/*module_name*.
   You don't have to name the folder the same name as your module machine name, however, you must remember to use the machine name programmatically within your module's code and filenames.
3. Create a *module_name*.info.yml file in your module folder.
   Where *module_name* is the short name, or machine name, that you chose in Step 1.
4. Insert the metadata for your custom module into the *module_name*.info.yml file as follows:

```
name: Example module name
description: Description of the module.
package: Custom

type: module
core: 8.x
core_version_requirement: '^8 || ^9'
version: 1.0

dependencies:
  - module_name

test_dependencies:
  - module_name

configure: example.settings

php: 7.1

hidden: true
```

   where
   - **`name`** (required) is the name of your module, and is the text that is shown on the module administration page in the Developer Portal UI.
   - **`description`** (optional) is a description of your module, and is the text that is shown on the module administration page in the Developer Portal UI.

- **package** (optional) is a key that enables you to group similar modules together.
- **type** (required) is the type of extension that you are creating, for example, a module, theme or profile. In this instance you are creating a module.
- **core** (optional) specifies with which Drupal core version your module is compatible.
- **core_version_requirement** (required) specifies which versions of Drupal your module is compatible with. This example specifies that the module is compatible with all versions of Drupal 8 and 9.
- **version** (required) is the version number of your module. Note that **version** is not required if you are publishing your module on Drupal.org.
- **dependencies** (optional) is a YAML list of any modules that your module depends on. They must be namespaced in the format ***module_name***, where *module_name* is the module's machine name.
- **test_dependencies** (optional) is list of any modules (in the same format as **dependencies**) that are needed to run certain automated tests for your module on Drupal's automated test runner (DrupalCI), but are not needed as module dependencies in general.
- **configure** (optional), if your module offers a configuration form, specify the route to this form here.
- **php** (optional) is the minimum PHP version that is required for your module. For the Developer Portal the minimum PHP version is 7.1.
- **hidden** (optional) is an option that, if set, will hide your module from the Extend section of the administrator dashboard on the Developer Portal UI. This option might be useful if your module only contains tests, or if the module is meant as an example to other developers.

5. Save your *module_name*.info.yml.

Results

You successfully created your module skeleton.

Example

An example .info.yml file:

```
name: User field example
type: module
description: Developer Portal tutorial about a user field example
package: IBM API Connect Tutorials
core: 8.x
core_version_requirement: '^8 || ^9'
version: 8.x-0.0.1
dependencies:
  - ibm_apim
  - auth_apic
```

What to do next

You now need to create the appropriate content for your custom module, depending on what you want the module to do. For information about the various options, see Creating custom modules on Drupal.org. There is also a walkthrough example of creating a basic custom module that is available on Drupal.org, see: A "Hello World" custom page module.
Note: If you are defining URL paths in the routing file of your module, you must consider any potential implications of those paths, and avoid conflicts with other parts of the Developer Portal. For example, you are recommended not to prefix any paths with **ibm_apic**.
After you have created your custom module content, you need to package your custom module files up into a zip, tar, tgz, gz, or bz2 file. This file can then be installed onto your Developer Portal site by using the Extend menu on the administrator dashboard. For more information, see Installing custom modules.

- Let Drupal know about your module with an .info.yml file

Custom module development: using hooks

You can use hooks in custom modules to alter the behavior of Drupal core or other modules in your Developer Portal.

Custom modules enable you to extend the functionality of your Developer Portal site. For more information about how to create custom modules, see Custom module development: an introduction to Drupal tools for PHP development, and Custom module development: background and prerequisites.

Hooks are one of the ways that custom modules can use to interact with other modules and with Drupal core subsystems. The following sections provide an overview of hooks, and a list of the IBM® API Connect specific hooks.

Important:

- You are not permitted to include any IBM API Connect modules within any custom modules that you create. Also, directly editing any API Connect themes, modules, included modules, or Drupal core on the file system is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.
- All custom development is your responsibility. Although the use of custom modules and themes is supported, IBM API Connect do not provide support in their development or modification.

About hooks

Hooks define functions that alter the behavior of Drupal core. So one way for custom modules to alter these functions, is to use hooks. Hooks are specially-named functions that a module defines (this is known as *implementing the hook*), these hooks are then discovered and called at specific times to alter or add to the base behavior or data (this is known as *invoking the hook*). Each hook has a name (for example: **hook_batch_alter()**), a defined set of parameters, and a defined return value. Your custom modules can implement hooks that are defined by Drupal core, by API Connect, or by other modules that they interact with. Your custom modules can also define their own hooks in order to let other modules interact with them. For more information, see Understanding Hooks on Drupal.org.

Note: If you write a hook implementation function, the function must not throw errors or exceptions, or use **alert** level log messages. Errors, exceptions, and **alert** level log messages can break all the processing in the parent code. For example, if you write a hook that calls an external server when an application is updated, the code needs

to have error handling in place to handle the server not being found, or not returning the expected result. Otherwise, Drupal stops parsing the function and the application might not get updated correctly. It can cause webhook and snapshot parsing to abort leaving the portal in an inconsistent state.
For a list of all the hooks that are available on Drupal core, and how to implement them in your custom module, see Drupal API Hooks.

For a list of all the API Connect specific hooks, see the following section.

Using hooks in custom modules

To invoke a hook you need to add a function to your .module file in your custom module, and prefix the hook with your custom module name. For example, when using an API Connect hook in a custom module, you must replace the word **hook** in the hook name with the name of your custom module. For example:

```
hook_apic_app_create
```

should be referenced in your custom module as:

```
moduleName_apic_app_create
```

See also the following example .module file that shows a custom module called user_field_example:

```
/**
 * Implementation of hook_form_alter() to alter the Sign up form
 */
function user_field_example_form_alter(&$form, FormStateInterface $form_state, $form_id) {
  if ($form_id === 'user_register_form') {
    // add our validator to the #validate array for the user_register_form
    $form['#validate'][] = 'user_field_example_validate_department_code';
  }
}

/**
 * Validate the Department code field on the Sign up form.
 *
 * Valid entry = DEPnnn
 *   where n = single figure digit.
 */
function user_field_example_validate_department_code($form, &$form_state) {
  if (isset($form_state->getValue('field_department_code')[0]['value'])) {
    $dept_code = $form_state->getValue('field_department_code')[0]['value'];
    $valid = preg_match('/^DEP\d{3}$/', $dept_code);
    if (!$valid) {
      // if the value is not valid then set an inline error on the relevant field
      $form_state->setErrorByName('field_department_code', t('Invalid department code.'));
    }
  }
}
```

API Connect specific hooks

The following tables list the hooks that are specific to the API Connect Developer Portal. Each section contains a link to the .php file on the API Connect Developer Portal repository on GitHub for those hooks. This file contains examples of how you can use the hooks in your modules.

Hooks about Applications

The following table lists the hooks that relate to Applications in the Developer Portal. For examples of how to use Application hooks, see apic_app/apic_app.api.php on GitHub.

Table 1. Hooks about Applications

Hook name	Description
hook_apic_app_create	Triggered when an Application is created.
hook_apic_app_update	Triggered when an Application is updated.
hook_apic_app_pre_delete	Triggered when an Application is deleted, before the node deletion or cascade has happened.
hook_apic_app_post_delete	Triggered when an Application is deleted, after the node deletion or cascade has happened.
hook_apic_app_promote	Triggered when an Application is promoted.
hook_apic_app_creds_create	Triggered when a new set of credentials is created for an Application.
hook_apic_app_creds_update	Triggered when a set of credentials is updated for an Application.
hook_apic_app_creds_delete	Triggered when a set of credentials is deleted for an Application.
hook_apic_app_subscribe	Triggered when a subscription is created.
hook_apic_app_migrate	Triggered when a subscription is migrated to a new Plan.
hook_apic_app_unsubscribe	Triggered when an Application is unsubscribed from a Plan.
hook_apic_app_image_create	Triggered when a custom Application image is created.
hook_apic_app_image_delete	Triggered when a custom Application image is deleted.
hook_apic_app_clientid_reset	Triggered when a credential client ID is reset.
hook_apic_app_clientsecret_reset	Triggered when a credential client secret is reset.
hook_apic_app_modify_getplaceholderimage_alter	Alter the Application placeholder image provided in \Drupal\apic_app\Application::getPlaceholderImage(). Can be used to define a specific placeholder image to use when the consumer has not uploaded their own custom image for their Application.
hook_apic_app_modify_getimageforapp_alter	Alter the Application placeholder image provided in \Drupal\apic_app\Application::getImageForApp(). Can be used to provide a full path to a specific image to use for an Application that overrides any custom image that might have been uploaded.

Hook name	Description
`hook_apic_app_modify_client_id_reset_alter`	Alter the client ID provided by API Manager when the ID is reset.
`hook_apic_app_modify_client_secret_reset_alter`	Alter the client secret provided by API Manager when the secret is reset.
`hook_apic_app_modify_create_alter`	Alter the credentials provided by API Manager when a new Application is created.
`hook_apic_app_modify_credentials_create_alter`	Alter the credentials provided by API Manager when new credentials are created.

Hooks about Consumer organizations

The following table lists the hooks that relate to Consumer organizations in the Developer Portal. For examples of how to use Consumer organization hooks, see consumerorg/consumerorg.api.php on GitHub.

Table 2. Hooks about Consumer organizations

Hook name	Description
`hook_consumerorg_create`	Triggered when a Consumer organization is created.
`hook_consumerorg_update`	Triggered when a Consumer organization is updated.
`hook_consumerorg_pre_delete`	Triggered when a Consumer organization is deleted, before the node deletion or cascade has happened.
`hook_consumerorg_post_delete`	Triggered when a Consumer organization is deleted, after the node deletion or cascade has happened.
`hook_consumerorg_payment_method_create_alter`	Triggered to allow modification of the payment method creation form.
`hook_consumerorg_myorg_tabs_alter`	Triggered to allow more tabs to be added to the `my organization` page.

Hooks about APIs

The following table lists the hooks that relate to APIs in the Developer Portal. For examples of how to use API hooks, see apic_api/apic_api.api.php on GitHub.

Table 3. Hooks about APIs

Hook name	Description
`hook_apic_api_create`	Triggered when an API is created.
`hook_apic_api_update`	Triggered when an API is updated.
`hook_apic_api_delete`	Triggered when an API is deleted.

Hooks about Products

The following table lists the hooks that relate to Products in the Developer Portal. For examples of how to use Product hooks, see product/product.api.php on GitHub.

Table 4. Hooks about Products

Hook name	Description
`hook_product_create`	Triggered when a Product is created.
`hook_product_update`	Triggered when a Product is updated.
`hook_product_delete`	Triggered when a Product is deleted.

Other IBM API Connect Hooks

The following table lists the hooks that can be for other uses.

Table 5. Other APIC Hooks

Hook name	Description
`hook_ibm_apim_subscription_wizard_summary_alter`	Triggered to allow modification of the summary page of the subscription wizard.

Related tasks

- Installing custom modules

Related information

- Creating custom modules

Installing custom modules

You can extend your Developer Portal site by installing custom modules that you created, and also installing contributed modules from the Drupal community.

Before you begin

You must have administrator access to complete this task.

About this task

You can add extra functions to your site by installing new custom or contributed modules. For more information on creating custom modules, see Custom module development: background and prerequisites. Contributed modules are modules that are contributed by Drupal community members. To search for contributed modules, go to Drupal Download & Extend. You can install both types of modules into your Developer Portal site by using the following instructions.
Note: The following modules are unsupported and their installation is blocked in the Developer Portal:

- `backup_migrate`
- `content_sync`
- `delete_all`
- `devel_themer`
- `domain`

- `php`
- `simple_html_mail`
- `swiftmailer`
- `tfa`
- `theme_editor`

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. In the administrator dashboard, click Extend.
   The List tab for the Extend page opens, and the list of installed modules is displayed. The list shows all the modules that are installed. The modules that are displayed with a selected checkbox are enabled, the modules that are displayed without a selected checkbox are not enabled.
3. Click + Install new module, and either complete the Install from a URL field, or click Choose file to upload a *filename*.tar.gz module file from your local computer.
4. Click Install.
   The Update manager confirms that the module was installed successfully.
5. Click Enable newly added modules to return to the List tab for the Extend page.
6. Find your newly added module in the list of modules, select its checkbox, and click Enable.
   Your newly added module is now enabled and available for you to use in the Developer Portal.

Deleting custom modules

You can delete custom modules from your Developer Portal if you want to remove them entirely from your site.

Before you begin

You must have administrator access to complete this task.

Note that any custom modules that you want to delete must be disabled first, including disabling any associated sub-modules. For more information, see Disabling modules. Any modules that are shipped with IBM® API Connect cannot be deleted.

Procedure

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. In the administrator dashboard, click Extend.
4. Click the Delete tab.
   The list of disabled custom modules that can be deleted is displayed. Note that any disabled modules that have sub-modules that are still enabled, are prevented from being disabled.
5. After you have found the module that you want to disable, select the check box next to the module, then click Delete.
6. At the confirmation dialogue, select Delete to delete the module completely from your site, or select Cancel to cancel the operation.

Results

You successfully deleted the module.

What to do next

To install a module, see Installing custom modules.

Disabling modules

You can disable an entire module in the Developer Portal if you want to improve performance, or remove functionality.

Before you begin

You must have administrator access to complete this task.

Note that the disable process removes all data related to a module.

Procedure

1. Log in to the Developer Portal as an administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. In the administrator dashboard, click Extend.
   The List tab for the Extend page opens, and the list of installed modules is displayed. The list shows all the modules that are installed, some of which are enabled (displayed with a selected check box), and some of which are not enabled (where the check box is not selected).
4. Click the Disable tab.
   The list of modules that can be disabled is displayed. Note that any modules that are required by other enabled modules, are prevented from being disabled.
5. Either enter the name of the module that you want to disable in the Filter by name or description field, or scroll through the list of modules.
6. After you have identified the module that you want to disable, select the check box next to the module, then click Disable.

7. At the confirmation dialogue, select Disable to disable the module and remove any data that relates to it, or select Cancel to cancel the operation.

Results

You successfully disabled the module.

What to do next

To enable a module, return to the List tab, select the check box next to the module that you want to enable, and click Enable.
You can also delete custom modules completely from your Developer Portal site; see Deleting custom modules.

Using Developer Portal metadata on API Manager

For content created or updated after Version 10.0.1.0, the Developer Portal propagates more metadata to API Manager for **consumerorgs**, **users**, and **applications**.

This metadata might be values that the user provided by adding extra fields to content types, or added programmatically by using custom modules.

The benefit of this is that when you add custom fields to **consumerorgs**, **users**, and **applications**, this data is now also stored as metadata in API Manager. Storing this data allows the Developer Portal to correct or repopulate the custom fields from a webhook or a snapshot.

Related tasks

Related information

- Creating custom modules

Using a custom module for payment method creation

You can offer free use of your products to your customers or you can configure your Developer Portal to bill your customers when they use your products. You can use a custom module to configure creation of payment methods.

Before you begin

You must have administrator access to complete this task.

You must have configured billing support in API Manager.

Create your custom module. Your custom module needs to implement the `consumerorg_payment_method_create_alter` hook, so it needs to have a function like this:

```
my_custom_module_consumerorg_payment_method_create_alter(&$form, $integration, $billing) {
// do this payment function with $form
}
```

For more information, see Custom module development: background and prerequisites.

Procedure

1. If the administrator dashboard is not displayed, click Manage to display it.
2. In the administrator dashboard, click Extend.
   The List tab for the Extend page opens, and the list of installed modules is displayed. The list shows all the modules that are installed. The enabled modules are displayed with a selected checkbox. The disabled modules are displayed without a selected checkbox.
3. Click + Install new module, and either complete the Install from a URL field, or click Choose file to upload a *filename*.tar.gz module file from your local computer.
4. Click Install.
   The Update manager confirms that the module was installed successfully.
5. Click Enable newly added modules to return to the List tab for the Extend page.
6. Find your newly added module in the list of modules, select its checkbox, and click Enable.
   Your newly added module is now enabled and available for you to use in the Developer Portal.
7. In the administrator dashboard, click Configuration > System > IBM API Connect Billing Settings in the administrator dashboard.
8. Change the drop-down option to be your newly enabled module for your billing provider.

Results

You successfully enabled your payment method by using a custom module.

Managing the Developer Portal by using the toolkit CLI

You can perform operations on your Developer Portal by using the API Connect toolkit CLI.

- **Getting started with the Portal CLI commands**
  The toolkit CLI provides developer portal-specific commands for managing your portal servers and sites.
- **Developer Portal CLI commands**
  A summary of the commands that are supported in the Developer Portal CLI.
- **Scenarios that use the Portal CLI**
  Here are some scenarios of how you can use the Portal commands in the toolkit CLI to accomplish tasks that are more complex to complete, or not possible in the Developer Portal UI.

Getting started with the Portal CLI commands

The toolkit CLI provides developer portal-specific commands for managing your portal servers and sites.

Procedure

1. Install the toolkit: Setting up the API Connect toolkit
2. Log in to the Management server: Toolkit CLI Login.

   ```
   apic login --server <management hostname/api base url> --username <username> --realm <realm>
   ```

   Where:
   - *<management hostname/api base url>* is the FQDN or base URL of your management API endpoints, for example: `mgmt.example.com` or `https://mgmt.example.com`.
   - *<username>* is either the admin user or provider org owner, depending on whether you want to run cloud or provider organization scoped operations.
   - *<realm>* is the user registry realm for the specified *<username>*. By default this is `admin/default-idp-1` for the admin user, and `provider/default-idp-2` for provider organization users.

   Note: All portal CLI commands are either cloud admin or provider org scoped.
3. View the available toolkit portal commands by using `-m portaladmin -h`. Example:

   ```
   apic -m portaladmin -h
   ...Usage:
     apic [flags]
     apic [command]

   Available Flags:
         --accept-license        Accept the license for API Connect
         --debug                 Enable debug output
         --debug-output string   Write debug output to file
     -h, --help                  Help for apic
         --live-help             Enable or disable tracking of limited usage information
     -m, --mode string           Toolkit operation mode (default "apim")

   Available Commands:

     Creating applications and artifacts
        config                               Manage configuration variables

     Publishing to the cloud
        api                                  Api operations
        apic-config                          Apic Config operations
        application                          Application operations
        backups                              Backups operations
        consumer-org                         Consumer Org operations
        custom-module                        Custom Module operations
        custom-theme                         Custom Theme operations
        custom-translation                   Custom Translation operations
        custom-webserver-page                Custom Webserver Page operations
        drupal-config                        Drupal Config operations
        drupal-state                         Drupal State operations
        entity                               Entity operations
        factory-reset                        Factory Reset operations
        ip-security-enabled                  Ip Security Enabled operations
        modules                              Modules operations
        php-memory                           Php Memory operations
        platforms                            Platforms operations
        product                              Product operations
        security                             Security operations
        service-ip-allowlist                 Service Ip Allowlist operations
        site                                 Site operations
        site-config                          Site Config operations
        sites                                Sites operations
        themes                               Themes operations
        twig                                 Twig operations

     Other commands
        licenses                             Review the license for API Connect
        validate                             Validate an API or product definition
        version                              Get the APIConnect toolkit version

   Additional help topics:

   Use "apic [command] --help" for more information about a command.
   ```

4. To view command-specific help, run the command with `-h`:

```
apic -m portaladmin php-memory -h
Usage: apic php-memory:list [flags]

Php Memory operations

Flags:
      --format string                 Output format. One of [json yaml go-template=... go-template-file=...], defaults to
yaml.
  -h, --help                          Help for list
      --portal_service_name string    The name of the portal service (required)
  -s, --server string                 management server endpoint (required)

Type "apic [command] --help" for help on the following related commands:
      php-memory:list    List the PHP memory limit on the platform.
      php-memory:update  Set the PHP memory limit on the portal platform.

apic -m portaladmin php-memory:list -h
Usage: apic php-memory:list [flags]

List the PHP memory limit on the platform.

Lists the PHP memory_limit setting on the portal platform.

Flags:
      --format string                 Output format. One of [json yaml go-template=... go-template-file=...], defaults to
yaml.
      --portal_service_name string    The name of the portal service (required)
  -s, --server string                 management server endpoint (required)
```

Developer Portal CLI commands

A summary of the commands that are supported in the Developer Portal CLI.

Authenticating

Use the **apic login** command to authenticate, and the **apic logout** command to remove your local authentication credentials. For more information, see Getting started with the Portal CLI commands.

Note: When you authenticate successfully, your credentials are stored, in plain text, in the file Linux .netrc or Windows _netrc. Therefore, you must set the file permissions in such a way that your credentials are not accessible by others.

Command summary

The following tables summarize **apic --mode portaladmin** commands.

Table 1. Summary of general-purpose commands

Command	Description	Subcommands
apic api	Manage your **api**.	• **apic api:add-attachment** - Add an attachment for an API • **apic api:add-tag** - Add a tag for an API. • **apic api:get** - Get an API from a portal service. • **apic api:get-document** - Get a specific entire API document from the portal of the given organization and catalog. • **apic api:list** - List the APIs of the given organization and catalog. • **apic api:set-icon** - Set an icon for an API. • **-s, --server** *mgmt_endpoint_url*. Use the value of the platform API endpoint URL for this entry. • **--org** *orgid* • **--catalog** *catalog id*. • **--debug**. If you need debug information. For more information, see Using the api commands.
apic apic-config	Manage your **apic-config**.	• **apic apic-config:get** - Get the configuration of a site. • **-s, --server** *mgmt_endpoint_url*. Use the value of the platform API endpoint URL for this entry. • **--org** *orgid* • **--catalog** *catalog id*. • **--debug**. If you need debug information. For more information, see Using the apic-config commands.
apic application	Manage your **application**.	• **apic application:get** - Get an application from a portal service. • **apic application:list** - List the applications on a portal service. • **-s, --server** *mgmt_endpoint_url*. Use the value of the platform API endpoint URL for this entry. • **--org** *orgid* • **--catalog** *catalog id*. • **--debug**. If you need debug information. For more information, see Using the application commands.

Command	Description	Subcommands
apic backups	Manage your **backups**.	• **apic backups:list** - List the backups of a portal service. • **-s, --server** *management_server*. • **--portal_service_name** *portal_service_name* • **--format** *format*. The options are **json** or **yaml**. For more information, see Using the backups commands.
apic consumer-org	Manage your **apic consumer-org**.	• **apic consumer-org:get** - Get a consumer org from a portal service. • **apic consumer-org:list** - List the consumer orgs on a portal service. • **-s, --server** *mgmt_endpoint_url*. Use the value of the platform API endpoint URL for this entry. • **--org** *orgid* • **--catalog** *catalog id*. • **--debug**. If you need debug information. For more information, see Using the consumer-org commands.
apic custom-module	Manage your **custom modules**.	• **apic custom-module:create-export** - Create an export of a **custom module**. • **apic custom-module:create-import** - Create an import of a **custom module**. • **apic custom-module:delete-export** - Delete an export of a **custom module**. • **apic custom-module:delete-import** - Delete an import of a **custom module**. • **apic custom-module:get-export** - Get an export of a **custom module**. • **apic custom-module:get-export-status** - Get the status of an export of a **custom module**. • **apic custom-module:get-import-status** - Get the status of an import of a **custom module**. • **-s, --server** *mgmt_endpoint_url*. Use the value of the platform API endpoint URL for this entry. • **--org** *orgid* • **--catalog** *catalog id*. • **--format** *format*. Note that this flag has no affect on the **create-export** and **create-import** subcommands. • **--debug**. If you need debug information. For more information, see Using the custom-module commands.
apic custom-theme	Manage your **custom themes**.	• **apic custom-theme:create-export** - Create an export of a **custom theme**. • **apic custom-theme:create-import** - Create an import of a **custom theme**. • **apic custom-theme:delete-export** - Delete an export of a **custom theme**. • **apic custom-theme:delete-import** - Delete an import of a **custom theme**. • **apic custom-theme:get-export** - Get an export of a **custom theme**. • **apic custom-theme:get-export-status** - Get the status of an export of a **custom theme**. • **apic custom-theme:get-import-status** - Get the status of an import of a **custom theme**. • **-s, --server** *mgmt_endpoint_url*. Use the value of the platform API endpoint URL for this entry. • **--org** *orgid* • **--catalog** *catalog id*. • **--format** *format*. Note that this flag has no affect on the **create-export** and **create-import** subcommands. • **--debug**. If you need debug information. For more information, see Using the custom-theme commands.

Command	Description	Subcommands
apic custom-translation	Manage your **custom translations**.	• **apic custom-translation:create-export** - Create a task to export a **custom translation**. • **apic custom-translation:create-import** - Create a task to import a **custom translation**. • **apic custom-translation:delete-export** - Cancel any ongoing or recently created export tasks. • **apic custom-translation:delete-import** - Cancel any ongoing or recently created import tasks. • **apic custom-translation:get-export** - Streams an export artifact of a **custom translation** back to the provided task ID. • **apic custom-translation:get-export-status** - Get the status of an export of a **custom translation**. • **apic custom-translation:get-import-status** - Get the status of an import of a **custom translation**. For more information, see Using the custom-translation commands.
apic custom-webserver-page	Manage your **custom-webserver-page** content.	• **apic custom-webserver-page:delete** - Delete a custom HTML web server error page. • **apic custom-webserver-page:get** - Get the content of a custom HTML web server error page. • **apic custom-webserver-page:set** - Set a custom HTML web server error page by using a valid HTML5 content file. For more information, see Using the custom-webserver-page commands.
apic drupal-config	Manage your **drupal-config**.	• **apic drupal-config:delete** - Delete a Drupal config object, or a specific config key. • **apic drupal-config:get** - Get all of the key values for a Drupal config object, or a specific config key value. • **apic drupal-config:list** - List the Drupal config names by prefix, or list all. • **apic drupal-config:set** - Set a new Drupal config key and value, or update an existing config key and value. For more information, see Using the drupal-config commands.
apic drupal-state	Manage your **drupal-state** keys and values.	• **apic drupal-state:delete** - Delete a specific Drupal state key and value. • **apic drupal-state:get** - Get a specific Drupal state key value. • **apic drupal-state:set** - Set a new Drupal state key and value, or update an existing state key value. For more information, see Using the drupal-state commands.
apic entity	Manage your **entity**.	• **apic entity:count** - A count of entities from a site. • **-s, --server** *mgmt_endpoint_url*. Use the value of the platform API endpoint URL for this entry. • **--org** *orgid* • **--catalog** *catalog id*. • **--debug**. If you need debug information. For more information, see Using the entity commands.
apic factory-reset	Perform a factory reset of your Developer Portal.	• **apic factory-reset:delete** - Perform a factory reset of your Developer Portal, deleting the portal service and all of its associated Developer Portal sites. • **--execute_reset** must be set to **true** to trigger the Developer Portal reset. If not set, the command performs a dry run status of a factory reset. • **--portal_service_endpoint** *portal_service_endpoint*. • **-s, --server** *management_server*. Warning: The **factory-reset** command is irreversible. You must ensure that you have backups created before running this command. For more information, see Using the factory-reset command.
apic forums	Manage your **forums**.	• **apic forums:disable** - disables the Forum module for a given site. • **apic forums:enable** - enables the Forum module for a given site. • **-s, --server** *mgmt_endpoint_url*. • **--org** *orgid* • **--catalog** *catalog id*. For more information, see Using the forums commands.
apic ip-security-enabled	Manage your **IP security**.	• **apic ip-security-enabled:update** - Enable or disable the IP security at the portal service level. • **--enabled** Set to *true* or *false* to enable or disable IP security. • **--portal_service_name** *portal_service_name*. • **-s, --server** *management_server*. For more information, see Using the ip-security-enabled command.

Command	Description	Subcommands
apic modules	Manage your **modules**.	• **apic modules:delete** - Delete **modules**. • **apic modules:disable** - Disable **modules**. • **apic modules:enable** - Enable **modules**. • **apic modules:list** - Get a list of your **modules**. For more information, see Using the modules commands.
apic php-memory	Manage your **php-memory**.	• **apic php-memory:list** - List the PHP memory limit on the platform. • **apic php-memory:update** - Set the PHP memory limit on the portal platform. • **-s, --server** *mgmt_endpoint_url*. Use the value of the platform API endpoint URL for this entry. • **--debug**. If you need debug information. For more information, see Using the php-memory commands.
apic platforms	Manage your **platforms**.	• **apic platforms:list** - List the platforms of a portal service. • **-s, --server** *management_server*. • **--portal_service_name** *portal_service_name* • **--format** *format*. The options are **json** or **yaml**. For more information, see Using the platforms commands.
apic product	Manage your **product**.	• **apic product:add-attachment** - Add an attachment for the given product. • **apic product:add-tag** - Add a tag for the given product. • **apic product:get** - Get a product from a portal service. • **apic product:get-document** - Get a specific entire product document from the portal of the given organization and catalog. • **apic product:list** - List the products on a portal service. • **apic product:set-icon** - Set an icon image for the given product. • **-s, --server** *mgmt_endpoint_url*. Use the value of the platform API endpoint URL for this entry. • **--org** *orgid* • **--catalog** *catalog id*. • **--debug**. If you need debug information. For more information, see Using the product commands.
apic security	Manage your **security**.	• **apic security:clear-bans** - Clear all of the banned user/IP addresses on a portal site. • **-s, --server** *mgmt_endpoint_url*. Use the value of the platform API endpoint URL for this entry. • **--org** *orgid* • **--catalog** *catalog id*. For more information, see Using the security command.
apic service-ip-allowlist	Manage your **service-ip-allowlist**, which enables specific IP addresses to be exempt from being blocked by portal security checks.	• **apic service-ip-allowlist:add** - Add specific IP addresses to the **allowlist**. • **apic service-ip-allowlist:delete** - Delete all of the IP addresses from the **allowlist**. • **apic service-ip-allowlist:list** - List all of the IP addresses that are currently on the **allowlist**. • **apic service-ip-allowlist:remove** - Remove one or more specific IP addresses from the **allowlist**. For more information, see Using the service-ip-allowlist commands.
apic site	Manage your **site**.	• **site:cache-rebuild** - Rebuild the cache of a portal site. • **apic site:check** - Run a platform check against a portal site. • **apic site:state** - Obtain the current state of a portal site. • **apic site:login-link** - Gets an admin login link for a specific portal site. • **-s, --server** *management_server*. • **--org** *orgid* • **--catalog** *catalog id*. • **--format** *format*. The options are **json** or **yaml**. For more information, see Using the site commands.

Command	Description	Subcommands
`apic site-config`	Manage your `site-config`.	• `apic site-config:create-export` - Create an export of a `site config`. • `apic site-config:create-import` - Create an import of a `site config`. • `apic site-config:delete-export` - Delete an export of a `site config`. • `apic site-config:delete-import` - Delete an import of a `site config`. • `apic site-config:get-export` - Get an export of a `site config`. • `apic site-config:get-export-status` - Get the status of an export of a `site config`. • `apic site-config:get-import-status` - Get the status of an import of a `site config`. For more information, see Using the site-config commands.
`apic sites`	Manage your `sites`.	• `apic sites:check` - Run a platform check against all portal sites on a portal service. • `apic sites:list` - List the sites of a portal service. • `-s, --server` *management_server*. • `--portal_service_name` *portal_service_name* • `--format` *format*. The options are `json` or `yaml`. For more information, see Using the sites commands.
`apic themes`	Manage your `themes`.	• `apic themes:delete` - Delete `themes`. • `apic themes:disable` - Disable `themes`. • `apic themes:enable` - Enable `themes`. • `apic themes:list` - Get a list of your `themes`. • `apic themes:set-default` - Set the default theme of the portal. For more information, see Using the themes commands.
`apic twig`	Manage the `twig` debugging operations on a specific portal site.	• `apic twig:debug-enable` - Enable twig debugging for a portal site. • `apic twig:debug-disable` - Disable twig debugging for a portal site. • `apic twig:debug-status` - Get the current state of twig debugging for a specific site. For more information, see Using the twig commands.
`apic version`	Get the version of your API Connect toolkit.	• `apic version --mode portaladmin` - Get toolkit version.

- **Using the api commands**
  You can use the **api** commands to get and list the APIs on your Developer Portal service.
- **Using the apic-config commands**
  You can use the **apic-config** commands to get the apic config of your Developer Portal service.
- **Using the application commands**
  You can use the **application** commands to get and list the applications on your Developer Portal service.
- **Using the backups commands**
  You can use the **backups** commands to list the backups on your Developer Portal service.
- **Using the consumer-org commands**
  You can use the **consumer-org** commands to get and list the consumer orgs on your Developer Portal service.
- **Using the custom-module commands**
  You can use the **custom-module** commands to create exports and imports, delete exports and imports, get the status of an export or import, and get an export, on your Developer Portal service.
- **Using the custom-theme commands**
  You can use the **custom-theme** commands to create export and import tasks, delete export and import tasks, get the status of an export or import task, and get an export artifact, on your Developer Portal service.
- **Using the custom-translation commands**
  You can use the **custom-translation** commands to create an import or export task that will import or export a .tgz of custom translations for a Developer Portal site. You can also delete the export and import tasks, get the status of an export or import task, and get a custom translation export artifact.
- **Using the custom-webserver-page commands**
  You can use the **custom-webserver-page** commands to customize the web server error pages on your Developer Portal service.
- **Using the drupal-config commands**
  You can use the **drupal-config** commands to list, get the values of, set values, create new, and delete the Drupal configuration objects on your Developer Portal service.
- **Using the drupal-state commands**
  You can use the **drupal-state** commands to store and retrieve information about the state of your Developer Portal system.
- **Using the entity commands**
  You can use the **entity** commands to get the entity count on your Developer Portal service.
- **Using the factory-reset command**
  You can use the **factory-reset** command to perform a factory reset of your Developer Portal, which will delete the portal service and all of its associated Developer Portal sites.
- **Using the forums commands**
  You can use the **forums** commands to disable or enable the forums on your Developer Portal service.
- **Using the ip-security-enabled command**
  You can use the **ip-security-enabled** commands to toggle IP security on your Developer Portal. When IP security is enabled, modules such as the Drupal Perimeter Defence module, or flood control, will block client IP addresses suspected of malicious behavior, as expected. Banned IP addresses can be cleared by using the `security:clear-bans` command. You might want to turn off IP security if you are performing penetration tests, or if you cannot pass through the client IP address from your external load balancer. Note that IP security is enabled by default on the Developer Portal.

- **Using the modules commands**
  You can use the **modules** commands to list, enable, disable and delete the modules on your Developer Portal service.
- **Using the php-memory commands**
  You can use the **php-memory** commands to list or update the PHP memory limits on your Developer Portal.
- **Using the platforms commands**
  You can use the **platforms** commands to list the platforms on your Developer Portal service.
- **Using the product commands**
  You can use the **product** commands to get and list the products on your Developer Portal service.
- **Using the security command**
  You can use the **security** command to clear all of the banned user/IP addresses on a Developer Portal site.
- **Using the service-ip-allowlist commands**
  You can use the **service-ip-allowlist** commands to add, remove, and list the IP addresses on your Developer Portal `allowlist`. IP addresses that are on the `allowlist` are exempt from being blocked by Developer Portal security checks, for example, load balancer and proxy IPs.
- **Using the site commands**
  You can use the **site** commands to check the site on your Developer Portal service.
- **Using the site-config commands**
  You can use the **site-config** commands to create exports and imports, delete exports and imports, get the status of an export or import, and get an export, on your Developer Portal service.
- **Using the sites commands**
  You can use the **sites** commands to check and list the sites on your Developer Portal service.
- **Using the themes commands**
  You can use the **themes** commands to list, enable, disable, delete, and set the default themes on your Developer Portal service.
- **Using the twig commands**
  You can use the **twig** commands to enable, disable, and check the state of twig debugging on a specific site on your Developer Portal service.

Using the api commands

You can use the **api** commands to get and list the APIs on your Developer Portal service.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

   For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. List the APIs from a site.
   For example,

   ```
   apic --mode portaladmin api:list --org orgid/name --server management_server --catalog catalogid/name
   ```

   - *management_server* is the endpoint URL of the management server (required).
   - *catalogid/name* is the ID or name of the catalog that the site belongs to (required).
   - *orgid/name* is the ID or name of the provider organization that the catalog belongs to (required).
   - *format_type* is the output format. Can be `json`, `yaml`, `go-template=...`, `go-template-file=...`. Defaults to `yaml`.

3. Get an API from a site by using the *id* or *name:version*.
   For example,

   ```
   apic --mode portaladmin api:get --org orgid/name --server management_server --catalog catalogid/name id/name:version
   ```

   - *id/name:version* - The ID or name:version of a specific API (required). For example, `id-of-api-called-example-3` or `example:3.0.0`.

4. Get a specific entire API document from the portal of the provided organization and catalog by using the *id* or *name:version*.

   ```
   apic --mode portaladmin api:get-document --org orgid/name --server management_server --catalog catalogid/name --format
   format_type  id/name:version
   ```

   For example,

   ```
   apic --mode portaladmin api:get-document --org ibm --server management_server --catalog portal-test --format yaml  intuiz-
   api:1.0.0
   ```

5. Add an attachment for your API within your Developer Portal.
   For example,

```
apic --mode portaladmin api:add-attachment -s management_server --org orgid/name --catalog catalogid/name --
attachment_name attachment.txt --attachment_description "API documentation" mortgage-management-api:1.0.0 ./attachment.txt
Loading File (Large files may take a while)...

Attachment successfully added to api mortgage-management-api:1.0.0.
  This product now has 4 attachments.
```

- `attachment_name` is the name given to the attachment when it is uploaded (required).
- `attachment_description` is the description of the attachment that is displayed to the users.

6. Set an icon for your API within your Developer Portal.
   For example,

```
apic --mode portaladmin api:set-icon -s management_server --org orgid/name --catalog catalogid/name --icon_description
"API icon" mortgage-management-api:1.0.0 ./icon.png
Loading File (Large files may take a while)...

Icon successfully set for api mortgage-management-api:1.0.0
```

- `icon_description` is the icon description to be displayed to users and it is used as an alt text for the image (required).

7. Add a tag (Category) for your API within your Developer Portal.
   For example,

```
apic --mode portaladmin api:add-tag -s management_server --org orgid/name --catalog catalogid/name --tag_name
top_level_element/next_level_element/lower_level_element mortgage-management-api:1.0.0
Successfully set taxonomy tag top_level_element/next_level_element/lower_level_element
  for api mortgage-management-api:1.0.0
```

- `tag_name` is the tag name. For example, `top_level_element/next_level_element` (required).

Using the apic-config commands

You can use the **apic-config** commands to get the apic config of your Developer Portal service.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

   For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Get the apic config of a site.
   For example,

```
apic --mode portaladmin apic-config:get --org orgid/name --server management_server --catalog name/id
```

Using the application commands

You can use the **application** commands to get and list the applications on your Developer Portal service.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

   For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
```

```
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

2. List the applications on a site.
   For example,

```
apic --mode portaladmin application:list --org orgid/name --server management_server --catalog name/id
```

3. Get an application from a site by using application id.
   For example,

```
apic --mode portaladmin application:get --org orgid/name --server management_server --catalog name/id id
```

Using the backups commands

You can use the **backups** commands to list the backups on your Developer Portal service.

1. Log in as Cloud manager:

```
apic login --server management_server --realm admin/identity_provider --username cloud_username --password cloud_password
```

   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

   For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

   The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.
   For full details of the **apic login** command, see Logging in to a management server.

2. Get the availability zone of the portal service's backups that you want to list:

```
apic availability-zones --org orgid/name --server management_server
```

3. List all the portal services in that availability zone

```
apic portal-services:list --org orgid/name --server management_server --availability-zone availability_zone
```

4. Get the selected portal service's name

```
apic portal-services:get --org orgid/name --server management_server --availability-zone availability_zone PORTAL-SERVICE-NAME
```

5. List the backups of the portal service

```
apic --mode portaladmin backups:list --server management_server --portal_service_name PORTAL-SERVICE-NAME --format json
```

Using the consumer-org commands

You can use the **consumer-org** commands to get and list the consumer orgs on your Developer Portal service.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

   For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

2. List the consumer orgs of a site.
   For example,

```
apic --mode portaladmin consumer-org:list --org orgid/name --server management_server --catalog name/id
```

3. Get a consumer org from a site by using org id.
   For example,

```
apic --mode portaladmin consumer-org:get --org orgid/name --server management_server --catalog name/id id
```

Using the custom-module commands

You can use the **custom-module** commands to create exports and imports, delete exports and imports, get the status of an export or import, and get an export, on your Developer Portal service.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

   For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

   The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
   For full details of the **apic login** command, see Logging in to a management server.

2. Export your custom modules.
   The **custom-module:create-export** command creates an export task against the portal of the specified **catalog** and **org**. The command then polls the status of the task until it has **FINISHED** and the artifacts are streamed back.
   Note: The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the commands **custom-module:get-export-status** and **custom-module:get-export** to get the status and potentially an artifact.

```
apic --mode portaladmin custom-module:create-export --catalog name/id --org orgid/name --server management_server
```

   - The module .tgz is saved to the directory in which you ran the command.
   - The saved .tgz has the format **custom_module_createExport-*20200217134637*.tgz**.
   - You can save your exports into your change control management system.

   For example,

```
apic --mode portaladmin custom-module:create-export --catalog dev --org ibm --server api.stagingexample.com
```

3. Import your custom modules.
   The **custom-module:create-import** command uses the supplied .tgz file to import the custom modules into the portal of the specified **catalog** and **org**. The command then polls the status of the task until the task has either **FINISHED** successfully, or failed because of an error.
   Note:
   - The higher level folders of the archive can contain only these characters, a-z and 0-9.
   - The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the command **custom-module:get-import-status** to get the status of the import.
   - If you import a custom module that already exists you overwrite the existing custom module.

```
apic --mode portaladmin custom-module:create-import --catalog name/id --org orgid/name --server management_server
/PATH/TO/MODULE/TGZ
```

   For example,

```
apic --mode portaladmin custom-module:create-import --catalog prod --org ibm --server api.productionexample.com
C:/users/example/desktop/custom_module_createExport-20200217134637.tgz
```

4. You can run the delete command to cancel any ongoing or recently created import or export tasks. Any temporarily created artifacts will be deleted from the portal filesystem. No custom modules are deleted.
   For example,

```
apic --mode portaladmin custom-module:delete-export --catalog name/id --org orgid/name --server management_server --format
json --task_id string
```

```
apic --mode portaladmin custom-module:delete-import --catalog name/id --org orgid/name --server management_server --format
json --task_id string
```

Using the custom-theme commands

You can use the **custom-theme** commands to create export and import tasks, delete export and import tasks, get the status of an export or import task, and get an export artifact, on your Developer Portal service.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Export your custom themes.
   The **custom-theme:create-export** command creates an export task against the portal of the specified `catalog` and `org`. The command then polls the status of the task until it has `FINISHED` and the artifacts are streamed back.
   Note: The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the commands **custom-theme:get-export-status** and **custom-theme:get-export** to get the status and potentially an artifact.

   ```
   apic --mode portaladmin custom-theme:create-export --catalog name/id --org orgid/name --server management_server
   ```

   - The theme .tgz is saved to the directory in which you ran the command.
   - The saved .tgz has the format `custom_theme_createExport-20200217134637.tgz`.
   - You can save your exports into your change control management system.

   For example,

   ```
   apic --mode portaladmin custom-theme:create-export --catalog dev --org ibm --server api.stagingexample.com
   ```

3. Import your custom themes.
   The **custom-theme:create-import** command uses the supplied .tgz file to import the custom themes into the portal of the specified `catalog` and `org`. The command then polls the status of the task until the task has either `FINISHED` successfully, or failed because of an error.
   Note:
   - The higher level folders of the archive can contain only these characters, a-z and 0-9.
   - The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the command **custom-theme:get-import-status** to get the status of the import.
   - If you import a custom theme that already exists you overwrite the existing custom theme.

   ```
   apic --mode portaladmin custom-theme:create-import --catalog name/id --org orgid/name --server management_server
   /PATH/TO/theme/TGZ
   ```

   For example,

   ```
   apic --mode portaladmin custom-theme:create-import --catalog prod --org ibm --server api.productionexample.com
   C:/users/example/desktop/custom_theme_createExport-20200217134637.tgz
   ```

4. You can run the delete command to cancel any ongoing or recently created import or export tasks. Any temporarily created artifacts will be deleted from the portal filesystem. No custom themes are deleted.
   For example,

   ```
   apic --mode portaladmin custom-theme:delete-export --catalog name/id --org orgid/name --server management_server --format
   json --task_id string
   ```

   ```
   apic --mode portaladmin custom-theme:delete-import --catalog name/id --org orgid/name --server management_server --format
   json --task_id string
   ```

Using the custom-translation commands

You can use the **custom-translation** commands to create an import or export task that will import or export a .tgz of custom translations for a Developer Portal site. You can also delete the export and import tasks, get the status of an export or import task, and get a custom translation export artifact.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

2. Export your custom translations.
The **custom-translation:create-export** command creates an export task against the portal of the specified `catalog` and `org`, to export an archive of the custom translations of the site. The command then polls the status of the task until it has `FINISHED` and the artifacts are streamed back. The task ID is printed to the terminal.
Note:
   - The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the commands **custom-translation:get-export-status** and **custom-translation:get-export** to get the status and potentially an artifact.
   - The translation .tgz archive is saved to the directory in which you ran the command.
   - The saved .tgz has the format `custom_translation_createExport-20210217134637.tgz`.
   - You can save your exports into your change control management system.

```
apic --mode portaladmin custom-translation:create-export --catalog catalogid/name --org orgid/name --server
management_server
```

   - *`catalogid/name`* is the ID or name of the catalog that the site belongs to (required).
   - *`orgid/name`* is the ID or name of the provider organization that the catalog belongs to (required).
   - *`management_server`* is the endpoint URL of the management server (required).
   - `--langcodes` is a comma separated list of the language codes, for example `es,zh-hans`. You can use this option to specify which custom translations to export.
   - `--no-poll` can be used to stop the command from polling the task, and just return the task ID.

For example:

```
apic --mode portaladmin custom-translation:create-export --catalog dev --org ibm --server api.stagingexample.com
```

3. Import your custom translations.
The **custom-translation:create-import** command uses the supplied .tgz file to create a task to import the custom translations into the portal of the specified `catalog` and `org`. The command then polls the status of the task until the task has either `FINISHED` successfully, or failed because of an error. The task ID is printed to the terminal.
Note:
   - The .tgz archive must contain only .po translation files, and nothing else.
   - The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the command **custom-translation:get-import-status** to get the status of the import.
   - If you import a custom translation that already exists, the existing custom translation is overwritten.

```
apic --mode portaladmin custom-translation:create-import --catalog catalogid/name --org orgid/name --server
management_server /PATH/TO/MODULE/TGZ
```

   - `--no-poll` can be used to stop the command from polling the task, and just return the task ID.

For example:

```
apic --mode portaladmin custom-translation:create-import --catalog prod --org ibm --server api.productionexample.com
C:/users/example/desktop/custom_translation_createExport-20210217134637.tgz
```

4. You can run the delete command to cancel any ongoing or recently created import or export tasks. Any temporarily created artifacts will be deleted from the portal filesystem. No custom translations are deleted.
For example,

```
apic --mode portaladmin custom-translation:delete-export --catalog catalogid/name --org orgid/name --server
management_server --format json --task_id taskid
```

```
apic --mode portaladmin custom-translation:delete-import --catalog catalogid/name --org orgid/name --server
management_server --format json --task_id taskid
```

   - *`taskid`* is the ID of the import or export task that was created on the queue (required).
   - `--format` is the output format that can be seen if you run the command with debug. Can be `json`, `yaml`, `go-template=...`, `go-template-file=...`. Defaults to `yaml`.

For example:

```
apic --mode portaladmin custom-translation:delete-import --catalog prod --org ibm --server api.productionexample.com  --
task_id 4hythbptta6z9lyx
```

Using the custom-webserver-page commands

You can use the **custom-webserver-page** commands to customize the web server error pages on your Developer Portal service.

The **custom-webserver-page** commands enable you to set, get, and delete custom HTML content for the web server error pages of index, 404, 40x, and 50x. You can embed base64 encoded images, such as .svg and .png, or inline .svg images in your content, but the maximum size of the content of each error page is 8 MB.
Note:

- The custom web server error pages that can be set by using the **custom-webserver-page** commands, are the pages that are returned when the URL of a specific portal site isn't used. For example, if your portal site was https://example.com/myorg/dev, but you went to https://example.com/myorg/deb, then this is when a custom 404 error page is returned. However, if the requested URL matches a portal site, then the web server will use the Drupal error handlers, and will respond according to the Drupal configuration.
- All custom content that you set must conform to the HTML5 specification. If you try to set custom content that doesn't conform to HTML5, it will fail with the following error message:

  ```
  Error: The supplied custom HTML failed validation.
  ```

- Setting and deleting custom web server pages can take several minutes to complete, depending on the size of the content.

1. Log in as Cloud manager:

   ```
   apic login --server management_server --realm admin/identity_provider --username admin --password cloud_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Set a custom HTML web server error page on the Developer Portal. The maximum size of the page is 8 MB, and you must ensure that the content conforms to the HTML5 specification, or the **custom-webserver-page:set** command will fail with a validation error.

   ```
   apic --mode portaladmin custom-webserver-page:set --server management_server --portal_service_name portal --page_type page_type filename.html
   ```

   - *management_server* is the endpoint URL of the management server (required).
   - *portal* is the name of the portal service (required).
   - *page_type* is the type of web server error page that you want to run the command against (required). Valid values are `index`, `404`, `40x`, or `50x`.
   - *filename* is the name of the HTML file that contains the content for the custom web server error page.

   For example, the following screen capture shows a standard 404 web server response:

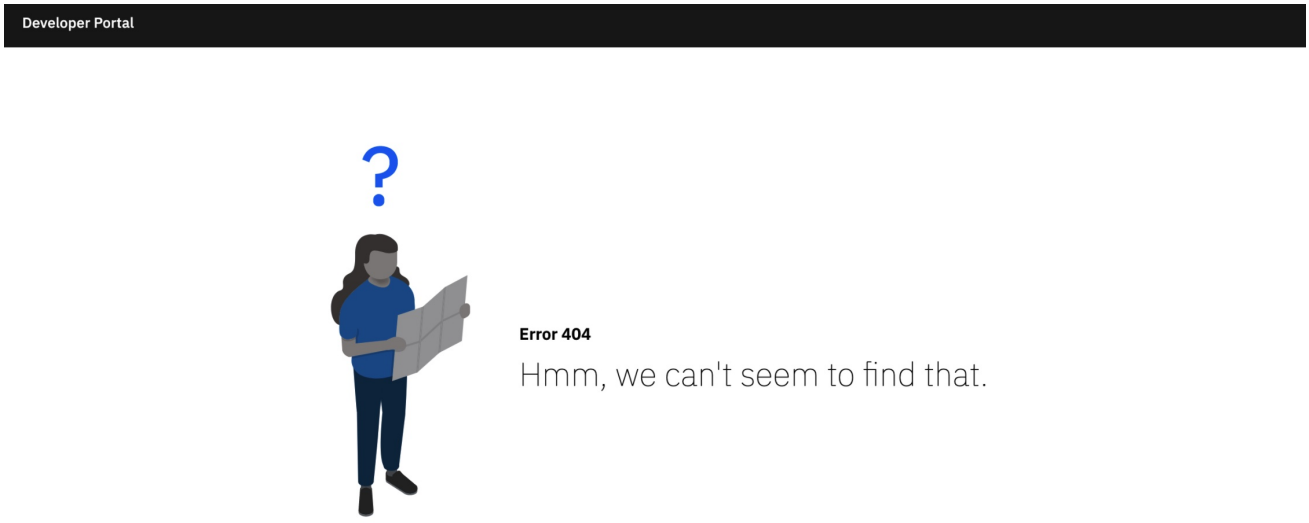
   404 Not Found

   Then the following **custom-webserver-page:set** command is run:

   ```
   apic --mode portaladmin custom-webserver-page:set --server my.management.server.com --portal_service_name portal --page_type 404 custom-404.html
   Loading File (Large files may take a while)...

   Successfully added the custom HTML content for page type 404.
   ```

   The following custom 404 error page is now displayed:



3. Get the custom content of a specific page type and save it to a file named <page_type>-timestamp.html.

```
apic --mode portaladmin custom-webserver-page:get --server management_server --portal_service_name portal --page_type
page_type
```

For example:

```
apic --mode portaladmin custom-webserver-page:get --server my.management.server.com --portal_service_name portal --
page_type 404
Incoming project saved to 404-20211027121830.html
```

If there is no custom content available for the page type, the following error is displayed:

```
apic --mode portaladmin custom-webserver-page:get --server my.management.server.com --portal_service_name portal --
page_type 50x
Error: There is currently no custom HTML content for page type 50x.
```

4. Delete the custom content of a specific page type. If there is no custom content available for a page type, the error response defaults to the standard web server error page.

```
apic --mode portaladmin custom-webserver-page:delete --server management_server --portal_service_name portal --page_type
page_type
```

For example:

```
apic --mode portaladmin custom-webserver-page:delete --server my.management.server.com --portal_service_name portal --
page_type 404
The custom HTML content for page type 404 has been deleted.
```

Using the drupal-config commands

You can use the **drupal-config** commands to list, get the values of, set values, create new, and delete the Drupal configuration objects on your Developer Portal service.

For example, you can use the **drupal-config** commands to disable CSS and JS aggregation to help with twig debug, see Example.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

2. List all of the available Drupal config for a site.

```
apic --mode portaladmin drupal-config:list --server management_server --catalog catalogid/name --org orgid/name --format
format_type
```

- *management_server* is the endpoint URL of the management server (required).
- *catalogid/name* is the ID or name of the catalog that the site belongs to (required).
- *orgid/name* is the ID or name of the provider organization that the catalog belongs to (required).
- *format_type* is the output format. Can be `json`, `yaml`, `go-template=...`, `go-template-file=...`. Defaults to `yaml`.

For example:

```
apic --mode portaladmin drupal-config:list --server my.management.server.com --org ibm --catalog portal-test --format yaml
admin_toolbar_tools.settings:
  name: admin_toolbar_tools.settings
adminimal_admin_toolbar.settings:
  name: adminimal_admin_toolbar.settings
advagg.settings:
  name: advagg.settings
advagg_css_minify.settings:
  name: advagg_css_minify.settings
advagg_js_minify.settings:
  name: advagg_js_minify.settings
autologout.settings:
  name: autologout.settings
...
```

Note that the example has been reduced as the full response is very large.

3. List a specific Drupal config for a site.

```
apic --mode portaladmin drupal-config:list --server management_server --catalog catalogid/name --org orgid/name --prefix
config_prefix --format format_type
```

- *config_prefix* is the prefix of the Drupal config, for example `system`. If omitted, the command returns all config names in the system.

For example:

```
apic --mode portaladmin drupal-config:list --server my.management.server.com --org ibm --catalog portal-test --format yaml
--prefix system.theme
system.theme:
  name: system.theme
system.theme.global:
  name: system.theme.global
```

4. Update a Drupal config key value.

```
apic --mode portaladmin drupal-config:set -server management_server --catalog catalogid/name --org orgid/name  --
config_name config_name --config_key config_key --config_value config_value
```

- *config_name* is the name of the Drupal config object, for example `system.site` (required).
- *config_key* is the Drupal config key, for example `page.front` (required).
- *config_value* is the value to assign to the config key (required).

For example, to set the default theme to `claro`:

```
apic --mode portaladmin drupal-config:set --server my.management.server.com --org ibm --catalog portal-test --config_name
system.theme --config_key default --config_value claro
// Do you want to update default key in system.theme config?: yes.
```

5. Create a new Drupal config key and set the value.

```
apic --mode portaladmin drupal-config:set -server management_server --catalog catalogid/name --org orgid/name  --
config_name config_name --config_key new_config_key --config_value new_config_value
```

For example, to create a new config key and set the value in the `system.site` config object:

```
apic --mode portaladmin drupal-config:set --server my.management.server.com --org ibm --catalog portal-test --config_name
system.site --config_key new_key --config_value new_value
// new_key key does not exist in system.site config. Do you want to create a new config key?: yes.
```

6. Get all of the key values for a Drupal config object.

```
apic --mode portaladmin drupal-config:get --server management_server --catalog catalogid/name --org orgid/name  --format
format_type --config_name config_name
```

For example, to find out what themes are available:

```
apic --mode portaladmin drupal-config:get --server my.management.server.com --org ibm --catalog portal-test --format json
--config_name system.theme
{
    "admin": "seven",
    "default": "claro",
    "_core": {
        "default_config_hash": "fOjer9hADYYnbCJVZMFZIIM1azTFWyg84ZkFDHfAbUg"
    },
    "defaultplus": "bartisk"
}
```

7. Get the value of a specific key for a Drupal config object.

```
apic --mode portaladmin drupal-config:get --server management_server --catalog catalogid/name --org orgid/name  --format
format_type --config_name config_name --config_key config_key
```

For example, to find out what the default theme is:

```
apic --mode portaladmin drupal-config:get --server my.management.server.com --org ibm --catalog portal-test --format json
--config_name system.theme --config_key default
{
```

```
    "system.theme:default": "claro"
}
```

8. Delete a Drupal config object, or a specific config key and its value.

```
apic --mode portaladmin drupal-config:delete --server management_server --catalog catalogid/name --org orgid/name  --
config_name config_name --config_key config_key
```

   - *config_key* is the Drupal config key, for example `page.front` (optional).

   For example, to delete the config key `new_key` and its value:

```
apic --mode portaladmin drupal-config:delete --server my.management.server.com --org ibm --catalog portal-test --
config_name system.site --config_key new_key
The config object/value was successfully deleted.
```

Example

The following scenario gives an example of how to turn off CSS and JS aggregation to help with twig debug. However, on a production system aggregation should be enabled for performance reasons.

1. Check the settings for performance, which include settings for CSS and JS aggregation:

```
apic --mode portaladmin drupal-config:get --server management_server --catalog catalogid/name --org orgid/name --
config_name system.performance
```

2. Check the settings for advanced aggregation:

```
apic --mode portaladmin drupal-config:get --server management_server --catalog catalogid/name --org orgid/name --
config_name advagg.settings
```

3. Turn off CSS aggregation:

```
apic --mode portaladmin drupal-config:set --server management_server --catalog catalogid/name --org orgid/name --
config_name system.performance --config_key css.preprocess --config_value 0
```

4. Turn off JS aggregation:

```
apic --mode portaladmin drupal-config:set --server management_server --catalog catalogid/name --org orgid/name --
config_name system.performance --config_key js.preprocess --config_value 0
```

5. Turn off advanced aggregation (this setting is needed for the previous aggregation settings to apply):

```
apic --mode portaladmin drupal-config:set --server management_server --catalog catalogid/name --org orgid/name --
config_name advagg.settings --config_key enabled --config_value 0
```

6. Then, rebuild the cache:

```
apic --mode portaladmin site:cache-rebuild  --server management_server --catalog catalogid/name --org orgid/name
```

When loading the site in a browser, you should now see CSS and JS aggregation is disabled when using development tools for site debug or customization.
Note:

- Disabling aggregation affects site performance, so if the site goes into production remember to turn aggregation back on again.
- Although the settings are shown as `true` or `false`, to set them by using the `drupal-config:set` command, you must apply a value of `1` for `true`, and `0` for `false`.

Using the drupal-state commands

You can use the **drupal-state** commands to store and retrieve information about the state of your Developer Portal system.

Information about the state of your Developer Portal system is stored in the Developer Portal database, and therefore this information is lost if the database is dropped, or the Developer Portal site is re-installed from configuration.

The **drupal-state** commands can be used to set, update, get, or delete a state key value. For example, you can use the **drupal-state** commands to enable and disable maintenance mode for your Developer Portal; for more information, see the scenario How to enable and disable maintenance mode on your Developer Portal.

Warning: Use the **drupal-state** command with caution. This command enables you to modify keys for your Developer Portal site state. Incorrect usage of this command can bring down your Developer Portal, and then require restoring it from a backup.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

   For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

2. Create a new Drupal state key, or update an existing key, and set the value.

```
apic --mode portaladmin drupal-state:set -server management_server --catalog catalogid/name --org orgid/name  --
input_format input_format_type --state_key state_key_name --state_value state_value
```

Where:
- *`management_server`* is the endpoint URL of the management server (required).
- *`catalogid/name`* is the ID or name of the catalog that the site belongs to (required).
- *`orgid/name`* is the ID or name of the provider organization that the catalog belongs to (required).
- *`input_format_type`* is the input format of the value for the state key. Can be `string`, `integer`, `float`, `boolean`, `json`, or `yaml`. Defaults to `auto`, which means that you can omit this parameter, and the toolkit CLI will decide which format to use.
- *`state_key_name`* is the name of the state key, for example `system.cron_last` (required).
- *`state_value`* is the value to assign to the state key (required).
- `--format` is the output format. Can be `json`, `yaml`, `go-template=...`, `go-template-file=...`. Defaults to `yaml`.

For example, to create a new key called `testKey`, and set the value to `123`:

```
apic --mode portaladmin drupal-state:set -s my.management.server.com -o myorg -c dev-catalog --input_format yaml --
state_key testKey --state_value 123
Successfully set state testKey to the value of 123
```

3. Get the value for a particular Drupal state key.

```
apic --mode portaladmin drupal-state:get --server management_server --catalog catalogid/name --org orgid/name  --format
format_type --state_key state_key_name
```

For example, to get the value of the state key `testKey`:

```
apic --mode portaladmin drupal-state:get -s my.management.server.com -c dev-catalog -o myorg --format yaml --state_key
testKey
testKey: 123
```

4. Delete a specific Drupal state key and its value.

```
apic --mode portaladmin drupal-state:delete --server management_server --catalog catalogid/name --org orgid/name --
state_key state_key_name
```

For example, to delete the state key `testKey` and its value:

```
apic --mode portaladmin drupal-state:delete -s my.management.server.com -c dev-catalog -o myorg --state_key testKey
The key/value was successfully deleted.
```

Related tasks

- Toggling the site in and out of maintenance mode

Using the entity commands

You can use the **entity** commands to get the entity count on your Developer Portal service.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

2. Get the entity count for a site.
For example,

```
apic --mode portaladmin entity:count --org orgid/name --server management_server --catalog name/id
```

Using the factory-reset command

You can use the **factory-reset** command to perform a factory reset of your Developer Portal, which will delete the portal service and all of its associated Developer Portal sites.

Warning: The **factory-reset** command is irreversible. You must ensure that you have backups created before running this command.

1. Log in as Cloud manager:

   ```
   apic login --server management_server --realm admin/identity_provider --username admin --password cloud_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Output a dry run status of a Developer Portal factory reset:

   ```
   apic --mode portaladmin factory-reset:delete --server management_server --portal_service_endpoint portal_endpoint
   ```

   - *management_server* is the endpoint URL of the management server.
   - *portal_endpoint* is the URL endpoint of the portal service.

   For example:

   ```
   apic --mode portaladmin factory-reset:delete --server api.stagingexample.com --portal_service_endpoint
   https://api.portal.mystack.com
   ```

3. Perform a factory reset of the Developer Portal, deleting the portal service and all of its associated Developer Portal sites:
   Warning: The **factory-reset** command is irreversible. You must ensure that you have backups created before running this command.

   ```
   apic --mode portaladmin factory-reset:delete --server management_server --portal_service_endpoint portal_endpoint --
   execute_reset true
   ```

   - `--execute_reset` must be set to `true` to trigger the Developer Portal reset.

   For example:

   ```
   apic --mode portaladmin factory-reset:delete --server api.stagingexample.com --portal_service_endpoint
   https://api.portal.mystack.com  --execute_reset true
   ```

Using the forums commands

You can use the **forums** commands to disable or enable the forums on your Developer Portal service.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Disable the Forum module on your Developer Portal site.
   This command deletes all of the taxonomy terms in the forum vocabulary, and then disables the Forum module.

```
apic --mode portaladmin forums:disable --org orgid/name --server management_server --catalog name/id
```

- *orgid/name* is the ID or name of the provider organization that the catalog belongs to (required).
- *management_server* is the endpoint URL of the management server (required).
- *name/id* is the ID or name of the catalog that the site belongs to (required).

For example,

```
apic --mode portaladmin forums:disable --org ibm --server api.stagingexample.com --catalog dev
```

3. Enable the Forum module on your Developer Portal site.

```
apic --mode portaladmin forums:enable --org orgid/name --server management_server --catalog name/id
```

For example,

```
apic --mode portaladmin forums:enable --org ibm --server api.stagingexample.com --catalog dev
```

Using the ip-security-enabled command

You can use the **ip-security-enabled** commands to toggle IP security on your Developer Portal. When IP security is enabled, modules such as the Drupal Perimeter Defence module, or flood control, will block client IP addresses suspected of malicious behavior, as expected. Banned IP addresses can be cleared by using the `security:clear-bans` command. You might want to turn off IP security if you are performing penetration tests, or if you cannot pass through the client IP address from your external load balancer. Note that IP security is enabled by default on the Developer Portal.

1. Log in as Cloud manager:

```
apic login --server management_server --realm admin/identity_provider --username admin --password cloud_password
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
For full details of the `apic login` command, see Logging in to a management server.

2. Enable IP security on the Developer Portal:

```
apic --mode portaladmin ip-security-enabled:update --server management_server --portal_service_name portal --enabled true
```

- *management_server* is the endpoint URL of the management server.
- *portal* is the name of the portal service.
- `--enabled` is set to `true` to enable IP security. Can be set to `false` to disable IP security.

For example:

```
apic --mode portaladmin ip-security-enabled:update --server my.management.server.com --portal_service_name
my_portal_service --enabled true
IP security has been successfully set to true
```

3. Disable IP security on the Developer Portal:

```
apic --mode portaladmin ip-security-enabled:update --server management_server --portal_service_name portal --enabled false
```

Using the modules commands

You can use the **modules** commands to list, enable, disable and delete the modules on your Developer Portal service.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
```

```
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. List the modules from a *packagename*.
   For example,

```
apic --mode portaladmin modules:list --org orgid/name --server management_server --catalog name/id --package
packagename1,packagename2
```

3. Enable the *modulename* module. You can upload this module by using the **custom-module:create-import** command. For more information, see Using the custom-module commands.
   For example,

```
apic --mode portaladmin modules:enable --org orgid/name --server management_server --catalog name/id --modules modulename
```

   - ***management_server*** is the endpoint URL of the management server (required).
   - ***catalogid/name*** is the ID or name of the catalog that the site belongs to (required).
   - ***orgid/name*** is the ID or name of the provider organization that the catalog belongs to (required).
   - **--package** enables you to filter by project packages. You can use multiple comma separated values.
   - **--status** enables you to filter by extension status. Can be **enabled**, **disabled** and/or **'not installed'**. You can use multiple comma separated values.
   - **--custom** enables you to filter your results to only the modules that you have installed on your Developer Portal site.
4. Disable the *modulename* module. If you disable a module, you must also disable all its dependencies.
   For example,

```
apic --mode portaladmin modules:disable --org orgid/name --server management_server --catalog name/id --modules
modulename,module_lib
```

5. Delete the *modulename* module. The module and all its dependencies must be disabled before you can delete them.
   For example,

```
apic --mode portaladmin modules:delete --org orgid/name --server management_server --catalog name/id --modules modulename
```

Note that if you want to manage the Forum module, you can use the **forums** commands. For more information, see Using the forums commands.

Using the php-memory commands

You can use the **php-memory** commands to list or update the PHP memory limits on your Developer Portal.

1. Log in as Cloud manager:

```
apic login --server management_server --realm admin/identity_provider --username cloud_username --password cloud_password
```

   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

   For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

   The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.
   For full details of the **apic login** command, see Logging in to a management server.

2. Get the availability zone of the portal service's sites that you want to list:

```
apic availability-zones --org orgid/name --server management_server
```

3. List all the portal services in that availability zone:

```
apic portal-services:list --org orgid/name --server management_server --availability-zone availability_zone
```

4. Get the selected portal service's name:

```
apic portal-services:get --org orgid/name --server management_server --availability-zone availability_zone PORTAL-SERVICE-
NAME
```

5. List the current PHP memory limits on the Developer Portal platform:

```
apic --mode portaladmin php-memory:list --server management_server --portal_service_name PORTAL-SERVICE-NAME
```

You receive output like this example:

```
Current web memory is set to: 768M
Current admin memory is set to: 768M
```

6. Update the current PHP memory limits on the Developer Portal platform:

```
apic --mode portaladmin php-memory:update --server management_server --portal_service_name PORTAL-SERVICE-NAME --
memory_value 1024
```

You receive output like this example:

```
Setting php memory limit to 1024M within the database
Setting php memory limit to 1024M in /var/devportal/storenosync/php.ini
Setting php memory limit to 1024M in /web/local/php_config/php.ini
Done
```

Note: Consider the memory resource limits that are allocated to your Developer Portal pods before you set this value. Setting this value too high can result in the portal pods restarting because the containers request more memory than is allowed by Kubernetes. Setting the value too low can result in the internal portal processes failing because of lack of available memory.

Using the platforms commands

You can use the **platforms** commands to list the platforms on your Developer Portal service.

1. Log in as Cloud manager:

```
apic login --server management_server --realm admin/identity_provider --username cloud_username --password cloud_password
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
For full details of the `apic login` command, see Logging in to a management server.

2. Get the availability zone of the portal service's platforms that you want to list:

```
apic availability-zones --org orgid/name --server management_server
```

3. List all the portal services in that availability zone

```
apic portal-services:list --org orgid/name --server management_server --availability-zone availability_zone
```

4. Get the selected portal service's name

```
apic portal-services:get --org orgid/name --server management_server --availability-zone availability_zone PORTAL-SERVICE-
NAME
```

5. List the platforms of the portal service

```
apic --mode portaladmin platforms:list --server management_server --portal_service_name PORTAL-SERVICE-NAME --format json
```

Using the product commands

You can use the **product** commands to get and list the products on your Developer Portal service.

1. Log in as Provider org as seen in the following example.

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
```

```
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. Get a list of products from a site.

   For example,

   ```
   apic --mode portaladmin product:list --org orgid/name --server management_server --catalog catalogid/name
   ```

   - *`management_server`* is the endpoint URL of the management server (required).
   - *`catalogid/name`* is the ID or name of the catalog that the site belongs to (required).
   - *`orgid/name`* is the ID or name of the provider organization that the catalog belongs to (required).
   - *`format_type`* is the output format. Can be `json`, `yaml`, `go-template=...`, `go-template-file=...`. Defaults to `yaml`.
3. Get a product from a site by using the *`id`* or *`name:version`*.

   For example,

   ```
   apic --mode portaladmin product:get --org orgid/name --server management_server --catalog catalogid/name id/name:version
   ```

   - *`id/name:version`* - The ID or name:version of a specific product (required). For example, `id-of-product-called-example-3` or `example:3.0.0`.
4. Get a specific entire product document from the portal of the provided organization and catalog by using the *`id`* or *`name:version`*.

   ```
   apic --mode portaladmin product:get-document --org orgid/name --server management_server --catalog catalogid/name --format
   format_type  id/name:version
   ```

   For example,

   ```
   apic --mode portaladmin product:get-document --org ibm --server my.management.server.com --catalog portal-test --format
   yaml  intuiz-product:1.0.0
   ```

5. Add an attachment for your product within your Developer Portal.

   For example,

   ```
   apic --mode portaladmin product:add-attachment -s management_server --org orgid/name --catalog catalogid/name --
   attachment_name attachment.txt --attachment_description "Product documentation" awesome-sleek-soft-chips-product:1.0.0
   ./attachment.txt
   Loading File (Large files may take a while)...

   Attachment successfully added to product awesome-sleek-soft-chips-product:1.0.0.
     This product now has 2 attachments.
   ```

   - *`attachment_name`* is the name given to the attachment when it is uploaded (required).
   - *`attachment_description`* is the description of the attachment that is displayed to the users.
6. Set an icon for your product within your Developer Portal.
   For example,

   ```
   apic --mode portaladmin product:set-icon -s management_server --org orgid/name --catalog catalogid/name --icon_description
   "product icon" awesome-sleek-soft-chips-product:1.0.0 ./icon.png
   Loading File (Large files may take a while)...

   Icon successfully set for product awesome-sleek-soft-chips-product:1.0.0
   ```

   - *`icon_description`* is the icon description to be displayed to users and it is used as an alt text for the image (required).
7. Add a tag (Category) for your product within your Developer Portal.
   For example,

   ```
   apic --mode portaladmin product:add-tag -s management_server--org orgid/name --catalog catalogid/name --tag_name
   top_level_element/next_level_element/lower_level_element awesome-sleek-soft-chips-product:1.0.0
   Successfully set taxonomy tag top_level_element/next_level_element/lower_level_element
     for product api-connect-cassin-llc-awesome-sleek-soft-chips-product:1.0.0
   ```

   - *`tag_name`* is the tag name. For example, *`top_level_element/next_level_element`* (required).

Using the security command

You can use the **security** command to clear all of the banned user/IP addresses on a Developer Portal site.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
   ```

   For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

2. Clear all of the user and IP addresses that are currently banned on a particular portal site:

```
apic --mode portaladmin security:clear-bans --server management_server --catalog catalogid/name --org orgid/name
```

- ***management_server*** is the endpoint URL of the management server.
- ***catalogid/name*** is the ID or name of the catalog that the site belongs to.
- ***orgid/name*** is the ID or name of the provider organization that the catalog belongs to.

For example:

```
apic --mode portaladmin security:clear-bans --server my.management.server.com --catalog portal-test --org ibm
[notice] All bans cleared.
```

Note: You can also manage banned IP addresses by using the Developer Portal UI. For more information, see Managing banned IP addresses.

Using the service-ip-allowlist commands

You can use the **service-ip-allowlist** commands to add, remove, and list the IP addresses on your Developer Portal **allowlist**. IP addresses that are on the **allowlist** are exempt from being blocked by Developer Portal security checks, for example, load balancer and proxy IPs.

1. Log in as Cloud manager:

```
apic login --server management_server --realm admin/identity_provider --username admin --password cloud_password
```

You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.
For full details of the **apic login** command, see Logging in to a management server.

2. Add one or more IP addresses to the **allowlist**:

```
apic --mode portaladmin service-ip-allowlist:add --server management_server --portal_service_name portal --ips
"list_of_ips"
```

- ***management_server*** is the endpoint URL of the management server.
- ***portal*** is the name of the portal service.
- ***list_of_ips*** is a comma separated list of the IP addresses that you want to add to the **allowlist**.

For example:

```
apic --mode portaladmin service-ip-allowlist:add --server my.management.server.com --portal_service_name my_portal_service
--ips "123.456.34.56,123.456.46.67"
Successfully added IP: 123.456.34.56.
Successfully added IP: 123.456.46.67.
```

3. Delete all of the IP addresses that are currently on the **allowlist**:

```
apic --mode portaladmin service-ip-allowlist:delete --server management_server --portal_service_name portal
```

4. List all of the IP addresses that are currently on the **allowlist**:

```
apic --mode portaladmin service-ip-allowlist:list --server management_server --portal_service_name portal
```

5. Remove one or more IP addresses from the **allowlist**:

```
apic --mode portaladmin service-ip-allowlist:remove --server management_server --portal_service_name portal --ips
"list_of_ips"
```

Using the site commands

You can use the **site** commands to check the site on your Developer Portal service.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

   For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. Check the site on your portal service. This command checks the file system, database, and API Manager on your portal site, which might identify platform-related problems on your portal site.

   ```
   apic --mode portaladmin site:check  --server management_server --catalog catalogid/name --org orgid/name --format
   format_type
   ```

   - *`management_server`* is the endpoint URL of the management server (required).
   - *`catalogid/name`* is the ID or name of the catalog that the site belongs to (required).
   - *`orgid/name`* is the ID or name of the provider organization that the catalog belongs to (required).
   - *`format_type`* is the output format. Can be `json`, `yaml`, `go-template=...`, `go-template-file=...`. Defaults to `yaml`.

3. Rebuild the cache of a specific portal site.

   ```
   apic --mode portaladmin site:cache-rebuild  --server management_server --catalog catalogid/name --org orgid/name
   ```

   For example:

   ```
   apic --mode portaladmin site:cache-rebuild --server management_server --org ibm --catalog portal-test
   [success] Cache rebuild complete.
   ```

4. Display the state of a portal site associated with a particular organization and catalog. This command is useful as a general health check of the site.

   ```
   apic --mode portaladmin site:state --server management_server --catalog catalogid/name --org orgid/name --format
   format_type
   ```

   ```
   apic --mode portaladmin site:state --server my.management.server.com --org ibm --catalog portal-test --format json
   {
       "alias": "ibm.portal-test.my.management.server.com",
       "check_state": "OK: 200",
       "content_refresh_required": false,
       "known_to_apim": 1,
       "platform": "platform_devportal_9_x_10_99_99_99_20210922_2000",
       "snapshot_first_requested": "0000-00-00 00:00:00",
       "snapshots_failed_processing_since_last_success": 0,
       "snapshots_requested_since_last_received": 0,
       "state": "INSTALLED",
       "subscribed_to_webhooks": true,
       "url": "my.management.server.com/ibm/portal-test",
       "uuid": "cc0ad766-e372-4988-9d45-744eb8d381de.1cd9dc41-b08d-xyz"
   }
   ```

5. Log in to your Developer Portal admin with a link. This command displays a one time login link for the admin account for your Developer Portal site that is specified by the catalog and organization.

   ```
    apic --mode portaladmin site:login-link  --server management_server --org ibm --catalog portal-test
   sample output:
   https://my.portal.server.com/ibm/portal-test/user/reset/1/12345678901/ABCde1f2gH3ijKL-
   4M_NOPqrs5TU6VWxy7ZABCDEFg7h8/new/login
   ```

Using the site-config commands

You can use the **site-config** commands to create exports and imports, delete exports and imports, get the status of an export or import, and get an export, on your Developer Portal service.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username cloud_username --password
   cloud_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

2. Export your site configs.
The **site-config:create-export** command creates an export task against the portal of the specified `catalog` and `org`. The command then polls the status of the task until it has `FINISHED` and the artifacts are streamed back.
Note: The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the commands **site-config:get-export-status** and **site-config:get-export** to get the status and potentially an artifact.

```
apic --mode portaladmin site-config:create-export --catalog name/id --org orgid/name --server management_server
```

- The site config .tgz is saved to the directory in which you ran the command.
- The saved .tgz has the format `site_config_createExport-20200217134637.tgz`.
- You can save your exports into your change control management system.

For example,

```
apic --mode portaladmin site-config:create-export --catalog dev --org ibm --server api.stagingexample.com
```

3. Import your site configs.
The **site-config:create-import** command uses the supplied .tgz file to import the site configs into the portal of the specified `catalog` and `org`. The command then polls the status of the task until the task has either `FINISHED` successfully, or failed because of an error.
Note: The higher level folders of the archive can contain only these characters, a-z and 0-9.
Note: The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the command **site-config:get-import-status** to get the status of the import.

```
apic --mode portaladmin site-config:create-import --catalog name/id --org orgid/name --server management_server
/PATH/TO/SITE_CONFIG/TGZ
```

For example,

```
apic --mode portaladmin site-config:create-import --catalog prod --org ibm --server api.productionexample.com
C:/users/example/desktop/site_config_createExport-20200217134637.tgz
```

4. You can run the delete command to cancel any ongoing or recently created import or export tasks. Any temporarily created artifacts will be deleted from the portal filesystem.
For example,

```
apic --mode portaladmin site-config:delete-export --catalog name/id --org orgid/name --server management_server --format
json --task_id string
```

```
apic --mode portaladmin site-config:delete-import --catalog name/id --org orgid/name --server management_server --format
json --task_id string
```

Using the sites commands

You can use the **sites** commands to check and list the sites on your Developer Portal service.

1. Log in as Cloud manager:

```
apic login --server management_server --realm admin/identity_provider --username cloud_username --password cloud_password
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
For full details of the `apic login` command, see Logging in to a management server.

2. Get the availability zone of the portal service's sites that you want to list.

```
apic availability-zones --org orgid/name --server management_server
```

3. List all the portal services in that availability zone.

```
apic portal-services:list --org orgid/name --server management_server --availability-zone availability_zone
```

4. Get the selected portal service's name.

```
apic portal-services:get --org orgid/name --server management_server --availability-zone availability_zone PORTAL-SERVICE-NAME
```

5. Check the sites on your portal service. This command checks the file system, database, and API Manager on all your portal sites, which might identify platform-related problems on one or more of your portal sites.

```
apic --mode portaladmin sites:check --server management_server --portal_service_name PORTAL-SERVICE-NAME --format yaml
```

6. List the sites of the portal service.

```
apic --mode portaladmin sites:list --server management_server --portal_service_name PORTAL-SERVICE-NAME --format json
```

Using the themes commands

You can use the **themes** commands to list, enable, disable, delete, and set the default themes on your Developer Portal service.

1. Log in as Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password provider_password
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

For a summary of the general-purpose commands and their use, see Developer Portal CLI commands.

2. List the themes from a *packagename*.
For example,

```
apic --mode portaladmin themes:list --org orgid/name --server management_server --catalog catalogid/name --package packagename1,packagename2
```

- `management_server` is the endpoint URL of the management server (required).
- `catalogid/name` is the ID or name of the catalog that the site belongs to (required).
- `orgid/name` is the ID or name of the provider organization that the catalog belongs to (required).
- `--package` enables you to filter by project packages. You can use multiple comma separated values.
- `--status` enables you to filter by extension status. Can be `enabled`, `disabled` and/or `'not installed'`. You can use multiple comma separated values.
- `--custom` enables you to filter your results to only the themes that you have installed on your Developer Portal site.

3. Enable the *themename* theme. You can upload this theme by using the **custom-theme:create-import** command. For more information, see Using the custom-theme commands.
For example,

```
apic --mode portaladmin themes:enable --org orgid/name --server management_server --catalog catalogid/name --themes themename
```

- `--themes` is the name of the theme, and can be multiple comma separated values (required).

4. Disable the *themename* theme.
For example,

```
apic --mode portaladmin themes:disable --org orgid/name --server management_server --catalog catalogid/name --themes themename,theme_lib
```

5. Delete the *themename* theme. The theme and all its dependencies must be disabled before you can delete them.
For example,

```
apic --mode portaladmin themes:delete --org orgid/name --server management_server --catalog catalogid/name --themes themename
```

6. Set the *themename* theme to be the default theme. The theme must exist and be enabled for it to be set as a default theme.
For example,

```
apic --mode portaladmin themes:set-default --org orgid/name --server management_server --catalog catalogid/name themename
```

- *themename* is the name of the theme to set as default.

Using the twig commands

You can use the **twig** commands to enable, disable, and check the state of twig debugging on a specific site on your Developer Portal service.

Note: Twig debugging should not be left enabled on production sites, as it causes performance issues, and can affect the caching on the site.

1. Log in as Provider org:

   ```
   apic login --server management_server --realm provider/identity_provider --username provider_username --password
   provider_password
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Enable twig debugging for a portal site.

   ```
   apic --mode portaladmin twig:debug-enable --server management_server --org orgid/name --catalog catalogid/name
   ```

   - *management_server* is the endpoint URL of the management server (required).
   - *orgid/name* is the ID or name of the provider organization that the catalog belongs to (required).
   - *catalogid/name* is the ID or name of the catalog that the site belongs to (required).

   For example:

   ```
   apic --mode portaladmin twig:debug-enable --server my.management.server.com --org ibm --catalog portal-test
   Setting twig debug to true for site my.management.server.com/ibm/portal-test.
   Rebuilding cache for my.management.server.com/ibm/portal-test so twig debug changes can take affect.
   ```

3. Disable twig debugging for a portal site.

   ```
   apic --mode portaladmin twig:debug-disable --server management_server --org orgid/name --catalog catalogid/name
   ```

   For example:

   ```
   apic --mode portaladmin twig:debug-disable --server my.management.server.com --org ibm --catalog portal-test
   Setting twig debug to false for site my.management.server.com/ibm/portal-test.
   Rebuilding cache for my.management.server.com/ibm/portal-test so twig debug changes can take affect.
   ```

4. Get the current state of twig debugging for a specific site.

   ```
   apic --mode portaladmin twig:debug-status --server management_server --org orgid/name --catalog catalogid/name
   ```

   For example:

   ```
   apic --mode portaladmin twig:debug-status --server my.management.server.com --org ibm --catalog portal-test
   The current state of twig debugging is true for my.management.server.com/ibm/portal-test.
   ```

Scenarios that use the Portal CLI

Here are some scenarios of how you can use the Portal commands in the toolkit CLI to accomplish tasks that are more complex to complete, or not possible in the Developer Portal UI.

- **Exporting and importing custom themes and site configuration**
  You can use the portal commands in the toolkit CLI to replicate changes from one Developer Portal instance to another. You might want to use these commands to copy your themes or a configuration change, from a staging environment to a production environment.
- **How to enable and disable maintenance mode on your Developer Portal**
  You can use the Portal commands in the toolkit CLI to enable and disable maintenance mode on your Developer Portal site.

Exporting and importing custom themes and site configuration

You can use the portal commands in the toolkit CLI to replicate changes from one Developer Portal instance to another. You might want to use these commands to copy your themes or a configuration change, from a staging environment to a production environment.

Before you begin

To complete this scenario, you must have a staging Developer Portal and a production Developer Portal enabled. You must have administrator access, and the permission **`settings:manage`**, to both to complete this scenario. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

About this scenario

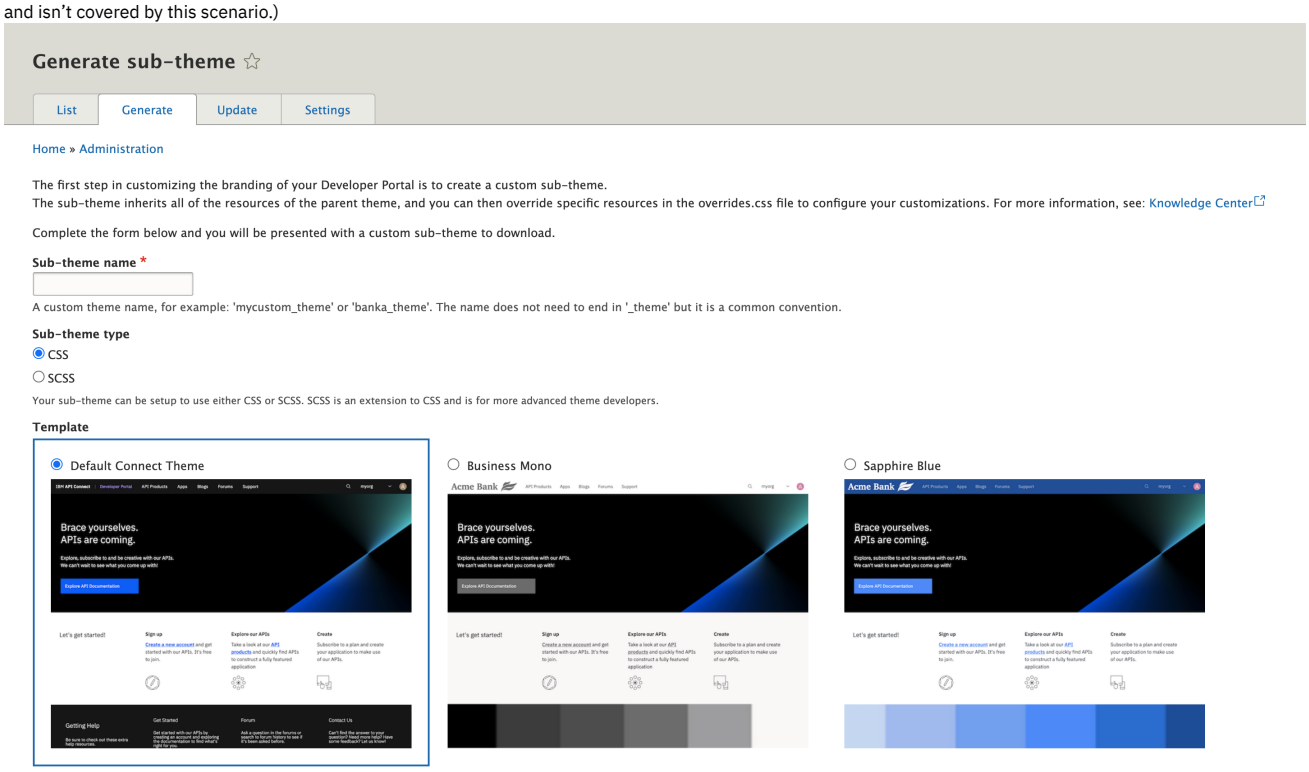
In this scenario, on your staging Developer Portal, you create a theme and make some configuration changes. Then, you use the toolkit CLI to replicate the changes on your production Developer Portal.

This scenario takes you through the following steps:

1. Create a custom theme on the staging Developer Portal.
2. Add a field to an application content type to change the **`site-config`** on the staging Developer Portal.
3. Use the **`cli`** to export the custom themes and **`site-config`** on the staging Developer Portal.
4. Use the **`cli`** to import the custom themes and **`site-config`** on the production Developer Portal.

Create a custom theme on the staging Developer Portal

1. Log in to your staging Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Appearance > Generate sub-theme. The **`Generate sub-theme`** window is displayed.
4. Enter a Sub-theme name, and select CSS for the Sub-theme type. (If you prefer, you can select SCSS, but this extension to CSS is for advanced theme developers, and isn't covered by this scenario.)



5. Select the Default template to base your **`sub-theme`** on. You can create a **`sub-theme`** based on a color template. However, for this scenario you use the default connect_theme template.
6. Click Generate.
7. Download the generated **`sub-theme`** to a location of your choice, and extract all the files from the .zip file.

On your computer, navigate to the files that you extracted. Find the overrides.css file in here banka_theme/banka_theme/css/overrides.css. You can now customize the overrides.css file.

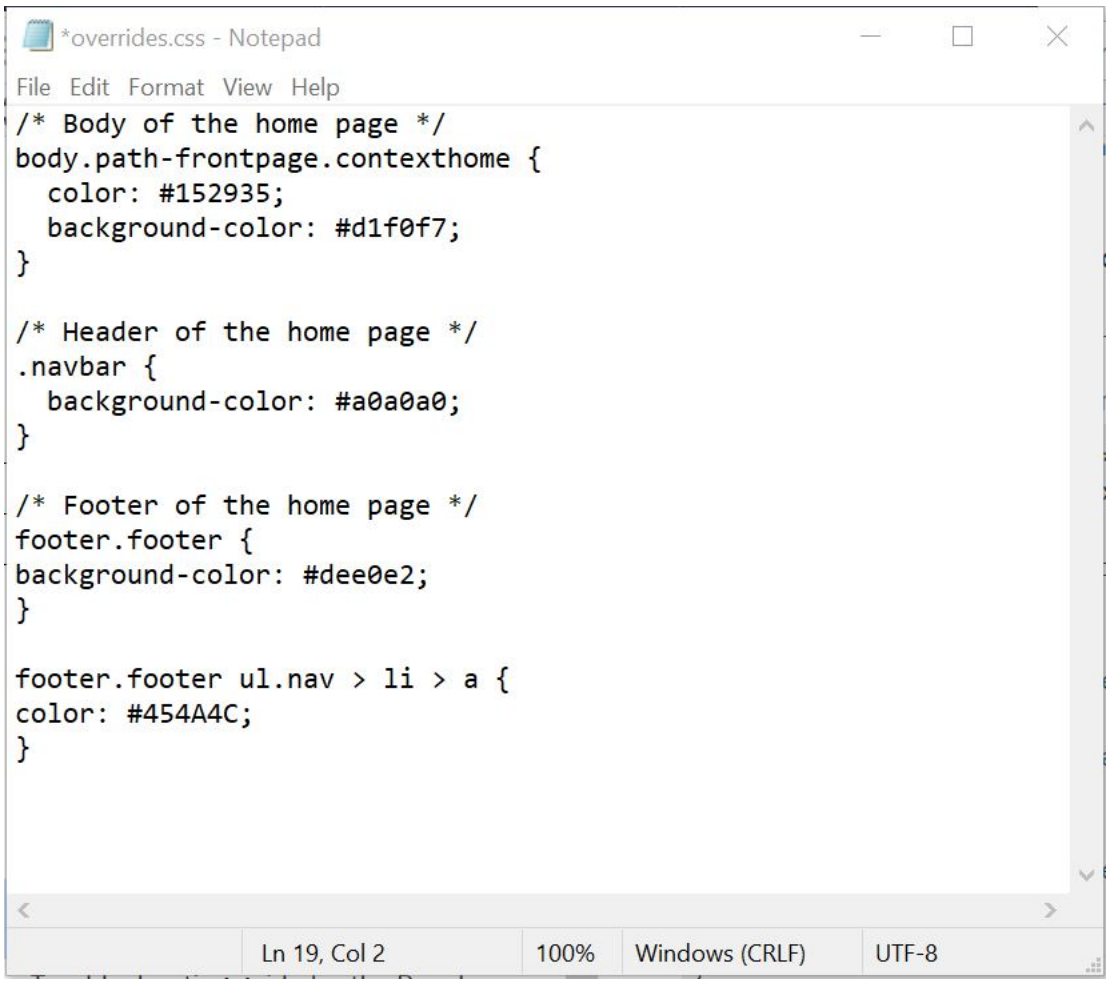
1. Open the overrides.css file in your chosen editor.
2. Customize your **`sub-theme`** by entering the following elements into the overrides.css file:

```
/* Body of the home page */
body.path-frontpage.contexthome {
  color: #152935;
  background-color: #d1f0f7;
}

/* Header of the home page */
.navbar {
  background-color: #a0a0a0;
}

/* Footer of the home page */
footer.footer {
background-color: #dee0e2;
}
```

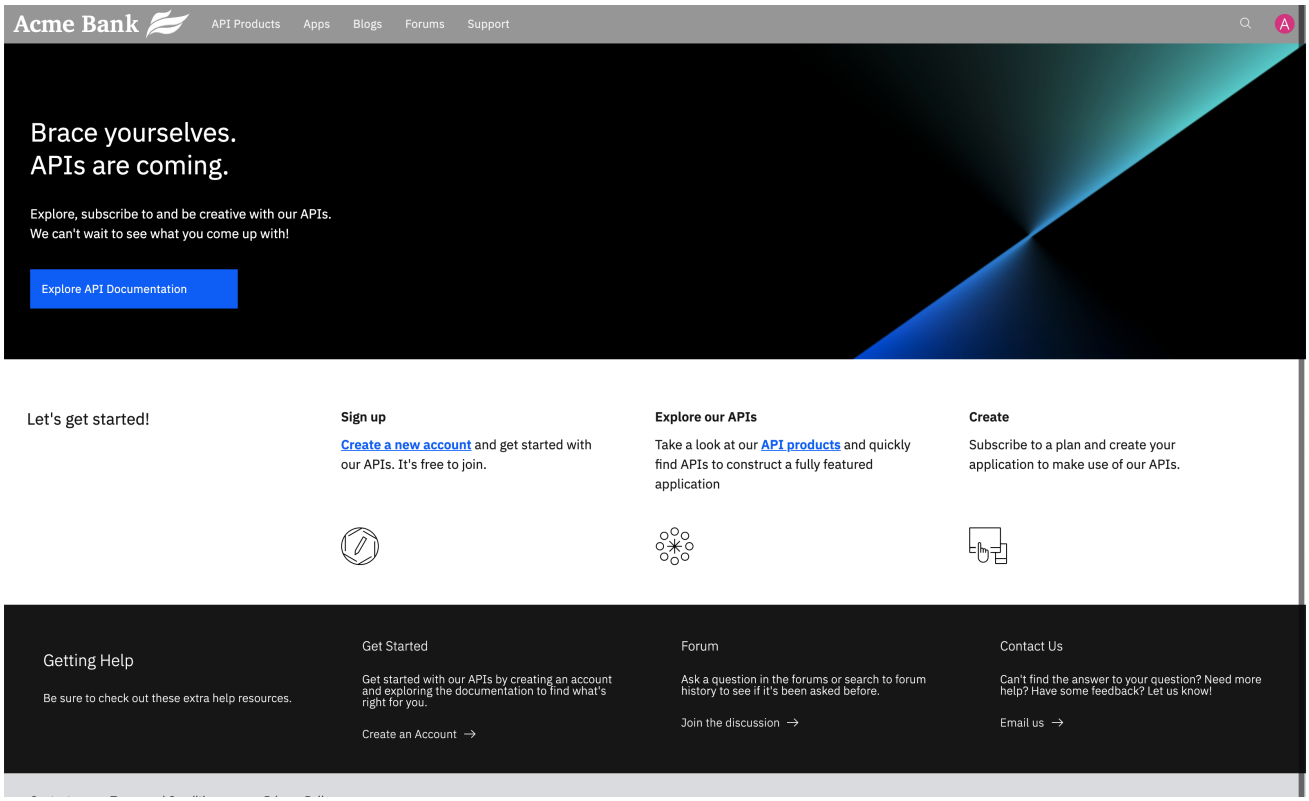
```
footer.footer ul.nav > li > a {
color: #454A4C;
}
```



3. Save the overrides.css file.

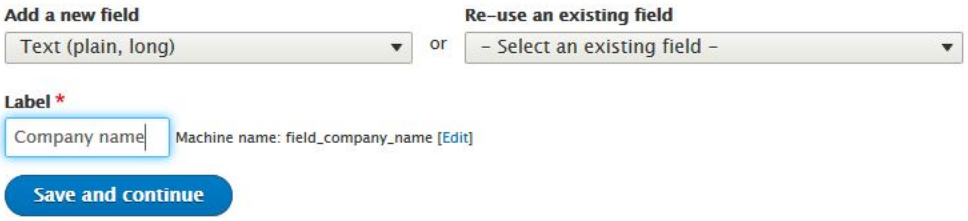
You can now install and enable your customized theme.

1. After you finish updating the overrides.css file, compress all the theme files back into the .zip **sub-theme** file that you downloaded originally.
2. In the Developer Portal, click Appearance > Install new theme. The **Install new theme** window is displayed.
3. In Upload a module or theme archive to install click Browse, and navigate to your newly updated compressed theme file.
4. Click Install to install the theme onto your site.
5. Click Enable newly added themes, and find your new theme in the list of **Disabled themes**. Click Enable and set as default to set your new custom **sub-theme** as the default theme for your site.
6. Return to the Developer Portal home page by clicking Back to site. You can now see your custom theme.



Add a field to an application content type to change the `site-config` on the staging Developer Portal

1. Log in to your staging Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Structure > Content types > Application > Manage fields.
4. Click + Add field.
5. In **`Add a new field`**, select Text (plain, long). Enter `Company name` as the label title.



6. Click Save and continue.
7. Leave the **`Allowed number of values`** set to 1 and click Save field settings.
8. Click Save field settings. You can now see your new field.

Use the toolkit CLI to export the custom themes and `site-config` on the staging Developer Portal

1. Log in to the management server.

   `apic login --server` ***`management_server`*** **`--realm`** ***`realm`*** **`--username`** ***`org_username`*** **`--password`** ***`org_password`***

   For example,

   `apic login -s api.stagingexample.com --realm provider/default-idp-2 --username ibm --password Qwerty123£`

   For more information about variable options, see Logging in to a management server.

2. Export your custom themes.
   The **custom-theme:create-export** command creates an export task against the portal of the specified **`catalog`** and **`org`**. The command then polls the status of the task until it has **`FINISHED`** and the artifacts are streamed back.
   Note: The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the commands **custom-theme:get-export-status** and **custom-theme:get-export** to get the status and potentially an artifact.

   `apic --mode portaladmin custom-theme:create-export --catalog` ***`name/id`*** **`--org`** ***`name/id`*** **`--server`** ***`management_server`***

- The theme .tgz is saved to the directory in which you ran the command.
- The saved .tgz has the format `custom_theme_createExport-20200217134637.tgz`.
- You can save your exports into your change control management system.

For example,

```
apic --mode portaladmin custom-theme:create-export --catalog dev --org ibm --server api.stagingexample.com
```

3. Export your site config.
   The **site-config:create-export** command creates an export task against the portal of the specified `catalog` and `org`, the command then polls the status of the task until it has `FINISHED` and the artifacts are streamed back.

```
apic --mode portaladmin site-config:create-export --catalog name/id --org name/id --server management_server
```

- The site config .tgz is saved to the directory in which you ran the command.
- The saved .tgz has the format `site_config_createExport-20200217134637.tgz`.
- You can save your exports into your change control management system.

For example,

```
apic --mode portaladmin site-config:create-export --catalog dev --org ibm --server api.stagingexample.com
```

Use the toolkit CLI to import the custom themes and `site-config` on the production Developer Portal

1. Log in to the management server.

```
apic login --server management_server --realm realm --username org_username --password org_password
```

For example,

```
apic login -s api.productionexample.com --realm provider/default-idp-2 --username ibm --password Qwerty123£
```

For more information about variable options, see Logging in to a management server.

2. Import your custom themes.
   The **custom-theme:create-import** command uses the supplied .tgz file to import the custom themes into the portal of the specified `catalog` and `org`. The command then polls the status of the task until the task has either `FINISHED` successfully, or failed because of an error.
   Note: The command continues to poll until the maximum polling time of 15 minutes is reached. At which point you can use the command **custom-theme:get-import-status** to get the status of the import.

```
apic --mode portaladmin custom-theme:create-import --catalog name/id --org name/id --server management_server
/PATH/TO/THEME/TGZ
```

For example,

```
apic --mode portaladmin custom-theme:create-import --catalog prod --org ibm --server api.productionexample.com
C:/users/example/desktop/custom_theme_createExport-20200217134637.tgz
```

3. Import your site config.
   The **site-config:create-import** command uses the supplied .tgz file to import the site config into the portal of the specified `catalog` and `org`. The command then polls the status of the task until the task has either `FINISHED` successfully, or failed because of an error.

```
apic --mode portaladmin site-config:create-import --catalog name/id --org name/id --server management_server
/PATH/TO/CONFIG/TGZ
```

For example,

```
apic --mode portaladmin site-config:create-import --catalog prod --org ibm --server api.productionexample.com
C:/users/example/desktop/site_config_createExport-20200217134637.tgz
```

What you did in this scenario

In this scenario, you created a theme and changed the configuration on your staging Developer Portal. Then, you used the toolkit CLI to replicate the changes on to your production Developer Portal.

You can now see the changes that you made on your production Developer Portal.

- **Exporting and importing custom themes and site configuration by using the Portal Admin API**
  The platform REST APIs for IBM® API Connect provide complete access to the capability of the platform. So, you can use the toolkit CLI to replicate changes from one Developer Portal instance to another. However, if the toolkit CLI was unavailable for some reason, you can use the Portal Admin API.

Exporting and importing custom themes and site configuration by using the Portal Admin API

The platform REST APIs for IBM® API Connect provide complete access to the capability of the platform. So, you can use the toolkit CLI to replicate changes from one Developer Portal instance to another. However, if the toolkit CLI was unavailable for some reason, you can use the Portal Admin API.

Before you begin

To complete this scenario, you must have a staging Developer Portal and a production Developer Portal enabled. You must have administrator access, or the permission `settings:manage`, to both to complete this scenario. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

Also, you must have downloaded and installed the toolkit. For more information, see Installing the toolkit.

About this scenario

In this scenario, you use the toolkit to obtain some authentication. Then, on your staging Developer Portal, you create a theme and make some configuration changes. Then, you use the Portal Admin API to replicate the changes on your production Developer Portal.

This scenario takes you through the following steps:

1. Obtaining the client ID and secret, and a bearer token.
2. Create a custom theme on the staging Developer Portal.
3. Add a field to an application content type to change the `site-config` on the staging Developer Portal.
4. Use the Portal Admin API to export the custom themes and `site-config` on the staging Developer Portal.
5. Use the Portal Admin API to import the custom themes and `site-config` on the production Developer Portal.

Obtaining the client ID and secret, and a bearer token.

From your toolkit:

1. Obtaining the client ID and secret.
   a. Obtain the list of administrator scoped providers to determine the correct realm to use:

      ```
      apic identity-providers:list --scope admin --server <management_server>
      ```

      For example,

      ```
      apic identity-providers:list --scope admin --server api.stagingexample.com
      ```

      Here is an example of some possible output:

      ```
      default-idp-1
      ```

   b. Run `apic login`, complete the details:

      ```
      apic login --server management_server --realm cloud_realm --username admin_username --password admin_password
      ```

      For example,

      ```
      apic login -s api.stagingexample.com --realm provider/default-idp-1 --username admin --password Qwerty123£
      ```

   c. Log in to cloud manager, and register an app. Make a new file locally and call it `app1.json`. Then, copy into it the following code snippet:

      ```
      {
        "name": "app1",
        "client_id": "app1id",
        "client_secret": "app1secret",
        "client_type": "toolkit"
      }
      ```

   d. Run the registration create command:

      ```
      apic registrations:create --server management_server app1.json
      ```

      For example,

      ```
      apic registrations:create --server api.stagingexample.com app1.json
      ```

      Here is an example of some possible output:

      ```
      app1    [state: enabled]   https://api.stagingexample.com/api/cloud/registrations/d2b7572f-3406-42a7-bdcc-
      85f177860df7
      ```

2. Now, you can get a bearer token from the provider org.
   a. To obtain a list of provider realms:

      ```
      apic identity-providers:list --scope provider --server management_server
      ```

      For example,

      ```
      apic identity-providers:list --scope provider --server api.stagingexample.com
      ```

      Here is an example of some possible output:

      ```
      default-idp-2
      ```

   b. Run `apic login`, complete the details:

      ```
      apic login --server management_server --realm provider_realm --username org_username --password org_password
      ```

      For example,

      ```
      apic login -s api.stagingexample.com --realm provider/default-idp-2 --username ibm --password Qwerty123£
      ```

   c. Create an HTTP request to obtain an access token:

      ```
      curl -k -X POST -d '{"username": "org_username", "password": "org_password", "realm": "provider/default-idp-2",
      "client_id": "app_id", "client_secret": "app_secret", "grant_type": "password"}' -H 'Content-Type: application/json'
      -H 'Accept: application/json' https://management_server/api/token
      ```

      For example,

```
curl -k -X POST -d '{"username": "steve", "password": "T****8", "realm": "provider/default-idp-2", "client_id":
"app1id", "client_secret": "app1secret", "grant_type": "password"}' -H 'Content-Type: application/json' -H 'Accept:
application/json' https://api.stagingexample.com/api/token
```

Here is an example of some possible output:

```
{
    "access_token":
"eyJhbGciOiJSUzI1NiIsInR5cCI6IkpXVCIsImtpZCI6IjBDQkI2Mjg5MkU4QUNFNEIzNDZCQzcyNDMxMUY0QzE4NTU2MUE4NjkifQ.eyJqdGkiOiJlN

vKUgJwrB7Bk6X2N6Cm3_QvCQtMCgTevBmwIzE9SIQiOV2041uRj5O0E3NASfacJsWOS4AzSPOMjgxMnWHIgP98MsU0u8v1Hf1VEn1wtrCO7FLiU7DeKYE
a1-1EbqUB0sejwQoKvSYHMFwnh3K8Y97g2lbdjkAcSwVOk02FpUMIIz4aeInYqwlUdzqww",
    "token_type": "Bearer",
    "expires_in": 28800
}
```

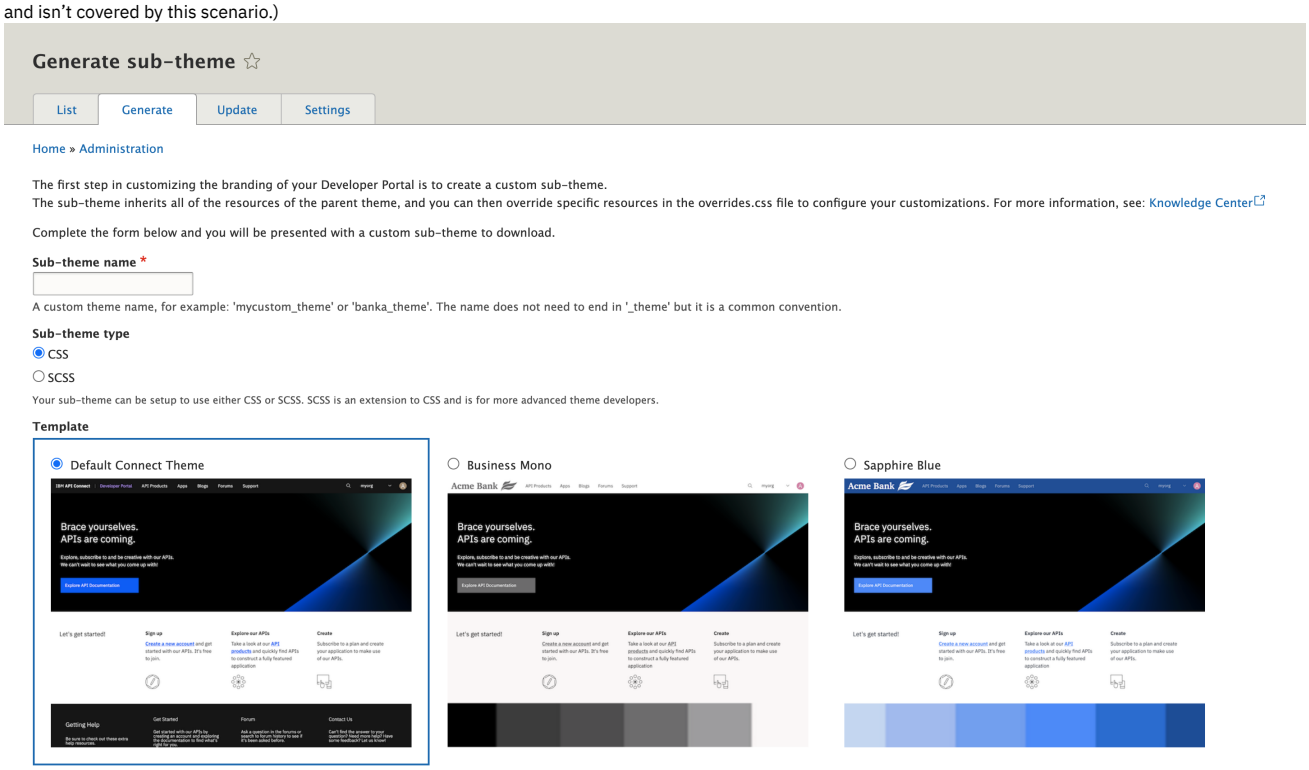
d. Save the token in a variable in your terminal:

```
TOKEN="<paste the access token that you obtained>"
```

You can now authenticate yourself when you invoke the toolkit CLI by using the REST API.

Create a custom theme on the staging Developer Portal

1. Log in to your staging Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Appearance > Generate sub-theme. The **Generate sub-theme** window is displayed.
4. Enter a Sub-theme name, and select CSS for the Sub-theme type. (If you prefer, you can select SCSS, but this extension to CSS is for advanced theme developers, and isn't covered by this scenario.)



5. Select the Default template to base your **sub-theme** on. You can create a **sub-theme** based on a color template. However, for this scenario you use the default connect_theme template.
6. Click Generate.
7. Download the generated **sub-theme** to a location of your choice, and extract all the files from the .zip file.

On your computer, navigate to the files that you extracted. Find the overrides.css file in here banka_theme/banka_theme/css/overrides.css. You can now customize the overrides.css file.

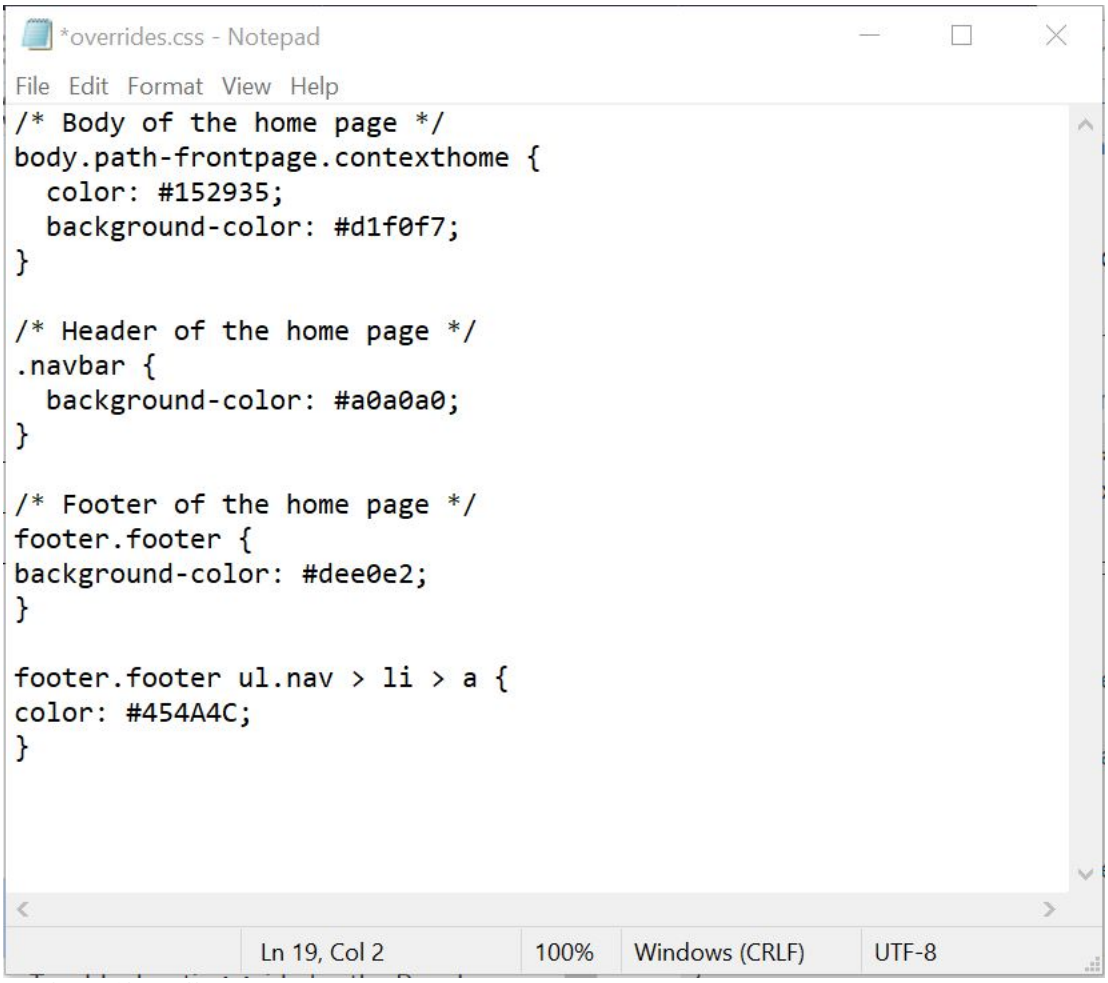
1. Open the overrides.css file in your chosen editor.
2. Customize your **sub-theme** by entering the following elements into the overrides.css file:

```
/* Body of the home page */
body.path-frontpage.contexthome {
  color: #152935;
  background-color: #d1f0f7;
}

/* Header of the home page */
.navbar {
  background-color: #a0a0a0;
}

/* Footer of the home page */
footer.footer {
background-color: #dee0e2;
}

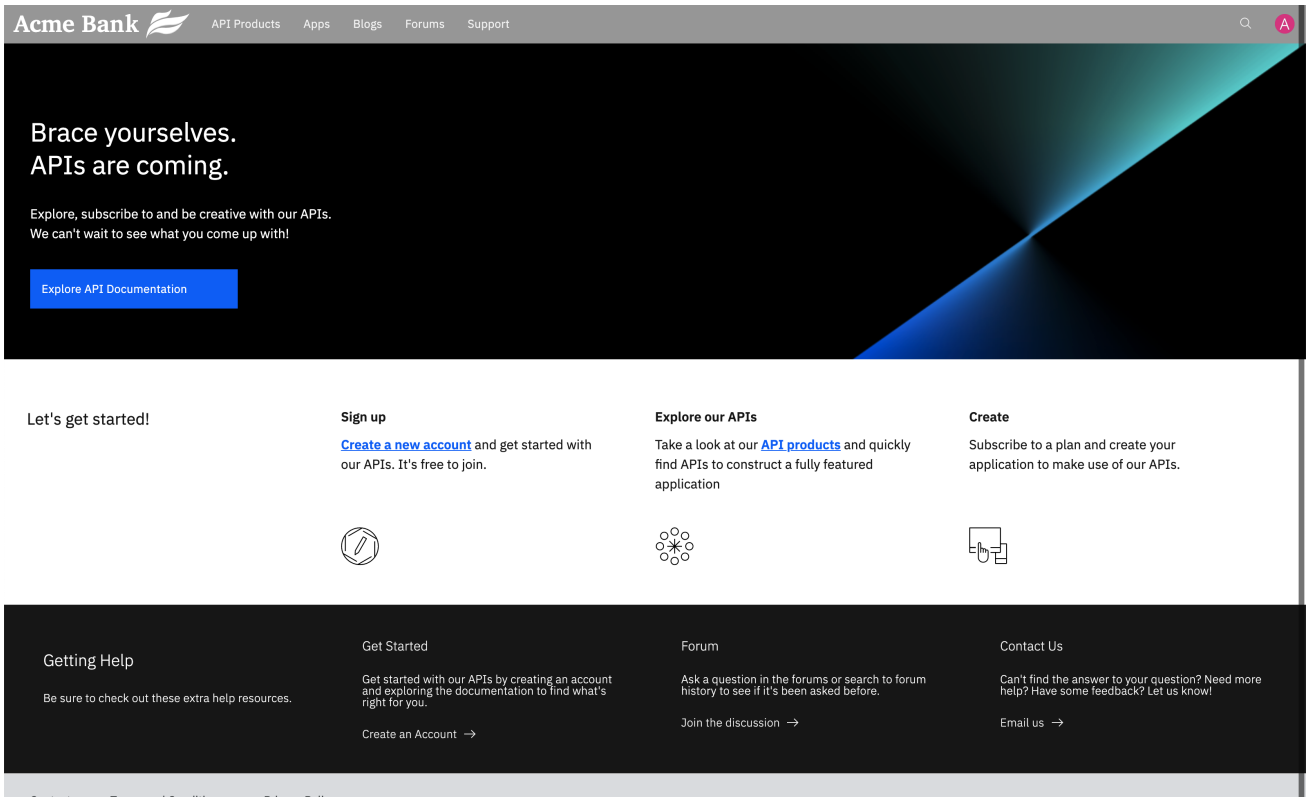
footer.footer ul.nav > li > a {
color: #454A4C;
}
```



3. Save the overrides.css file.

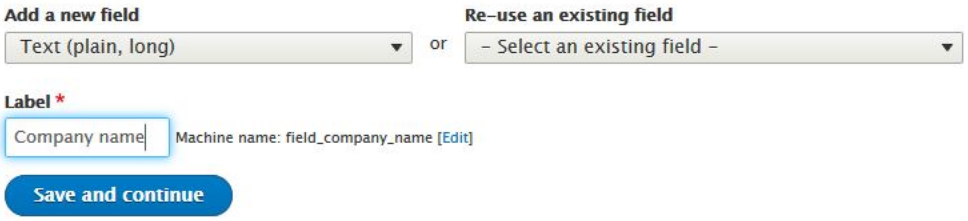
You can now install and enable your customized theme.

1. After you finish updating the overrides.css file, compress all the theme files back into the .zip **sub-theme** file that you downloaded originally.
2. In the Developer Portal, click Appearance > Install new theme. The **Install new theme** window is displayed.
3. In Upload a module or theme archive to install click Browse, and navigate to your newly updated compressed theme file.
4. Click Install to install the theme onto your site.
5. Click Enable newly added themes, and find your new theme in the list of **Disabled themes**. Click Enable and set as default to set your new custom **sub-theme** as the default theme for your site.
6. Return to the Developer Portal home page by clicking Back to site. You can now see your custom theme.



Add a field to an application content type to change the `site-config` on the staging Developer Portal

1. Log in to your staging Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Structure > Content types > Application > Manage fields.
4. Click + Add field.
5. In **`Add a new field`**, select Text (plain, long). Enter `Company name` as the label title.



6. Click Save and continue.
7. Leave the **`Allowed number of values`** set to 1 and click Save field settings.
8. Click Save field settings. You can now see your new field.

Use the Portal Admin API to export the custom themes and `site-config` on the staging Developer Portal

1. Export your custom themes.
   a. Create the export job by using this command:

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/yaml'
'https://<management_server>/portal/catalogs/<org>/<catalog>/custom-theme/export'
```

   For example,

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/yaml'
'https://api.stagingexample.com/portal/catalogs/ibm/staging/custom-theme/export'
```

   Here is an example of some possible output:

```
status: 201
message:
  stdout: >-
    /catalogs/75cfdc05-e818-408e-8ce6-fd3fd61c8756/f09602a2-a0e4-40dc-a82d-d1af326ad092/custom-
```

```
theme/export/85z2m39znojolv2s/status
  stderr: ''
errors: []
```

b. You can check the status of the export job by invoking the `/status` endpoint.

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN"  -H 'Accept: application/yaml'
'https://<management_server>/portal/catalogs/<org>/<catalog>/custom-theme/export/<task_id>/status'
```

For example,

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/yaml'
'https://api.stagingexample.com/portal/catalogs/ibm/staging/custom-theme/export/85z2m39znojolv2s/status'
```

Here is an example of some possible output:

```
{
  "status": 200,
  "message": {
    "stdout": "The status of this task is: FINISHED and the artifact can now be streamed"
  },
  "errors": []
}
```

c. You can now download the custom theme file onto your machine.

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/octet-stream'
'https://<management_server>/portal/catalogs/<org>/<catalog>/custom-theme/export/<task_id>' -o <theme_name>
```

For example,

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/octet-stream'
'https://api.stagingexample.com/portal/catalogs/ibm/staging/custom-theme/export/85z2m39znojolv2s' -o mytheme.tgz
```

Note: When you use the `curl` commands to download files, if you do not specify an output with `-o`, it incorrectly prints the output as binary onto the terminal screen.

d. On Mac and Linux® machines, you can verify that you have a valid theme export `.tgz` file by invoking the tar `t --list` argument.

```
tar -tvf <theme_name>
```

For example,

```
tar -tvf mytheme.tgz
```

Here is an example of some possible output:

```
drwxrwsr-x  0 aegir  aegir       0  9 Jun 13:40 ./
drwxr-sr-x  0 aegir  aegir       0  9 Jun 13:40 emerald_theme_css/
-rw-r--r--  0 aegir  aegir       7  9 Jun 13:40 emerald_theme_css/emerald_theme_css.theme
-rw-r--r--  0 aegir  aegir   29224  9 Jun 13:40 emerald_theme_css/screenshot.png
-rw-r--r--  0 aegir  aegir     442  9 Jun 13:40 emerald_theme_css/composer.json
-rw-r--r--  0 aegir  aegir     599  9 Jun 13:40 emerald_theme_css/emerald_theme_css.info.yml
-rw-r--r--  0 aegir  aegir    1150  9 Jun 13:40 emerald_theme_css/favicon.ico
-rw-r--r--  0 aegir  aegir    5932  9 Jun 13:40 emerald_theme_css/logo.svg
-rw-r--r--  0 aegir  aegir      61  9 Jun 13:40 emerald_theme_css/emerald_theme_css.libraries.yml
drwxr-sr-x  0 aegir  aegir       0  9 Jun 13:40 emerald_theme_css/css/
-rw-r--r--  0 aegir  aegir   47249  9 Jun 13:40 emerald_theme_css/css/overrides.css
```

2. Export your site config.

a. Create the export job by using this command:

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json'
'https://<management_server>/portal/catalogs/<org>/<catalog>/config/export'
```

For example,

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json'
'https://api.stagingexample.com/portal/catalogs/ibm/staging/config/export'
```

Here is an example of some possible output:

```
{
    "status": 201,
    "message": {
        "stdout": "/catalogs/75cfdc05-e818-408e-8ce6-fd3fd61c8756/f09602a2-a0e4-40dc-a82d-
d1af326ad092/config/export/5cy1gk55ciiwn190/status",
        "stderr": ""
    },
    "errors": []
}
```

b. You can check the status of the export job by invoking the `/status` endpoint.

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json'
'https://<management_server>/portal/catalogs/<org>/<catalog>/config/export/<task_id>/status'
```

For example,

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json'
'https://api.stagingexample.com/portal/catalogs/ibm/staging/config/export/5cy1gk55ciiwn190/status'
```

Here is an example of some possible output:

```
{
  "status": 200,
  "message": {
    "stdout": "The status of this task is: FINISHED and the artifact can now be streamed"
  },
  "errors": []
}
```

c. You can now download the site-config file onto your machine.

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/octet-stream'
'https://<management_server>/portal/catalogs/<org>/<catalog>/config/export/<task_id>' -o <config_name>
```

For example,

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/octet-stream'
'https://api.stagingexample.com/portal/catalogs/ibm/staging/config/export/5cy1gk55ciiwn190' -o myconfig.tgz
```

Note: When you use the `curl` commands to download files, if you do not specify an output with `-o`, it incorrectly prints the output as binary onto the terminal screen.

d. On Mac and Linux machines, you can verify that you have a valid theme export `.tgz` file by invoking the tar `t --list` argument. The `head -n 10` option returns the first 10 lines of the result.

```
tar -tvf <config_name> | head -n 10
```

For example,

```
tar -tvf myconfig.tgz | head -n 10
```

Here is an example of some possible output, which should be a list of yaml files:

```
-rw-rw-r--  0 aegir  aegir 393 11 Jun 15:54 block.block.bartik_page_title.yml
-rw-rw-r--  0 aegir  aegir 577 11 Jun 15:54 filter.format.plain_text.yml
-rw-rw-r--  0 aegir  aegir 256 11 Jun 15:54 captcha.captcha_point.consumerorg_invite_user_form.yml
-rw-rw-r--  0 aegir  aegir 741 11 Jun 15:54 block.block.emerald_theme_css_account_menu.yml
-rw-rw-r--  0 aegir  aegir 488 11 Jun 15:54 field.field.node.application.apic_hostname.yml
-rw-rw-r--  0 aegir  aegir 460 11 Jun 15:54 field.storage.node.apic_catalog_id.yml
-rw-rw-r--  0 aegir  aegir 545 11 Jun 15:54 field.field.user.user.apic_user_registry_url.yml
-rw-rw-r--  0 aegir  aegir 427 11 Jun 15:54 language.content_settings.shortcut.default.yml
-rw-rw-r--  0 aegir  aegir 460 11 Jun 15:54 field.storage.node.api_soapversion.yml
-rw-rw-r--  0 aegir  aegir 148 11 Jun 15:54 captcha.captcha_point.node_product_form.yml
```

Use the Portal Admin API to import the custom themes and `site-config` on the production Developer Portal

Note: If you are importing your custom theme onto a new server, then before you continue, follow step 1 of this tutorial to obtain a new token to authenticate with your second server. If you are using the same server, and are importing the theme into a new catalog, then the current TOKEN remains valid for the rest of the steps.
Note: You must import the custom theme before you import the site config. This order is because the site config contains information about the default theme, and so your custom theme must exist on the portal when the site config is imported so that it can be set upon import.

1. Import your custom themes.
   a. On the production catalog, import the custom theme onto the production catalog `prod` by using this command:

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/yaml' -H 'Content-Type:
application/octet-stream' 'https://<management_server>/portal/catalogs/<org>/<catalog>/custom-theme/import' --data-
binary @<path_to_theme_file>
```

For example,

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/yaml' -H 'Content-Type:
application/octet-stream' 'https://api.productionexample.com/portal/catalogs/ibm/prod/custom-theme/import' --data-
binary @/Users/steve/PortaladminCLI/mytheme.tgz
```

Here is an example of some possible output:

```
status: 201
message:
  stdout: >-
    /catalogs/75cfdc05-e818-408e-8ce6-fd3fd61c8756/56f3d4ca-8be2-48f7-8f91-3d654c2b91f2/custom-
theme/import/vtscpucj08i0hfo6/status
  stderr: ''
errors: []
```

   b. You can check the status of the import job by invoking the `/status` endpoint on this command:

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/yaml'
'https://<management_server>/portal/catalogs/<org>/<catalog>/custom-theme/import/<task_id>/status'
```

For example,

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/yaml'
'https://api.productionexample.com/portal/catalogs/ibm/prod/custom-theme/import/vtscpucj08i0hfo6/status'
```

Here is an example of some possible output:

```
{
  "status": 200,
  "message": {
    "stdout": "2020-06-09 13:00:59: CLI task (custom_theme:import) starting.\n2020-06-09 13:00:59: Importing custom
theme emerald_theme_css\n2020-06-09 13:01:18: CLI task (custom_theme:import) completed successfully.",
    "stderr": ""
  },
```

```
  "errors": []
}
```

2. Import your site config.
   a. Import the existing site-config onto the production catalog `prod` by using this command:

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json' -H 'Content-Type:
application/octet-stream' 'https://<management_server>/portal/catalogs/<org>/<catalog>/config/import' --data-binary
@<path_to_config_import>
```

   For example,

```
curl -k -X 'POST' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json' -H 'Content-Type:
application/octet-stream' 'https://api.productionexample.com/portal/catalogs/ibm/prod/config/import' --data-binary
@/Users/steve/PortaladminCLI/myconfig.tgz
```

   Here is an example of some possible output:

```
{
  "status": 201,
  "message": {
      "stdout": "/catalogs/75cfdc05-e818-408e-8ce6-fd3fd61c8756/56f3d4ca-8be2-48f7-8f91-
3d654c2b91f2/config/import/kzyozx4v5sfa8la5/status",
      "stderr": ""
  },
  "errors": []
}
```

   b. You can check the status of the config import job by invoking the `/status` endpoint:

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json'
'https://<management_server>/portal/catalogs/<org>/<catalog>/config/import/<task_id>/status'
```

   For example,

```
curl -k -X 'GET' -H "Authorization: bearer $TOKEN" -H 'Accept: application/json'
'https://api.productionexample.com/portal/catalogs/ibm/prod/config/import/kzyozx4v5sfa8la5/status'
```

   Here is an example of some possible output:

```
{
  "status": 200,
  "message": {
      "stdout": "2020-06-11 15:42:55: CLI task (site_config:import) starting.\n2020-06-11 15:43:29: CLI task
(site_config:import) completed successfully.",
      "stderr": ""
  },
  "errors": []
}
```

What you did in this scenario

In this scenario, you created a theme and changed the configuration on your staging Developer Portal. Then, you used the Portal Admin API to replicate the changes on to your production Developer Portal.

You can now see the changes that you made on your production Developer Portal.

How to enable and disable maintenance mode on your Developer Portal

You can use the Portal commands in the toolkit CLI to enable and disable maintenance mode on your Developer Portal site.

Before you begin

To complete this Portal CLI scenario, you must have a Developer Portal enabled. You must also have administrator access to this site, and the permission **`settings:manage`**, to complete this scenario. The tutorial Creating the Portal explains how to enable the portal if you haven't enabled it already.

For more information about using the toolkit CLI with the Developer Portal, see Getting started with the Portal CLI commands.

Important: Maintenance mode is designed for short-term site maintenance; it is not meant for long-term usage. While a site is in maintenance mode, the database is not updated with new content from API Manager.

About this scenario

In this scenario, you use the toolkit CLI to enable, and then disable, maintenance mode on your Developer Portal site.

The scenario takes you through the following steps:

1. Log in to the management server as a Provider organization by using the toolkit CLI
2. Use the toolkit CLI to enable maintenance mode
3. Use the toolkit CLI to disable maintenance mode

Log in to the management server as a Provider organization by using the toolkit CLI

- Log in to the toolkit CLI as a Provider org:

```
apic login --server management_server --realm provider/identity_provider --username provider_username --password
provider_password
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm
```

For example,

```
apic identity-providers:list --scope provider --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: provider/default-idp-2
  - title: Corporate LDAP user registry
    realm: provider/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details of the `apic login` command, see Logging in to a management server.

Use the toolkit CLI to enable maintenance mode

- Run the following command to enable maintenance mode on your Developer Portal:

```
apic --mode portaladmin drupal-state:set --server management_server --org orgid/name --catalog catalogid/name --state_key
system.maintenance_mode  --input_format integer --state_value 1
```

Where:
  - *`management_server`* is the endpoint URL of your management server (required).
  - *`catalogid/name`* is the ID or name of the catalog that your site belongs to (required).
  - *`orgid/name`* is the ID or name of the provider organization that the catalog belongs to (required).
  - `--state_key` is the name of the state key (required). Must be set to `system.maintenance_mode`.
  - `--input_format` is the input format of the value of the state key. Must be set to `integer` for configuring the maintenance mode.
  - `--state_value` is the value to assign to the state key (required). Set to `1` to enable maintenance mode.

For example, to enable maintenance mode for a Developer Portal in the `myOrg` organization, and in the `dev` catalog:

```
apic --mode portaladmin drupal-state:set --server my.management.server.com --org myOrg --catalog dev --state_key
system.maintenance_mode  --input_format integer --state_value 1
Successfully set state system.maintenance_mode to the value of 1.
```

The Developer Portal site is now inaccessible to everyone apart from an administrator. All other users who enter the site URL will see a maintenance message set by the administrator.

Use the toolkit CLI to disable maintenance mode

- Run the following command to disable maintenance mode on your Developer Portal:

```
apic --mode portaladmin drupal-state:set --server management_server --org orgid/name --catalog catalogid/name --state_key
system.maintenance_mode  --input_format integer --state_value 0
```

Where:
  - *`management_server`* is the endpoint URL of your management server (required).
  - *`catalogid/name`* is the ID or name of the catalog that your site belongs to (required).
  - *`orgid/name`* is the ID or name of the provider organization that the catalog belongs to (required).
  - `--state_key` is the name of the state key (required). Must be set to `system.maintenance_mode`.
  - `--input_format` is the input format of the value of the state key. Must be set to `integer` for configuring the maintenance mode.
  - `--state_value` is the value to assign to the state key (required). Set to `0` to disable maintenance mode.

For example, to disable maintenance mode for a Developer Portal in the `myOrg` organization, and in the `dev` catalog:

```
apic --mode portaladmin drupal-state:set --server my.management.server.com --org myOrg --catalog dev --state_key
system.maintenance_mode  --input_format integer --state_value 0
Successfully set state system.maintenance_mode to the value of 0.
```

Your Developer Portal site is now accessible to everyone again.

What you did in this scenario

In this scenario, you used the toolkit CLI to put your Developer Portal site into maintenance mode, and to turn maintenance mode off again.

Related tasks

- Toggling the site in and out of maintenance mode

Troubleshooting guide for the Developer Portal

Use this guide to help you diagnose and resolve Developer Portal issues in IBM® API Connect. For example, why is the Developer Portal not connecting to the Management server, why is my site not created, and why can't I log in?

About

The following sections provide advice about how to diagnose and resolve some common problems. This information can help you to identify whether a specific IBM API Connect Version 10 component is failing, whether it's an environmental problem, and whether you should raise a support request. Some advice includes reviewing specific log files so you can narrow down the source of the problem.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

Why is the Developer Portal not connecting to the Management server?

Problems with connecting to the Management server can be due to connectivity or TLS issues. You should check the following areas:

- Can the Management server actually reach the Developer Portal?
- Is SSL passthrough enabled or required on any load balancer that sits between the Management server and the Developer Portal? For more information, see JWT security on Kubernetes and OpenShift, JWT security on OVA.

If you need to open a Service Request, include the following information:

- The IBM API Connect MustGather Information.
- Details of the date and time that the connection attempts were made.

Why is my Developer Portal site not being created?

If you are having problems creating a site, you should take the following actions to help diagnose the issue:

1. Tail the nginx container log to confirm that the site create request reached the portal, for example:

   ```
   kubectl logs rb93d4fb118-apic-portal-nginx-7c7b464fb6-vvx5m
   ```

2. Look in the container log for a site create request, for example:

   ```
   POST /portal-service-configuration-create HTTP/1.1" 200
   ```

   a. If you don't find a site create request in the log, then the create request is not reaching the Developer Portal from the Management. Follow the instructions in Why is the Developer Portal not connecting to the Management server? to diagnose the connectivity issues.
   b. If a site create request is in the log, then further diagnostics can be found in the admin pod log, for example:

   ```
   kubectl logs -f rb93d4fb118-apic-portal-www-p4bhj -c admin
   ```

   Look in the admin pod log for messages that refer to `create_site`, as well as the name of the site.

Why can't I register a user?

If you are having problems registering a user, take the following actions to help diagnose the issue:

- The user registration links in the emails are only valid for 24 hours, so check that the system time is correctly configured across all of the pods.
- If emails aren't being received, check that the email server is correctly configured; see Configuring an email server for notifications. Also, if possible, check whether other emails such as publish approval alerts or password reset emails are being received.

If you need to open a Service Request, please take the following steps:

1. Note which user registry type is being used, such as Local User Registry (LUR), or LDAP user registry.
2. Enable the debug REST server and method trace in the Developer Portal UI. Click Configuration > Development > IBM Development on the administrator dashboard. Then select the Enable method entry / exit trace and Enable API Manager REST interface debug check boxes. Click Save configuration.
3. Re-create the issue, making a note of the time, the username, and any messages displayed on the screen.
4. Gather the web container log for the www pod, for example:

   ```
   kubectl logs portal-apic-portal-www-zhqxf web > web.log
   ```

5. Gather all of the Management server logs and the logs for the user registry type that is being used; see IBM API Connect MustGather Information for details.

Why can't I login?

If users are having problems with logging in to the Developer Portal, please take the following steps before opening a Service Request:

1. Note which user registry type is being used, such as Local User Registry (LUR), or LDAP user registry.
2. Enable the debug REST server and method trace in the Developer Portal UI. Click Configuration > Development > IBM Development on the administrator dashboard. Then select the Enable method entry / exit trace and Enable API Manager REST interface debug check boxes. Click Save configuration.
3. Recreate the issue, making a note of the time, the username, and any messages printed to the screen.
4. Gather the web container log for the www pod, for example:

```
kubectl logs portal-apic-portal-www-zhqxf web > web.log
```

5. Gather all of the Management server logs and the logs for the user registry type that is being used; see IBM API Connect MustGather Information for details.

Why are changes to Products not appearing in the Developer Portal?

To determine whether the problem is with the Portal server (either the nginx or the www pod), the Management server, or the network, please make the following diagnostic checks.

Portal nginx pod

1. Tail the nginx pod log on the Portal, for example:

   ```
   kubectl logs -f portal-apic-portal-nginx-866c977c4c-n9gbf
   ```

2. Make a publish request to the Catalog (note that the request must be a Publish or Retire operation, not a Stage operation).
3. In the log being tailed, see if the following message appears:

   ```
   ...POST /event-create...
   ```

If the POST message appears in the nginx log, then the publish webhook that was sent from the Management server did arrive at the Portal. If there is an error message in place of a POST message, then the problem is likely to be with the nginx pod. If there is no message at all, then it's likely that the webhook from the Management server is not reaching the Portal and there is a network problem.

Portal www pod

1. Tail the www pod admin container log on the Portal, for example:

   ```
   kubectl logs -f portal-apic-portal-www-dtbzw -c admin
   ```

2. Make a publish request to the Catalog (note that the request must be a Publish or Retire operation, not a Stage operation).
3. In the log being tailed, see if the following message appears:

   ```
   Received webhook event 'product_lifecycle' for catalog
   ```

If no such message appears, it suggests that the webhook is either not arriving at the Portal, or not getting beyond the nginx pod (see the previous section Portal nginx pod). Any errors that the admin container has in processing the webhook will be logged in the www pod admin container log.

Management server apim pod

1. Tail the apim pod log on the Management server, for example:

   ```
   kubectl logs -f apiconnect-apim-v2-86b464c4f5-4cx6r
   ```

2. Make a publish request to the Catalog (note that the request must be a Publish or Retire operation, not a Stage operation).
3. In the log being tailed, see if there any error messages.

Search for the word 'sending', you should see the message `webhook: sending successful` if the webhook is sent, or error messages indicating why if the webhook is not sent.

Why am I having problems with my Developer Portal user interface?

If you are having user interface (UI) problems, make the following checks:

- Try clearing the cache from your browser, try using private browsing, and try using different browsers - see whether there are any differences in behavior.
- Check your browser window size and screen resolution, and try increasing and decreasing the settings.
- Investigate the browser developer tools console and network tabs, as they might provide some diagnostic clues.
- Try clearing the Drupal caches from within the Developer Portal; see Clearing the server caches for details.

If you need to open a Service Request, along with the IBM API Connect MustGather Information logs, also include details of the time and date when the problem was reproduced. In addition, an export of the browser developer tools console and network output would be helpful.

Why am I having problems with my Kubernetes system?

Kubernetes provides a DNS server as one of the pods in the kube-system namespace (unless you have configured your Kubernetes setup differently), and sometimes this DNS server can silently fail. When the Portal www or db pods restart, they check that their own hostname and IP address is in the service that is defined for the pod. If the DNS server is down, this check fails. An indication that the DNS server is down is seeing the following log lines printed endlessly in the admin or db containers:

```
[     admin stdout] 2cd141dc:2cd141dc:2cd141dc 2018-10-08 07:27:54: service-ready:
[     admin stdout] 2cd141dc:2cd141dc:2cd141dc 2018-10-08 07:27:54: service-all:
[     admin stdout] 2cd141dc:2cd141dc:2cd141dc 2018-10-08 07:27:54: Waiting for sleep in service all check. Pid(s) 352  Seconds
24
[     admin stdout] 2cd141dc:2cd141dc:2cd141dc 2018-10-08 07:27:59: Finished waiting for sleep in service all check. Pid(s)
352  Seconds 29
[     admin stdout] 2cd141dc:2cd141dc:2cd141dc 2018-10-08 07:28:01: WARNING 5: r4c09b98d02-apic-portal-admin-all doesn't
include this pod or r4c09b98d02-apic-portal-director does. Checking again in 5 seconds.
```

To fix this problem, delete the DNS pod in the kube-system namespace to force it to restart, for example:

```
kubectl -n kube-system delete pod kube-dns-b76db4f7f-n4lvt
```

Where *kube-dns-b76db4f7f-n4lvt* is the full name of the DNS pod.
Note: To find out the full name of the DNS pod in your Kubernetes system, run the following command:

```
kubectl -n kube-system get pods
```

This command will return data like the following example:

```
$ kubectl -n kube-system get pods
NAME READY STATUS RESTARTS AGE
default-http-backend-5bccfbdc8-mjnnb 1/1 Running 0 4d
etcd-minikube 1/1 Running 0 4d
kube-addon-manager-minikube 1/1 Running 0 4d
kube-apiserver-minikube 1/1 Running 0 4d
kube-controller-manager-minikube 1/1 Running 0 4d
kube-dns-6f4fd4bdf-7zslq 3/3 Running 0 4d
kube-proxy-mddmj 1/1 Running 0 4d
kube-registry-proxy-99qml 1/1 Running 0 4d
kube-registry-v0-zt8pv 1/1 Running 0 4d
kube-scheduler-minikube 1/1 Running 0 4d
kubernetes-dashboard-77d8b98585-dczcs 1/1 Running 0 4d
nginx-ingress-controller-57bcfc76d6-z775d 1/1 Running 0 4d
storage-provisioner 1/1 Running 0 4d
tiller-deploy-587df449fb-bpwhq 1/1 Running 0 4d
```

Why am I having problems with my Developer Portal backup?

If you attempt to back up your portal system or site:

```
apicup subsys exec <portal_subsystem> backup-system|backup-site|backup-all
```

You might encounter the following message:

```
curl: (6) Could not resolve host: apic-portal-apic-portal-director
```

This error is the result of a failure of the SFTP backup file transfer to the backup system, caused by missing authentication with the portal node. To correct this error, `ssh` from the backup system to the portal node, and accept the authentication key when prompted:

1. Enter the portal-www admin container, for example:

   ```
   kubectl exec -it WWW_POD_NAME -c admin bash
   ```

2. `ssh` to your backup server and accept any authentication prompts, for example:

   ```
   ssh BACKUP_SERVER_HOSTNAME
   ```

When you have successfully authenticated with your backup server, you can close the session. This action needs to be done only once. Portal backups can then run without any issues.

Why am I having problems installing Drupal 8 based custom modules or sub-themes into the Drupal 9 based Developer Portal?

From IBM API Connect 10.0.3.0, the Developer Portal is based on the Drupal 9 content management system. If you want to install Drupal 8 custom modules or sub-themes into the Drupal 9 based Developer Portal, you must ensure that they are compatible with Drupal 9, including any custom code that they contain, and not using any deprecated APIs, for example. There are tools available for checking your custom code, such as drupal_check on GitHub, which checks Drupal code for deprecations.

For example, any Developer Portal sites that contain modules or sub-themes that don't contain a Drupal 9 version declaration will fail to upgrade, and errors like the following output will be seen in the `admin` logs:

```
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: Checking theme: emeraldgreen
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '' found for emeraldgreen
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: Checking theme: rubyred
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '8.x' found for rubyred
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: Found themes incompatible with
Drupal 9: emeraldgreen rubyred
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:34:49: check_d9_compat: ERROR: /tmp/restore_site.355ec8 is NOT
Drupal 9 compatible
...
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: Checking module: custom_mod_1
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '' found for custom_mod_1
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: Checking module: custom_mod_2
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Incompatible
core_version_requirement '8.x' found for custom_mod_2
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: Found modules incompatible with
Drupal 9: emeraldgreen rubyred
[     queue stdout] 14834 729319:355ec8:a7d29c 2021-09-04 20:44:49: check_d9_compat: ERROR: site1.com is NOT Drupal 9
compatible
```

To fix version compatibility errors, all custom modules and sub-themes should declare a `core_version_requirement` key in their *.info.yml file that indicates Drupal 9 compatibility. For example:

```
name: Example module
type: module
description: Purely an example
core: 8.x
core_version_requirement: '^8 || ^9'
package: Example module

# Information added by Drupal.org packaging script on 2020-05-31
version: '8.x-1.3'
project: 'example_module'
datestamp: 1590905415
```

This example specifies that the module is compatible with all versions of Drupal 8 and 9. For more information, see Let Drupal know about your module with an .info.yml file on the drupal.org website.

If you have a backup of a site that you need to restore and are getting the version compatibility error, but the module or theme *.info.yml file cannot be changed easily, then you can modify the site backup.

To modify the site backup, extract the it, edit the relevant files inside it, and then tar the backup file again. Note that this procedure will overwrite the original backup file, so ensure that you keep a separate copy of the original file before you start the extraction. For example:

1. `mkdir /tmp/backup`
2. `cd /tmp/backup`
3. `tar xfz path_to_backup.tar.gz`
4. Edit the custom module and theme files to make them Drupal 9 compatible, and add the correct `core_version_requirement` setting.
5. `rm -f path_to_backup.tar.gz`
6. `tar cfz path_to_backup.tar.gz`
7. `cd /`
8. `rm -rf /tmp/backup`

Migrating your Developer Portal from Version 5 to Version 10

Guidance on how to migrate a Developer Portal site from IBM® API Connect Version 5, to IBM API Connect Version 10.

In IBM API Connect Version 10 the Developer Portal is based on the open source Drupal 9 content management software, which enables more advanced, flexible, and powerful customization capabilities. However, in IBM API Connect Version 5 the Developer Portal is based on Drupal 7. The migration tooling in Version 10 will create a new Developer Portal site, and migrate all of the associated APIs and Products, user information, and subscriptions over. However, customizations such as modules and themes cannot be automatically migrated, as the Drupal 9 baseline is very different to Drupal 7. For more information about upgrading from a Drupal 7 baseline to a Drupal 9 baseline, see Upgrading Drupal in the Drupal documentation.

The following sections take you through the migration process for the Developer Portal, and provide guidance on how to manually migrate any specific customizations to Drupal 9.

- Migration process for the Developer Portal
- Portal Delegated User Registries
- Custom themes
- Custom modules
- Custom Rules
- Custom content types and fields
- Advanced theme development
- Changing the page layout
- Changing the front page
- Features no longer available in the Developer Portal

Note: The ability to migrate is available only from IBM API Connect Version 5.0.8.7 onwards. If your deployment is at an earlier version, you must upgrade before migrating. See Upgrading your API Connect cloud for information about upgrading in Version 5. For more information about the supported versions for migration, see Migrating a Version 5 deployment.
Note: In Version 5, it was possible, though not recommended, to modify files on the Developer Portal server directly. For more information, see Developer Portal best practices for administrators. However, in Version 10, you should not make any system changes. Do not use the **kubectl exec** command to make changes inside the Developer Portal containers, and on OVA deployments do not make any modifications on the Developer Portal VM. Make any customizations on your Developer Portal by using the UI or CLI. Do not run a **kubectl exec** command on any Developer Portal containers unless asked to by IBM.

Migration process for the Developer Portal

The migration process for the Developer Portal migrates all of the following information to Version 10 for each site in your cluster:

- User information (if Portal Delegated User Registry is enabled, the process is slightly different; see Portal Delegated User Registries).
- Products and APIs.
- Consumer organizations.
- Applications.
- Subscriptions.

For information about the main migration process, see Migrating a Version 5 deployment.

Portal Delegated User Registries

In IBM API Connect Version 5, if Portal Delegated User Registry (PDUR) was selected for a Catalog, the user management was delegated from the management server to the Developer Portal. The site administrator within the Portal then performed the configuration of user registries, and the management server recorded that the delegation had taken place, and stored a record of the users that existed in the Catalog. However, the management service maintained no information about the configuration of the specific registries or how users mapped to them. In IBM API Connect Version 10, all user registry configuration takes place in the management server, and PDUR is no longer needed. Therefore, to migrate the PDUR user registries and users from v5 to v10, configuration information must be gathered from both the management server and the Portal node.

If your IBM API Connect Version 5 Developer Portal uses Portal Delegated User Registry (PDUR), you must first export the user information that is stored in the Version 5 Developer Portal local database. This user information can then be fed into the migration tooling so that the correct user registries can be created in the newer version of API Connect.

For more information about how to export the PDUR information from v5, see Exporting Portal Delegated User Registry user information. For more information about the migration process in v10, see Migration steps with PDUR.

Custom themes

If your Version 5 Developer Portal is using a custom theme, you'll need to create the custom theme again for the Drupal 9 baseline. Start by creating a sub-theme of the new Version 10 Developer Portal site by using the theme generator, and then manually customize the sub-theme to your specifications for Drupal 9 by using Cascading Style Sheets (CSS), or Sass CSS (SCSS). Note that using SCSS in your theme makes it far simpler to change colors. We've also added a color template theme generator, which means you can quickly generate a base color theme on which to build your customized site branding. For more information, see Creating a sub-theme.

Note, directly editing the API Connect theme is not permitted or supported, as edited versions of these files are overwritten when a fix pack or iFix is installed.

Other useful resources:

- Tutorial: Creating a custom theme for the Developer Portal - takes you through how to use the theme generator, customize a theme, and install a custom theme.
- Changing the site logo - how to change your site logo.
- Changing the shortcut icon - how to change the shortcut icon (favicon).
- Creating sub-themes - Drupal documentation about creating a sub-themes.
- Theming differences between Drupal 6, 7 & 8 - Drupal documentation about theming differences.

Custom modules

If your Version 5 Developer Portal is using any custom modules, you will need to create these custom modules again for the Drupal 9 baseline. For more information on writing custom modules, see Extend.

Other useful resources:

- Creating custom modules - Drupal documentation about creating custom modules.
- Getting started creating custom modules - Drupal documentation giving background information and prerequisites needed for custom module development.
- Understanding hooks - Drupal documentations about hooks.
- Drupal API hooks - Drupal documentation about the hooks that are available.

Custom Rules

If your Version 5 Developer Portal is using any custom Rules, you will need to create them as custom modules for the Drupal 9 baseline. You cannot export the Drupal 7 Rules, and then import them into the Drupal 9 baseline, as the events and actions are implemented in a different way. For more information about custom modules, see the Custom modules section.

Custom content types and fields

If your Version 5 Developer Portal is using any custom content, you will need to create this content again for the Drupal 9 baseline.

For information about creating custom content types, see the following topics:

- Creating content types
- Adding fields to content types
- Adding custom fields to user records

Advanced theme development

If your Version 5 Developer Portal is using modified content type templates, you must create these templates again for the Drupal 9 baseline. In Drupal 9 the templates are Twig files that define the actual HTML output for a particular piece of content. You can override a Twig template by copying the original template into the templates folder of your custom sub-theme, and then editing the template to your specification. The Developer Portal then uses your template in preference to the original one. For more information, see Applying a modified content type template, and Creating a sub-theme. You can also follow a guided example of how to create a new theme, see Tutorial: Creating a custom theme for the Developer Portal.

Note:
Modifying Twig templates allows very fine-grained control over the structure of pages. However, it also means you might miss new features and defect fixes that are made to the original templates, as your Developer Portal is using your overrides instead of the originals. So, if you override a template, it is your responsibility to check the templates in the latest API Connect Version 10 releases, and to ensure that any equivalent changes that are needed to your overrides to maintain functional equivalence are made.

Changing the page layout

If your Version 5 Developer Portal is using a different page layout, you will need to create this layout again for the Drupal 9 baseline. The page layout is defined by configuring which blocks appear in which regions. Blocks are controlled by using the Structure > Block layout options on the Developer Portal administrator dashboard.

For information about how to configure the page layout, see Adding and changing the blocks displayed on Developer Portal pages.

Changing the front page

If your Version 5 Developer Portal is using a different front page, you will need to create this front page again for the Drupal 9 baseline. The front page is configured from the Structure > Pages options on the Developer Portal administrator dashboard.

For information about how to configure the front page, see Configuring the front page, and Adding custom pages.

Further options that you might want to consider when designing your front page include:

- Change the banner block content or image: Changing the front page banner block.
- Display featured API Products by creating a featured content block: Changing the front page Featured Content block.
- Create custom blocks with your own HTML content: Adding and changing the blocks displayed on Developer Portal pages.
- Set up the social block to include your organization Twitter feed: Integrating Twitter data into the social block.

Features no longer available in the Developer Portal

The following features that are available in IBM API Connect Version 5, are not available in IBM API Connect Version 10:

- Security questions - these can now be created inside an OpenID Connect provider.
- Two-factor authentication - this can now be performed inside an OpenID Connect provider.
- Support tickets - no Drupal 9 equivalent module is currently available.

Guidelines on upgrading your Developer Portal from Drupal 9 to Drupal 10

Information about the upgrade of the Developer Portal from Drupal 9 to Drupal 10.

The Developer Portal is based on the open source Drupal content management system. From API Connect 10.0.5.3, Drupal 9 is upgrading to Drupal 10, which also requires PHP 8.1. All existing Developer Portal sites will be upgraded to, and all new sites will be based on Drupal 10. Therefore, all modules and themes on your Developer Portal site must be compatible with Drupal 10 and PHP 8.1. The core modules and themes are automatically made compatible as part of the upgrade. However, if your Developer Portal sites contain any custom modules or themes, either written in-house or contributed by the Drupal community, it is your responsibility to ensure that they are Drupal 10 and PHP 8.1 compatible before the upgrade.

See the following topics for more detailed information about how to prepare your Developer Portal sites for the upgrade to Drupal 10.

- How to find your custom modules and themes on your Developer Portal.
- Prepare your Developer Portal for the update for Drupal 10.
- Upgrade your custom modules to be Drupal 10 and PHP 8.1 compliant.

Upgrading from older versions of API Connect v10

If you are upgrading to 10.0.5.3 from 10.0.1.7 or earlier, or coming from 10.0.5.0 or earlier, your Developer Portal sites will first be upgraded to Drupal 9.5 and then to Drupal 10. This is because upgrading to Drupal 10 requires your site to be on at least Drupal 9.4.4.

Note that if you are in the category where a double upgrade occurs, your Developer Portal sites are going to take double the time to upgrade compared to your normal experience, because upgrading from Drupal 9 to Drupal 10 is a major upgrade. Therefore, when you are planning your maintenance window for upgrading to 10.0.5.3, you need to be aware of the extended time frame. To shorten your upgrade window, consider removing the Developer Portal sites that you do not need.

How to find your custom modules and themes on your Developer Portal

Guidance on how to find what custom modules and themes you installed on your Developer Portal.

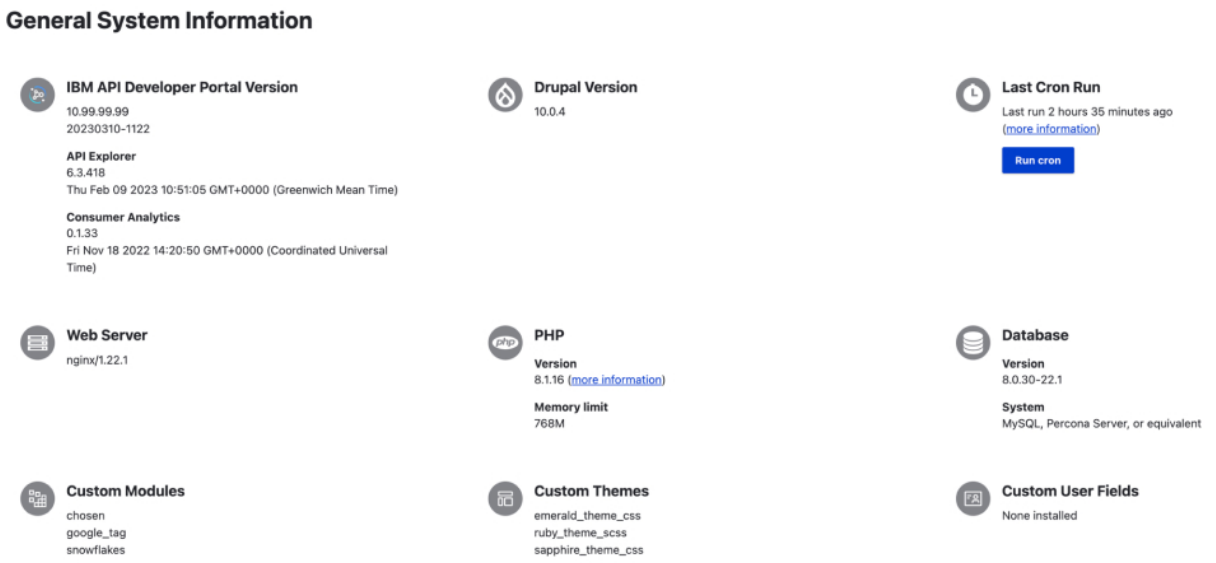
The Developer Portal within API Connect comes with built-in modules and themes that you can use to customize your site. You can extend your customizations by installing external custom modules and themes, or even ones written by yourself. If you are unsure which custom modules and themes are installed on your Developer Portal, you can use one of the following methods to find out.

1. Method 1. Developer Portal admin status report (recommended)
2. Method 2. Developer Portal toolkit CLI
3. Method 3. Developer Portal container

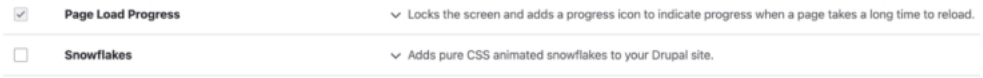
Method 1. Developer Portal admin status report (recommended)

1. Log in to your Developer Portal as the administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Click Manage > Reports > Status report.

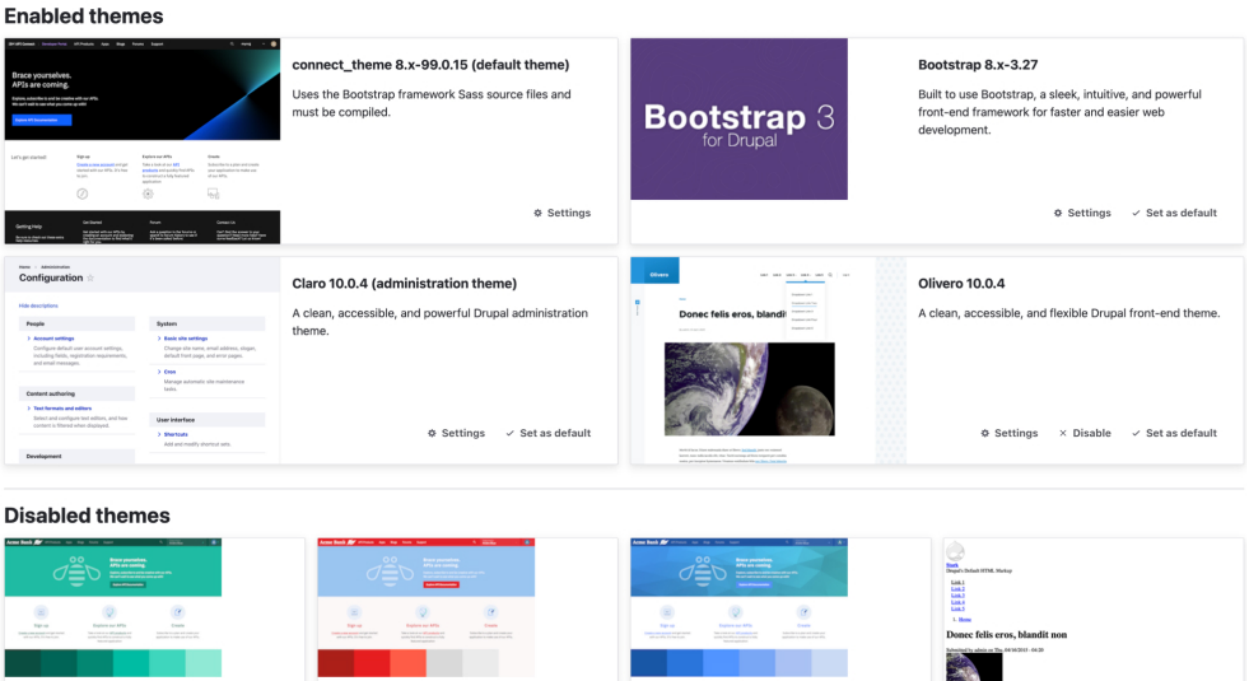
- The custom modules and themes are listed in the Custom Modules and Custom Themes sections at the end of the page.



4. Check which of your custom modules are enabled or disabled by clicking Manage > Extend.
   - The enabled modules are displayed with a selected checkbox, and the disabled ones are not selected as seen in the following example.



5. Check which of your custom themes are enabled or disabled by clicking Manage > Appearance.
   - Find your themes that are categorized into Enabled and Disabled sections.



Method 2. Developer Portal toolkit CLI

Use the **`custom-module:create-export`** and **`custom-theme:create-export`** commands to extract your custom modules and themes into a compressed file.

The compressed file includes a list of your custom modules and themes. For more information about using the Developer Portal toolkit CLI and all the other features it offers, see Overview of the Developer Portal command-line tool.

1. To list your modules, implement the following steps:
   a. Log in to the Developer Portal toolkit CLI as a provider organization.
   b. Run the following **`custom-module:create-export`** command against the Developer Portal.

```
apic custom-module:create-export --mode portaladmin [flags]
```

   c. Specify the appropriate **`org`** and **`catalog`** name.

For example,

```
❯ SERVER=myserver.ibm.com
❯ apic login -s $SERVER -r provider/default-idp-2 -u steve
```

```
Warning: Using default toolkit credentials.
Enter your API Connect credentials
Password?
Logged into myserver.ibm.com successfully

❯ apic -s $SERVER -m portaladmin custom-module:create-export -o ibm -c api-connect-catalog-1
201 CREATED - Task ID: x8jupowmktkf8f2r

Incoming project saved to custom_module_createExport-20230322143819.tgz
```

After the command has run, extract your compressed export to see the modules inside. Or use **tar** directly as shown in the following example.

```
❯ tar --exclude='*/*' -tvf custom_module_createExport-20230322143819.tgz
drwxr-sr-x aegir/aegir       0 2023-03-22 12:05 chosen/
drwxr-sr-x aegir/aegir       0 2023-03-22 12:05 google_tag/
drwxr-sr-x aegir/aegir       0 2023-03-22 12:05 snowflakes/
```

2. To check which one of your custom modules are enabled or disabled, implement the following steps:
   a. Run the following **modules:list** command to print the list of installed modules.

   ```
   apic modules:list --mode portaladmin [flags]
   ```

   b. Search for your custom modules from the result.
   For example,

   ```
   ❯ SERVER=myserver.ibm.com
   ❯ apic -s $SERVER -m portaladmin modules:list -o ibm -c api-connect-catalog-1 --no-core
   .
   .
   .
   chosen:
     package: 'User interface'
     display_name: 'Chosen (chosen)'
     status: Disabled
     version: 3.0.5
   google_tag:
     package: Statistics
     display_name: 'Google Tag Manager (google_tag)'
     status: Enabled
     version: 8.x-1.6
   snowflakes:
     package: 'User interface'
     display_name: 'Snowflakes (snowflakes)'
     status: Enabled
     version: 2.0.1
   .
   .
   ```

3. To list your custom themes, implement the following steps:
   a. Log in to the Developer Portal toolkit CLI as a provider organization.
   b. Run the following **custom-theme:create-export** command against the Developer Portal.

   ```
   apic custom-theme:create-export --mode portaladmin [flags]
   ```

   c. Specify the appropriate **org** and **catalog** name.
   For example,

   ```
   ❯ SERVER=myserver.ibm.com
   ❯ apic login -s $SERVER -r provider/default-idp-2 -u steve
   Warning: Using default toolkit credentials.
   Enter your API Connect credentials
   Password?
   Logged into api.fyre-ci-136264-master.fyre.ibm.com successfully

   ❯ apic -s $SERVER -m portaladmin custom-theme:create-export -o ibm -c api-connect-catalog-1
   201 CREATED - Task ID: oh595vuywxsz3526

   Response Code - 202:

   Message(s) -
   The status of this task is: QUEUED

   Response Code - 200:

   Message(s) -
   The status of this task is: FINISHED and the artifact can now be streamed

   Saving File (Large files may take a while)...
   Incoming project saved to custom_theme_createExport-20230322143856.tgz
   ```

   After the command has run, extract your compressed export to see the themes inside. Or use **tar** to view the contents directly as shown in the following example.

```
❯ tar --exclude='*/*' -tvf custom_theme_createExport-20230322143856.tgz
drwxr-sr-x aegir/aegir       0 2023-03-22 14:36 emerald_theme_css/
drwxr-sr-x aegir/aegir       0 2023-03-22 14:36 ruby_theme_scss/
drwxr-sr-x aegir/aegir       0 2023-03-22 14:36 sapphire_theme_css/
```

4. To check which of your custom themes are enabled or disabled, implement the following steps:
   a. Run the following **themes:list** command to print the list of installed themes.

   ```
   apic themes:list --mode portaladmin [flags]
   ```

   b. Search for your custom themes from the result.
   For example,

   ```
   ❯ SERVER=myserver.ibm.com
   ❯ apic -s $SERVER -m portaladmin themes:list -o ibm -c api-connect-catalog-1 --no-core
   bootstrap:
     package: Bootstrap
     display_name: 'Bootstrap (bootstrap)'
     status: Enabled
     version: 8.x-3.27
   .
   .
   .
   emerald_theme_css:
     package: Bootstrap
     display_name: 'emerald_theme_css (emerald_theme_css)'
     status: Disabled
     version: null
   ruby_theme_scss:
     package: Bootstrap
     display_name: 'ruby_theme_scss (ruby_theme_scss)'
     status: Disabled
     version: null
   sapphire_theme_css:
     package: Bootstrap
     display_name: 'sapphire_theme_css (sapphire_theme_css)'
     status: Disabled
     version: null
   ```

Method 3. Developer Portal container

If you are unable to access the Developer Portal settings or the Developer Portal toolkit CLI, check the Developer Portal container running within your Kubernetes or Red Hat OpenShift environment.

Note: You need access to the Developer Portal Kubernetes pods to be able to perform these steps.

1. Use **kubectl** or **oc** for Red Hat OpenShift environment to obtain a shell to the Developer Portal running container.

   Your Developer Portal sites are located within the **portal-www** pod in the **admin** container within the namespace that your Developer Portal subsystem is deployed to as seen in the following example.

   ```
   ❯ kubectl get pods -n apic | grep www
   portal-014179b4-www-0     2/2     Running     0          8d

   ❯ kubectl exec -n apic -it portal-014179b4-www-0 -c admin -- bash
   bash-4.4$
   ```

2. After you access the container, use the command **list_sites -a** to obtain the site alias for your Developer Portal. For example,

   ```
   bash-4.4$ list_sites -a
   daae4642-b1e2-4fd8-a5a7-77a68ed812ef.944dce4f-bbad-41ce-b166-aa2c9f8c4b17 => ibm.api-connect-catalog-1.portal.fyre-ci-
   136264-master.fyre.ibm.com (INSTALLED)
   daae4642-b1e2-4fd8-a5a7-77a68ed812ef.c560c004-852d-42c3-ae4e-797144a857af => ibm.api-connect-catalog-2.portal.fyre-ci-
   136264-master.fyre.ibm.com (INSTALLED)
   ```

   The Developer Portal **portal.fyre-ci-136264-master.fyre.ibm.com/ibm/api-connect-catalog-1** has the site alias **ibm.api-connect-catalog-1.portal.fyre-ci-136264-master.fyre.ibm.com**.

3. After you identify the Developer Portal that you want to look at, use the alias string within a **find** command to list your modules and themes, as shown in the following example.

   ```
   bash-4.4$ find /web/platforms/devportal*/sites/myserver.ibm.com/modules -mindepth 1 -maxdepth 1 -type d -exec basename {}
   \;
   chosen
   google_tag
   snowflake

   bash-4.4$ find /web/platforms/devportal*/sites/ibm.api-connect-catalog-1.portal.fyre-ci-136264-master.fyre.ibm.com/themes
   -mindepth 1 -maxdepth 1 -type d -exec basename {} \;
   emerald_theme_css
   ruby_theme_scss
   sapphire_theme_css
   ```

4. To check which of your custom modules and themes are enabled or disabled, implement the following sub-steps:
   a. Use the **drush** command-line tool within the container to print the list of installed modules and themes for your Developer Portal.
   b. Then, use the site alias that you obtained earlier to run the following **drush** command and find your custom modules and themes.

   ```
   bash-4.4$ drush @myserver.ibm.com pml --no-core
   Running: drush -y @daae4642-b1e2-4fd8-a5a7-77a68ed812ef-944dce4f-bbad-41ce-b166-aa2c9f8c4b17 pml --no-core
    -------------------------------- ------------------------------------------------------------------------------------------
   - ---------- ----------------
     Package                        Name
   ```

```
Status     Version
 ---------------------------------- ----------------------------------------------------------------------------------------------------
- ---------- ----------------
  User                              Account Field Split (account_field_split)
Enabled
  Access control                    ACL (acl)
Enabled
  .
  .
  .
  User interface                    Chosen (chosen)
Disabled   3.0.5
  Statistics                        Google Tag Manager (google_tag)
Disabled   8.x-1.6
  User interface                    Snowflakes (snowflakes)
Disabled   2.0.1

  Bootstrap                         Bootstrap (bootstrap)
Enabled    8.x-3.27
  Bootstrap                         connect_theme (connect_theme)
Enabled    8.x-99.0.15
  Bootstrap                         emerald_theme_css (emerald_theme_css)
Disabled
  Bootstrap                         ruby_theme_scss (ruby_theme_scss)
Disabled
  Bootstrap                         sapphire_theme_css (sapphire_theme_css)
Disabled
```

Results

By using one of the three methods discussed in the topic, you managed to successfully list the custom modules and themes installed on your Developer Portal. This also allowed you to see which of these custom modules and themes are enabled or disabled.

1. Method 1. Developer Portal admin status report (recommended)
2. Method 2. Developer Portal toolkit CLI
3. Method 3. Developer Portal container

Next steps

Ensure that you keep your custom modules and themes up to date, and remove deprecated code within your own written custom modules and themes. If you are not using a custom module or theme, consider removing it. This helps mitigate problems when you want to migrate or upgrade your Developer Portal.

Prepare your Developer Portal for the update for Drupal 10

Guidance on how to prepare your Developer Portal site from Drupal 9 to Drupal 10.

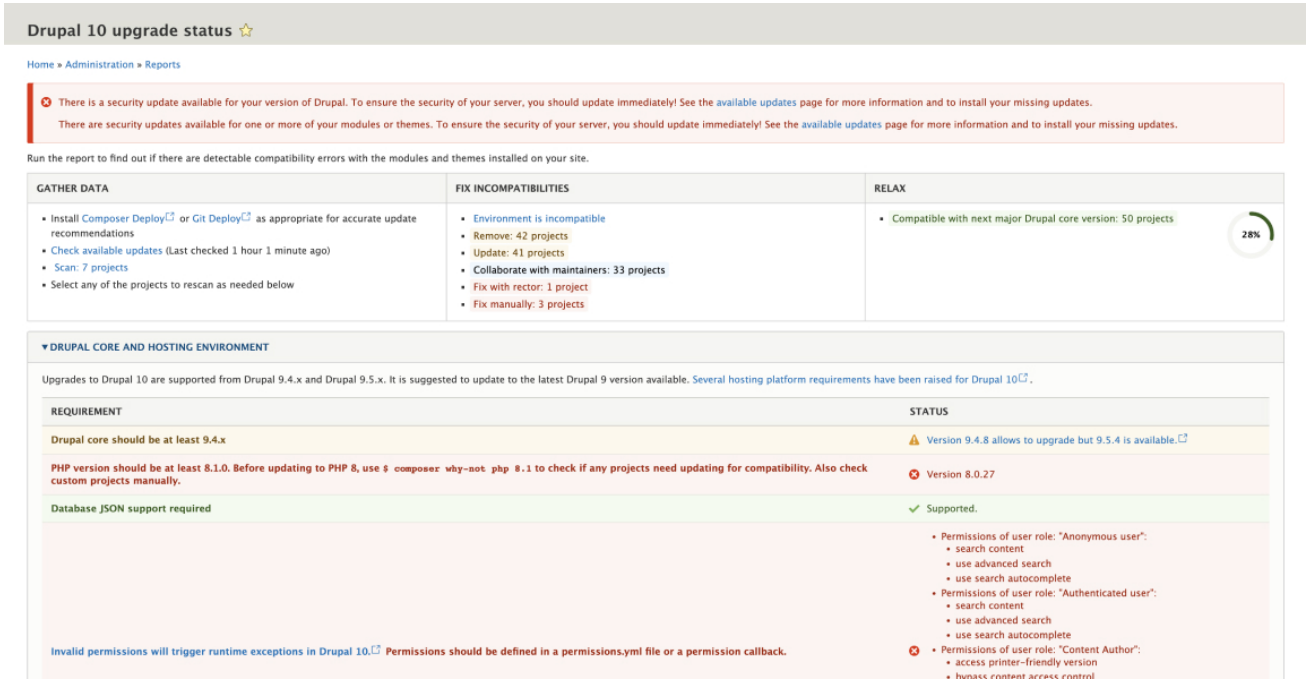
If your Developer Portal contains custom modules and themes that are written by yourself or downloaded from elsewhere, ensure that they are Drupal 10 compatible before you start the upgrade process. This action aims toward a seamless IBM® API Connect upgrade experience. To find more information about your modules and themes compatibility, download the Upgrade Status module available here.

Note: Before you start the upgrade, check the status of your modules and themes and if they are in use. Remove the ones that you do not use.
To learn more on how to prepare your Developer Portal for the Drupal 10 upgrade, check the following steps.

1. Installing the Upgrade Status module
2. Upgrading your module to be Drupal 10 compatible
3. Import your module into your Developer Portal
4. Verifying that your module is Drupal 10 compatible

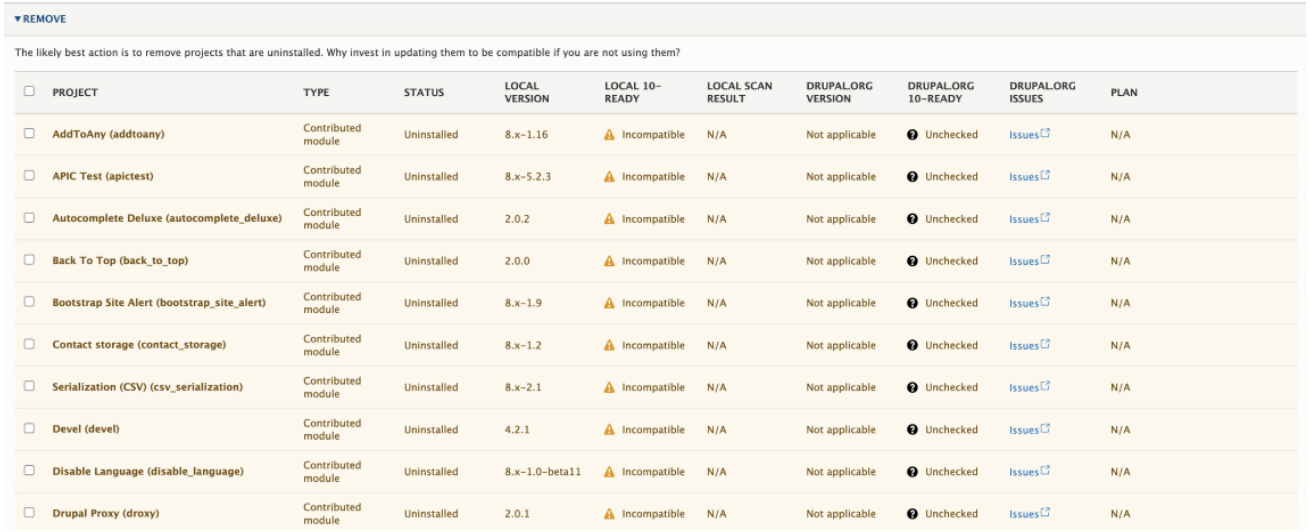
Installing the Upgrade Status module

1. Log in to your Developer Portal as the administrator.
2. If the administrator dashboard is not displayed, click Manage to display it.
3. Install the Upgrade Status module. For more information about how to install the Upgrade Status, see Installing custom modules.
4. When you finish your Upgrade Status installment, click Admin > Reports > Upgrade-status.

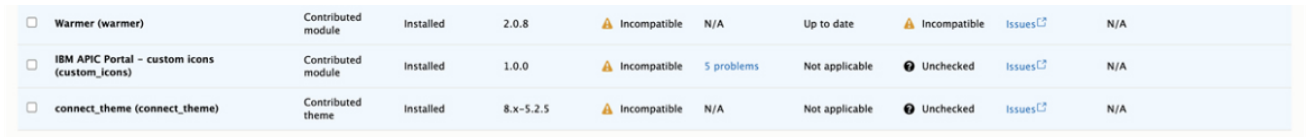


5. The DRUPAL CORE AND HOSTING ENVIRONMENT section can be ignored. This area is managed by IBM API Connect and gets resolved when you upgrade.
   Note: Your custom modules and themes must be PHP 8.1 compatible before you upgrade to Drupal 10, and you are responsible for doing the upgrade.
6. The list of projects further on the page are the ones that your Upgrade Status believes are not compatible with Drupal 10. These projects are categorized into sections, for example: REMOVE, UPDATE, COLLABORATE WITH MAINTAINERS.

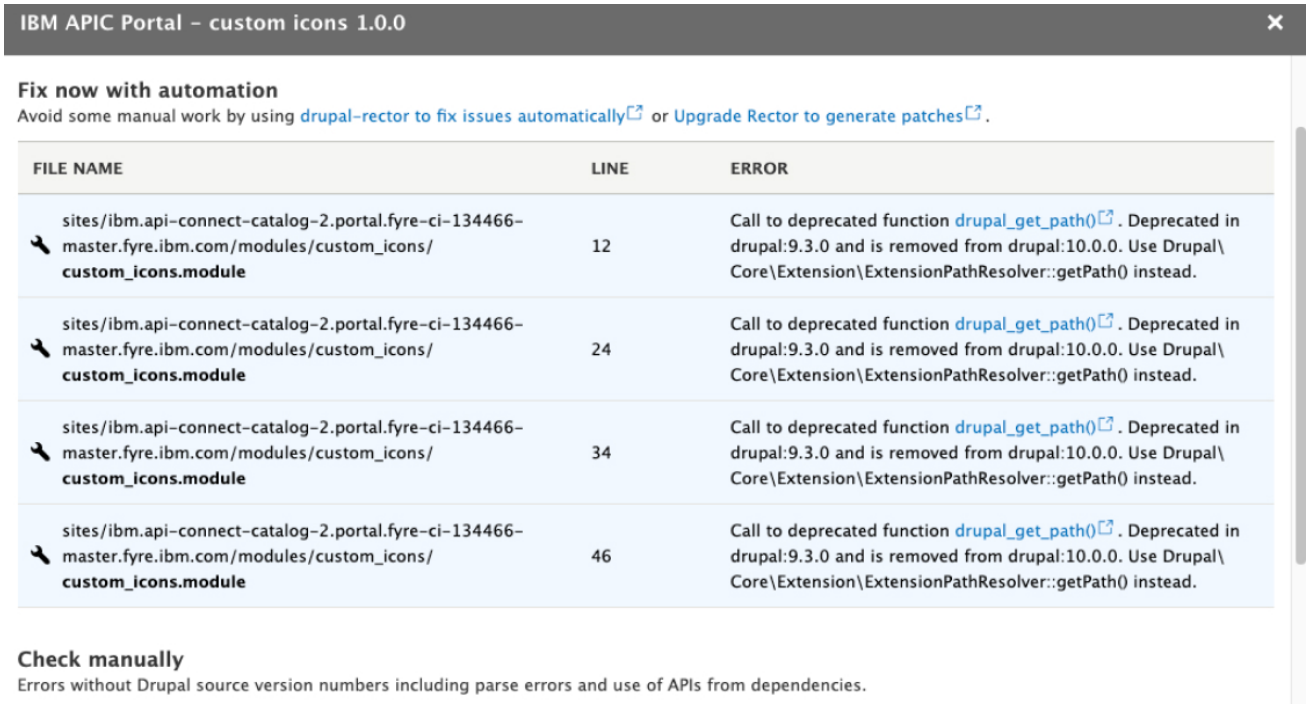
   When you upgrade IBM API Connect, the Drupal 10 compatibility is automatically given to the modules and themes that you have not created or installed manually.



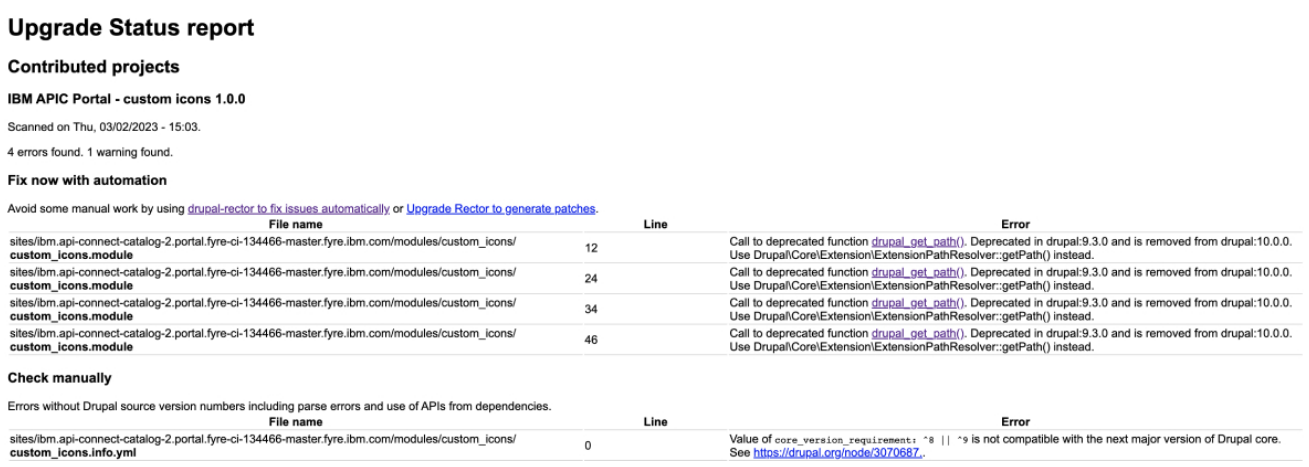
7. If you find your custom modules and themes there, you can scan them to reveal what changes are needed to make them Drupal 10 compatible. For instance, the following image demonstrates the process of scanning an installed custom module, named **`custom_icons`**.



8. Select your custom modules and themes and then click Scan selected. When completed, if your custom module or theme requires changes, you see a link on the row of them.
   Note: For Upgrade Status to identify all of the Drupal 10 compatibility issues in your custom modules and themes, you must have them enabled before scanning it.



9. Click export as HTML to see a clear view.



Upgrading your module to be Drupal 10 compatible

This module is an example of how you can read the report and fix your code to be compatible with Drupal 10.

1. The report shows that drupal_get_path() is deprecated, and the code must be changed to use the newer function **`getPath()`**. The following examples demonstrate the change to the newer extension type-specific version.

Before

```
 $name = preg_replace("/[^A-Za-z0-9]/", '', $returnValue);
  $returnValue = Url::fromUri('internal:/' . drupal_get_path('module', 'custom_icons') . '/images/' .
_custom_image_getRandomImageName($name))
    ->toString();
```

After

```
$name = preg_replace("/[^A-Za-z0-9]/", '', $returnValue);
  $iconPath = \Drupal::service('extension.list.module')->getPath('custom_icons');
  $returnValue = Url::fromUri('internal:/' . $iconPath . '/images/' . _custom_image_getRandomImageName($name))
    ->toString();
```

2. Add the new version into the **`info.yml`** file.
3. **`Drupal/Core/Extension/Extension List`** is still present in Drupal 8 and Drupal 9, so you can keep them, and add on support for Drupal 10.
4. Modify the version number when you make a new change to the module as seen in the following example.

Before

```
 name: 'IBM APIC Portal - custom icons'
type: module
description: 'IBM API Connect Developer Portal tutorial - Example of custom product icons'
package: 'Custom'
core_version_requirement: ^8 || ^9
```

```
version: 1.0.1
project: 'custom_icons'
dependencies:
  - ibm_apim

After

name: 'IBM APIC Portal - custom icons'
type: module
description: 'IBM API Connect Developer Portal tutorial - Example of custom product icons'
package: 'Custom'
core_version_requirement: ^8 || ^9 || ^10
version: 1.0.2
project: 'custom_icons'
dependencies:
  - ibm_apim
```

Import your module into your Developer Portal

Import the module by using the Developer Portal Toolkit CLI. For more information about how to use the Developer Portal CLI, see Getting started with the Portal CLI commands.

For example,

```
❯ apic login -s $SERVER -r provider/default-idp-2 -u steve
Warning: Using default toolkit credentials.
Enter your API Connect credentials
Password?
Logged into api.fyre-ci-134466-master.fyre.ibm.com successfully

❯ apic -s $SERVER -m portaladmin custom-module:create-import -o ibm -c api-connect-catalog-2 /tmp/custom_icons.zip
Loading File (Large files may take a while)...

201 CREATED - Task ID: wp5fhmm9l74pmkw1

Message(s) -
The status of this task is: QUEUED

Response Code - 202:

Message(s) -
The status of this task is: RUNNING

Response Code - 200:

Message(s) -
2023-02-27 14:39:38: CLI task (custom_module:import) starting.
2023-02-27 14:39:40: Deleting existing custom module /var/aegir/platforms/devportal-9.x-10.0.5.2-20230105-1720/sites/ibm.api-connect-catalog-2.portal.fyre-ci-134466-master.fyre.ibm.com/modules/custom_icons
2023-02-27 14:39:40: Importing custom module custom_icons
2023-02-27 14:40:25: CLI task (custom_module:import) completed successfully.
```

Alternatively, import your updated module by installing it again using the Developer Portal UI. For more information about how to install custom modules, see Installing custom modules.

Verifying that your module is Drupal 10 compatible

The updated module is now imported into the Developer Portal. Return to the Upgrade Status report page to rescan the module. When it becomes compatible with Drupal 10, it appears at the end of the page.

Workbench (workbench)	Contributed module	Installed	8.x-1.4	✓ Compatible	N/A	Up to date	✓ Compatible	Issues	N/A
IBM APIC Portal - custom icons (custom_icons)	Contributed module	Installed	1.0.0	✓ Compatible	No problems found	Not applicable	? Unchecked	Issues	N/A
Snowflakes (snowflakes)	Contributed module	Uninstalled	2.0.1	✓ Compatible	3 problems	Not applicable	? Unchecked	Issues	N/A

Results

You used the Upgrade Status module to identify and fix the Drupal 10 compatibility problems with your custom modules and themes. However, this process might not cover everything that you need to be ready for the upgrade to Drupal 10. Drupal 10 requires PHP 8.1, so you might need to change your custom modules and themes to support it. Remember to keep your custom modules and themes up to date, and to remove deprecated code within your own written custom modules and themes.

Upgrade your custom modules to be Drupal 10 and PHP 8.1 compliant

Guidance on how to upgrade your custom modules to be Drupal 10 and PHP 8.1 compliant.

The following sections provide examples of the most common updates that you might need to make. However, you must check the deprecation lists for Drupal and PHP to ensure that you cover all of the scenarios in your Developer Portal sites.

Notable changes the update brings

The following items are some of the key changes in Drupal 10.

- **`CKEditor4`** is removed and **`CKEditor5`** is now the default text editor.
- **`Claro`** is now the default theme for the Admin UI, which gives it a modern and refreshing look.
- Ensure that none of your custom modules depend on them as they will not be there after the upgrade.

  The following modules are uninstalled as they do not support Drupal 10:
  - ckeditor_media_embed
  - console
  - flood_unblock
  - message
  - message_notify
  - message_subscribe
  - video_embed_field
  - video_embed_html5
  - content_browser
  - entity_browser
  - entity_browser_enhanced
  - entity_embed
  - file_browser
  - editor_file
  - color
  - Unlimited_number
  - embed
  - ckeditor
  - quickedit
- The Drupal 10 upgrade comes with a major Symfony upgrade version. Drupal 9 used Symfony 4.4, and Drupal 10 now uses Symfony 6, so if you are using any Symfony ensure that they have not been deprecated. Symfony provides a guide at the following link https://symfony.com/doc/current/setup/upgrade_major.html.
- The default Drush version is now Drush 11. If you are writing Drush commands in your custom modules, you must ensure they are Drush 11 compatible. The following links provide examples on how you can achieve compatibility, https://www.specbee.com/blogs/writing-your-own-custom-drush-9-and-10-commands and https://www.drush.org/11.x/commands/.

PHP 8.1 deprecations

The following items are some of the key PHP 8.1 deprecations.

Passing null to non-nullable internal function parameters is deprecated
: There are multiple scenarios that require a fix with the possibility to pass a **`null`** to some PHP functions.
The following example is the most common PHP deprecation.
`Before:`

```
$redacted_url = $url;
if (strlen($redacted_url) > 0 && strpos($redacted_url, '/') !== 0) {
```

`After:`

```
$redacted_url = $url ?? '';
if (strlen($redacted_url) > 0 && strpos($redacted_url, '/') !== 0) {
```

Optional parameters specified before the required parameters
: Some functions in code have optional parameters before the required ones. However, in PHP 8.1, the required parameters come after the optional ones.

Improved type safety
: PHP 8.1 improves the type of safety, which can result in numerous warnings that might require changing functions and variable declarations.
The following example addresses the improved safety and the optional parameters before required parameters deprecations.
`Before:`

```
protected $id;

public function oldFunction($url = '', $data) {
  return $id;
}
```

`After:`

```

/**
 * Drupal entity ID
```

```
 *
 * @var string
 */
protected $id;

public function newFunction(someObject $data, string $url = ''): string {
  return $id;
}
```

Drupal 10 deprecations

The following items are some of the key PHP 8.1 deprecations.

Entity queries now require an `accessCheck`

If you have custom modules with entities, you must do an `accessCheck`. For more information about access checking, see https://www.drupal.org/node/3201242.
For example,
Before:

```
$query = \Drupal::entityQuery('node');
$query->condition('type', 'api');
$query->condition('status', 1);
$nids = $query->execute();
```

After:

```
$query = \Drupal::entityQuery('node');
$query->condition('type', 'api');
$query->condition('status', 1);
$nids = $query->accessCheck()->execute();
```

The `Once` function is removed from the jQuery library and added to its own core library

If you have any modules that use the `once`function in your JavaScript files, you need an update to pull in the new library. For more information about how to remove jQuery dependency, see https://www.drupal.org/node/3158256.
For more examples on how you might upgrade your code, see https://www.drupal.org/project/drupal/issues/3183149.
For example,
Before:

```
// ibm_apim.libraries.yml
validate_password:
  version: 1.x

// validate_password.js
(function($, Drupal, drupalSettings) {
  var $passwordInput = $(context).find('input.js-password-field').once('ibmApimValidatePassword');
})(jQuery, Drupal, drupalSettings);
```

After:

```
// ibm_apim.libraries.yml
validate_password:
  version: 1.x
  dependencies:
    - core/once

// validate_password.js
(function($, Drupal, drupalSettings, once) {
  var $passwordInput = $(once('ibmApimValidatePassword', context)).find('input.js-password-field');
})(jQuery, Drupal, drupalSettings, once);
```

The `app.root` and `site.path` services that are converted into container parameters

If you use the `app.root` and `site.path` services in your custom modules, you must ensure they are converted into container parameters.
For example,
Before:

```
 \Drupal::service('config.factory')
    ->getEditable('locale.settings')
    ->set('translation.use_source', 'local')
    ->set('translation.path', \Drupal::service('site.path') . '/translations')
    ->save();
```

After:

```
\Drupal::service('config.factory')
    ->getEditable('locale.settings')
    ->set('translation.use_source', 'local')
    ->set('translation.path', \Drupal::getContainer()->getParameter('site.path') . '/translations')
    ->save();
```

The parameters of some `Forms`are updated, so be aware if you are extending them.

If you are extending your `Forms`, note the parameters of some of them have changed. For more information about the updated parameters, see https://www.drupal.org/node/3251987.

Next steps

This topic covers the key upgrades you might need when upgrading your custom modules to be Drupal 10 and PHP 8.1 compliant. However, note that it is your responsibility to check the deprecation lists for Drupal and PHP to ensure that you cover all of the scenarios in your Developer Portal sites.

For more information about making your custom modules Drupal 10 and PHP 8.1 compliant, see the following links:

- Deprecation checking and correction tools.
- Deprecated modules and themes.
- List of APIs deprecated and now removed from Drupal 10.
- Whats new in PHP 8.1.
- Symfony Upgrade Guide.
- Drush 11 commands.

Developer Portal tutorials

Tutorials for using the Developer Portal.

The following guided examples help you through some of the most common user scenarios in the Developer Portal, as well as some of the more complex areas.

Developer Portal tutorials by category
For API consumers Create an Application
User authentication Adding a field to the sign up form Adding validation to a field on the sign up form Adding a field group to group fields in a content type
Getting started configuring the Developer Portal Creating the Portal Creating a private Portal site Customizing themes
Advanced customization Changing the front page Grouping products by category Adding a custom block to the front page Adding a custom block to a page other than the front page Using avatars Using image optimization Adding a Back to top button Creating a drop-down menu link Displaying blog posts on the front page Displaying tweets on the front page Changing the profile page to display firstname lastname, instead of username Using a custom weighting sort order on the product list page Configuring the RobotsTxt file Configuring the SecurityTxt file Synchronizing application credentials with an external server

Tutorial: Creating the Developer Portal

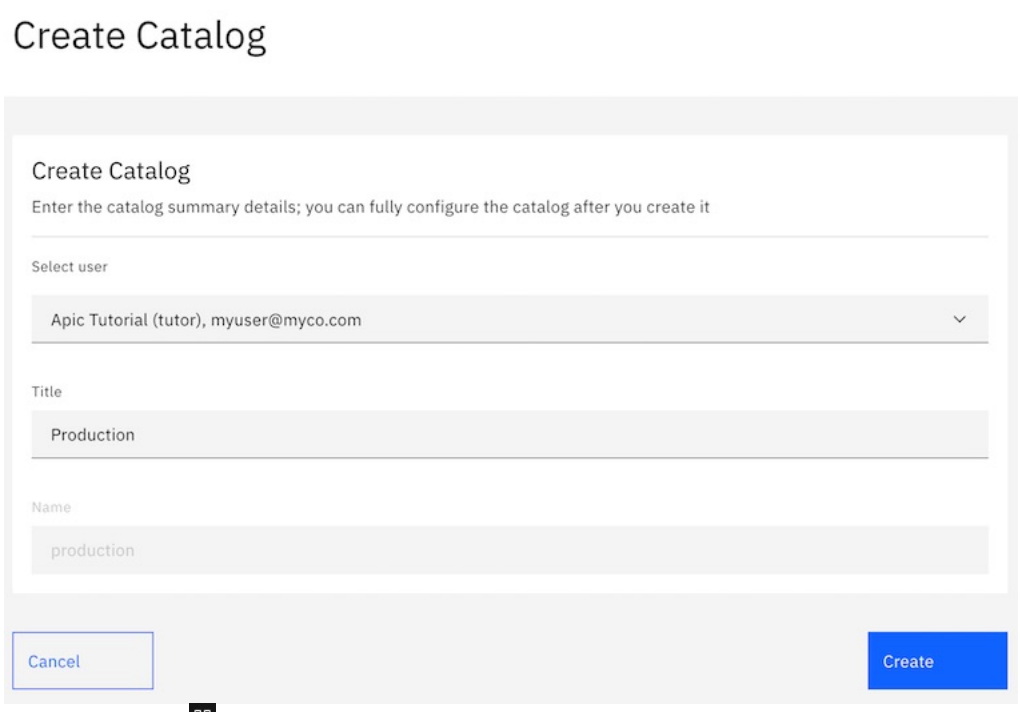
About this task

In this tutorial, you are going to complete the following lessons:

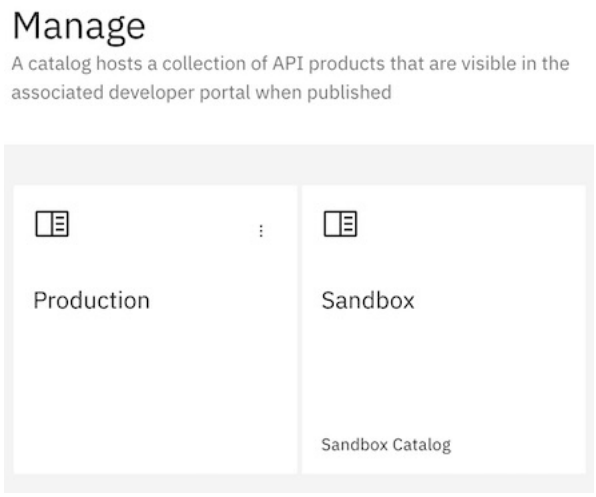
Enabling the Developer Portal through the API Manager

By proceeding with the following steps, you create an administrator account:

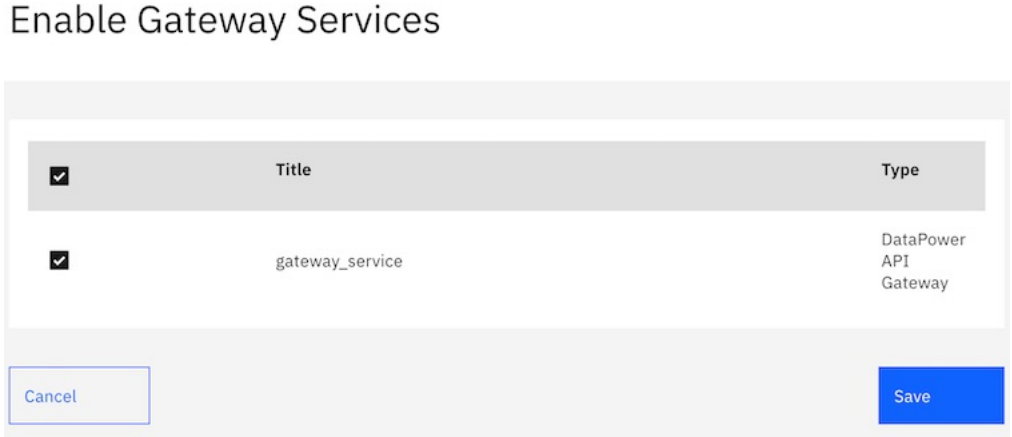
1. Log in to the API Manager
2. Click Manage, then click Add, and select Create catalog.
3. Select the owner from the **`Select user`** list, then enter a **`Title`** for your catalog, for example `Production`.



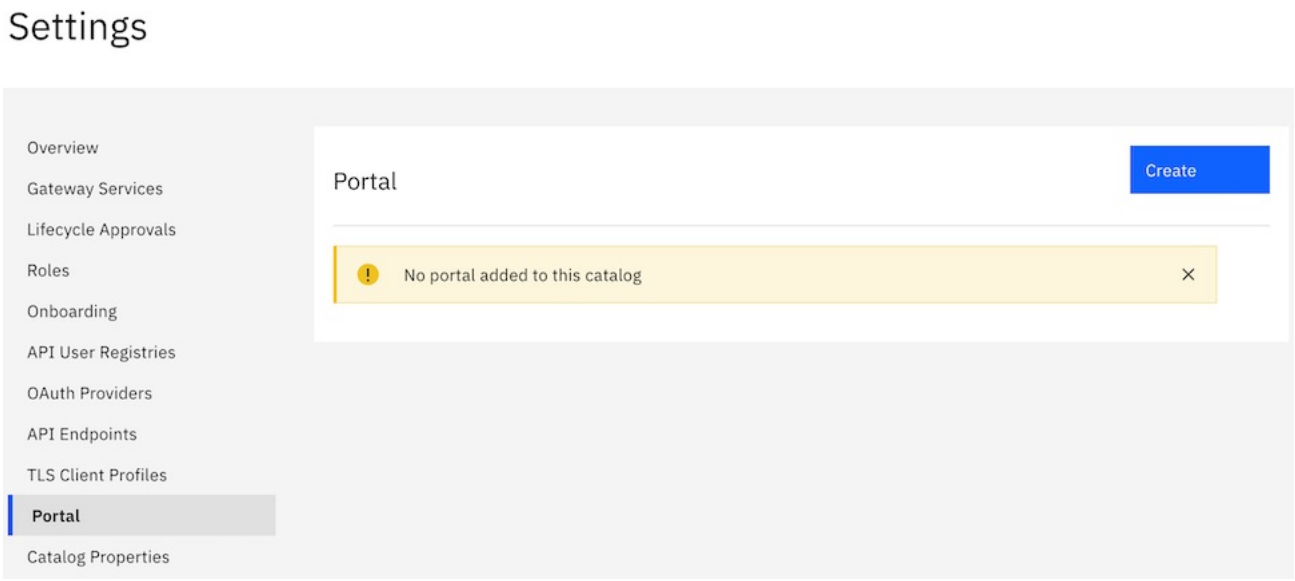
4. Click Create, then click Manage.



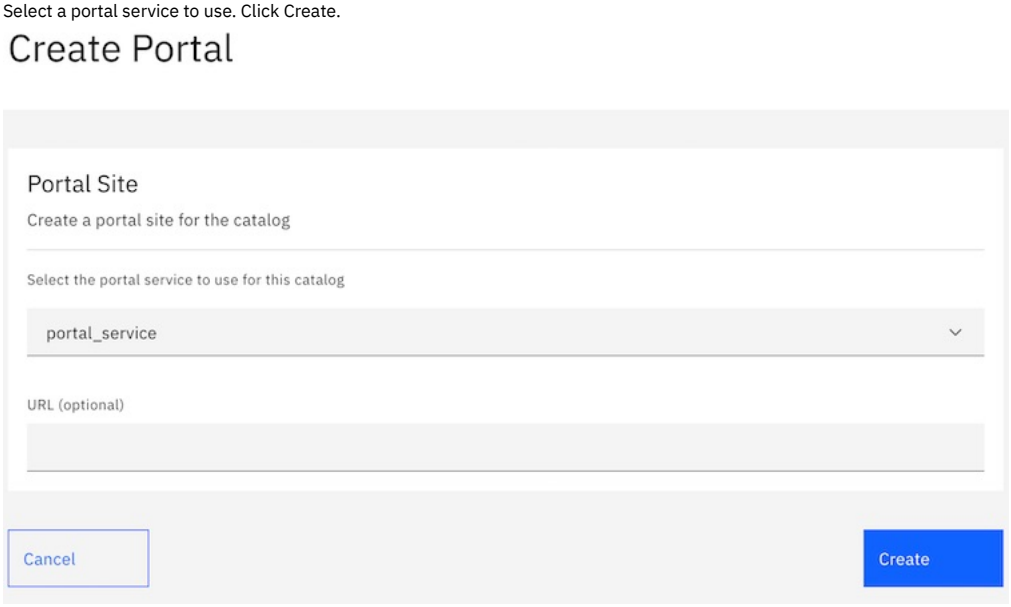
5. Click your new catalog, for example **`Production`**.
6. Click Catalog settings.
7. Click Gateway Services. If the message **`You currently don't have any gateway services`** is displayed, click Edit, select gateway_service, then click Save.



8. Click Portal.
9. Click Create.



10. Select a portal service to use. Click Create.



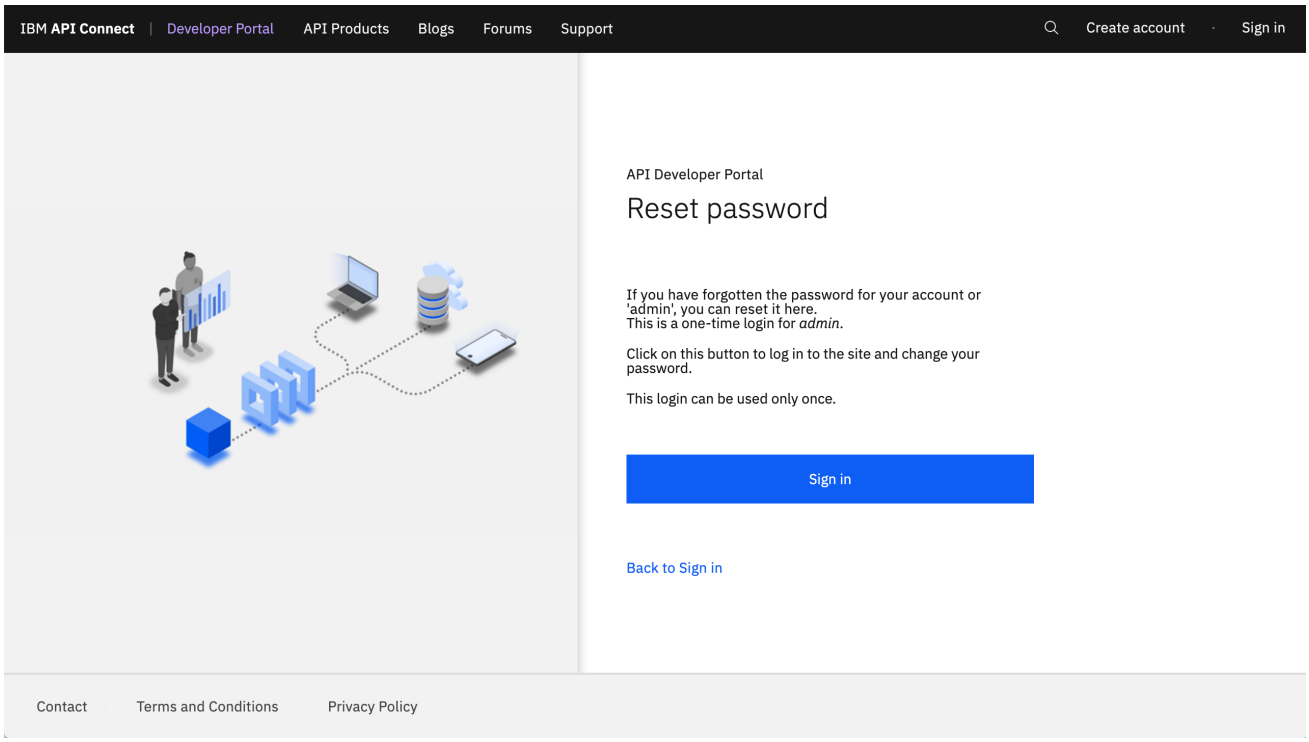
After a few minutes, you receive an email with a link to your Developer Portal site for that catalog. The link is a single use only link for the administrator account.

Administrator (admin),

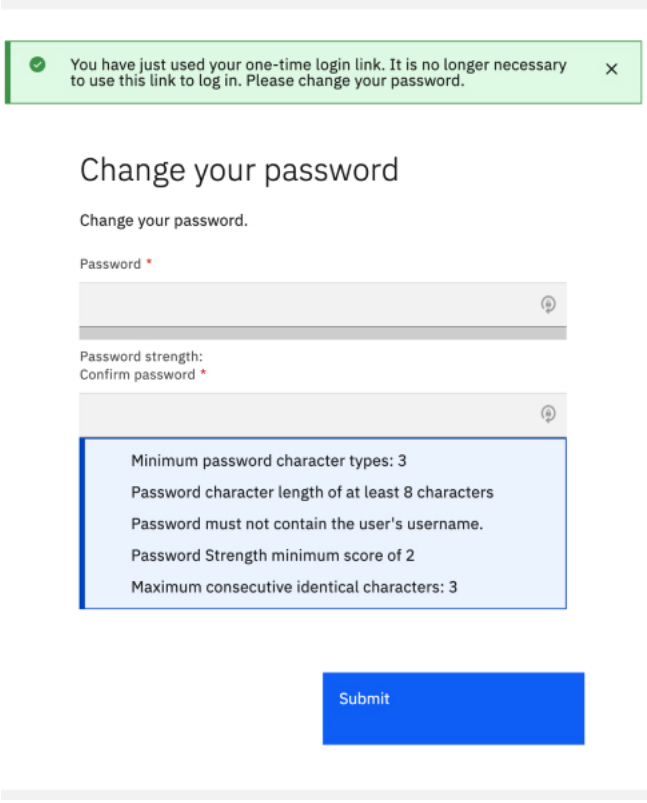
Your Developer Portal site has been created. You can log in as the 'admin' user by using the following one-time log in link. After you have logged in with the following link, you must change the password for the 'admin' user account immediately.

https://portal.apidemo.demo.ibm.com/tutorial/production/user/reset/1/1591727237/h26vxzf2e51UqqK7vf10LNbHiVEC5VQ_AZAoKCYH72C/new/login

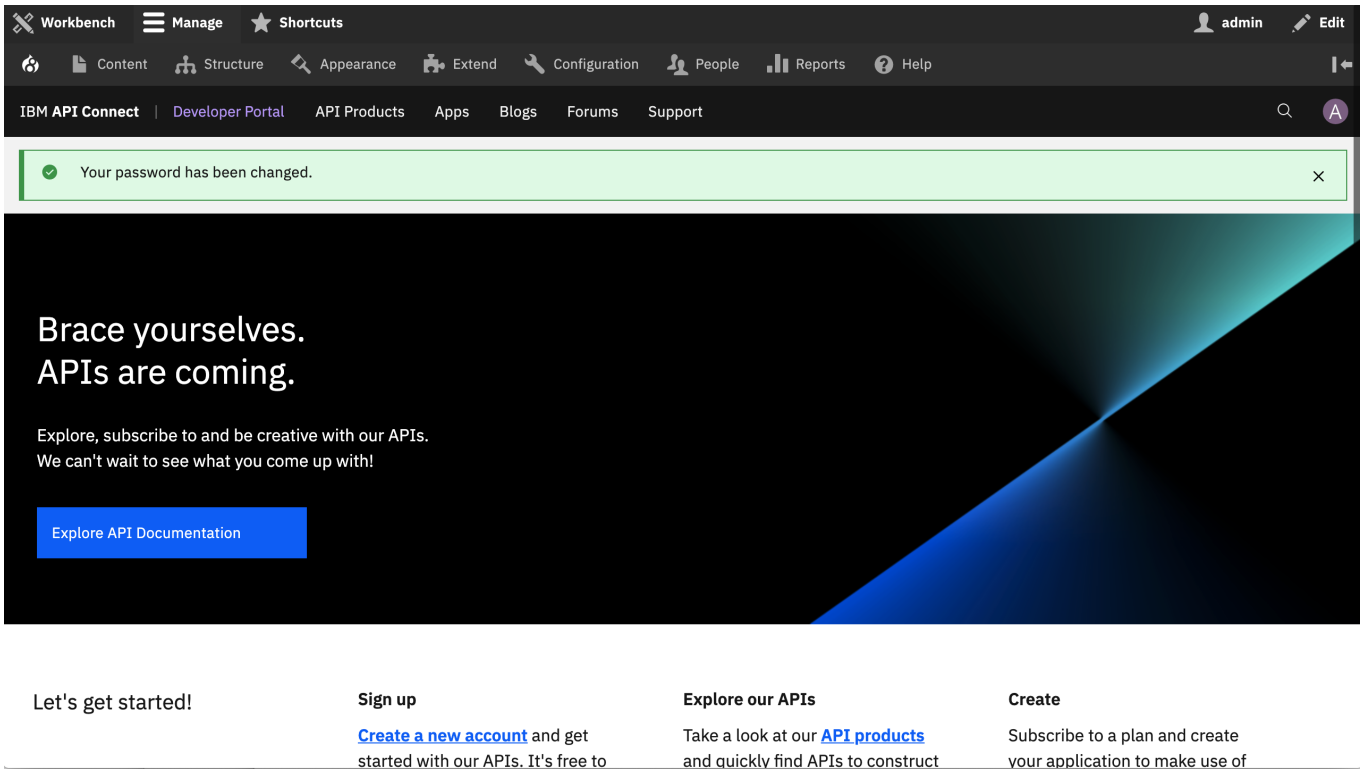
11. Click the email link. Click Sign in.



12. Change the password. Click Submit.



The portal site for the Production catalog is now active. The admin account cannot create applications or subscriptions. You must create a new account to complete those tasks.



What you did in this tutorial

In this tutorial, you completed the following activities:

- Enabled a Developer Portal site and created an administrator account.

Note: To ensure that your desired content is displayed, it is crucial to publish your product containing APIs to the appropriate catalog.

What to do next

- Create a Developer Account and Application

Related information

- Importing an API

Tutorial: Creating a private Developer Portal site

You can create a private version of the Developer Portal, so that authenticated users only can access content on the site. You might want to do this if you want to restrict public access to your content unless they are logged in.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

About this tutorial

In this tutorial, you are going to restrict access for all the content to authenticated users only. This gives access to all users from **`Content Author`** to **`Superuser`**, as they are all required to authenticate to access their roles. You will then add the login form to the home page, so that public users will be able to view the public home page that contains the login form only.

This tutorial takes you through the following steps:

1. Export your configuration settings.
2. Restrict all permissions to authenticated users.
3. Restrict blocks to authenticated users.
4. Add login form to the home page.

Export your configuration settings

In case you make an error, or want to revert all of the changes made during this tutorial, you can back up your configuration settings to your machine before you make any changes.

The tutorial Exporting and importing custom themes and site configuration provides further details on how to export your configuration settings using the Developer Portal CLI.

Restrict all permissions to authenticated users

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to People > Permissions.
3. Clear all check boxes that are associated with **ANONYMOUS USER**.
4. Click **Save permissions** at the end of the page.

Restrict blocks to authenticated users

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to Structure > Block layout.
3. Find the row that is labeled **Main menu** and click **Configure**.
4. Find the setting **Roles** under the category **Visibility**.
5. Check the box **Authenticated user**.
6. Click **Save block**.
7. Repeat from step 3 for the **Footer menu**.
8. Click **Save blocks**.

Add login form to the home page

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to Structure > Pages.
3. Click **Edit** on the **Welcome** page.
4. Navigate to Panels > Content.
5. Click **+ Add new block**.
6. Find and click **User login**, under the **FORMS** section.
7. Clear the **Display title** check box.
8. Click **Add block**.
9. Rearrange the new login block so that it is underneath the **Welcome Banner**.
10. Click **Update and save**.

What you did in this tutorial

On your Developer Portal, you restricted access for all the content to authenticated users only. Now when you access your home page as an unauthenticated user, you see that the login form appears underneath the welcome banner. Navigating to other URLs on the site presents an **unauthorized** page to appear.

When you log in, the login form disappears from the home page and you are able to access all of the pages that are visible to your role.

Tutorial: Creating Accounts and Applications on the Developer Portal

This tutorial shows you how to create a developer account and register an application on the Developer Portal.

Before you begin

You must have a Developer Portal installed, and created and published at least one API product.

If you do not have a Developer Portal available, complete the tutorial Creating a Developer Portal.

If you don't have an API product available, you can download one of the following APIs, and then import and activate it:

- If your Sandbox catalog uses a DataPower® Gateway (v5 compatible) (as one of the gateways, or as the only gateway), download the findbranch.txt file to your local filesystem. Rename this file `findbranch.yaml`.
- If your Sandbox catalog uses a DataPower API Gateway, download the findbranch_v6.txt file to your local filesystem. Rename this file `findbranch.yaml`.

For more information about importing an API, see Adding a REST API by importing an OpenAPI definition file.

About this task

In this tutorial you are going to complete the following lessons:

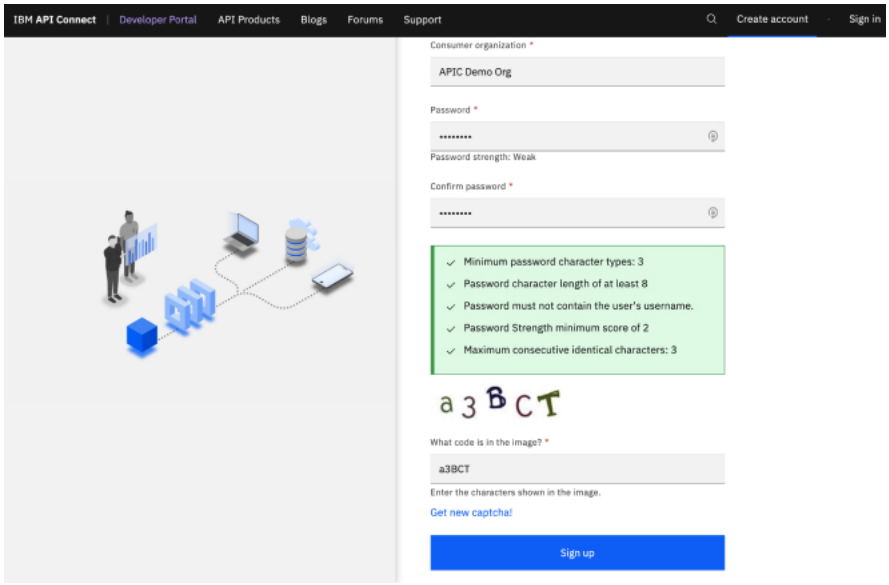
- Creating a developer account in the Developer Portal
- Creating a developer application in the Developer Portal
- Testing the Branches API in the Developer Portal

Note: The administrator account cannot create an App, or register to an App. To create or register to an App, you must have a developer account. A developer account that has been assigned administrator privileges can create and register Apps.

Creating a developer account in the Developer Portal

Take the following steps to create a developer account:

1. Open a Developer Portal at the previously specified URL, then click Create an account and complete the fields. If the Create an account link is not visible, log out as Admin from the Developer Portal first.
   Note: Your email is used as your user name for the Developer Portal. The email address must be different from the address used for creating the administrator account.
2. Go to the home page of the Developer Portal
3. Click Create an account.
4. Complete the sign up form. The email address you provide must be functional. Click Sign up. A confirmation message is sent to the email address provided in the form.

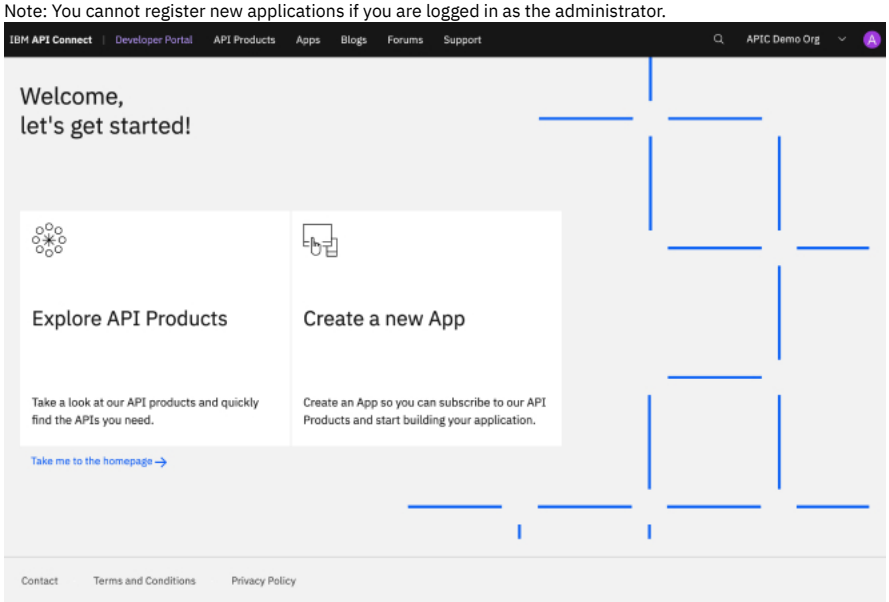


5. Click the account activation link in the confirmation email to activate your account.
6. To use the Developer Portal, click Login and sign in with the user credentials you specified.

Creating a Developer Portal Application

To create and register a new App:

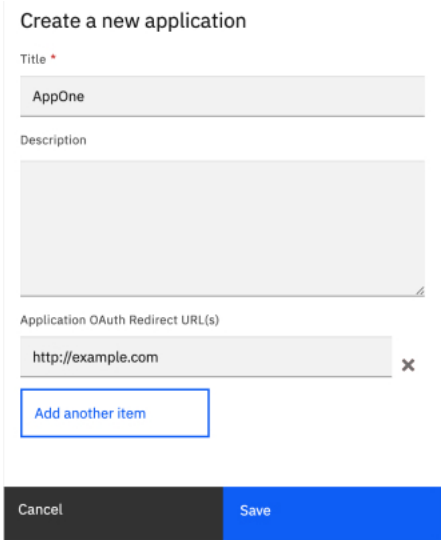
1. In the Developer Portal, click Create an App.
   Note: You cannot register new applications if you are logged in as the administrator.



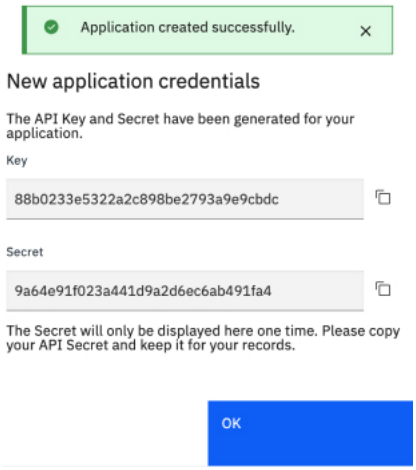
2. Enter the following values for the application that is being registered.

Table 1. Values for registering the application

Field Name	Value
Title	`AppOne`
Application OAuth Redirect URL(s)	`http://example.com`

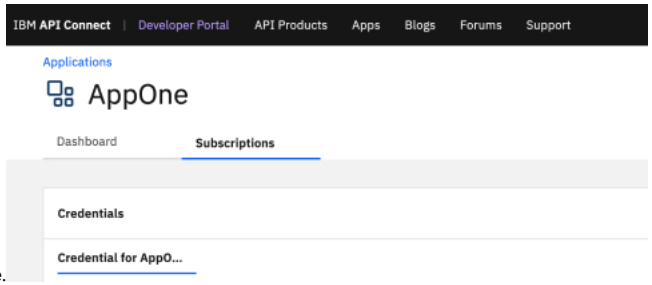


3. Click Save.
4. Copy the key and secret values for the new app. Click OK.



5. Click Continue.

You see a usage statistics page.

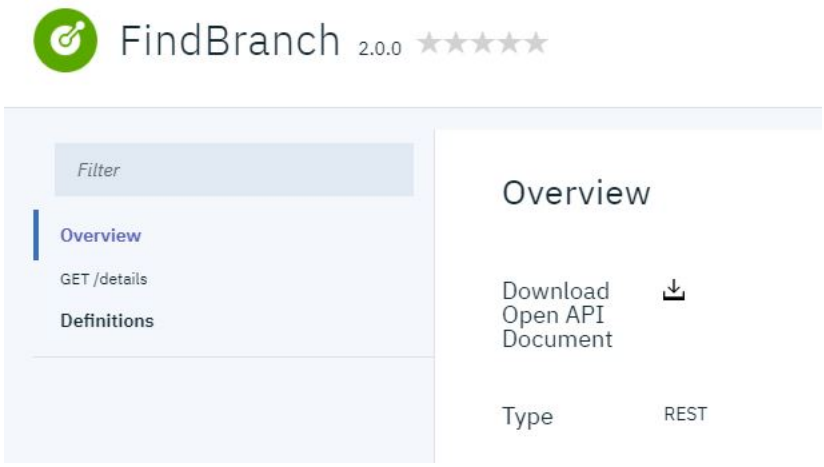


Subscribing to an API in the Developer Portal

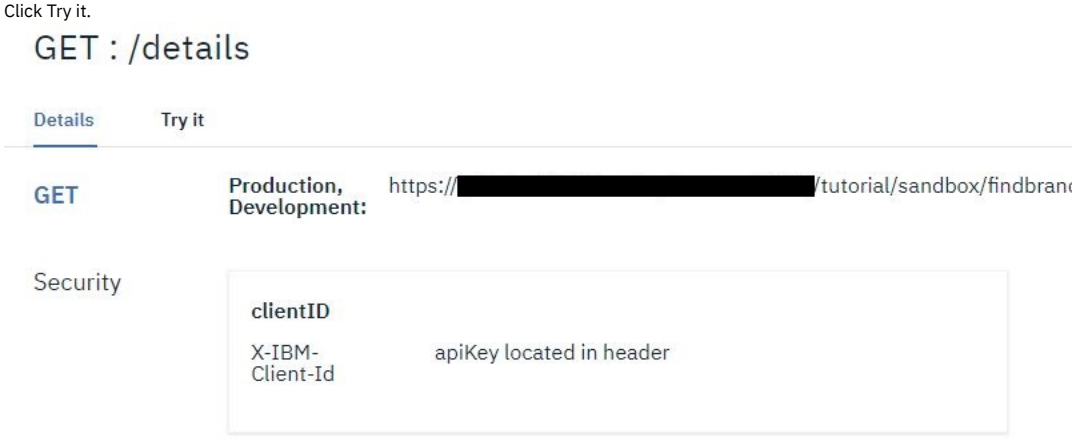
1. Click API Products.
2. Click FindBranch.
3. Click Subscribe.
4. Under the Application heading, click Select App for your new application.
5. Click Next.
6. Click Done.

Testing An API in the Developer Portal

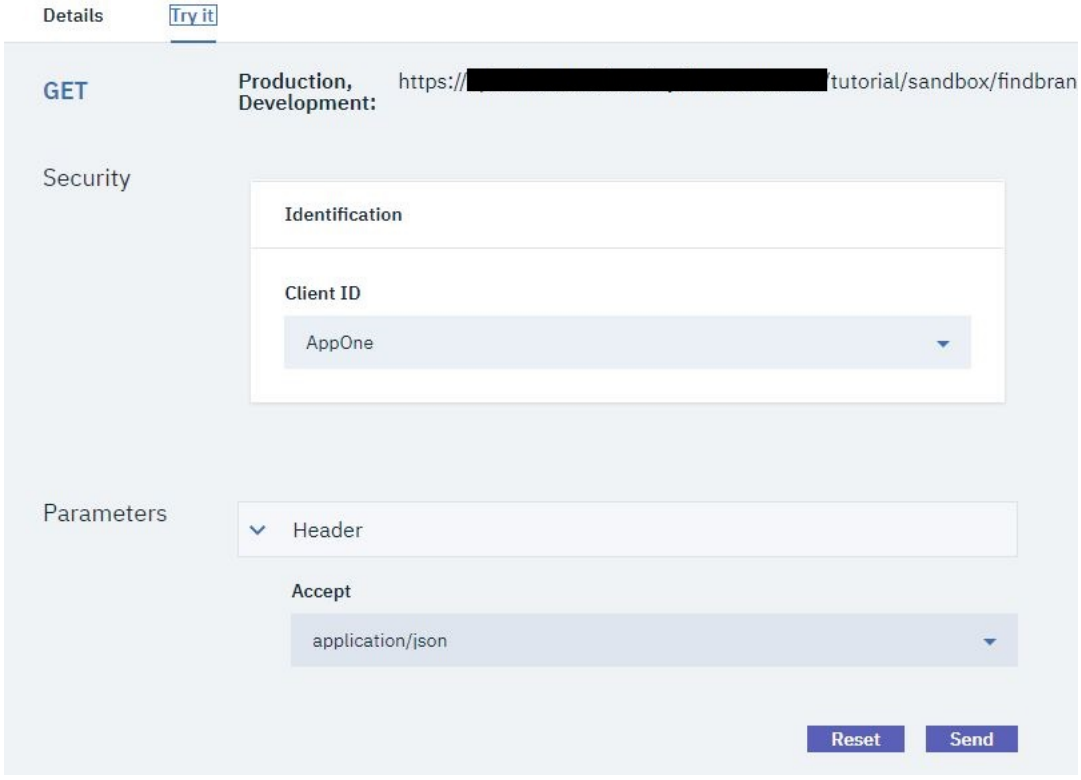
1. Click API Products in the Developer Portal dashboard.
2. Click a Product, such as FindBranch auto product , then select the FindBranch API from the list.
3. Click GET /details.



4. Click Try it.

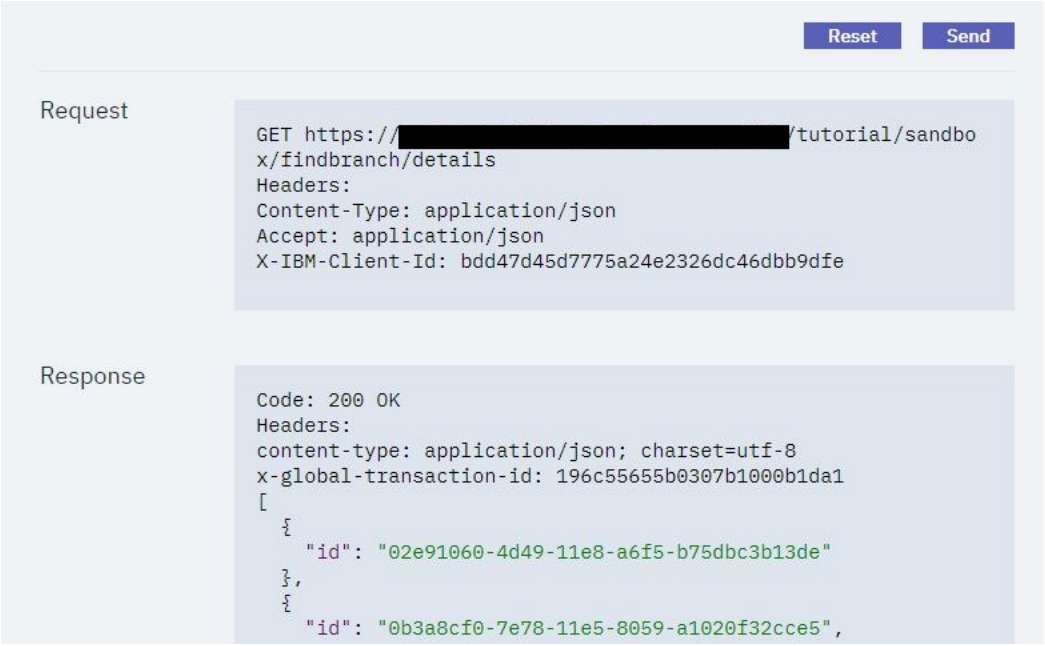


5. Click Send.



Note: If no response is received, navigate to the URL that is displayed at the beginning of the Try this operation section, in a new browser tab. Accept the security certificate, and then call the operation again.

6. A returned response of `200 OK` and the message body are displayed, indicating that the REST API operation call was successful.



What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a developer account in the Developer Portal.
- Created and registered a new App, and subscribed it to a Plan.
- Tested an API in the Developer Portal.

Tutorial: Creating a custom theme for the Developer Portal

Customize the appearance of your Developer Portal home page, by generating a sub-theme, configuring the overrides.css file, and installing the newly customized theme.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.
Important: You're not permitted to include any IBM® API Connect code within any custom themes that you create.

About this tutorial

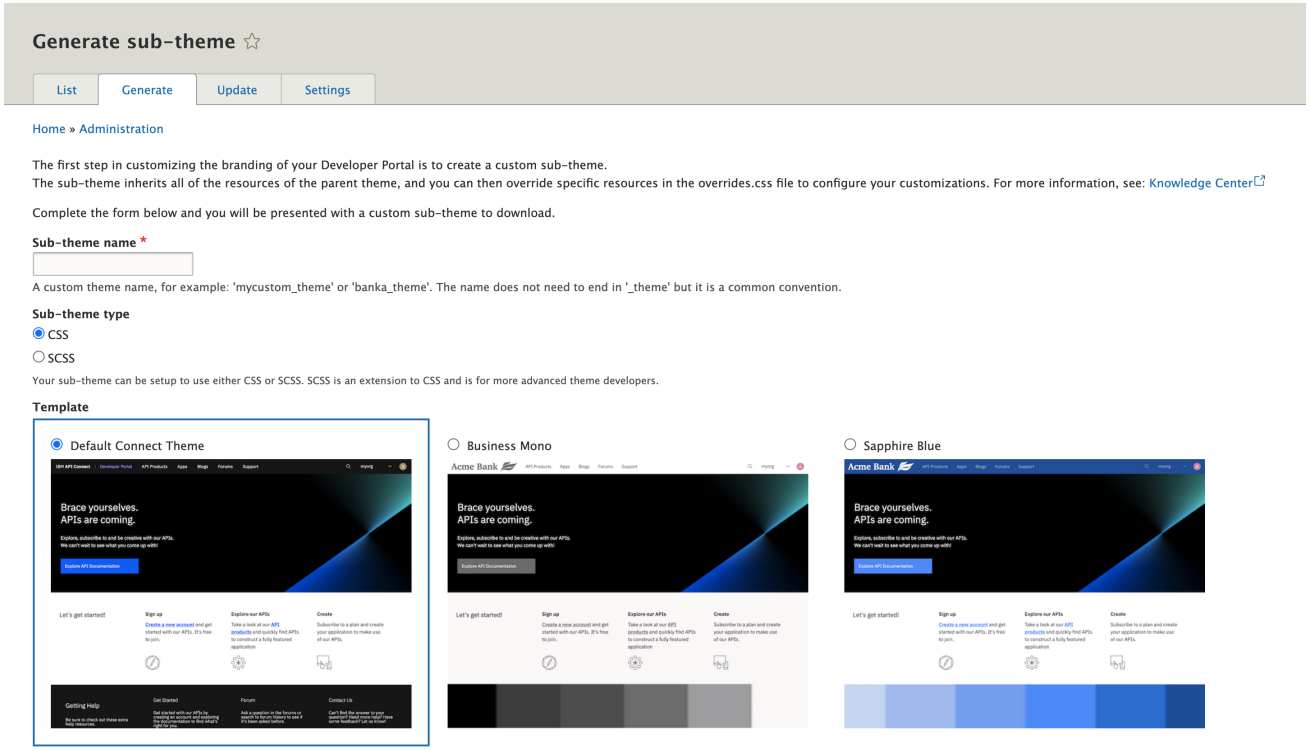
The way to create a custom theme is to create a custom sub-theme of the standard API Connect theme that the Developer Portal uses by default. The sub-theme inherits all of the resources of the parent theme, and you can then override specific resources to configure the required customizations.

This tutorial takes you through the following lessons:

1. Creating a sub-theme by using the theme generator.
2. Customizing the overrides.css file.
3. Installing and enabling your customized theme.

Creating a sub-theme

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Appearance > Generate sub-theme. The Generate sub-theme window is displayed.
4. Enter a Sub-theme name, and select CSS for the Sub-theme type. (If you prefer, you can select SCSS, but this extension to CSS is for advanced theme developers, and isn't covered by this tutorial.)



5. Select the Default template to base your **`sub-theme`** on. You can create a sub-theme based on a color template. However, for this tutorial you use the default connect_theme template.
6. Click Generate.
7. Download the generated sub-theme to a location of your choice, and extract all the files from the .zip file.

Customizing the overrides.css file

On your computer, navigate to the files that you extracted. You can now customize the overrides.css file.

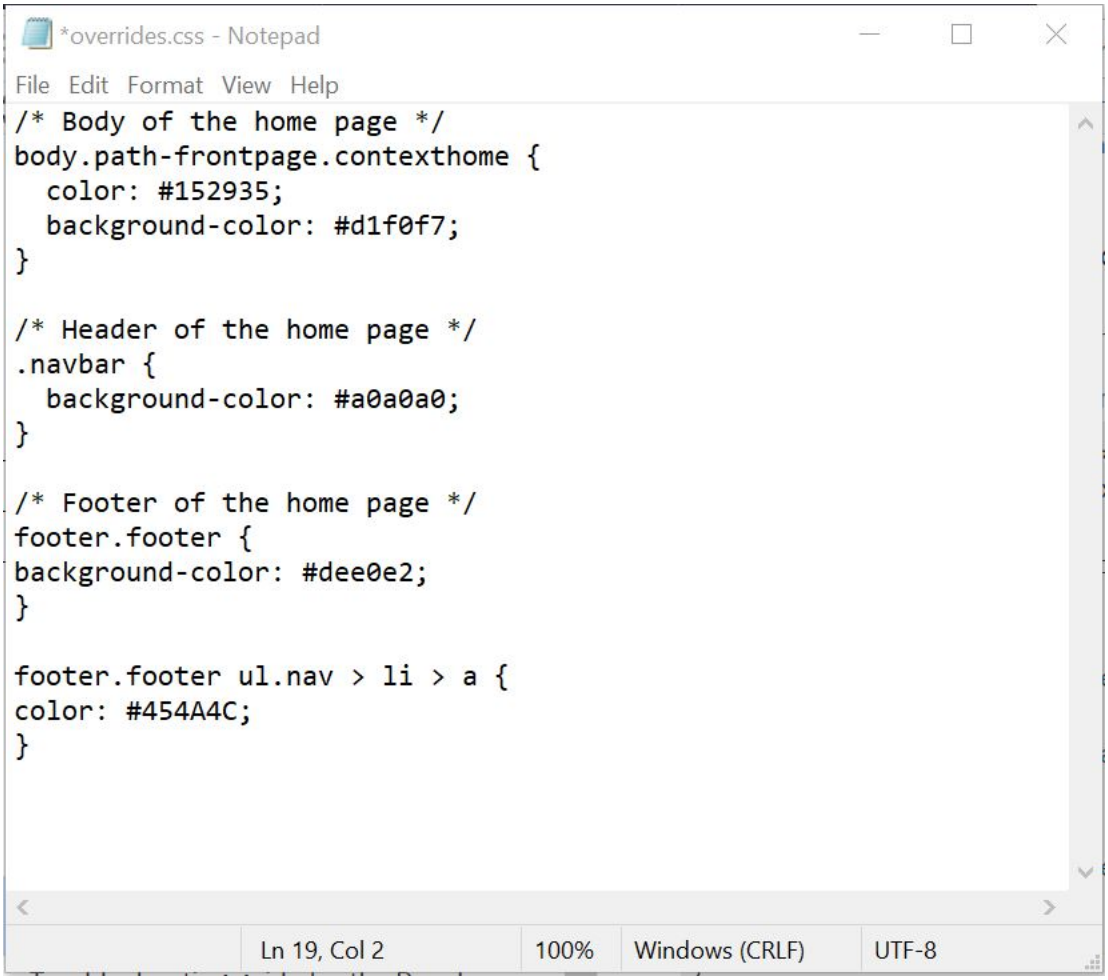
1. Open the overrides.css file in your chosen editor.
2. Customize your sub-theme by entering the following elements into the overrides.css file:

```
/* Body of the home page */
body.path-frontpage.contexthome {
  color: #152935;
  background-color: #d1f0f7;
}

/* Header of the home page */
.navbar {
  background-color: #a0a0a0;
}

/* Footer of the home page */
footer.footer {
background-color: #dee0e2;
}

footer.footer ul.nav > li > a {
color: #454A4C;
}
```

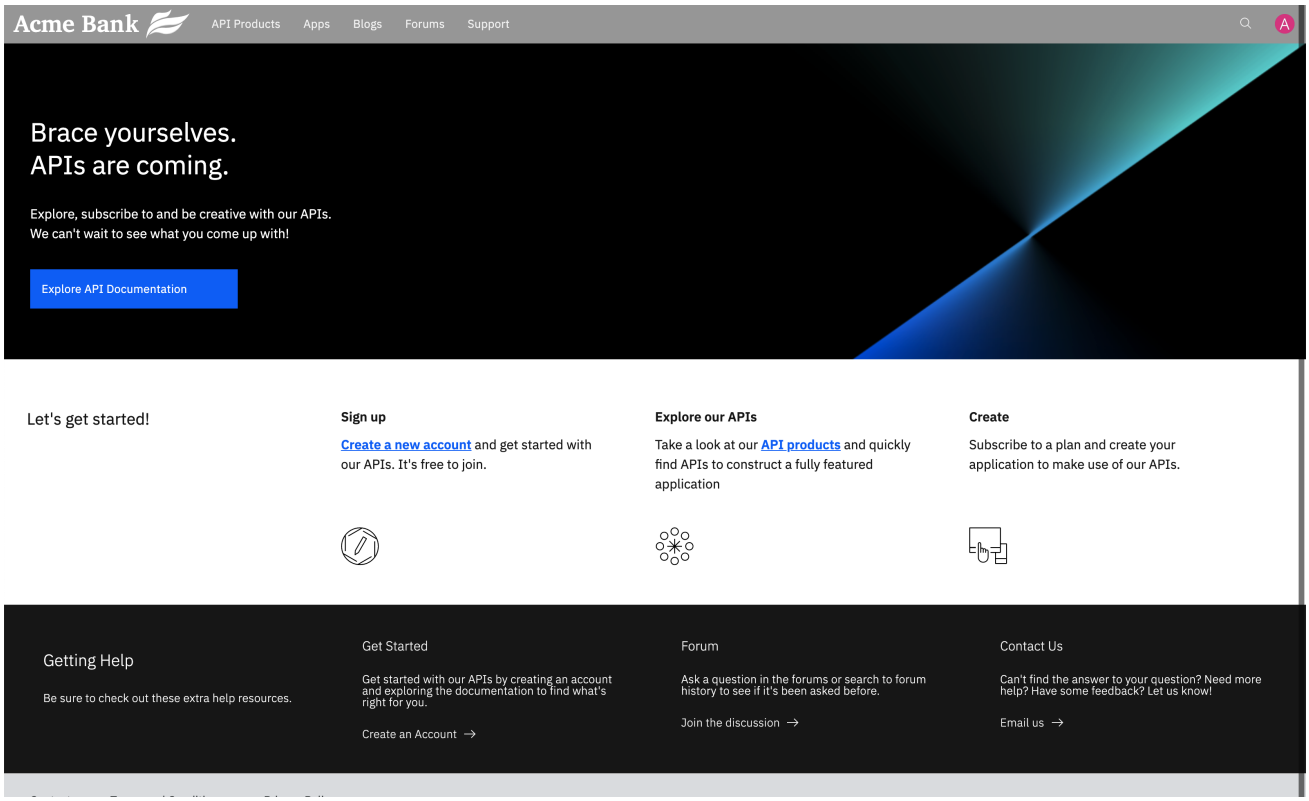


3. Save the overrides.css file.

Installing and enabling your customized theme

1. After you have finished updating the overrides.css file, compress all the theme files back into the .zip sub-theme file that you downloaded originally.
   Note that you can also include your own custom logo and favicon in your theme files, and these are then included as part of your theme when it is installed. These files must use the naming convention logo.svg, and favicon.ico, respectively. You can also change your logo and favicon at a later time, see Changing the site logo and Changing the shortcut icon.

2. In the Developer Portal, click Appearance > Install new theme. The **`Install new theme`** window is displayed.
3. In Upload a module or theme archive to install click Browse, and navigate to your newly updated compressed theme file.
4. Click Install to install the theme onto your site.
5. Click Enable newly added themes, and find your new theme in the list of Disabled themes. Click Enable and set as default to set your new custom sub-theme as the default theme for your site.
6. Return to the Developer Portal home page by clicking Back to site. You can now see your custom theme.



What you did in this tutorial

In this tutorial, you completed the following tasks:

- Created a sub-theme of your Developer Portal site by using the theme generator.
- Configured some customized home page elements in the overrides.css file of your sub-theme.
- Uploaded and installed your customized theme in your Developer Portal site.
- Successfully customized the appearance of your Developer Portal home page.

Tutorial: Using avatars

You can use an avatar generator to better represent the branding of your site, and add a sense of community for your users, than the default name initial that is provided in the Developer Portal.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

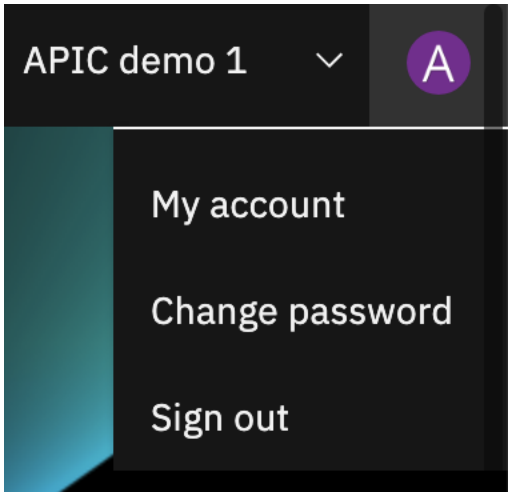
About this tutorial

In this task, you add the **Robohash** avatar generator to your Developer Portal site, and assign it as the primary avatar generator for all users.

This tutorial takes you through the following steps:

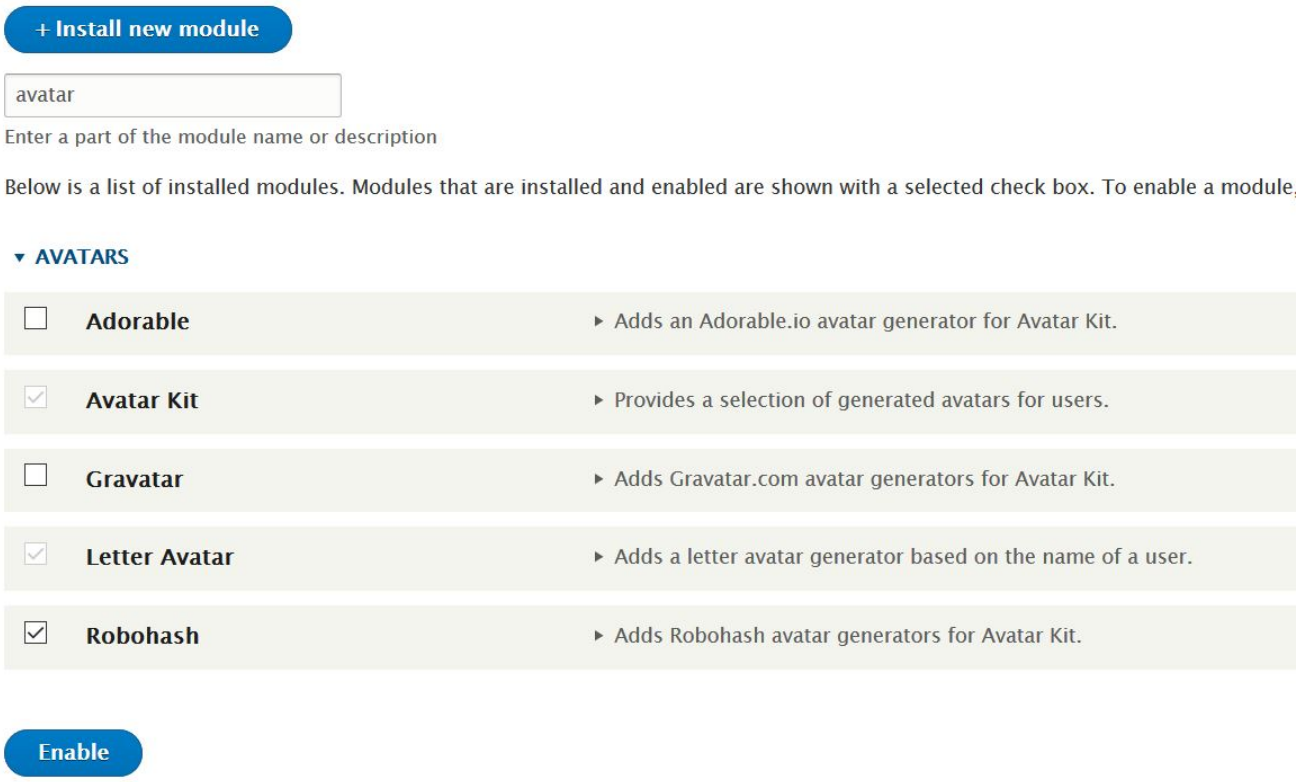
1. Install the **Robohash** avatar generator.
2. Set **Robohash** as the preferred avatar generator for your site.
3. Configure the permissions for the **Robohash** avatar generator.

The avatar of the admin user displays like this before the block is added.



Enable the `Robohash` avatar generator

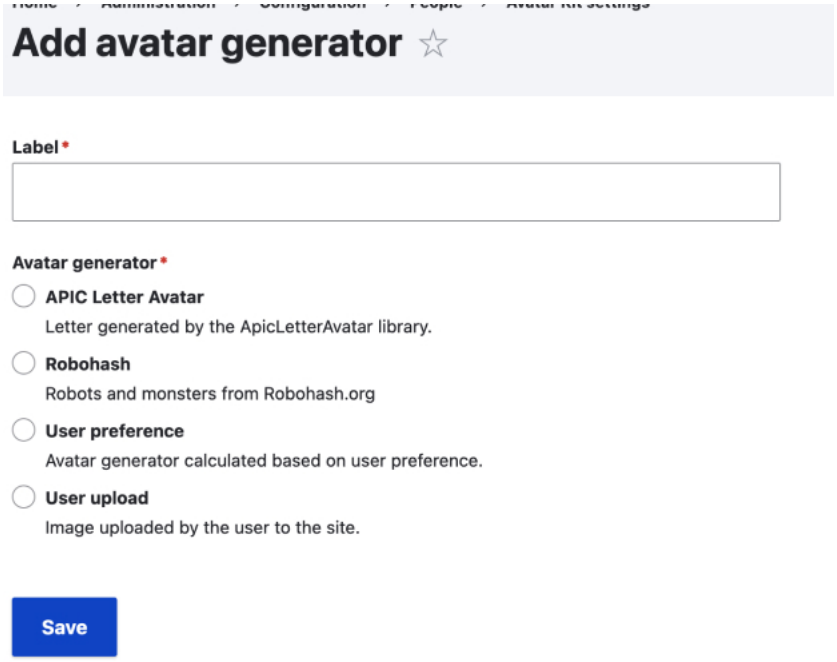
1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Extend.
4. In the text box, enter `avatar` in the **`Block description`**.
5. Check the **`Robohash`** box, click Enable.



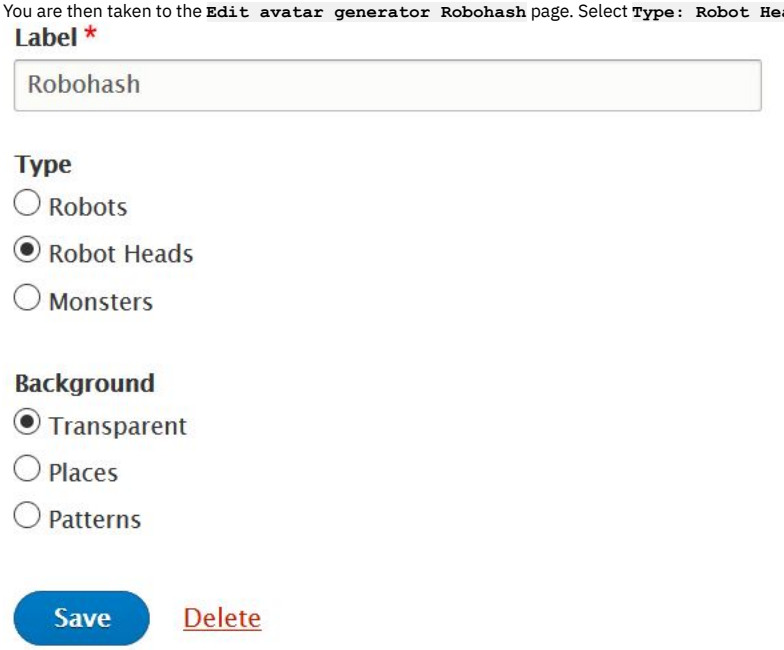
When the module is enabled, you receive a **`Module Robohash has been enabled`** message.

Set `Robohash` as the preferred avatar generator for your site

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to Configuration > People > Avatar settings.
3. Click **`+ Add avatar generator`**.
4. Enter `Robohash` as the label.
5. Check **`Robohash`** for the avatar generator.
6. Click Save



7. You are then taken to the **`Edit avatar generator Robohash`** page. Select **`Type: Robot Heads`** and **`Background: Transparent`**. Click Save.



8. You are now on the avatar generator page. Drag **`Robohash`** to be first in the list, and check **`Enabled`**, then click Save configuration.

You have now set **`Robohash`** as the preferred avatar generator for your site.

Configure the permissions for the `Robohash` avatar generator

The default setting for the **`Robohash`** avatar generator is to generate avatars for users with **`superuser`** access only. In this example, the permissions are changed so that all **`authenticated users`** can access **`Robohash`**.

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to People > Permissions.
3. Find **`Use Robohash`** under the permission type **`Avatar Kit`**.
4. Check **`AUTHENTICATED USER`** for **`Use Robohash`** to enable the generator for all authenticated users.
   Notice that all the boxes for this user type are then automatically checked because all of those users have the same permissions as an authenticated user, or higher.

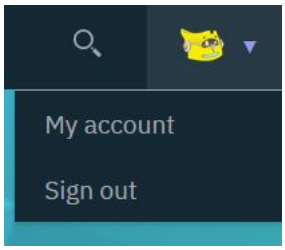
PERMISSION	ANONYMOUS USER	AUTHENTICATED USER	FORUM MODERATOR	CONTENT AUTHOR	ADMINISTRATOR	SUPERUSER
Change own logout threshold	☐	☐	☐	☐	☑	☑
Avatar Kit						
Administer Avatar Kit *Warning: Give to trusted roles only; this permission has security implications.* Manage settings for Avatar Kit.	☐	☐	☐	☐	☑	☑
Use *Letter Generator* User can select *Letter Generator* avatar generator.	☐	☑	☑	☑	☑	☑
Use *Robohash* User can select *Robohash* avatar generator.	☐	☑	☑	☑	☑	☑

5. Click Save permissions.

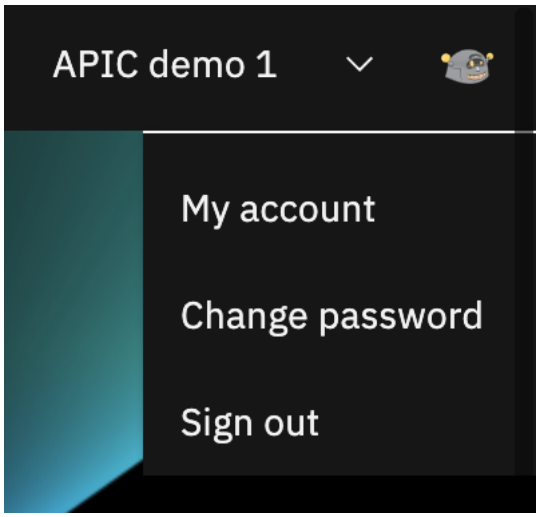
What you did in this tutorial

The avatars of all users now have the **robohash** avatar.

You can check that the avatar of the admin user has changed by looking at your site page.



You can check that the avatars of other users have changed by finding their published content and looking for their avatar. Or, you can navigate to Manage > People, click a user, and see their avatar on their profile page.



What to do next

You can disable the **robohash** avatar generator.

1. Navigating to Extend > Disable module.
2. Search for **avatar** in the filter text box.
3. Check **Robohash**, click Disable
4. Click Disable.

You can also disable the **robohash** avatar generator by clearing it within Configuration > People > Avatar settings, or, reducing its preference by dragging it to a different order in the list. Click Save configuration.

Tutorial: Using image optimization

You can use image optimization on your Developer Portal site to enhance the use of images.

Optimized images do not overload your website and significantly increase its performance compared to using the original images. Your customer satisfaction and brand reputation improve with fast-loading and trimmed visual assets. Automatic optimization can save time and effort on editing and content moderation.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

About this tutorial

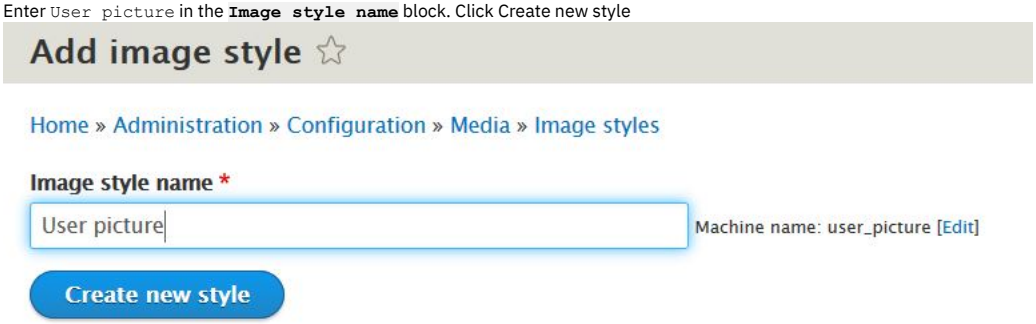
In this task, you create an image style that is called `User picture`, and give it a scale and crop effect. Then, use the `User picture` as the **`Picture`** field in the user account.

This tutorial takes you through the following steps:

1. Create the image style **`User picture`**.
2. Edit the image style **`User picture`**.
3. Assign **`User picture`** to the **`picture`** option in **`Account settings`**..

Create the image style `User picture`

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Configuration > Media > Image styles.
4. Click + Add image style.
5. Enter `User picture` in the **`Image style name`** block. Click Create new style

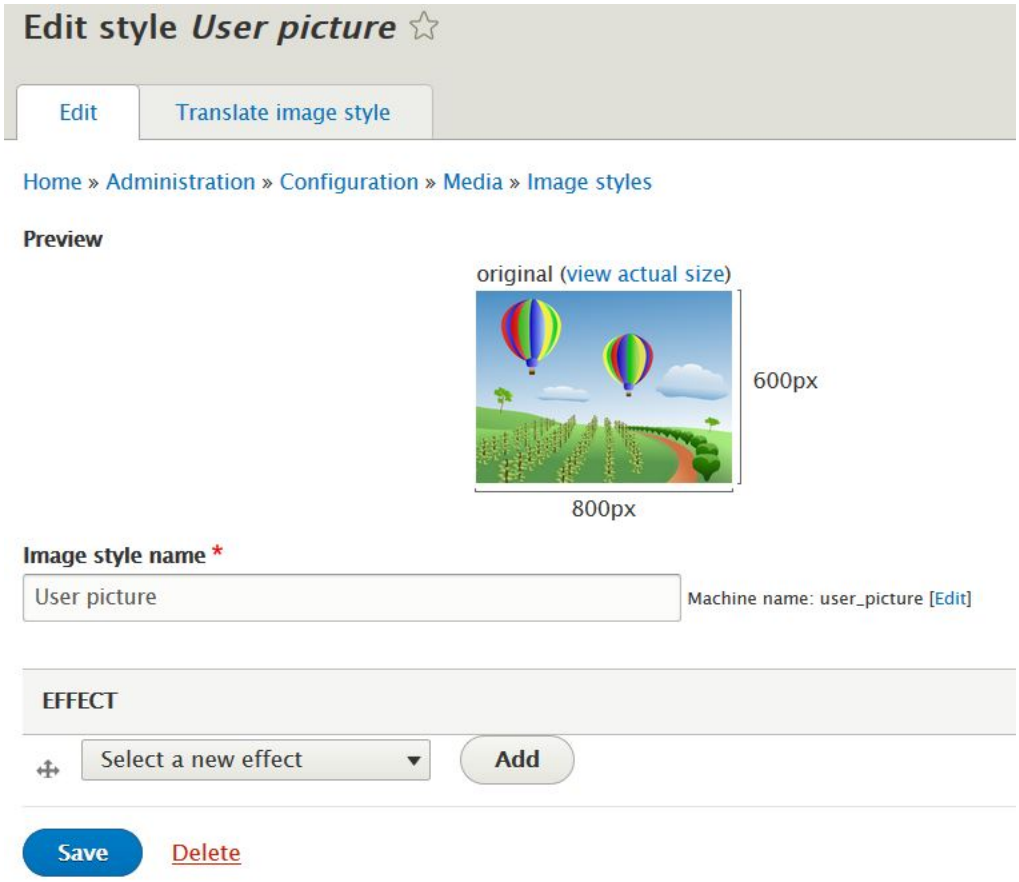


You created the image style **`User picture`**.

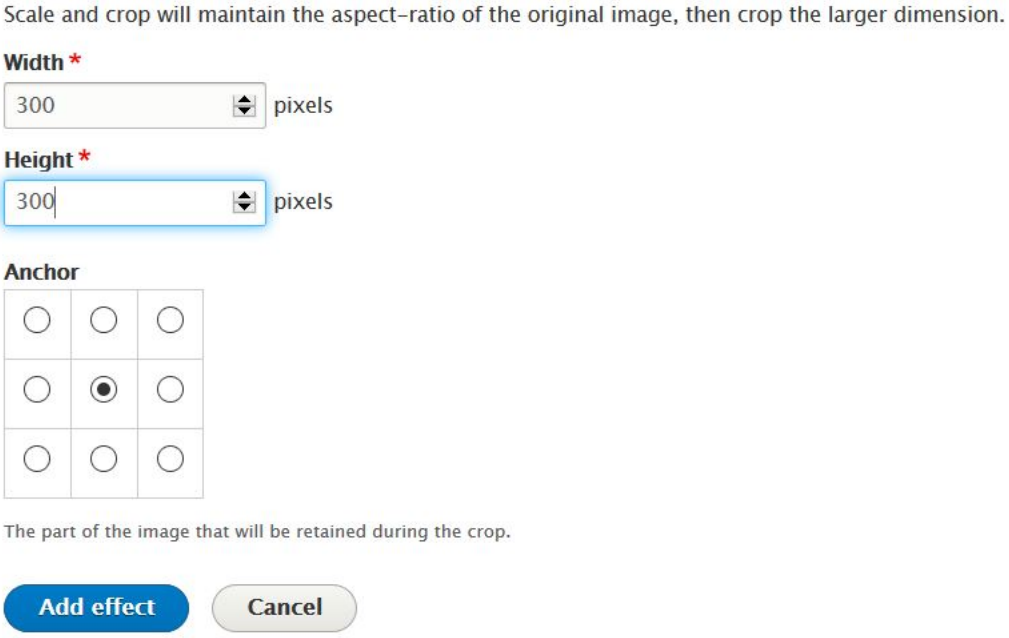
Edit the image style `User picture`

When you edit this style, you choose the width and height settings. Also, the part of the picture to retain during the crop, for example, the center.

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to Configuration > Media > Image styles.
3. Click Edit on the **`User picture`** style name.



4. Select **`Scale and crop`** from **`Select a new effect`**, then click Add.
5. Enter `300` in the **`Width`** and **`Height`** boxes. Leave the **`Anchor`** as the middle setting. Click Add effect.



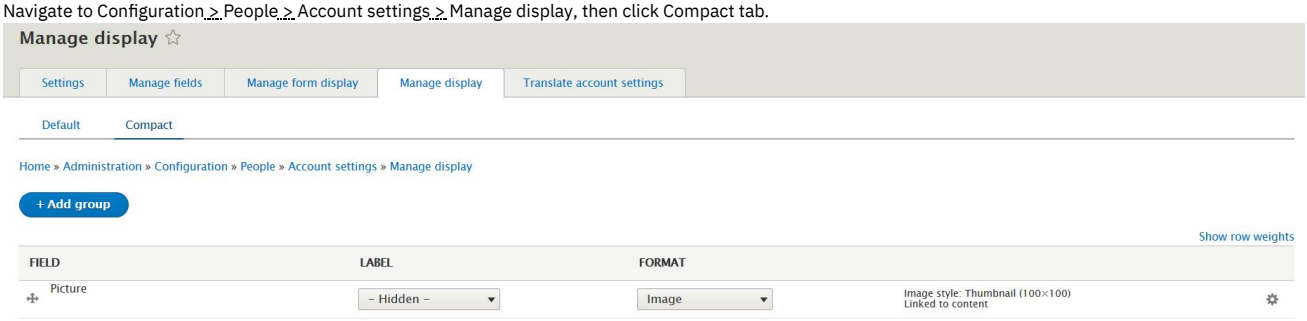
6. Click Save.

You edited the image style **`User picture`**.

Assign `User picture` to the `picture` option in `Account settings`

1. If the administrator dashboard isn't displayed, click Manage to display it.

2. Navigate to Configuration > People > Account settings > Manage display, then click Compact tab.



3. On the **`Picture`** row, click ⚙.
4. Select **`User picture`** from the **`Image style`** drop-down.
5. Click Update and Save.

You set the **`User picture`** image style for all accounts.

What you did in this tutorial

You changed your account settings so that if the user displays a picture it is within the limits of the image style **`User picture`**.

To check the picture used by a user, navigate to Manage > People, click a user, and see their picture on their profile page. Right-click the image, then click **`View image info`**, you can see that the dimensions are scaled.

Type:	JPEG Image
Size:	29.95 KB (30,667 bytes)
Dimensions:	620px × 413px (scaled to 240px × 160px)
Associated Text:	Profile picture for user apicdemo1

Tutorial: Adding a Back to top button

You might want to add a Back to top button, as a navigation enhancement to help your Developer Portal users get back to the top of the page that they are viewing, instead of scrolling.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial.

About this tutorial

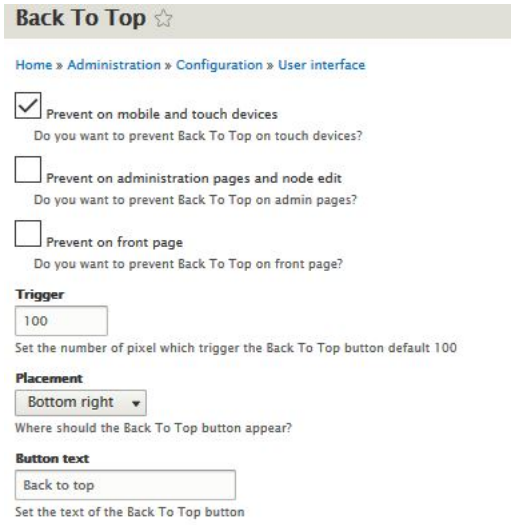
In this tutorial, you add a Back to top button to your Developer Portal.

Before you begin, ensure that the **`Back to top`** module is installed and enabled:

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Extend.
4. In the text box, enter `back to top` in the **`Block description`**.
5. Check the **`Back To Top`** box, click Enable.

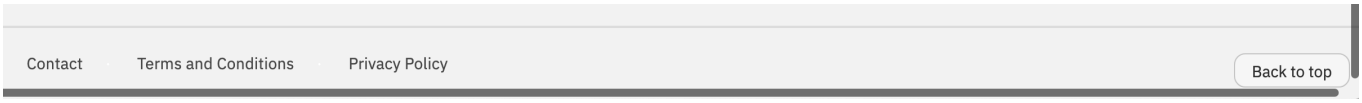
Configure the `Back to top` module

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to Configuration > User interface > Back to Top.



3. Change any settings as required, or keep the defaults.
4. Click Save configuration

You now have a Back to Top button.



What you did in this tutorial

You added a Back to Top button, as a navigation enhancement to help your users get back to the beginning of a page that they are viewing, instead of scrolling.

Tutorial: Creating a drop-down menu link

You can create and use drop-down menus, or nested menus, to enhance the use of your Developer Portal .

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

About this tutorial

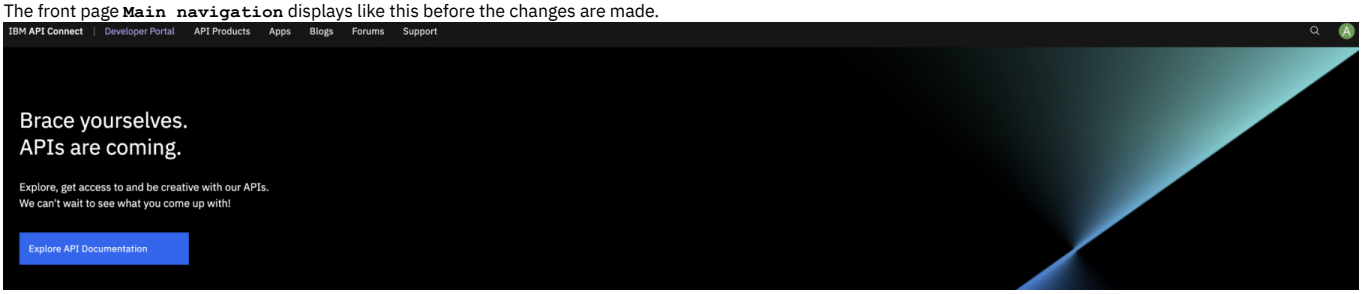
In this tutorial, you create a drop-down menu link on the **`Main navigation`** menu.

Note:
Although drop-down menu links can be created in the Developer portal, the drop-down menu doesn't expand by default. To make the drop-down menu expand, you need to use the **`Superfish`** module.

This tutorial takes you through the following steps:

1. Add menu links to the main navigation menu.
2. Make the drop-down menu expand by using the Superfish module.

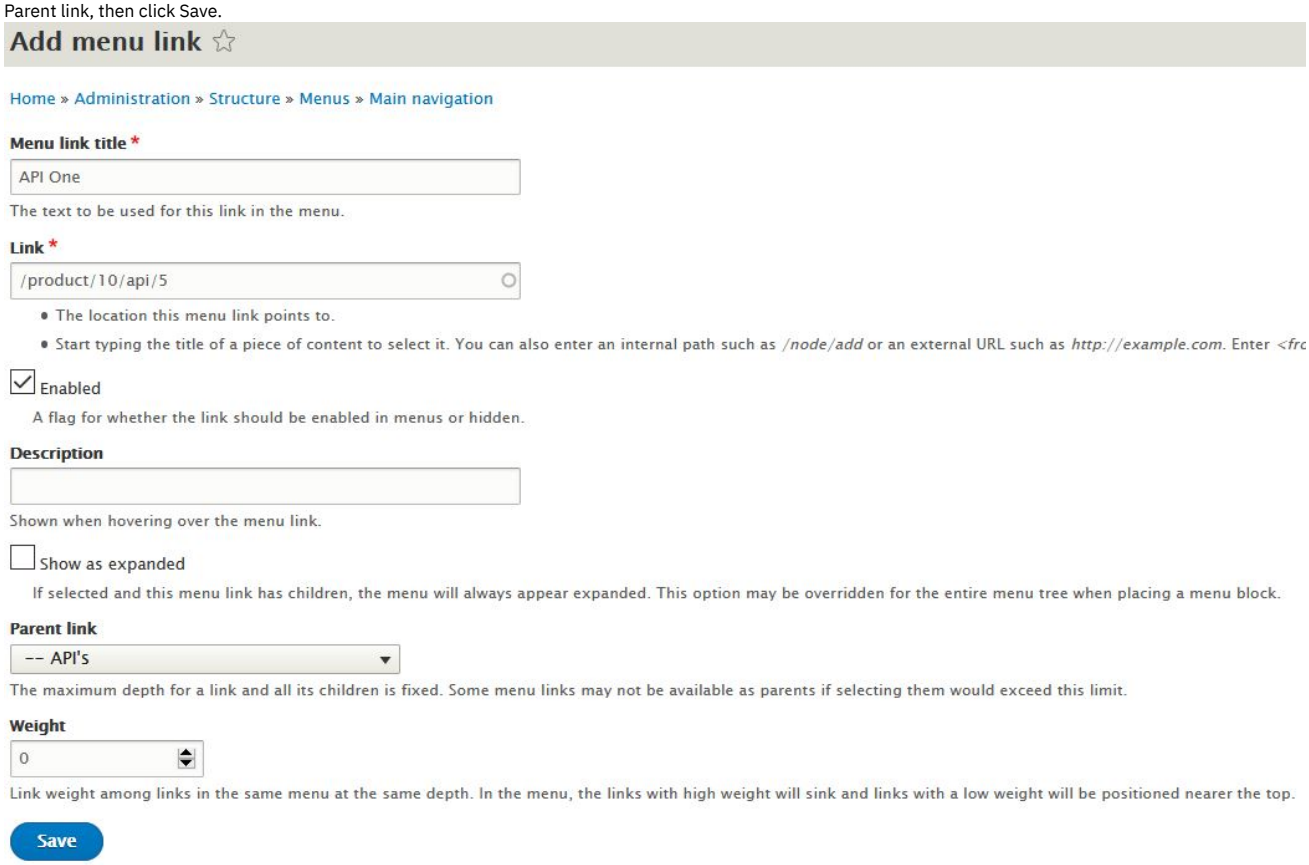
The front page **`Main navigation`** displays like this before the changes are made.



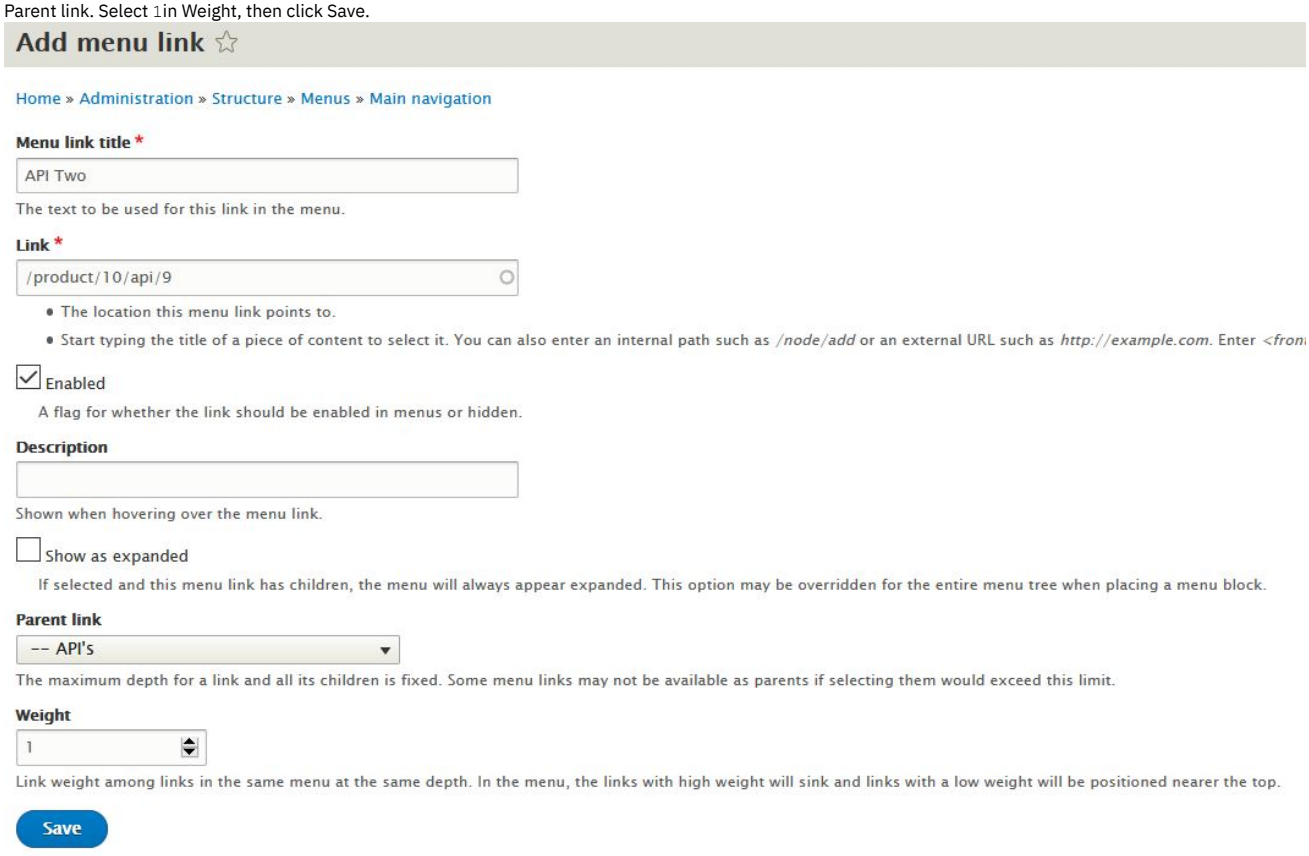
Add menu links to the main navigation menu

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.

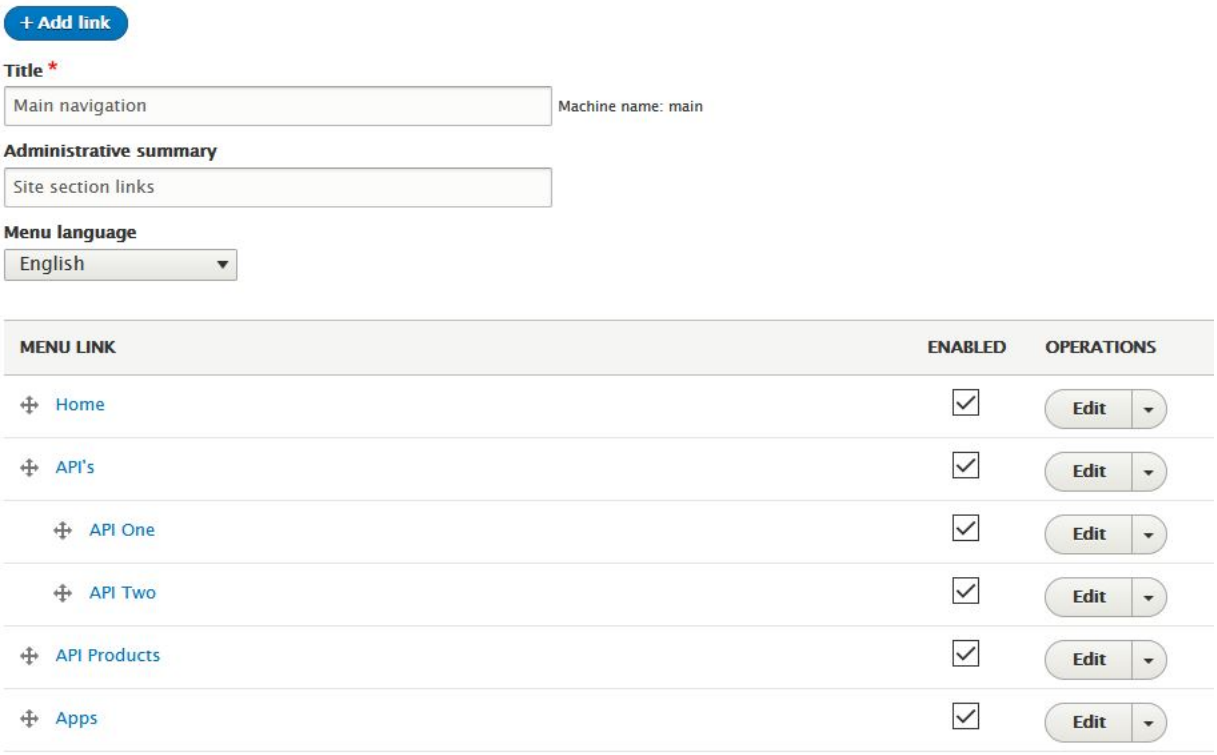
3. Navigate to Structure > Menus > Main navigation > Add link
4. Enter `API's` in the **`Menu link title`**. Enter `/api` in the **`Link`**. Check Show as expanded, then click Save.
   Note: Ensure Show as expanded is checked as this is the parent link for the submenu links.
5. Add another menu link to the main navigation menu. Enter `API One` in the **`Menu link title`**. Enter `/product/10/api/5` in the **`Link`**. Select -- API's in the Parent link, then click Save.



6. Add another menu link to the main navigation menu. Enter `API Two` in the **`Menu link title`**. Enter `/product/10/api/9` in the **`Link`**. Select -- API's in the Parent link. Select `1`in Weight, then click Save.



7. Navigate to Structure > Menus > Main navigation. The hierarchy of the menu links now looks like this:

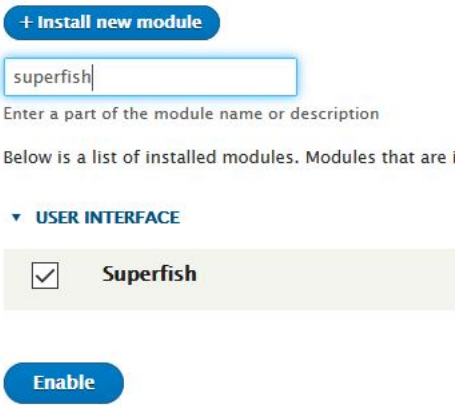


8. Navigate to the home page. The **`APIs`** menu link that you added to the main navigation menu does appear, but the submenus links don't expand when you hover over it.

Make the drop-down menu expand by using the Superfish module

To make the drop-down menu expand when you hover over it, you need to use the **`Superfish`** module and configure the **`Block Layout`**.

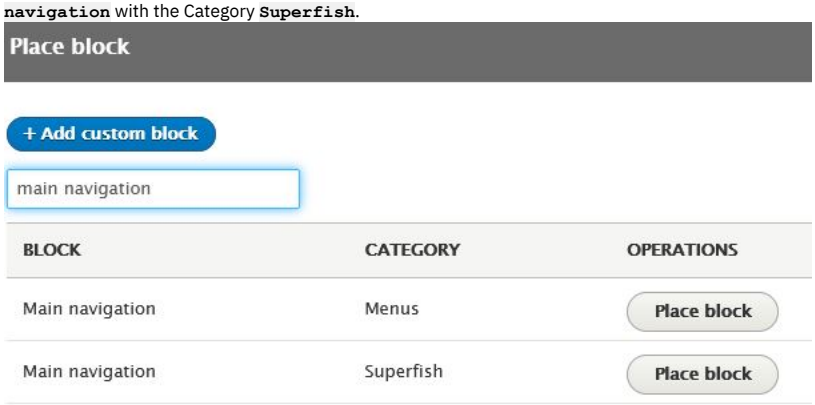
1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to Extend. Search for **`superfish`**, check the **`Superfish`** box, click Enable.



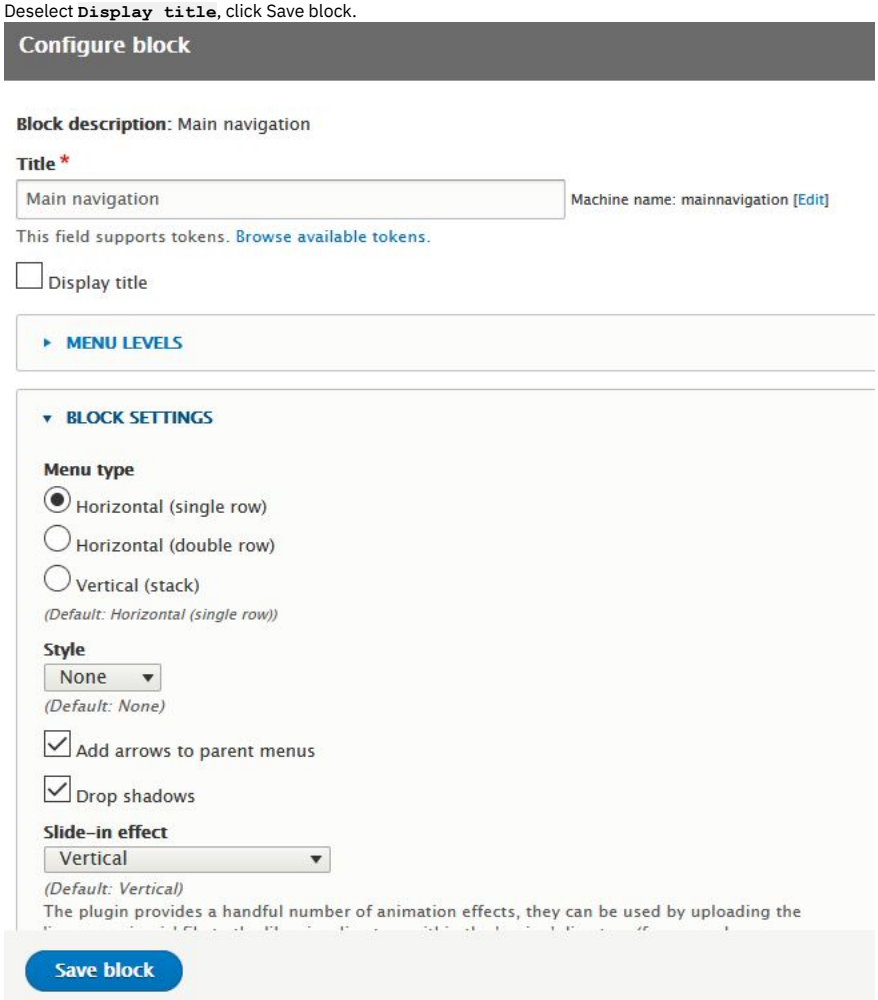
3. Navigate to Structure > Block layout.

4. Click Configure, and select Disable for the **`Main menu`** block.

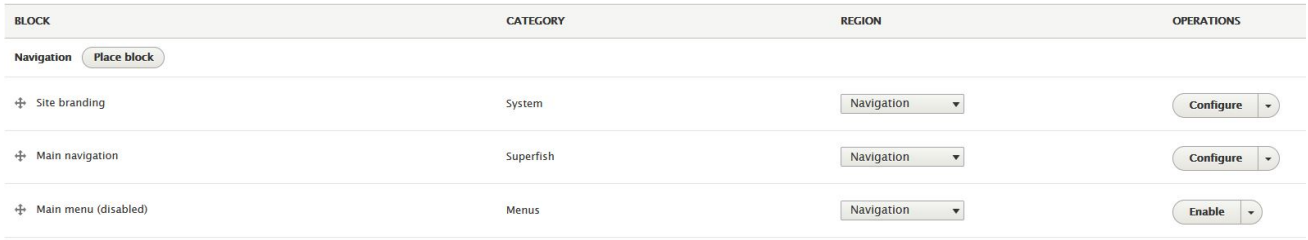
5. Click Place block for Navigation, Then search for `main navigation` in the box. The filtered results might show two or more options. Click Place block for the **`Main navigation`** with the Category **`Superfish`**.



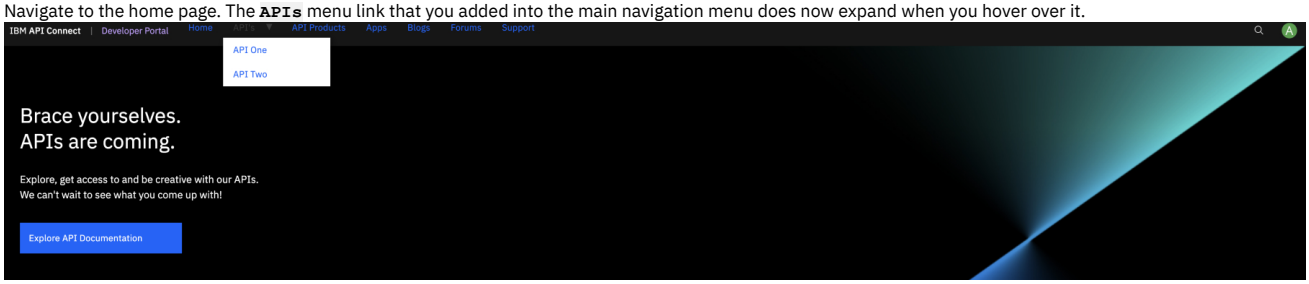
6. Deselect **`Display title`**, click Save block.



7. Drag **`Main navigation`** to be under **`Site branding`**.



8. Click Save blocks.
9. Navigate to the home page. The **`APIs`** menu link that you added into the main navigation menu does now expand when you hover over it.



What you did in this tutorial

You created a drop-down menu link on the **`Main navigation`** menu.

What to do next

You can consider any other uses of the drop-down menu to enhance your users experience on your Developer Portal.

Tutorial: Displaying blog posts on the front page

You can customize the appearance of the front page of your Developer Portal to display recent blog posts. You might use the blog posts to provide your users with information, such as service availability or marketing campaigns.

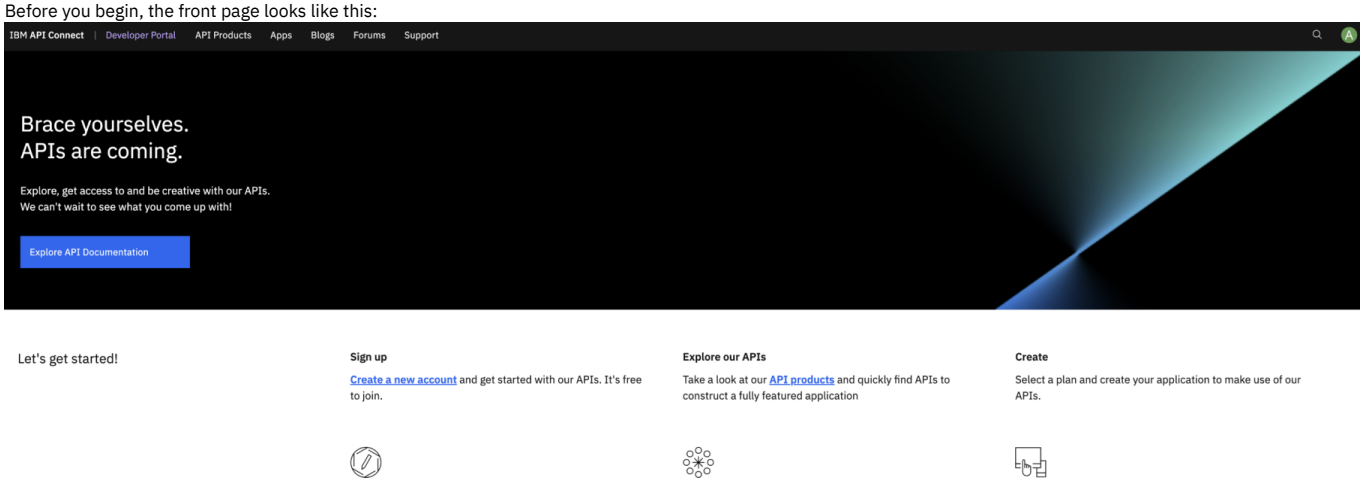
Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

About this tutorial

In this task, you create a view, customize that view to show blog posts, then embed that view on the front page of your Developer Portal site.

Before you begin, the front page looks like this:

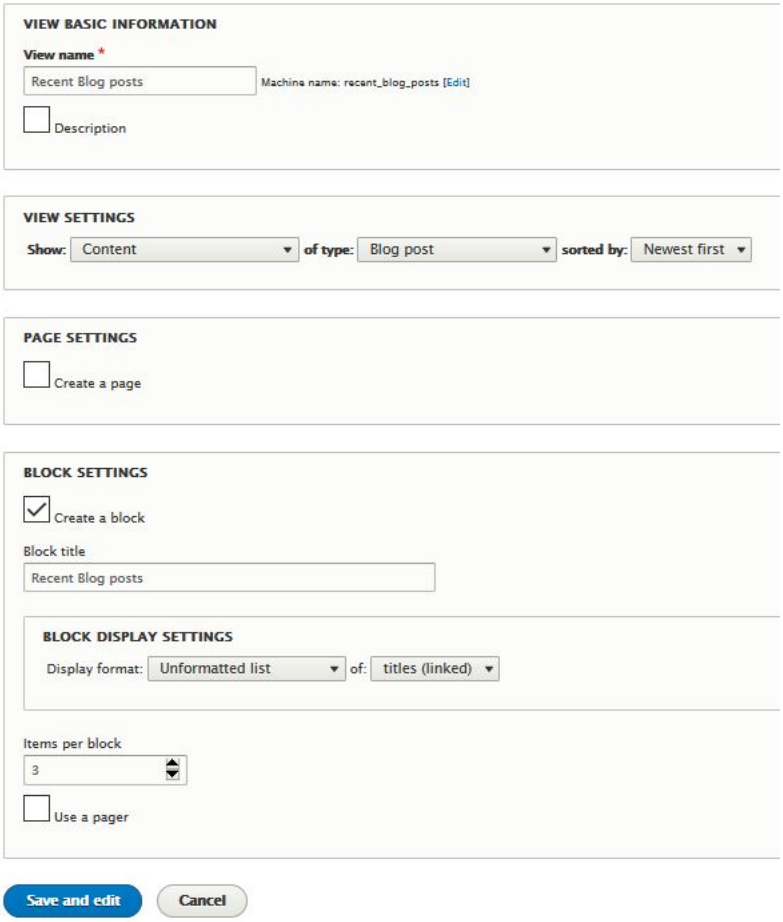


This tutorial takes you through the following steps:

1. Create a view.
2. Customize the view.
3. Embed the view on the front page of your Developer Portal.

Create a view

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Structure > Views > Add view.
4. In the **View name** block, enter a name for your view, for example Recent Blog posts.
5. Under **VIEW SETTINGS**, show **Content** of type **Blog Post** sorted by **Newest first**.
6. Check **Create a block** in **BLOCK SETTINGS**, and choose the number of blog posts that you want to be displayed.



7. Click Save and edit.

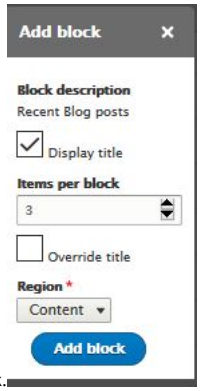
Customize the view

You are now on the page where you can edit your view.

1. If you are not on the edit view page, navigate to Structure > Views, find the name of the view that you created, and click Edit.
2. Click Unformatted list in the **Format** section.
3. Select **Bootstrap List Group**, then click Apply.
4. Select Content: Title in the **Title field** drop-down, then click Apply.
5. Click Save.

Embed the view on the front page of your Developer Portal

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to Structure > Pages.
3. Click **Edit** on the welcome page.
4. Click **Panels**, then **Content**.
5. Click +Add new block.
6. Select your new block, which is under **LISTS (VIEWS)**.



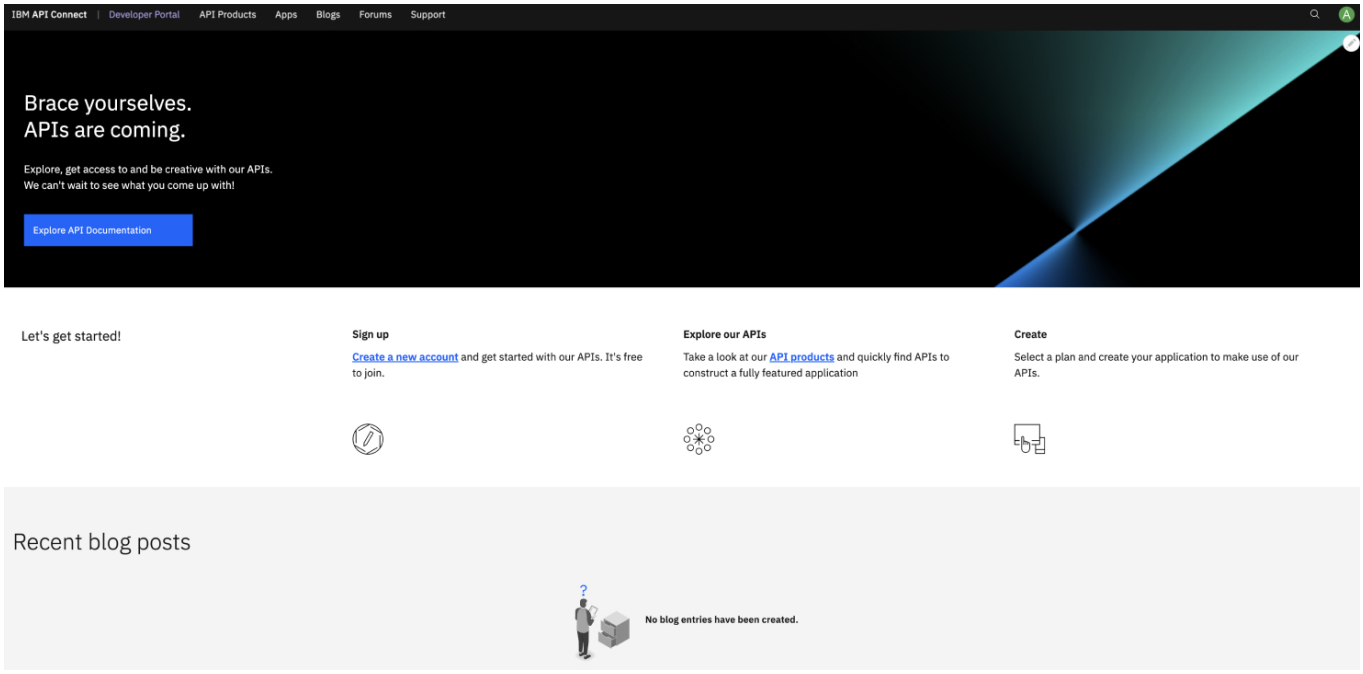
7. Select the number of **`Items per block`**, then click Add block.
8. You can now rearrange your view to be where you would like it on the front page.

LABEL	PLUGIN ID
Content	
Welcome Banner	block_content:2fcdb632-d4b9-44d9-b195-359e751966a1
Featured Content	featuredcontent
Recent Blog posts	views_block:recent_blog_posts-block_1
Getting Started	block_content:f2b7762b-97f4-4d51-b7dc-d6de5be6d0ce

9. Click Update and save.

What you did in this tutorial

You can check that the view you created appears on the front page of your site page.



What to do next

You can edit your view at any time by navigating to Structure > Views and selecting your view by its name. You can also modify or delete the view's layout on the front page by navigating back to the layout section of your page under Structure > Pages.

Tutorial: Displaying tweets on the front page

You can customize the appearance of the front page of your Developer Portal to display recent tweets. You might use the tweets to provide your users with information, such as service availability or marketing campaigns.

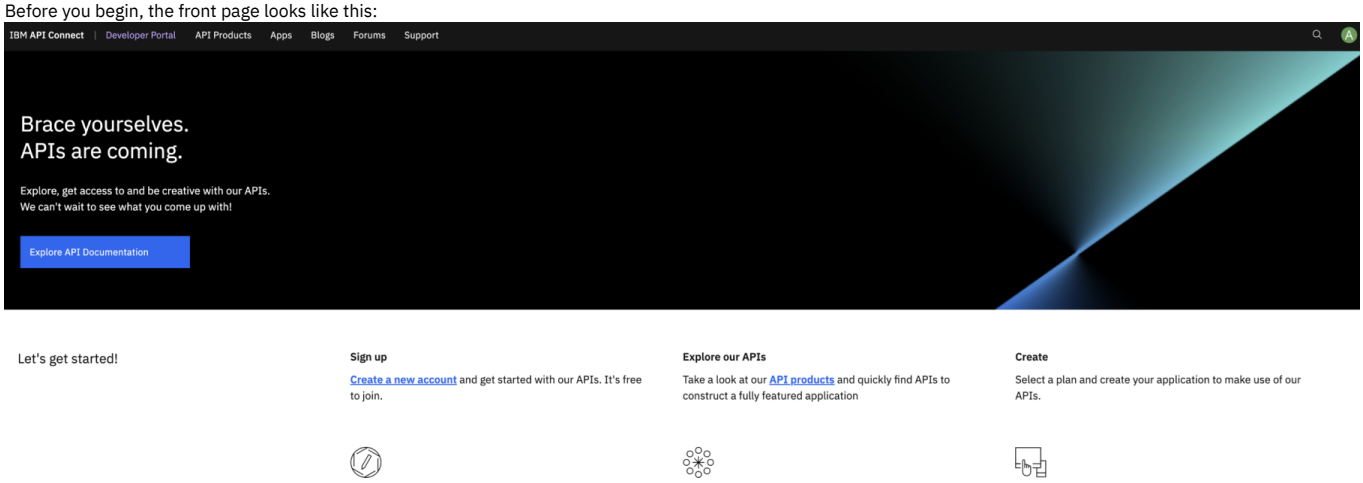
Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

About this tutorial

In this task, you create a view, customize that view to show tweets, then embed that view on the front page of your Developer Portal site.

Before you begin, the front page looks like this:

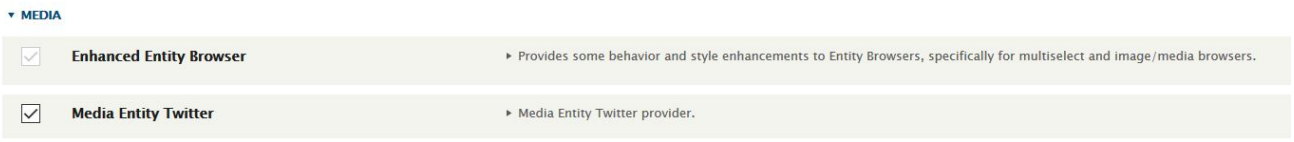


This tutorial takes you through the following steps:

1. Enable the Media entity Twitter module.
2. Create an entity called Twitter to store the tweets.
3. Add media items.
4. Create a carousel view.
5. Customize the carousel view.
6. Embed the carousel view on the front page of your Developer Portal.

Enable the `Media entity twitter` module

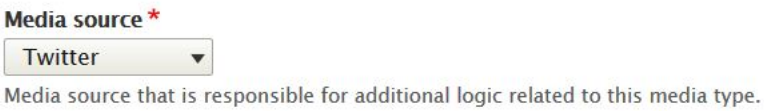
1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Extend, enter media in the search bar.
4. Check Media Entity Twitter, under MEDIA.



5. Click Enable.

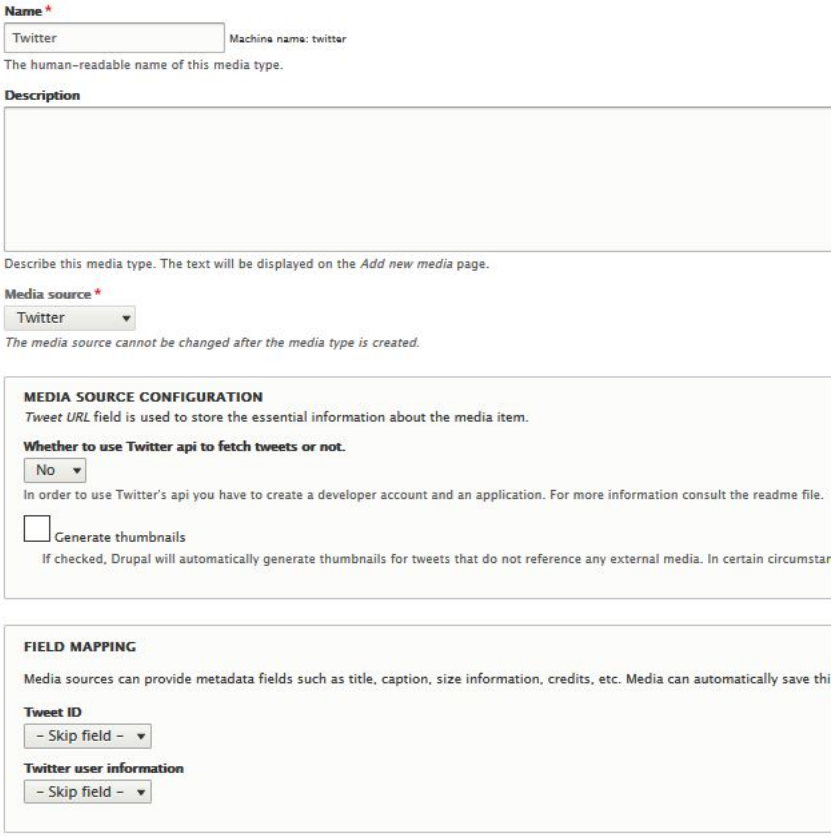
Create an entity called `Twitter` to store the tweets

1. Navigate to Structure > Media types > Add media type.
2. In the Name field, enter Twitter.

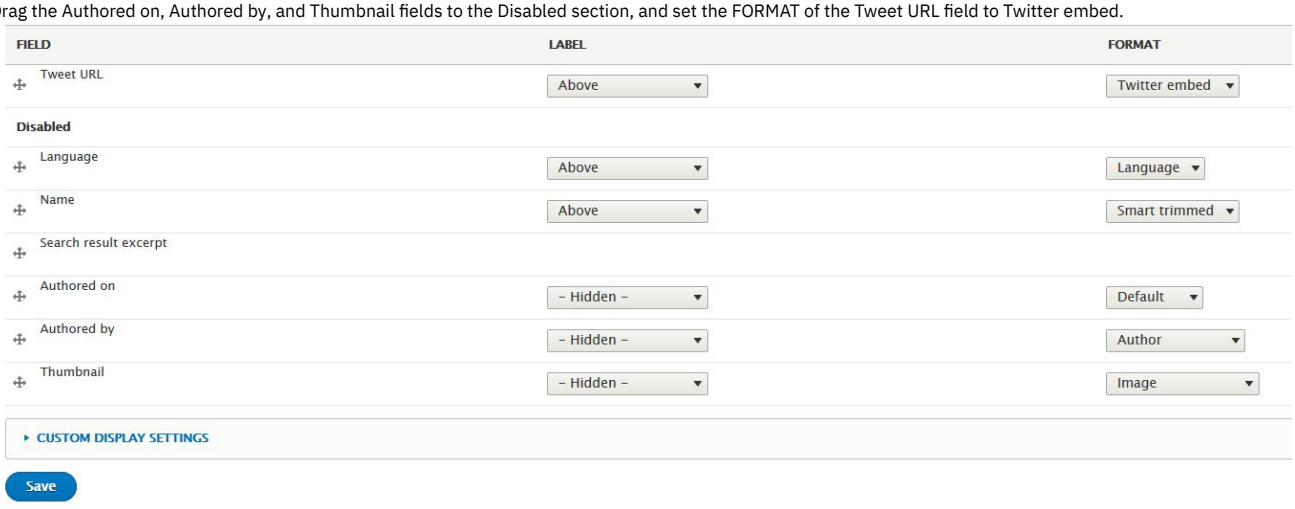


3. In the Media source drop-down, select Twitter.
4. Ensure that Whether to use Twitter api to fetch tweets or not value is set to No.

5. Ensure the values in the FIELD MAPPING section are set to - Skip field -.



6. Click Save.
7. Click Manage display from the Edit dropdown for the new `Twitter` media type.
8. Drag the Authored on, Authored by, and Thumbnail fields to the Disabled section, and set the FORMAT of the Tweet URL field to Twitter embed.

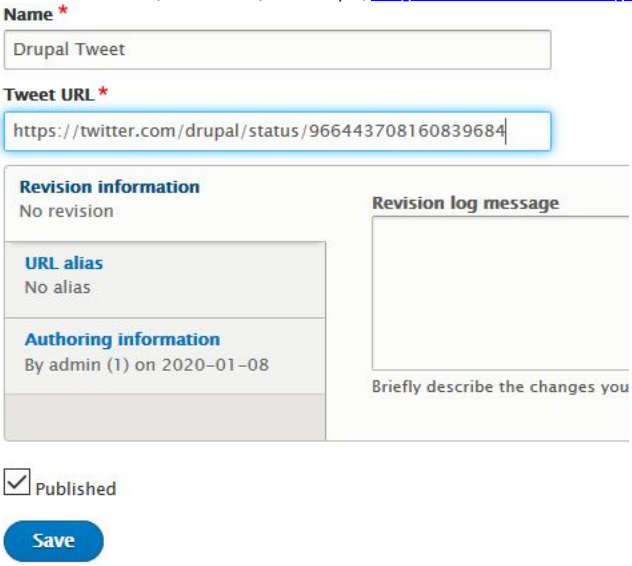


9. Click Save.

Add media items

1. Navigate to Content > Media > Add media > Twitter.
2. In the Name field, enter a name for the media, for example Drupal Tweet.

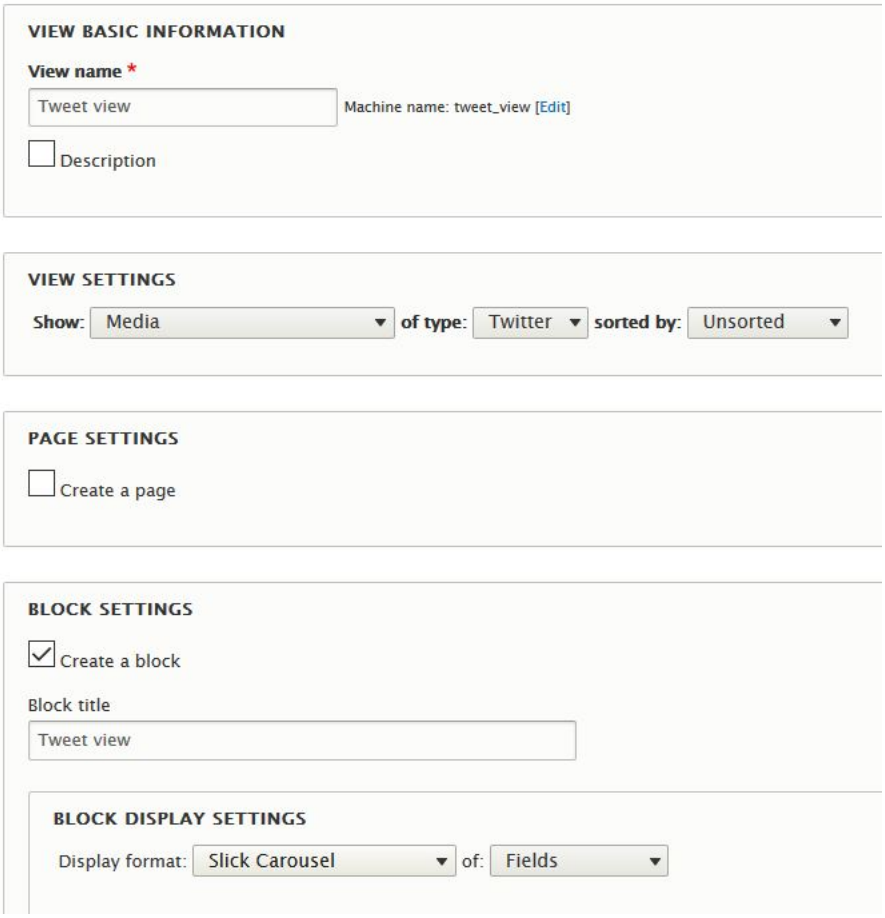
3. In the Tweet URL field, enter a URL, for example, https://twitter.com/drupal/status/966443708160839684.



4. Click Save.
5. Repeat these steps to add more tweets, you need at least 2 to make a carousel view.

Create a carousel view

1. Navigate to Structure > Views > Add view.
2. In the View name block, enter a name for your view, for example Tweet view.
3. Under VIEW SETTINGS, show Media of type Twitter sorted by Unsorted.
4. In the BLOCK SETTINGS, section check Create a block and ensure it is Display formatSlick Carousel of fields.

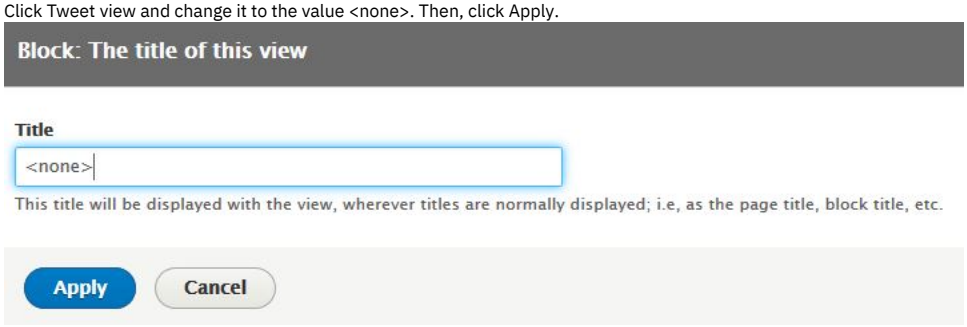


5. Click Save and edit.

Customize the carousel view

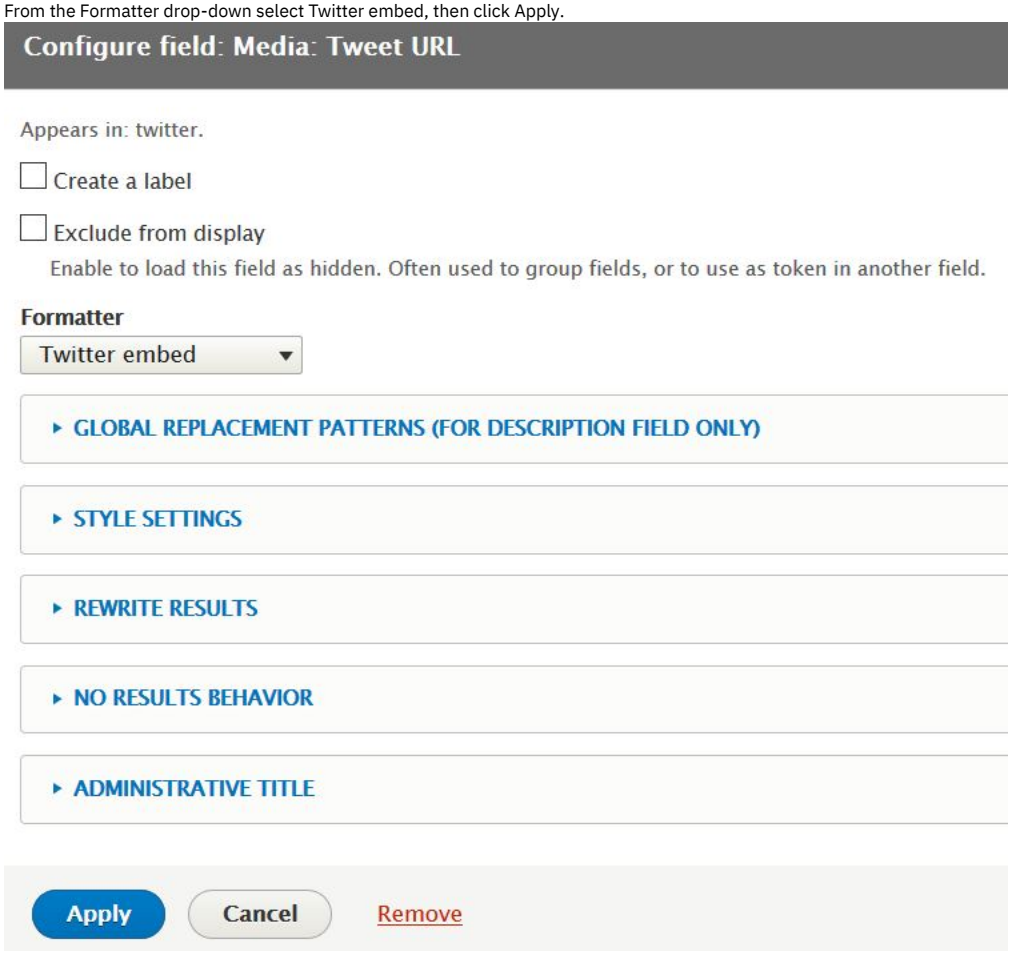
You are now on the page where you can edit your view.

1. If you are not the edit view page, navigate to Structure > Views, find the name of the view that you created, and click Edit.
2. Click Tweet view and change it to the value <none>. Then, click Apply.

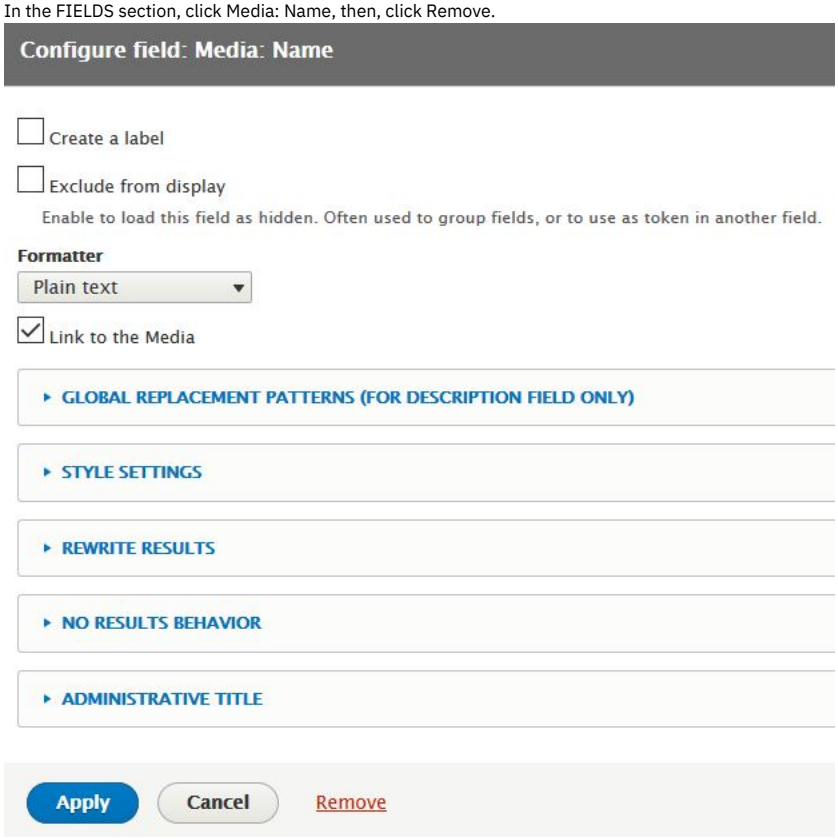


3. Click Add in the FIELDS section, then search for tweets, select the check box for Tweet URL. Then, click Add and configure fields.

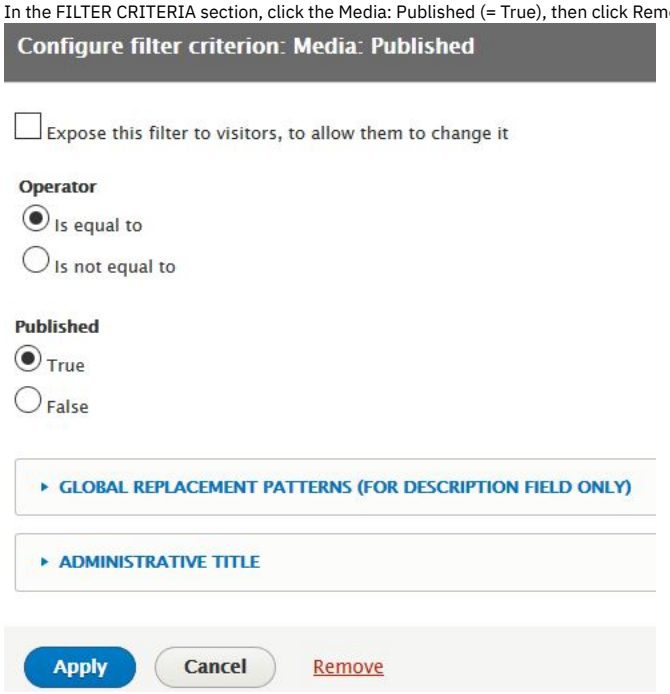
4. From the Formatter drop-down select Twitter embed, then click Apply.



5. In the FIELDS section, click Media: Name, then, click Remove.

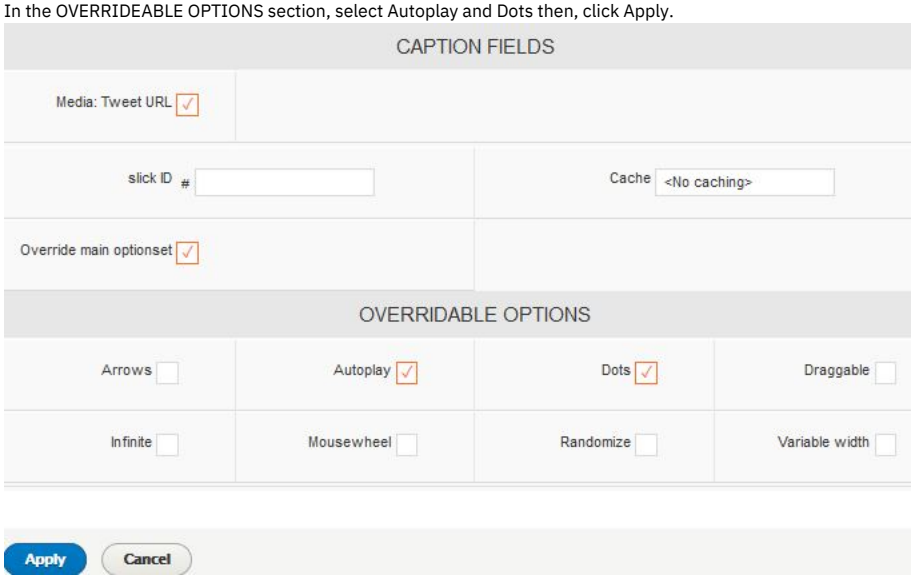


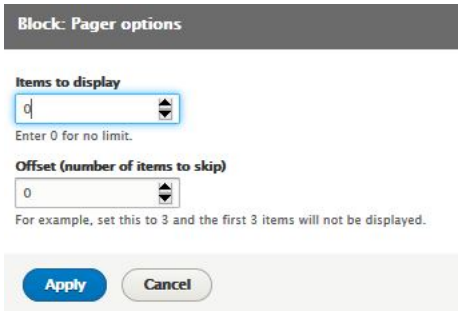
6. In the FILTER CRITERIA section, click the Media: Published (= True), then click Remove.



7. In the FORMAT section, click Settings next to Slick Carousel.
8. Set Skin Main to Default.
9. In the CAPTION FIELDS section, check Media: Tweet URL, and Override main optionset.

10. In the OVERRIDEABLE OPTIONS section, select Autoplay and Dots then, click Apply.

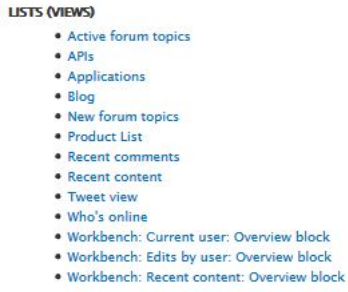




11. In the PAGER section, clickItems, set the field to 0 then, click Apply.
12. Click Save.

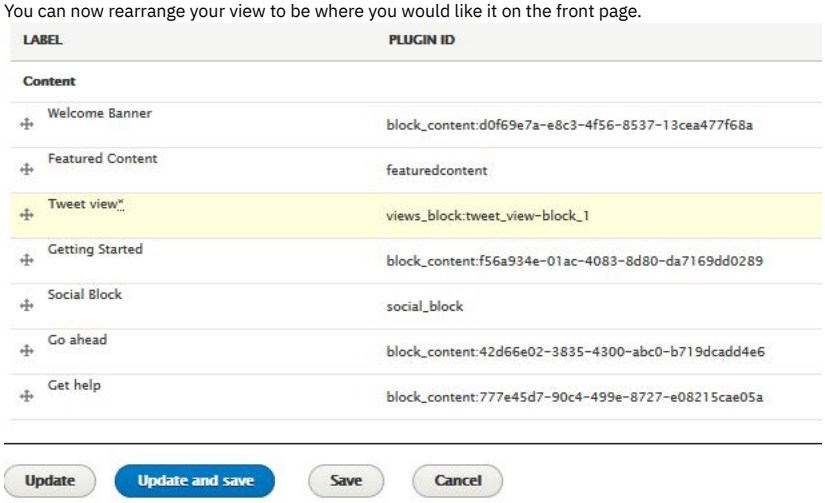
Embed the view on the front page of your Developer Portal

1. Navigate to Structure > Pages.
2. Click Edit on the welcome page.
3. Click Panels, then Content.
4. Click Add new block.



5. Select your new block, which is under LISTS(VIEWS).
6. Deselect Display title then, click Add block.

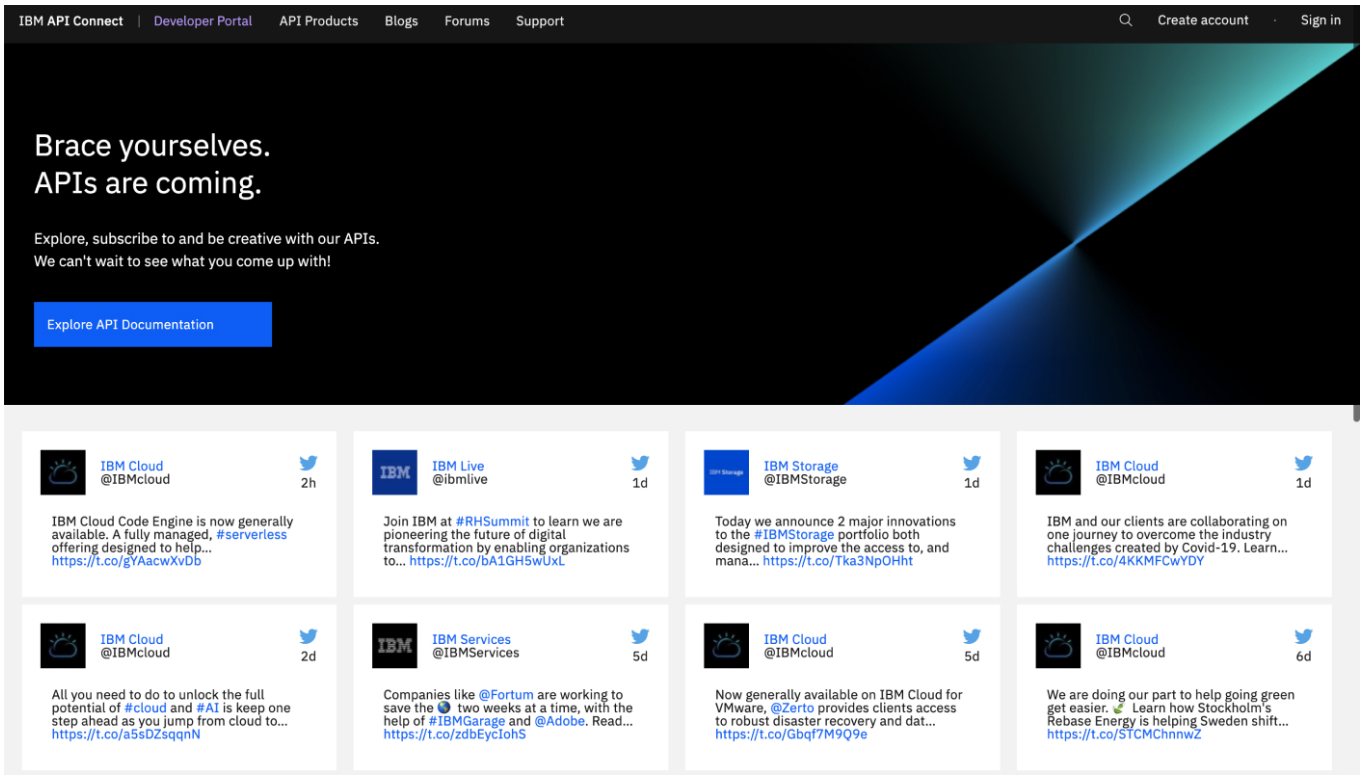
7. You can now rearrange your view to be where you would like it on the front page.



8. Click Update and save.

What you did in this tutorial

You can check that the view you created appears on the front page of your site page.



What to do next

You can edit your view at any time by navigating to Structure > Views and selecting your view by its name. You can also modify or delete the view's layout on the front page by navigating back to the layout section of your page under Structure > Pages.

You can also integrate your Twitter data dynamically. For more information, see the links below.

Tutorial: Changing the front page of your Developer Portal

You can create and arrange content in your Developer Portal to provide a front page that aligns with your brand, and helps your users discover your APIs.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

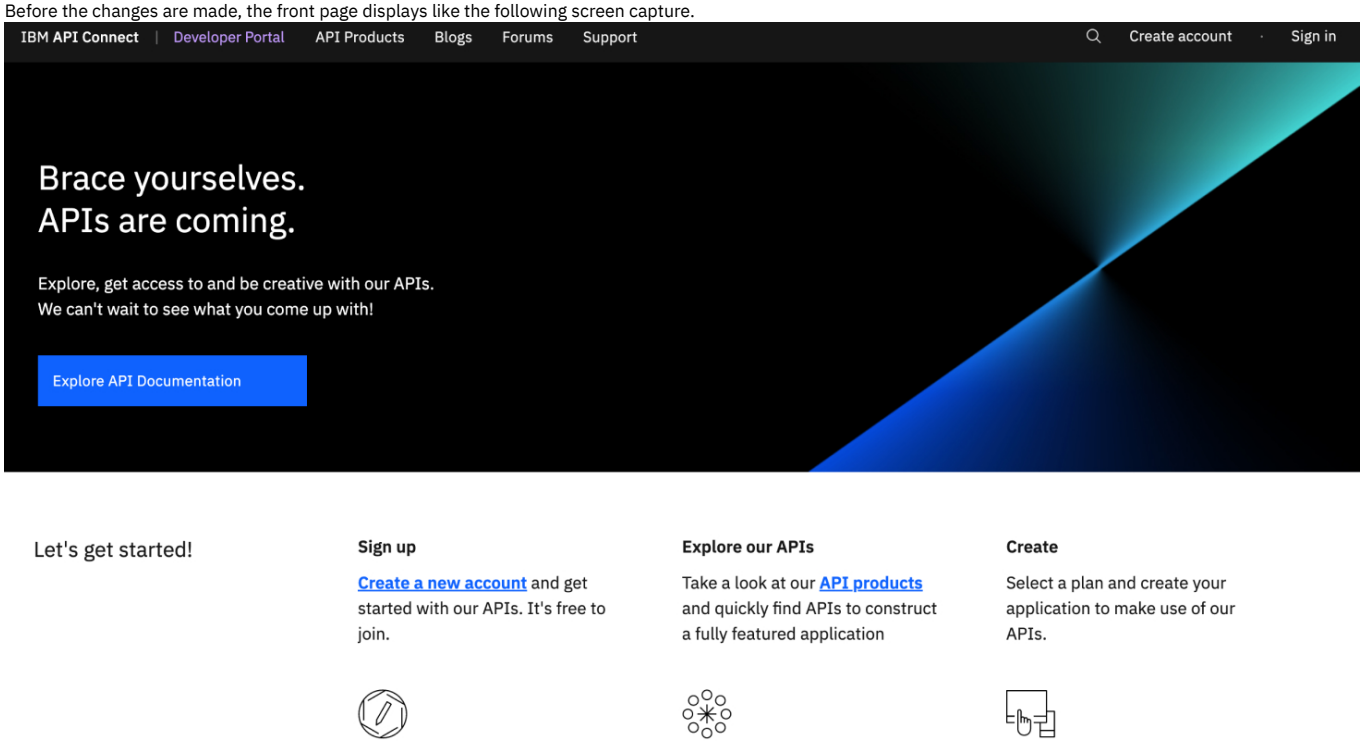
About this tutorial

In this tutorial, you create some content for a page, and then change the front page to be your new page.

This tutorial takes you through the following steps:

1. Creating some custom blocks.
2. Create and configure a page.
3. Adding the custom blocks to the page.
4. Changing the front page to be your new page.

Before the changes are made, the front page displays like the following screen capture.

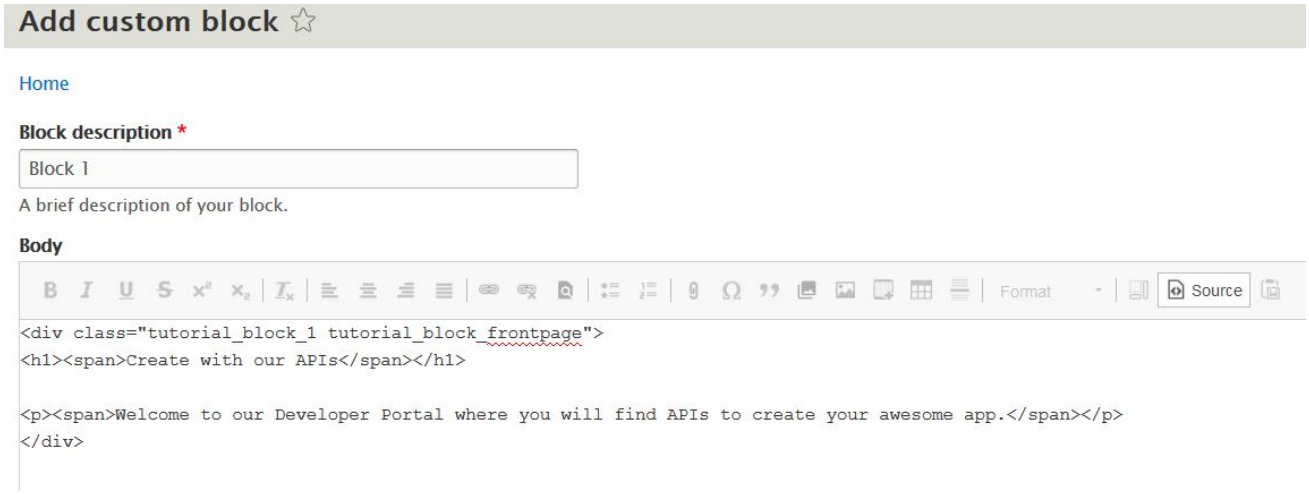


Creating some custom blocks

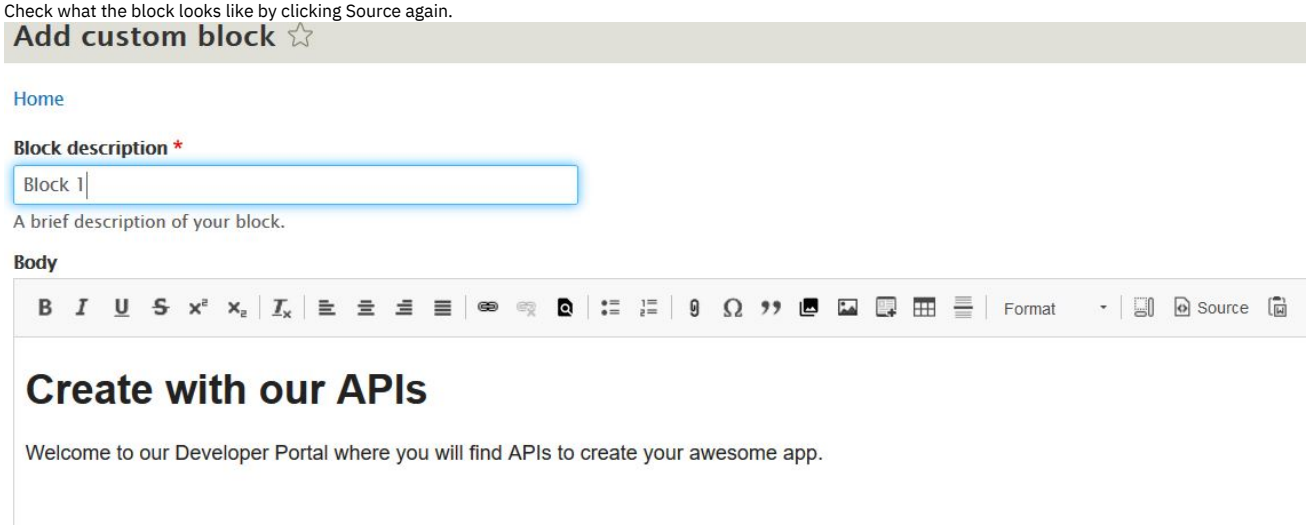
1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Structure > Block layout > Add custom block
4. Enter `Block 1` in theBlock description.
5. In the body area, click Source, then enter the following HTML:

```
<div class="tutorial_block_1 tutorial_block_frontpage">
<h1><span>Create with our APIs</span></h1>

<p><span>Welcome to our Developer Portal where you will find APIs to create your awesome app.</span></p>
</div>
```



6. Check what the block looks like by clicking Source again.



Note: This block uses no inline-styling, instead it allows your theme to decide how it is rendered. The advantage of this set up is that you can easily change the rendering without modifying existing content in the database. Any styling that is required can be added to a custom theme. For more information, see Tutorial: Creating a custom theme for the Developer Portal.

7. Click Save.
You have created `Block 1`, repeat steps 3 to 7 to create `Block 2`, `Block 3`, and `Block 4`.

8. Enter `Block 2` in the Block description. In the body area, click Source, then enter the following HTML:

```
<div class="tutorial_block_2 tutorial_block_frontpage">
<p class="text-align-center">Explore and subscribe to our APIs.<br />
See what you come up with!</p>

<p class="text-align-center"> </p>

<div class="bannerButtonRow text-align-center"><a class="button cta-btns--white__btn"
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.devportal.doc_product">Explore API
Documentation</a></div>
</div>
```

9. Enter `Block 3` in the Block description. In the body area, click Source, then enter the following HTML:

```
<div class="tutorial_block_3">
<p class="text-align-center"><a
href="#_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.4_com.ibm.apic.devportal.doc_user_register">Create a new
account</a> and get started with our APIs. It's free to join.</p>
</div>
```

10. Enter `Block 4` in the Block description. In the body area, click Source, then enter the following HTML:

```
<div class="block-get-help">
<div class="get_help">
<div class="column col1">
<h3>Getting Help</h3>

<div>Be sure to check out these extra help resources.</div>
</div>

<div class="column col2">
<h4>Get Started</h4>

<div>Get started with our APIs by creating an account and exploring the documentation to find what's right for you.</div>
```

```

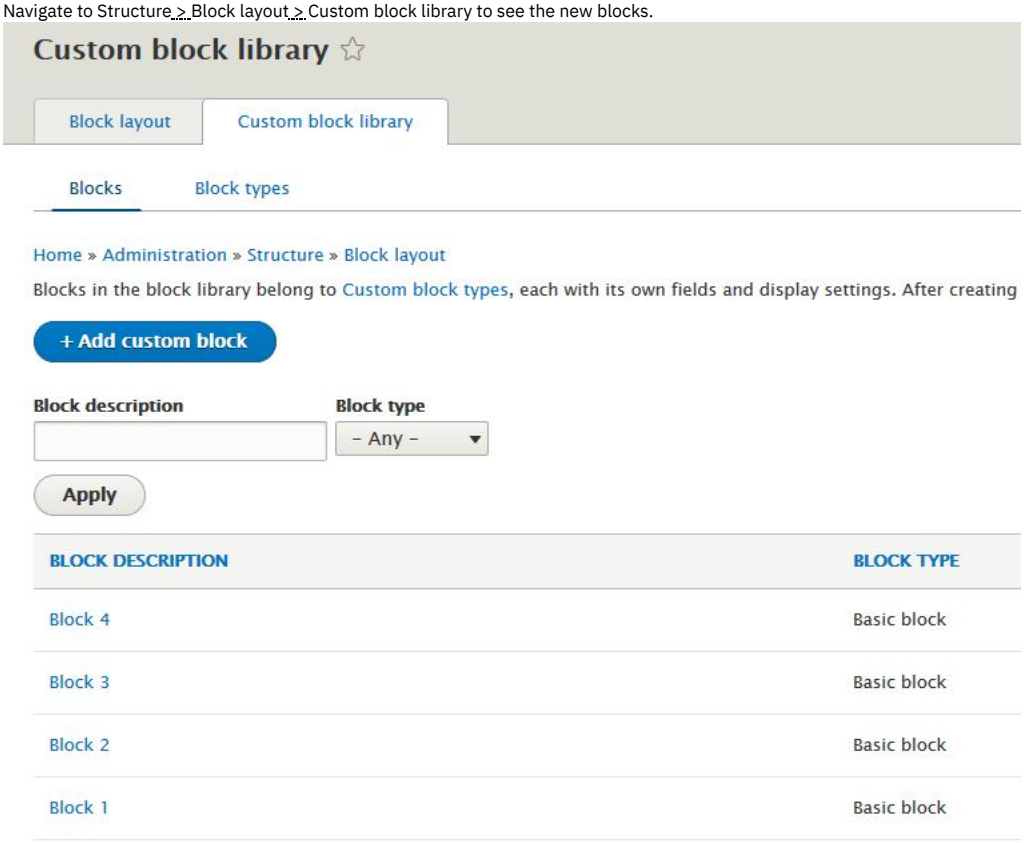
```

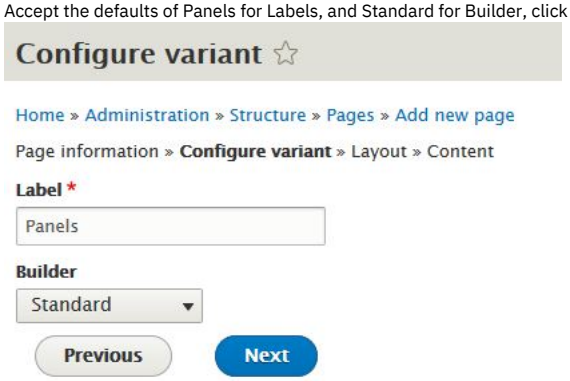
11. Navigate to Structure > Block layout > Custom block library to see the new blocks.



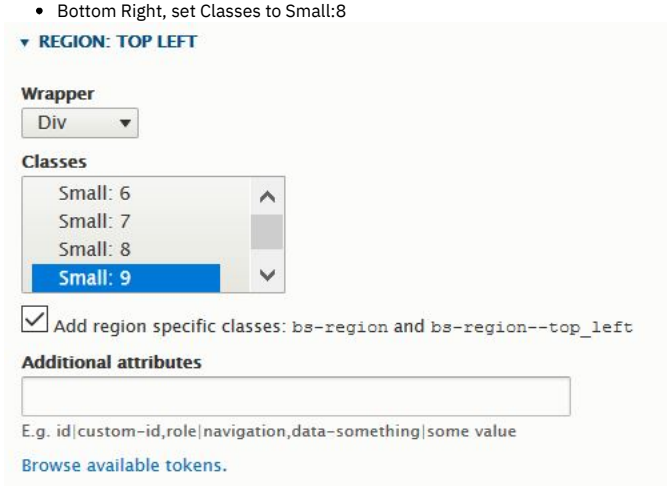
Create and configure a page

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to Structure > Pages, clickAdd page.

3. Enter `Portal home` in the Administrative title field.
4. Enter `newhome` in the Path field.
5. Select **`Panels`** in the Variant title drop-down.
6. Leave other fields clear.
7. Click Next.
8. Accept the defaults of Panels for Labels, and Standard for Builder, click Next.



9. Select Two column bricks from Layout drop-down. Click Next.
10. Keep all settings except for the following:
    - Top Left, set Classes to Small:9
    - Top Right, set Classes to Small:3
    - Bottom Left, set Classes to Small:4
    - Bottom Right, set Classes to Small:8

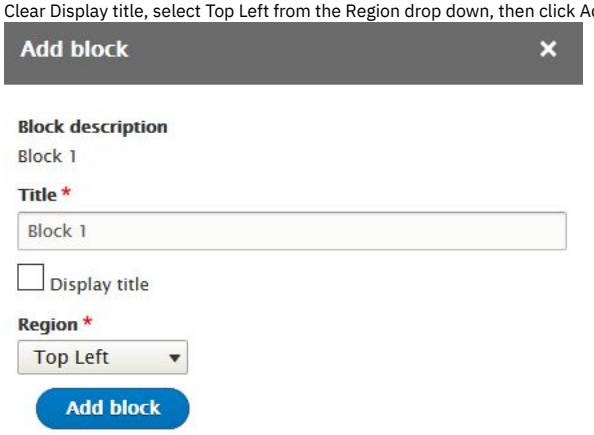


11. Click Next.

Adding the custom blocks to the page

1. Leaving Page title blank, click Add new block.
2. Select Block 1 from the Custom block list.

3. Clear Display title, select Top Left from the Region drop down, then click Add block.



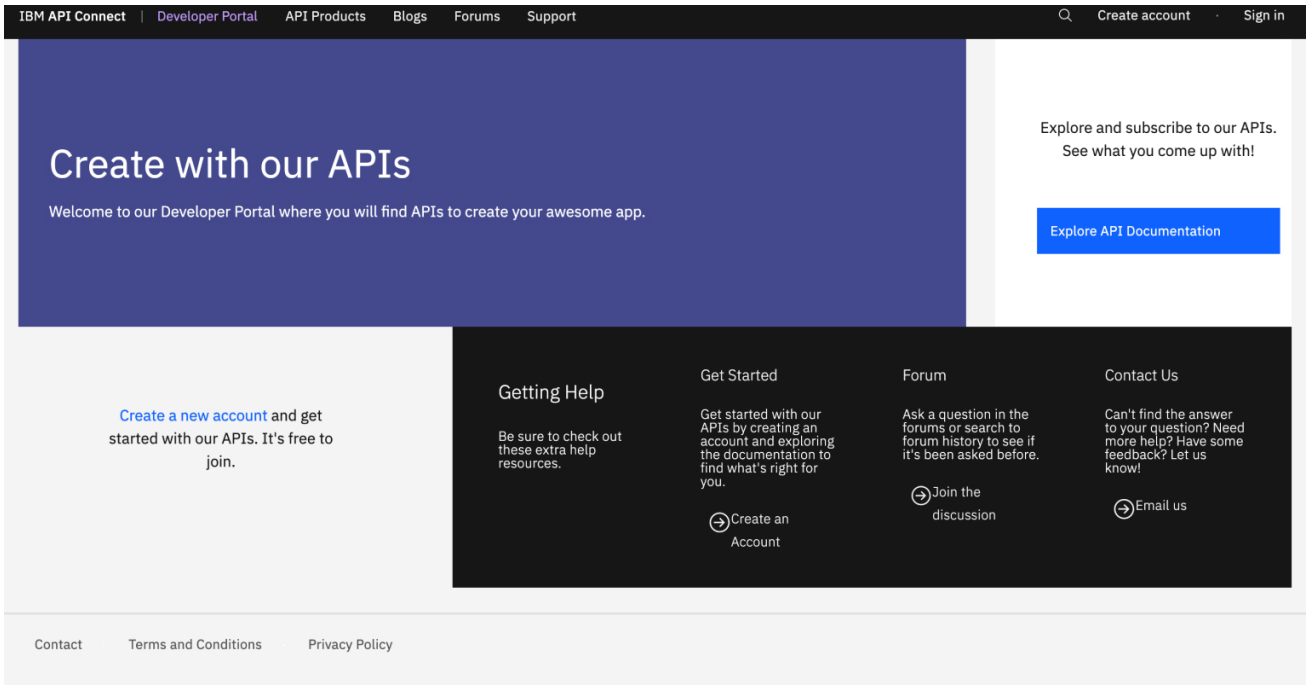
You added Block 1, repeat steps 1 to 3 to add Block 2, Block 3, and Block 4.

4. For Block 2 select region Top Right.
5. For Block 3 select region Bottom Left.
6. For Block 4 select region Bottom Right.
7. ClickFinish.
8. Click Update and save.

Changing the front page to be your new page

Note: In this tutorial, you create a new page and swap it with the default. If errors are made, the default page is still available as a backup.

1. Navigate to Structure > Pages.
2. Click the newhome URL link for your new Portal home page, check that your page looks as designed.



3. Navigate to Configuration > System > Basic site settings
4. In Front Page region set Default front page field tonewhome .
5. Click Save configuratoin.

What you did in this tutorial

The front page of your Developer Portal is now changed and laid out with the blocks of content that you specified.

What to do next

You can add further branding by adding content to your custom blocks such as images, or try to use one of the provided custom blocks such as the Featured Content Block. By default this block is English, you might want to consider adding versions in other languages.

Tutorial: Grouping products by category

You can configure the Developer Portal so that products are displayed in groups according to the category that they are tagged with.

You can use the **`Views`** module to fetch content from your Developer Portal site, such as lists of products, and present the content to users in different formats. You can combine multiple views on a new page to display whatever content you want.

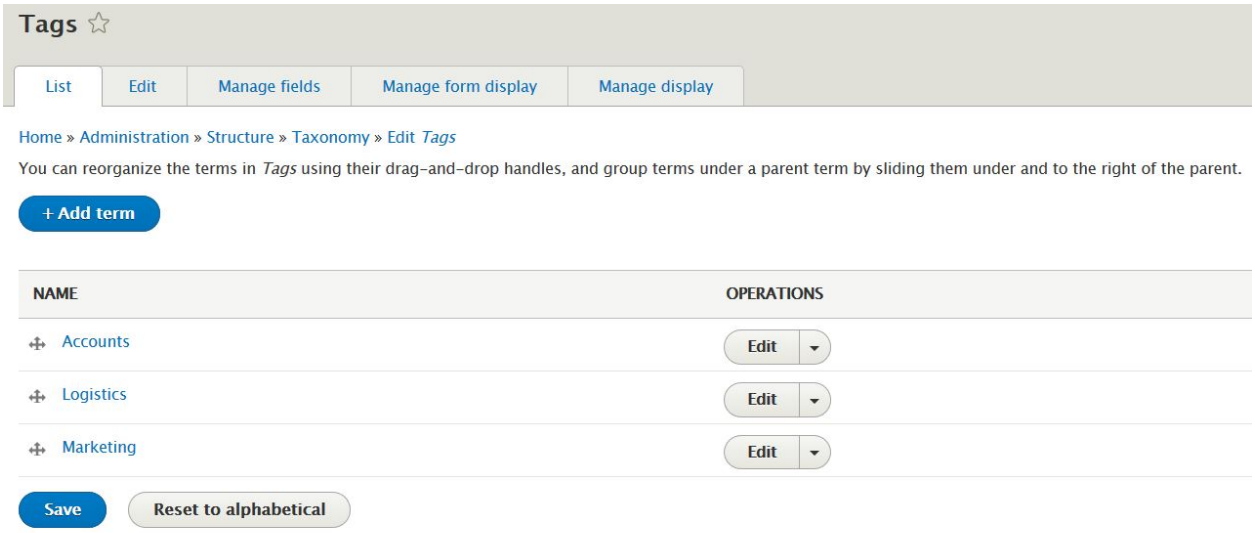
Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

About this tutorial

In this tutorial you create three views in the Developer Portal, each one is configured to display a list of products according to their category. You then create a new page to show the views, where you see products that are grouped by category.

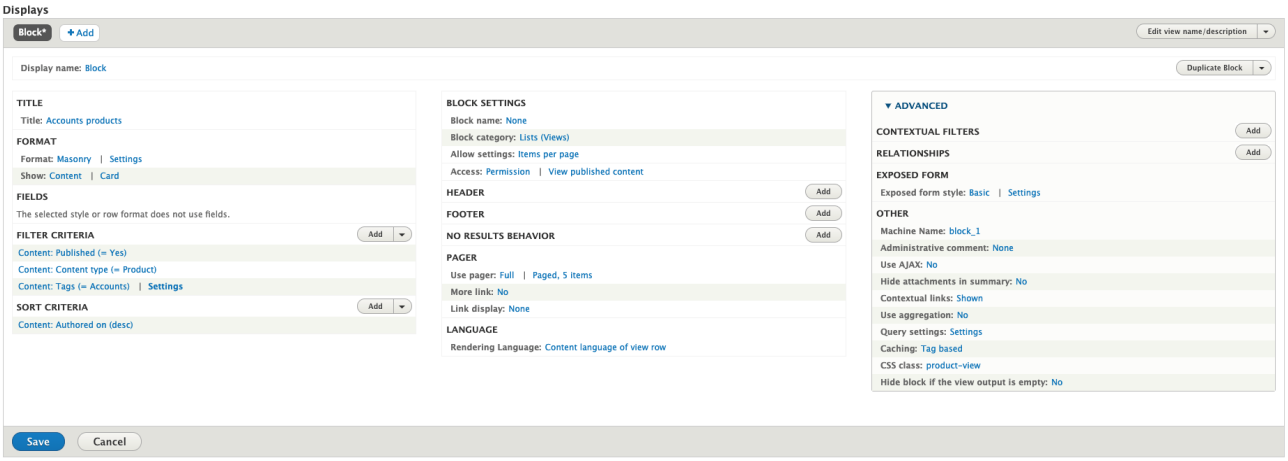
1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Create three new taxonomy tags.
    a. Navigate to Structure > Taxonomy > Tags.
    b. Click **`Add term`**.
    c. Enter `Accounts` in the **`Name`** field and click **`Save`**.
    d. Enter `Logistics` in the **`Name`** field and click **`Save`**.
    e. Enter `Marketing` in the **`Name`** field and click **`Save`**.
    f. Navigate to Structure > Taxonomy > Tags to show the list of the new tags.



4. Create a view to display products with the **`Accounts`** category.
   a. Navigate to Structure > Views > Add new view.
   b. Enter `Accounts products` in the **`View name`** field.
   c. In **`View Settings`**, select **`Show`**: **`Content`**, **`of type`**: **`Product`**, **`sorted by`**: **`Newest first`**, from the drop-down lists.
   d. In **`Page settings`** leave the **`Create a page`** cleared.
   e. In **`Block settings`** select **`Create a block`** and enter `Accounts products` in the **`Block title`**.
   f. Ensure **`Block Display Settings`** has **`Display format`**: **`Masonry`**, **`of`**: **`tiles (linked)`**, and select **`Use a pager`**.

   g. Click **`Save and edit`**.
5. Configure the view block settings.
   a. Under the **`Format`** section click the **`Fields`** link next to the **`Show`** label.
   b. In the dialog box, select the **`Content`** radio button then click **`Apply`**.
   c. Select **`Card`** from the **`View mode`** drop-down list, then click **`Apply`**.
   d. Click **`Add`** next to the **`Filter Criteria`** section.

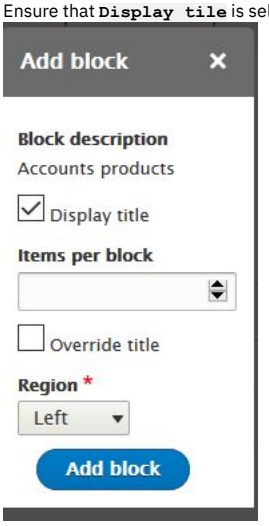
e. In the dialog box, search for `tag` then select the option **`Tags (apic_tags)`** from the list then click **`Add and configure filter criteria`**.
f. In the next dialog box, select the **`Tags`** radio button and the **`Client-side hierarchical`** then click **`Apply and continue`**.
g. Next set the **`Operator`** to **`Is all of`**, and from the **`Select terms from vocabulary Tags`** drop-down select **`Accounts`** and click **`Apply`**.
h. Under the **`Advanced`** options, click the **`None`** link next to the **`CSS class`** label.
i. If you are using the default API connect theme, then enter the CSS class name **`product-view`** and click **`Apply`**. If you have your own css class that you want to use, then enter its name in here instead.
j. Click **`Save`** to save all the changes.



6. Create a view for the Logistics products.
   a. Select Structure > Views.
   b. Navigate to the **`Accounts products`** view and select the **`Duplicate`** option.
   c. Give the duplicated view the name **`Logistics products`** and click **`Duplicate`**.
   d. Click the Title **`Accounts products`** and change it to **`Logistics products`** and click **`Apply`**.
   e. Under the **`Filter Criteria`** section click the **`Content: Tags: (=Accounts)`** link.
   f. Change the value in the **`Select terms from vocabulary Tags`** drop-down to **`Logistics`** and click **`Apply`**.
   g. Click **`Save`** to save all the changes.
7. Repeat step 6 for Marketing products.
8. Next, create a page to display the views.
   a. Select Structure > Pages.
   b. Click **`Add page`**.
   c. Enter `Products by category` in the **`Administrative title`**, and `products-by-category` in the **`Path`**. Select the **`Panels`** option from the **`Variant type`** drop-down list then click **`Next`**.

   d. Change the **`Label`** value to `Products grouped by category` and set the **`Builder`** to **`Standard`** then click **`Next`**.
   e. From the **`Layout`** drop-down list select the value **`Three column`** then click **`Next`**.
   f. Leave all the defaults on the next page and click **`Next`**.
   g. Click **`+Add new block`**.
   h. Select **`Accounts products`** from the **`Lists (views)`** section.

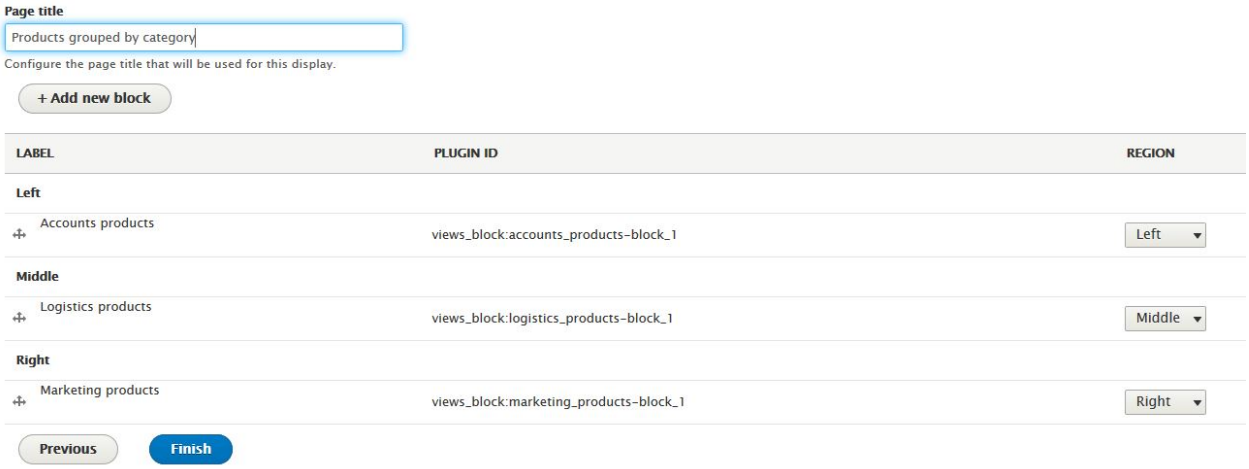
i. Ensure that **`Display tile`** is selected and **`Region`** is set to **`Left`**, click **`Add block`**.



j. Click **`Add new block`**. Select **`Logistics products`** view from the list and set the **`Region`** to **`Middle`**, click **`Add block`**.

k. Click **`Add new block`**. Select **`Marketing products`** view from the list and set the **`Region`** to **`Right`**, click **`Add block`**.

l. Enter `Products grouped by category` in the **`Page title`** field, and click **`Finish`**.



9. From your API Manager, create three new products, or update existing ones, to give each one a category value of either Accounts, Logistics, or Marketing. Publish each of the products to the catalog with the configured Developer Portal.
10. Check that the **`Products grouped by category`** page shows your published products by category.
    a. Select Structure > Pages.
    b. Click the **`/products-by-category`** path link.
    c. You are redirected to the **`/products-by-category`** page and can see the products that you assigned to these categories.

What you did in this tutorial

You created three new views in the Developer Portal, and configured each one to display a list of products according to their category. You then created a new page to show the views.

Tutorial: Adding a field to the sign up form

You might want to collect and store additional information about your Developer Portal users. For example, you might want to collect a department name, employee ID, or similar data when a user registers for an account on the portal.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

About this tutorial

In this tutorial, you will add a Department code field to the Sign up form. This field is required for all portal users.

This tutorial takes you through the following steps:

1. Adding a field to a user entity.
2. Adding the new field to the Sign up form.
3. Testing the new field.

Adding a field to a user entity

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Configuration > People > Account settings > Manage fields

You are on the **`Manage fields`** tab.

1. Click **`+ Add field`**.
2. In the **`Select a field type`** dropdown, select **`Text (plain)`**.
3. In the **`Label`** field enter, **`Department code`**.
4. Click **`Save and continue`**.

You are on the **`Field settings`** tab.

1. Accept the defaults of **`Maximum length`** (255) and **`Allowed number of values`** (Limited:1).
2. Click **`Save field settings`**.

You are on the **`Edit`** tab.

1. Add some help text. This is information that is displayed to the user to assist them completing the field on a form. Examples or links to further information are useful here. We are going to add an example in this tutorial.
2. Add **`Example department code: DEP123.`** into the **`Help text`** field.
3. Check the **`Required field`**.
4. Click **`Save settings`**.

The field has now been created. You are back on the **`Manage fields`** tab.

1. Check that **`Department code`** is a listed field.

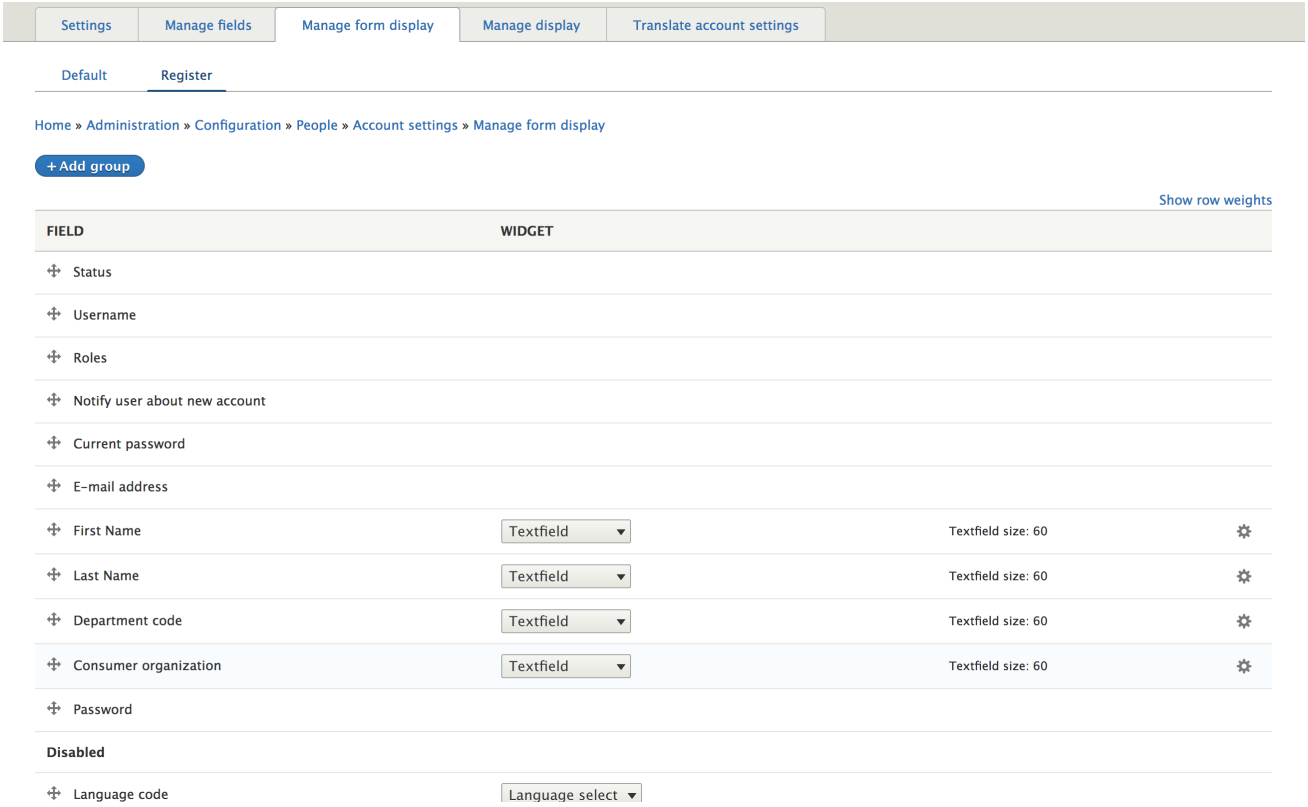
Adding the new field to the Sign up form

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to Configuration > People > Account settings > Manage form display

You are on the *Manage form display* tab. These tabs, one for each form, show the fields that are displayed from the user entity, and in which order.

1. Switch to the **`Register`** tab. Notice that initially the new **`Department code`** field is underneath the **`Disabled row`** in the page. This means that it isn't shown on the form.

2. Click the Department code icon and drag it so that it is between Last name and Consumer organization in the list.



3. Click Save.

Testing the new field

1. Sign out as the Admin user.
2. Click **`Create account`**.
3. Observe that the **`Department code`** field is now part of the sign up form.

What you did in this tutorial

You added a Department code field to the Sign up form, then tested the form to ensure that the **`Department code`** field is now part of the sign up form.

In reality, you would need to add this configuration in such a way that it is available for all sites. To achieve this you would include the configuration in your custom module. For more information, see this Drupal documentation.

You might want to add extra validation to the Department code field on the Sign up form. For more information, see Tutorial: Adding validation to a field on the sign-up form.

Tutorial: Adding validation to a field on the sign-up form

You might want to add extra validation to a field to help your Developer Portal users. For example, you might want to validate a department name, employee ID, or similar data when a user registers for an account on the portal.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. You must have completed the tutorial about Adding a field to the sign up form, where you added a Department code field to the Sign-up form.

About this tutorial

In this tutorial, you add some validation to the Department code field on the Sign-up form. This is a required field for all portal users and is a string of the format **`DEPnnn`**, where **`DEP`** is the string prefix and **`nnn`** is a three-digit number, for example, **`DEP123`**. The validation is done by using a custom module that is already available in IBM APIC Portal - addons. However, for more information, see Custom module development: creating a module skeleton.

This tutorial takes you through the following steps:

1. Cloning and packaging the validation module.
2. Installing and enabling the validation module.
3. Testing the validation in the sign up form.

Look at the files we will use in this link IBM APIC Portal - addons.

- user_field_example.info.yml - this is the metadata for the module, defining things like the name and version, and containing other important information that is required by Drupal to import and enable the module.

```
name: 'IBM APIC Portal - user field example'
type: module
description: 'IBM API Connect Developer Portal tutorial - Example of validating a custom user field'
package: 'Custom'
core_version_requirement: ^8 || ^9
version: 1.0.0
project: 'user_field_example'
dependencies:
  - ibm_apim
  - auth_apic
```

- user_field_example.module - this contains a validation function and adds this to the Sign-up form by using the `hook_form_alter` function.

```
<?php
use Drupal\Core\Form\FormStateInterface;

/**
 * Implementation of hook_form_alter() to alter the Sign up form
 */
function user_field_example_form_alter(&$form, FormStateInterface $form_state, $form_id) {
  if ($form_id === 'user_register_form' ) {
      $form['#validate'][] = 'user_field_example_validate_department_code';
  }
}

/**
 * Validate the Department code field on the Sign up form.
 *
 * Valid entry = DEPnnn
 *   where n = single figure digit.
 */
function user_field_example_validate_department_code($form, &$form_state) {
  $dept_code = $form_state->getValue('field_department_code')[0]['value'];
  $valid = preg_match('/^DEP\d{3}$/', $dept_code);
  if (!$valid) {
    $form_state->setErrorByName('field_department_code', t('Invalid department code.'));
  }
}
```

Cloning and packaging the validation module

Validation is added to the **Department code** field on the Sign-up form by using a custom module.

1. Clone the custom module. Here is an example command if you are using Mac and Linux:

   ```
   git clone https://github.com/ibm-apiconnect/devportal-addons
   ```

2. Package up the custom module.

   ```
   cd devportal-addons/apic_v10/modules
   tar -czf user_field_example.tgz user_field_example/
   ```

Installing and enabling the validation module

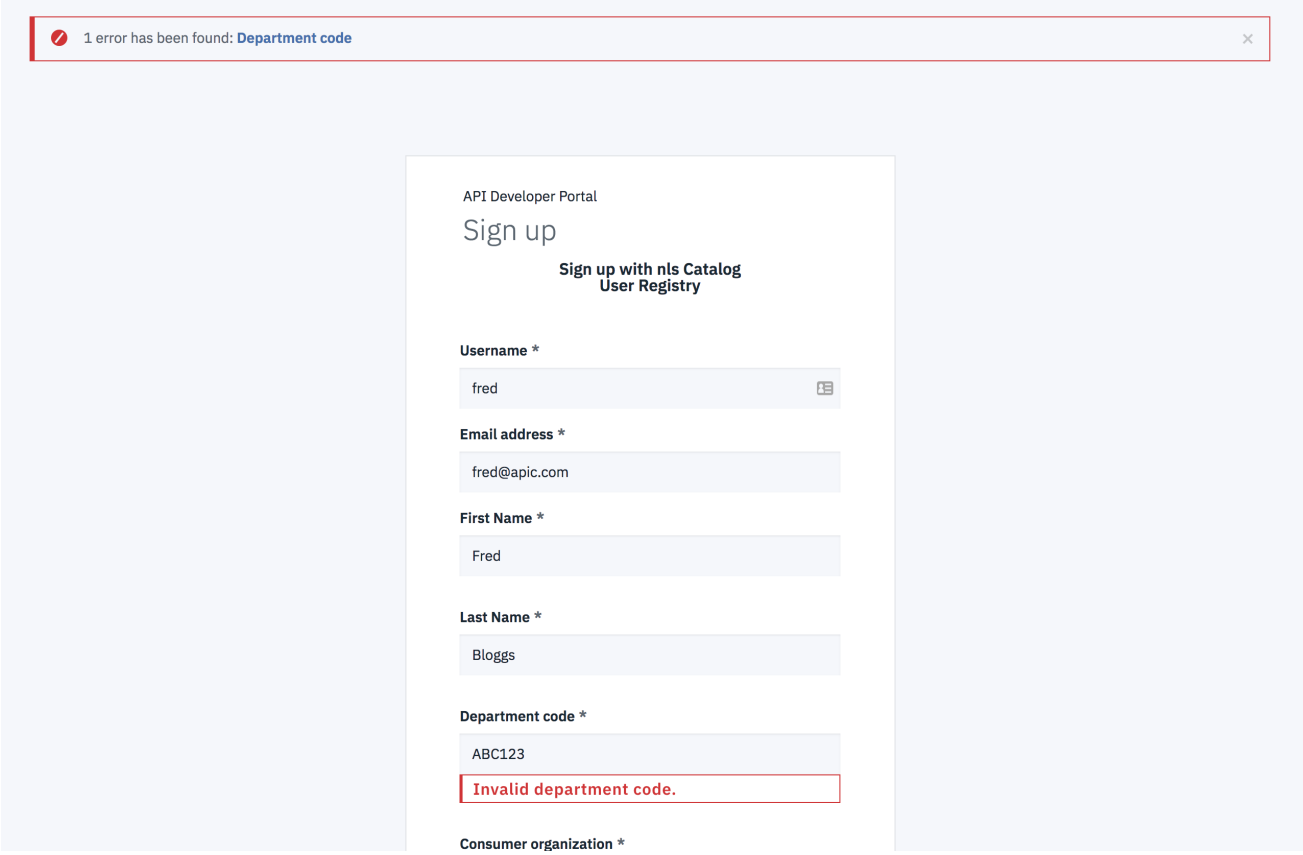
1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Extend > Install new module.
4. Click **Choose file** from the **Upload a module or theme archive to install** section.
5. Browse to and select **user_field_example.tgz**, the packaged custom module that you created earlier. Click **Open**.
6. Click **Install**.
7. Click the **Enable newly added modules** link.
8. Enter **IBM APIC Portal - user field example** in the filter box.
9. Check the checkbox next to **IBM APIC Portal - user field example**.
10. Click **Enable**.

The module is now installed and enabled.

Testing the validation in the sign-up form

1. Sign out as the Admin user.
2. Click **Create account**.
3. Complete all fields, set **Department code** to **ABC123**.
4. Click **Sign up**.

5. Observe the failure message and highlighting on the **`Department code`** field.



6. Change the **`Department code`** field to **`DEP245`**, reenter the password and click **`Sign up`** to see that a valid code is accepted.

What you did in this tutorial

You added some validation to the Department code field on the Sign-up form, then tested the form to ensure that the **`Department code`** field accepts only codes in the format of **`DEPnnn`**.

In reality, you would need to add this configuration in such a way that it is available for all sites. To achieve this availability, you would include the configuration in your custom module. For more information, see Drupal custom modules.

Tutorial: Adding a field group to group fields in a content type

You might want to change how your user account pages are displayed when you have lots of fields.

If you have many fields for one of your content types, for example, a user, then you might want to group some of these fields together when you display them to other users, or when these fields are being edited inside a user form.

Field groups allow you to create a parent field that contains other fields, set up as children, within that group. The **`Fieldgroup`** forms come with default HTML wrappers such as vertical tabs, horizontal tabs, accordions, fieldsets, or div wrappers.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial.

About this tutorial

You will create field groups for various groups of user information. These groups can then be seen under the users own section on the account view and edit pages.

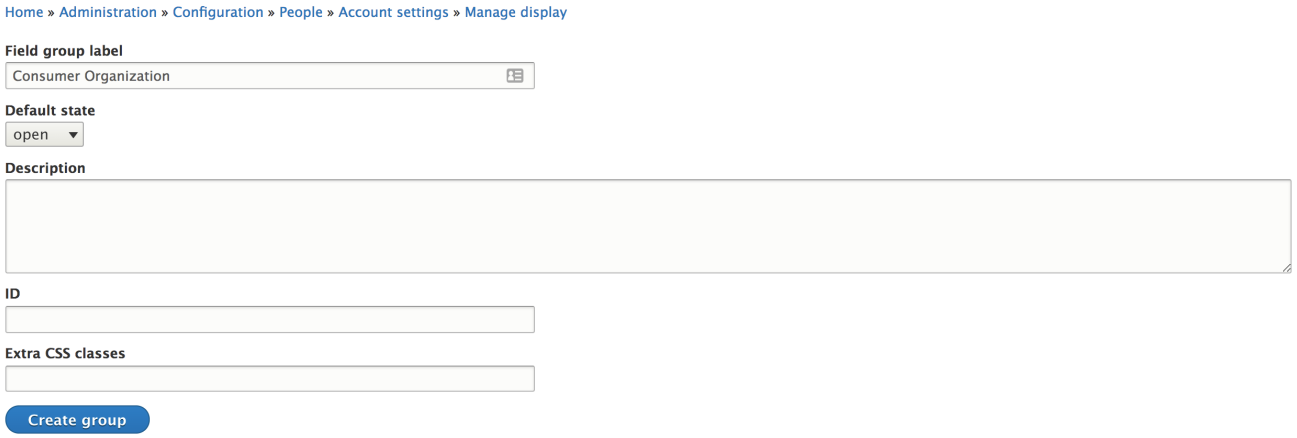
This tutorial takes you through the following steps:

1. Adding a field group called Consumer Organization to the user account display.
2. Adding a field group called Personal Details to the user form display.

Adding a field group called Consumer Organization to the user account display

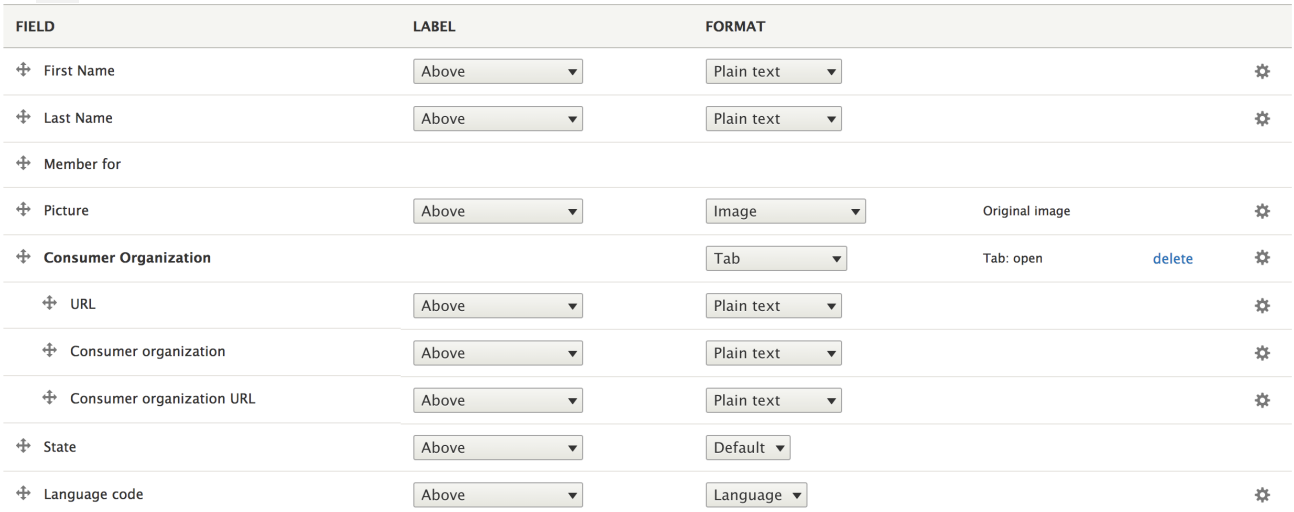
1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Configuration > People > Account settings > Manage display.
4. Click **`+ Add field group`**.

5. Select **tab** as your group type.
6. Enter **Consumer Organization** as the label.
7. Click **Save and continue**.
8. Set the default state to **open**. This sets the tab to be expanded by default.
9. Click **Create group**.

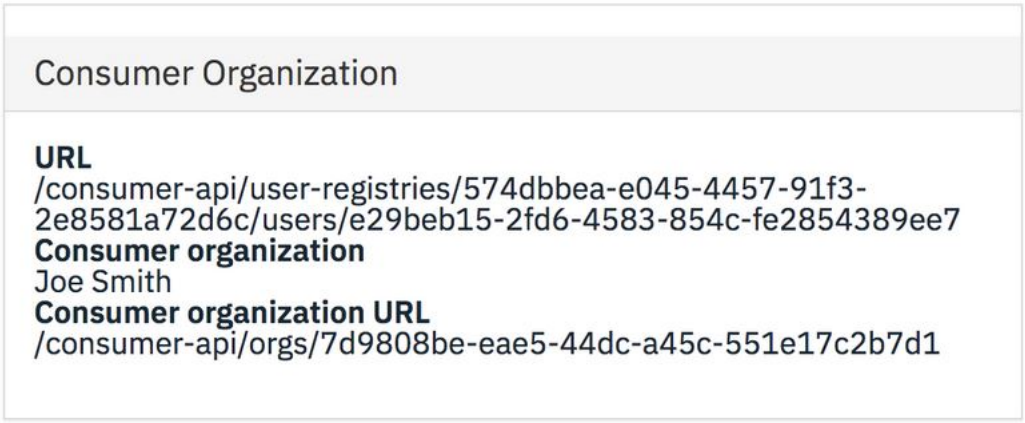


When the group is created, you can assign fields to that group and rearrange the group on the page. After you create the group, you are on the **Manage Display** page.

1. Drag your new group from the disable section up into the higher section, just underneath **Picture**.
2. Drag **URL**, **Consumer Organization**, and **Consumer Organization URL** underneath the **Consumer Organization** group row, and slightly to one side. It fixates itself underneath the parent, and this is now set as the child of that group.
3. Click **Save**.



You are now able to see the new group of fields on the account page of a user.



Adding a field group called Personal Details to the user form display

1. Navigate to Configuration > People > Account settings > Manage form display.

2. Click **`Add field group`**.
3. Select **`tab`** as your group type.
4. Enter **`Personal Details`** as the label.

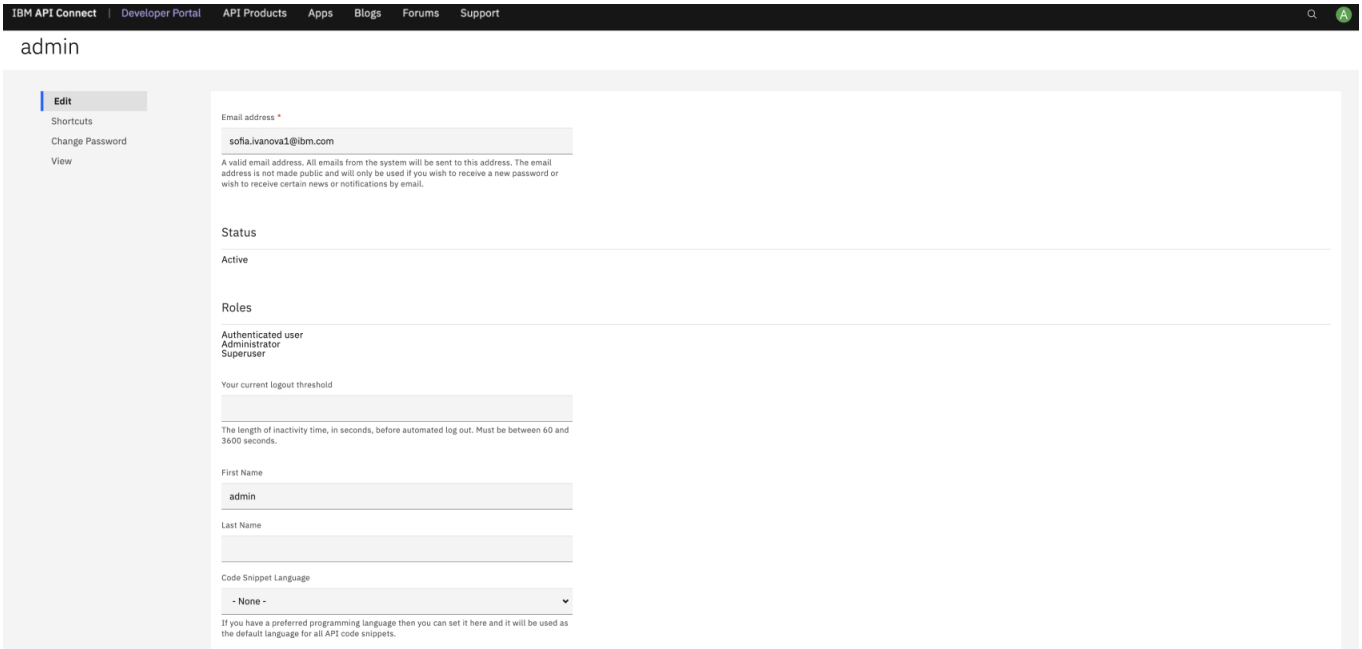
5. Click **`Save and continue`**.
6. Set the default state to **`open`**. This sets the tab to be expanded by default.
7. Click **`Create group`**.

Again, when the group is created, you can assign fields to that group and then rearrange the group on the page as you require. After you create the group, you are returned to the **`Manage Display`** page.

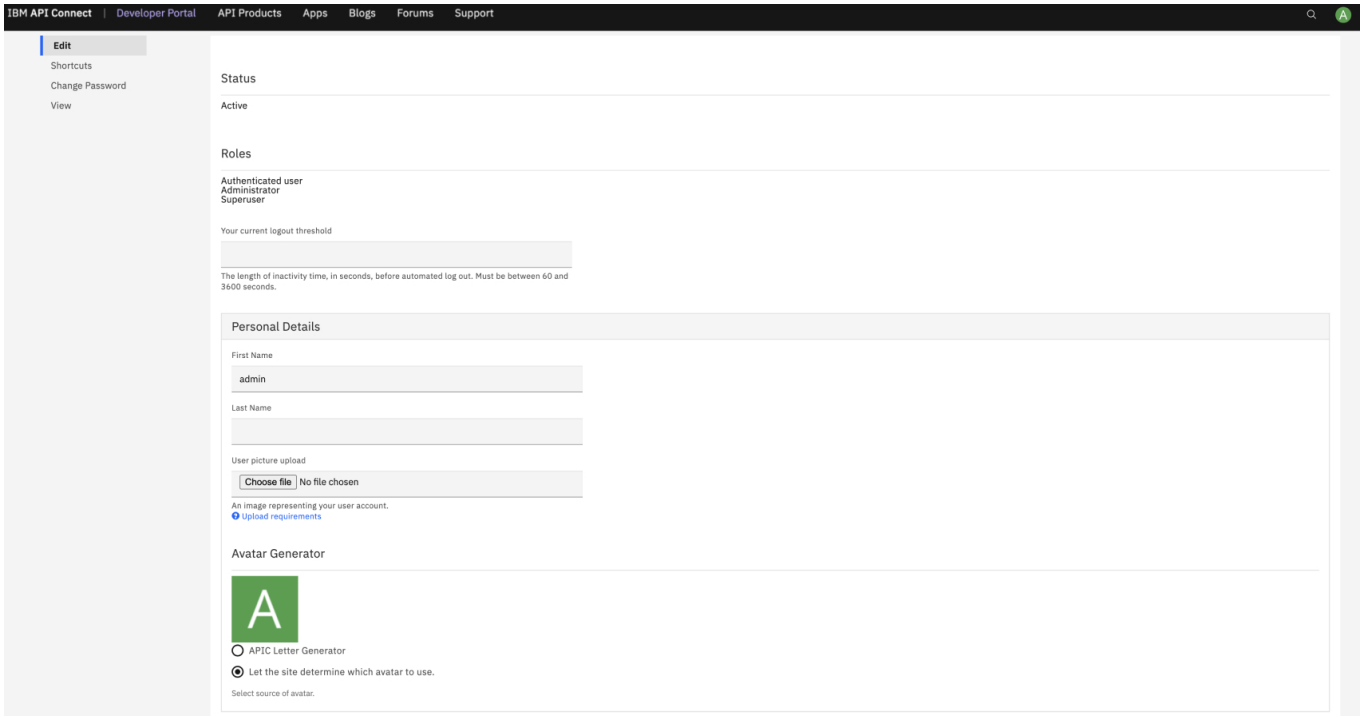
1. Drag your new group from the disabled section up into the higher section, onto the highest row.
2. Drag **`First Name`**, **`Last Name`**, **`User picture upload`**, and **`Avatar Generator`** to underneath the **`Personal Details`** group row. It fixates itself underneath the parent, and this is now set as the child of that group.
3. Click **`Save`**.

You and your user can now see the new grouped section when you edit their account.

Before:



After:



What you did in this tutorial

You have successfully created field groups for various groups of user information, and presented them to the user in its own section on the account view and edit pages.

You can check whether your field groups are applied, by viewing the profile of another user. Do this check by finding any other users published content and clicking the associated avatar. Or, from the administrator dashboard you can click People and then click a user. You can see the new Consumer Organization field group on their profile page. If you then click **`Edit`** for the user, you can see the Personal Details field group.

What to do next

You can edit the user displays anytime by navigating back to Configuration > People > Account settings > Manage display or Manage form display.

You can delete the field group by clicking the **`delete`** button in the field group row on either of these pages. You can also modify the type of group it is, for example, vertical tabs, horizontal tabs, accordions, and field sets.

Tutorial: Adding a custom block to the front page

You can customize the appearance of the front page of your Developer Portal by adding a custom block. Blocks are boxes of content that are rendered into an area, or region, of a web page such as the Products page or Apps page that can be displayed in regions, such as footer or sidebar, on your page.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so. The tutorial Adding a custom block to a page other than the front page explains how to add a custom block to any other page.

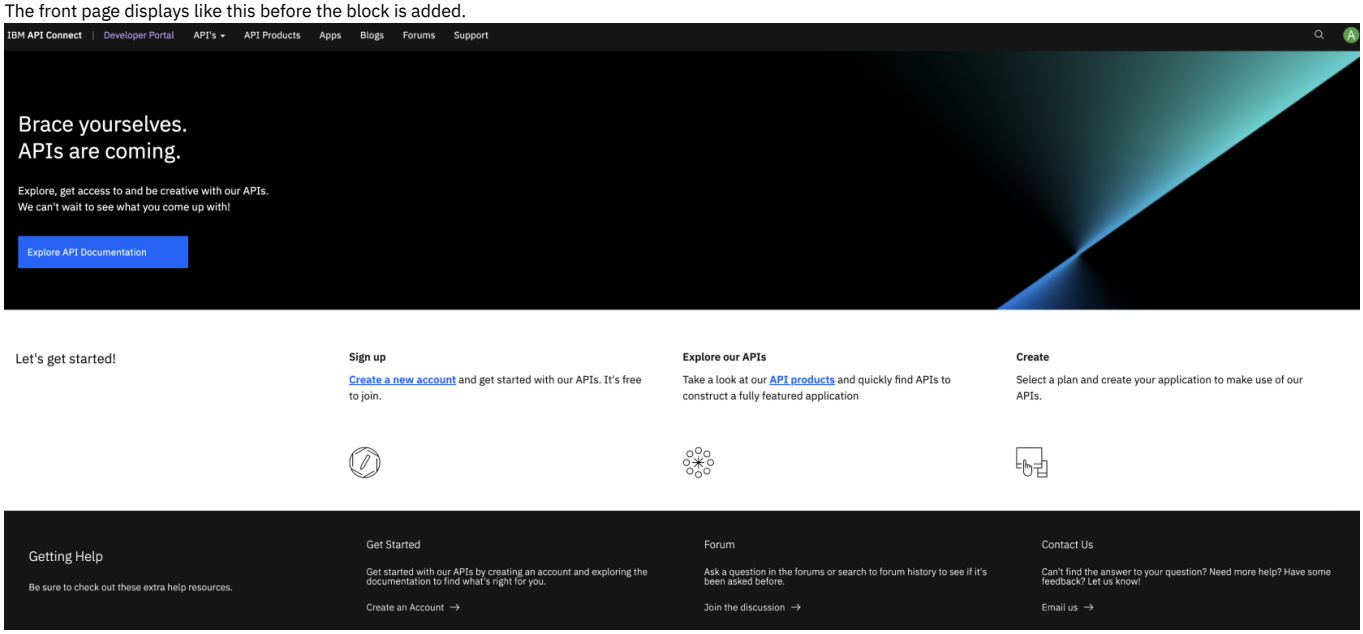
About this tutorial

In this tutorial, you create a block that contains a marketing announcement and add it to the front page of your Developer Portal.

This tutorial takes you through the following steps:

1. Creating a custom block.
2. Adding the custom block to the front page.

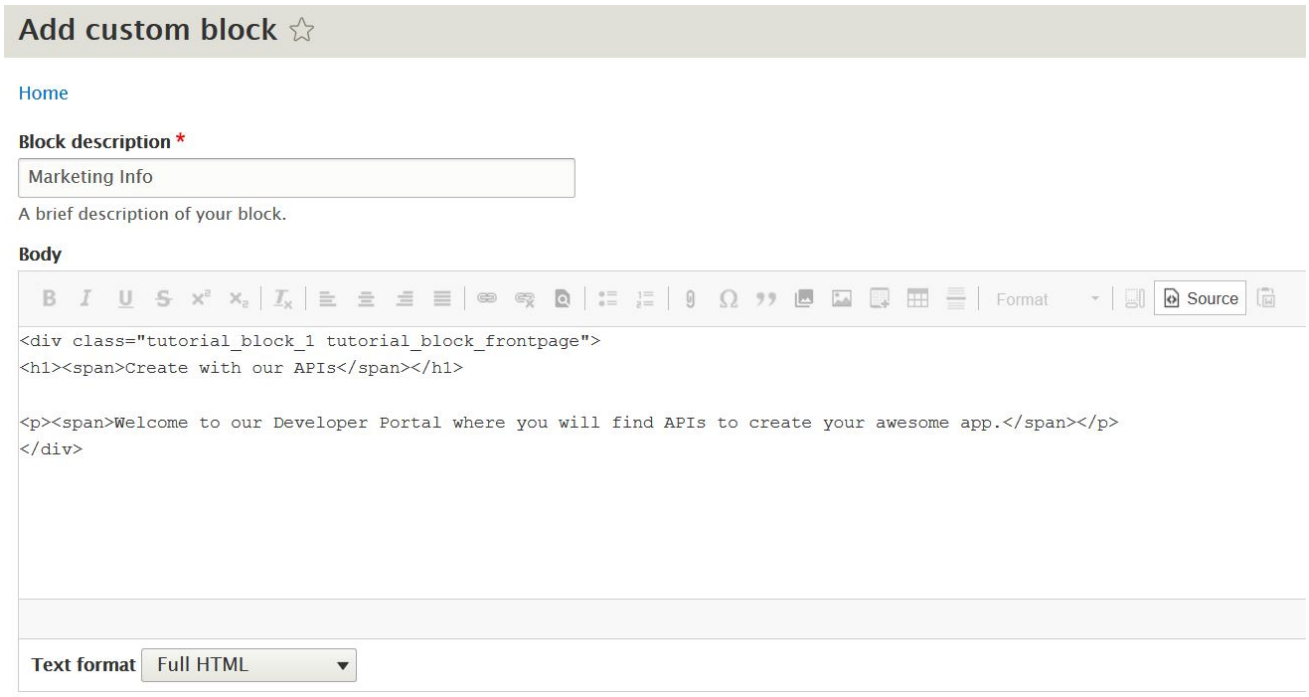
The front page displays like this before the block is added.



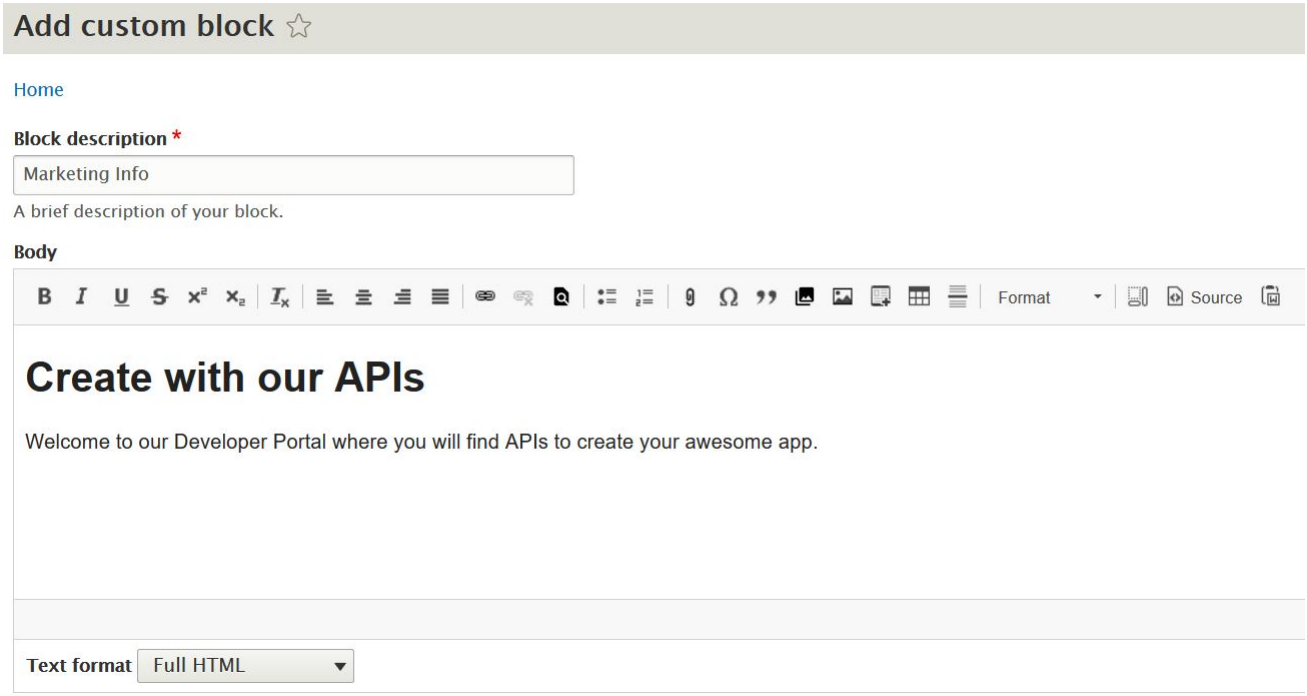
Creating a custom block

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Structure > Block layout > Add custom block.
4. Enter `Marketing Info` in the **`Block description`**.
5. In the body area, click **`Source`**, then enter this HTML:

```
<div class="tutorial_block_1 tutorial_block_frontpage">
<h1><span>Create with our APIs</span></h1>
<p><span>Welcome to our Developer Portal where you will find APIs to create your awesome app.</span></p>
</div>
```



6. To see a preview of the block click **`Source`** again.



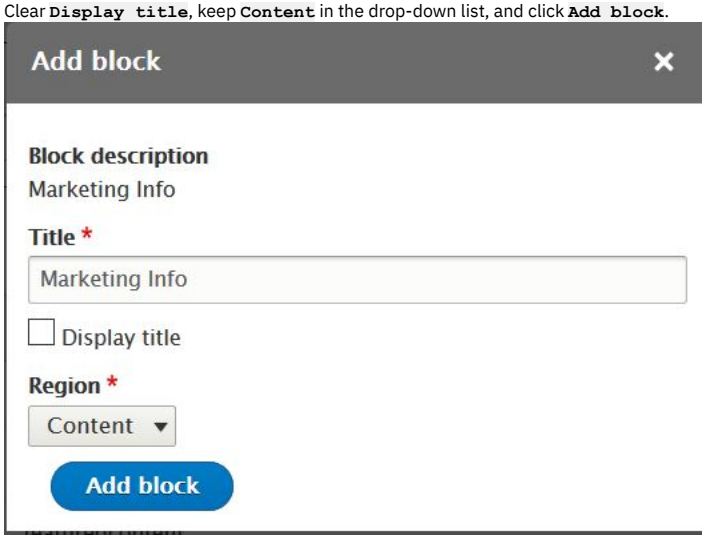
Note: This block uses almost no inline-styling, instead it allows your theme to decide how it is rendered. The advantage of this set up is that you can easily change the rendering without modifying existing content in the database. Any styling that is required can be added to a custom theme. For more information, see Tutorial: Creating a custom theme for the Developer Portal.

7. Click **Save**.

You have now created the custom block.

Adding the custom block to the front page

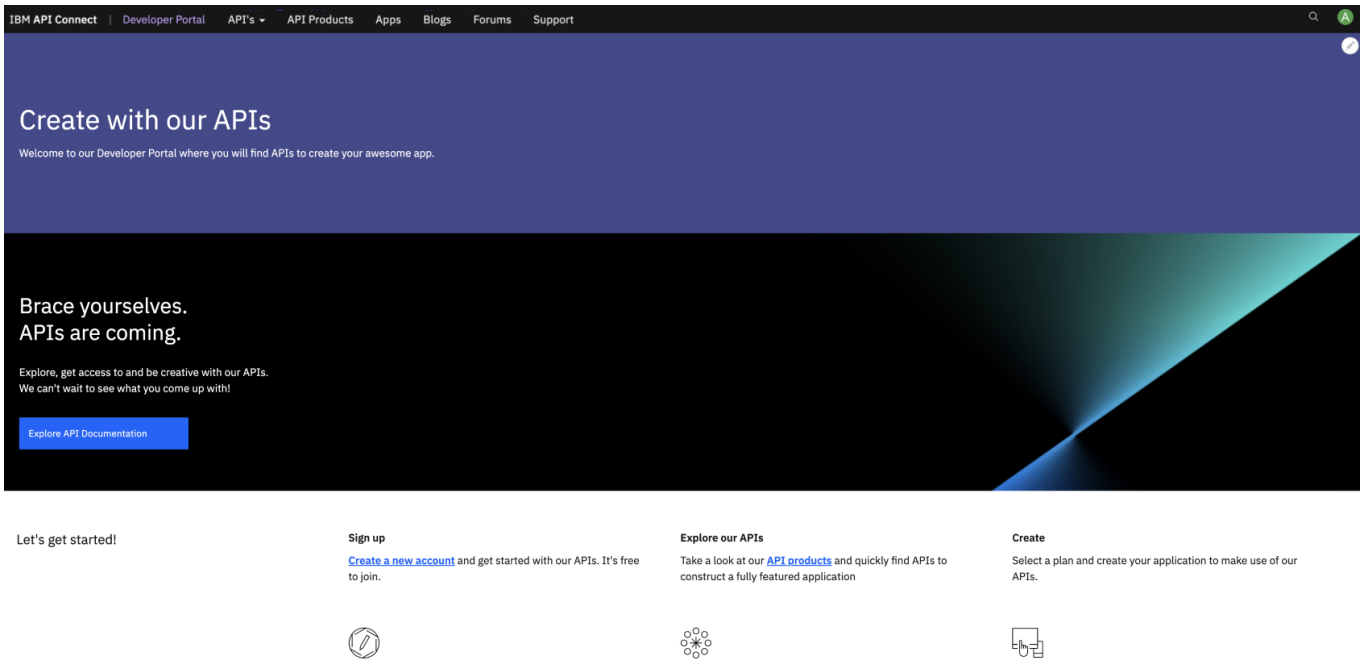
1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to Structure > Pages.
3. Click **Edit** on the Welcome page label.
4. Click **Panels** in the **Variants** section.
5. Click **Content** on the expanded menu.
6. Click **+ Add new block**.
7. Click **Marketing Info** in the Custom list.
8. Clear **Display title**, keep **Content** in the drop-down list, and click **Add block**.



9. Drag **Marketing Info** to the order you want, in this example before the **Welcome banner** content.
10. Click **Update and save**.

What you did in this tutorial

The front page now has the new block with a marketing message.



What to do next

You can add further branding by adding content to your custom blocks such as images, or try using one of the provided custom blocks such as the Featured Content Block. Instead of using inline styling like that provided in the html, adopt best practice by adding class selectors and developing a custom theme. By default this block is English, you might want to consider adding translated versions.

Tutorial: Adding a custom block to a page other than the front page

You can customize the appearance of a page on your Developer Portal by adding a custom block. Blocks are boxes of content that are rendered into an area or region of a web page, such as the Products page or Apps page. Blocks can be displayed in regions, such as footer or sidebar, on your page.

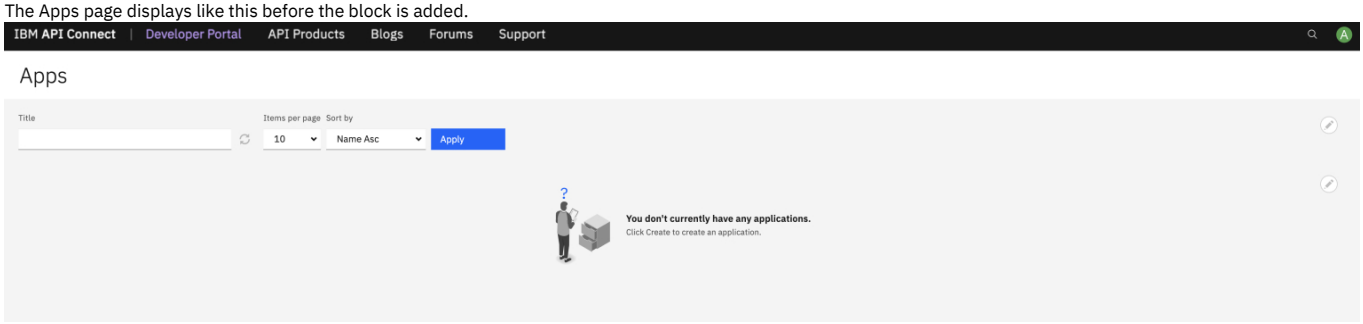
Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so. The tutorial Adding a custom block to the front page explains how to add a custom block to the front page.

About this tutorial

In this tutorial, you create a custom block that contains extra guidance on application creation and registration, and add that custom block to the Apps page of your Developer Portal.

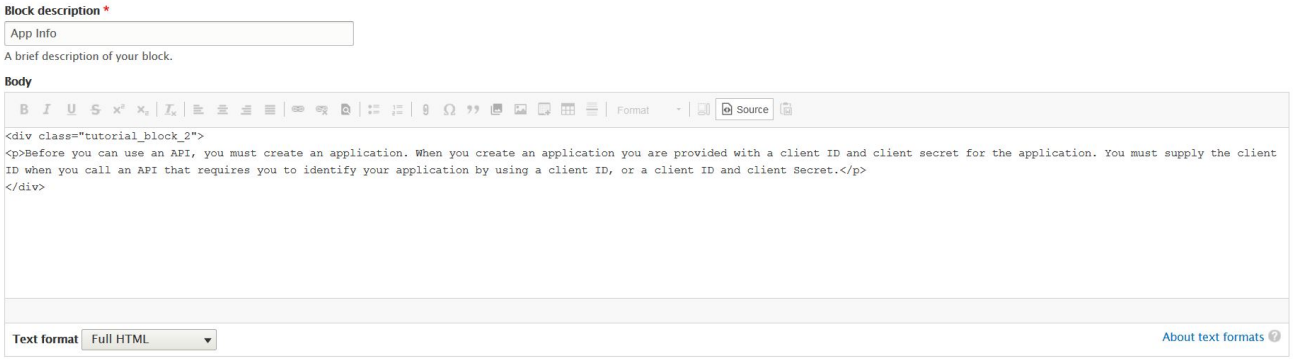
The Apps page displays like this before the block is added.



This tutorial takes you through creating a custom block, and configuring it to show on the Apps page.

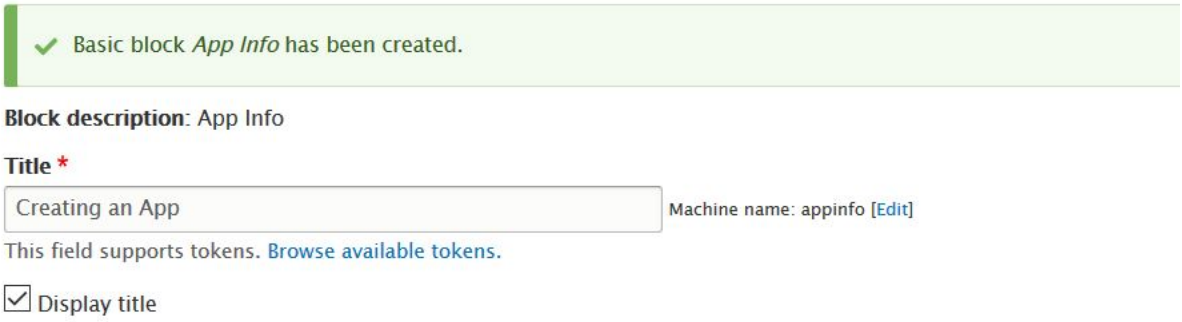
1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Structure > Block layout > Add custom block.
4. Enter `App Info` in the **`Block description`**.
5. In the body area, click **`Source`**, then enter this HTML:

```
<div class="tutorial_block_2">
<p>Before you can use an API, you must create an application. When you create an application you are provided with a client ID and client secret for the application. You must supply the client ID when you call an API that requires you to identify your application by using a client ID, or a client ID and client Secret.</p>
</div>
```



6. To see a preview of the block click **`Source`** again.

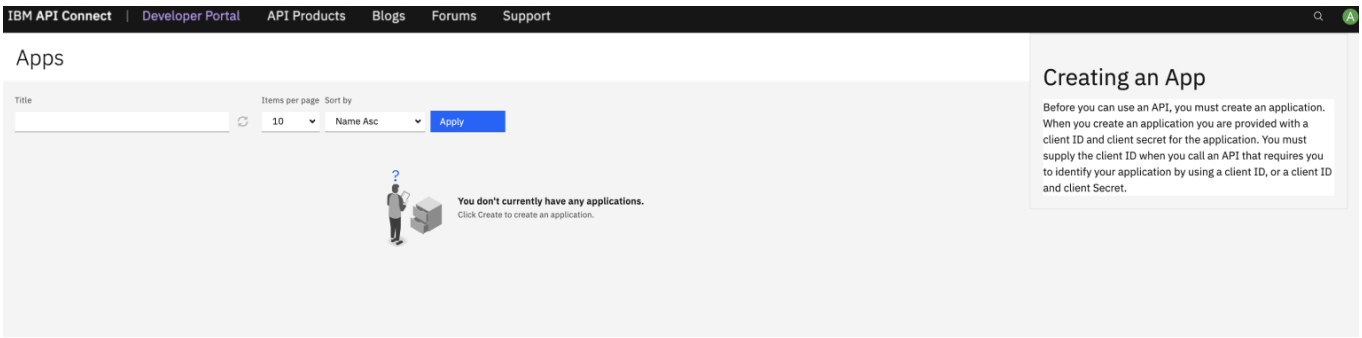
   Note: This block uses almost no inline-styling, instead it allows your theme to decide how it is rendered. The advantage of this set up is that you can easily change the rendering without modifying existing content in the database. Any styling that is required can be added to a custom theme. For more information, see Tutorial: Creating a custom theme for the Developer Portal.
7. Click **`Save`**.
8. Enter `Creating an App` in the **`Title`** box, keep the **`Display title`** selected.



9. Click **`Pages`** in the **`Visibility`** list.
10. Enter `/application` in the **`Pages`** text area, keep the **`Show for the listed pages`** selected.
11. Select **`Secondary`** from the **`Region`** drop-down menu.
12. Click **`Save block`**.
13. Click **`Save blocks`**.

What you did in this tutorial

The Apps page now has an additional block with a guidance message.



What to do next

Instead of using inline styling like that provided in the html, adopt best practice by adding class selectors and developing a custom theme. By default this block is English, so you might want to consider adding translated versions.

Tutorial: Configuring the RobotsTxt file

You can control the access of a visiting Web robot. You can configure the **`robots.txt`** file that exists on your web server, usually at the root level, to control access. Web robots are programs that crawl through the web to obtain web content for all the sites that are visited, and provide indexing for better performance of search engines. You can also specify separate rules for different robots.

Why would I want to edit Drupal's pre-existing robots.txt file?

Malicious robots might choose not to honor the **`robots.txt`** file, and by editing this file you are broadcasting which sites you do not want others to see. Therefore, you should not use this file to hide sensitive data. Instead, you might want to edit your **`robots.txt`** file to:

- Prevent duplicate information from being identified on your site
- Prevent internal pages from appearing in search engines
- Prevent private pages from appearing in search engines
- Prevent particular images, files, and so on, from bring crawled
- Specify a **`crawl-delay`** attribute to prevent robots from overloading your server at load time
- Exclude a particular robot

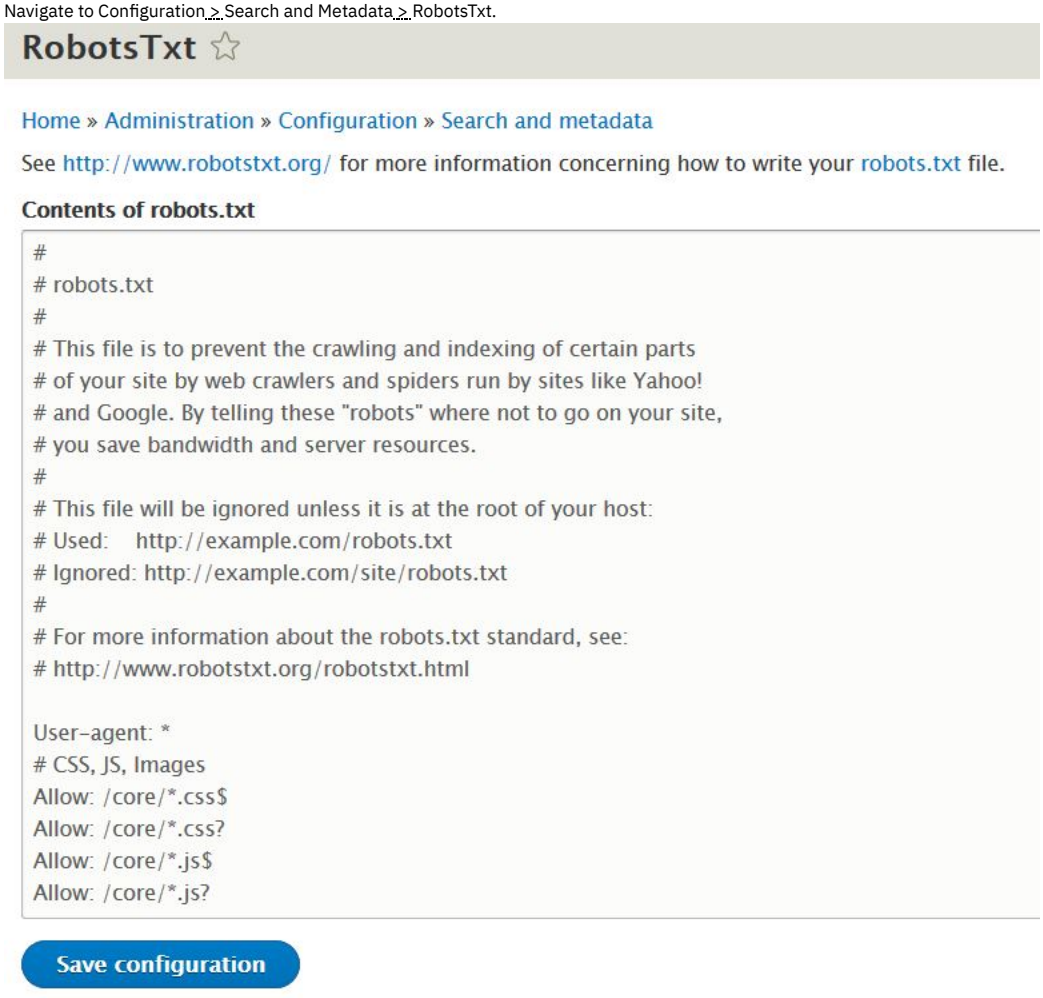
Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial.

About this tutorial

You will edit the pre-existing **`robots.txt`** file and exclude access to a visiting robot called BadBot.

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Configuration > Search and Metadata > RobotsTxt.



4. Enter the policy to exclude access to a robot called BadBot.

```
User-agent: BadBot
Disallow: /
```

5. Click **Save Configuration** to save your changes.

What you did in this tutorial

You have now successfully customized the **robots.txt** file. Robots now use this updated file to decide where they can crawl on your site. The BadBot robot is excluded access.

You can check whether your **robots.txt** file is successfully changed by navigating to your site and appending /robots.txt. You should see the content you entered into that file.

```
#
# robots.txt
#
# This file is to prevent the crawling and indexing of certain parts
# of your site by web crawlers and spiders run by sites like Yahoo!
# and Google. By telling these "robots" where not to go on your site,
# you save bandwidth and server resources.
#
# This file will be ignored unless it is at the root of your host:
# Used:    http://example.com/robots.txt
# Ignored: http://example.com/site/robots.txt
#
# For more information about the robots.txt standard, see:
# http://www.robotstxt.org/robotstxt.html

User-agent: BadBot
Disallow: /

User-agent: *
# CSS, JS, Images
Allow: /core/*.css$
Allow: /core/*.css?
Allow: /core/*.js$
Allow: /core/*.js?
```

For more information on how to edit your **robots.txt** file, see https://www.robotstxt.org/.

What to do next

You can edit the **robots.txt** at any time by navigating back to the page within the configuration settings. You might choose to duplicate this file across all of your sites, or choose different policies for different sites.

Tutorial: Configuring the SecurityTxt file

You can use the **security.txt** file to provide your users with a standard way to report security vulnerabilities with your site.

The **security.txt** file is a file format that is designed to help your users disclose any security vulnerability. For more information, see securitytxt.org or A File Format to Aid in Security Vulnerability Disclosure.

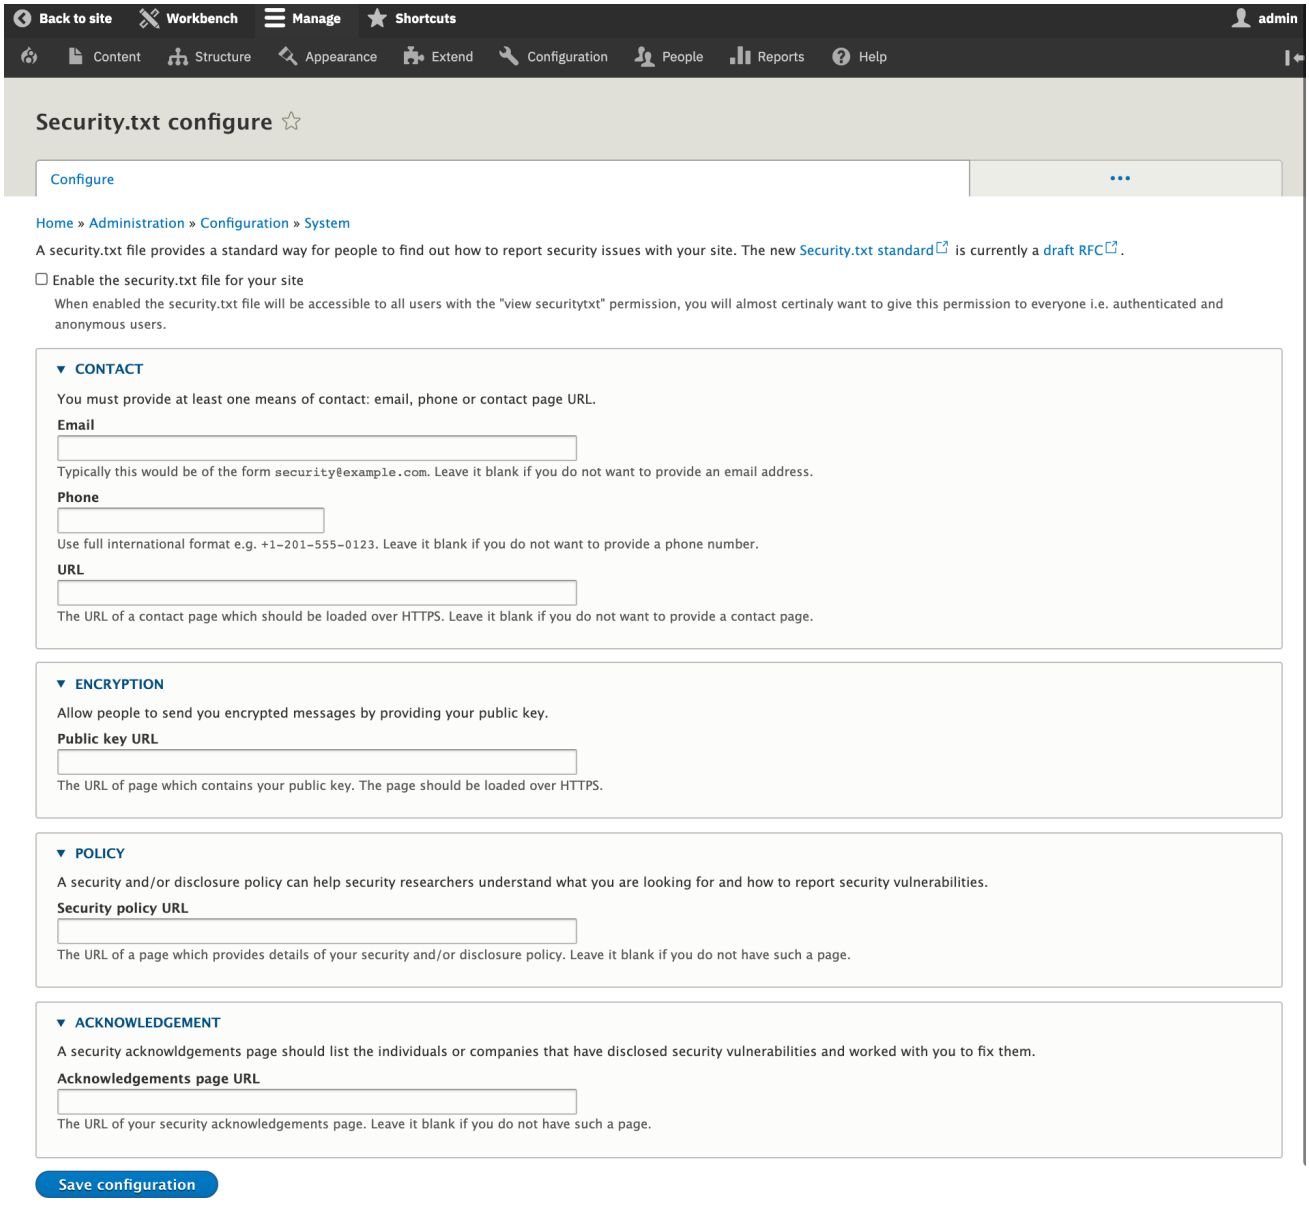
Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial.

About this tutorial

You edit the **security.txt** file and provide information such as a URL of a contact page, for your customers to use if they have a security vulnerability.

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Navigate to Configuration > System > Security.txt.



4. Select the checkbox for **`Enable the security text file for your site`**.
5. Complete the form for your requirements.
6. Click **`Save Configuration`** to save your changes.

What you did in this tutorial

You successfully customized the **`security.txt`** file.

What to do next

You can edit the **`security.txt`** at any time by navigating back to the page within the configuration settings.

Tutorials for using custom modules in the Developer Portal

You can configure custom modules to complete specific actions in the Developer Portal.

Note: You must have administrator access to complete the tutorials.
You can configure rules for the following events that occur in the Developer Portal:

- Change the profile page to display **`firstname last name`**, instead of **`username`**.
- Add validation to a field on the sign up form.

Tutorial: Changing the profile page to display firstname lastname, instead of username

You might want to change the profile page of your users on your Developer Portal to display their **firstname** and **lastname** rather than their **username**.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial.

About this tutorial

In this tutorial, you change the profile page of your users to display their **firstname** and **lastname** rather than their **username**. The change to the profile page is done by using the custom module **change account display** that is already available in IBM APIC Portal - addons. However, for more information, see Custom module development: creating a module skeleton.

This tutorial takes you through the following steps:

1. Cloning and packaging the **change account display** module.
2. Installing and enabling the **change account display** module.

Cloning and packaging the change account display module

1. Clone the custom module. Here is an example command if you are using Mac and Linux:

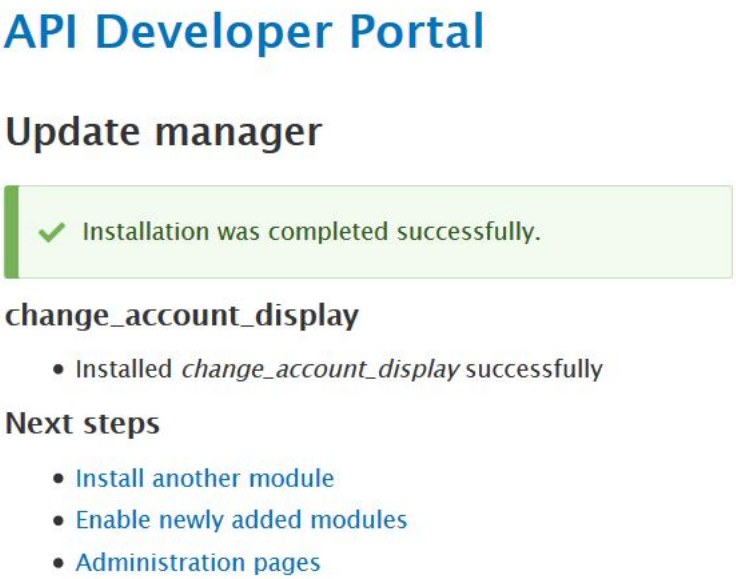
   ```
   git clone https://github.com/ibm-apiconnect/devportal-addons
   ```

2. Package up the custom module.

   ```
   cd devportal-addons/apic_v10/modules
   tar -czf change_account_display.tar.gz change_account_display/
   ```

Installing and enabling the change account display module

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Extend > Install new module.
4. Click **Browse** from the **Upload a module or theme archive to install** section.
5. Navigate to and select the packaged custom module that you created earlier. For example, **change_account_display.tgz**, then click **Open**.

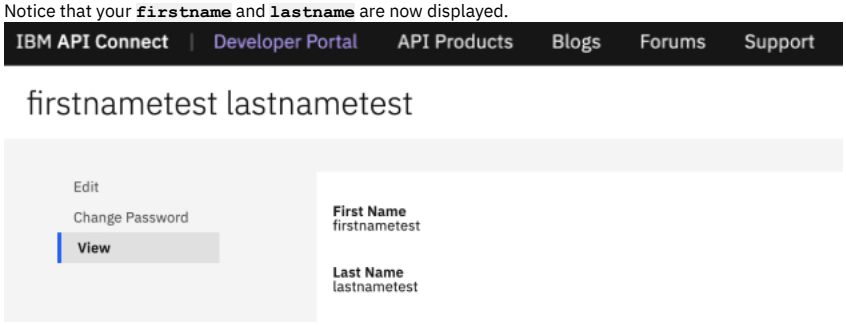


6. Click **Install**.
7. Click the **Enable newly added modules** link.
8. Enter **Change Account Display** in the filter box.
9. Check the check box next to **Change Account Display**.
10. Click **Enable**.

The module is now installed and enabled.

Test the profile page change

1. Sign out as the Admin user.
2. Sign in as a user of your Developer Portal.
3. Click **My account** from the drop down next to your **username**.
4. Notice that your **firstname** and **lastname** are now displayed.



What you did in this tutorial

You used a custom module to change the profile page display for the users of your Developer Portal.

Tutorial: Adding validation to a field on the sign-up form

You might want to add extra validation to a field to help your Developer Portal users. For example, you might want to validate a department name, employee ID, or similar data when a user registers for an account on the portal.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. You must have completed the tutorial about Adding a field to the sign up form, where you added a Department code field to the Sign-up form.

About this tutorial

In this tutorial, you add some validation to the Department code field on the Sign-up form. This is a required field for all portal users and is a string of the format **DEPnnn**, where **DEP** is the string prefix and **nnn** is a three-digit number, for example, **DEP123**. The validation is done by using a custom module that is already available in IBM APIC Portal - addons. However, for more information, see Custom module development: creating a module skeleton.

This tutorial takes you through the following steps:

1. Cloning and packaging the validation module.
2. Installing and enabling the validation module.
3. Testing the validation in the sign up form.

Look at the files we will use in this link IBM APIC Portal - addons.

- user_field_example.info.yml - this is the metadata for the module, defining things like the name and version, and containing other important information that is required by Drupal to import and enable the module.

```
name: 'IBM APIC Portal - user field example'
type: module
description: 'IBM API Connect Developer Portal tutorial - Example of validating a custom user field'
package: 'Custom'
core_version_requirement: ^8 || ^9
version: 1.0.0
project: 'user_field_example'
dependencies:
  - ibm_apim
  - auth_apic
```

- user_field_example.module - this contains a validation function and adds this to the Sign-up form by using the **hook_form_alter** function.

```
<?php
use Drupal\Core\Form\FormStateInterface;

/**
 * Implementation of hook_form_alter() to alter the Sign up form
 */
function user_field_example_form_alter(&$form, FormStateInterface $form_state, $form_id) {
  if ($form_id === 'user_register_form' ) {
      $form['#validate'][] = 'user_field_example_validate_department_code';
  }
}

/**
 * Validate the Department code field on the Sign up form.
 *
 * Valid entry = DEPnnn
 *   where n = single figure digit.
 */
function user_field_example_validate_department_code($form, &$form_state) {
  $dept_code = $form_state->getValue('field_department_code')[0]['value'];
```

```
  $valid = preg_match('/^DEP\d{3}$/', $dept_code);
  if (!$valid) {
    $form_state->setErrorByName('field_department_code', t('Invalid department code.'));
  }
}
```

Cloning and packaging the validation module

Validation is added to the **Department code** field on the Sign-up form by using a custom module.

1. Clone the custom module. Here is an example command if you are using Mac and Linux:

   ```
   git clone https://github.com/ibm-apiconnect/devportal-addons
   ```

2. Package up the custom module.

   ```
   cd devportal-addons/apic_v10/modules
   tar -czf user_field_example.tgz user_field_example/
   ```

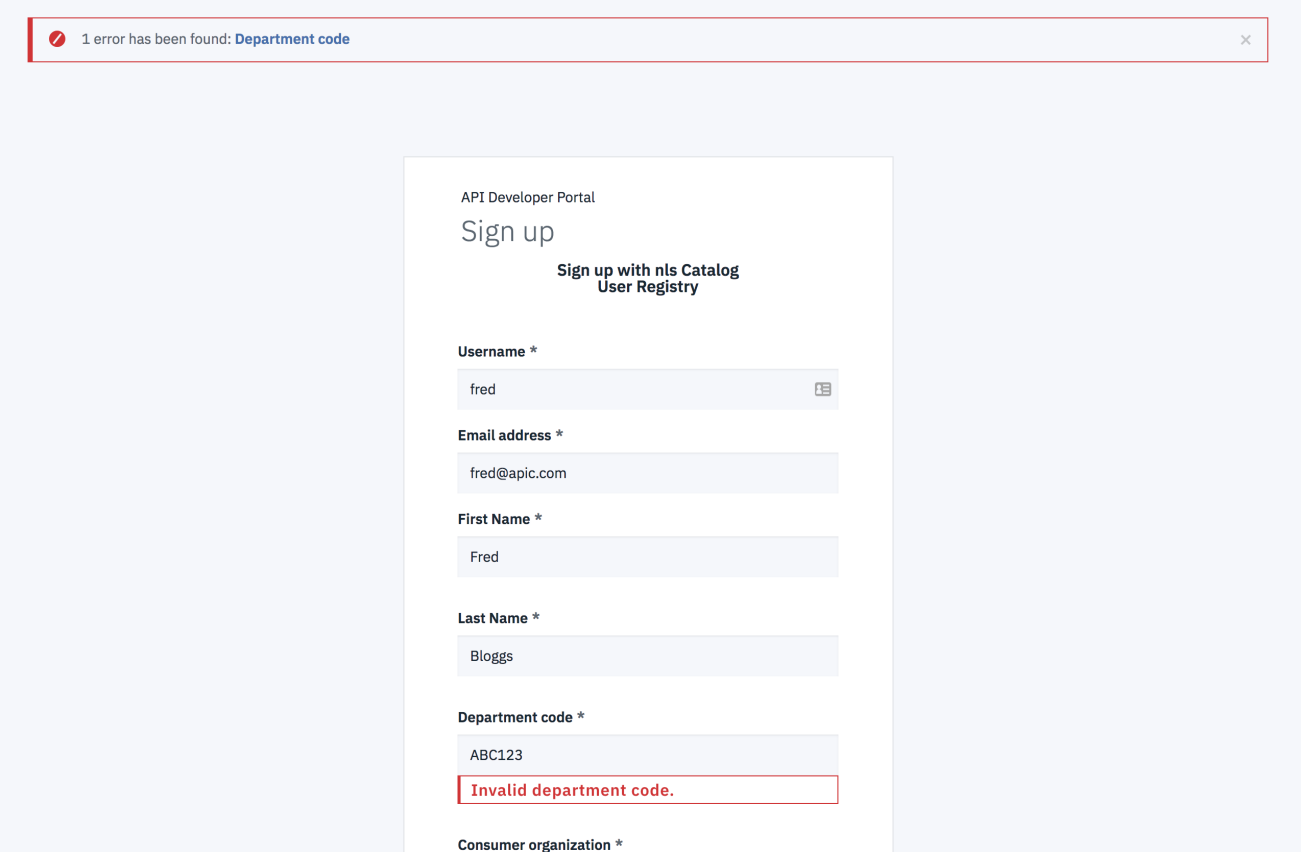
Installing and enabling the validation module

1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Extend > Install new module.
4. Click **Choose file** from the **Upload a module or theme archive to install** section.
5. Browse to and select **user_field_example.tgz**, the packaged custom module that you created earlier. Click **Open**.
6. Click **Install**.
7. Click the **Enable newly added modules** link.
8. Enter **IBM APIC Portal - user field example** in the filter box.
9. Check the checkbox next to **IBM APIC Portal - user field example**.
10. Click **Enable**.

The module is now installed and enabled.

Testing the validation in the sign-up form

1. Sign out as the Admin user.
2. Click **Create account**.
3. Complete all fields, set **Department code** to **ABC123**.
4. Click **Sign up**.
5. Observe the failure message and highlighting on the **Department code** field.



6. Change the **Department code** field to **DEP245**, reenter the password and click **Sign up** to see that a valid code is accepted.

What you did in this tutorial

You added some validation to the Department code field on the Sign-up form, then tested the form to ensure that the **`Department code`** field accepts only codes in the format of **`DEPnnn`**.

In reality, you would need to add this configuration in such a way that it is available for all sites. To achieve this availability, you would include the configuration in your custom module. For more information, see Drupal custom modules.

Tutorial: Using a custom weighting sort order on the product list page

You can use a custom weighting to sort your products on the API products list page of your Developer Portal.

Before you begin

You must have a Developer Portal enabled, and you must have administrator access to complete this tutorial. The tutorial Creating the Portal explains how to enable the portal if you have not already done so.

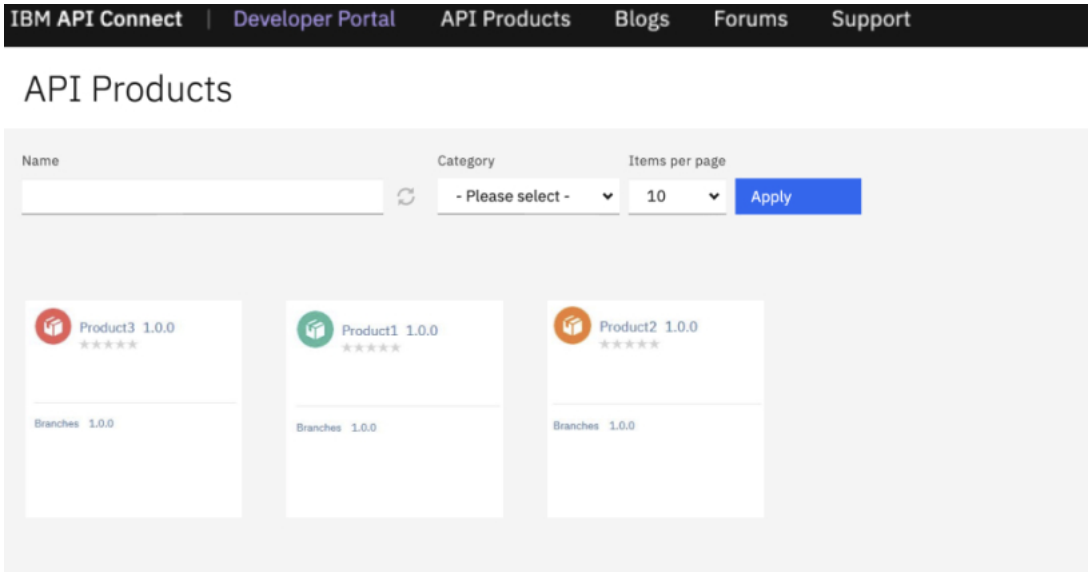
About this tutorial

In this task, you set up a weighting sort criteria and use it to list your products, on the API Products page, in a particular order. You set up the weightings so the order reads, Product3, Product1, and Product2.

This tutorial takes you through the following steps:

1. Add a custom integer field to the API content type.
2. Modify the Products view to change the sort order.
3. Add a weighting to each Product.

Note: To complete this tutorial, you will need to have API products.
For example, the following API Products page displays Product1, Product2, and Product3 in this order before the weightings are added.



Add a custom integer field to the API content type

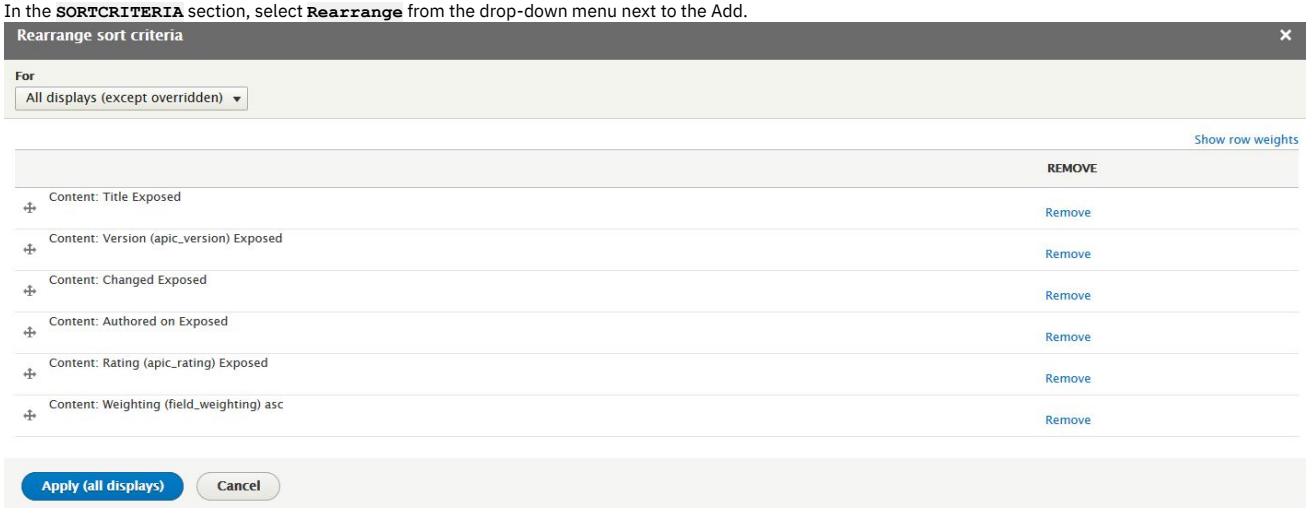
1. Log in to your Developer Portal as an administrator.
2. If the administrator dashboard isn't displayed, click Manage to display it.
3. Click Structure > Content types > Product > Manage fields.
4. Click + Add field.
5. In **`Add a new field`**, select Number (Integer). Enter `Weighting` as the label title.

6. Click Save and continue.
7. Leave the **`Allowed number of values`** set to 1 and click Save field settings.
8. Enter `0` as the default value, click Save settings.
9. Click Save.

The **`Weighting`** field now shows in the **`Manage fields`** list.

Modify the Products view to change the sort order

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Navigate to Structure > Views, scroll down to the **`Products`** view and click Edit.
3. In the **`SORT CRITERIA`** section click Add.
4. Enter `weight` in the search box. Then, select **`Weighting (field_weighting)`**, and click Apply (all displays).
5. Leave the **`Order`** as **`Sort ascending`**, click Apply (all displays).
6. In the **`SORTCRITERIA`** section, select **`Rearrange`** from the drop-down menu next to the Add.

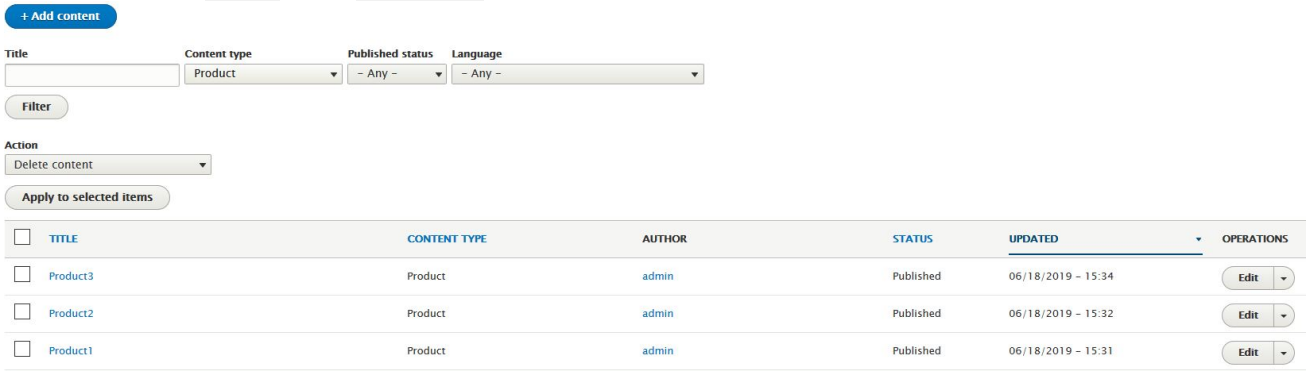


7. For all rows except **`Weighting (field_weighting)`**, click **`Remove`**.
8. Click Apply (all displays).

You modified the **`Products`** view to sort based on **`Weighting (field_weighting)`**.

Add a weighting to each Product

1. If the administrator dashboard isn't displayed, click Manage to display it.
2. Click Content, and select **`Product`** from the **`Content type`**, click Filter. A list of available Products on your site is displayed.

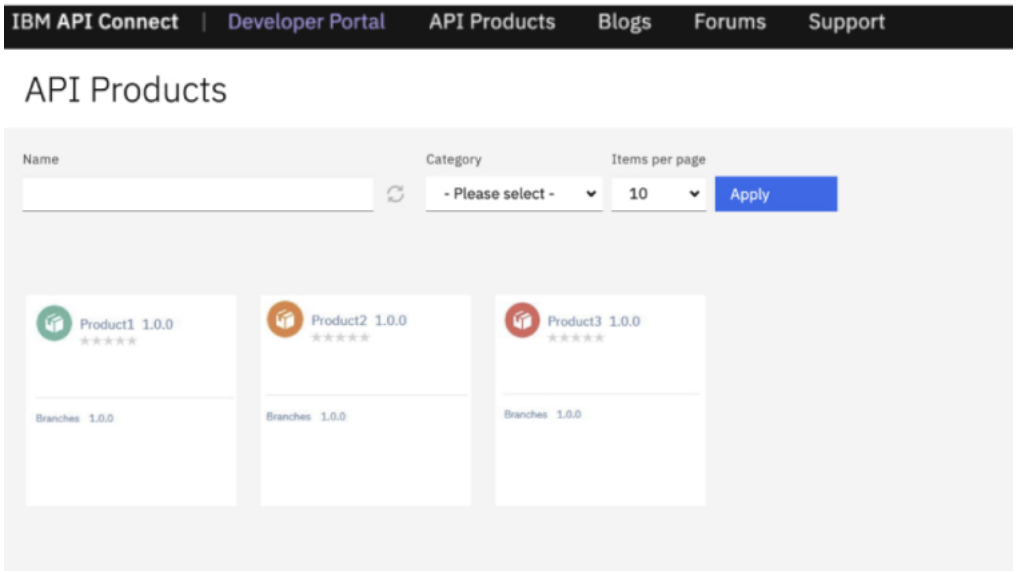


3. For Product1 click edit, in the **`Weighting field`**, select `2` as the value, click Save.
4. For Product2 click edit, in the **`Weighting field`**, select `3` as the value, click Save.
5. For Product3 click edit, in the **`Weighting field`**, select `1` as the value, click Save.

The API Products page displays Product3, Product1, and Product2 in this order after the weightings are added.

What you did in this tutorial

You changed the order that the API Products appear on the products page.



Tutorial: Synchronizing application credentials from the Developer Portal with an external server

You can synchronize application credentials from the Developer Portal with an external server.

Before you begin

You must have administrator access to complete this task.

Download the Application credential synchronization module.

About this task

In this tutorial, you can synchronize the application credentials from the Developer Portal with an external credentials server that you organization might already have. This is done by configuring a custom module and installing it in the Developer Portal.

The file that you have downloaded is a custom module that contains multiple methods that can be configured with your REST endpoints, and any further specifications that you want to define, to synchronize your Developer Portal application credentials with an external credential server.

For more information, see Custom module development: background and prerequisites.

Procedure

To configure the custom module to synchronize application credentials:

1. In the appcreds_sync.module file, replace **`example.com`** with your REST endpoint for the following method types:
   - **`http://example.com/app/create`**
   - **`http://example.com/app/delete`**
   - **`http://example.com/app/creds/create`**
   - **`http://example.com/app/creds/update`**
   - **`http://example.com/app/creds/delete`**
   - **`http://example.com/app/clientid/reset`**
   - **`http://example.com/app/clientsecret/reset`**
2. Optional: Replace **`username`** and **`password`** with your username and password in the **`_appcreds_sync_json_http_request`** function:

   ```
   ('username' . ':' . 'password')
   ```

   Note: You can also configure the SSL settings if you need to.
3. After you have finished configuring the module, click Save, and zip up the module.

To install the configured custom module in the Developer Portal:

4. On the administrator dashboard, click Modules
5. Click Install new modules.
6. You can enter a path to the module in the Install from a URL field. Alternatively, you can upload a module under the Upload a module or theme archive to install heading.
7. Click Install.

To enable the module:

8. On the administrator dashboard, click Modules.
9. Search for and enable the custom module.
10. Click Save configuration.

Results

You have configured a custom module that synchronizes application credentials from the Developer Portal, installed that module in the Developer Portal, and enabled it. No further action or configuration is required.

Reference information

Reference information for IBM® API Connect, including summary reference material for the developer toolkit command-line tool (CLI), a link to the API Connect Version 10.x Whitepaper, and information about the API Connect platform REST APIs.

Reference item	Description
Command-line tool reference for the developer toolkit	Summary reference material for each of the available commands for the developer toolkit command-line tool (CLI). (For more detailed information about how to use the command-line tool, see Using the developer toolkit command-line tool.)
Command-line tool reference for the Developer Portal	Summary reference material for each of the available commands for the Developer Portal command-line tool (CLI). (For more detailed information about how to use the command-line tool, see Using the Developer Portal command-line tool.)
API Connect REST APIs	The platform REST APIs that can be used to manage the API Connect cloud configuration, access the API provider capability, and use the consumer API microservice.
API Connect v10.x Whitepaper	A comprehensive technical guide to best practices, considerations, and deployment options for API Connect. The whitepaper covers the major components of API Connect, as well as considerations for configuring different clouds and environments, to help users with their API strategies. The target audience for the whitepaper are solution and integration architects.

APIConnect toolkit a7bbaf073f79ac4f140fb3d78c7a8937e3d1fde5 (Built 2023-06-02T18:13:39Z)

Synopsis

APIConnect toolkit a7bbaf073f79ac4f140fb3d78c7a8937e3d1fde5 (Built 2023-06-02T18:13:39Z)

```
apic [flags]
```

Options

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
  -h, --help                   Help for apic
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic activations

Activations operations

Synopsis

Activations operations

```
apic activations [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for activations
      --limit int32      Maximum number of items to return
```

```
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic activations:clear

Activations clear operations

Synopsis

Activations clear operations

```
apic activations:clear [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for activations:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic activations:delete

Activations delete operations

Synopsis

Activations delete operations

```
apic activations:delete [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for activations:delete
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic activations:get

Activations get operations

Synopsis

Activations get operations

```
apic activations:get [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for activations:get
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, use - for STDOUT. (default: cwd)
      --scope string     scope
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic activations:list

Activations list operations

Synopsis

Activations list operations

```
apic activations:list [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for activations:list
      --limit int32      Maximum number of items to return
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
```

  -m, --mode string            Toolkit operation mode (default "apim")
```

apic analytics-services:create

Create a Analytics Service object

Synopsis

Create a Analytics Service object Fields not allowed:\ - gateway_service_urls - ingestion_endpoint - client_endpoint Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - availability_zone_url

```
apic analytics-services:create [flags]
```

Options

```
      --availability-zone string   Availability Zone name or id (required)
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                       Help for analytics-services:create
  -o, --org string                 Organization name or id (required)
      --output string              Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string              management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic analytics-services:delete

Delete the Analytics Service object by name or id

Synopsis

Delete the Analytics Service object by name or id

```
apic analytics-services:delete [flags]
```

Options

```
      --availability-zone string   Availability Zone name or id (required)
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                       Help for analytics-services:delete
  -o, --org string                 Organization name or id (required)
      --output string              Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string              management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic analytics-services:get

Get the Analytics Service object by name or id

Synopsis

Get the Analytics Service object by name or id

```
apic analytics-services:get [flags]
```

Options

```
      --availability-zone string   Availability Zone name or id (required)
  -c, --catalog string             Catalog name or id (required)
      --fields string              List of field names to return
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                       Help for analytics-services:get
  -o, --org string                 Organization name or id (required)
      --output string              Write file(s) to directory, use - for STDOUT. (default: cwd)
      --query string               Add query to request
      --scope string               scope
  -s, --server string              management server endpoint (required)
      --space string               Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic analytics-services:list

List the Analytics Service objects

Synopsis

List the Analytics Service objects

```
apic analytics-services:list [flags]
```

Options

```
      --availability-zone string   Availability Zone name or id (required)
  -c, --catalog string             Catalog name or id (required)
      --fields string              List of field names to return
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                       Help for analytics-services:list
      --limit int32                Maximum number of items to return
      --offset int32               Offset item number from list to begin return
  -o, --org string                 Organization name or id (required)
      --output string              Write file(s) to directory, instead of STDOUT (default "-")
      --scope string               scope
  -s, --server string              management server endpoint (required)
      --space string               Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic analytics-services:update

Update the Analytics Service object by name or id

Synopsis

Update the Analytics Service object by name or id Fields not allowed to be null:\ - ingestion_endpoint_tls_client_profile_url - client_endpoint_tls_client_profile_url Fields not allowed:\ - endpoint - ingestion_endpoint - client_endpoint Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - availability_zone_url

```
apic analytics-services:update [flags]
```

Options

```
      --availability-zone string   Availability Zone name or id (required)
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                       Help for analytics-services:update
  -o, --org string                 Organization name or id (required)
      --output string              Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string              management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic api-keys

Api Keys operations

Synopsis

Api Keys operations

```
apic api-keys [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for api-keys
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic api-keys:create

Create a API Key object

Synopsis

Create a API Key object Required fields:\ - client_type - description Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url

```
apic api-keys:create [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for api-keys:create
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic api-keys:delete

Delete the API Key object by name or id

Synopsis

Delete the API Key object by name or id

```
apic api-keys:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for api-keys:delete
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file

  -m, --mode string           Toolkit operation mode (default "apim")
```

apic api-keys:get

Get the API Key object by name or id

Synopsis

Get the API Key object by name or id

```
apic api-keys:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for api-keys:get
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic api-keys:list

List the API Key objects

Synopsis

List the API Key objects

```
apic api-keys:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for api-keys:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
```

```
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic apis

Apis operations

Synopsis

Apis operations

```
apic apis [flags]
```

Options

```
      --api_type string    The type of api (asyncapi, rest, graphql, wsdl_to_rest, or wsdl)
      --base_path string   Base path of the API
  -c, --catalog string     Catalog name or id (required)
      --enforced           Whether the API is enforced or not
      --expand string      List of transient field to expand
      --fields string      List of field names to return
      --format string      Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help               Help for apis
      --limit int32        Maximum number of items to return
      --metadata string    List of metadata fields in the api to filter on
      --offset int32       Offset item number from list to begin return
  -o, --org string         Organization name or id (required)
      --output string      Write file(s) to directory, instead of STDOUT (default "-")
      --scope string       scope
  -s, --server string      management server endpoint (required)
      --space string       Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect

      --offset int32       Offset item number from list to begin return
  -o, --org string         Organization name or id (required)
      --output string      Write file(s) to directory, use - for STDOUT. (default: cwd)
      --scope string       scope
  -s, --server string      management server endpoint (required)
      --space string       Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic apis:document

Apis document operations

Synopsis

Apis document operations

```
apic apis:document [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for apis:document
      --id               id
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic apis:get

Apis get operations

Synopsis

Apis get operations

```
apic apis:get [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return (default "add(wsdl,api)")
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for apis:get
      --id               id
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, use - for STDOUT. (default: cwd)
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic apis:list

Apis list operations

Synopsis

Apis list operations

```
apic apis:list [flags]
```

Options

```
      --api_type string    The type of api (asyncapi, rest, graphql, wsdl_to_rest, or wsdl)
      --base_path string   Base path of the API
  -c, --catalog string     Catalog name or id (required)
      --enforced           Whether the API is enforced or not
      --expand string      List of transient field to expand
      --fields string      List of field names to return
      --format string      Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help               Help for apis:list
      --limit int32        Maximum number of items to return
      --metadata string    List of metadata fields in the api to filter on
      --offset int32       Offset item number from list to begin return
  -o, --org string         Organization name or id (required)
      --output string      Write file(s) to directory, instead of STDOUT (default "-")
      --scope string       scope
  -s, --server string      management server endpoint (required)
      --space string       Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic apis:list-all

Apis list-all operations

Synopsis

Apis list-all operations

```
apic apis:list-all [flags]
```

Options

```
      --api_type string    The type of api (asyncapi, rest, graphql, wsdl_to_rest, or wsdl)
      --base_path string   Base path of the API
  -c, --catalog string     Catalog name or id (required)
      --enforced           Whether the API is enforced or not
      --expand string      List of transient field to expand
      --fields string      List of field names to return
      --format string      Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help               Help for apis:list-all
      --limit int32        Maximum number of items to return

      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic apis:update

Apis update operations

Synopsis

Apis update operations

```
apic apis:update [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for apis:update
      --id               id
  -o, --org string       Organization name or id (required)
```

```
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic apis:validate

Validate the draft api object

Synopsis

Validate the draft api object

```
apic apis:validate [flags]
```

Options

```
      --catalog_name string             Name of a catalog
      --format string                   Output format. One of [json yaml go-template=... go-template-file=...], defaults to
yaml.
      --gateway_service_names string    Names of Gateway Services
  -h, --help                            Help for apis:validate
  -o, --org string                      Organization name or id (required)
      --output string                   Write file(s) to directory, instead of STDOUT (default "-")
      --scope string                    scope
  -s, --server string                   management server endpoint (required)
      --space_name string               Name of a space
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic apis:wsdl

Apis wsdl operations

Synopsis

Apis wsdl operations

```
apic apis:wsdl [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for apis:wsdl
      --id               id
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, use - for STDOUT. (default: cwd)
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic apps

Apps operations

Synopsis

Apps operations

```
apic apps [flags]
```

Options

```
  -c, --catalog string          Catalog name or id (required)
      --consumer-org string     Consumer Organization name or id (required)
      --expand string           List of transient field to expand
      --fields string           List of field names to return
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for apps
      --limit int32             Maximum number of items to return
      --offset int32            Offset item number from list to begin return
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
      --scope string            scope
  -s, --server string           management server endpoint (required)
      --space string            Space name or id (required)
      --space-initiated         space-initiated
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic apps:clear

Clear the Application objects

Synopsis

Clear the Application objects

```
apic apps:clear [flags]
```

Options

```
  -c, --catalog string          Catalog name or id (required)
      --confirm string          Confirmation for critical updates (required)
      --consumer-org string     Consumer Organization name or id (required)
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for apps:clear
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string           management server endpoint (required)
      --space string            Space name or id (required)
      --space-initiated         space-initiated
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic apps:create

Create a Application object

Synopsis

Create a Application object Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - catalog_url - consumer_org_url

```
apic apps:create [flags]
```

Options

```
  -c, --catalog string          Catalog name or id (required)
      --consumer-org string     Consumer Organization name or id (required)
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for apps:create
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string           management server endpoint (required)
      --space string            Space name or id (required)
      --space-initiated         space-initiated
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic apps:delete

Delete the Application object by name or id

Synopsis

Delete the Application object by name or id

```
apic apps:delete [flags]
```

Options

```
  -c, --catalog string          Catalog name or id (required)
      --consumer-org string     Consumer Organization name or id (required)
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for apps:delete
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string           management server endpoint (required)
      --space string            Space name or id (required)
      --space-initiated         space-initiated
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic apps:get

Get the Application object by name or id

Synopsis

Get the Application object by name or id

```
apic apps:get [flags]
```

Options

```
  -c, --catalog string          Catalog name or id (required)
      --consumer-org string     Consumer Organization name or id (required)
      --fields string           List of field names to return
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for apps:get
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string           management server endpoint (required)
      --space string            Space name or id (required)
      --space-initiated         space-initiated
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic apps:list

List the Application objects

Synopsis

List the Application objects

```
apic apps:list [flags]
```

Options

```
  -c, --catalog string          Catalog name or id (required)
      --consumer-org string     Consumer Organization name or id (required)
      --expand string           List of transient field to expand
      --fields string           List of field names to return
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for apps:list
      --limit int32             Maximum number of items to return
      --offset int32            Offset item number from list to begin return

      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic availability-zones:clear

Clear the Availability Zone objects

Synopsis

Clear the Availability Zone objects

```
apic availability-zones:clear [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for availability-zones:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic availability-zones:create

Create a Availability Zone object

Synopsis

Create a Availability Zone object Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url

```
apic availability-zones:create [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for availability-zones:create
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic availability-zones:delete

Delete the Availability Zone object by name or id

Synopsis

Delete the Availability Zone object by name or id

```
apic availability-zones:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for availability-zones:delete
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic availability-zones:get

Get the Availability Zone object by name or id

Synopsis

Get the Availability Zone object by name or id

```
apic availability-zones:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for availability-zones:get
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic availability-zones:list

List the Availability Zone objects

Synopsis

List the Availability Zone objects

```
apic availability-zones:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for availability-zones:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic availability-zones:update

Update the Availability Zone object by name or id

Synopsis

Update the Availability Zone object by name or id Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url

```
apic availability-zones:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for availability-zones:update
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic billings

Billings operations

Synopsis

Billings operations

```
apic billings [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for billings
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
```

```
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic billings:clear

Clear the Billing objects

Synopsis

Clear the Billing objects

```
apic billings:clear [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for billings:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic billings:delete

Delete the Billing object by name or id

Synopsis

Delete the Billing object by name or id

```
apic billings:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for billings:delete
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic billings:get

Get the Billing object by name or id

Synopsis

Get the Billing object by name or id

```
apic billings:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for billings:get
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic billings:list

List the Billing objects

Synopsis

List the Billing objects

```
apic billings:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for billings:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic billings:update

Update the Billing object by name or id

Synopsis

Update the Billing object by name or id Fields not allowed to be null:\ - integration_url Fields not allowed:\ - job_queue_status Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url

```
apic billings:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for billings:update
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic catalog-settings

Catalog Settings operations

Synopsis

Catalog Settings operations

```
apic catalog-settings [flags]
```

Options

```
  -h, --help   Help for catalog-settings
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic catalog-settings:get

Get the Catalog Setting object

Synopsis

Get the Catalog Setting object

```
apic catalog-settings:get [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for catalog-settings:get
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic catalog-settings:update

Update the Catalog Setting object

Synopsis

Update the Catalog Setting object Fields allowed but ignored:\ - name - type - api_version - scope - created_at - updated_at - url - org_url - catalog_url

```
apic catalog-settings:update [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --force            Force the operation
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for catalog-settings:update
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic catalogs

Catalogs operations

Synopsis

Catalogs operations

```
apic catalogs [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for catalogs
      --limit int32     Maximum number of items to return
      --my              my
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic catalogs:clear

Clear the Catalog objects

Synopsis

Clear the Catalog objects

```
apic catalogs:clear [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for catalogs:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic catalogs:create

Create a Catalog object

Synopsis

Create a Catalog object Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url

```
apic catalogs:create [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for catalogs:create
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic catalogs:delete

Delete the Catalog object by name or id

Synopsis

Delete the Catalog object by name or id

```
apic catalogs:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for catalogs:delete
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic catalogs:email-to-owners

Send email to owners of consumer organizations

Synopsis

Send email to owners of consumer organizations, given consumer org and consumer group urls. For consumer group, email owners of all consumer orgs in the group.

```
apic catalogs:email-to-owners [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for catalogs:email-to-owners
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic catalogs:get

Get the Catalog object by name or id

Synopsis

Get the Catalog object by name or id

```
apic catalogs:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for catalogs:get
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic catalogs:list

List the Catalog objects

Synopsis

List the Catalog objects

```
apic catalogs:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for catalogs:list
      --limit int32     Maximum number of items to return
      --my              my
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic catalogs:transfer-owner

Transfer owner to an associate

Synopsis

Transfer owner to an associate

```
apic catalogs:transfer-owner [flags]
```

Options

```
      --cascade            Cascade the behavior
      --delete_old_owner   Delete old owner
      --format string      Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help               Help for catalogs:transfer-owner
  -o, --org string         Organization name or id (required)
      --output string      Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string      management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic catalogs:update

Update the Catalog object by name or id

Synopsis

Update the Catalog object by name or id Fields not allowed:\ - name Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url

```
apic catalogs:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for catalogs:update
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic client-creds

Manage the client configuration parameters. Client ID and Client Secret.

Synopsis

Manage the client configuration parameters. Client ID and Client Secret.

```
apic client-creds [flags]
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for client-creds
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic client-creds:clear

clear the set client credentials.

Synopsis

clear the set client credentials.

```
apic client-creds:clear [flags]
```

Examples

```
$ apic client-creds:clear
Deleted client credentials.
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for client-creds:clear
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic client-creds:list

List the set clientID/secret parameters.

Synopsis

List the set clientID/secret parameters.

```
apic client-creds:list [flags]
```

Examples

```
$ apic client-creds:list
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for client-creds:list
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic client-creds:set

Set the client configuration parameters. ClientID and Client Secret.

Synopsis

Set the client configuration parameters. ClientID and Client Secret.

```
apic client-creds:set /path/to/creds/json ... [flags]
```

Examples

```
$ apic client-creds:set /Users/local_user/credential.json
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for client-creds:set
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic cloud-emails

Cloud Emails operations

Synopsis

Cloud Emails operations

```
apic cloud-emails [flags]
```

Options

```
  -h, --help   Help for cloud-emails
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic cloud-emails:send-to-owners

Email provider org owners

Synopsis

Send an email to owners of provider orgs

```
apic cloud-emails:send-to-owners [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for cloud-emails:send-to-owners
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic cloud-settings

Cloud Settings operations

Synopsis

Cloud Settings operations

```
apic cloud-settings [flags]
```

Options

```
  -h, --help   Help for cloud-settings
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic cloud-settings:about

Return information about the cloud

Synopsis

Return public information about the cloud. You MUST supply the --format option when using this command from the API Connect toolkit.

```
apic cloud-settings:about [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for cloud-settings:about
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic cloud-settings:audit-endpoint-test-connection

Test an audit endpoint connection

Synopsis

Test an audit endpoint connection

```
apic cloud-settings:audit-endpoint-test-connection [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for cloud-settings:audit-endpoint-test-connection
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic cloud-settings:designer-credentials-list

List credential for designer

Synopsis

List credential for designer

```
apic cloud-settings:designer-credentials-list [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for cloud-settings:designer-credentials-list
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic cloud-settings:get

Get the Cloud Setting object

Synopsis

Get the Cloud Setting object

```
apic cloud-settings:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for cloud-settings:get
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic cloud-settings:info

Return public information about the cloud deployment

Synopsis

Return public information about the cloud deployment

```
apic cloud-settings:info [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for cloud-settings:info
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic cloud-settings:mail-server-configured

Return true or false based on if mail server is configured or not

Synopsis

Return true or false based on if mail server is configured or not. You MUST supply the --format option when using this command from the API Connect toolkit.

```
apic cloud-settings:mail-server-configured [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for cloud-settings:mail-server-configured
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic cloud-settings:oauth2-certs

Support JWKS_URI endpoint, conform to OIDC specification

Synopsis

Return JWKS that is used to issue token. You MUST supply the --format option when using this command from the API Connect toolkit.

```
apic cloud-settings:oauth2-certs [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for cloud-settings:oauth2-certs
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic cloud-settings:toolkit-credentials-list

List credential for toolkit and consumer toolkit

Synopsis

List credential for toolkit and consumer toolkit

```
apic cloud-settings:toolkit-credentials-list [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for cloud-settings:toolkit-credentials-list
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic cloud-settings:topology

Return the topology of the cloud for governance

Synopsis

Return the topology of the cloud for governance. You MUST supply the --format option when using this command from the API Connect toolkit.

```
apic cloud-settings:topology [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for cloud-settings:topology
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
```

```
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic cloud-settings:update

Update the Cloud Setting object

Synopsis

Update the Cloud Setting object Fields not allowed to be null:\ - email_sender - tls_client_profile_default_url Fields not allowed:\ - service_type - cloud_id - ibm_cloud Fields allowed but ignored:\ - name - type - api_version - scope - created_at - updated_at - url

```
apic cloud-settings:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for cloud-settings:update
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic config

Manage configuration variables

Synopsis

Manage configuration variables

```
apic config [flags]
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for config
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic config:clear

Delete all configuration variables

Synopsis

Delete all configuration variables

```
apic config:clear [flags]
```

Examples

```
$ apic config:clear
Deleted config catalog
Deleted config org
Deleted config space
```

```
$ apic config:clear --global
Deleted config catalog
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for config:clear
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic config:delete

Delete a configuration variable

Synopsis

Configuration variables:

catalog The catalog configuration variable should be set to the URI of an API Connect catalog. The value of the catalog provides the default identity of a catalog for all the commands that are used to manage aspects of a catalog. The default values defined by the catalog's URI can be overridden using the --server, --organization, and --catalog command line options. The catalog URI has the form: https://MANAGEMENT_SERVER/api/catalogs/ORGANIZATION_NAME/CATALOG_NAME

org The default value of org defined by the app's or catalog's URI can be set using the org URI. The org URI has the form: https://MANAGEMENT_SERVER/api/orgs/ORGANIZATION_NAME

space The space configuration variable should be set to the URI of an API Connect space. The value of the space provides the default identity of a space for all the commands that are used to manage aspects of a space. The default values defined by the spaces's URI can be overridden using the --server, --organization, --catalog, and --space command line options. The space URI has the form: https://MANAGEMENT_SERVER/api/spaces/ORGANIZATION_NAME/CATALOG_NAME/SPACE_NAME

consumer The consumer configuration variable should be set to the URI of an API Connect consumer. The value of the consumer-org provides the default identity of a consumer. The default values defined by the consumer URI can be overridden using the --server, --organization, --catalog, and --consumer command line options. The consumer URI has the form: https://MANAGEMENT_SERVER/api/consumer-orgs/ORGANIZATION_NAME/CATALOG_NAME/CONSUMER_ORG_NAME

cloud The cloud configuration variable should be set to the management server URI. The value of the cloud variable provides default server URI for cloud admin commands. It can be overridden using the --server and --mode command line options. The cloud URI has the form: https://MANAGEMENT_SERVER/api/

mode The value of mode configruation variable defines the toolkit operation mode. It can be overridden using the --mode command line option. The value can be set to apim or consumer

template-path List of places to look for handlebar templates

template-default-api Defines the default api template

template-default-product Defines the default product template

```
apic config:delete NAME... [flags]
```

Examples

```
$ apic config:delete catalog
Deleted config catalog

$ apic config:delete org
Deleted config org

$ apic config:delete template-path
Deleted config template-path
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for config:delete
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic config:get

Get a configuration variable

Synopsis

Configuration variables:

catalog The catalog configuration variable should be set to the URI of an API Connect catalog. The value of the catalog provides the default identity of a catalog for all the commands that are used to manage aspects of a catalog. The default values defined by the catalog's URI can be overridden using the --server, --organization, and --catalog command line options. The catalog URI has the form: https://MANAGEMENT_SERVER/api/catalogs/ORGANIZATION_NAME/CATALOG_NAME

org The default value of org defined by the app's or catalog's URI can be set using the org URI. The org URI has the form: https://MANAGEMENT_SERVER/api/orgs/ORGANIZATION_NAME

space The space configuration variable should be set to the URI of an API Connect space. The value of the space provides the default identity of a space for all the commands that are used to manage aspects of a space. The default values defined by the spaces's URI can be overridden using the --server, --organization, --catalog, and --space command line options. The space URI has the form: https://MANAGEMENT_SERVER/api/spaces/ORGANIZATION_NAME/CATALOG_NAME/SPACE_NAME

consumer The consumer configuration variable should be set to the URI of an API Connect consumer. The value of the consumer-org provides the default identity of a consumer. The default values defined by the consumer URI can be overridden using the --server, --organization, --catalog, and --consumer command line options. The consumer URI has the form: https://MANAGEMENT_SERVER/api/consumer-orgs/ORGANIZATION_NAME/CATALOG_NAME/CONSUMER_ORG_NAME

cloud The cloud configuration variable should be set to the management server URI. The value of the cloud variable provides default server URI for cloud admin commands. It can be overridden using the --server and --mode command line options. The cloud URI has the form: https://MANAGEMENT_SERVER/api/

mode The value of mode configruation variable defines the toolkit operation mode. It can be overridden using the --mode command line option. The value can be set to apim or consumer

template-path List of places to look for handlebar templates

template-default-api Defines the default api template

template-default-product Defines the default product template

```
apic config:get NAME [flags]
```

Examples

```
$ apic config:get catalog
catalog: https://mgmnthost.com/api/catalogs/climbon/sb

$ apic config:get org
org: https://mgmnthost.com/api/orgs/climbon

$ apic config:get template-path
template-path: /etc/templates
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for config:get
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic config:list

List the application and global configuration variables

Synopsis

Configuration variables:

catalog The catalog configuration variable should be set to the URI of an API Connect catalog. The value of the catalog provides the default identity of a catalog for all the commands that are used to manage aspects of a catalog. The default values defined by the catalog's URI can be overridden using the --server, --organization, and --catalog command line options. The catalog URI has the form: https://MANAGEMENT_SERVER/api/catalogs/ORGANIZATION_NAME/CATALOG_NAME

org The default value of org defined by the app's or catalog's URI can be set using the org URI. The org URI has the form: https://MANAGEMENT_SERVER/api/orgs/ORGANIZATION_NAME

space The space configuration variable should be set to the URI of an API Connect space. The value of the space provides the default identity of a space for all the commands that are used to manage aspects of a space. The default values defined by the spaces's URI can be overridden using the --server, --organization, --catalog, and --space command line options. The space URI has the form: https://MANAGEMENT_SERVER/api/spaces/ORGANIZATION_NAME/CATALOG_NAME/SPACE_NAME

consumer The consumer configuration variable should be set to the URI of an API Connect consumer. The value of the consumer-org provides the default identity of a consumer. The default values defined by the consumer URI can be overridden using the --server, --organization, --catalog, and --consumer command line options. The consumer URI has the form: https://MANAGEMENT_SERVER/api/consumer-orgs/ORGANIZATION_NAME/CATALOG_NAME/CONSUMER_ORG_NAME

cloud The cloud configuration variable should be set to the management server URI. The value of the cloud variable provides default server URI for cloud admin commands. It can be overridden using the --server and --mode command line options. The cloud URI has the form: https://MANAGEMENT_SERVER/api/

mode The value of mode configruation variable defines the toolkit operation mode. It can be overridden using the --mode command line option. The value can be set to apim or consumer

template-path List of places to look for handlebar templates

template-default-api Defines the default api template

template-default-product Defines the default product template

```
apic config:list [flags]
```

Examples

```
$ apic config
catalog: https://mgmnthost.com/api/catalogs/climbon/sb
org: https://mgmnthost.com/api/orgs/climbon

$ apic config --global
catalog: https://mgmnthost.com/api/catlogs/climbon/sb
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for config:list
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic config:set

Set or update configuration variables

Synopsis

Configuration variables:

catalog The catalog configuration variable should be set to the URI of an API Connect catalog. The value of the catalog provides the default identity of a catalog for all the commands that are used to manage aspects of a catalog. The default values defined by the catalog's URI can be overridden using the --server, --organization, and --catalog command line options. The catalog URI has the form: https://MANAGEMENT_SERVER/api/catalogs/ORGANIZATION_NAME/CATALOG_NAME

org The default value of org defined by the app's or catalog's URI can be set using the org URI. The org URI has the form: https://MANAGEMENT_SERVER/api/orgs/ORGANIZATION_NAME

space The space configuration variable should be set to the URI of an API Connect space. The value of the space provides the default identity of a space for all the commands that are used to manage aspects of a space. The default values defined by the spaces's URI can be overridden using the --server, --organization, --catalog, and --space command line options. The space URI has the form: https://MANAGEMENT_SERVER/api/spaces/ORGANIZATION_NAME/CATALOG_NAME/SPACE_NAME

consumer The consumer configuration variable should be set to the URI of an API Connect consumer. The value of the consumer-org provides the default identity of a consumer. The default values defined by the consumer URI can be overridden using the --server, --organization, --catalog, and --consumer command line options. The consumer URI has the form: https://MANAGEMENT_SERVER/api/consumer-orgs/ORGANIZATION_NAME/CATALOG_NAME/CONSUMER_ORG_NAME

cloud The cloud configuration variable should be set to the management server URI. The value of the cloud variable provides default server URI for cloud admin commands. It can be overridden using the --server and --mode command line options. The cloud URI has the form: https://MANAGEMENT_SERVER/api/

mode The value of mode configruation variable defines the toolkit operation mode. It can be overridden using the --mode command line option. The value can be set to apim or consumer

template-path List of places to look for handlebar templates

template-default-api Defines the default api template

template-default-product Defines the default product template

```
apic config:set NAME=VALUE ... [flags]
```

Examples

```
$ apic config:set catalog=https://mgmnthost.com/api/catalogs/climbon/sb
catalog: https://mgmnthost.com/api/catalogs/climbon/sb

$ apic config:set org=https://mgmnthost2.com/api/orgs/hikeon
org: https://mgmnthost2.com/api/orgs/hikeon

$ apic config:set --global template-path="/etc/templates"
template-path: /etc/templates
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for config:set
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-api-user-registries

Configured Api User Registries operations

Synopsis

Configured Api User Registries operations

```
apic configured-api-user-registries [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-api-user-registries
      --limit int32      Maximum number of items to return
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-api-user-registries:clear

Configured Api User Registries clear operations

Synopsis

Configured Api User Registries clear operations

```
apic configured-api-user-registries:clear [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-api-user-registries:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
```

```
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-api-user-registries:create

Configured Api User Registries create operations

Synopsis

Configured Api User Registries create operations

```
apic configured-api-user-registries:create [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-api-user-registries:create
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-api-user-registries:delete

Configured Api User Registries delete operations

Synopsis

Configured Api User Registries delete operations

```
apic configured-api-user-registries:delete [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-api-user-registries:delete
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-api-user-registries:get

Configured Api User Registries get operations

Synopsis

Configured Api User Registries get operations

```
apic configured-api-user-registries:get [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-api-user-registries:get
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, use - for STDOUT. (default: cwd)
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-api-user-registries:list

Configured Api User Registries list operations

Synopsis

Configured Api User Registries list operations

```
apic configured-api-user-registries:list [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-api-user-registries:list
      --limit int32      Maximum number of items to return
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-billings

Configured Billings operations

Synopsis

Configured Billings operations

```
apic configured-billings [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-billings
      --limit int32      Maximum number of items to return
      --offset int32     Offset item number from list to begin return
```

```
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-billings:clear

Clear the Configured Billing objects

Synopsis

Clear the Configured Billing objects

```
apic configured-billings:clear [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-billings:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-billings:create

Create a Configured Billing object

Synopsis

Create a Configured Billing object Required fields:\ - billing_url Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - catalog_url

```
apic configured-billings:create [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-billings:create
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-billings:delete

Delete the Configured Billing object by name or id

Synopsis

Delete the Configured Billing object by name or id

```
apic configured-billings:delete [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-billings:delete
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file

      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-catalog-user-registries:search

Search for users in the catalog user registry

Synopsis

Search for users in the catalog user registry

```
apic configured-catalog-user-registries:search [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-catalog-user-registries:search
      --limit int32      Maximum number of items to return
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-gateway-services

Configured Gateway Services operations

Synopsis

Configured Gateway Services operations

```
apic configured-gateway-services [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-gateway-services
      --limit int32      Maximum number of items to return
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-gateway-services:clear

Configured Gateway Services clear operations

Synopsis

Configured Gateway Services clear operations

```
apic configured-gateway-services:clear [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-gateway-services:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-gateway-services:create

Configured Gateway Services create operations

Synopsis

Configured Gateway Services create operations

```
apic configured-gateway-services:create [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-gateway-services:create
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file

  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-gateway-services:delete

Configured Gateway Services delete operations

Synopsis

Configured Gateway Services delete operations

```
apic configured-gateway-services:delete [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-gateway-services:delete
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-gateway-services:get

Configured Gateway Services get operations

Synopsis

Configured Gateway Services get operations

```
apic configured-gateway-services:get [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-gateway-services:get
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, use - for STDOUT. (default: cwd)
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-tls-client-profiles:list

Configured Tls Client Profiles list operations

Synopsis

Configured Tls Client Profiles list operations

```
apic configured-tls-client-profiles:list [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-tls-client-profiles:list
      --limit int32      Maximum number of items to return
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic configured-tls-client-profiles:list-all

Configured Tls Client Profiles list-all operations

Synopsis

Configured Tls Client Profiles list-all operations

```
apic configured-tls-client-profiles:list-all [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for configured-tls-client-profiles:list-all
      --limit int32      Maximum number of items to return
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic consumer-org-settings

Consumer Org Settings operations

Synopsis

Consumer Org Settings operations

```
apic consumer-org-settings [flags]
```

Options

```
  -h, --help   Help for consumer-org-settings
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic consumer-org-settings:delete

Delete the Consumer Organization Setting object

Synopsis

Delete the Consumer Organization Setting object

```
apic consumer-org-settings:delete [flags]
```

Options

```
  -c, --catalog string         Catalog name or id (required)
      --consumer-org string    Consumer Organization name or id (required)
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                   Help for consumer-org-settings:delete
  -o, --org string             Organization name or id (required)
      --output string          Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string          management server endpoint (required)
      --space string           Space name or id (required)
      --space-initiated        space-initiated
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic consumer-org-settings:get

Get the Consumer Organization Setting object

Synopsis

Get the Consumer Organization Setting object

```
apic consumer-org-settings:get [flags]
```

Options

```
  -c, --catalog string         Catalog name or id (required)
      --consumer-org string    Consumer Organization name or id (required)
      --fields string          List of field names to return
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                   Help for consumer-org-settings:get
  -o, --org string             Organization name or id (required)
      --output string          Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string          management server endpoint (required)
      --space string           Space name or id (required)
      --space-initiated        space-initiated
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic consumer-org-settings:update

Update the Consumer Organization Setting object

Synopsis

Update the Consumer Organization Setting object Fields allowed but ignored:\ - name - type - api_version - scope - created_at - updated_at - url

```
apic consumer-org-settings:update [flags]
```

Options

```
  -c, --catalog string         Catalog name or id (required)
      --consumer-org string    Consumer Organization name or id (required)
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                   Help for consumer-org-settings:update
  -o, --org string             Organization name or id (required)
      --output string          Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string          management server endpoint (required)
      --space string           Space name or id (required)
      --space-initiated        space-initiated
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic consumer-orgs

Consumer Orgs operations

Synopsis

Consumer Orgs operations

```
apic consumer-orgs [flags]
```

Options

```
  -c, --catalog string    Catalog name or id (required)
      --expand string     List of transient field to expand
      --fields string     List of field names to return
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for consumer-orgs
      --limit int32       Maximum number of items to return
      --offset int32      Offset item number from list to begin return
  -o, --org string        Organization name or id (required)
      --output string     Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string     management server endpoint (required)
      --space string      Space name or id (required)
      --space-initiated   space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic consumer-orgs:clear

Clear the Consumer Organization objects

Synopsis

Clear the Consumer Organization objects

```
apic consumer-orgs:clear [flags]
```

Options

```
  -c, --catalog string    Catalog name or id (required)
      --confirm string    Confirmation for critical updates (required)
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for consumer-orgs:clear
  -o, --org string        Organization name or id (required)
      --output string     Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string     management server endpoint (required)
      --space string      Space name or id (required)
      --space-initiated   space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic consumer-orgs:create

Create a Consumer Organization object

Synopsis

Create a Consumer Organization object Required fields:\ - owner_url Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - catalog_url

```
apic consumer-orgs:create [flags]
```

Options

```
  -c, --catalog string    Catalog name or id (required)
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for consumer-orgs:create
  -o, --org string        Organization name or id (required)
      --output string     Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string     management server endpoint (required)
      --space string      Space name or id (required)
      --space-initiated   space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic consumer-orgs:delete

Delete the Consumer Organization object by name or id

Synopsis

Delete the Consumer Organization object by name or id

```
apic consumer-orgs:delete [flags]
```

Options

```
  -c, --catalog string    Catalog name or id (required)
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for consumer-orgs:delete
  -o, --org string        Organization name or id (required)
      --output string     Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string     management server endpoint (required)
      --space string      Space name or id (required)
      --space-initiated   space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic consumer-orgs:get

Get the Consumer Organization object by name or id

Synopsis

Get the Consumer Organization object by name or id

```
apic consumer-orgs:get [flags]
```

Options

```
  -c, --catalog string    Catalog name or id (required)
      --fields string     List of field names to return
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for consumer-orgs:get
  -o, --org string        Organization name or id (required)
      --output string     Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string     management server endpoint (required)
      --space string      Space name or id (required)
      --space-initiated   space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
```

```
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic consumer-orgs:list

List the Consumer Organization objects

Synopsis

List the Consumer Organization objects

```
apic consumer-orgs:list [flags]
```

Options

```
  -c, --catalog string     Catalog name or id (required)
      --expand string      List of transient field to expand
      --fields string      List of field names to return
      --format string      Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help               Help for consumer-orgs:list
      --limit int32        Maximum number of items to return
      --offset int32       Offset item number from list to begin return
  -o, --org string         Organization name or id (required)
      --output string      Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string      management server endpoint (required)
      --space string       Space name or id (required)
      --space-initiated    space-initiated
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic consumer-orgs:transfer-owner

Transfer owner to an associate

Synopsis

Transfer owner to an associate

```
apic consumer-orgs:transfer-owner [flags]
```

Options

```
      --cascade              Cascade the behavior
  -c, --catalog string       Catalog name or id (required)
      --delete_old_owner     Delete old owner
      --format string        Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                 Help for consumer-orgs:transfer-owner
  -o, --org string           Organization name or id (required)
      --output string        Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string        management server endpoint (required)
      --space string         Space name or id (required)
      --space-initiated      space-initiated
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic consumer-orgs:update

Update the Consumer Organization object by name or id

Synopsis

Update the Consumer Organization object by name or id Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - catalog_url

```
apic consumer-orgs:update [flags]
```

Options

```
  -c, --catalog string    Catalog name or id (required)
      --fields string     List of field names to return
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for consumer-orgs:update
  -o, --org string        Organization name or id (required)
      --output string     Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string     management server endpoint (required)
      --space string      Space name or id (required)
      --space-initiated   space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic create

Create an API or product definition

Synopsis

Create an API or product definition

```
apic create [flags]
```

Options

```
  -h, --help          Help for create
  -i, --interactive   use interactive mode
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic create:api

Create an OpenAPI (Swagger) definition

Synopsis

Create an OpenAPI (Swagger) definition

```
apic create:api [flags]
```

Examples

```
Create an API
  $ apic create:api --title Routes
  Created routes.yaml API definition [routes:1.0.0]

Create an API and generate a product referencing the API
  $ apic create:api --title Routes --product "Climb On"
  Created routes.yaml API definition [routes:1.0.0]
  Created climb-on.yaml product definition [climb-on:1.0.0]

Create an API interactively
  $ apic create:api
  Title: Routes
  Name (routes): routes
  File (routes.yaml): routes.yaml
  Template: ()
  Basepath (/routes): /routes
  Hostname ($(catalog.host)): $(catalog.host)
  Schemes:
```

```
  Target url: ()
  Create product [true]: true
  Product title (Routes Product): Climb On
  Product name (climb-on): climb-on
  Product file (climb-on.yaml): climb-on.yaml
  Created routes.yaml API definition [routes:1.0.0]
  Created climb-on.yaml product definition [climb-on:1.0.0]

Create an API from a WSDL document
  $ apic create:api --wsdl globalweather.wsdl
  Created globalweather.yaml API definition [globalweather.yaml:1.0.0]

Create an API using APIC's default OAuth 2 provider template
  $ apic create:api --title "OAuth2 Provider" --template oauth2
  Created oauth2-provider.yaml API definition [oauth2-provider:1.0.0]

Create an API using one of your templates
  $ apic config:set --global template-path="/etc/templates"
  $ ls /etc/templates
  proxy.hbs staging.hbs
  $ apic create:api --title "Proxy Provider" --template proxy
  Created proxy-provider.yaml API definition [proxy-provider:1.0.0]

Create an API using your default template
  $ apic config:set --global template-path="/etc/templates"
  $ ls /etc/templates
  proxy.hbs staging.hbs
  $ apic config:set --global template-default-api=staging
  $ apic create:api --title "Staging Provider"
  Created staging-provider.yaml API definition [staging-provider:1.0.0]
```

Options

```
      --api_type string       The type of api (rest, wsdl-to-rest, or wsdl) (default "wsdl")
      --basepath string       basepath value (default derived from name)
      --disable_ws_security   Disable generation of WS-Security definitions in api
      --filename string       filename (default derived from name)
      --gateway-type string   The type of the gateway (datapower-gateway, datapower-api-gateway, event-gateway) (default
"datapower-gateway")
  -h, --help                  Help for create:api
      --hostname string       host value (default $(catalog.host)
  -i, --interactive           use interactive mode
      --name string           x-ibm-name value (default derived from title)
      --product string        generate a product definition referencing the API
      --schemes string        list of schemes (valid options are http, https, ws and wss)
      --services string       service names separated by space
      --target-url string     target url
      --template string       use a provider template (if empty defaults to apic template)
      --title string          title value (required)
  -v, --version string        version value (default "1.0.0")
      --wsdl string           wsdl file to use as the source (required authentication via apic login)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic create:product

Create a product definition

Synopsis

Create a product definition

```
apic create:product [flags]
```

Examples

```
Create a product
  $ apic create:product --title "Climb On"
  Created climb-on.yaml product definition [climb-on:1.0.0]
Create a product interactively
  $ apic create:product
  ? Title: Climb On
  ? Name: climb-on
  ? File: climb-on.yaml
  ? Template:
  ? API Files:
  Created climb-on.yaml product definition [climb-on:1.0.0]
Create a product referencing existing APIs
  $ apic create:product --title "Climb On" --apis "routes.yaml ascents.yaml"
  Created climb-on.yaml product definition [climb-on:1.0.0]
```

```
Create an product using one of your templates
  $ apic config:set --global template-path="/etc/templates"
  $ ls /etc/templates
  proxy-product.hbs staging-product.hbs
  $ apic create:product --title "Proxy Product" --template proxy
  Created proxy-product.yaml product definition [proxy-product:1.0.0]
Create a product using your default template
  $ apic config:set --global template-path="/etc/templates"
  $ ls /etc/templates
  proxy-product.hbs staging-product.hbs
  $ apic config:set --global template-default-product=staging
  $ apic create:product --title "Staging Product"
  Created staging-product.yaml product definition [staging-product:1.0.0]
```

Options

```
      --apis string            api file names separated by a space
      --filename string        filename (default derived from name)
      --gateway-type string    The type of the gateway (datapower-gateway, datapower-api-gateway, event-gateway) (default
"datapower-gateway")
  -h, --help                   Help for create:product
  -i, --interactive            use interactive mode
      --name string            x-ibm-name value (default derived from title)
      --template string        use a provider template (if empty defaults to apic template)
      --title string           title value (required)
  -v, --version string         version value (default "1.0.0")
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic credentials

Credentials operations

Synopsis

Credentials operations

```
apic credentials [flags]
```

Options

```
  -a, --app string             Application name or id (required)
  -c, --catalog string         Catalog name or id (required)
      --consumer-org string    Consumer Organization name or id (required)
      --fields string          List of field names to return
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                   Help for credentials
      --limit int32            Maximum number of items to return
      --offset int32           Offset item number from list to begin return
  -o, --org string             Organization name or id (required)
      --output string          Write file(s) to directory, instead of STDOUT (default "-")
      --scope string           scope
  -s, --server string          management server endpoint (required)
      --space string           Space name or id (required)
      --space-initiated        space-initiated
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic credentials:clear

Credentials clear operations

Synopsis

Credentials clear operations

```
apic credentials:clear [flags]
```

Options

```
  -a, --app string              Application name or id (required)
  -c, --catalog string          Catalog name or id (required)
      --confirm string          Confirmation for critical updates (required)
      --consumer-org string     Consumer Organization name or id (required)
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for credentials:clear
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string           management server endpoint (required)
      --space string            Space name or id (required)
      --space-initiated         space-initiated
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic credentials:create

Create a Application Credential object

Synopsis

Create a Application Credential object Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - catalog_url - consumer_org_url - app_url

```
apic credentials:create [flags]
```

Options

```
  -a, --app string              Application name or id (required)
  -c, --catalog string          Catalog name or id (required)
      --consumer-org string     Consumer Organization name or id (required)
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for credentials:create
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string           management server endpoint (required)
      --space string            Space name or id (required)
      --space-initiated         space-initiated
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic credentials:delete

Delete the Application Credential object by name or id

Synopsis

Delete the Application Credential object by name or id

```
apic credentials:delete [flags]
```

Options

```
  -a, --app string              Application name or id (required)
  -c, --catalog string          Catalog name or id (required)
      --consumer-org string     Consumer Organization name or id (required)
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for credentials:delete
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string           management server endpoint (required)
      --space string            Space name or id (required)
      --space-initiated         space-initiated
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic credentials:get

Get the Application Credential object by name or id

Synopsis

Get the Application Credential object by name or id

```
apic credentials:get [flags]
```

Options

```
  -a, --app string             Application name or id (required)
  -c, --catalog string         Catalog name or id (required)
      --consumer-org string    Consumer Organization name or id (required)
      --fields string          List of field names to return
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                   Help for credentials:get
  -o, --org string             Organization name or id (required)
      --output string          Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string          management server endpoint (required)
      --space string           Space name or id (required)
      --space-initiated        space-initiated
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic credentials:list

List the Application Credential objects

Synopsis

List the Application Credential objects

```
apic credentials:list [flags]
```

Options

```
  -a, --app string             Application name or id (required)
  -c, --catalog string         Catalog name or id (required)
      --consumer-org string    Consumer Organization name or id (required)
      --fields string          List of field names to return
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                   Help for credentials:list
      --limit int32            Maximum number of items to return
      --offset int32           Offset item number from list to begin return
  -o, --org string             Organization name or id (required)
      --output string          Write file(s) to directory, instead of STDOUT (default "-")
      --scope string           scope
  -s, --server string          management server endpoint (required)
      --space string           Space name or id (required)
      --space-initiated        space-initiated
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic credentials:reset-client-secret

Reset the client secret

Synopsis

Reset the client secret

```
apic credentials:reset-client-secret [flags]
```

Options

```
  -a, --app string             Application name or id (required)
  -c, --catalog string         Catalog name or id (required)
      --consumer-org string    Consumer Organization name or id (required)
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                   Help for credentials:reset-client-secret
  -o, --org string             Organization name or id (required)
      --output string          Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string          management server endpoint (required)
      --space string           Space name or id (required)
      --space-initiated        space-initiated
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic credentials:reset

Reset the client id and client secret

Synopsis

Reset the client id and client secret

```
apic credentials:reset [flags]
```

Options

```
  -a, --app string             Application name or id (required)
  -c, --catalog string         Catalog name or id (required)
      --consumer-org string    Consumer Organization name or id (required)
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                   Help for credentials:reset
  -o, --org string             Organization name or id (required)
      --output string          Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string          management server endpoint (required)
      --space string           Space name or id (required)
      --space-initiated        space-initiated
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic credentials:update

Update the Application Credential object by name or id

Synopsis

Update the Application Credential object by name or id Fields not allowed to be null:\ - client_id Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - catalog_url - consumer_org_url - app_url

```
apic credentials:update [flags]
```

Options

```
  -a, --app string              Application name or id (required)
  -c, --catalog string          Catalog name or id (required)
      --consumer-org string     Consumer Organization name or id (required)
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for credentials:update
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string           management server endpoint (required)
      --space string            Space name or id (required)
      --space-initiated         space-initiated
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic credentials:verify-client-secret

Verify the client secret

Synopsis

Verify the client secret

```
apic credentials:verify-client-secret [flags]
```

Options

```
  -a, --app string              Application name or id (required)
  -c, --catalog string          Catalog name or id (required)
      --consumer-org string     Consumer Organization name or id (required)
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for credentials:verify-client-secret
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string           management server endpoint (required)
      --space string            Space name or id (required)
      --space-initiated         space-initiated
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic draft-apis

Draft Apis operations

Synopsis

Draft Apis operations

```
apic draft-apis [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-apis
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-apis:clear-all

Clear all Draft API objects in all collections

Synopsis

Clear all Draft API objects in all collections

```
apic draft-apis:clear-all [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for draft-apis:clear-all
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-apis:clear

Clear the Draft API objects

Synopsis

Clear the Draft API objects

```
apic draft-apis:clear [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for draft-apis:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-apis:clone

Clone the draft-api objects

Synopsis

Clone the draft-api objects

```
apic draft-apis:clone [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-apis:clone
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-apis:create

Create a Draft API object

Synopsis

Create a Draft API object Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url

```
apic draft-apis:create [flags]
```

Options

```
      --api_type string         The type of api (asyncapi, rest, graphql, wsdl_to_rest, or wsdl)
      --assembly_type string    The type of the assembly to generate (rest_to_proxy)
      --disable_ws_security     Disable generation of WS-Security definitions in api
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
      --gateway_type string     The type of the gateway (datapower-gateway, datapower-api-gateway, event-gateway)
  -h, --help                    Help for draft-apis:create
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string           management server endpoint (required)
      --wsdl_service string     Name of WSDL service to create the OpenAPI definition from
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-apis:delete

Delete a Draft API

Synopsis

Delete a Draft API

```
apic draft-apis:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-apis:delete
      --id              id
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-apis:document

Get the Draft API document by name and version

Synopsis

Get the Draft API document by name and version

```
apic draft-apis:document [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-apis:document
      --id              id
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-apis:get

Get the Draft API object by name and version

Synopsis

Get the Draft API object by name and version

```
apic draft-apis:get [flags]
```

Options

```
      --fields string   List of field names to return (default "add(wsdl,draft_api)")
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-apis:get
      --id              id
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-apis:list

List the Draft API objects

Synopsis

List the Draft API objects

```
apic draft-apis:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-apis:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
```

```
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-apis:list-all

List all Draft API objects in all collections

Synopsis

List all Draft API objects in all collections

```
apic draft-apis:list-all [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-apis:list-all
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-apis:update

Update the Draft API object by name and version

Synopsis

Update the Draft API object by name and version Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url

```
apic draft-apis:update [flags]
```

Options

```
      --api_type string       The type of api (asyncapi, rest, graphql, wsdl_to_rest, or wsdl)
      --disable_ws_security   Disable generation of WS-Security definitions in api
      --format string         Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                  Help for draft-apis:update
      --id                    id
  -o, --org string            Organization name or id (required)
      --output string         Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string         management server endpoint (required)
      --wsdl_service string   Name of WSDL service to create the OpenAPI definition from
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-apis:update-wsdl

Update with a new wsdl

Synopsis

Update with a new wsdl

```
apic draft-apis:update-wsdl [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-apis:update-wsdl
      --id              id
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-apis:validate

Validate the draft api

Synopsis

Validate the draft api

```
apic draft-apis:validate [flags]
```

Options

```
      --catalog_name string             Name of a catalog
      --format string                   Output format. One of [json yaml go-template=... go-template-file=...], defaults to
yaml.
      --gateway_service_names string    Names of Gateway Services
  -h, --help                            Help for draft-apis:validate
      --id                              id
  -o, --org string                      Organization name or id (required)
      --output string                   Write file(s) to directory, instead of STDOUT (default "-")
      --scope string                    scope
  -s, --server string                   management server endpoint (required)
      --space_name string               Name of a space
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-apis:wsdl

Get the Draft API wsdl document by name and version

Synopsis

Get the Draft API wsdl document by name and version

```
apic draft-apis:wsdl [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-apis:wsdl
      --id              id
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-products

Draft Products operations

Synopsis

Draft Products operations

```
apic draft-products [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-products
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-products:clear-all

Clear all Draft Product objects in all collections

Synopsis

Clear all Draft Product objects in all collections

```
apic draft-products:clear-all [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for draft-products:clear-all
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-products:clear

Clear the Draft Product objects

Synopsis

Clear the Draft Product objects

```
apic draft-products:clear [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for draft-products:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-products:clone

Clone the draft-product objects

Synopsis

Clone the draft-product objects

```
apic draft-products:clone [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-products:clone
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-products:create

Create a Draft Product object

Synopsis

Create a Draft Product object Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url

```
apic draft-products:create [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-products:create
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
      --product-only    Upload only the product document
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-products:delete

Delete a Draft Product

Synopsis

Delete a Draft Product

```
apic draft-products:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-products:delete
      --id              id
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-products:document

Get the Draft Product document by name and version

Synopsis

Get the Draft Product document by name and version

```
apic draft-products:document [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-products:document
      --id              id
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-products:get

Get the Draft Product object by name and version

Synopsis

Get the Draft Product object by name and version

```
apic draft-products:get [flags]
```

Options

```
      --fields string   List of field names to return (default "add(draft_product,url)")
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-products:get
      --id              id
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-products:list-all

List all Draft Product objects in all collections

Synopsis

List all Draft Product objects in all collections

```
apic draft-products:list-all [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-products:list-all
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return

      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-products:list

List the Draft Product objects

Synopsis

List the Draft Product objects

```
apic draft-products:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-products:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic draft-products:publish

Publish a draft product

Synopsis

Publish a draft product

```
apic draft-products:publish [flags]
```

Options

```
  -c, --catalog string             Catalog name or id (required)
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
      --gateway_services string    The list of gateway service names to support partial publishing
  -h, --help                       Help for draft-products:publish
      --migrate_subscriptions      Migrate subscription when republish product
  -o, --org string                 Organization name or id (required)
      --output string              Write file(s) to directory, instead of STDOUT (default "-")
      --scope string               scope
  -s, --server string              management server endpoint (required)
      --space string               Space name or id (required)
      --stage                      stage
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic draft-products:update

Update the Draft Product object by name and version

Synopsis

Update the Draft Product object by name and version Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url

```
apic draft-products:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for draft-products:update
      --id              id

      --id                              id
  -o, --org string                      Organization name or id (required)
      --output string                   Write file(s) to directory, instead of STDOUT (default "-")
      --scope string                    scope
  -s, --server string                   management server endpoint (required)
      --space_name string               Name of a space
      --validate_apis                   Whether to validate APIs also
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic drafts

Drafts operations

Synopsis

Drafts operations

```
apic drafts [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for drafts
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic drafts:clear

Clear the Draft objects

Synopsis

Clear the Draft objects

```
apic drafts:clear [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for drafts:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic drafts:list

List the Draft objects

Synopsis

List the Draft objects

```
apic drafts:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for drafts:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic entries

Entries operations

Synopsis

Entries operations

```
apic entries [flags]
```

Options

```
      --fields string       List of field names to return
      --format string       Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                Help for entries
      --limit int32         Maximum number of items to return
      --offset int32        Offset item number from list to begin return
  -o, --org string          Organization name or id (required)
      --output string       Write file(s) to directory, instead of STDOUT (default "-")
      --scope string        scope
  -s, --server string       management server endpoint (required)
      --truststore string   Truststore name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic entries:clear

Entries clear operations

Synopsis

Entries clear operations

```
apic entries:clear [flags]
```

Options

```
      --confirm string      Confirmation for critical updates (required)
      --format string       Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                Help for entries:clear
  -o, --org string          Organization name or id (required)
      --output string       Write file(s) to directory, instead of STDOUT (default "-")
      --scope string        scope
  -s, --server string       management server endpoint (required)
      --truststore string   Truststore name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect

```

apic gateway-services:list

List the Gateway Service objects

Synopsis

List the Gateway Service objects

```
apic gateway-services:list [flags]
```

Options

```
      --availability-zone string   Availability Zone name or id (required)
      --fields string              List of field names to return
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                       Help for gateway-services:list
      --limit int32                Maximum number of items to return
      --offset int32               Offset item number from list to begin return
  -o, --org string                 Organization name or id (required)
      --output string              Write file(s) to directory, instead of STDOUT (default "-")
      --scope string               scope
  -s, --server string              management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic gateway-services:reset-oauth-secret

Reset the oauth shared crypto material

Synopsis

Reset the oauth shared crypto material

```
apic gateway-services:reset-oauth-secret [flags]
```

Options

```
      --availability-zone string   Availability Zone name or id (required)
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                       Help for gateway-services:reset-oauth-secret
  -o, --org string                 Organization name or id (required)
      --output string              Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string              management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic gateway-services:update

Update the Gateway Service object by name or id

Synopsis

Update the Gateway Service object by name or id Fields not allowed to be null:\ - endpoint - api_endpoint_base - sni Fields not allowed:\ - owned - endpoint - integration_url - gateway_service_type - api_endpoint_base Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - availability_zone_url

```
apic gateway-services:update [flags]
```

Options

```
      --availability-zone string   Availability Zone name or id (required)
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                       Help for gateway-services:update
  -o, --org string                 Organization name or id (required)
      --output string              Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string              management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic global-policies

Global Policies operations

Synopsis

Global Policies operations

```
apic global-policies [flags]
```

Options

```
  -c, --catalog string                        Catalog name or id (required)
      --configured-gateway-service string   Configured Gateway Service name or id (required)
      --fields string                       List of field names to return
      --format string                       Output format. One of [json yaml go-template=... go-template-file=...], defaults to
yaml.
  -h, --help                                Help for global-policies

```

apic groups:create

Groups create operations

Synopsis

Groups create operations

```
apic groups:create [flags]
```

Options

```
  -c, --catalog string    Catalog name or id (required)
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for groups:create
  -o, --org string        Organization name or id (required)
      --output string     Write file(s) to directory, instead of STDOUT (default "-")
      --scope string      scope
  -s, --server string     management server endpoint (required)
      --space string      Space name or id (required)
      --space-initiated   space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic groups:delete

Groups delete operations

Synopsis

Groups delete operations

```
apic groups:delete [flags]
```

Options

```
  -c, --catalog string    Catalog name or id (required)
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for groups:delete
  -o, --org string        Organization name or id (required)
      --output string     Write file(s) to directory, instead of STDOUT (default "-")
      --scope string      scope
  -s, --server string     management server endpoint (required)
      --space string      Space name or id (required)
      --space-initiated   space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic groups:get

Groups get operations

Synopsis

Groups get operations

```
apic groups:get [flags]
```

Options

```
  -c, --catalog string    Catalog name or id (required)
      --fields string     List of field names to return
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for groups:get
  -o, --org string        Organization name or id (required)
      --output string     Write file(s) to directory, use - for STDOUT. (default: cwd)
      --scope string      scope
  -s, --server string     management server endpoint (required)
      --space string      Space name or id (required)
      --space-initiated   space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file

  -m, --mode string           Toolkit operation mode (default "apim")
```

apic iam-apikey

Log in to an IBM API Connect cloud Reserved Instance using an IBM Cloud API key

Synopsis

Log in to an IBM API Connect cloud Reserved Instance using an IBM Cloud API key

```
apic iam-apikey [flags]
```

Examples

```
Interactive iam-apikey login
$ apic iam-apikey
Enter your IBM Cloud details
? Server: mgmnthost.com
? IBM Cloud API Key?: my-apikey
 Logged into mgmnthost.com successfully

Non-interactive
$ apic iam-apikey --apiKey <apikey> --server mgmnthost.com
Logged into mgmnthost.com successfully
```

Options

```
      --apiKey string          IBM cloud api key
  -h, --help                   Help for iam-apikey
  -s, --server string          management server endpoint
      --tokenendpoint string   iam server endpoint (default: iam.cloud.ibm.com)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic identity-providers

Identity Providers operations

Synopsis

Identity Providers operations

```
apic identity-providers [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for identity-providers
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
```

```
      --scope string    scope
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic identity-providers:list

Identity Providers list operations

Synopsis

Identity Providers list operations

```
apic identity-providers:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for identity-providers:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
      --scope string    scope
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic integrations

Integrations operations

Synopsis

Integrations operations

```
apic integrations [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for integrations
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect

Options

```
  -c, --catalog string    Catalog name or id (required)
      --fields string     List of field names to return
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for invitations:get
  -o, --org string        Organization name or id (required)
      --output string     Write file(s) to directory, use - for STDOUT. (default: cwd)
      --scope string      scope
  -s, --server string     management server endpoint (required)
      --space string      Space name or id (required)
      --space-initiated   space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic invitations:list

Invitations list operations

Synopsis

Invitations list operations

```
apic invitations:list [flags]
```

Options

```
  -c, --catalog string    Catalog name or id (required)
      --fields string     List of field names to return
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for invitations:list
      --limit int32       Maximum number of items to return
      --offset int32      Offset item number from list to begin return
  -o, --org string        Organization name or id (required)
      --output string     Write file(s) to directory, instead of STDOUT (default "-")
      --scope string      scope
  -s, --server string     management server endpoint (required)
      --space string      Space name or id (required)
      --space-initiated   space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic invitations:update

Invitations update operations

Synopsis

Invitations update operations

```
apic invitations:update [flags]
```

Options

```
  -c, --catalog string    Catalog name or id (required)
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for invitations:update
  -o, --org string        Organization name or id (required)
      --output string     Write file(s) to directory, instead of STDOUT (default "-")
      --scope string      scope
  -s, --server string     management server endpoint (required)
      --space string      Space name or id (required)
      --space-initiated   space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic jobs

Jobs operations

Synopsis

Jobs operations

```
apic jobs [flags]
```

Options

```
      --billing string   Billing name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for jobs
      --limit int32      Maximum number of items to return
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic jobs:clear

Clear the Job objects

Synopsis

Clear the Job objects

```
apic jobs:clear [flags]
```

Options

```
      --billing string   Billing name or id (required)
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for jobs:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic jobs:delete

Delete the Job object by name or id

Synopsis

Delete the Job object by name or id

```
apic jobs:delete [flags]
```

Options

```
      --billing string   Billing name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for jobs:delete
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic jobs:get

Get the Job object by name or id

Synopsis

Get the Job object by name or id

```
apic jobs:get [flags]
```

Options

```
      --billing string   Billing name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for jobs:get
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic jobs:list

List the Job objects

Synopsis

List the Job objects

```
apic jobs:list [flags]
```

Options

```
      --billing string   Billing name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for jobs:list
      --limit int32      Maximum number of items to return
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic jobs:retry

Re-attempt blocked or failed job

Synopsis

Re-attempt blocked or failed job

```
apic jobs:retry [flags]
```

Options

```
      --billing string   Billing name or id (required)
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for jobs:retry
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic keystores

Keystores operations

Synopsis

Keystores operations

```
apic keystores [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for keystores
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic keystores:clear

Clear the Keystore objects

Synopsis

Clear the Keystore objects

```
apic keystores:clear [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for keystores:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic keystores:create

Create a Keystore object

Synopsis

Create a Keystore object Required fields:\ - keystore Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url

```
apic keystores:create [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for keystores:create
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic keystores:delete

Delete the Keystore object by name or id

Synopsis

Delete the Keystore object by name or id

```
apic keystores:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for keystores:delete
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic keystores:get

Get the Keystore object by name or id

Synopsis

Get the Keystore object by name or id

```
apic keystores:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for keystores:get
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic keystores:list

List the Keystore objects

Synopsis

List the Keystore objects

```
apic keystores:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for keystores:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic keystores:update

Update the Keystore object by name or id

Synopsis

Update the Keystore object by name or id Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url

```
apic keystores:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for keystores:update
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic licenses

Review the license for API Connect

Synopsis

Review the license for API Connect

```
apic licenses [flags]
```

Options

```
  -h, --help              Help for licenses
      --non-ibm-license   Display the non IBM license files.
      --notices           Display the notices file
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic log-spec

Log Spec operations

Synopsis

Log Spec operations

```
apic log-spec [flags]
```

Options

```
  -h, --help   Help for log-spec
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic log-spec:get

Get the Log Spec object

Synopsis

Get the Log Spec object

```
apic log-spec:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for log-spec:get
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic log-spec:update

Update the Log Spec object

Synopsis

Update the Log Spec object Fields allowed but ignored:\ - name - type - api_version - scope - created_at - updated_at - url

```
apic log-spec:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for log-spec:update
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic login

Log in to an IBM API Connect cloud

Synopsis

Log in to an IBM API Connect cloud

```
apic login [flags]
```

Examples

```
Interactive login
$ apic login
Enter your API Connect credentials
? Server: mgmnthost.com
? Realm: company/realm
? Username: tommy
? Password: password
Logged into mgmnthost.com successfully

Non-interactive login
$ apic login --username tommy --password password --server mgmnthost.com --realm company/realm
Logged into mgmnthost.com successfully
```

Options

```
      --apiKey string     apiKey
      --context string    context
  -h, --help              Help for login
  -p, --password string   password
  -r, --realm string      realm
  -s, --server string     management server endpoint
      --sso               sso
  -u, --username string   user name
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic logout

Log out of an IBM API Connect cloud

Synopsis

Log out of an IBM API Connect cloud

```
apic logout [flags]
```

Examples

```
Clear the local authentication credentials for mgmnthost.com
$ apic logout --server mgmnthost.com
Logged out of server mgmnthost.com
```

Options

```
  -h, --help            Help for logout
  -s, --server string   management server endpoint
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic mail-servers

Mail Servers operations

Synopsis

Mail Servers operations

```
apic mail-servers [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for mail-servers
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
```

```
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic mail-servers:clear

Clear the Mail Server objects

Synopsis

Clear the Mail Server objects

```
apic mail-servers:clear [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for mail-servers:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic mail-servers:create

Create a Mail Server object

Synopsis

Create a Mail Server object Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url

```
apic mail-servers:create [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for mail-servers:create
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic mail-servers:delete

Delete the Mail Server object by name or id

Synopsis

Delete the Mail Server object by name or id

```
apic mail-servers:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for mail-servers:delete
  -o, --org string      Organization name or id (required)
```

```
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic mail-servers:get

Get the Mail Server object by name or id

Synopsis

Get the Mail Server object by name or id

```
apic mail-servers:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for mail-servers:get
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic mail-servers:list

List the Mail Server objects

Synopsis

List the Mail Server objects

```
apic mail-servers:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for mail-servers:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic mail-servers:test-connection

Test a Mail Server connection

Synopsis

Test a Mail Server connection

```
apic mail-servers:test-connection [flags]
```

Options

```
      --format string      Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help               Help for mail-servers:test-connection
  -o, --org string         Organization name or id (required)
      --output string      Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string      management server endpoint (required)
      --test-config-only   test-config-only
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic mail-servers:update

Update the Mail Server object by name or id

Synopsis

Update the Mail Server object by name or id Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url

```
apic mail-servers:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for mail-servers:update
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic me

Me operations

Synopsis

Me operations

```
apic me [flags]
```

Options

```
  -h, --help   Help for me
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic me:change-password

Change my password

Synopsis

Change my password

```
apic me:change-password [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for me:change-password
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic me:delete

Delete the Me object

Synopsis

Delete the Me object

```
apic me:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for me:delete
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic me:get

Get the Me object

Synopsis

Get the Me object

```
apic me:get [flags]
```

Options

```
      --context string   user's login context admin/manager
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for me:get
      --output string    Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic me:update

Update the Me object

Synopsis

Update the Me object Fields allowed but ignored:\ - name - type - api_version - scope - created_at - updated_at - url

```
apic me:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for me:update
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic member-invitations

Member Invitations operations

Synopsis

Member Invitations operations

```
apic member-invitations [flags]
```

Options

```
  -c, --catalog string         Catalog name or id (required)
      --consumer-org string    Consumer Organization name or id (required)
      --fields string          List of field names to return
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                   Help for member-invitations
      --limit int32            Maximum number of items to return
      --offset int32           Offset item number from list to begin return
  -o, --org string             Organization name or id (required)
      --output string          Write file(s) to directory, instead of STDOUT (default "-")
      --scope string           scope
  -s, --server string          management server endpoint (required)
      --space string           Space name or id (required)
      --space-initiated        space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic member-invitations:clear

Member Invitations clear operations

Synopsis

Member Invitations clear operations

```
apic member-invitations:clear [flags]
```

Options

```
  -c, --catalog string         Catalog name or id (required)
      --confirm string         Confirmation for critical updates (required)
```

```
      --consumer-org string   Consumer Organization name or id (required)
      --format string         Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                  Help for member-invitations:clear
  -o, --org string            Organization name or id (required)
      --output string         Write file(s) to directory, instead of STDOUT (default "-")
      --scope string          scope
  -s, --server string         management server endpoint (required)
      --space string          Space name or id (required)
      --space-initiated       space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect

  -s, --server string           management server endpoint (required)
      --space string            Space name or id (required)
      --subcollection string    subcollection
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic oauth-providers

Oauth Providers operations

Synopsis

Oauth Providers operations

```
apic oauth-providers [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for oauth-providers
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic oauth-providers:clear

Clear the Oauth Provider objects

Synopsis

Clear the Oauth Provider objects

```
apic oauth-providers:clear [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for oauth-providers:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic oauth-providers:create

Create a Oauth Provider object

Synopsis

Create a Oauth Provider object Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url

```
apic oauth-providers:create [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for oauth-providers:create
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic oauth-providers:delete

Delete the Oauth Provider object by name or id

Synopsis

Delete the Oauth Provider object by name or id

```
apic oauth-providers:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for oauth-providers:delete
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic oauth-providers:get

Get the Oauth Provider object by name or id

Synopsis

Get the Oauth Provider object by name or id

```
apic oauth-providers:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for oauth-providers:get
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic oauth-providers:list

List the Oauth Provider objects

Synopsis

List the Oauth Provider objects

```
apic oauth-providers:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for oauth-providers:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic oauth-providers:update

Update the Oauth Provider object by name or id

Synopsis

Update the Oauth Provider object by name or id Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url

```
apic oauth-providers:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for oauth-providers:update
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic org-settings

Org Settings operations

Synopsis

Org Settings operations

```
apic org-settings [flags]
```

Options

```
  -h, --help   Help for org-settings
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic org-settings:get

Get the Organization Setting object

Synopsis

Get the Organization Setting object

```
apic org-settings:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for org-settings:get
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic org-settings:update

Update the Organization Setting object

Synopsis

Update the Organization Setting object Fields allowed but ignored:\ - name - type - api_version - scope - created_at - updated_at - url

```
apic org-settings:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for org-settings:update
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic orgs

Orgs operations

Synopsis

Orgs operations

```
apic orgs [flags]
```

Options

```
      --expand string     List of transient field to expand
      --fields string     List of field names to return
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for orgs
      --limit int32       Maximum number of items to return
      --my                my
      --offset int32      Offset item number from list to begin return
      --org_type string   Type of orgs to return
      --output string     Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string     management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic orgs:clear

Clear the Organization objects

Synopsis

Clear the Organization objects

```
apic orgs:clear [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for orgs:clear
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic orgs:create

Create an Organization object

Synopsis

Create an Organization object Required fields:\ - owner_url Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url

```
apic orgs:create [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for orgs:create
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic orgs:delete

Delete the Organization object by name or id

Synopsis

Delete the Organization object by name or id

```
apic orgs:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for orgs:delete
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic orgs:get

Get the Organization object by name or id

Synopsis

Get the Organization object by name or id

```
apic orgs:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for orgs:get
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic orgs:list

List the Organization objects

Synopsis

List the Organization objects

```
apic orgs:list [flags]
```

Options

```
      --expand string     List of transient field to expand
      --fields string     List of field names to return
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for orgs:list
      --limit int32       Maximum number of items to return
      --my                my
      --offset int32      Offset item number from list to begin return
      --org_type string   Type of orgs to return
      --output string     Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string     management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
```

```
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic orgs:transfer-owner

Transfer owner to an associate

Synopsis

Transfer owner to an associate

```
apic orgs:transfer-owner [flags]
```

Options

```
      --cascade              Cascade the behavior
      --delete_old_owner     Delete old owner
      --format string        Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                 Help for orgs:transfer-owner
      --output string        Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string        management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic orgs:update

Update the Organization object by name or id

Synopsis

Update the Organization object by name or id Fields not allowed:\ - name - org_type Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url

```
apic orgs:update [flags]
```

Options

```
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for orgs:update
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic payment-methods

Payment Methods operations

Synopsis

Payment Methods operations

```
apic payment-methods [flags]
```

Options

```
  -c, --catalog string         Catalog name or id (required)
      --consumer-org string    Consumer Organization name or id (required)
      --fields string          List of field names to return
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
```

```
  -h, --help                    Help for payment-methods
      --limit int32             Maximum number of items to return

  -m, --mode string            Toolkit operation mode (default "apim")
```

apic payment-methods:update

Update the Payment Method object by name or id

Synopsis

Update the Payment Method object by name or id Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - consumer_org_url

```
apic payment-methods:update [flags]
```

Options

```
  -c, --catalog string          Catalog name or id (required)
      --consumer-org string     Consumer Organization name or id (required)
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for payment-methods:update
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string           management server endpoint (required)
      --space string            Space name or id (required)
      --space-initiated         space-initiated
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic permissions

Permissions operations

Synopsis

Permissions operations

```
apic permissions [flags]
```

Options

```
      --fields string     List of field names to return
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for permissions
      --limit int32       Maximum number of items to return
      --offset int32      Offset item number from list to begin return
      --output string     Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string     management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic permissions:get

Permissions get operations

Synopsis

Permissions get operations

```
apic permissions:get [flags]
```

Options

```
      --fields string           List of field names to return
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for permissions:get
      --output string           Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string           management server endpoint (required)
      --subcollection string    subcollection
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output

      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic permissions:list

Permissions list operations

Synopsis

Permissions list operations

```
apic permissions:list [flags]
```

Options

```
      --fields string           List of field names to return
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for permissions:list
      --limit int32             Maximum number of items to return
      --my                      my
      --offset int32            Offset item number from list to begin return
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string           management server endpoint (required)
      --subcollection string    subcollection
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic permissions:list-all

List all Permission objects in all collections

Synopsis

List all Permission objects in all collections

```
apic permissions:list-all [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for permissions:list-all
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic policies

Policies operations

Synopsis

Policies operations

```
apic policies [flags]
```

Options

```
      --availability-zone string            Availability Zone name or id (required)
  -c, --catalog string                      Catalog name or id (required)
      --configured-gateway-service string   Configured Gateway Service name or id (required)
```

```
      --fields string                       List of field names to return
      --format string                       Output format. One of [json yaml go-template=... go-template-file=...], defaults to
yaml.
      --gateway-service string              Gateway Service name or id (required)
  -h, --help                                Help for policies

  -m, --mode string            Toolkit operation mode (default "apim")
```

apic portal-services:create

Create a Portal Service object

Synopsis

Create a Portal Service object Required fields:\ - endpoint - web_endpoint_base Fields not allowed:\ - owned Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - availability_zone_url

```
apic portal-services:create [flags]
```

Options

```
      --availability-zone string   Availability Zone name or id (required)
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                       Help for portal-services:create
  -o, --org string                 Organization name or id (required)
      --output string              Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string              management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic portal-services:delete

Delete the Portal Service object by name or id

Synopsis

Delete the Portal Service object by name or id

```
apic portal-services:delete [flags]
```

Options

```
      --availability-zone string   Availability Zone name or id (required)
      --force                      Force the operation
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                       Help for portal-services:delete
  -o, --org string                 Organization name or id (required)
      --output string              Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string              management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic portal-services:get

Get the Portal Service object by name or id

Synopsis

Get the Portal Service object by name or id

```
apic portal-services:get [flags]
```

Options

```
      --availability-zone string   Availability Zone name or id (required)
      --fields string              List of field names to return
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                       Help for portal-services:get
  -o, --org string                 Organization name or id (required)
      --output string              Write file(s) to directory, use - for STDOUT. (default: cwd)
      --scope string               scope
  -s, --server string              management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic portal-services:list

List the Portal Service objects

Synopsis

List the Portal Service objects

```
apic portal-services:list [flags]
```

Options

```
      --availability-zone string   Availability Zone name or id (required)
      --fields string              List of field names to return
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                       Help for portal-services:list
      --limit int32                Maximum number of items to return
      --offset int32               Offset item number from list to begin return
  -o, --org string                 Organization name or id (required)
      --output string              Write file(s) to directory, instead of STDOUT (default "-")
      --scope string               scope
  -s, --server string              management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic portal-services:update-credentials

Update the Portal Service configuration

Synopsis

Update the Portal Service configuration

```
apic portal-services:update-credentials [flags]
```

Options

```
      --availability-zone string   Availability Zone name or id (required)
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                       Help for portal-services:update-credentials
  -o, --org string                 Organization name or id (required)
      --output string              Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string              management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic portal-services:update

Update the Portal Service object by name or id

Synopsis

Update the Portal Service object by name or id Fields not allowed to be null:\ - endpoint_tls_client_profile_url - web_endpoint_base Fields not allowed:\ - owned - endpoint Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - availability_zone_url

```
apic portal-services:update [flags]
```

Options

```
      --availability-zone string   Availability Zone name or id (required)
      --format string              Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
```

```
  -h, --help                        Help for portal-services:update
  -o, --org string                  Organization name or id (required)
      --output string               Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string               management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic primary-events

Primary Events operations

Synopsis

Primary Events operations

```
apic primary-events [flags]
```

Options

```
      --availability-zone string             Availability Zone name or id (required)
  -c, --catalog string                       Catalog name or id (required)

      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic registrations:clear

Clear the Registration objects

Synopsis

Clear the Registration objects

```
apic registrations:clear [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for registrations:clear
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
```

```
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic registrations:create

Create a Registration object

Synopsis

Create a Registration object Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url

```
apic registrations:create [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for registrations:create
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic registrations:delete

Delete the Registration object by name or id

Synopsis

Delete the Registration object by name or id

```
apic registrations:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for registrations:delete
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic registrations:get

Get the Registration object by name or id

Synopsis

Get the Registration object by name or id

```
apic registrations:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for registrations:get
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic registrations:list

List the Registration objects

Synopsis

List the Registration objects

```
apic registrations:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for registrations:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic registrations:update

Update the Registration object by name or id

Synopsis

Update the Registration object by name or id Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url

```
apic registrations:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for registrations:update
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic role-defaults

Role Defaults operations

Synopsis

Role Defaults operations

```
apic role-defaults [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for role-defaults
      --limit int32      Maximum number of items to return
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic role-defaults:clear

Role Defaults clear operations

Synopsis

Role Defaults clear operations

```
apic role-defaults:clear [flags]
```

Options

```
      --confirm string         Confirmation for critical updates (required)
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                   Help for role-defaults:clear
      --output string          Write file(s) to directory, instead of STDOUT (default "-")
      --scope string           scope
  -s, --server string          management server endpoint (required)
      --subcollection string   subcollection
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file

      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic space-settings

Space Settings operations

Synopsis

Space Settings operations

```
apic space-settings [flags]
```

Options

```
  -h, --help   Help for space-settings
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic space-settings:get

Get the Space Setting object

Synopsis

Get the Space Setting object

```
apic space-settings:get [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for space-settings:get
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic space-settings:update

Update the Space Setting object

Synopsis

Update the Space Setting object Fields allowed but ignored:\ - name - type - api_version - scope - created_at - updated_at - url - org_url - catalog_url - space_url

```
apic space-settings:update [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for space-settings:update
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
      --space string     Space name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic spaces

Spaces operations

Synopsis

Spaces operations

```
apic spaces [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for spaces
```

```
      --limit int32      Maximum number of items to return
      --my               my
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic spaces:clear

Clear the Space objects

Synopsis

Clear the Space objects

```
apic spaces:clear [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for spaces:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic spaces:create

Create a Space object

Synopsis

Create a Space object Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - catalog_url

```
apic spaces:create [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for spaces:create
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic spaces:delete

Delete the Space object by name or id

Synopsis

Delete the Space object by name or id

```
apic spaces:delete [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for spaces:delete
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic spaces:email-to-owners

Send email to owners of consumer organizations

Synopsis

Send email to owners of consumer organizations, given consumer org and consumer group urls. For consumer group, email owners of all consumer orgs in the group.

```
apic spaces:email-to-owners [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for spaces:email-to-owners
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic spaces:get

Get the Space object by name or id

Synopsis

Get the Space object by name or id

```
apic spaces:get [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for spaces:get
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
```

```
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic spaces:list

List the Space objects

Synopsis

List the Space objects

```
apic spaces:list [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for spaces:list
      --limit int32      Maximum number of items to return
      --my               my
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic spaces:transfer-owner

Transfer owner to an associate

Synopsis

Transfer owner to an associate

```
apic spaces:transfer-owner [flags]
```

Options

```
      --cascade              Cascade the behavior
  -c, --catalog string       Catalog name or id (required)
      --delete_old_owner     Delete old owner
      --format string        Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                 Help for spaces:transfer-owner
  -o, --org string           Organization name or id (required)
      --output string        Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string        management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic spaces:update

Update the Space object by name or id

Synopsis

Update the Space object by name or id Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - catalog_url

```
apic spaces:update [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for spaces:update
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic subscriber-events

Subscriber Events operations

Synopsis

Subscriber Events operations

```
apic subscriber-events [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for subscriber-events
      --limit int32      Maximum number of items to return
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --state string     State for a webhook event in subscriber queue
      --webhook string   Webhook name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file

```

apic subscriptions:delete

Delete the Subscription object by name or id

Synopsis

Delete the Subscription object by name or id

```
apic subscriptions:delete [flags]
```

Options

```
  -a, --app string              Application name or id (required)
  -c, --catalog string          Catalog name or id (required)
      --consumer-org string     Consumer Organization name or id (required)
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for subscriptions:delete
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string           management server endpoint (required)
      --space string            Space name or id (required)
      --space-initiated         space-initiated
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic subscriptions:get

Get the Subscription object by name or id

Synopsis

Get the Subscription object by name or id

```
apic subscriptions:get [flags]
```

Options

```
  -a, --app string              Application name or id (required)
  -c, --catalog string          Catalog name or id (required)
      --consumer-org string     Consumer Organization name or id (required)
      --fields string           List of field names to return
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for subscriptions:get
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string           management server endpoint (required)
      --space string            Space name or id (required)
      --space-initiated         space-initiated
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic subscriptions:list

List the Subscription objects

Synopsis

List the Subscription objects

```
apic subscriptions:list [flags]
```

Options

```
  -a, --app string                  Application name or id (required)
  -c, --catalog string              Catalog name or id (required)
      --consumer-org string         Consumer Organization name or id (required)
      --consumer_org_url string     Consumer Org Url
      --expand string               List of transient field to expand
      --fields string               List of field names to return
      --format string               Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                        Help for subscriptions:list
      --limit int32                 Maximum number of items to return
      --offset int32                Offset item number from list to begin return
  -o, --org string                  Organization name or id (required)
      --output string               Write file(s) to directory, instead of STDOUT (default "-")
      --plan string                 Plan Name
```

```
      --product_url string        Product Url
      --scope string              scope
  -s, --server string             management server endpoint (required)
      --space string              Space name or id (required)
      --space-initiated           space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic subscriptions:update

Update the Subscription object by name or id

Synopsis

Update the Subscription object by name or id Fields not allowed:\ - billing_identifiers - plan_title Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - catalog_url - consumer_org_url - app_url

```
apic subscriptions:update [flags]
```

Options

```
  -a, --app string            Application name or id (required)
  -c, --catalog string        Catalog name or id (required)
      --consumer-org string   Consumer Organization name or id (required)
      --format string         Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                  Help for subscriptions:update
  -o, --org string            Organization name or id (required)
      --output string         Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string         management server endpoint (required)
      --space string          Space name or id (required)
      --space-initiated       space-initiated
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic task-queues

Task Queues operations

Synopsis

Task Queues operations

```
apic task-queues [flags]
```

Options

```
      --apply_filter    Filter tasks
      --cascade         Cascade the behavior
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for task-queues
      --kind string     kind of item
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
      --query string    Add query to request
      --scope string    scope
  -s, --server string   management server endpoint (required)
      --state string    State for a webhook event in subscriber queue
      --target string   target for the task
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
```

```
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic task-queues:get

Task Queues get operations

Synopsis

Task Queues get operations

```
apic task-queues:get [flags]
```

Options

```
      --cascade          Cascade the behavior
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for task-queues:get
      --kind string      kind of item
      --output string    Write file(s) to directory, use - for STDOUT. (default: cwd)
      --query string     Add query to request
      --scope string     scope
  -s, --server string    management server endpoint (required)
      --state string     State for a webhook event in subscriber queue
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic task-queues:list

Task Queues list operations

Synopsis

Task Queues list operations

```
apic task-queues:list [flags]
```

Options

```
      --apply_filter     Filter tasks
      --cascade          Cascade the behavior
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for task-queues:list
      --kind string      kind of item
      --limit int32      Maximum number of items to return

      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-client-profiles

Tls Client Profiles operations

Synopsis

Tls Client Profiles operations

```
apic tls-client-profiles [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for tls-client-profiles
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-client-profiles:clear

Clear the TLS Client Profile objects

Synopsis

Clear the TLS Client Profile objects

```
apic tls-client-profiles:clear [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for tls-client-profiles:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-client-profiles:clear-all

Clear all TLS Client Profile objects in all collections

Synopsis

Clear all TLS Client Profile objects in all collections

```
apic tls-client-profiles:clear-all [flags]
```

Options

```
      --cascade          Cascade the behavior
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for tls-client-profiles:clear-all
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-client-profiles:create

Create a TLS Client Profile object

Synopsis

Create a TLS Client Profile object Fields not allowed:\ - owned Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url

```
apic tls-client-profiles:create [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for tls-client-profiles:create
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-client-profiles:delete

Delete a TLS Client Profile

Synopsis

Delete a TLS Client Profile

```
apic tls-client-profiles:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for tls-client-profiles:delete
      --id              id
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-client-profiles:get

Get the TLS Client Profile object by name and version

Synopsis

Get the TLS Client Profile object by name and version

```
apic tls-client-profiles:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for tls-client-profiles:get
      --id              id
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-client-profiles:list

List the TLS Client Profile objects

Synopsis

List the TLS Client Profile objects

```
apic tls-client-profiles:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for tls-client-profiles:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-client-profiles:list-all

List all TLS Client Profile objects in all collections

Synopsis

List all TLS Client Profile objects in all collections

```
apic tls-client-profiles:list-all [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for tls-client-profiles:list-all
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-client-profiles:update

Update the TLS Client Profile object by name and version

Synopsis

Update the TLS Client Profile object by name and version Fields not allowed:\ - owned Fields not allowed to be null:\ - ciphers - protocols Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url

```
apic tls-client-profiles:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for tls-client-profiles:update
      --id              id
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-server-profiles

Tls Server Profiles operations

Synopsis

Tls Server Profiles operations

```
apic tls-server-profiles [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for tls-server-profiles
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-server-profiles:clear

Clear the TLS Server Profile objects

Synopsis

Clear the TLS Server Profile objects

```
apic tls-server-profiles:clear [flags]
```

Options

```
      --cascade          Cascade the behavior
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for tls-server-profiles:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-server-profiles:clear-all

Clear all TLS Server Profile objects in all collections

Synopsis

Clear all TLS Server Profile objects in all collections

```
apic tls-server-profiles:clear-all [flags]
```

Options

```
      --cascade          Cascade the behavior
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for tls-server-profiles:clear-all
```

```
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-server-profiles:create

Create a TLS Server Profile object

Synopsis

Create a TLS Server Profile object Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url

```
apic tls-server-profiles:create [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for tls-server-profiles:create
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-server-profiles:delete

Delete a TLS Server Profile

Synopsis

Delete a TLS Server Profile

```
apic tls-server-profiles:delete [flags]
```

Options

```
      --cascade         Cascade the behavior
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for tls-server-profiles:delete
      --id              id
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-server-profiles:get

Get the TLS Server Profile object by name and version

Synopsis

Get the TLS Server Profile object by name and version

```
apic tls-server-profiles:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for tls-server-profiles:get
      --id              id
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-server-profiles:list

List the TLS Server Profile objects

Synopsis

List the TLS Server Profile objects

```
apic tls-server-profiles:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for tls-server-profiles:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-server-profiles:list-all

List all TLS Server Profile objects in all collections

Synopsis

List all TLS Server Profile objects in all collections

```
apic tls-server-profiles:list-all [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for tls-server-profiles:list-all
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
```

```
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic tls-server-profiles:update

Update the TLS Server Profile object by name and version

Synopsis

Update the TLS Server Profile object by name and version Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url

```
apic tls-server-profiles:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for tls-server-profiles:update
      --id              id
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic truststores

Truststores operations

Synopsis

Truststores operations

```
apic truststores [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for truststores
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic truststores:clear

Clear the Truststore objects

Synopsis

Clear the Truststore objects

```
apic truststores:clear [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for truststores:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic truststores:create

Create a Truststore object

Synopsis

Create a Truststore object Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url

```
apic truststores:create [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for truststores:create
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic truststores:delete

Delete the Truststore object by name or id

Synopsis

Delete the Truststore object by name or id

```
apic truststores:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for truststores:delete
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic truststores:get

Get the Truststore object by name or id

Synopsis

Get the Truststore object by name or id

```
apic truststores:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for truststores:get
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic truststores:list

List the Truststore objects

Synopsis

List the Truststore objects

```
apic truststores:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for truststores:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic truststores:update

Update the Truststore object by name or id

Synopsis

Update the Truststore object by name or id Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url

```
apic truststores:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for truststores:update
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic user-registries

User Registries operations

Synopsis

User Registries operations

```
apic user-registries [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for user-registries
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic user-registries:clear

Clear the User Registry objects

Synopsis

Clear the User Registry objects

```
apic user-registries:clear [flags]
```

Options

```
      --confirm string   Confirmation for critical updates (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for user-registries:clear
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic user-registries:create

Create a User Registry object

Synopsis

Create a User Registry object Required fields:\ - integration_url Fields not allowed:\ - owned Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url

```
apic user-registries:create [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for user-registries:create
  -o, --org string      Organization name or id (required)
```

```
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic user-registries:delete

Delete the User Registry object by name or id

Synopsis

Delete the User Registry object by name or id

```
apic user-registries:delete [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for user-registries:delete
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic user-registries:execute

Execute a User Registry operation

Synopsis

Execute a User Registry operation

```
apic user-registries:execute [flags]
```

Options

```
      --format string      Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help               Help for user-registries:execute
      --operation string   Operation to perform on the user registry (get_base_dn_list, validate_password) (required)
  -o, --org string         Organization name or id (required)
      --output string      Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string      management server endpoint (required)
      --test-config-only   test-config-only
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic user-registries:get

Get the User Registry object by name or id

Synopsis

Get the User Registry object by name or id

```
apic user-registries:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for user-registries:get
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic user-registries:list

List the User Registry objects

Synopsis

List the User Registry objects

```
apic user-registries:list [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for user-registries:list
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic user-registries:search

Search for users in the user registry

Synopsis

Search for users in the user registry

```
apic user-registries:search [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for user-registries:search
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic user-registries:test-connection

Test a User Registry connection

Synopsis

Test a User Registry connection

```
apic user-registries:test-connection [flags]
```

Options

```
      --format string      Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help               Help for user-registries:test-connection
  -o, --org string         Organization name or id (required)
      --output string      Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string      management server endpoint (required)
      --test-config-only   test-config-only
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic user-registries:update

Update the User Registry object by name or id

Synopsis

Update the User Registry object by name or id Fields not allowed:\ - owned - registry_type - user_registry_managed - correlation_data - integration_url Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url

```
apic user-registries:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for user-registries:update
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic user-registry-settings

User Registry Settings operations

Synopsis

User Registry Settings operations

```
apic user-registry-settings [flags]
```

Options

```
  -h, --help   Help for user-registry-settings
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic user-registry-settings:get

Get the User Registry Setting object

Synopsis

Get the User Registry Setting object

```
apic user-registry-settings:get [flags]
```

Options

```
      --fields string   List of field names to return
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for user-registry-settings:get
      --output string   Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic user-registry-settings:update

Update the User Registry Setting object

Synopsis

Update the User Registry Setting object Fields allowed but ignored:\ - name - type - api_version - scope - created_at - updated_at - url

```
apic user-registry-settings:update [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for user-registry-settings:update
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic users

Users operations

Synopsis

Users operations

```
apic users [flags]
```

Options

```
      --fields string          List of field names to return
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                   Help for users
```

```
      --limit int32              Maximum number of items to return
      --offset int32             Offset item number from list to begin return
  -o, --org string               Organization name or id (required)
      --output string            Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string            management server endpoint (required)
      --user-registry string     User Registry name or id (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic users:clear

Clear the User objects

Synopsis

Clear the User objects

```
apic users:clear [flags]
```

Options

```
      --confirm string           Confirmation for critical updates (required)
      --format string            Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                     Help for users:clear
  -o, --org string               Organization name or id (required)
      --output string            Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string            management server endpoint (required)
      --user-registry string     User Registry name or id (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic users:create

Create a User object

Synopsis

Create a User object Required fields:\ - username Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - user_registry_url

```
apic users:create [flags]
```

Options

```
      --format string            Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                     Help for users:create
  -o, --org string               Organization name or id (required)
      --output string            Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string            management server endpoint (required)
      --user-registry string     User Registry name or id (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic users:delete

Delete the User object by name or id

Synopsis

Delete the User object by name or id

```
apic users:delete [flags]
```

Options

```
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for users:delete
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string           management server endpoint (required)
      --user-registry string    User Registry name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic users:get

Get the User object by name or id

Synopsis

Get the User object by name or id

```
apic users:get [flags]
```

Options

```
      --fields string           List of field names to return
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for users:get
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, use - for STDOUT. (default: cwd)
  -s, --server string           management server endpoint (required)
      --user-registry string    User Registry name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic users:list

List the User objects

Synopsis

List the User objects

```
apic users:list [flags]
```

Options

```
      --fields string           List of field names to return
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for users:list
      --limit int32             Maximum number of items to return
      --offset int32            Offset item number from list to begin return
  -o, --org string              Organization name or id (required)
      --output string           Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string           management server endpoint (required)
      --user-registry string    User Registry name or id (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic users:request-password-reset

Send reset password link

Synopsis

Send reset password link

```
apic users:request-password-reset [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for users:request-password-reset
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic users:search-provider

Users search-provider operations

Synopsis

Users search-provider operations

```
apic users:search-provider [flags]
```

Options

```
      --format string   Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help            Help for users:search-provider
      --limit int32     Maximum number of items to return
      --offset int32    Offset item number from list to begin return
  -o, --org string      Organization name or id (required)
      --output string   Write file(s) to directory, instead of STDOUT (default "-")
      --scope string    scope
  -s, --server string   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic users:update

Update the User object by name or id

Synopsis

Update the User object by name or id Fields not allowed:\ - identity_provider - username - salt - correlation_data - force_password_change - last_login_at Fields allowed but ignored:\ - id - type - api_version - scope - created_at - updated_at - url - org_url - user_registry_url

```
apic users:update [flags]
```

Options

```
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                   Help for users:update
  -o, --org string             Organization name or id (required)
      --output string          Write file(s) to directory, instead of STDOUT (default "-")
  -s, --server string          management server endpoint (required)
      --user-registry string   User Registry name or id (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic validate

Validate an API or product definition

Synopsis

Validate an API or product definition

```
apic validate [FILE] [flags]
```

Examples

```
Validate an API definition
  $ apic validate routes.yaml
  Validated routes.yaml API definition [routes:1.0]
Validate an API definition without IBM extensions
  $ apic validate --no-extensions routes.yaml
  Validated routes.yaml API definition [routes:1.0]
Validate a product definition and its referenced APIs
  $ apic validate climb-on.yaml
  Validated climb-on.yaml product definition [climb-on:1.0.0]
  Validated routes.yaml API definition [valid:1.0]
Validate a product definition without validating its referenced APIs
  $ apic validate --product-only climb-on.yaml
  Validated climb-on.yaml product definition [climb-on:1.0.0]
```

Options

```
  -h, --help             Help for validate
      --no-extensions    for API definitions, do not validate against IBM Swagger extensions
  -p, --product-only     for products definitions, do not validate referenced APIs
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic version

Get the APIConnect toolkit version

Synopsis

Get the APIConnect toolkit version

```
apic version [flags]
```

Options

```
  -h, --help   Help for version
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic webhooks

Webhooks operations

Synopsis

Webhooks operations

```
apic webhooks [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for webhooks
      --limit int32      Maximum number of items to return
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic webhooks:get

Webhooks get operations

Synopsis

Webhooks get operations

```
apic webhooks:get [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for webhooks:get
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, use - for STDOUT. (default: cwd)
      --scope string     scope
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic webhooks:list

Webhooks list operations

Synopsis

Webhooks list operations

```
apic webhooks:list [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --fields string    List of field names to return
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for webhooks:list
      --limit int32      Maximum number of items to return
      --offset int32     Offset item number from list to begin return
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic webhooks:update

Webhooks update operations

Synopsis

Webhooks update operations

```
apic webhooks:update [flags]
```

Options

```
  -c, --catalog string   Catalog name or id (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for webhooks:update
  -o, --org string       Organization name or id (required)
      --output string    Write file(s) to directory, instead of STDOUT (default "-")
      --scope string     scope
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic wsdl

Introspect WSDL files

Synopsis

Introspect a WSDL file displaying all its services $ apic wsdl WSDL_FILE $ apic wsdl:introspect WSDL_FILE

```
apic wsdl [flags]
```

Options

```
  -h, --help   Help for wsdl
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic wsdl:introspect

Introspect a WSDL file displaying all its services

Synopsis

Introspect a WSDL file displaying all its services

```
apic wsdl:introspect WSDL_FILE [flags]
```

Options

```
  -h, --help   Help for wsdl:introspect
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic

APIConnect toolkit 61bd16316ae32e02b6cd8e72d4b18e02560de16f (Built 2020-09-23T09:51:50Z)

Synopsis

APIConnect toolkit 61bd16316ae32e02b6cd8e72d4b18e02560de16f (Built 2020-09-23T09:51:50Z)

```
apic [flags]
```

Options

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
  -h, --help                  Help for apic
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic api

Api operations

Synopsis

Api operations

```
apic api --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for api
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic api:add-attachment

Add an attachment for the given api.

Synopsis

Add an attachment for a api within the developer portal of the provided org and catalog. A api can hold 10 attachments. The id or name:version of a specific api needs to be provided. e.g. 'id-of-api-called-example-3' or 'example:3.0.0'.

```
apic api:add-attachment --mode portaladmin [flags]
```

Options

```
      --attachment_description string   A description of the attachment to be displayed to users.
      --attachment_name string          The name given to the attachment once it has been uploaded e.g. my-file.txt (required)
  -c, --catalog string                  Name or ID of the catalog that the site belongs to. (required)
      --format string                   Output format. One of [json yaml go-template=... go-template-file=...], defaults to
yaml.
  -h, --help                            Help for api:add-attachment
  -o, --org string                      Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string                   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic api:add-tag

Add a tag for the given api.

Synopsis

Add a tag for a api within the developer portal of the provided org and catalog. The id or name:version of a specific api needs to be provided. e.g. 'id-of-api-called-example-3' or 'example:3.0.0'.

```
apic api:add-tag --mode portaladmin [flags]
```

Options

```
  -c, --catalog string    Name or ID of the catalog that the site belongs to. (required)
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for api:add-tag
  -o, --org string        Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string     management server endpoint (required)
      --tag_name string   The tag name e.g. top_level_element/next_level_element (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic api:get

Get a specific api from a developer portal.

Synopsis

Get a specific api from the developer portal of the provided org and catalog. The id or name:version of a specific api needs to be provided. e.g. 'id-of-api-called-example-3' or 'example:3.0.0'.

```
apic api:get --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for api:get
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic api:get-document

Get a specific entire api document from a portal.

Synopsis

Get a specific entire api document from the portal of the provided organization and catalog. The id or name:version of a specific api needs to be provided. For example, 'id-of-api-called-example-3' or 'example:3.0.0'.

```
apic api:get-document --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for api:get-document
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic api:list

Shows a list of apis from a site.

Synopsis

Show a list of apis of the provided org and catalog.

```
apic api:list --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for api:list
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic api:set-icon

Set an icon image for the given api.

Synopsis

Set an icon image for a api within the developer portal of the provided org and catalog. The existing icon will be overwritten. The id or name:version of a specific api needs to be provided. e.g. 'id-of-api-called-example-3' or 'example:3.0.0'.

```
apic api:set-icon --mode portaladmin [flags]
```

Options

```
  -c, --catalog string            Name or ID of the catalog that the site belongs to. (required)
      --format string             Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                      Help for api:set-icon
      --icon_description string   A description of the icon to be displayed to users. Used as alt text for the image.
(required)
```

```
  -o, --org string                Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string             management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic apic-config

Apic Config operations

Synopsis

Apic Config operations

```
apic apic-config --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for apic-config
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic apic-config:get

Get the configuration object that the developer portal holds.

Synopsis

Get the configuration object that the developer portal holds that was sent by APIM.

```
apic apic-config:get --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for apic-config:get
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic application

Application operations

Synopsis

Application operations

```
apic application --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for application
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic application:get

Get a specific application from a developer portal.

Synopsis

Get a specific application from the developer portal of the provided org and catalog. The id of a specific consumer organization needs to be provided.

```
apic application:get --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for application:get
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic application:list

Shows a list of applications from a site.

Synopsis

Show a list of applications of the provided org and catalog.

```
apic application:list --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for application:list
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic backups

Backups operations

Synopsis

Backups operations

```
apic backups --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for backups
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic backups:list

List the backups present on the remote backup server.

Synopsis

Lists all the backups that are currently present on the remote backup server, if one has been set.

```
apic backups:list --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for backups:list
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic config

Manage configuration variables

Synopsis

Manage configuration variables

```
apic config --mode portaladmin [flags]
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for config
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic config:clear

Delete all configuration variables

Synopsis

Delete all configuration variables

```
apic config:clear --mode portaladmin [flags]
```

Examples

```
$ apic config:clear --mode consumer
Deleted config catalog
Deleted config org
Deleted config space

$ apic config:clear --global --mode consumer
Deleted config catalog
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for config:clear
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic config:delete

Delete a configuration variable

Synopsis

Configuration variables:

catalog The catalog configuration variable should be set to the URI of an API Connect catalog. The value of the catalog provides the default identity of a catalog for all the commands that are used to manage aspects of a catalog. The default values defined by the catalog's URI can be overridden using the --server, --organization, and --catalog command line options. The catalog URI has the form: https://MANAGEMENT_SERVER/consumer-api/catalogs/CONSUMER_ORG_NAME/CATALOG_NAME

org The default value of org defined by the app's or catalog's URI can be set using the org URI. The org URI has the form: https://MANAGEMENT_SERVER/consumer-api/orgs/CONSUMER_ORG_NAME

space The space configuration variable should be set to the URI of an API Connect space. The value of the space provides the default identity of a space for all the commands that are used to manage aspects of a space. The default values defined by the spaces's URI can be overridden using the --server, --organization, --catalog, and --space command line options. The space URI has the form: https://MANAGEMENT_SERVER/consumer-api/spaces/CONSUMER_ORG_NAME/CATALOG_NAME/SPACE_NAME

cloud The cloud configuration variable should be set to the management server URI. The value of the cloud variable provides default server URI for cloud admin commands. It can be overridden using the --server and --mode command line options. The cloud URI has the form: https://MANAGEMENT_SERVER/consumer-api/

mode The value of mode configruation variable defines the toolkit operation mode. It can be overridden using the --mode command line option. The value can be set to apim or consumer

template-path List of places to look for handlebar templates

template-default-api Defines the default api template

template-default-product Defines the default product template

```
apic config:delete NAME... --mode portaladmin [flags]
```

Examples

```
$ apic config:delete catalog --mode consumer
Deleted config catalog

$ apic config:delete org --mode consumer
Deleted config org
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for config:delete
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic config:get

Get a configuration variable

Synopsis

Configuration variables:

catalog The catalog configuration variable should be set to the URI of an API Connect catalog. The value of the catalog provides the default identity of a catalog for all the commands that are used to manage aspects of a catalog. The default values defined by the catalog's URI can be overridden using the --server, --organization, and --catalog command line options. The catalog URI has the form: https://MANAGEMENT_SERVER/consumer-api/catalogs/CONSUMER_ORG_NAME/CATALOG_NAME

org The default value of org defined by the app's or catalog's URI can be set using the org URI. The org URI has the form: https://MANAGEMENT_SERVER/consumer-api/orgs/CONSUMER_ORG_NAME

space The space configuration variable should be set to the URI of an API Connect space. The value of the space provides the default identity of a space for all the commands that are used to manage aspects of a space. The default values defined by the spaces's URI can be overridden using the --server, --organization, --catalog, and --space command line options. The space URI has the form: https://MANAGEMENT_SERVER/consumer-api/spaces/CONSUMER_ORG_NAME/CATALOG_NAME/SPACE_NAME

cloud The cloud configuration variable should be set to the management server URI. The value of the cloud variable provides default server URI for cloud admin commands. It can be overridden using the --server and --mode command line options. The cloud URI has the form: https://MANAGEMENT_SERVER/consumer-api/

mode The value of mode configruation variable defines the toolkit operation mode. It can be overridden using the --mode command line option. The value can be set to apim or consumer

template-path List of places to look for handlebar templates

template-default-api Defines the default api template

template-default-product Defines the default product template

```
apic config:get NAME --mode portaladmin [flags]
```

Examples

```
$ apic config:get catalog --mode consumer
catalog: https://mgmnthost.com/consumer-api/catalogs/climbon/sb

$ apic config:get org --mode consumer
org: https://mgmnthost.com/consumer-api/orgs/climbon
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for config:get
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic config:list

List the application and global configuration variables

Synopsis

Configuration variables:

catalog The catalog configuration variable should be set to the URI of an API Connect catalog. The value of the catalog provides the default identity of a catalog for all the commands that are used to manage aspects of a catalog. The default values defined by the catalog's URI can be overridden using the --server, --organization, and --catalog command line options. The catalog URI has the form: https://MANAGEMENT_SERVER/consumer-api/catalogs/CONSUMER_ORG_NAME/CATALOG_NAME

org The default value of org defined by the app's or catalog's URI can be set using the org URI. The org URI has the form: https://MANAGEMENT_SERVER/consumer-api/orgs/CONSUMER_ORG_NAME

space The space configuration variable should be set to the URI of an API Connect space. The value of the space provides the default identity of a space for all the commands that are used to manage aspects of a space. The default values defined by the spaces's URI can be overridden using the --server, --organization, --catalog, and --space command line options. The space URI has the form: https://MANAGEMENT_SERVER/consumer-api/spaces/CONSUMER_ORG_NAME/CATALOG_NAME/SPACE_NAME

cloud The cloud configuration variable should be set to the management server URI. The value of the cloud variable provides default server URI for cloud admin commands. It can be overridden using the --server and --mode command line options. The cloud URI has the form: https://MANAGEMENT_SERVER/consumer-api/

mode The value of mode configruation variable defines the toolkit operation mode. It can be overridden using the --mode command line option. The value can be set to apim or consumer

template-path List of places to look for handlebar templates

template-default-api Defines the default api template

template-default-product Defines the default product template

```
apic config:list --mode portaladmin [flags]
```

Examples

```
$ apic config --mode consumer
catalog: https://mgmnthost.com/consumer-api/catalogs/climbon/sb
org: https://mgmnthost.com/consumer-api/orgs/climbon

$ apic config --global --mode consumer
catalog: https://mgmnthost.com/consumer-api/catalogs/climbon/sb
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for config:list
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic config:set

Set or update configuration variables

Synopsis

Configuration variables:

catalog The catalog configuration variable should be set to the URI of an API Connect catalog. The value of the catalog provides the default identity of a catalog for all the commands that are used to manage aspects of a catalog. The default values defined by the catalog's URI can be overridden using the --server, --organization, and --catalog command line options. The catalog URI has the form: https://MANAGEMENT_SERVER/consumer-api/catalogs/CONSUMER_ORG_NAME/CATALOG_NAME

org The default value of org defined by the app's or catalog's URI can be set using the org URI. The org URI has the form: https://MANAGEMENT_SERVER/consumer-api/orgs/CONSUMER_ORG_NAME

space The space configuration variable should be set to the URI of an API Connect space. The value of the space provides the default identity of a space for all the commands that are used to manage aspects of a space. The default values defined by the spaces's URI can be overridden using the --server, --organization, --catalog, and --space command line options. The space URI has the form: https://MANAGEMENT_SERVER/consumer-api/spaces/CONSUMER_ORG_NAME/CATALOG_NAME/SPACE_NAME

cloud The cloud configuration variable should be set to the management server URI. The value of the cloud variable provides default server URI for cloud admin commands. It can be overridden using the --server and --mode command line options. The cloud URI has the form: https://MANAGEMENT_SERVER/consumer-api/

mode The value of mode configruation variable defines the toolkit operation mode. It can be overridden using the --mode command line option. The value can be set to apim or consumer

template-path List of places to look for handlebar templates

template-default-api Defines the default api template

template-default-product Defines the default product template

```
apic config:set NAME=VALUE ... --mode portaladmin [flags]
```

Examples

```
$ apic config:set --mode consumer catalog=https://mgmnthost.com/consumer-api/catalogs/climbon/sb
catalog: https://mgmnthost.com/consumer-api/catalogs/climbon/sb

$ apic config:set --mode consumer org=https://mgmnthost2.com/consumer-api/orgs/hikeon
org: https://mgmnthost2.com/consumer-api/orgs/hikeon
```

Options

```
  -g, --global   list the global configuration variables
  -h, --help     Help for config:set
  -l, --local    list the local application configuration variables
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic consumer-org

Consumer Org operations

Synopsis

Consumer Org operations

```
apic consumer-org --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for consumer-org
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic consumer-org:get

Get a specific consumer org from a developer portal.

Synopsis

Get a specific consumer org from the developer portal of the provided org and catalog. The id of a specific consumer organization needs to be provided.

```
apic consumer-org:get --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for consumer-org:get
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic consumer-org:list

Shows a list of consumer orgs from a site.

Synopsis

Show a list of consumer orgs of the provided org and catalog.

```
apic consumer-org:list --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for consumer-org:list
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-module

Custom Module operations

Synopsis

Custom Module operations

```
apic custom-module --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for custom-module
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-module:create-export

Create a task that exports an archive that contains the custom modules of a site.

Synopsis

You can create a task to export an archive of the custom modules of a site. You can then use that archive to quickly and simply override the custom modules on another site.

```
apic custom-module:create-export --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-module:create-export
      --no-poll          Do not poll the created task and just return the task ID
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-module:create-import

Create a task that imports an archive that contains the custom modules of a site.

Synopsis

You can create a task to import an archive of the custom modules of a site. You can use the imported archive to quickly and simply override the custom modules for the specified site.

```
apic custom-module:create-import --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-module:create-import
      --no-poll          Do not poll the created task and just return the task ID
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-module:delete-export

If running, cancels a custom module export task.

Synopsis

If running, cancels the custom module export task and deletes any related artifacts that have been generated.

```
apic custom-module:delete-export --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-module:delete-export
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-module:delete-import

If running, cancels a custom module import task.

Synopsis

If running, cancels the custom module import task and deletes any related artifacts that have been generated.

```
apic custom-module:delete-import --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-module:delete-import
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-module:get-export

When ready, streams a custom module export artifact.

Synopsis

When ready, streams a custom module export artifact back to the related task id that is provided in the arguments.

```
apic custom-module:get-export --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-module:get-export
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-module:get-export-status

Returns information about the status of this task.

Synopsis

Returns information related to the task id that is provided in the arguments.

```
apic custom-module:get-export-status --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-module:get-export-status
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-module:get-import-status

Get the result of the custom module import task.

Synopsis

Get the result of the custom module import task. If the import task has completed on the portal system, this command returns the result of the command. If the import task has not completed on the portal system, it returns the current status of the task.

```
apic custom-module:get-import-status --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-module:get-import-status
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-theme

Custom Theme operations

Synopsis

Custom Theme operations

```
apic custom-theme --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for custom-theme
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-theme:create-export

Create a task that exports an archive that contains the custom themes of a site.

Synopsis

You can create a task to export an archive of the custom themes of a site. You can then use that archive to quickly and simply override the custom themes on another site.

```
apic custom-theme:create-export --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-theme:create-export
      --no-poll          Do not poll the created task and just return the task ID
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-theme:create-import

Create a task that imports an archive that contains the custom themes of a site.

Synopsis

You can create a task to import an archive of the custom themes of a site. You can use the imported archive to quickly and simply override the custom themes for the specified site.

```
apic custom-theme:create-import --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-theme:create-import
      --no-poll          Do not poll the created task and just return the task ID
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-theme:delete-export

If running, cancels a custom theme export task.

Synopsis

If running, cancels the custom theme export task and deletes any related artifacts that have been generated. This does not delete any custom themes.

```
apic custom-theme:delete-export --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-theme:delete-export
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-theme:delete-import

Cancels a running custom theme import task.

Synopsis

Cancels the custom theme import task and deletes any generated artifacts.

```
apic custom-theme:delete-import --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-theme:delete-import
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-theme:get-export

When ready, streams a custom theme export artifact.

Synopsis

When ready, streams a custom theme export artifact back to the related task id that is provided in the arguments.

```
apic custom-theme:get-export --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-theme:get-export
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-theme:get-export-status

Returns information about the status of this task.

Synopsis

Returns information related to the task id that is provided in the arguments.

```
apic custom-theme:get-export-status --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-theme:get-export-status
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-theme:get-import-status

Get the result of the custom theme import task.

Synopsis

Get the result of the custom theme import task. If the import task has completed on the portal system, this command returns the result of the command. If the import task has not completed on the portal system, it returns the current status of the task.

```
apic custom-theme:get-import-status --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-theme:get-import-status
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-translation

Custom Translation operations

Synopsis

Custom Translation operations

```
apic custom-translation --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for custom-translation
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-translation:create-export

Create a task that exports an archive that contains the custom translation of a site.

Synopsis

You can create a task to export an archive of the custom translation of a site. You can then use that archive to quickly and simply override the custom translations on another site.

```
apic custom-translation:create-export --mode portaladmin [flags]
```

Options

```
  -c, --catalog string     Name or ID of the catalog that the site belongs to. (required)
      --format string      Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help               Help for custom-translation:create-export
      --langcodes string   A comma separated list of language codes e.g. "es,zh-hans"
      --no-poll            Do not poll the created task and just return the task ID
  -o, --org string         Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string      management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-translation:create-import

Create a task that imports an archive that contains the custom translations of a site.

Synopsis

You can create a task to import an archive of the custom translations of a site. You can use the imported archive to simply override the custom translations for the specified site. This command may take several minutes to complete.

```
apic custom-translation:create-import --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-translation:create-import
      --no-poll          Do not poll the created task and just return the task ID
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-translation:delete-export

If running, cancels a custom translation export task.

Synopsis

If running, cancels the custom translation export task and deletes any related artifacts that have been generated. This does not delete any custom translations.

```
apic custom-translation:delete-export --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-translation:delete-export
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-translation:delete-import

If running, cancels a custom translation import task.

Synopsis

If running, cancels the custom translation import task and deletes any related artifacts that have been generated. This does not delete any custom translations.

```
apic custom-translation:delete-import --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-translation:delete-import
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-translation:get-export

When ready, streams a custom translation export artifact.

Synopsis

When ready, streams a custom translation export artifact back to the related task id that is provided in the arguments.

```
apic custom-translation:get-export --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-translation:get-export
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-translation:get-export-status

Returns information about the status of this task.

Synopsis

Returns information related to the task id that is provided in the arguments.

```
apic custom-translation:get-export-status --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-translation:get-export-status
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-translation:get-import-status

Get the result of the custom translation import task.

Synopsis

Get the result of the custom translation import task. If the import task has completed on the portal system, this command returns the result of the command. If the import task has not completed on the portal system, it returns the current status of the task.

```
apic custom-translation:get-import-status --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for custom-translation:get-import-status
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
```

```
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic custom-webserver-page

Custom Web Server Page operations

Synopsis

Custom Web Server Page operations

```
apic custom-webserver-page --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for custom-webserver-page
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic custom-webserver-page:delete

Delete the custom HTML for a web server page.

Synopsis

Delete the custom web server HTML content of a specific web server page (index, 404, 40x, 50x). (Will fallback to a default.)

```
apic custom-webserver-page:delete --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for custom-webserver-page:delete
      --page_type string             The page type you want to run this command against. Values: index, 404, 40x, 50x
(required)
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic custom-webserver-page:get

Get the HTML for a web server page.

Synopsis

Get the web server HTML content of a specific web server page (index, 404, 40x, 50x).

```
apic custom-webserver-page:get --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for custom-webserver-page:get
      --page_type string             The page type you want to run this command against. Values: index, 404, 40x, 50x
(required)
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic custom-webserver-page:set

Set a custom HTML page for a web server page type.

Synopsis

Set the custom web server HTML content of a specific web server page (index, 404, 40x, 50x). Maximum size of 8 MB.

```
apic custom-webserver-page:set --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for custom-webserver-page:set
      --page_type string             The page type you want to run this command against. Values: index, 404, 40x, 50x
(required)
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic drupal-config

Drupal Config operations

Synopsis

Drupal Config operations

```
apic drupal-config --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for drupal-config
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
      --prefix string    The config prefix. For example, "system". No prefix will return all names in the system.
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic drupal-config:delete

Delete the Config object.

Synopsis

Delete the Config object or a specific config key.

```
apic drupal-config:delete --mode portaladmin [flags]
```

Options

```
  -c, --catalog string        Name or ID of the catalog that the site belongs to. (required)
      --config_name string    The config object name, for example "system.site". (required)
      --format string         Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                  Help for drupal-config:delete
      --config_key string     A config key, for example "page.front".
  -o, --org string            Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string         management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic drupal-config:get

Get the Config object

Synopsis

Get the Config object or a specific config key value.

```
apic drupal-config:get --mode portaladmin [flags]
```

Options

```
  -c, --catalog string        Name or ID of the catalog that the site belongs to. (required)
      --config_key string     A config key, for example "page.front".
      --config_name string    The config object name, for example "system.site". (required)
      --format string         Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                  Help for drupal-config:get
  -o, --org string            Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string         management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic drupal-config:list

List the config names by prefix

Synopsis

List the config names by prefix or provide no prefix to see all.

```
apic drupal-config:list --mode portaladmin [flags]
```

Options

```
  -c, --catalog string    Name or ID of the catalog that the site belongs to. (required)
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for drupal-config:list
  -o, --org string        Name or ID of the organization that the catalog belongs to. (required)
      --prefix string     The config prefix. For example, "system". No prefix will return all names in the system.
  -s, --server string     management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic drupal-config:set

Set a config value.

Synopsis

Can set a new config value or update an already existing key-value.

```
apic drupal-config:set --mode portaladmin [flags]
```

Options

```
  -c, --catalog string         Name or ID of the catalog that the site belongs to. (required)
      --config_key string      A config key, for example "page.front". (required)
      --config_name string     The config object name, for example "system.site". (required)
      --config_value string    The value to assign to the config key. (required)
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                   Help for drupal-config:set
  -o, --org string             Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string          management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic drupal-state

Drupal State operations

Synopsis

Drupal State operations

```
apic drupal-state --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for drupal-state
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic drupal-state:delete

Delete the State key.

Synopsis

Delete the specific state key.

```
apic drupal-state:delete --mode portaladmin [flags]
```

Options

```
  -c, --catalog string     Name or ID of the catalog that the site belongs to. (required)
      --format string      Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help               Help for drupal-state:delete
  -o, --org string         Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string      management server endpoint (required)
      --state_key string   The state key, for example "system.cron_last". (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic drupal-state:get

Get the State key

Synopsis

Get the State key value.

```
apic drupal-state:get --mode portaladmin [flags]
```

Options

```
  -c, --catalog string     Name or ID of the catalog that the site belongs to. (required)
      --format string      Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help               Help for drupal-state:get
  -o, --org string         Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string      management server endpoint (required)
      --state_key string   The state key, for example "system.cron_last". (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic drupal-state:set

Set a state key value.

Synopsis

Can set a new state value or update an already existing key-value.

```
apic drupal-state:set --mode portaladmin [flags]
```

Options

```
  -c, --catalog string         Name or ID of the catalog that the site belongs to. (required)
      --format string          Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                   Help for drupal-state:set
      --input_format string    The input format of the value for the state key. Values: string, integer, float, boolean, json,
yaml. [default: auto]
  -o, --org string             Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string          management server endpoint (required)
      --state_key string       The state key, for example "system.cron_last". (required)
      --state_value string     The value to assign to the state key. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic drupal-state

Drupal State operations

Synopsis

Drupal State operations

```
apic drupal-state --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for drupal-state
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic drupal-state:delete

Delete the State key.

Synopsis

Delete the specific state key.

```
apic drupal-state:delete --mode portaladmin [flags]
```

Options

```
  -c, --catalog string     Name or ID of the catalog that the site belongs to. (required)
      --format string      Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help               Help for drupal-state:delete
  -o, --org string         Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string      management server endpoint (required)
      --state_key string   The state key, for example "system.cron_last". (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic drupal-state:get

Get the State key

Synopsis

Get the State key value.

```
apic drupal-state:get --mode portaladmin [flags]
```

Options

```
  -c, --catalog string     Name or ID of the catalog that the site belongs to. (required)
      --format string      Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help               Help for drupal-state:get
  -o, --org string         Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string      management server endpoint (required)
      --state_key string   The state key, for example "system.cron_last". (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic drupal-state:set

Set a state key value.

Synopsis

Can set a new state value or update an already existing key-value.

```
apic drupal-state:set --mode portaladmin [flags]
```

Options

```
  -c, --catalog string          Name or ID of the catalog that the site belongs to. (required)
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for drupal-state:set
      --input_format string     The input format of the value for the state key. Values: string, integer, float, boolean, json,
yaml. [default: auto]
  -o, --org string              Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string           management server endpoint (required)
      --state_key string        The state key, for example "system.cron_last". (required)
      --state_value string      The value to assign to the state key. (required)
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic entity

Entity operations

Synopsis

Entity operations

```
apic entity --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for entity
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic entity:count

Shows a count of entities from a site.

Synopsis

Show a count of entities of the provided org and catalog.

```
apic entity:count --mode portaladmin [flags]
```

Options

```
  -c, --catalog string    Name or ID of the catalog that the site belongs to. (required)
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for entity:count
  -o, --org string        Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string     management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic factory-reset

Factory Reset operations

Synopsis

Factory Reset operations

```
apic factory-reset --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for factory-reset
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic factory-reset:delete

Factory resets the Developer Portal.

Synopsis

Performs a factory reset of the Developer Portal, deleting the portal service and all portal sites. WARNING: This command is irreversible - please ensure you have backups configured.

```
apic factory-reset:delete --mode portaladmin [flags]
```

Options

```
      --execute_reset string              Set to true to trigger the Developer Portal reset
      --format string                     Output format. One of [json yaml go-template=... go-template-file=...], defaults to
yaml.
  -h, --help                              Help for factory-reset:delete
      --portal_service_endpoint string    The URL endpoint of the portal service (required)
  -s, --server string                     Management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic forums

Forums operations

Synopsis

Forums operations

```
apic forums --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for forums
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic forums:disable

Disable the forum module for a given site

Synopsis

Removes all forums vocabulary taxonomy terms before disabling the forum module for a given site.

```
apic forums:disable --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for forums:disable
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic forums:enable

Enable the forum module for a given site

Synopsis

Enables the forum module for a given site.

```
apic forums:enable --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for forums:enable
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic ip-security-enabled

IP Security Enabled operations.

Synopsis

IP Security Enabled operations. Toggle the IP security on your Developer Portal between enabled and disabled. IP security is enabled by default.

```
apic ip-security-enabled --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for ip-security-enabled
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic ip-security-enabled:update

Enable or disable IP security functionality within the Developer Portal.

Synopsis

Enable or disable IP security functionality within the Developer Portal. IP security is enabled by default.

```
apic ip-security-enabled:update --mode portaladmin [flags]
```

Options

```
      --enabled string               Set to true or false to enable or disable IP security (required)
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for ip-security-enabled:update
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                Management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic licenses

Review the license for API Connect

Synopsis

Review the license for API Connect

```
apic licenses --mode portaladmin [flags]
```

Options

```
  -h, --help              Help for licenses
      --non-ibm-license   Display the non IBM license files.
      --notices           Display the notices file
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic modules

Modules operations

Synopsis

Modules operations

```
apic modules --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --core             Filter out extensions that are not in drupal core.
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for modules
      --no-core          Filter out extensions that are provided by drupal core.
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
      --package string   Filter by project packages. You can use multiple comma separated values.
  -s, --server string    management server endpoint (required)
      --status string    Filter by extension status. Choices _ enabled, disabled and/or 'not installed'. You can use multiple
comma separated values.
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
```

```
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic modules:delete

Deletes one or more modules.

Synopsis

Deletes one or more modules. The provided list of modules must be comma separated.

```
apic modules:delete --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for modules:delete
      --modules string   A list of modules separated by a comma. (required)
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic modules:disable

Disable one or more modules and their dependent modules.

Synopsis

Disable one or more modules and their dependent modules. The provided list of modules must be comma separated.

```
apic modules:disable --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for modules:disable
      --modules string   A list of modules separated by a comma. (required)
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic modules:enable

Enable one or more module.

Synopsis

Enable one or more module by providing a comma separated list.

```
apic modules:enable --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
```

```
  -h, --help                    Help for modules:enable
      --modules string          A list of modules separated by a comma. (required)
  -o, --org string              Name or ID of the organization that the catalog belongs to. (required)
      --resolve-dependencies    Attempt to download any missing dependencies. At the moment, only works when the module name is
the same as the project name.
  -s, --server string           management server endpoint (required)
      --skip                    Skip automatic downloading of libraries (c.f. devel).
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic modules:list

Shows a list of available modules.

Synopsis

Show a list of modules for the portal of the provided org and catalog.

```
apic modules:list --mode portaladmin [flags]
```

Options

```
  -c, --catalog string    Name or ID of the catalog that the site belongs to. (required)
      --core              Filter out extensions that are not in drupal core.
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for modules:list
      --no-core           Filter out extensions that are provided by drupal core.
  -o, --org string        Name or ID of the organization that the catalog belongs to. (required)
      --package string    Filter by project packages. You can use multiple comma separated values.
  -s, --server string     management server endpoint (required)
      --status string     Filter by extension status. Choices _ enabled, disabled and/or 'not installed'. You can use multiple
comma separated values.
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic php-memory

Php Memory operations

Synopsis

Php Memory operations

```
apic php-memory --mode portaladmin [flags]
```

Options

```
      --format string                 Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                          Help for php-memory
      --portal_service_name string    The name of the portal service (required)
  -s, --server string                 management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license          Accept the license for API Connect
      --debug                   Enable debug output
      --debug-output string     Write debug output to file
      --live-help               Enable or disable tracking of limited usage information
  -m, --mode string             Toolkit operation mode (default "apim")
```

apic php-memory:list

List the PHP memory limit on the platform.

Synopsis

Lists the PHP memory_limit setting on the portal platform.

```
apic php-memory:list --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for php-memory:list
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic php-memory:update

Set the PHP memory limit on the portal platform.

Synopsis

Sets the PHP memory limit on the portal platform for both admin and web containers

```
apic php-memory:update --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for php-memory:update
      --memory_value string          The memory value in megabytes (mb) (required)
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic platforms

Platforms operations

Synopsis

Platforms operations

```
apic platforms --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for platforms
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic platforms:list

List the platforms present on the portal service.

Synopsis

Lists all the platforms that are currently present on the Portal service.

```
apic platforms:list --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for platforms:list
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic product

Product operations

Synopsis

Product operations

```
apic product --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for product
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic product:add-attachment

Add an attachment for the given product.

Synopsis

Add an attachment for a product within the developer portal of the provided org and catalog. A product can hold 10 attachments. The id or name:version of a specific product needs to be provided. e.g. 'id-of-product-called-example-3' or 'example:3.0.0'.

```
apic product:add-attachment --mode portaladmin [flags]
```

Options

```
      --attachment_description string   A description of the attachment to be displayed to users.
      --attachment_name string          The name given to the attachment once it has been uploaded e.g. my-file.txt (required)
  -c, --catalog string                  Name or ID of the catalog that the site belongs to. (required)
      --format string                   Output format. One of [json yaml go-template=... go-template-file=...], defaults to
yaml.
  -h, --help                            Help for product:add-attachment
  -o, --org string                      Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string                   management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic product:add-tag

Add a tag for the given product.

Synopsis

Add a tag for a product within the developer portal of the provided org and catalog. The id or name:version of a specific product needs to be provided. e.g. 'id-of-product-called-example-3' or 'example:3.0.0'.

```
apic product:add-tag --mode portaladmin [flags]
```

Options

```
  -c, --catalog string     Name or ID of the catalog that the site belongs to. (required)
      --format string      Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help               Help for product:add-tag
  -o, --org string         Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string      management server endpoint (required)
      --tag_name string    The tag name e.g. top_level_element/next_level_element (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic product:get

Get a specific product from a developer portal.

Synopsis

Get a specific product from the developer portal of the provided org and catalog. The id or name:version of a specific api needs to be provided. e.g. 'id-of-api-called-example-3' or 'example:3.0.0'.

```
apic product:get --mode portaladmin [flags]
```

Options

```
  -c, --catalog string    Name or ID of the catalog that the site belongs to. (required)
      --format string     Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help              Help for product:get
  -o, --org string        Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string     management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic product:get-document

Get a specific entire product document from a portal.

Synopsis

Get a specific entire product document from the portal of the provided organization and catalog. The id or name:version of a specific api needs to be provided. For example, 'id-of-api-called-example-3' or 'example:3.0.0'.

```
apic product:get-document --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for product:get-document
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic product:list

Shows a list of products from a site.

Synopsis

Show a list of products of the provided org and catalog.

```
apic product:list --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for product:list
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic product:set-icon

Set an icon image for the given product.

Synopsis

Set an icon image for a product within the developer portal of the provided org and catalog. The existing icon will be overwritten. The id or name:version of a specific product needs to be provided. e.g. 'id-of-product-called-example-3' or 'example:3.0.0'.

```
apic product:set-icon --mode portaladmin [flags]
```

Options

```
  -c, --catalog string            Name or ID of the catalog that the site belongs to. (required)
      --format string             Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                      Help for product:set-icon
      --icon_description string   A description of the icon to be displayed to users. Used as alt text for the image.
(required)
  -o, --org string                Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string             management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic security

Security operations

Synopsis

Security operations

```
apic security --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for security
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic security:clear-bans

Clear all user/IP bans for a site.

Synopsis

Clear any existing user/IP bans.

```
apic security:clear-bans --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for security:clear-bans
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    Management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic service-ip-allowlist

Service IP Allowlist operations.

Synopsis

Service IP Allowlist operations. The allowlist service enables specific IPs to be exempt from being blocked by portal security checks, for example, load balancer and proxy IPs.

```
apic service-ip-allowlist --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for service-ip-allowlist
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                Management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
```

```
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic service-ip-allowlist:add

Add IP(s) to the allowlist.

Synopsis

Add specific IP(s) to the allowlist.

```
apic service-ip-allowlist:add --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for service-ip-allowlist:add
      --ips string                   Comma separated list of IPs (required)
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                Management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic service-ip-allowlist:delete

Delete all IPs from the allowlist.

Synopsis

Delete all of the IPs from the allowlist.

```
apic service-ip-allowlist:delete --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for service-ip-allowlist:delete
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                Management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic service-ip-allowlist:list

List IP(s) currently on the allowlist.

Synopsis

List all of the IP(s) that are currently on the allowlist.

```
apic service-ip-allowlist:list --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for service-ip-allowlist:list
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                Management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic service-ip-allowlist:remove

Remove specific IP(s) from the allowlist.

Synopsis

Remove one or more specific IP(s) from the allowlist.

```
apic service-ip-allowlist:remove --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for service-ip-allowlist:remove
      --ips string                   Comma separated list of IPs (required)
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                Management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic site

Site operations

Synopsis

Site operations

```
apic site --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for site
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic site:cache-rebuild

Rebuilds the cache of a specific portal site.

Synopsis

Clears the existing cache and rebuilds a new one for a specific portal site.

```
apic site:cache-rebuild --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for site:cache-rebuild
```

```
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic site:check

Run a platform check against a portal site

Synopsis

Performs filesystem, database and API Manager checks against a portal site. This command is useful when trying to identify platform related problems if you are having issues with your portal site.

```
apic site:check --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for site:check
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic site:login-link

Gets an admin login link for a specific Portal site.

Synopsis

Returns a one time login link for the Drupal admin account for the site specified by org and catalog parameters

```
apic site:login-link --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for site:login-link
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic site:state

Obtain the current state of a portal site.

Synopsis

Returns the state of a portal site. This command is useful as a general health check analysis of the portal site.

```
apic site:state --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for site:state
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic site-config

Site Config operations

Synopsis

Site Config operations

```
apic site-config --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for site-config
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic site-config:create-export

Create a task that exports an archive that contains the configuration of a site.

Synopsis

You can create a task to export an archive of the configuration of a site. You can then use that archive to quickly and simply override the configuration on another site.

```
apic site-config:create-export --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for site-config:create-export
      --no-poll          Do not poll the created task and just return the task ID
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic site-config:create-import

Create a task that imports an archive that contains the configuration of a site.

Synopsis

You can create a task to import an archive of the configuration of a site. You can use the imported archive to quickly and simply override the configuration for the specified site.

```
apic site-config:create-import --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for site-config:create-import
      --no-poll          Do not poll the created task and just return the task ID
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic site-config:delete-export

If running, cancels a site configuration export task.

Synopsis

If running, cancels the site configuration export task and deletes any related artifacts that have been generated.

```
apic site-config:delete-export --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for site-config:delete-export
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic site-config:delete-import

Cancels a running site configuration import task.

Synopsis

Cancels the site configuration import task and deletes any generated artifacts.

```
apic site-config:delete-import --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for site-config:delete-import
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
```

```
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic site-config:get-export

When ready, streams a site configuration export artifact.

Synopsis

When ready, streams a site configuration export artifact back to the related task id that is provided in the arguments.

```
apic site-config:get-export --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for site-config:get-export
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic site-config:get-export-status

Returns information about the status of this task.

Synopsis

Returns information related to the task id that is provided in the arguments.

```
apic site-config:get-export-status --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for site-config:get-export-status
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license         Accept the license for API Connect
      --debug                  Enable debug output
      --debug-output string    Write debug output to file
      --live-help              Enable or disable tracking of limited usage information
  -m, --mode string            Toolkit operation mode (default "apim")
```

apic site-config:get-import-status

Get the result of the site configuration import task.

Synopsis

Get the result of the site configuration import task. If the import task has completed on the portal system, this command returns the result of the command. If the import task has not completed on the portal system, it returns the current status of the task.

```
apic site-config:get-import-status --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
```

```
  -h, --help             Help for site-config:get-import-status
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --task_id string   ID of the task created on the queue. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic sites

Sites operations

Synopsis

Sites operations

```
apic sites --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for sites
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic sites:check

Run a platform check against all portal sites present on a portal service.

Synopsis

Performs filesystem, database and API Manager checks against all portal sites on a given portal service. This command is useful when trying to identify platform related problems on one of more of your portal sites.

```
apic sites:check --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for sites:check
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic sites:list

List the sites present on the Portal service.

Synopsis

Lists all the sites that are currently present on the Portal service.

```
apic sites:list --mode portaladmin [flags]
```

Options

```
      --format string                Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                         Help for sites:list
      --portal_service_name string   The name of the portal service (required)
  -s, --server string                management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic themes

Themes operations

Synopsis

Themes operations

```
apic themes --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --core             Filter out extensions that are not in drupal core.
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for themes
      --no-core          Filter out extensions that are provided by drupal core.
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
      --package string   Filter by project packages. You can use multiple comma separated values.
  -s, --server string    management server endpoint (required)
      --status string    Filter by extension status. Choices _ enabled, disabled and/or 'not installed'. You can use multiple
comma separated values.
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic themes:delete

Deletes one or more themes.

Synopsis

Deletes one or more themes. The provided list of themes must be comma separated.

```
apic themes:delete --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for themes:delete
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --themes string    A list of themes separated by a comma. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic themes:disable

Disable one or more themes.

Synopsis

Disable one or more themes and their dependent modules. The provided list of themes must be comma separated.

```
apic themes:disable --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for themes:disable
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
      --themes string    A list of themes separated by a comma. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic themes:enable

Enable one or more theme.

Synopsis

Enable one or more theme by providing a comma separated list.

```
apic themes:enable --mode portaladmin [flags]
```

Options

```
  -c, --catalog string          Name or ID of the catalog that the site belongs to. (required)
      --format string           Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help                    Help for themes:enable
  -o, --org string              Name or ID of the organization that the catalog belongs to. (required)
      --resolve-dependencies    Attempt to download any missing dependencies. At the moment, only works when the module name is
the same as the project name.
  -s, --server string           management server endpoint (required)
      --skip                    Skip automatic downloading of libraries (c.f. devel).
      --themes string           A list of themes separated by a comma. (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic themes:list

Shows a list of available themes.

Synopsis

Show a list of themes for the portal of the provided org and catalog.

```
apic themes:list --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --core             Filter out extensions that are not in drupal core.
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for themes:list
```

```
      --no-core           Filter out extensions that are provided by drupal core.
  -o, --org string        Name or ID of the organization that the catalog belongs to. (required)
      --package string    Filter by project packages. You can use multiple comma separated values.
  -s, --server string     management server endpoint (required)
      --status string     Filter by extension status. Choices _ enabled, disabled and/or 'not installed'. You can use multiple
comma separated values.
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic themes:set-default

Set a portal's default theme.

Synopsis

Set a portal's default theme. The theme provided must be one that is already enabled.

```
apic themes:set-default --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for themes:set-default
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic twig

Twig operations.

Synopsis

Twig operations.

```
apic twig --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for twig
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic twig:debug-disable

Disable twig debugging on a specific portal site.

Synopsis

Disable twig debugging on a specific portal site. Twig debugging helps locate twig template issues.

```
apic twig:debug-disable --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for twig:debug-disable
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic twig:debug-enable

Enables twig debugging on a specific portal site.

Synopsis

Enables twig debugging on a specific portal site. Twig debugging helps locate twig template issues.

```
apic twig:debug-enable --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for twig:debug-enable
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic twig:debug-status

Shows the current state of twig debugging on a specific portal site.

Synopsis

View the current state of twig debugging on a specific portal site, if you are unsure whether it is enabled or disabled.

```
apic twig:debug-status --mode portaladmin [flags]
```

Options

```
  -c, --catalog string   Name or ID of the catalog that the site belongs to. (required)
      --format string    Output format. One of [json yaml go-template=... go-template-file=...], defaults to yaml.
  -h, --help             Help for twig:debug-status
  -o, --org string       Name or ID of the organization that the catalog belongs to. (required)
  -s, --server string    management server endpoint (required)
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

apic version

Get the APIConnect toolkit version

Synopsis

Get the APIConnect toolkit version

```
apic version --mode portaladmin [flags]
```

Options

```
  -h, --help   Help for version
```

Options inherited from parent commands

```
      --accept-license        Accept the license for API Connect
      --debug                 Enable debug output
      --debug-output string   Write debug output to file
      --live-help             Enable or disable tracking of limited usage information
  -m, --mode string           Toolkit operation mode (default "apim")
```

API Connect REST APIs

The API Connect platform REST APIs provide complete access to the capability of the platform.

The API Connect platform REST APIs can be used for the following actions:

- Automate the administration of the platform.
- Implement scripts and tools to support a continuous integration environment for API development and publishing.
- Manage catalogs of APIs, and their subscribers.

Note: To authenticate with the API Connect Platform REST APIs, generate an API Key and then exchange it for an access token to use when calling the APIs. You can exchange it for an access token with the following example:

```
curl -v -k -X POST -d '{"api_key": "****", "client_id": "client-id", "client_secret": "client-secret", "grant_type":
"api_key"}' -H 'Content-Type: application/json' -H 'Accept: application/json' https://platform-api.
{{region}}.apiconnect.automation.ibm.com/api/token
```

The operations provided in the REST APIs also correspond directly with the commands in the developer toolkit command-line tool (CLI).

You can use the URL to navigate directly to specific APIs and operations in the OpenAPI Explorer Documentation for the API Connect REST APIs. You can also select the APIs for a specific version by using the drop-down menu in the header bar.

For descriptions of the platform APIs, see the API Connect REST API documentation.

Example: Using the platform REST APIs to publish a product containing a SOAP API

Review this sample scenario to see how you can use the API Connect platform REST APIs to publish a product that contains a SOAP API.

This example demonstrates how to format a request to publish the product, and includes sample files that illustrate the product definition, the API definition, and the SOAP API's WSDL description.

Using the `Catalogs` API

Publish the product using the API Connect platform **`Catalogs`** API:

- To publish a product to a catalog, use the following syntax:

  `POST catalogs/{org}/{catalog}/publish`

- To publish a product to a space within a catalog, additionally specify the space with the following syntax:

  `POST catalogs/{org}/{catalog}/{space}/publish`

The payload in both cases is a multipart, form-encoded body containing three required parts and one optional part:

- (Required) A part named **`product`** with media type **`application/yaml`** or **`application/json`**, containing the yaml or JSON source for the product to be published.
- (Required) One or more occurrences of a part named **`openapi`** with media type **`application/yaml`** or **`application/json`**, containing the YAML or JSON source for each API in the product.
- (Required for SOAP APIs) One or more occurrences of a part named **`wsdl`** with media type **`application/wsdl`**, **`application/wsdl+xml`**, **`text/xml`**, or **`application/zip`** containing the WSDL definitions (and referenced XSD files if applicable) associated with the API content.
- (Optional) A part named **`gateway_service_urls`** with media type **`application/yaml`** or **`application/json`** which is a YAML or JSON array of URLs to specify a subset of the configured gateway services within the catalog or space as publish targets. These URLs can be obtained using the following calls:
  - For a catalog:

    `GET /api/catalogs/{org}/{catalog}/configured-gateway-services`

  - For a space:

    `GET /spaces/{org}/{catalog}/{space}/configured-gateway-services`

Within the **product** content, the form of the references to APIs in the **apis** section is significant. Each API reference must use the **name** property instead of the **$ref** form that may appear in other situations. Here is an example showing a product that refers to the API **globalweather** version **1.0.0** in the correct form:

```
info:
  version: 1.0.0
  title: GlobalWeatherProduct
  name: globalweatherproduct
plans:
  ...
apis:
  globalweather1.0.0:
    name: globalweather:1.0.0
...
```

Example publish operation using cURL

This example publishes a product containing a SOAP API to the *Sandbox* catalog of the *onlinebanking* provider organization, using the **curl -F** option to create a set of form-encoded payload parts and the **@** prefix to read the content for each part from a file. Note the part name (**product**, **openapi**, **wsdl**) and the content type of each part given by the **type=** value.

In this example, the access token has been retrieved earlier and placed in an environment variable named **TOKEN**. The command is split onto multiple lines for ease of reading but must be entered as a single line.

Request:

```
curl -v -k
  -F "product=@globalweatherproduct_1.0.0.yaml;type=application/yaml"
  -F "openapi=@globalweather_1.0.0.yaml;type=application/yaml"
  -F "wsdl=@globalweather.wsdl;type=application/wsdl"
  -H "Authorization: Bearer $TOKEN"
  -H 'Content-Type: multipart/form-data'
  -H 'Accept: */*' https://dev.apic.example.com/api/catalogs/onlinebanking/sandbox/publish
```

Response:

```

```

The request specifies three files, which are included with this example for reference:

- Product definition `-F "product=@globalweatherproduct_1.0.0.yaml;type=application/yaml"`
- API definition `-F "openapi=@globalweather_1.0.0.yaml;type=application/yaml"`
- WSDL description `-F "wsdl=@globalweather.wsdl;type=application/wsdl"`

Example Product file: globalweatherproduct_1.0.0.yaml

The following code sample contains a Product definition.

The Product definition file globalweatherproduct_1.0.0.yaml is referenced by the example scenario in Example: Using the platform REST APIs to publish a product containing a SOAP API.

```
info:
  version: 1.0.0
  title: GlobalWeatherProduct
  name: globalweatherproduct
gateways:
  - datapower-api-gateway
plans:
  default-plan:
    title: Default Plan
    description: Default Plan
    rate-limits:

```

API Connect TLS certificates

Details of all Kubernetes TLS certificate objects that are created and used in a default installation of API Connect.

Overview

TLS is used to secure communications between API Connect pods, subsystems, external services, and users. The TLS certificates that are used by API Connect are created automatically during the installation of API Connect. The certificates are managed by an open source product called cert-manager.

The certificates that are described in this topic all exist as Kubernetes certificate objects in the API Connect namespace where the subsystem that uses the certificate is installed. Run **`kubectl get certs -n <namespace>`** to see the certificates in your environment. Some of the API Connect Kubernetes certificates are also stored in the management subsystem database. These certificates can be seen in the Cloud Manager UI, in the truststores and keystores of the subsystem default TLS profiles. When the management subsystem **`apim`** pod is restarted, the certificates in the management database are reloaded from the Kubernetes certificates.

This topic does not cover additional TLS profiles and certificates that API Connect administrators and provider organization owners can create and configure in the Cloud Manager and API Manager UIs. These certificates are stored in the management subsystem database only and do not exist in the Kubernetes environment.

The certificates that are created and used by API Connect are categorized as follows:

- CA certificates - API Connect creates self-signed CA certificates to sign all the API Connect end-entity certificates. The CA certificates are:
  - **ingress-ca** - used by the ingress-issuer. The ingress-ca signs all user-facing and inter-subsystem certificates.
  - **management-ca** - signs all the management intra-subsystem certificates.
  - **portal-ca** - signs all the portal intra-subsystem certificates.
  - **analytics-ca** - signs all the analytics intra-subsystem certificates.

  CA certificates have a default duration of 10 years. All the end-entity certificates have a default duration of 2 years.
- Ingress certificates - API Connect creates a self-signed issuer that is called the ingress-issuer. Ingress certificates are the API Connect certificates that are issued by the ingress-issuer. Ingress certificates are divided into two types:
  - Inter-subsystem certificates - certificates that are used for communication between API Connect subsystems, for example between the management subsystem and gateway. By default, communication between most subsystems uses mTLS. From v10.0.5.3, it is possible to use JWT instead of mTLS: Using JWT instead of mTLS on Kubernetes and OpenShift, Using JWT instead of mTLS on OVA.
  - User-facing certificates - certificates that API Connect users see when they interact with the API Connect UIs and REST API.
- Intra-subsystem certificates - certificates that are used between pods in the same subsystem. Intra-subsystem certificates are signed by a subsystem specific CA certificate: **management-ca**, **portal-ca**, **analytics-ca**. The gateway subsystem is a single pod, and has no intra-subsystem certificates.

On OVA deployments, certificate management is done with the **apicup** command, see Setting and managing certificates on OVA. Do not login to your VMs by **ssh** and attempt to modify certificates directly, unless advised by IBM.

Note: On Cloud Pak for Integration, and OpenShift top-level CR deployments, some certificate names are contracted and prefixed with the **APIConnectCluster** instance name. For example, the certificate **managment-ca** is called ***<apic instance name>*-mgmt-ca**.

Customizing certificates

It is possible to customize certificates with ones from your own organization. However it is recommended to customize only the user-facing certificates, which are the certificates that your users see when they access the API Connect UIs, CLI, and the REST API.

All other certificates are used internally between API Connect microservices.
Note: The inter and intra-subsystem certificates use of a self-signed root CA presents no security risk. For internal communications with a limited number of predefined endpoints, use of locally generated self-signed CA certificates can be more secure than external CA certificates, as certificates are only ever issued for the known components and the domain of trust is kept as small as possible.

Renewing certificates

Cert-manager handles the renewal of expired certificates so that the user does not need to monitor or manually renew any of the certificates. However, there are scenarios where the renewal of certificates must be triggered manually. Every API Connect certificate has a corresponding Kubernetes secret object of the same name, deleting this secret triggers cert-manager to re-create the secret with a new TLS certificate. For more information about certificate renewal, see Renewing TLS certificates.
Remember: The Kubernetes certificate objects do not contain the TLS certificates themselves, they are pointers to Kubernetes secrets that contain the TLS certificate. See Key Concepts: Cert-manager, Issuers, and Secrets.
For most of the certificates, when they are renewed, the pods that use those certificates are automatically restarted so that they pick up the updated certificate. The minority of certificates that require manual pod restarts after renewal are identified in the reference tables.

If you renew a CA certificate, any end-entity certificates that use this CA certificate must also be renewed.

Reference tables

The tables show all the API Connect certificates that are created in all possible deployment configurations.

Each table corresponds to a subsystem, and shows the certificates that are used by that subsystem.
Note: On Cloud Pak for Integration or top-level CR deployments, some of the certificates have a shortened name. Where two names for a certificate are shown in the tables, the second name is the name that is used on Cloud Pak for Integration or top-level CR deployments. For example, **management-ca or mgmt-ca**.

Table 1. Management certificates

Certificate name	Issuer	Description
-ingress-ca	**selfsigning-issuer**	The CA and issuer of all API Connect inter-subsystem and user-facing certificates. If there is a problem with this certificate, then all API Connect subsystems are inaccessible and unable to sync with each other. Update this certificate with kubectl. When updated, all child certificates must also be updated by deleting their corresponding secrets. The ingress-ca certificate is also stored in the management subsystem database. It is visible from the Cloud Manager UI, in the truststores of the analytics, gateway, event gateway, and portal default TLS client profiles. When the management subsystem **apim** pod is restarted the certificate is reloaded into the database from the Kubernetes ingress-ca certificate. Do not attempt to update this certificate from the Cloud Manager UI. In 2DCDR deployments, and when you have subsystems in different namespaces, it is necessary to manually copy the ingress-ca certificate from the management subsystem to the other subsystems. Steps are provided in the 2DCDR and multi-namespace install sections of this documentation.
management-ca or mgmt-ca	**selfsigning-issuer**	The issuer for the management subsystems intra-subsystem certificates: management-client, management-server, postgres, and nats certificates. Communication between management subsystem pods fails if there is a problem with this certificate. This certificate is also used as the CA for REST API calls to the management subsystem from the other subsystems, when using **in-cluster** communication. See In-cluster service communication between subsystems
management-client or mgmt-client	**management-ca**	Client certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate.

Certificate name	Issuer	Description
`management-server or mgmt-server`	`management-ca`	Server certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate. Required DNS names in the certificate: `*.<namespace>` `*.<namespace>.svc` `*.<instance name>-server.<namespace>.svc` `<instance name>-server`
`analytics-client-client or a7s-cl-client`	`ingress-issuer`	Legacy certificate from pre-v10.0.5 releases. Not used for anything and safe to delete. In v10.0.5, communication with the analytics subsystem uses the `analytics-ingestion-client` certificate.
`analytics-ingestion-client or a7s-ing-client`	`ingress-issuer`	Client certificate used for communication with the analytics subsystem on the ingestion endpoint. This certificate must have: • The same CA as the server certificate `analytics-ai-endpoint` on the analytics subsystem. • The common name must match the `spec.clientSubjectDN` in the analytics CR: `kubectl describe cert analytics-admin-client` `Spec:` `  Common Name:  a7s-ing-client` `kubectl get ptl -o yaml` `  spec:` `    clientSubjectDN: CN=a7s-ing-client` For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=a7s-ingestion-client`, or they could both be `CN=a7s-ingestion-client, O=cert-manager`, but they must be identical. To update this certificate, use kubectl. Restart the `apim`, `taskmanager`, and `analytics-proxy` pods after the update. This certificate is also used by the gateways for sending API events to the analytics subsystem. The updated certificate is sent by the management subsystem to the gateways, it is not necessary to restart any gateway pods.
`portal-admin-client or ptl-adm-client`	`ingress-issuer`	Client certificate used for communication with the portal subsystem on the `portalAdminEndpoint`. This certificate must have: • The same CA as the server certificate `portal-admin or ptl-director` on the portal subsystem. • The common name must match the `spec.adminClientSubjectDN` in the portal CR: `kubectl describe cert portal-admin-client` `Spec:` `  Common Name:  ptl-adm-client` `kubectl get ptl -o yaml` `  spec:` `    adminClientSubjectDN: CN=ptl-adm-client` For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=portal-admin-client`, or they could both be `CN=ptl-adm-client, O=cert-manager`, but they must be identical.
`gateway-client-client or gw-dr-client`	`ingress-issuer`	Client certificate for communications with the gateway service. Restart the `apim`, and `taskmanager` pods after update. This certificate must have the same CA as the `gwv6-manager-endpoint or gw-gateway-manager` certificate on the gateway.
`api-endpoint or mgmt-platform-api`	`ingress-issuer`	Platform API endpoint server certificate. The certificate that is presented to callers of the platform REST API, and to the toolkit CLI.
`consumer-endpoint or mgmt-consumer-api`	`ingress-issuer`	Consumer API endpoint server certificate. The certificate presented that is presented to callers of the consumer REST API, and to the toolkit CLI.
`apim-endpoint or mgmt-api-manager`	`ingress-issuer`	API Manager UI server certificate.
`cm-endpoint or mgmt-admin`	`ingress-issuer`	Cloud Manager UI server certificate.
`db-client-apicuser`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`db-client-pgbouncer`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`db-client-postgres`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`db-client-primaryuser`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`postgres`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`postgres-pgbouncer`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`postgres-operator`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`natscluster-mgmt`	`management-ca`	Intra-subsystem certificate for the `nats` pods.
`db-client-replicator`	`management-ca`	2DCDR deployments only. Client certificate used by the `<management_CR>-tunnel` pod to connect to the other data center's `<management_CR>-tunnel` pod.

Certificate name	Issuer	Description
mgmt-replication-client	**ingress-issuer**	2DCDR deployments only. Client certificate used in the warm-standby data center's **<remote-sitename>-postgres** pod to connect to the active data center.
mgmt-replication-server	**ingress-issuer**	2DCDR deployments only. Server certificate used in the active data center's **<management_CR>-tunnel** pod. This certificate must contain the DNS Subject Alternative Name of this data center's hostname.
hub-endpoint	**ingress-issuer**	Used by the Automated API behavior testing application. User-facing server certificate for the **hub-endpoint**. If there is a problem with this certificate, then the user's browser shows a warning or error message.
turnstile-endpoint	**ingress-issuer**	Used by the Automated API behavior testing application. User-facing server certificate for the **turnstile-endpoint**. If there is a problem with this certificate, then the user's browser shows a warning or error message.

Table 2. Analytics certificates

Certificate name	Issuer	Description
analytics-ai-endpoint or a7s-ai-endpoint	**ingress-issuer**	Server certificate used on the analytics ingestion endpoint, in the **mtls-gw** pod. Management and gateway subsystems communicate with the analytics subsystem on this endpoint. The client certificates that are used by the management and gateway subsystems must use the same CA certificate as the **analytics-ai-endpoint** certificate. If this certificate is updated, restart the **mtls-gw** pod for the update to take effect.
analytics-ca or a7s-ca	**selfsigning-issuer**	The issuer for the analytics-client and analytics-server certificates. Communication between analytics subsystem pods fails if there is a problem with this certificate. If this certificate is updated, restart the **storage** and **ingestion** pods for the update to take effect.
analytics-client or a7s-client	**analytics-ca**	Client certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. If this certificate is updated, restart the **storage** and **ingestion** pods for the update to take effect.
analytics-server or a7s-server	**analytics-ca**	Server certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. Required DNS names in the certificate: ***.<namespace>** ***.<namespace>.svc** ***.<instance name>-server.<namespace>.svc** **<instance name>-server** **<instance name>-storage** If this certificate is updated, restart the **storage** and **ingestion** pods for the update to take effect.

Table 3. Portal certificates

Certificate name	Issuer	Description
portal-ca or ptl-ca	**selfsigning-issuer**	The issuer for the portal-client and portal-server certificates. Communication between portal subsystem pods fails if there is a problem with this certificate.
portal-client or ptl-client	**portal-ca**	Client certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate.
portal-server or ptl-server	**portal-ca**	Server certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate. Required DNS names in the certificate: ***.<namespace>** ***.<namespace>.svc** ***.<instance name>-server.<namespace>.svc** **<instance name>-server** ***.<instance name>-<site name>-db-all.<namespace>.svc** ***.<instance name>-<site name>-www-all.<namespace>.svc** ***.<instance name>-<site name>-db-all.<namespace>.svc.cluster.local** ***.<instance name>-<site name>-www-all.<namespace>.svc.cluster.local** ***.<namespace>.svc.cluster.local** **<instance name>-db** **#<remote portal CR name>-db # For 2DCDR only.** *<instance name>* and *<remote portal CR name>* are truncated if more than 15 characters.
portal-admin or ptl-director	**ingress-issuer**	Server certificate used on the **portalAdminEndpoint**. The management subsystem communicates with the portal subsystem on this endpoint. The corresponding client certificate used in the management to portal communication is the **portal-admin-client** certificate. This certificate must have the same CA as the **portal-admin-client** certificate on the management subsystem.
portal-web	**ingress-issuer**	The server certificate used on the **portalUIEndpoint**. It is the server certificate that is presented to portal site users, and which their browser authenticates. If there is a problem with this certificate, then users see an error message about an invalid or insecure certificate in their browser when they access a portal site. The default **portal-web** certificate is issued by the **ingress-issuer**, which has a self-signed root certificate. Portal users might see a browser warning about use of a self-signed certificate.
ptl-replication-client	**ingress-issuer**	2DCDR deployments only. Client certificate that is used in the warm-standby data center's **<remote-sitename>-www** and **<remote-sitename>-db** pods to connect to the active data center.
ptl-replication-server	**ingress-issuer**	2DCDR deployments only. Server certificate used in the active data center's **<portal_CR>-tunnel** pod, the counterpart to the **ptl-replication-client** certificate. This certificate must contain the DNS Subject Alternative Name of this data center's hostname.

Table 4. Gateway certificates

Certificate name	Issuer	Description
gateway-peering or gw-peer	**ingress-issuer**	This certificate secures the communication between gateways in your gateway cluster.

Certificate name	Issuer	Description
`gateway-service or gw-svc`	`ingress-issuer`	Legacy certificate that is not used.
`gwv6-endpoint or gw-gateway`	`ingress-issuer`	
`gwv6-manager-endpoint or gw-gateway-manager`	`ingress-issuer`	The `gatewayManager` endpoint certificate. This is the server certificate on the gateway director endpoint, which the management subsystem communicates with. This certificate must be signed by the same CA as the `gateway-client-client` certificate on management subsystem

Table 5. Event gateway certificates -Cloud Pak for Integration only

Certificate name	Issuer	Description
`event-gateway-management-client`	`ingress-issuer`	The `event-gateway-management-client` certificate exists only on Cloud Pak for Integration deployments.

TLS certificates organized by usage

Table of API Connect certificates organized by where they are used.

Table 1. Management to gateway communication

Certificate name	Issuer	Description
`-ingress-ca`	`selfsigning-issuer`	The CA and issuer of all API Connect inter-subsystem and user-facing certificates. If there is a problem with this certificate, then all API Connect subsystems are inaccessible and unable to sync with each other. Update this certificate with kubectl. When updated, all child certificates must also be updated by deleting their corresponding secrets. The ingress-ca certificate is also stored in the management subsystem database. It is visible from the Cloud Manager UI, in the truststores of the analytics, gateway, event gateway, and portal default TLS client profiles. When the management subsystem `apim` pod is restarted the certificate is reloaded into the database from the Kubernetes ingress-ca certificate. Do not attempt to update this certificate from the Cloud Manager UI. In 2DCDR deployments, and when you have subsystems in different namespaces, it is necessary to manually copy the ingress-ca certificate from the management subsystem to the other subsystems. Steps are provided in the 2DCDR and multi-namespace install sections of this documentation.
`gateway-client-client or gw-dr-client`	`ingress-issuer`	Client certificate for communications with the gateway service. Restart the `apim`, and `taskmanager` pods after update. This certificate must have the same CA as the `gwv6-manager-endpoint or gw-gateway-manager` certificate on the gateway.
`gwv6-manager-endpoint or gw-gateway-manager`	`ingress-issuer`	The `gatewayManager` endpoint certificate. This is the server certificate on the gateway director endpoint, which the management subsystem communicates with. This certificate must be signed by the same CA as the `gateway-client-client` certificate on management subsystem

Table 2. Management to portal communication

Certificate name	Issuer	Description
`-ingress-ca`	`selfsigning-issuer`	The CA and issuer of all API Connect inter-subsystem and user-facing certificates. If there is a problem with this certificate, then all API Connect subsystems are inaccessible and unable to sync with each other. Update this certificate with kubectl. When updated, all child certificates must also be updated by deleting their corresponding secrets. The ingress-ca certificate is also stored in the management subsystem database. It is visible from the Cloud Manager UI, in the truststores of the analytics, gateway, event gateway, and portal default TLS client profiles. When the management subsystem `apim` pod is restarted the certificate is reloaded into the database from the Kubernetes ingress-ca certificate. Do not attempt to update this certificate from the Cloud Manager UI. In 2DCDR deployments, and when you have subsystems in different namespaces, it is necessary to manually copy the ingress-ca certificate from the management subsystem to the other subsystems. Steps are provided in the 2DCDR and multi-namespace install sections of this documentation.
`portal-admin-client or ptl-adm-client`	`ingress-issuer`	Client certificate used for communication with the portal subsystem on the `portalAdminEndpoint`. This certificate must have: • The same CA as the server certificate `portal-admin or ptl-director` on the portal subsystem. • The common name must match the `spec.adminClientSubjectDN` in the portal CR: `kubectl describe cert portal-admin-client` `Spec:` `  Common Name:  ptl-adm-client` `kubectl get ptl -o yaml` `  spec:` `    adminClientSubjectDN: CN=ptl-adm-client` For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=portal-admin-client`, or they could both be `CN=ptl-adm-client, O=cert-manager`, but they must be identical.

Certificate name	Issuer	Description
`portal-admin or ptl-director`	`ingress-issuer`	Server certificate used on the **`portalAdminEndpoint`**. The management subsystem communicates with the portal subsystem on this endpoint. The corresponding client certificate used in the management to portal communication is the **`portal-admin-client`** certificate. This certificate must have the same CA as the **`portal-admin-client`** certificate on the management subsystem.

Table 3. Management and gateway to analytics communication

Certificate name	Issuer	Description
`-ingress-ca`	`selfsigning-issuer`	The CA and issuer of all API Connect inter-subsystem and user-facing certificates. If there is a problem with this certificate, then all API Connect subsystems are inaccessible and unable to sync with each other. Update this certificate with kubectl. When updated, all child certificates must also be updated by deleting their corresponding secrets. The ingress-ca certificate is also stored in the management subsystem database. It is visible from the Cloud Manager UI, in the truststores of the analytics, gateway, event gateway, and portal default TLS client profiles. When the management subsystem **`apim`** pod is restarted the certificate is reloaded into the database from the Kubernetes ingress-ca certificate. Do not attempt to update this certificate from the Cloud Manager UI. In 2DCDR deployments, and when you have subsystems in different namespaces, it is necessary to manually copy the ingress-ca certificate from the management subsystem to the other subsystems. Steps are provided in the 2DCDR and multi-namespace install sections of this documentation.
`analytics-ingestion-client or a7s-ing-client`	`ingress-issuer`	Client certificate used for communication with the analytics subsystem on the ingestion endpoint. This certificate must have: • The same CA as the server certificate **`analytics-ai-endpoint`** on the analytics subsystem. • The common name must match the **`spec.clientSubjectDN`** in the analytics CR: `kubectl describe cert analytics-admin-client` `Spec:` `  Common Name:  a7s-ing-client` `kubectl get ptl -o yaml` `  spec:` `    clientSubjectDN: CN=a7s-ing-client` For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be **`CN=a7s-ingestion-client`**, or they could both be **`CN=a7s-ingestion-client, O=cert-manager`**, but they must be identical. To update this certificate, use kubectl. Restart the **`apim`**, **`taskmanager`**, and **`analytics-proxy`** pods after the update. This certificate is also used by the gateways for sending API events to the analytics subsystem. The updated certificate is sent by the management subsystem to the gateways, it is not necessary to restart any gateway pods.
`analytics-ai-endpoint or a7s-ai-endpoint`	`ingress-issuer`	Server certificate used on the analytics ingestion endpoint, in the **`mtls-gw`** pod. Management and gateway subsystems communicate with the analytics subsystem on this endpoint. The client certificates that are used by the management and gateway subsystems must use the same CA certificate as the **`analytics-ai-endpoint`** certificate. If this certificate is updated, restart the **`mtls-gw`** pod for the update to take effect.

Table 4. User-facing certificates

Certificate name	Issuer	Description
`api-endpoint or mgmt-platform-api`	`ingress-issuer`	Platform API endpoint server certificate. The certificate that is presented to callers of the platform REST API, and to the toolkit CLI.
`consumer-endpoint or mgmt-consumer-api`	`ingress-issuer`	Consumer API endpoint server certificate. The certificate presented that is presented to callers of the consumer REST API, and to the toolkit CLI.
`apim-endpoint or mgmt-api-manager`	`ingress-issuer`	API Manager UI server certificate.
`cm-endpoint or mgmt-admin`	`ingress-issuer`	Cloud Manager UI server certificate.
`portal-web`	`ingress-issuer`	The server certificate used on the **`portalUIEndpoint`**. It is the server certificate that is presented to portal site users, and which their browser authenticates. If there is a problem with this certificate, then users see an error message about an invalid or insecure certificate in their browser when they access a portal site. The default **`portal-web`** certificate is issued by the **`ingress-issuer`**, which has a self-signed root certificate. Portal users might see a browser warning about use of a self-signed certificate.
`hub-endpoint`	`ingress-issuer`	Used by the Automated API behavior testing application. User-facing server certificate for the **`hub-endpoint`**. If there is a problem with this certificate, then the user's browser shows a warning or error message.
`turnstile-endpoint`	`ingress-issuer`	Used by the Automated API behavior testing application. User-facing server certificate for the **`turnstile-endpoint`**. If there is a problem with this certificate, then the user's browser shows a warning or error message.

Table 5. Inter-subsystem certificates

Certificate name	Issuer	Description

Certificate name	Issuer	Description
-ingress-ca	**selfsigning-issuer**	The CA and issuer of all API Connect inter-subsystem and user-facing certificates. If there is a problem with this certificate, then all API Connect subsystems are inaccessible and unable to sync with each other. Update this certificate with kubectl. When updated, all child certificates must also be updated by deleting their corresponding secrets. The ingress-ca certificate is also stored in the management subsystem database. It is visible from the Cloud Manager UI, in the truststores of the analytics, gateway, event gateway, and portal default TLS client profiles. When the management subsystem **apim** pod is restarted the certificate is reloaded into the database from the Kubernetes ingress-ca certificate. Do not attempt to update this certificate from the Cloud Manager UI. In 2DCDR deployments, and when you have subsystems in different namespaces, it is necessary to manually copy the ingress-ca certificate from the management subsystem to the other subsystems. Steps are provided in the 2DCDR and multi-namespace install sections of this documentation.
analytics-ingestion-client or a7s-ing-client	**ingress-issuer**	Client certificate used for communication with the analytics subsystem on the ingestion endpoint. This certificate must have: • The same CA as the server certificate **analytics-ai-endpoint** on the analytics subsystem. • The common name must match the **spec.clientSubjectDN** in the analytics CR: **kubectl describe cert analytics-admin-client** **Spec:** **Common Name: a7s-ing-client** **kubectl get ptl -o yaml** **spec:** **clientSubjectDN: CN=a7s-ing-client** For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be **CN=a7s-ingestion-client**, or they could both be **CN=a7s-ingestion-client, O=cert-manager**, but they must be identical. To update this certificate, use kubectl. Restart the **apim**, **taskmanager**, and **analytics-proxy** pods after the update. This certificate is also used by the gateways for sending API events to the analytics subsystem. The updated certificate is sent by the management subsystem to the gateways, it is not necessary to restart any gateway pods.
portal-admin-client or ptl-adm-client	**ingress-issuer**	Client certificate used for communication with the portal subsystem on the **portalAdminEndpoint**. This certificate must have: • The same CA as the server certificate **portal-admin or ptl-director** on the portal subsystem. • The common name must match the **spec.adminClientSubjectDN** in the portal CR: **kubectl describe cert portal-admin-client** **Spec:** **Common Name: ptl-adm-client** **kubectl get ptl -o yaml** **spec:** **adminClientSubjectDN: CN=ptl-adm-client** For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be **CN=portal-admin-client**, or they could both be **CN=ptl-adm-client, O=cert-manager**, but they must be identical.
gateway-client-client or gw-dr-client	**ingress-issuer**	Client certificate for communications with the gateway service. Restart the **apim**, and **taskmanager** pods after update. This certificate must have the same CA as the **gwv6-manager-endpoint or gw-gateway-manager** certificate on the gateway.
api-endpoint or mgmt-platform-api	**ingress-issuer**	Platform API endpoint server certificate. The certificate that is presented to callers of the platform REST API, and to the toolkit CLI.
consumer-endpoint or mgmt-consumer-api	**ingress-issuer**	Consumer API endpoint server certificate. The certificate presented that is presented to callers of the consumer REST API, and to the toolkit CLI.
apim-endpoint or mgmt-api-manager	**ingress-issuer**	API Manager UI server certificate.
cm-endpoint or mgmt-admin	**ingress-issuer**	Cloud Manager UI server certificate.
mgmt-replication-client	**ingress-issuer**	2DCDR deployments only. Client certificate used in the warm-standby data center's **<remote-sitename>-postgres** pod to connect to the active data center.
mgmt-replication-server	**ingress-issuer**	2DCDR deployments only. Server certificate used in the active data center's **<management_CR>-tunnel** pod. This certificate must contain the DNS Subject Alternative Name of this data center's hostname.
hub-endpoint	**ingress-issuer**	Used by the Automated API behavior testing application. User-facing server certificate for the **hub-endpoint**. If there is a problem with this certificate, then the user's browser shows a warning or error message.
turnstile-endpoint	**ingress-issuer**	Used by the Automated API behavior testing application. User-facing server certificate for the **turnstile-endpoint**. If there is a problem with this certificate, then the user's browser shows a warning or error message.
analytics-ai-endpoint or a7s-ai-endpoint	**ingress-issuer**	Server certificate used on the analytics ingestion endpoint, in the **mtls-gw** pod. Management and gateway subsystems communicate with the analytics subsystem on this endpoint. The client certificates that are used by the management and gateway subsystems must use the same CA certificate as the **analytics-ai-endpoint** certificate. If this certificate is updated, restart the **mtls-gw** pod for the update to take effect.

Certificate name	Issuer	Description
`portal-admin or ptl-director`	`ingress-issuer`	Server certificate used on the **`portalAdminEndpoint`**. The management subsystem communicates with the portal subsystem on this endpoint. The corresponding client certificate used in the management to portal communication is the **`portal-admin-client`** certificate. This certificate must have the same CA as the **`portal-admin-client`** certificate on the management subsystem.
`portal-web`	`ingress-issuer`	The server certificate used on the **`portalUIEndpoint`**. It is the server certificate that is presented to portal site users, and which their browser authenticates. If there is a problem with this certificate, then users see an error message about an invalid or insecure certificate in their browser when they access a portal site. The default **`portal-web`** certificate is issued by the **`ingress-issuer`**, which has a self-signed root certificate. Portal users might see a browser warning about use of a self-signed certificate.
`ptl-replication-client`	`ingress-issuer`	2DCDR deployments only. Client certificate that is used in the warm-standby data center's **`<remote-sitename>-www`** and **`<remote-sitename>-db`** pods to connect to the active data center.
`ptl-replication-server`	`ingress-issuer`	2DCDR deployments only. Server certificate used in the active data center's **`<portal_CR>-tunnel`** pod, the counterpart to the **`ptl-replication-client`** certificate. This certificate must contain the DNS Subject Alternative Name of this data center's hostname.
`gateway-peering or gw-peer`	`ingress-issuer`	This certificate secures the communication between gateways in your gateway cluster.
`gwv6-endpoint or gw-gateway`	`ingress-issuer`	
`gwv6-manager-endpoint or gw-gateway-manager`	`ingress-issuer`	The **`gatewayManager`** endpoint certificate. This is the server certificate on the gateway director endpoint, which the management subsystem communicates with. This certificate must be signed by the same CA as the **`gateway-client-client`** certificate on management subsystem
`event-gateway-management-client`	`ingress-issuer`	The **`event-gateway-management-client`** certificate exists only on Cloud Pak for Integration deployments.

Table 6. Intra-subsystem certificates

Certificate name	Issuer	Description
`management-ca or mgmt-ca`	`selfsigning-issuer`	The issuer for the management subsystems intra-subsystem certificates: management-client, management-server, postgres, and nats certificates. Communication between management subsystem pods fails if there is a problem with this certificate. This certificate is also used as the CA for REST API calls to the management subsystem from the other subsystems, when using **`in-cluster`** communication. See In-cluster service communication between subsystems
`management-client or mgmt-client`	`management-ca`	Client certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate.
`management-server or mgmt-server`	`management-ca`	Server certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate. Required DNS names in the certificate: **`*.<namespace>`** **`*.<namespace>.svc`** **`*.<instance name>-server.<namespace>.svc`** **`<instance name>-server`**
`db-client-apicuser`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`db-client-pgbouncer`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`db-client-postgres`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`db-client-primaryuser`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`postgres`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`postgres-pgbouncer`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`postgres-operator`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`natscluster-mgmt`	`management-ca`	Intra-subsystem certificate for the **`nats`** pods.
`db-client-replicator`	`management-ca`	2DCDR deployments only. Client certificate used by the **`<management_CR>-tunnel`** pod to connect to the other data center's **`<management_CR>-tunnel`** pod.
`analytics-ca or a7s-ca`	`selfsigning-issuer`	The issuer for the analytics-client and analytics-server certificates. Communication between analytics subsystem pods fails if there is a problem with this certificate. If this certificate is updated, restart the **`storage`** and **`ingestion`** pods for the update to take effect.
`analytics-client or a7s-client`	`analytics-ca`	Client certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. If this certificate is updated, restart the **`storage`** and **`ingestion`** pods for the update to take effect.
`analytics-server or a7s-server`	`analytics-ca`	Server certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. Required DNS names in the certificate: **`*.<namespace>`** **`*.<namespace>.svc`** **`*.<instance name>-server.<namespace>.svc`** **`<instance name>-server`** **`<instance name>-storage`** If this certificate is updated, restart the **`storage`** and **`ingestion`** pods for the update to take effect.

Certificate name	Issuer	Description
`portal-ca or ptl-ca`	`selfsigning-issuer`	The issuer for the portal-client and portal-server certificates. Communication between portal subsystem pods fails if there is a problem with this certificate.
`portal-client or ptl-client`	`portal-ca`	Client certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate.
`portal-server or ptl-server`	`portal-ca`	Server certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate. Required DNS names in the certificate: `*.<namespace>` `*.<namespace>.svc` `*.<instance name>-server.<namespace>.svc` `<instance name>-server` `*.<instance name>-<site name>-db-all.<namespace>.svc` `*.<instance name>-<site name>-www-all.<namespace>.svc` `*.<instance name>-<site name>-db-all.<namespace>.svc.cluster.local` `*.<instance name>-<site name>-www-all.<namespace>.svc.cluster.local` `*.<namespace>.svc.cluster.local` `<instance name>-db` `#<remote portal CR name>-db # For 2DCDR only.` *<instance name>* and *<remote portal CR name>* are truncated if more than 15 characters.

Troubleshooting API Connect

This section provides some general troubleshooting steps for use when encountering common problems with API Connect.

About

The following sections provide advice on diagnosing some common problems. This information can help you to identify whether a specific API Connect component is failing, whether it's an environmental problem, and whether you should raise a support request. Some advice includes reviewing specific log files so you can narrow down the source of the problem.

- Unable to access Management UIs
- Unable to access the Portal sites
- Login failure on Management UIs
- Login failure on Portal sites
- Management operations not reflected on Gateway or Portal

Related tasks

- Gathering post-mortem logs
- Gathering logs for a VMware environment

Related information

- IBM Support Service Requests and PMRs

Unable to access Management UIs

If you are unable to access the UI login page, getting a blank page, an HTTP 404, or some other error.

When this happens it means that either the Management subsystem is down, or the access attempt is not reaching the Management subsystem due to a problem in the environment.

Note: For OVA users some of the following checks involve running kubectl commands on your VMs. To access your VMs for running kubectl commands:

1. ssh to one of your Management VMs as the user 'apicadm', for example: `ssh apicadm@mgmt1.example.com`
2. Sudo to the root user: `sudo -i`
3. From here you will be able to run kubectl commands, for example:

```
# kubectl get pods
NAME                                                              READY   STATUS      RESTARTS      AGE
abc-management-analytics-proxy-5f8bcd74c4-jbhch                   1/1     Running     1 (97d ago)   113d
...
```

4. API Connect pods run in the default namespace on OVA, so there is no need to specify the namespace with `-n` in the kubectl commands.

Check the following:

- Is the access attempt actually reaching the Management subsystem? To confirm this, check what is in the logs of the `juhu` pods which run on the Management subsystem. The `juhu` pods are the entry point for all UI, REST, and CLI requests to the Management subsystem. For every access request there should be line logged by the `juhu`pod, for example: When the user attempts to access the admin UI login page, the following is logged by the juhu pod:

```
kubectl logs abc-management-juhu-fc8f6bb5d-jnw2q --since=5m
...
```

```
9.20.85.205 - - [27/May/2022:10:35:49 +0000] [675fa59030a1a68028712ad2fdb2fdb1] "GET /api/cloud/admin/identity-providers
HTTP/1.1" 200 301 "https://apimsvc20.hursley.ibm.com/auth/admin/sign-in/" "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7)
AppleWebKit/537.36 (KHTML, like Gecko) Chrome/101.0.4951.64 Safari/537.36" "9.145.13.216" [127.0.0.1:2000]
request_time=0.222 upstream_response_time=0.224
...
```

Note that the timestamp of these log records are not the time when the request arrived, but the time when the response to the request was sent back. To work out the arrival time you can subtract the `request_time=0.222` that appears later in the log message. If there is nothing logged in the `juhu` pods at the time the UI access is attempted, then check if you have any network problems between your browser and the Management subsystem. If you are on OVA then the tcpdump utility is available which you can use to confirm if traffic is reaching your Management VM, for example `tcpdump -i any src host 9.20.86.22 and dst port 443`

- Are the Management subsystem pods all up and running? Check this with `kubectl get ManagementCluster -n <namespace>`. If this does not show all pods running, then check which pods are failing: `kubectl get pods -n <namespace>`. If you are on OVA then gather postmortem logs and open a support case at this point. Otherwise it's worth checking the reasons why the pods are failing to start with `kubectl describe` as it might be something in your kubernetes environment that you can fix. Note that on the Management subsystem the `postgres` pods will need to be running first, so if these are not running then most other Management pods will not start.
- Check the logs of the `apim` pods while attempting to access the UI. The `juhu` pods receive the requests from the UI, and send them on to the `apim` pods for processing. The logs of the `apim` pods may reveal some clues as to the cause of the problem. If nothing is logged in the `apim` pods at the time of the access attempt then it suggests a problem in the environment, the `juhu` pods unable to forward requests to `apim`.

- IBM Support Service Requests and PMRs

Unable to access the Portal sites

If you are unable to access the login page of a Portal site, getting a blank page, an HTTP 404, or some other error.

When this happens it means that either the Portal site is down, the Portal subsystem is down, or the access attempt is not reaching the Portal due to a problem in the environment.

Note: For OVA users some of the following checks involve running kubectl commands on your VMs. To access your VMs for running kubectl commands:

1. ssh to one of your Management VMs as the user 'apicadm', for example: `ssh apicadm@mgmt1.example.com`
2. Sudo to the root user: `sudo -i`
3. From here you will be able to run kubectl commands, for example:

```
# kubectl get pods
NAME                                                              READY   STATUS      RESTARTS      AGE
abc-management-analytics-proxy-5f8bcd74c4-jbhch                   1/1     Running     1 (97d ago)   113d
...
```

4. API Connect pods run in the default namespace on OVA, so there is no need to specify the namespace with `-n` in the kubectl commands.

Check the following:

- Is the access attempt actually reaching the Portal subsystem? To confirm this, check what is in the logs of the `web` container which runs in the `www` pods which run on the Portal subsystem. The `web` containers are where the interactions between users and the Portal sites are logged. Specifically the nginx process that runs in the web container is the entry point for site access. For every attempt to access a portal site there should be line logged by the `web` container, for example: When the user attempts to access a sites home page, the following is logged by the `web` container:

```
# kubectl logs abc-portal-site1-www-0 -c web | grep nginx
...
[     nginx stdout]   584 ce6ce0:adad58:00580c 2022-05-27 12:57:38: "9.145.11.161, 9.20.85.206" portal.site1.example.com
"GET /providerorg1/sandbox/ HTTP/1.1" 200 5026 5315 5992 "-" "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7)
AppleWebKit/537.36 (KHTML, like Gecko) Chrome/101.0.4951.64 Safari/537.36" 0.330 "-"
...
```

  If there is nothing logged by the `web` containers `nginx` process at the time the site access is attempted, then check if you have any network problems between your browser and the Portal subsystem, or problems with kubernetes ingresses/OCP routes to the portal web endpoint. If you are on OVA then the tcpdump utility is available which you can use to confirm if traffic is reaching your Portal VM, for example `tcpdump -i any src host 9.20.86.22 and dst port 443`
- Are the Portal subsystem pods all up and running? Check this with `kubectl get PortalCluster -n <namespace>`. If this does not show all pods running, then check which pods are failing: `kubectl get pods -n <namespace>`. If you are on OVA then gather postmortem logs and open a support case at this point. Otherwise it's worth checking the reasons why the pods are failing to start with `kubectl describe` as it might be something in your kubernetes environment that you can fix. Note that on the Portal subsystem the `-db-` pods will need to be running first, so if these are not running then the other Portal pods will not start.
- If the `web` container logs show the access attempt being received, there may be clues as to the problem in what is logged immediately after this.

Login failure on Management UIs

If you are able to access the Management UIs login page, but the login attempt is failing.

Note: For OVA users some of the following checks involve running kubectl commands on your VMs. To access your VMs for running kubectl commands:

1. ssh to one of your Management VMs as the user 'apicadm', for example: `ssh apicadm@mgmt1.example.com`
2. Sudo to the root user: `sudo -i`
3. From here you will be able to run kubectl commands, for example:

```
# kubectl get pods
NAME                                                              READY   STATUS      RESTARTS      AGE
abc-management-analytics-proxy-5f8bcd74c4-jbhch                   1/1     Running     1 (97d ago)   113d
...
```

4. API Connect pods run in the default namespace on OVA, so there is no need to specify the namespace with `-n` in the kubectl commands.

Check the logs of the `juhu` and `apim` pods at the time of the login attempt to confirm that the login attempt did reach the Management subsystem. For more information on the `juhu` logs see Unable to access Management UIs. If the login attempt reached the Management subsystem, more details of the login failure for Local User Registry users can be found in the `lur` pod logs, and for LDAP users in the `ldap` pods. Example:

```
# kubectl logs abc-management-lur-8bbc47b54-9vl8q --since=1m -f
...
2022-05-27T13:41:13.511Z audit [4d55be1800dcef18c64e0470484e6eac] START: >>>>>>>> [POST]: /user-login
2022-05-27T13:41:13.704Z lur:error [4d55be1800dcef18c64e0470484e6eac] Requested login, but user, notauser not found in user
registry,
2022-05-27T13:41:13.706Z bhendi:error [4d55be1800dcef18c64e0470484e6eac] Error in POST post:/user-login (user.js:login)
  - status : 401
...
```

Related tasks

Login failure on Portal sites

If you are able to access the Portal sites login page, but the login attempt is failing.

Note: For OVA users some of the following checks involve running kubectl commands on your VMs. To access your VMs for running kubectl commands:

1. ssh to one of your Management VMs as the user 'apicadm', for example: `ssh apicadm@mgmt1.example.com`
2. Sudo to the root user: `sudo -i`
3. From here you will be able to run kubectl commands, for example:

```
# kubectl get pods
NAME                                                              READY   STATUS      RESTARTS      AGE
abc-management-analytics-proxy-5f8bcd74c4-jbhch                   1/1     Running     1 (97d ago)   113d
...
```

4. API Connect pods run in the default namespace on OVA, so there is no need to specify the namespace with `-n` in the kubectl commands.

All Portal users except for the site Admin user are ultimately authenticated by the Management subsystem, however Portal adds additional security controls such as IP banning and Flood control which should be first place to check for portal login issues: Managing Developer Portal security.

If the login problem is with the Admin user, then check the logs of the `web` container in the `www` pod at the time of the attempt, for example:

```
# kubectl logs abc-portal-site1-www-0 -c web --since=1m
...
[   php-fpm stderr]   585 ce6ce0:adad58:c3852e 2022-05-27 14:16:49: WARNING: [pool www] child 1023 said into stderr: "WATCHDOG:
[NOTICE] [user] Login attempt failed for admin. | user: anonymous | uri:
https://provorg1.sandbox.portal.apimsvc21.hursley.ibm.com/provorg1/sandbox/user/login | referer:
https://portal.site1.example.com/provorg1/sandbox/user/login
...
```

If the Portal site itself is not rejecting the user login, then check the Management server logs during the login attempt: Login failure on Management UIs. It may also be worth checking the logs of the `admin` container in the `www` pod, which manages the Portal end of the communications with the Management subsystem.

Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account. For example, if you configure three different user registries for a particular Developer Portal site, the email address *alice@acme.com* can be used to log in to the site from only

one of the user registries. The default email address for the Admin account is the email address of the Catalog owner. It is not possible to create a user account (and associated Consumer organization) with the same email address as the Admin account (or that of the Catalog owner if their email address is different). Any attempts to create an account with the same email address results in the new account not functioning correctly, and returning the following error message when trying to log in: `A user already exists with this email address`.

Management operations not reflected on Gateway or Portal

Where publishes or deletes executed on the Management subsystem are not reflected on the gateway or portal within a few minutes. These problems are often caused by a network failure between Management and the other subsystems, or due to TLS handshaking failures.

Note: For OVA users some of the following checks involve running kubectl commands on your VMs. To access your VMs for running kubectl commands:

1. ssh to one of your Management VMs as the user 'apicadm', for example: `ssh apicadm@mgmt1.example.com`
2. Sudo to the root user: `sudo -i`
3. From here you will be able to run kubectl commands, for example:

```
# kubectl get pods
NAME                                                      READY   STATUS      RESTARTS      AGE
abc-management-analytics-proxy-5f8bcd74c4-jbhch           1/1     Running     1 (97d ago)   113d
...
```

4. API Connect pods run in the default namespace on OVA, so there is no need to specify the namespace with `-n` in the kubectl commands.

For Gateway, the first place to check is the processing status page: Reviewing a gateway's processing status

For Portal and Gateway check the logs of the `taskmanager` pods at the time of the publish attempt. These pods send the publish operations to the gateway and portals via webhooks. If there is a network problem you may see socket timeout errors in the logs of these pods, or TLS errors if there is problem with your certificates. A common problem are load-balancers doing TLS termination instead of passthrough (where JWT security is not used, see Using JWT instead of mTLS on Kubernetes and OpenShift, Using JWT instead of mTLS on OVA). If the logs suggest that the webhook was sent successfully then check the gateway director (gwd) logs on the Gateway, and the `www` pod `admin` container logs on the portal, for example:

```
kubectl logs abc-portal-site1-www-0 -c admin
```

Taskmanager pods execute "send" tasks to publish operations to the gateways and portals. The taskmanager pods log messages about the progress of tasks, so there should be messages in a taskmanager pod for a send task soon after applying a change on the Management subsystem. A "send running in pod" message like the following example means the send task is running:

```
2023-05-05 14:02:37.270 management-taskmanager-f5d6fd77-dmnnt taskmanager apim:taskmanager:info:taskProcessor [0d30189c-db39-4260-bb1f-a75a3ac5f1ba] task id: b3933261-5799-473d-9b83-9e29c245fde8 / kind: send running in pod: management-taskmanager-f5d6fd77-dmnnt / containerId: cri-o://d5afe6d3960e333c1ea5d8f95b79564e769bc2ed5de9d8baebebd84b3f3ad4be 269ms after claimed
```

If the taskmanager logs an error containing "dispatching task failed for task"(logged when attempting to start a task) or an error containing "Stale claimed task" (logged 15 minutes later), API Connect might have a problem running tasks. A small number of these errors might be reported from time to time, and the system recovers automatically. But if the errors continue being reported, restart the natscluster pods (all together) and then restart the taskmanager pods to recover by running the following commands:

```
kubectl -n <namespace> delete po -l app.kubernetes.io/name=natscluster
kubectl -n <namespace> delete po -l app.kubernetes.io/name=taskmanager
```

When raising a support case, be sure to include logs from both the Management subsystem and the affected subsystems gateway/portal, stating when the publish attempt was made.

Management subsystem Postgres failover steps

If your Postgres leader pod is not the original Postgres leader, complete the failover steps to restore the original pod as leader.

Before you begin

This topic applies only to three replica deployments of API Connect.

Follow the steps in this topic if one or more of the following conditions are reported:

- If the **apicops version:pre-upgrade** command reports:

`Current postgres leader is not the original leader`

- Openshift and Cloud Pak for Integration only: Your API Connect cluster CR reports `Error` status, and the output of:

  `oc get apiconnectcluster -n <namespace> -o yaml`

  shows:

  ```
  Original PostgreSQL primary is running as replica, please perform failover to original primary before attempting upgrade.
  Refer - https://ibm.biz/BdPLWU
  ```

- When you attempt to upgrade the management subsystem by editing the management CR to change the version and license and you see this error:

  ```
  Original PostgreSQL primary is running as replica, please perform failover to original primary before attempting upgrade.
  Refer - https://ibm.biz/BdPLWU
  ```

About this task

The management subsystem uses Postgres as the database. A three replica API Connect deployment has a Postgres cluster that consists of 1 Postgres leader, and 2 Postgres replicas.
Note: In Kubernetes terminology, every pod in a cluster is called a "replica". In Postgres terminology, a Postgres cluster consists of "members", one of the members is designated as the leader, and the others are designated as "replicas". During normal operation, the Postgres cluster member that is the leader can change; one of the Postgres replicas can become the leader, and the original leader become a replica.
If the current Postgres cluster leader in your management deployment is not the original leader, then problems can occur during upgrade. To prevent upgrade problems, follow the steps in this topic to identify the original Postgres leader and assign it as the leader again.
Note: If you have an OVA deployment, run the steps that are documented in this topic from your management virtual appliance, as the root user: Login to your management virtual appliance with an SSH client and the username `apicadm`, then switch to the root user with `sudo -i`.

Procedure

1. Assign your management subsystem namespace to a new environment variable called `$NAMESPACE`

   `export NAMESPACE=<management namespace>`

   Note: On OVA deployments, set this to "default":

   `export NAMESPACE=default`

2. Identify the original name of your Postgres cluster, and assign it to a new environment variable `$PGCLUSTER_NAME`.

   `export PGCLUSTER_NAME=$(kubectl -n $NAMESPACE get pgcluster | awk 'NR==2{print $1}')`

   Confirm the variable is set correctly with:

   `echo $PGCLUSTER_NAME`

3. Get a list of the PVCs whose names start with `$PGCLUSTER_NAME` in your API Connect namespace.

   `kubectl -n $NAMESPACE get pvc $PGCLUSTER_NAME $PGCLUSTER_NAME-wal`

   ```
   NAME                       STATUS   VOLUME                CAPACITY   ACCESS MODES   STORAGECLASS    AGE
   m1-33253de3-postgres       Bound    local-pv-2b61c0bd     234Gi      RWO            local-storage   6h42m
   m1-33253de3-postgres-wal   Bound    local-pv-bd893695     234Gi      RWO            local-storage   6h42m
   ```

   Note: If no PVCs are returned then check the `apicops` error or management CR warning, if it says "The original primary PVC is not attached to any pods in this namespace", then do not proceed with these steps. Instead, to re-create your Postgres cluster with a new leader:
   a. Take a new management database backup Backup and restore.
   b. Restore the management database from the new backup.

4. Get the names of all the Postgres pods.

   `kubectl get pods -n $NAMESPACE -l 'role in (master,replica)'`

   ```
   NAME                                          READY   STATUS    RESTARTS   AGE
   m1-33253de3-postgres-dbd7966db-ltfhq          1/1     Running   0          61s
   m1-33253de3-postgres-dxxx-c54776d87-wldgb     1/1     Running   0          26m
   m1-33253de3-postgres-xwjf-8577b6c669-9chcp    1/1     Running   0          26m
   ```

5. Identify which pod was the original Postgres leader.
   Describe each Postgres pod to see which one is using the two PVCs identified in step 3.

   `kubectl -n $NAMESPACE describe pod <pod-name> | grep 'ClaimName'`

   ```
   k describe pod m1-33253de3-postgres-dbd7966db-ltfhq | grep ClaimName
       ClaimName:  m1-33253de3-postgres
       ClaimName:  m1-33253de3-postgres-wal

   k describe pod m1-33253de3-postgres-dxxx-c54776d87-wldgb | grep ClaimName
       ClaimName:  m1-33253de3-postgres-dxxx
       ClaimName:  m1-33253de3-postgres-dxxx-wal

   k describe pod m1-33253de3-postgres-xwjf-8577b6c669-9chcp | grep ClaimName
       ClaimName:  m1-33253de3-postgres-xwjf
       ClaimName:  m1-33253de3-postgres-xwjf-wal
   ```

   In this example, the highlighted pod `m1-33253de3-postgres-dbd7966db-ltfhq` is the pod that is using the PVCs identified in step 3.
   Set this pod to the environment variable *$ORIGINAL_POSTGRES_LEADER*:

   `export ORIGINAL_POSTGRES_LEADER=<pod-name>`

Note: If none of the Postgres pods are using the PVCs identified in step 3, then do not proceed with these steps. Instead, to re-create your Postgres cluster with a new leader:

a. Take a new management database backup Backup and restore.
b. Restore the management database from the new backup.

6. Run the **patronictl list** command in each Postgres pod and examine the output.

```
kubectl -n $NAMESPACE exec -it <postgres-pod> -- patronictl list
```

Example output for each Postgres pod:

```
Defaulted container "database" out of: database, set-libpq-certs (init)
+-----------------------------------------+-----------------+---------+---------+----+-----------+
| Member                                  | Host            | Role    | State   | TL | Lag in MB |
+ Cluster: m1-33253de3-postgres (7039951359768572098) ---------+---------+---------+----+-----------+
| m1-33253de3-postgres-dbd7966db-ltfhq    | 192.168.51.112  | Replica | running |  8 |         0 |
| m1-33253de3-postgres-dxxx-c54776d87-wldgb  | 192.168.112.17  | Replica | running |  8 |         0 |
| m1-33253de3-postgres-xwjf-8577b6c669-9chcp | 192.168.117.219 | Leader  | running |  8 |           |
+-----------------------------------------+-----------------+---------+---------+----+-----------+
```

Each Postgres pod should show the same output, although the order of the records might differ. The names in the `Member` column should match the names of the Postgres pods. Check the following:

- If the original Postgres pod that you identified in step 5 has a `Lag in MB` of zero and a `TL` the same as the `Leader` pod, then continue to step 7.
- If the pod labeled `Leader` shows a `TL` that is less than the other pods, or a non-null `Lag in MB`, then proceed no further and open a support case.
- If the original Postgres pod that you identified in step 5 shows a lower `TL` than the other pods, or a nonzero value in `Lag in MB`, then reinitialize that pod:

  ```
  kubectl exec -it $ORIGINAL_POSTGRES_LEADER -n $NAMESPACE -- patronictl reinit <cluster name>
  $ORIGINAL_POSTGRES_LEADER
  ```

  where:

  - *<cluster name>* is the name of the Postgres cluster that is shown in the **patronictl list** output:

    ```
    + Cluster: <cluster name> ...
    ```

  Run **patronictl list** again to confirm that the `Lag in MB` is reducing. Do not proceed until it is zero. If it is not reducing, open a support case.

7. Make the pod that you identified in step 5 the `Leader`.
Run:

```
kubectl -n $NAMESPACE exec -it <postgres pod> -- patronictl failover
```

and select your $ORIGINAL_POSTGRES_LEADER as the candidate to failover to:

```
Candidate ['m1-33253de3-postgres-dbd7966db-ltfhq', 'm1-33253de3-postgres-dxxx-c54776d87-wldgb'] []: m1-33253de3-postgres-
dbd7966db-ltfhq
